III Out-Of-School Virtual Learning Environments

Abstract

What is virtual reality and how do we conceptualize, create, use, and inquire into learning settings that capture the possibilities of virtual life? The International Handbook of Virtual Learning Environments was developed to explore Virtual Learning Environments (VLE's), and their relationships with digital, in real life and virtual worlds.

Three issues are explored and used as organizers for The Handbook. First, a distinction is made between virtual learning and learning virtually. Second, since the focus is on learning, an educational framework is developed as a means of bringing coherence to the available literature. Third, learning is defined broadly as a process of knowledge creation for transforming experience to reflect different facets of "the curriculum of life".

To reflect these issues The Handbook is divided into four sections: **Foundations of Virtual Learning Environments; Schooling, Professional Learning and Knowledge Management; Out-of-School Learning Environments; and Challenges for Virtual Learning Environments**. A variety of chapters representing different academic and professional fields are included. These chapters cover topics ranging from philosophical perspectives, historical, sociological, political and educational analyses, case studies from practical and research settings, as well as several provocative 'classics' originally published in other settings.

Biographies of the Editors and Contributors

EDITORS

Jeremy Hunsinger manages the Center for Digital Discourse and Culture at Virginia Tech where he is also completing his Ph.D. in Science and Technology Studies. He is an instructor of political science and teaches courses centered on political theory, political economy, and information/research/education policy. He is supposed to be writing his dissertation on the political economy of the Internet, but more often than not is working on a myriad of other projects related to his job, research, and teaching interests in online environments. He has also worked as Director of VTOnline, a university-wide e-learning project, and has worked on the award winning On-Line M.A. in Political Science.

Jason Nolan is an Assistant Professor with the School of Early Childhood Education at Ryerson University in Toronto. His research interests include the pedagogy of technology, critical and reflective practice, and learning technologies for very young children. He is co-editor of the journal *Learning Inquiry*, and serves in an editorial capacity with *Canadian Children's Literature*, *the Journal of Dracula Studies*, and *The Harrow*.

Peter Pericles Trifonas is a Professor of Education at OISE/UT. He has published extensively in the areas of philosophy, cultural studies, and media.

Joel Weiss is the first Senior Fellow at the Knowledge Media Design Institute (KMDI) of the University of Toronto (UT), and was a long-time faculty member at the Ontario Institute for Studies in Education (OISE/UT). His background in chemistry and social science research procedures, as well as his appreciation of curriculum and learning issues in formal, non-formal and informal situations, provides interesting vantage points for his recent conversion to the virtual world. He was the Founding Editor of *Curriculum Inquiry*, and held several positions in Division B (Curriculum Studies) of the American Educational Research Association (AERA). His publications include chapters in Building virtual communities: Learning and change in cyberspace and AERA's Second handbook of research on teaching, and it's Review of research in education. His next publishing venture will be serving as Editor-in-Chief of The encyclopedia of learning. As the Chair of the Educational Advisory Committee of The Toronto Zoo, Joel has facilitated the development of an International Learning Centre, and The City of Toronto's UN sponsored Regional Centre of Expertise for Education for Sustainable Development.

Annette Adler is a Research Manager at Agilent Labs. She manages the multidisciplinary Systems Biology Program which includes four projects: Proteomics, Metabolomics, Primary Data Analysis and Systems Informatics, with an interdisciplinary team of analytical chemists, biologists, and computer scientists. She is an anthropologist whose early experience was studying the historical development and current dynamics of social identities in the context of plantation economies and slavery. After leaving academics, she spent many years as a researcher looking at interactions between people and technologies, with a particular interest in technology-mediated collaboration, online communities and systems architecture designed to accommodate people as users. She has brought this interest to Agilent in how her project approaches understanding its end-users and develops its work accordingly.

Associate Professor Matthew Allen runs the Internet Studies program at Curtin University of Technology in Perth, Australia. Matthew had published 2 books and a dozen papers, and had a background in history, cultural theory and epistemology before turning to Internet Studies. He currently supervises several doctoral students in Internet Studies, is the in-coming President of the Association of Internet Researchers and is researching how broadband technologies are changing cultural and economic understandings of the Internet.

Melissa Altman is interested in critical understandings of meaning-making at the intersection of virtual and real environments. She is working on her Ph.D. in American Culture Studies at Bowling Green State University and is doing research on production of subjectivity, postcolonial feminisms, virtual learning environments, and other critical investigations of everyday meaning-making.

Christine Armatas is currently working as a researcher in the Human Factors group at Telstra Research Laboratories in Melbourne, Australia. Previously she was a Senior Lecturer in the School of Psychology, at Deakin University, Geelong. During her time there, she was involved in developing courses for delivery in fully online and mixed delivery modes. As part of this work, she has published a number of papers on how using computer-mediated technologies to deliver learning material affects the quality of the student learning experience. Her current research interests include the use of mobile technologies to enhance teaching and learning.

Ms. Naomi Augar completed her Bachelor of Computing (Applied Computing) with Honours in 2002 at Deakin University, Melbourne, Australia. Presently she is a Ph.D. candidate in the School of Information Technology at Deakin University. Her Ph.D. research focuses on Virtual Learning

Communities. Her research interests include issues related to constructing an online identity, virtual communication and e-learning.

Ronald Baecker is Professor of Computer Science, Bell University Laboratories Chair in Human-Computer Interaction, and founder and Chief Scientist of the Knowledge Media Design Institute at the University of Toronto. He is also Affiliate Scientist with the Kunin-Lunenfeld Applied Research Unit of the Baycrest Centre for Geriatric Care. He has been named a Computer Graphics Pioneer by ACM SIGGRAPH, has been elected to the CHI Academy by ACM SIGCHI, and has been given the Canadian Human Computer Communications Society Achievement Award. Baecker is an active researcher, lecturer, and consultant on human-computer interaction and user-interface design, cognitive prostheses, software visualization, multimedia, computer-supported cooperative work and learning, and software entrepreneurship. He has published over 100 papers and articles, is author or co-author of four books and co-holder of two patents, and has founded and run two software companies. His B.Sc., M.Sc., and Ph.D. are from M.I.T.

Professor Mark Balnaves is Chair of New Media, School of Communications and Multimedia, at Edith Cowan University, Perth, Western Australia. He co-authored The Penguin atlas of media and information and the University of Queensland Press' Mobilising the audience. He is an expert in audience research and new media.

Brandon Barr is an advertising copywriter who lives in Rochester, NY. He holds an M.A. in English Literature from the University of Rochester and remains interested in the poetics of new media—in the arts, in video games, in TV & radio, and in advertising. His current art projects and writing are available at his website, texturl.net.

Dr. Joanna Black is an Assistant Professor of Art Education in the Faculty of Education at the University of Manitoba in Manitoba, Canada. She teaches visual arts and new media education. Her research interests and published works are on the subjects of the virtual arts classroom, the relationship dynamics between teachers and students in digital arts classrooms, new media integration in arts curriculum and teacher training, and model digital visual arts schools. Dr. Black has worked as an art director, curator, museum art educator and K-12 teacher in public and alternative school settings.

Megan Boler is an Associate Professor at the University of Toronto and earned her Ph.D. at the History of Consciousness Program at the University of California Santa Cruz. Her book Feeling power: Emotions and education was published by Routledge in 1999, and she recently published an edited collection, Dialogue in education: Troubling speech, disturbing silences (Peter Lang, 2004). Her research and graduate courses address critical theory, media literacy, feminist theory, and philosophy of technology. Her essays have been published in such journals as *Hypatia*, *Educational Theory*, and *Cultural Studies*. Her multimedia website Critical Media Literacy in Times of War (www.tandl.vt.edu/Foundations/mediaproject) is widely used; she is producing a study guide to accompany the 2003 documentary The Corporation; and her current research focus is on how web-based multimedia political satire influences the public sphere.

Nicholas Bowskill is an e-learning consultant currently working with The University of Sheffield, UK as an e-tutor in a self-employed role. In addition, he is also working with Lancaster University on the eChina Project. This has involved him in visits to Chinese Universities and online involvement across the eChina Project consortium. Nicholas is providing tutoring and technical support. His interests include informal learning in online environments and podcasting. He has a good research background and a record of research publications over the past 10 years of his involvement in e-learning.

Peter Brophy is Director of the Centre for Research in Library & Information Management (CERLIM) at the Manchester Metropolitan University, UK and holds the Chair in Information Management at that University. He has directed a number of international research projects, many funded by the European Commission's Telematics/Information Society Technologies Programmes, and has a particular interest in the integration of networked information systems and eLearning. He is the author of The library in the twenty-first century (Facet Publishing, 2001) and The academic library (Facet, 2nd ed., 2005).

Robert S. Brown has been in the field of applied research for twenty years. Before joining the Toronto Board's research department in 1991, he worked as a media analyst at TVOntario and as a research consultant in private market research. He is currently a project coordinator in Research and Information Services of the Toronto District School Board and is a past president of AERO (the Association of Educational Researchers of Ontario). Publications include "Psychological needs of post-war children in Kosovo: A preliminary analysis," with Ester Cole (*School Psychology International*, 2002, Vol. 23, no. 2), and Telling tales over time: Constructing and deconstructing the school calendar" with Joel Weiss (*Teachers College Record*, 2003, Vol. 105, no. 9).

Amy Bruckman is an Associate Professor at the College of Computing at Georgia Tech, and a member of the Graphics, Visualization, and Usability (GVU) Center. She received her Ph.D. from the Epistemology and Learning Group at the MIT Media Lab in 1997, and her B.A. in physics from Harvard University in 1987. She does research on online communities and education, and is the founder of the Electronic Learning Communities (ELC) research group.

Nicholas C. Burbules is Professor of Educational Policy Studies in the College of Education at the University of Illinois. He is the editor of *Educational Theory*. His recent articles have appeared in *Access, Philosophy of Education*, and the *Electronic Journal of Sociology*.

Rhiannon Bury received her Ph.D. from the University of Toronto (Ontario Institute for Studies in Education) in 2000. She is Assistant Professor and Acting Director of Women's Studies at the University of Waterloo, Ontario, Canada. Her work on women, fan culture and cyberspace has appeared in a number of journals and edited collections including *Convergence: The Journal of Media Technologies*; *Popular Communication*; *Resources for Feminist Research*; and *The Post-Subcultures Reader,* edited by D. Muggleton & R. Weinzierl.

Bryan Carter is an assistant professor of literature at Central Missouri State University, specializing in African American literature of the 20th Century with a primary focus on the Harlem Renaissance and a secondary emphasis on visual culture. He has published numerous articles on Virtual Harlem and has presented it at locations around the world. In the spring of 2004, he served as Professeur Invité at the University of Paris IV-Sorbonne where he taught Digital Communications and Cultural Studies. Dr. Carter has recently incorporated desktop videoconferencing, podcasting, Internet radio broadcasts and blogging into each of his courses.

Suzanne de Castell is a Professor of Education at Simon Fraser University specializing in multi-modal literacies, new media studies and educational technologies. Her research focuses on epistemic implications of representational tools. She is currently studying informal learning environments, and specifically the impacts of computer-supported play on the development of new 'economies' of attention.

Dr. Der-Thanq Chen is a Senior Lecturer in the University Centre for Teaching and Learning at the University of Canterbury. He currently leads various e-learning initiatives at the University and lectures in courses in instructional design and interactive multimedia design. His areas of research interest include online learning communities and the design of socio-technological architecture for learning.

Dr. Paul F. Conway is a College Lecturer in the Education Department, National University of Ireland (NUI), Cork and has also been a Visiting Professor in the College of Education, Michigan State University since 2000.

Prior to that he was Assistant Professor of Educational Psychology and Human Development at Cleveland State University, Ohio, USA. He is currently Co-editor of *Irish Educational Studies* (published by Routledge). His publications have appeared in the following journals: *Teachers College Record*, *Journal of Applied Developmental Psychology*, *Teaching and Teacher Education* among others. Research interests include learning theories, ICT policies in education in the context of globalisation, teacher education, and international and comparative education.

Dr. Jackie Cook teaches new media in graduate programs at the University of South Australia's School of Communication, Information and New Media in Adelaide, and also in the University's off-shore graduate degrees in Hong Kong, Singapore and Kuala Lumpur. She has just completed a five-year secondment into the University's Journalism programs, and is moving to a new focus promoting publication and media promotion of doctoral student research. She is a regular broadcaster on Australian radio, specialising in analytical commentary on new media culture.

Jim Cummins received his Ph.D. in 1974 from the University of Alberta in the area of educational psychology. He is currently a professor in the Department of Curriculum, Teaching, Learning in the Ontario Institute for Studies in Education of the University of Toronto. His research has focused on the nature of language proficiency and second language acquisition with particular emphasis on the social and educational barriers that limit academic success for culturally diverse students. He has served as a consultant on language planning in education to numerous international agencies.

Dr. Giuseppe D'Ancona is an internationally well-known cardiac surgeon—working at the present in the Republic of Ireland—who has published more than 100 articles in peer-reviewed international journals, with topics ranging from surgical treatment of cardiovascular pathology, new technologies in surgery (i.e. robotics), doctors' medical education, and interdisciplinary approach to patients' e-education and internet behaviour. He is the author and co-author of 3 highly diffused surgical manuals (Blackwell, Futura publishers) aimed at educating colleague surgeons in the innovative fields of cardiac surgery and perioperative evaluation of coronary surgery results. Dr. D'Ancona has participated to numerous international conferences in the interdisciplinary field of e-health. He has dedicated his medical career to both clinical activity and scientific research in the field of innovations in cardiac surgery and medicine. He collaborated with institutions such as State University of New York (SUNY) at Buffalo (USA), the Erasmus Academic Hospital in Rotterdam (NL), and the University of Florence (IT).

Julia Dicum is a doctoral candidate in OISE/UT's Collaborative Program in Comparative International Development Education and a Research Associate at York University's Centre for Refugee Studies, where her work is funded by a Social Science Humanities Research Council doctoral fellowship. An experienced aid worker, her primary research interests in education are innovation in learning delivery for marginalised communities in war-torn countries, critical theory, and sustainable ICTs as community development tools in less developed countries.

Martin Dodge works at University College London as a researcher in the Centre for Advanced Spatial Analysis and lecturer in the Department of Geography. He has a degree in geography and computing, an M.Sc. in geographical information systems and is currently completing his Ph.D. His work has been primarily concerned with developing a new research area of the geography of cyberspace, focusing in large part on the ways to map and visualise the Internet and the Web. He is the curator of a web-based Atlas of cyberspace (www.cybergeography.org/atlas) and has co-authored two books, Mapping cyberspace (Routledge, 2000) and Atlas of cyberspace (Addison-Wesley 2001).

Jim Dwight is an assistant professor at Millersville University, specializing in the Cultural Foundations of Education, Philosophy of Education, and Instructional Technology. His particular interest resides in intersections of e-learning and the metaphysics of presence and this intersection's subsequent effects on educational policies. His interests have led him to formulate a theory of hyperpedagogy that seeks ways in which e-learning can deny traditional metaphysical theories and thereby better address the concerns of historically marginalized learners.

Radhika Gajjala (Ph.D., University of Pittsburgh, 1998) is Associate Professor in Interpersonal Communication/Communication Studies at Bowling Green State University, Ohio. Her research interests include information communication technologies (ICTs) and globalization and production of race in cyberspace and virtual learning environments. Her work has appeared in journals such as *Feminist Media Studies*, *International and Intercultural Annual, Contemporary South Asia* and *Works and Days,* and in books such as Technospaces: Inside the new media (2001) and Domain errors! Cyberfeminist practices (2003). Her book Cyberselves: Feminist ethnographies of South Asian women was recently published by Altamira Press.

Alexander Halavais is an Assistant Professor of Communication and Graduate Director of the School of Informatics at The State University of New

York (SUNY) at Buffalo. His research explores the interactions between the structure of technical and social systems. He has published on the political implications of the hyperlinked structure of the World Wide Web, and on the impact of blogging on society.

Noriko Hara is an Assistant Professor of Information Science at Indiana University and a Fellow of the Rob Kling Center for Social Informatics. She held a position as a National Science Foundation (NSF) Postdoctoral Research Fellow in the School of Information and Library Science, University of North Carolina at Chapel Hill, before joining the faculty of the School of Library and Information Science, Indiana University in 2002. Her research focuses on studying collective behaviors with information technologies, including online learning, communities of practice, and online activism. Dr. Hara holds a Ph.D. in Instructional Systems Technology from Indiana University.

Linda Harasim Professor at Simon Fraser University holds a Ph.D. in Educational Theory from the University of Toronto and has been active for over a decade in researching educational applications of computer networking. She has designed, implemented, and evaluated networking applications in Canada, the U.S., and Latin America. She is also leading the Virtual-U Project, one of the first networked multimedia learning systems in the world that is customized for course delivery and course enhancement at all levels of education.

Donna Haraway is a Professor in the History of Consciousness Department at the University of California at Santa Cruz, where she teaches feminist theory, science studies, and animal studies. She earned her Ph.D. in Biology at Yale in 1972 and has taught biology at the University of Hawaii and the history of science at The Johns Hopkins University. Haraway is the author of <u>Crystals, fabrics, and fields: Metaphors that shape embryos</u> (Berkeley: North Atlantic Books, 2004, originally Yale University Press, 1976); <u>Primate visions: Gender, race, and nature in the world of modern science</u> (New York: Routledge, 1989); <u>Simians, cyborgs, and women: The reinvention of nature</u> (Routledge, 1991); <u>Modest_Witness@Second_Millennium.FemaleMan© Meets OncoMouse™</u> (New York: Routledge, 1997); and <u>The companion species manifesto: Dogs, people, and significant otherness</u> (Chicago: Prickly Paradigm Press, 2003).

Elizabeth Henning is Special Professor of Qualitative Research Methodology in the Faculty of Education at the University of Johannesburg. She is currently the Chair of an international UNESCO UNITWIN research project on Values in Education, lead researcher in a National Research Foundation project on Educational ICT in South Africa and also lead researcher in a research project of the South African Netherlands Research Programme for Alternatives in Development. She was awarded a Spencer Post Doctoral Fellowship by the National Academy of Education in the USA for research on teacher development in schools in informal settlements in 1995.

Kathryn M. Hibbert, after teaching for sixteen years completed a doctoral dissertation, Examining 'enunciative space' in an online community of practice. The study looked at how practicing teachers in a virtual Reading course understood that their literacy practices, and subsequently their teaching, lives through online dialogue in a supportive community of professional practice. Her research interests include; teaching and learning in the virtual world, teacher professional development in a culture of standards and efficiency, and the power of online dialogue for developing a scholarship of teaching. She has presented at both national and international conferences, with recent publications in *The Reading Teacher, The Journal for Adult and Adolescent Literacy,* as well as conference proceedings of *IADIS: The International Conference e-Society* (Avila, Spain) and the *20th Annual Conference on Distance Teaching and Learning*, (Madison, Wisconsin). She recently participated as a guest researcher in Etienne Wenger's online forum, *CPSquare*. Currently, Kathy is the Distance Education Coordinator at the Faculty of Education, University of Western Ontario.

Dr. David Hung is currently Head of the Learning Sciences and Technologies academic department at the National Institute of Education, Nanyang Technological University. He is also a key initiator and member of the Learning Sciences Lab engaged in research in IT and learning within social-cultural contexts. Currently an associate professor, his interests span situated cognition, communities of practice, activity theory, neuroscience, and how technologies support meaningful and engageful learning. He publishes regularly in journals across instructional systems design and the learning sciences. He is a Contributing Editor to *Educational Technology* and Associate Editor for the *International Journal of Learning Technologies*.

Dr. (Ms.) Ahbul Zailani Begum Mohamed Ibrahim began her career as a Science Officer at the Science University of Malaysia (USM). She then migrated to teaching English as a Second Language (ESL) and served in the Northern University of Malaysia before joining the Mara University of Technology. Although teaching ESL is her forte, Begum has been watching the growth of online learning technologies closely; hence her participation in the World Association for Online Education (www.waoe.org). She is a firm believer in the importance of learner autonomy in language learning and finds that virtual learning provides an amazing avenue for capitalizing on this potential.

Mizuko (Mimi) Ito is a cultural anthropologist of technology use, focusing on children and youth's changing relationships to media and communications.

She has been conducting ongoing research on kids' technoculture in Japan and the US, and is co-editor of, Personal, portable, pedestrian: Mobile phones in Japanese life. She is a Research Scientist at the Annenberg Center for Communication and a Visiting Associate Professor at Keio University in Japan.

Jennifer Jenson is Assistant Professor of Pedagogy and Technology in the Faculty of Education at York University. She has published on gender and technology, cultural studies of technology and technology in education. Her current interests include gender, education and digital game play.

Steve Jones is Professor of Communication, Research Associate in the Electronic Visualization Laboratory, Adjunct Professor of Art & Design at the University of Illinois—Chicago, and Adjunct Research Professor in the Institute of Communications Research at the University of Illinois at Urbana-Champaign. He holds the Ph.D. in Communication from the Institute of Communications Research, University of Illinois at Urbana-Champaign. Jones is author and editor of numerous books, including Society Online, CyberSociety, Virtual culture; Doing internet research; CyberSociety 2.0; The encyclopedia of new media; Rock formation: Technology, music and mass communication (all published by Sage); The Internet for educators and homeschoolers (ETC Publications); and Pop music & the press (Temple University Press). He was first President and co-founder of the Association of Internet Researchers and serves as Senior Research Fellow at the Pew Internet & American Life Project.

Daniel P. Keating is Research Professor and Director of the Center for Human Growth and Development, and Professor of Psychology, Psychiatry, and Pediatrics at the University of Michigan. He is a Fellow of the Canadian Institute for Advanced Research.

Douglas Kellner is George Kneller Chair in the Philosophy of Education at UCLA and is author of many books on social theory, politics, history, and culture, including (with Michael Ryan) Camera politica: The politics and ideology of contemporary Hollywood film; Critical theory, Marxism, and modernity; Jean Baudrillard: From Marxism to postmodernism and beyond; (with Steven Best) Postmodern theory: Critical interrogations; Television and the crisis of democracy; the Persian Gulf TV war; (with Steven Best) Media culture, and The postmodern turn.

Kinshuk is Director of the Advanced Learning Technology Research Centre and Associate Professor of Information Systems at Massey University, New Zealand. He has been involved in large-scale research projects for exploration based adaptive educational environments and has published over 150 research papers in international refereed journals, conferences and book chapters. He is Chair of the IEEE Technical Committee on Learning Technology and International Forum of Educational Technology & Society. He is also Editor of the SSCI indexed *Journal of Educational Technology & Society* (ISSN 1436-4522).

Rob Kitchin is Director of the National Institute of Regional and Spatial Analysis (NIRSA) at the National University of Ireland, Maynooth. He is the Managing Editor of the journal *Social and Cultural Geography* and author/editor of twelve books, including Mapping cyberspace and Atlas of cyberspace, both written with Martin Dodge.

Rob Kling was Professor of Information Science and Information Systems at Indiana University, where he directed the Center for Social Informatics, an interdisciplinary research center, and was Editor-in-Chief of *The Information Society*. Since the early 1970s Dr. Kling had studied the social opportunities and dilemmas of computerization for managers, professionals, workers, and the public. Computerization and controversy: Value conflicts & social choices, perhaps his best-known work, examined the consequences and effects of computerization in organizations and social life, focusing on issues of productivity, work life, personal privacy, risks, and ethics. He passed away unexpectedly on May 15th, 2003.

Emmanuel Koku is a visiting Assistant Professor of Sociology at Temple University. His research and applied interests lie in the areas of social network analysis, research methods and statistics, virtual organizations, the structure of online and offline communities, and social epidemiology. His current research investigates consultation and advice-seeking networks among scholars and other knowledge workers, and their use of computer-mediated communication media. In addition, he is currently examining the links between sexual behaviors, sexual/social networks, HIV transmission and prevention. He recently received his Ph.D. in Sociology from University of Toronto, Canada.

Lisa Korteweg is a tenure-track faculty member at Lakehead University, Ontario, Canada. Her Ph.D. dissertation, Portals, practitioners, and public knowledge: A sociotechnical analysis of digital teacher education (University of British Columbia, 2005), explored the issues of online teacher education portals and the possibilities of a digital epistemic community of practitioners and researchers.

Vasilia Kourtis-Kazoullis received her Ph.D. from the Department of Primary Education, University of the Aegean. The topic of her Ph.D. was DiaLogos: Bilingualism and second language learning on the Internet.

She received a M.Ed. from the University of Wales, Swansea and a B.A. in English Literature and Linguistics from Youngstown State University, U.S.A. She has been teaching English in the Greek Public School System, Secondary Education, since 1990 and has also taught English at the Department of Preschool Education and Educational Design, University of the Aegean. She now teaches courses related to language learning and new technologies at the Department of Mediterranean Studies, and in the Master's Program at the Department of Primary Education, University of the Aegean.

Miss Elicia Lanham received her B.Computing (Information Management) and B. Computing (Honours) degrees from Deakin University, Melbourne, Australia in 2001 and 2002, respectively, and a Certificate II in Small Business Management from the Vocational and Educational Training Accreditation Board (VETAB), Australia, 2000. She is currently a Ph.D. Candidate in the School of Information Technology, Deakin University, Melbourne, Australia. Her research interests include practical and cultural issues of Internet education, cross-cultural learning styles and e-learning.

Benjamin Lefebvre is writing his doctoral dissertation in English at McMaster University on ideology and child protagonists in Canadian and Québécois fiction. He recently guest-edited a double issue of *Canadian Children's Literature/Littérature canadienne pour la jeunesse* on "Reassessments of L.M. Montgomery" (2004). His latest academic contributions have appeared or are forthcoming in *Children's Literature Association Quarterly*, *English Studies in Canada*, *Children's Literature*, Voix plurielles, and The Oxford Encyclopedia of children's literature, edited by Jack Zipes (Oxford University Press, 2006).

Jing Lei is a doctoral candidate in the Learning, Technology, and Culture Program in the College of Education at Michigan State University. Her dissertation concerns conditions for effective technology use by students.

Michelle Levesque is currently studying Computer Science at the University of Toronto. She also spends her time working at the Citizen Lab, where she designs and implements programs to enumerate and circumvent state-imposed Internet content filtering.

Taiyu Lin is a doctoral student in the Advanced Learning Technology Research Centre at Massey University, New Zealand. His research interests include cognitive profiling of the learners.

Dr. Charlotte Linde is a Senior Research Scientist at NASA Ames Research Center, working on issues of narrative and institutional memory, knowledge management, human-centered computing, and work systems design and evaluation. She holds a doctorate in linguistics from Columbia University, and is the author of a book on the use of narrative in the social negotiation of the self (Life stories: The creation of coherence, Oxford University Press).

John Logie is an Assistant Professor of Rhetoric at the University of Minnesota. His scholarship addresses authorship and rhetorical invention, with a particular emphasis on the implications of digital media for these practices. His articles have appeared in *First Monday, Rhetoric Society Quarterly, Rhetoric Review, Computers & Composition, KB Journal,* and a number of anthologies. He is currently completing a book-length project on the rhetoric of the peer-to-peer debates, to be published by Parlor Press.

Carmen Luke is Professor at the University of Queensland in Australia. Her work has been in the areas of media literacy and new media, feminist studies, globalization and higher education. Her principal research focus has been on young people's relationships to 'old' and 'new' media, new technologies and popular culture, and the role of schooling in providing critical media and ICT skills. Her current theoretical interests are in cultural globalization theory and cosmopolitan 'democracy', and she is currently conducting research on the future of public education and public archives of knowledge in the context of globalization and commercialization of knowledge.

Robert Luke, Ph.D., is the Manager of Educational Informatics, Department of Radiation Oncology, Princess Margaret Hospital at the University Health Network, University of Toronto. He studies community learning networks, with an emphasis on learning environments for health and education. This includes work on online interprofessional education for healthcare teams, as well as for patient learning. He is actively involved in the development of standards and technologies that assist people with various abilities and learning styles. This is explored through community informatics and the design of information and communications technology systems that enhance community health, social, economic, and political development.

Timothy W. Luke is University Distinguished Professor of Political Science at Virginia Polytechnic Institute and State University in Blacksburg, Virginia. He also is the Program Chair for Government and International Affairs in the School of Public and International Affairs, and he serves as Director of the Center for Digital Discourse and Culture in the College of Liberal Arts and Human Sciences at Virginia Tech. From 1997 through 2002, he was Executive Director of the Institute for Distance and Distributed Learning, which is the university's main on-line learning environment. His recent books are Capitalism, democracy, and ecology: Departing from Marx (University of Illinois Press, 1999); The politics of cyberspace, ed. with Chris Toulouse (Routledge, 1998); and Ecocritique: Contesting the politics of nature, economy, and culture (University of Minnesota Press, 1997). His latest book, Museum politics: Powerplays at the exhibition, was published in 2002 with the University of Minnesota Press.

Steve Mann has written more than 200 research publications and has been the keynote speaker at more than 25 scholarly and industry symposia and conferences and has also been an invited speaker at more than 50 university Distinguished Lecture Series and Colloquia. He received his Ph.D. degree from MIT in 1997 for work including the invention of Humanistic Intelligence. He is also inventor of the Chirplet Transform, a new mathematical framework for signal processing, of Comparametric Equations, a new mathematical framework for computer mediated reality, and of the FUNtain fluid user interface. He is currently a tenured faculty member at the University of Toronto.

John W. Maxwell is a faculty member of the Master of Publishing Program at Simon Fraser University in Vancouver, where his focus is on the impact of digital technology in the cultural sector. His research interests include the history of computing and new media, and contemporary myth-making in the face of digital media.

Rochelle Mazar has a B.A. in English, a masters degree in Theological Studies, and spent a couple of years in a Ph.D. program in History before seeing the light and going to library school. Currently she is an Instructional Technology Liaison Librarian at the University of Toronto at Mississauga. She has been involved in online educational environments since 1993, and likes to write fiction in her spare time.

Ken S. McAllister is an Associate Professor of Rhetoric at the University of Arizona and the Co-Director of the Learning Games Initiative (http://lgi.mesmernet.org), an international research organization that studies, teaches with, and builds computer games. He also runs the Arizona Chapter of Alternative Educational Environments, which works with teachers, scientists, inventors, artists, and humanities scholars to develop innovative instructional technologies and contexts for learning.

Steve McCarty is a Professor at Osaka Jogakuin College in Japan. Since 1998 he has been re-elected President of the World Association for Online Education (www.waoe.org). He teaches English as a Foreign Language (EFL) through topics such as current events, human rights and bilingualism. His college was the first in the world, before Duke University, where all entering students receive iPods with listening materials. Born in Boston, he specialized in Japan at the University of Hawaii. His Website of online publications received a four-star rating, very useful for research, in 1997, 2001 and 2005 from the Asian Studies WWW Virtual Library.

Dr. Ronen Mir is the Executive Director of SciTech Hands On Museum in Aurora, Illinois and a guest scientist at the Fermi National Accelerator Laboratory. Dr. Mir focuses on Science Education for the public, helping to develop Science Centers in the US, South America and Israel. He received his Ph.D. in Physics from the Weizmann Institute of Science, Israel, and a Museology Certificate from Tel Aviv University, Israel. He and his wife, Dr. Debby Mir, are the parents of Shlomi (18), Adva (16) and Julia (12).

Jane Mitchell is a senior lecturer in the Faculty of Education at Monash University (Australia). Her research interests focus on curriculum and pedagogy in teacher education. A particular aspect of her research is concerned with the design and analysis of new learning spaces using web-based technology.

Ryan M. Moeller is an assistant professor in the Department of English at Utah State University. He teaches courses in professional writing, rhetorical theory, and the rhetorics of technology. His research is focused on the relationships among technique, technology, and rhetorical agency. His work has appeared in *Technical Communication Quarterly*, *Kairos*, *Works and Days*, and in book chapters. He is currently working on a book manuscript that examines the rhetoric of consumer electronics through political economy analysis.

Gale Moore is the Director of the Knowledge Media Design Institute (KMDI), an interdisciplinary research and teaching institute and intellectual incubator at the University of Toronto, and a professor in the Department of Sociology. As sociologist-designer, her primary interests for the past 15 years have been the social impacts of ICTs in everyday life, and on bringing an understanding of peoples' experience and practice into the design of new technologies. As a sociologist of work and organisations, her interests have been in understanding collaboration as a nexus of people, practice and technology, and in interdisciplinarity and innovation in the contemporary university. Moore is a co-inventor of ePresence Interactive Media.

Monica Murero is the Director of the E-Life International Institute, and Professor in Communication and Media Integration at the Center of Excellence MICC (Media Integration and Communication), University of Florence in Italy. She is a consultant working for the European Commission, and she is the Treasurer of the International Association of Internet Researchers (aoir.org). In 2002 she founded the International Network of Excellence in E-Health Research (INoEHR) with Susannah Fox (Pew Internet). Her interdisciplinary work has appeared in several international journals, publications and television programs. Prof. Murero has received several international awards and grants, including the "Rientro Cervelli"—the most prestigious Italian award granted to distinguished scientists working in the international community—and has authored and co-edited three books. Her next book, with R. E. Rice, projected for 2006 is Internet and health care: Theory, research and practices, Lawrence Erlbaum Associates.

Elizabeth D. Mynatt is the GVU Center Director, the HCC Ph.D. Program Faculty Coordinator and an Associate Professor in the College of Computing at the Georgia Institute of Technology. There, she directs the research program in Everyday Computing—examining the human-computer interface implications of having computation continuously present in many aspects of everyday life. Themes in her research include supporting informal collaboration and awareness in office environments, enabling creative work and visual communication, and augmenting social processes for managing personal information. Dr. Mynatt is one of the principal researchers in the Aware Home Research Initiative which is investigating the design of future home technologies, especially those that enable older adults to continue living independently as opposed to moving to an institutional care setting.

Gary Natriello is the Gottesman Professor of Educational Research and Professor of Sociology and Education at Teachers College, Columbia University. Professor Natriello's work has focused on the education of at-risk youth, the evaluation of student performance, the social organization of schools, and the sociology of online learning. He is a past Editor of the *American Educational Research Journal* and the current Executive Editor of the *Teachers College Record*.

Vera Nincic received her Ph.D. from the Ontario Institute for Studies in Education at the University of Toronto. Her research explores the intersections of immigration, language, and computer technologies, and her dissertation focused in particular on the uses of computer technologies by nonnative English speaking students in academic contexts. She is now the Research Coordinator of a major research project in the Faculty of Nursing, University of Toronto.

Jeff Noon was born in 1957, in Manchester, England. He was trained in the visual arts, and was musically active in the punk scene, before starting to write plays for the theatre. Since his first novel, Vurt, published in 1993, he has concentrated on finding new ways of writing, suitable for portraying the modern world in all its complexity, taking ideas and methods from musical composition and applying them to narrative. His other books include Automated Alice, Pixel Juice, Needle in the Groove and Falling Out Of Cars. His plays include Woundings, The Modernists and Dead Code.

Vicki O'Day is a doctoral student in cultural anthropology at U.C. Santa Cruz. She is currently studying the uses of computational materials and ideas in biological research, particularly in the context of research into age-related genes and new models of human aging. Before returning to student life, she worked in several research labs in Silicon Valley, where she designed software and studied technology use in offices, schools, and libraries. Her earlier work addressed problems in information access, collaborative work, and online communities for senior citizens and children. She is the author (with Bonnie A. Nardi) of Information ecologies: Using technology with heart.

Ashok Patel is Director of CAL Research at De Montfort University, United Kingdom. A professional accountant, his research interests have expanded to intelligent tutoring and adaptive learning. He is Co-Editor of the SSCI indexed *Journal of Educational Technology & Society* (ISSN 1436-4522) and executive committee member of the IEEE Technical Committee on Learning Technology.

Brian Pauling's employment background spans many years of working in radio, television, bookselling, publishing, community education, adult education and tertiary education in New Zealand. He is a regular broadcaster and has published and presented, nationally and internationally, on media and education issues. He was also responsible for the establishment of the first independent community access radio station, PLAINSFM, which began intermittent broadcasting in 1984 and full-time broadcasting in 1987. He has a particular interest in the educational theories of capability learning, cooperative education, immersion learning and independent learning, all of which inform the qualifications and the teaching practices of the School. His current research involves a study of the impact of converging technologies (television, telecommunications and computers) on the delivery of teaching and learning. He is media consultant for a number of regional and national organisations. Brian began the broadcasting programme at CPIT in 1983 and was the first Head of School.

Roy Pea is Stanford University Professor of the Learning Sciences and Director of the Stanford Center for Innovations in Learning. He has published 120 chapters and articles on such topics as distributed cognition, learning and education fostered by advanced technologies including scientific visualization, on-line communities, digital video collaboratories, and wireless handheld computers. He was co-author of the National Academy Press's How people learn. Dr. Pea is a Fellow of the National Academy of Education, American Psychological Society, and the Center for Advanced Study in the Behavioral Sciences. He received his doctorate in developmental psychology from Oxford as a Rhodes Scholar.

Michael A. Peters is Professor of Education at the University of Illinois. He held a chair as Professor of Education in the Department of Educational Studies at the University of Glasgow (2000–2005) as well as positions as Adjunct Professor at the University of Auckland and the Auckland University of Technology. He is the author or editor of over twenty-five books and the editor of Educational Philosophy and Theory, Policy Futures in Education and E-Learning. His research interests include educational philosophy, education and public policy, social and political theory.

Ruth Raitman received her BSc (Mathematics) and BComputing (Honours) degrees from Deakin University, Australia in 2000 and 2001, respectively, and is currently a Ph.D. candidate in the same university, soon to complete all requirements. She is the HDR Representative of the Faculty of Science and Technology School of Information Technology School Board at Deakin and also acts as an online facilitator and tutor for several units. Her research interests include e-learning, online collaboration and the employment of wikis in the virtual environment.

Michael Rennick is the Director of Online Publishing for the *Teachers College Record* at Teachers College, Columbia University and a doctoral student in the interdisciplinary program in education. His research interests include constructivist approaches to education, and social interaction in online environments.

Sharon J. Rich is a Professor and Dean of Education at the University of New Brunswick in Canada. She has published several papers about teaching and learning in the virtual environment. Together with her team of collaborators she was responsible for developing the online continuing teacher education program at the University of Western Ontario. Her research interests include the development of online community.

Rhonna J. Robbins-Sponaas earned her Master's in English (Creative Writing) from The Florida State University, and is working toward a doctoral defense in American Literature. Currently residing in Norway, she teaches writing and literature to Norwegian and American students at the university level, both online and face-to-face, and teaches English (ESOL) to Norwegian students. Rhonna is a member of the enCore Consortium, has served as executive director for an academic MOO, and as editor-in-chief for a recognized online literary journal. Current projects include a book on Norway for junior readers, and another about teaching writing online for higher education students.

Vera Roberts is a researcher at the University of Toronto's Adaptive Technology Resource Centre where her primary interests are inclusive design, software usability, inclusive usability testing methods, as well as ways to use the capability of new technology to enhance new media so that it is fully accessible. At the ATRC, Vera has been involved in many projects including Barrier-Free Access to Broadband Education (http://barrierfree.ca), The Inclusive Learning Exchange (www.inclusivelearning.ca) and The Canadian Network for Inclusive Cultural Exchange (www.cnice.utoronto.ca). As part of her research, Vera has developed and tested a usability testing method (gestural think-aloud protocol) for individuals who are deaf and communicate with American Sign Language.

Dr. Glenn Russell has had more than thirty years experience teaching in Australian schools and universities. He currently lectures in ICTE (information and communications technology in education) in the Faculty of Education at Monash University. He has an international reputation in virtual schooling, cyberspace, and educational uses of hypertext. His current research involves ethical uses of information and communications technology in school education, virtual schools, and future trends in instructional technology and school education.

Janet Ward Schofield is a Professor of Psychology and a Senior Scientist at the Learning Research and Development Center at the University of Pittsburgh. Her research focuses on two areas—the social psychology of educational technology use, and race relations. She has published over ninety papers and four books including Black and white in school, Computers and classroom culture, and Bringing the Internet to school. She has served as a consultant to local, state and national governments, as a member of boards and committees at the U.S. National Academy of Sciences, and as an elected member of the American Psychological Association's governing body, the Council of Representatives.

Pris Sears is currently the Network Administrator for the Department of Horticulture at Virginia Tech. Her recently taught courses addressed web site design and development, semiotic theory, and graphic design. She earned her M.A. in the Instructional Technology Program at Virginia Tech. Previous publications include "HTML origins, owners, good practices," in WWW: Beyond the basics, and "Preparing tomorrow's teachers to be socially and ethically aware producers and consumers of interactive technologies," in Contemporary issues in technology and teacher education.

Boris I. Sedunov is Deputy Rector of the Moscow State Institute of Business Administration and the leader of its International Virtual University project. Born in Eastern Siberia, he received a Master of Science degree in Engineering-Physics and a doctorate in Physics-Math Sciences from the Moscow Institute of Physics and Technology. He instructs courses on general, strategic and innovation management, presentation techniques, and modern concepts of natural physics for managers. He developed and promoted the methodology on how to effectively involve English-speaking business teachers from the United States in the current educational process. He has created new theories in statistical physics and the philosophy of management.

Cynthia L. Selfe is Humanities Distinguished Professor in the Department of English at The Ohio State University, and the co-editor, with Gail Hawisher, of*Computers and Composition: An International Journal*. In 1996, Selfe was recognized as an EDUCOM Medal award winner for innovative computer use in higher education-the first woman and the first English teacher ever to receive this award. In 2000, Selfe and her long-time collaborator, Gail Hawisher, were presented with the 'Outstanding Technology Innovator Award' by the CCCC Committee on Computers. Selfe has served as the Chair of the Conference on College Composition and Communication and the Chair of the College Section of the National Council of Teachers of English. She is the author of numerous articles and books on literacy and computers.

Dr. Ramesh Sharma holds a Ph.D. in Education in the area of Educational Technology and since 1996 has been working as Regional Director in Indira Gandhi National Open University (IGNOU). Before joining IGNOU, he was with a Teacher Training College for nearly ten years and has taught Educational Technology, Educational Research and Statistics, Educational Measurement and Evaluation, Psychodynamics of Mental Health Courses for the B.Ed. and M.Ed. Programmes. He has conducted training programmes for the in- and pre-service teachers on the use of multimedia in teaching and instruction, and established a Centre of ICT in the College. His interests include the areas of open and distance learning, ICT applications, on-line learning, and teacher education.

Mark Shepard is an artist and architect whose cross-disciplinary practice draws on architecture, film, and new media in addressing new social spaces and signifying structures of emergent digital cultures. He is a founding member dotsperinch—a collaborative network of artists, architects, technologists, and programmers developing new media environments for the arts, museum, design, and education communities. Mark holds an M.S. in Advanced Architectural Design from Columbia University; an MFA in Combined Media from Hunter College, CUNY; and a BArch from Cornell University. He is an Assistant Professor of Architecture and Media Study at the State University of New York (SUNY), Buffalo.

Professor Brian Shoesmith is Adjunct Professor, School of Communications and Multimedia at Edith Cowan University, Perth, Australia. He has conducted extensive research in Asian media and digital culture. His recent publications have focused on the emergence of digital culture in international contexts and the different interventions that new media have on different societies.

Dr. Eleni Skourtou is Assistant Professor at the University of the Aegean, Department of Primary Education. Her research areas are: bilingualism and bilingual education, orality/literacy/multiliteracies, bilingualism and language contact, bilingualism and second language learning/teaching in an electronic environment.

Erin Smith is an Assistant Professor of New Media at Michigan Technological University. She has published on literacy in relationship to video games and other new media. The focus of her current research is on data-base driven writing systems and literacy.

James J. Sosnoski is the author of Token professionals and master critics; Modern Skeletons in postmodern closets and essays on instructional technology. He co-edited The geography of cyberspace; Conversations in honor of James Berlin; and The TicToc conversations. He directed the Society for Critical Exchange, the GRIP and TicToc projects. He coordinated the Virtual Harlem project and co-edited Teaching history and configuring virtual worlds: Virtual Harlem and the VERITAS studies. He is writing Configuring: The art of understanding virtual worlds, on the role of virtual experiences in interpersonal understanding.

Kevin Sumption is the Associate Director of Knowledge and Information Management at Australia's largest science museum, the Powerhouse Museum. For 15 years he worked as both a science and social history curator and for much of this time has focused his research energies on the creation of computer-based education programs and regularly publishes articles re online learning. Kevin is also a lecturer in Design Theory and History at the University of Technology, Sydney and has been an invited speaker at conferences in the UK, France, USA and Japan. He has also worked for UNESCO on a range of cultural informatics projects in central Asia.

Jutta Treviranus is the coordinator of The Inclusive Learning Exchange (TILE) project, and also coordinated the now completed Barrierfree project. Jutta established and directs the Adaptive Technology Resource Centre at the University of Toronto, a centre of expertise on barrierfree access to information technology. She directs the Resource Centre for Academic Technology and is the chair of international interoperability specification working groups in the World Wide Web Consortium and the IMS Global Learning Consortium. Status faculty appointments are held in the Faculty of Medicine, and the Knowledge Media Design Institute, University of Toronto.

Kylie Veale is a Ph.D. candidate in Media and Information at Curtin University of Technology, Australia, and has recently graduated from the Master of Internet Studies programme. Her current research interests revolve around environments of use within online communities, and the balance of online activities among publishing, transacting, interacting, and collaborating. Her Ph.D. research programme combines her academic interest in the Internet with a long-time hobby—genealogy—by investigating a broad set of interactions of the online genealogical community, as a case in point for hobbyist usage of the Internet.

Dr. Lucas Walsh is currently a postdoctoral research fellow within the School of Communications and Multimedia at Edith Cowan University, where he is engaged in research on democracy and interactive environments. He is also a Fellow of the Department of Learning and Educational Development at the University of Melbourne, in Australia.

Prof. Barry Wellman leads the NetLab at the University of Toronto, studying the intersection of computer, communication, and social networks in the communities (the "Connected Lives" project) and organizations ("Transnational Immigrant Entrepreneurs"; "Media Use in Organizations). He's the founder of the International Network for Social Network Analysis, the chair of the Communication and Information Technologies section of the American Sociological Association, and the chair-emeritus of the ASA's Community and Urban Sociology section. Prof. Wellman has co-authored more than 200 articles and is the co-editor of <u>Social structures: A network approach</u> (1988); <u>Networks in the global village</u> (1999), and <u>The Internet in everyday life</u> (2002).

Dr. Angela F.L. Wong is an Associate Professor with the Learning Sciences and Technologies Academic Group, National Institute of Education (NIE), Nanyang Technological University, Singapore. She is also the Associate Dean for Practicum and School Matters in the Foundation Programmes Office. The practicum is the teaching practice component of all initial teacher-training programmes at NIE. She currently lectures in instructional technology and classroom management modules. Her research interests include learning environments, science education, instructional technology and practicum-related issues in teacher education.

Yong Zhao is Professor of Educational Psychology and Educational Technology at College of Education, Michigan State University. He is also the founding director of the Center for Teaching and Technology as well as the US-China Center for Research on Educational Excellence. His research interests include educational uses of technology, school adoption of technology, and international education. Zhao received his Ph.D in Education from the University of Illinois at Urbana-Champaign.

Professor Wanlei Zhou received the B.Eng and M.Eng degrees from Harbin Institute of Technology, Harbin, China in 1982 and 1984, respectively, and the Ph.D. degree from The Australian National University, Canberra, Australia, in 1991. He is currently the Chair Professor of IT and the Head of the School of Information Technology, Deakin University, Melbourne, Australia. Before joining Deakin University, Professor Zhou had been a programmer in Apollo/HP in Massachusetts, USA; a Chief Software Engineer in High-Tech Computers in Sydney, Australia; a Lecturer in the National University of Singapore; and a Lecturer in Monash University, Melbourne, Australia. His research interests include theory and practical issues of building distributed systems, Internet computing and security, and e-learning. Professor Zhou is a member of the IEEE and IEEE Computer Society.

Anita Zijdemans is a doctoral candidate in Applied Cognitive Science in the Department of Human Development and Applied Psychology at OISE/UT. Her interests lie in fostering and supporting communities of learning in diverse contexts and settings, through the creation of virtual environments based on design principles informed by human development & education, learning & technology, sociology, and human/computer interaction. Anita holds an Honours degree in English/French, a Bachelor of Education from York University, and a Master of Arts degree in Human Development and Applied Psychology from the University of Toronto.

Slavoj Zizek is a Slovenian sociologist, philosopher and cultural critic. Zizek was born in Ljubljana, Slovenia (then part of Yugoslavia). He received a Ph.D. in Philosophy in Ljubljana, studied Psychoanalysis at the University of Paris, is currently a professor at the European Graduate School and a senior researcher at the Institute of Sociology, University of Ljubljana, Slovenia. He is a visiting professor at Columbia, Princeton, New School for Social Research, New York, and the University of Michigan.

Introduction: Virtual Learning and Learning Virtually[1]

JOEL WEISS

> . . . imagine for one full day what life would be like without access to current technologies such as computers, cell phones, handheld devices, DVD's, the internet, data systems, or e-mail. (Bromfield, 2005, 1)

This is a description of a recent internet-based school curriculum initiative for students, teachers and parents to imagine life without modern technologies. While the context is North American schooling, the implications are far-reaching for all. Regardless of our location on the planet, and the cultural and language spaces in which we work and live, computers and other technological innovations influence our lives to a greater extent all the time. As computers take on a more visible role in our lives, moving from government and research institutions into our communities, schools, and homes, we become more aware of how these are both mediators of, and in themselves, learning settings.

Created learning environments are as old as societies' first attempts at socializing its young, and these settings have taken a variety of forms ranging from the concrete literal to the creative imaginary. The relatively recent development of the digital age has spawned interest in what has come to be called 'virtual reality' and in delineating what this means for learning and the creation of 'virtual learning environments'. This Handbook was created to explore features of virtual worlds and the relationships with diverse learning settings. Since the concept of, and discourse surrounding, virtual learning environments are not well developed in the literature, a deliberate strategy has been to be expansive in choosing contributions. We sought out numerous contributors representing multiple discourses with the aim of creating some coherence in a complex field.

The resultant inclusion of sixty-three chapters requires creating some advanced organizers by which to view the project. First, what is meant by

[1] The International Handbook of Virtual Learning Environments has been quite the transformative experience. Jason Nolan has been his usual provocative self, pushing me in new directions throughout the various stages of the Handbook's development. Jeremy Hunsinger added some new directions when he joined us two years ago to replace Peter Trifonas who took on other professional responsibilities. Vera Nincic's skills in the virtual world enriched the project. From the beginning, Michel Lokhorst, a former Senior Editor at Springer, encouraged us to make this an enjoyable, worthwhile professional experience.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1–33.

technology and does 'virtual' always, implicitly or explicitly, require modern technology ushered in by the 'computer age'? Second, what view of learning allows for the broad spectrum of possible situations that people interact with in their complicated lives? Third, since the editors are primarily educators, is there an educational framework that provides a useful form of coherence for the topic of virtual learning environments? What follows immediately are sections which discuss technology and its relationship with virtual learning, a delineation of views about learning and an educational framework that relies upon perspectives on curriculum. Following that is a section on The Curriculum of the Handbook, including a description of its structure and each of the included chapters, and some thoughts about future activities.

TECHNOLOGY AND THE VIRTUAL WORLD

Technology is a complex construction: "It includes activities as well as a body of knowledge, structures as well as the act of structuring." (Franklin, 1990, 14) Its complexity has been evident throughout the history of considering the so-called real world. When we turn to a consideration of cyberspace, this complexity is no less evident. Technology helps to create, and is also the site for, virtual learning environments. It's both part of the process and is also a product.

It has become commonplace to describe the learning environments mediated by computers and digital technologies as virtual learning environments (VLEs) in order to separate them from the real world learning environments that have been with us since individuals came together to form communities and societies at the dawn of our various cultures. However, as Burbules points out in the first chapter of this volume, virtual can be an illusory concept, one with multiple meanings. A learning environment doesn't necessarily have to involve digital technologies in order for it to be considered a virtual learning environment. People over the centuries, especially through the arts, have developed learning settings where individuals need to use their imagination, often including the realm of fantasy, thus creating VLE's.

I believe the confusing element in the virtual equation is the view that only computer technology is both the necessary and sufficient criterion for a virtual learning environment. It is a misunderstanding of technology that is clearly enunciated by Ursula Franklin in The Real World of Technology (1990). She describes technology: as 'a practice' and her description of what it is not is informative for this discussion. She writes: "Technology is not the sum of the artifacts, of the wheels and gears, of the rails and electronic transmitters. Technology is a *system*. . . . Technology involves organization, procedures, symbols, new words, equations, and most of all, a mindset." (12) It is the idea of mindset that suggests that the virtual is a concept of the imagination, the power of constructing possible models of human experience (Fry, 1969).

There are a variety of media for imaginative learning environments including oral speech, writing, print, movement, photographic, electronic as well as digital. Educators of a variety of backgrounds from formal, informal and non- formal groups, including parents, media specialists and artists have used a variety of practices for stirring the imagination of learners. Who hasn't experienced, for example, literature, creative writing, music, role-playing as settings for learning? This presumes a more historically focused long-term perspective on technology, which includes such examples as the development of the printing press, the use of pen and ink, photographic process, film, radio, television and the like.

In order to indicate that there are many types of virtual experiences, I make a distinction between virtual learning and learning virtually. Virtual learning is reserved for digital/ computer-based learning environments. Learning virtually is a much broader term signifying any context that allows for imaginative possibilities. It includes environments utilizing a broad array of traditional media and contexts for meaning making. For example, the use of settings employing literature (in its various forms) engenders a process of interpretation by a learner, leading to the creation of virtual, different from actual, texts (Bruner, 1986). The process of creating a virtual text can be seen as initiating a learning journey that uses previous experiences and images as markers in, and of, the creation. Bruner suggests that features of discourse enable readers to create their own virtual worlds through making implicit interpretations, depicting reality through a lens of the consciousness of characters, and often filtering the world through multiple interpretive screens. He also presents concrete comparisons between a reader's created virtual, and the actual, text (Bruner, 1986, 161–171). Learning virtually is possible with other settings that enable learners to make imaginative interpretations. Interactions with other objects (paintings, prints, photographs, musical and dramatic presentations) and media (radio, movies, television, television) are but a few of the possibilities for creating virtual texts.

Where the two terms merge is where digital representations of learning environments use procedures that existed prior to the computer age. Examples of VLE's that are primarily complex transformations of activities that exist in the real world without computers include writing an essay or sending a message by e-mail, viewing a page of text or an image, perhaps reading an e-book, or undertaking some teaching or training activity. Other VLEs are more fully realized virtual experiences for which no analog exists outside of the computer; the ability to create new worlds, new topologies, new people, and experience them, embody them, transform them in collaboration with individuals from around the globe is truly a virtual experience. However, from an educational perspective, both types of learning environments are subject to similar criteria for success in whatever is supposed to be learned. Some criteria may be more appropriate for some environments than for others, but it's not so clear as to whether virtual learning requires substantially different ones than other types of learning environments. Perhaps the imaginative use of technology creates differences of kind as opposed to type.

Often, the rhetoric surrounding any important innovation can be fraught with hyperbole. With more and more changes in technology and applications associated with the technology becoming mainstream, there is the real concern that expectations for what virtual life means for learning and the creation of learning settings outstrips the capability. The existence of an application does not necessarily guarantee success as intended. Technology and associated applications start with potential, but there are many features that guide the direction of where and how that potential becomes realized. The application of technology cannot be considered in the abstract- it requires an understanding of the educational landscape in which it is considered. The next section provides the view of learning that helped to frame choices included in the Handbook. I also present an educational framework from a curricular perspective that has been useful in analyzing the rich complexities of VLE's.

LEARNING, CURRICULUM AND VIRTUAL LEARNING ENVIRONMENTS

The view of learning that informs our work is an amalgam of traditions best summarized by Kolb as "... learning is the process whereby knowledge is created through the transformation of experience' (1984, 41). The importance of learning in all facets of our lives, and our experience with the world around us, can be seen as the participation in an interconnected series of learning environments. Some we engage with as part of social, educational and economic interactions, and some as personal and spiritual experiences. In reality, these experiences are located in, and mediated through, learning environments. These environments should not be viewed as belonging exclusively to the formal educational sector. There are plentiful informal and non-formal contexts that are potential situations for 'learning moments'. Our encounters with the natural environment provided the impetus for the 'romantic 'view of learning espoused by Rousseau. For the most part, however, we usually consider creating settings for maximizing the possibilities of 'learning moments'. These settings may differ depending upon specific cultural arrangements that help to describe the practices of any particular society. However, there are situations common to all societies where learning is necessary. Such examples include childrearing, physical and emotional survival, work, spiritual activities, leisure time pursuits, and life ritual situations of birth, coming of age, procreation and dying. Later, I discuss the concept of the curriculum of life that includes these, and other potential learning settings.

In searching for a perspective for the Handbook, there's both an embarrassment of riches, as well as a paucity of material related to VLE's. There is no shortage of writing about the virtual world. Beyond Marshall McLuhan, William Gibson, Bruce Sterling and other writers of science fiction and future worlds, there has been an explosion of both popular and academic material. Many fields of study and disciplines have important contributions to make about this world. Several come to mind- political science and politics; anthropology; history; sociology; cultural studies and media; literature and English studies; computer science; communication; feminist studies; medicine, law, architecture, engineering, design and other professional fields; geography; psychology and cognitive science. People trained in the field of education have made their own contributions, especially in computer studies, higher education, teacher education and learning networks. While all of these areas have contributed to our understanding of virtual worlds, I suggest that our knowledge of virtual learning environments is still somewhat opaque and requires more clarity. Because the editors of this Handbook have approached this project from an educational stance, it is incumbent upon us to further clarify how an educational stance is one perspective by which to develop discourse on virtual learning and virtual learning environments. This perspective assumes a broad reach on what education is and who is an educator. Although many of the contributors in this volume would not self-identify as trained in education, we have assumed that regardless of their background, they are educators in an important sense-interested in communicating and involved in the teaching/ learning process. Thus, from our perspective, they're all engaged in a curriculum-making activity.

I have chosen to use some of the discourses surrounding the concept of curriculum as an approach to elucidate aspects of virtual learning environments. This provides a metaphoric compass, enabling some boundaries to be placed on analyzing the multiple discourses that are found in the literature of virtual learning environments.

Curriculum Commonplaces

The term "curriculum" is deliberately used as something broader than its usual location as an aspect of schooling, because curriculum is something that provides scaffolding for learning in any setting. A conceptual tool for understanding this structure is a set of commonplace terms containing a minimum required for describing any curricular situation (Weiss, 1989). These include 'learner', teacher', 'subject matter', and 'milieu' in which these other concepts function. I view these commonplaces as a generative metaphor (Schon, 1979) representing a pervasive tacit image that influences actions, such as development and policy activities. Since curriculum is a value-laden concept, each of the commonplaces represents the potential for different points of view, and potential action. As an example, there are different perspectives on "the learner", ranging from an empty vessel receiving information, to a stimulus-seeking, curiosity driven person constructing his/her own sense of the world. Notions of "the teacher" are representations of different approaches to pedagogy including people, machines and other forms of technology used to engage learners. Every curricular engagement deals with learning/teaching about content, the commonplace of "subject matter". This represents a wide spectrum of possibilities including school subject matter, information for our personal life, such as medical or travel possibilities, or even processes involved in exposure to that setting. "Milieu" refers to the variety of conditions under which the learner, teacher and subject matter interact. This includes the specific conditions, such as setting, materials used, time of day, and the like. It also includes the broader historical, political, social and economic factors that shape the context for any particular learning engagement. Any curriculum "moment" is a distillation of the complex interactions among the commonplaces.

Hidden and Null Curricula

The field of curriculum continually wrestles with the dilemma of what language to use in characterizing its structure. Jackson (1992) presents an extensive discussion of the various terminologies used over the years to describe what counts as "curriculum". Generally, it is defined in terms of the outcomes of a complex teaching-learning context. However, two contrasting sets of outcomes, characterized as positive or negative, frame the discussion so that two separate curricula have become the norm in curriculum discourse. One is explicitly endorsed, while the other is not. Labels attached to this dichotomy include: intended/unintended, accomplished/unaccomplished, written/unwritten, delivered/received or experienced. The most popular representation of the negative curriculum is the 'hidden curriculum'. The term was coined by Jackson in Life in Classrooms (1968) and has assumed mantra-like importance to critics of educational structures and institutions (Apple, 1980; Vallance, 1977). The concept has been useful in exposing the values, attitudes and structural mechanisms underlying curriculum decision-making and activities and may provide a way to look at what's transpiring in creating and maintaining VLE's.

A related aspect of the hidden curriculum is the notion of the 'null curriculum' (Eisner, 1979; Flinders, Noddings, and Thornton, 1986). This concept is based on the recognition that learning involves both opportunities and lost opportunities; that every choice may exclude other possibilities. The underlying issue of the null curriculum is the opportunity to learn, or more appropriately, lost learning opportunity. This is similar to what economists refer to as opportunity costs. In the context of formal learning environments, the null curriculum may be in operation when basic skills are chosen over the arts as an explicit indicator of setting priorities. But on a systemic level, the null curriculum is more problematic. Content, language, and evaluative structures that privilege one culture, gender or language group over another represents the outcomes of a null curriculum that limits opportunities for some learners while providing advantages for others. At a deeper level, funding strategies that privilege different social groups or place restrictions on the scope and choice of available learning environments influence what kinds of things *can* be learned. These examples are not necessarily hidden, but they are often ignored for what they are, and are taken for granted as factors effecting the creation of learning environments by educators, parents, students and policy makers. For example, in the context of the internet, there are numerous examples of such lost opportunities, ones in which individuals make conscious choices of what to attend to, and those which are structured so that there is little or no choice in one's activities. The latter is where the hidden and null curricula intersect.

The hidden curriculum represents the barriers that cannot be easily identified and rendered problematic. What people think they are experiencing and participating in *is* the curriculum and often the hidden curriculum is what ensures the maintenance of the null curriculum. Encountering both involves unpacking these curricula by identifying the 'taken for granted' features and to suggest strategies for finding the complexities and values that are not explicit. This helps to direct what and how we can learn.

Just as there was a real person manipulating events behind the screen in "The Wizard of Oz", so there are people making curriculum decisions behind the technology in learning environments. Whoever is behind the screen, such as teacher or software developer, makes value choices from among competing perspectives about the various commonplaces. Choices made about obvious categories of the learner, such as age, gender, language competence, social background are grounded in images of these characteristics. These competing images can be represented as questions of choice. Are learners seen as being active or passive, flexible or rigid, knowledge constructor or empty vessel? How much experience have they acquired with settings that require imagination and fantasy? Is there a particular modality, or familiarity with media/technology favored within the setting? Is there interest in individual learners or with a community of learners? Questions related to choices made about the nature of knowledge might be: What kinds of previous knowledge and skills must be accounted for in creating a learning environment? Is it assumed that knowledge is personal or general? How valid is the information that is found on a particular website? Are there conflicts among various groups and/or individuals as to what is acceptable for people to know? How do you negotiate between process and substance considerations? Are the materials and/or settings novel or familiar to learners?

What views of teaching inform the structure of the learning engagement? Is it structured as an information provider solely, or as enabling a more constructivist approach? Does the use of sophisticated technology make a difference to the underlying approach? To what extent do learners encounter in real life people (parents, teachers, friends, professionals) as well as those behind the screen?

How much of the learning encounter is framed by the technology so that learners interact in ways that differ from more traditional settings? Are materials readily available or does the setting encourage learners to shape the conditions for learning? What are the limits for technology to shape vicarious experiences? Is technology viewed as a neutral tool, a variable kept under control, or as a socially situated setting where technologies serve as mediators? How much does the reality of the digital divide influence the larger picture of access to resources? How do policies and programs from governments, the private sector and non-governmental organizations (NGO's) influence the conditions for learning virtually and virtual learning?

Curriculum of Virtual Community

Some of these features of curriculum discourse have facilitated an understanding of virtual learning environments. In a book devoted to an exploration of the concept of virtual community, Nolan and Weiss (2002) conceptualized a Curriculum of Virtual Community to explore some of their learning features. They posited three broad locations for learning: Initiation and Governance; Access; and Membership. There is the location associated with first initiating and then maintaining the locus of interaction, The Curriculum of Initiation and Governance is associated with the learning required for initiating and maintaining the site of a virtual community. Curriculum of Access is associated with accessing and becoming socialized to virtual community itself, which includes what is required to become a member: learning about the site, how to access it, and the rules that govern membership. Finally, there is the Curriculum of Membership that relates the actual engagements in the community, the purposes for which the site was constructed and the gains people expect from it.

Many features of virtual community may translate to the larger community of the internet. This meta-community comprises almost limitless numbers of communities, and information nodes and networks devoted to among other things: commerce, education, governance, and social life. The internet requires interactions among five key industries: telecommunication, software, internet service providers, search engine providers, and web content providers.

Much of what transpires *on* the internet is largely opaque, often seen as value neutral. Weiss and Nolan (2001) expanded their conception of the Curriculum of Virtual Community to discuss some of the learning features of the internet. Using the concepts of curriculum commonplaces, null curriculum and hidden curriculum, they analyzed some of the taken for granted structural features of the internet. Since that time, there have been a number of developments that have impacted our knowledge base of the internet, rendering it as a more transparent structure. For example, while its early development had been dominated by contributions of white Western males, now much of the technology and use has become more widespread, witness the contributions from India, China, other Asian countries, as well as those from the Spanish-speaking world. Clearly, there are now many more contributions being made by females. Perhaps the most visible sign of the changes is the creation of the World Summit on the Information Society, and the very open process being conducted by the Working Group on Internet Governance (WGIG) whose tasks were to: "develop a working definition of Internet Governance; identify the public policy issues that are relevant to Internet Governance". The results of this activity have been disseminated for worldwide discussion by making information available in numerous languages and in several formats (http://www.wgig.org/).

Other examples of changes in the internet can be found in the ways that individuals and groups have become involved in more open-ended, empowering formats. The process of blogging has become an important, often creative, activity in many peoples' lives, touching upon the personal, political, social and the aesthetic. It has had serious impact upon the conduct of the media, governments and the political process. Another prominent example of the empowering nature of the internet is the development of Wikipedia, a web-based, multi-language, free content encyclopedia (en.wikipedia.org). It is written by volunteers and sponsored by a not-for profit foundation, Wikimedia Foundation. It has been created and distributed as a free encyclopedia in over two hundred languages, and has become one of the most popular internet reference sites. It differs from the conventional encyclopedia first developed by Diderot because anyone can contribute, regardless of any claim to authority on a subject. It is interactive since readers can edit an entry and have it instantaneously recorded online. Editorial policies are derived through consensus and occasional vote. Wikipedia has served as a model set of procedures for other groups to create their own communities of use. There are any number of curricular issues highlighted by this endeavor, especially ones related to views on the nature of knowledge, characteristics of learners, and issues of power and control.

These are but a few examples of many more complex issues and situations in which a curricular perspective might allow useful analyses. My purpose has been to provide a brief elucidation of some of the concepts that have helped me to unpack some of the features of a virtual learning environment. A number of the issues represented here are part of the stories told, in their own terms, by many of the authors in this Handbook. With this in mind, I now turn to a more focused description of this Handbook.

Any text should be seen as a set of curriculum materials, developed by some individuals for the use of others. This requires a set of intentions by the developers, in this case the Editors, through choices dictated by their views on the curriculum commonplaces around the topic of virtual learning environments. The Editors' backgrounds have driven the choices made of the framework, the medium, and the various represented topics. This translated into decisions about authors and genres. At one level, the Editors and authors provide the *teacher* aspect of the commonplaces. These decisions were determined with a view of the audience, the potential *learners*.

The *subject matter* of this project has been to describe the wide landscape of possibilities for discussing, conceptualizing, creating and inquiring into, virtual learning environments. The approach has been to consider a spectrum of discourses and the choice of authors and chapters attests to that accomplishment. This broad framework includes locating some of the historical narratives of various features and milestones of VLE development; exploring the differing conceptions of what VLEs were, are and might be; discussing issues surrounding the construction and governance of VLEs, including curricular and pedagogical features; describing case studies of created virtual learning environments in a variety of formal and informal parts of our everyday lives; and inquiring into the conceptions and forms of educational research that shed light on the development and application of VLEs in various social contexts and cultures.

Part of the story is told by recounting important parts of the past as well as the present scene. We have viewed learning in a diversity of environments to which people are exposed. Consistent with our framework, a curriculum of life was a useful organizer for the types of settings discussed by many of the contributors. We divided this curriculum into two broad categories: one concerned with more traditional aspects of schooling, professional learning and knowledge management; and the other with many of the other important learning settings in people's lives.

The content is divided into four sections: 1. Foundations of Virtual Learning Environments; 2. Schooling, Professional Learning and Knowledge Management; 3. Out-of-School Virtual Learning Environments; and 4. Challenges for Virtual Learning Environments.

Given its topicality, there is potential interest in this subject matter for a variety of audiences (*learners*). Most of the contributors are academics deliberately chosen for their expertise and often, their provocative views on their topic. Since so many different disciplines and fields are represented, we hope that readers will not only seek out material from their own areas, but will benefit from an understanding presented from other perspectives. Any piece of curricular material should have the potential for a learner creating new knowledge through transforming experiences. We also hope that a wide spectrum of practitioners in a variety of educational settings, such as schools, libraries, museums, health care, leisure industries, communities and others will find some of the material appropriate for their practices.

In considerations of *milieu*, our choice of a two-dimensional text medium is admittedly traditional for investigating virtual worlds. In part, this reflects the political economy of publishing in spite of the rise of e-books and possibilities for the Net. However, we like to think that many of the contributions provide the possibility for learning virtually, that is, they stimulate the imagination and suggest a sense of fantasy. This point is elegantly made by Burbules in our first chapter: "... an academic article can also be a virtual environment-one that you complement through your own interest, involvement, imagination and interaction.". We also decided to reprint several provocative pieces originally published for audiences different in many ways from the present context. This includes Donna Haraway's classic "Cyborg manifesto"; Slavoj Zizek's "The Matrix, or, the two sides of perversion", an analysis of the influential film to develop important theoretical formulations; and Jeff Noon's "Chromosoft mirrors", a pithy description of the dark side of virtual worlds. While a few in our audience may be familiar with one or more of these imaginative pieces, we believe that the wider audience should be exposed to their ideas. We especially wanted educators to visit, and in some cases, re-visit Haraway's ideas through the prism of relevance to classroom teaching/learning. Another contribution that should engage the reader with concrete manifestations of the fantasy world of cyberspace is found in Steve Mann's intriguing description of this engineer's life as a virtual learning environment.

Any presentation of the story of an important topic needs not only content from past and present, but also a sense of future issues. This requires a rendering of ideas developed out of relevant inquiry and of considered thought on potential possibilities/constraints. No less than other areas, virtual learning environments require a strong basis for inquiry to investigate the myriad claims made for education in cyberspace. How salient will exciting technological innovations be for changing the learning equation?

Section One: Foundations of Virtual Learning

The opening section of the Handbook, **Foundations of Virtual Learning Environments**, provides a number of perspectives for an understanding of the virtual world and learning. The idea of the virtual is laid bare in the introductory chapter by Burbules. He questions the several different interpretations placed on the concept and sets the stage by suggesting that virtual learning is closely linked with learning virtually through the "as if" experience. Digital technology is not viewed as necessary and sufficient criteria for learning in a virtual way.

However, the topic of technology can be seen as leitmotif for several of the other contributions in this section. Harasim's extensive history of e-learning traces the role of technology and discusses its impact on a shift in the calculus of learning. For her, this shift represents an optimistic future for the digital world to be influential in creating more relevant learning environments. Other contributors take a more nuanced view of the role of technology in learning. Peters believes that our philosophical knowledge base about technology is not well formed and suggests that a theoretical discussion on technologies would equip us to better understand the issues at hand. He analyzes several approaches to technology for their implications for a knowledge economy. Such a mapping strategy is an attempt to move beyond economic theories and technological innovations in order to shape public policy and create new fields of knowledge and research. Haraway's original contribution, "The Cyborg Manifesto", was a demonstration of political activism in using the concept of the cyborg to show how humans are implicated in technological systems. Working from feminist and socially conscious frameworks, she opened up the discourse about classroom technology issues and pedagogy in computer-mediated settings. She discussed a number of signifying practices in efforts at meaning making, cultural coding and social system construction, and has had great impact on academics in a number of areas, but especially those teaching composition and feminist studies. Selfe and Smith provide a discussion of the impact of "The Cyborg Manifesto" on both academics and practitioners and suggest that this work permanently joined class, race, sexuality and gender to technology discourse. An important part of the Selfe and Smith contribution is a global history of the importance of technology from a political economy perspective.

Hunsinger also addresses technology through issues of power relationships as embedded in informational capitalism. He suggests that there is a need to understand underlying biases, values and ideological positions embedded in the milieu as part of the responsibility toward technology's usages. By rejecting conformation to the business model, and treating education as a public good, he suggests that VLE's can be transformative regarding learning and the world. (This is in direct contrast to the argument made earlier by Davis and Botkin (1994) that schools have become irrelevant in the learning society.) Issues of resistance and transformation are also topics discussed by Nolan and by Kellner. The former looks at what is happening in the Net as a means of engaging "... the deep structure of hegemony of digital technology revolution". Nolan goes well beyond my earlier remarks on the curriculum of the internet, by providing a history of its foundation and genesis and by suggesting several technologies of resistance, such as consumers acting as prosumers, for learning to be a transformative experience. Kellner challenges educators to make changes in order to cultivate the multiple literacies required for technological and multicultural societies. Like John Dewey and Ivan Illich, he believes that education is a necessary ingredient in bringing about true democracy. Whereas he believes that Dewey failed in that objective, he suggests that pragmatic experimentation regarding technology and multiculturalism should lead to a re-visioning of education. Carmen Luke also wants to transform education in the fluid and mobile 'wired society' that has reconfigured our notions of time and space. She believes that the current challenge is to "... devise flexible, innovative, analytical tools with which to track the fluidity and mobility of 'travel' across the semioscape of links, knowledge fields, web pages, chat rooms, e-mail routes, inter-subjective and intercultural relationships".

Ito goes beyond the screen to investigate the human-machine interface. She looked at how young children interact with the software of games and determined that whatever the intentions of the software developers, learners can have a sense of agency in what they do and how they engage in the setting. By calling attention to the sociality of the interactions, she suggests that we have to question our prior understandings of social structures co-constituted by people and machines encountering one another across an increasingly complex set of interface conventions, as well as the relations of production and consumption that bring these actors together. The final contribution in this section by Maxwell addresses the important concept of constructionism, which has been featured in the discourse and practice of the digital age, for discussions about the nature of learning. He traces the pioneering work by Papert, Turkle and others in the Epistemology and Learning Group at MIT's Media Lab that articulated that 'learning happens best when children are engaged in creating personally meaningful objects and sharing them with their peers'. Maxwell re-examines the concept in terms of other ideas from situated learning, media theory and science and technology studies (STS), and suggests a new approach, "distributed constructionism'. His work should stimulate reflection on past ideas as well as provide a provocative way to introduce an ecological perspective on the topic.

Section Two: Schooling, Professional Learning and Knowledge Management

The second section of the Handbook, **Schooling, Professional Learning and Knowledge Management** represents more traditional settings for VLE's. However, the authors develop their ideas in important ways, and in some cases explore unmarked terrain. This includes chapters that discuss various aspects of schooling including issues related to school culture and organization, learner considerations, specific classroom related practices in language development, inclusive learning, and applications of virtual environments. Discussion about schooling and virtual learning requires attention to the teacher in this learning equation. It comes as no surprise that teachers are required to be learners in an environment where many have little background. Three chapters provide material on different aspects: student/teacher interaction in the virtual learning setting; narrative inquiry about how rural African teachers engage the digital world with few resources; how teachers create virtual communities of practice; and VLE's in teacher education. There is probably no formal educational location that is changing more rapidly in the digital age than is Higher Education. Several chapters address the history as well as personal observations about this important site. Much has been written about the global effects of the digital age on education systems and educators. Contributions on this topic include viewing national educational technology plans, VLE's in the Asia-Pacific region, and global online education and organizations for online educator activities. Academic publishing is an area that has been greatly influenced by the digital revolution, and we present a chapter that provides a fascinating case study of the conversion of a mainstream journal into an online professional learning environment. The last contribution discusses the interface of forms of professional development and knowledge management strategies in the virtual environment.

This section starts with a realistic appraisal of the use of the internet in the school setting. While no one questions the internet as an important innovation, Schofield's research indicates that its existence alone doesn't guarantee success. The culture of schooling contains many complex processes and activities and this contribution analyzes four factors inhibiting the use of the internet. The optimism for virtual learning in schools has lead to some believing that a school can be transformed into a virtual school. Russell explores some of the important issues surrounding background, features of online school environments, how they compare with traditional schooling, research possibilities and musings on the future of this concept. Brown and Weiss question the rhetoric surrounding the claims made for virtual schools. They discuss the concept relative to time and space issues surrounding the organizational arrangement of the school calendar, and the bricks and mortar components of most so-called virtual schools.

Ainley and Armatas provide an extensive overview of issues related to learners, and learning in the virtual environment. They discuss useful information about the impact of both situational and individual factors in the learning setting, introduce research evidence from comparisons between traditional and virtual settings, and suggest that our knowledge base about learning is enhanced by studying the virtual environment. Kinshuk and colleagues offer some ideas from cognitive science to issues about user adaptation in virtual learning environments. They describe the development of learner modeling techniques for monitoring and measuring various attributes, such as working memory capacity, inductive reasoning skill, domain experiences as well as setting complexity. They suggest that such information would be useful for curriculum developers of virtual learning environments. Underlying their approach is a view of technology as a neutral set of practices in the learning context.

From the use of pens and chalkboards to more current innovations, the application of technology in school settings is potentially limitless. Numerous examples of technology usage has indicated mixed results, not a surprising result given the complexities of curricular work. We have included several contributions that illustrate either an important application, setting or subject matter area. Sponaas-Robbins and Nolan present a topic that might be included almost anyplace in the Handbook because of its widespread history and application to different parts of life. However, because MOO's represent polychronous collaborative virtual environments and have had applications in the classroom setting, it seemed appropriate for this section. The application derives from Multi-User Domain (MUD) that is Object Oriented, hence the term MOO. It is a text-based online setting that allows users to be creative in developing representations of people, places and things (the objects) to be shared with one another. This is a good example of a convergence between virtual learning and learning virtually, and the authors have addressed the topic with a critical eye. Since language text is usually the edifice upon which learning is built, it made sense to include a contribution about virtual learning environments for this area. Skourtu, Kourtis-Kazoullis and Cummins discuss their experiences in designing VLE's for academic language development. They discuss the use of Instructional Technology (IT) within a Habermasian framework of three different pedagogical approaches: transmission-oriented, social-constructionist and transformative. The important message from their work is that IT may be more meaningfully employed with certain forms of pedagogy than with others. Their findings suggest that more progressive approaches than the transmission model are more efficacious in learning academic language, problem-solving, thinking and imaginative skills, and affirmation of self-identity. The important concepts of disability and inclusive E-learning are extensively discussed in the chapter by Trevarinus and Roberts. Their approach turns disability from just considering the commonplace of a learner's personal characteristic into the relationship between the learner and the broader educational environment. This suggests a truly inclusive perspective about learning that defines accessibility as the need for educational systems and personnel to adjust to all learners, and is in keeping with the Handbook's orientation which defines learning as the transformation of experience for the creation of new knowledge. These authors present material that indicates that computer-mediated learning can benefit marginalized students or those who do poorly in more traditional learning environments.

The role of teaching in any setting is complex, and especially in the virtual learning environment. Black provides a fascinating account of the topsy-turvy situation where teachers and their students reverse roles. Because so many students are often highly skilled with technology and many teachers lack their students' skills in virtual settings, students become the expert in the classroom. How teachers cope with the role of learner to their student's role as expert presents an unusual, but increasingly familiar setting for understanding issues of power in the classroom. Henning presents a very different setting for teachers in her country of South Africa. In addition to a recognition of how the digital divide operates in nonprivileged settings where even access to phones, let alone computers, is difficult she provides a narrative inquiry of six teachers' experiences in the wired world. It's an excellent illustration of how the use of technology education necessitated the development of spontaneously developed informal learning groups. In the much more privileged environment of a major Canadian university, Hibbert and Rich explore the purposes of VLE's in professional development. They contrast two types of environments, one that prepares teachers as disseminators, and the other as knowledge constructors. They suggest that the latter leads to virtual communities of practice as the preferred setting for creating articulated space for participants to learn and grow and re-energize. Otherwise, technological saturation and fatigue may result. A related aspect of virtual life in professional development is the issue of how teachers and researchers communicate with each other using web tools. Korteweg and Mitchell discuss the interface between teachers and teacher educators through their use of technology. They look at how researchers and teachers communicate through the use of web tools, and their research suggests, once again, that the efficacious use of a virtual learning environment depends more on non-technological events and social situations than on technology itself.

One level of education that has been much influenced by the digital age is Higher Education. There are some who are suggesting that the traditional university will become obsolete in favour of the "virtual university", and there's no question that universities are in a change state. We present two views on the impact of technology on this institution: one from a small country, New Zealand, and the other from an American perspective. Both view the events in Higher Education through the lens of increasing globalization in the knowledge business through corporations and media institutions. Pauling provides an extensive background history of developments in New Zealand and some of the ways that technology is impacting its' system. He opines as to whether trends in competition, globalization and media concentration are threatening to the indigenous nature of his country's Higher Education system, or the possibility that a newer socially positive institution will emerge. Luke provides some critical observations on a decade of digital impact on distance learning. He provides an extensive case study of his own university's efforts, including resistance to these efforts, and discusses the realities of unintended outcomes and aspects of a hidden curriculum. He too sees two possible outcomes of these efforts, and suggests that both positions have to be more clearly articulated and understood.

The world-wide situation of embracing the concept of global competition in the digital age has influenced the rhetoric and some of the practices of national education systems. But what do we actually know about the policies and practices of different countries related to the provision of virtual learning environments, especially given the bias in the literature toward information from North America? Zhao, Lei and Conway complement their past research by providing information from a variety of countries on their national technology plans.

Information on virtual learning environments in the Asia-Pacific region (Hong Kong, Taiwan, China, Korea, Japan, Singapore, Australia and New Zealand) is contributed by Hung, Der-Thanq and Wong. In addition to descriptive detail about activities in each country, they raise important issues, such as the influence of Western culture on Eastern culture, especially around views on the curriculum commonplaces; the dominance of the English language; how flexibility and accessibility may contribute to a furthering of the digital divide (ironically, flexibility may enhance the null curriculum); and confusion over adopting standards for learning objects and web pages.

The importance of virtual learning environments providing opportunities for professional development and networking in a non-institutional context is the subject of the last chapters in this section. This includes contributions that discuss how academics have developed and use a global online network, how electronic journals enhance the possibilities for more interactive learning for professionals, and issues surrounding professional development and knowledge management in virtual spaces.

A group of educators from around the world have demonstrated how the internet is transforming ways in which academics can network both for research and professional development. It was not long ago that academics of like interests created "invisible colleges" that were limited to a small number of individuals, and communication about this work was generally tightly controlled (Price, 1961). The World Association for Online Education (WAOE) is an academic guild, or network, that was developed to go beyond governments and individual institutions so that educators from around the world could work co-operatively. We have included two examples of the activities of WAOE. McCarty and several colleagues, representing the diverse geographic regions of Japan, Malaysia, Russia and India, report on a multidimensional investigation of the educational impact of the internet. This includes the framing of some of the issues through the use of a Global Online Education Questionnaire, conceptualizing important issues about online education for developing countries, and presenting in-depth case studies. Although each author spoke the language of their region which was useful for their case study activity, all of the other communications were in English. Their results highlight important issues surrounding the intersection of context with the other curriculum commonplaces. From a process perspective, their work is an interesting example of online international collaborative projects and their intercultural significance. Another example of those involved with WAOE is the chapter by Bowskill and colleagues who, like Hibbert and Rich in the previous section, specifically frame their work in terms of communities of practice. Two themes permeate their work: online informal learning as an approach to professional development, and the concept of transfer into self as a process for empowering participants.They believe that such a community of practice can function in a distributed environment to support learning about learning, and learning about learning online. Their approach to the process of transfer into self relates directly to transfer into practice in a context supporting diversity of culture in a global environment.

A very different milieu for online professional development is described by Natriello and Rennick. They discuss the case study of the recent conversion of a major established education journal of over one hundred years, **Teachers College Record**, from print to online format. The creation of online journals is but one important aspect of the impact of the digital age on the field of publishing. This impact is felt in the various processes of solicitation of manuscripts, to their development and production, as well as marketing and distribution. In addition to the creation of e-books and electronic versions of reference works, publishers now produce hundreds of online journals and sell bundles of them to tailor the needs of specific libraries in the academy and other institutional settings. This case study details the process of original resistance from the editorial board to their subsequent conversion to the exciting learning possibilities provided by the online format. This format provides an interactive professional development environment for teachers and other educators that has lead to increased readership and with more flexibility in how the journal is organized and what supplementary "curriculum materials" readers can access.

The last contribution about professional development expands our horizons about the broader applications of its role in knowledge management through virtual spaces. Norika Hara and the late Rob Kling discuss the various discourses about professional development and knowledge management through applications of IT. They provide case study data from four different contexts and determine that knowledge management through solely technical means is too narrow to support the view of learning we're using in this Handbook, the creation of new knowledge. This contribution reinforces one of the themes that emerges from many of the chapters: to be effective, virtual learning must seriously include the milieu of the social system.

Section Three: Out-of-School Learning Environments

Section Three of The Handbook, **Out-of-School Learning Environments**, moves to a consideration of other environments for virtual learning. This addresses the broader representation of the curriculum of life, diverse settings which often define our relationships with institutions and others, as well as our sense of ourselves. Because virtual life has infused so much of society we don't presume to cover all possible settings. However, we have included a number of life's areas in order to provide some of its diversity. The first contribution represents interesting observations about initiation to the virtual world by novices, seniors who represent a population usually considered uncomfortable in the networked society. We then discuss how some of the important traditional societal institutions (libraries, museums, and healthcare) adapt to the digital age. One of the hallmarks of contemporary society is how much of our lives are spent in leisure activities. The impact on some aspects of leisure time is discussed for hobby genealogy, gaming, and the virtual leisure industries related to sports and sex. The intertwining of political and social aspects of our lives has been impacted by the virtual world. We have included chapters that touch on issues in e-democracy, virtual memorialization, diaspora in virtual spaces, and how virtual environments may be implicated in producing racial identity. Another area that touches upon both virtual learning and learning virtually is the realm of popular culture. Several chapters analyze the political economies associated with two of our cherished icons, Disney and Anne of Green Gables. Additionally, we've included chapters that discuss the importance of virtual life in the development of the genre of slash fiction, an increasingly influenial aspect of popular culture.

In "Cemetaries, oak trees, and black and white cows: Newcomers' understandings of the networked world", O'Day and colleagues address important issues about novice learners to the wired world. They chose to study seniors' introduction to the internet, since they are a group most likely to be unsophisticated about modern technologies and the associated complex social practices. This interactive study of the questions generated by the learners about their online experiences provided useful information about often assumed views about identity on the internet, the boundaries and scope of both personal computers and the internet, and about how the networked world is organized.

The digital age has had important effects upon a number of societal institutions that have served as learning contexts. Brophy discusses the development of e-libraries, the response of this field to utilize technology for facilitating learners' engagements with the global information universe. While libraries are usually known as places to learn content, whether it be reference material or reading for pleasure, they are also social contexts where people socialize and engage with techniques for finding materials. Computer classes are popular with those who may not otherwise have wired accessibility, such as seniors and students, and thus have become places for reducing the digital divide. In spite of the importance of technology, librarians act as facilitators for a wide range of learning styles within a range of pedagogical frameworks. Brophy sees future libraries as making incremental changes, with the e-library coexisting along with more traditional features.

Sumption presents interesting observations about the impact of the digital age on the traditional, artefactually-oriented learning environment of museums. He presents some interesting historical developments about learning in the museum setting and the possibilities of developing interactive, multimedia, computer-based learning environments. The challenges are formidable for an institution where learners have been immersed one on one with objects in the 'sacred grove", and which relies upon in-real-life attendance figures for justifying their existence. Sumption provides useful illustrative information from his own museum in Australia as to how the World Wide Web can be instrumental in helping learners move beyond collections, and at the same time, alleviate some of the political economic pressures on the institution.

There is probably no aspect of the "curriculum of life" that has been more influenced by modern technology than that of healthcare. It is an environment which includes important sites where learners may work together to support the use of a variety of tools and information resources to pursue critical learning goals and problem-solving activities. Internet-mediated learning environments provide possibilities for overcoming traditional boundaries characterizing learning experiences regarding medical education and the profession itself. It provides opportunities to help educate patients and those seeking health-related content. Just as Black has suggested that computer technologies have provided the basis for topsy- turvy learning relationships between teachers and students in the formal school setting, so the internet enables those seeking medical information to engage with health professionals far more knowledgeably than ever before. In some cases, patients may have more information than the professionals because of their ability to search for information that otherwise might have been difficult to obtain. Of course, part of the problem may be that novices may have difficulty determining the validity of information available through the internet.

The digital age has certainly impacted upon how we spend our time away from work. The concept of leisure time has had an interesting history in its linkage to changes in the workplace setting, the development of the weekend (Rybczynski, 1991), the advent of new technologies, and medical advances lengthening life expectancies. With more supposed "free time" available, people have turned to a variety of activities to occupy their time. Computer technology has made accessible a number of opportunities for amusement and for learning new information and to develop new skills in political, social, economic and personal areas of people's lives.

As people have more time available, they often turn to activities that relate to their family and other personal interests. One of the fascinating uses of the internet has been the increasing interest in amateur genealogy, the practice of studying family origins, in order to create family trees and pedigree charts.Veale presents a chapter in which she discusses the various ways in which the internet is an environment for learning genealogical methods. As part of her inquiry, she obtained fifteen million websites in response to her Google exploration of the topic. Her survey disclosed three emerging themes in the employment of the internet for genealogical purposes. The *scholarly* theme is represented by formal courses run by various groups-for example, the University of Toronto, in conjunction with National Institute of Genealogical Studies, offers the oldest web-based certificate program. The *topical* theme is represented by companies and individuals offering less scholarly, often more topical stand-alone web pages. This material may include libraries of articles or webpages and tutorials for novices to the area. The *ad hoc* theme includes mailing lists, online forums, newsgroups, and presentations of personal situations and advice asking appear with little pre-planned structure. Veale believes that too much of the online curriculum in this area uses pre-internet traditional instructional methods and she suggests a variety of approaches that would more readily take advantage of the Internet's possibilities, especially to teach problem-solving.

De Castell and Jensen present observations about the importance of the learner's attention in any learning context, and focus on its relevance to the digital milieu. They discuss the significance of childrens' frames of perception in the conjunction of the entertainment and education settings by concentrating on the important area of gaming. They believe that the ability of video games to capture and hold attention has theoretical implications for the impact of newer technologies on structures and forms of knowledge. The tasks, puzzles and questions associated with games has both commercial and intellectual merits. The educational implications are to look to play to influence pleasure, choice and immersion, speed and efficiency of learning, meaningfulness of topics, subject matter and the learners' experiences.

Cook suggests that even though there has been an enormous impact of the digital world on leisure life, there hasn't been commensurate inquiry about virtual leisure industries. Although her chapter discusses issues in teaching about leisure industries at the university level (potentially suggesting placement in the previous section dealing with schooling) she incorporates an incredible array of information about their importance to self expression, popular culture and social life. Some of these areas involve sport participation and fan activity, organized travel and tourism, gambling, sex, shopping, fashion and design, food and hospitality, and computer games. She includes two in-depth examples of sport and online sex-pornography and the sex industries-from her online curriculum, In the process, she raises some interesting curricular value issues around contradictory themes of public acceptance/censorship (based on moral or legal criteria), public knowledge/ private information, production/consumption. An important observation is the suggestion that the internet (and the social order producing it) is a space for contestations, re-articulations and convergences.

Digital technology offers possibilities for creating intriguing learning settings for shaping political and social identities. Balnaves and his colleagues suggest that the decline in traditional civic participation can be countered by using participatory technologies in the form of interactive media as part of an e-democracy movement. They see media as a liminal space for encouraging both individual and collaborative learning and for mobilizing digital resources. For example, internet and interactive TV are being used for citizen polling, electronic town meetings and televoting for mass decision-making. These authors raise an interesting contradiction, one that suggests a disconnect between the explicit and hidden curricula around e-democracy. How can the digital world reduce differences between representational government structures and the voter-citizen when the internet is controlled by political forces? The curriculum of these new learning environments is seen as a complex triangulation among medium, the learning environments in which people learn to use the medium, and the reality of how a medium is used. One result could be a more independent citizenship learner who participates in civil disobedience through hacktivism. This is in keeping with seeing it as a very positive activity, a very different view than one ordinarily associated with hacktivism, as enunciated in a later chapter by Levesque.

An activity practiced by all societies is memorialization, the process of formulating and reformulating images of valued cultural practices and icons. This generally conjures up images of statues and other time and space related memorial settings. One recent event that has shaken the world was the destruction of The World Trade Center in NYC, and there have been many attempts at trying to memorialize this horrific event. Shepard's chapter on the Sonic Memorial provides an opportunity to re-think conventions of memorial-making that are locked into concrete time/space/place considerations and to suggest the efficacy of creating three-dimensional virtual learning environments for nuanced, meditative, non-linear learning moments.He describes the process of developing a site which used incredibly diverse material contributed by individuals from around the world to create sound artifacts, where this sense becomes the learner's compass. The site has three purposes; to continue building an archive through online web interface; to create a catalogue (curriculum materials) for future use; and create a place of remembrance recreating before, during and after 9/11. This virtual learning site is the creation of a distinct space/place, it allows learners to drive the curriculum, offers multiple points of entry, engages the learner as a participant and fosters social collaboration.

Another potential social collaborative environment is the development of diasporic web communities as learning spaces. Over the centuries, individuals and whole groups of people have been forced or have voluntarily migrated to other locations, potentially creating difficulties in the new setting and at the same time with potential loss of features of the homeland. Virtual learning sites have been developed for individuals to learn and possibly re-learn what it means to be an immigrant, how to understand and interpret immigrant experience, and to imagine a relationship between homeland and host-land. Nincic's chapter questions the subject matter of what diaspora is, and suggests the investigation of discourses around cyberspace, diaspora-related themes and their particular configurations. She dispels the myth, a form of the hidden curriculum, of the homogeneity of the image of diaspora. In questioning the romantic notion of the memory of homeland, she posits the view of a complex community that is influenced by local economic, social and political conditions in both the homeland and the host-land.

Another identity issue is how VLE's provide a setting for the production of racial identity. Altman and Gajjala see this as part of the larger platform of the online production of self, a curriculum of the interaction of the production of cultural experiences and the materiality of virtuality. They point out that meaning-making is made through doing, the acts of coding, programming, typing oneself into existence and building objects of self. Their research suggests that in order to understand this curriculum of meaning-making, researchers have to be engaged in production of culture and subjectivity. In particular, it is important to understand how features of the technological milieu of VLE's engage with IRL environments, and to focus on learners' cultural competencies and literacies.

What we choose to identify with is a function of exposure to various forms of popular culture. Our fantasy lives are products of cultural production and reproduction brought about through a combination of what we choose or not choose to engage with (null curriculum) and the curriculum (mostly hidden) of corporations and other entities engaged in the manufacture of popular cultural images. Perhaps the most well known icons are associated with the Disney world, a land that uses fantasy to create virtual learning environments without necessarily using digital technology. In his chapter, Trifonas reprises his review of Giroux's *The Mouse That Roared* (1999) and believes that corporations use media as a pedagogical device for engaging the public in real moments of miseducative teaching/learning of cultural reproduction. In his view, Disney represents possible worlds with ideology, which appeals to common sense while actually shaping political policies and programs that serve corporate interests. It is important to reclaim the space of public memory by determining how to read the text and to understand the significance of the signs of the 'squeaky clean image, false happiness and cartoonish social imagery'. Another cultural icon that has had world-wide appeal is the imagined community of Avonlea in Canada developed by Lucy Maud Montgomery who wrote about Anne of Green Gables in books and short stories. Lefebvre describes the Avonlea site as constructed from the real and imagined in Montgomery's life, controlled by heirs and trademarks, so that she has become a cultural ideological commodity separate from the individual. Like Disney, this icon has been constructed as fiction, representing a copy of an original that didn't exist. This chapter discusses the simulated online communities that have formed that represent a "regional idyll", a genre of that time which provided sentimental relief from increasing urbanization and industrialization. Internet users of these virtual sites engage in, and with, replicas that are free of context, history, nation, religion and culture. These virtual learning environments allow other peoples to populate this milieu, and in borrowing from the Disney construction, Lefebvre suggests that this helps to conflate Montgomery's world into 'a small world after all'.

If the Disney and Montgomery examples suggest popular culture virtual learning environments where learners are in milieus manipulated by external forces, fan fiction and slash fiction represent milieus created by and contributed to, learners themselves. Mazur discusses how the internet is a rich environment for fan fiction, which is virtual unauthorized writing of stories with bootlegged characters and settings from a variety of media. For example, Fanfiction.net is a site containing hundreds of categories with thousands of stories mostly written by women for the love of: the story, the process of writing, particular characters, and community. It represents one big writing workshop allowing for interactive feedback, and is a contradictory learning environment born from plagiarism but with built-in detectors for standards of writing. This site suggests useful examples of how learners can engage with the various Curricula of the internet (Initiation, Governance, Access, Membership). Slash fiction represents a subset of fan fiction using same sex romantic pairings. Bury's chapter discusses the complex process of making meanings and pleasures within this virtual genre, best understood as 'queer romance'. There are parallels with virtual learning environments, since a learner's cultural and linguistic resources are literally on the line, there is engagement with canonical text and issues of legitimate interpretation, and there is the tension of keeping standards, especially for groups often seen as outsiders. The chapter devotes space mapping out the performance of gender, sexuality and class on an e-mailing list of fans of a Canadian TV series, Due South, where action takes place in Canada and the U.S. She suggests that pleasures of those engaged with this virtual site go beyond 'queer desire' but to issues of high standards of writing and adherence to the canon of the primary text. Slash fiction represents just one of many ways in which gender issues get played out in the virtual world (Turkle, 1995).

Section Four: Challenges for Virtual Learning Environments

The previous material represented contributions suggesting a range of discourses about virtual learning environments. The last part of the Handbook, **Section Four**, **Challenges for Virtual Learning Environments**, looks at a variety of issues generated by ways of engaging with the internet, innovative forms and technical advances, new roles and settings, and research about virtual learning environments. The expectation is that this will stimulate an expansion of perspectives and highlight challenges for the future. In orienting these challenges and issues, I take editorial license with Gadamer's view that "... all understanding is a fusion of horizons" (Gadamer, 1960, 302). Since he suggested that this fusion includes all that can be seen from a particular perspective, I choose to define horizon as that which fuses past, present and future. The preconceptions of the past are constantly helping to shape the present which together form predispositions to future understandings and actions. Although previous entries have touched upon material from the past, the present and even the future, this section of the Handbook deliberately contains chapters that bring in perspectives from all three considerations in taking up some of the challenges and possibilities for VLE's.

Fantasy provides the leitmotif for the beginning and penultimate contributions to this section. The contributions by Noon and Zizek represent two pieces that illustrate the importance of past images in the fusion of horizons. Noon's brief literary gem provocatively illustrates what many have considered to be the dark side of the world of virtual reality; an image that often influences feelings of mistrust in what technology may have wrought. The development of a thought recognition system coupled with a usable feedback loop created an imaginary about dreams that leads to the most extreme mis-educative experience, the destruction of mind. This science fiction image of virtual life has implications for how we view the roles of business and government in shaping future virtual learning settings. Zizek's contribution serves as the introduction to the final chapter.

Previous material in the Handbook discussed several features of the structure of the internet. However, these discussions are at a conceptual level suggesting an outline for a Curriculum of the internet. More concrete procedures are needed for users to realistically understand its politics and implications. Dodge and Kitchin describe a geographic guide for internet exploration and mapping. They see it as a set of techniques and tools for people to cope with several features of the internet, including dealing with worms and viruses and developments in search engine capabilities. They also point to potential difficulties that may lie ahead in the expansion of internet technologies. NET: GEOGRAPHY FAQ provides a useful set of virtual learning tools for interrogating the media that supports virtual learning itself.

Another example of providing curriculum material about the internet is found in Levesque's chapter on hacktivism. Discussion about hacking and hackers has been an important part of the story of the internet, and she clarifies the distinction between crackers, those who break in for destructive ends, and hackers who use their skills to invent, modify and refine systems. Often, hacker activity brings about unintended consequences from the original aims for a system. The origins of hacktivism derive from the blending of this work with those who believe that people should have free access to this virtual learning environment. Hacktivists believe that the internet is a site of contestation, and their efforts are an attempt to flush out the hidden curriculum as a reaction to perceived oppressive use of laws and technologies by private corporations and governments for monitor and control issues. Levesque provides useful content about issues and techniques associated with censorship and surveillance. One of the interesting contradictions is that some of this effort may be illegal, but seen to be supportive of broader principles of human rights.

There have been several recent innovative developments in ways that the internet is used for web publishing purposes. Central to this work is the development of weblogs and wikis, which allow for flexible opportunities for individuals and groups. These opportunities potentially enable much more control of the internet through personal expression and by making the technology openly available to all interested parties. Halavais discusses web-based logs, or blogs, and wikis as important learning environments in student-centered education. He discusses his personal experiences in determining that students should not only learn about the technology but the social practices that are so much a part of these sites. Weblogs present challenges to educators because they should be used in a milieu emphasizing a constructionist view of learning where different discourses and perspectives interact with one another, in a spirit of co-learning. Halevais suggests that each of the curriculum commonplaces need to be addressed in re-formulating traditional views of educational environments. A very different milieu for blog application is how digital media are helping to re-shape both text and professional life in the academic world. Barr discusses how weblogs have potential for changing procedures in academic publishing that have relied upon gatekeeper, blind peer-reviewed publications as the currency for evaluating performance. He suggests that the procedural organization of blogs may more readily accomplish the goal of evaluating a researcher's professional success. This potential change in the milieu of the academy has vast implications for the curriculum associated with becoming an academic researcher.

Another fully editable website is the wiki, previously discussed in the description of Wikipedia. Augar and her colleagues present a description of wikis, how they work, how their features make them highly suitable as virtual learning environments, and present examples of practical application and research situations. What makes them desirable as useful collaborative sites is their flexibility for different purposes: they can support a simple edit style that uses an editing toolbar, or for more sophisticated purposes, knowledge of wiki syntax. For teaching and learning online, more complex features such as authentication and tracking are necessary for tracing edits back to an author that allows for an assessment process, and also securing content against possible misuse. Wiki sites offer useful information for novices in the Curricula of Initiation and Membership.

Peer-to-peer networking represents an important use for virtual learning environments. Logie presents a fascinating account of the Napster music story weaving past, present and future themes about a site that became in 1999 the most popular file-transfer service on the internet at the time and many users' initiation into virtual learning environments. The story demonstrates the importance of larger social, political and economic influences on the Curriculum of the Net. A history of legal and political events moved this concept from free to pay-for-play, peer-to-peer networking, and the story became a two-dimensional characterization of a battle between 'pirates" and "property-holders". It has led to a free site, Kazaa Media Desktop, which has become one of the most downloaded software in internet history. Additionally, it has led to the "napsterization" of other cultural artifacts (film, video, photographic files). Logie believes that 'partying like it's still 1999", that is, downloading without compunction, can't be sustained and that the academy has to provide useful procedures and examples of virtual learning environments.

An important activity in any knowledge-oriented endeavor is the ability to incorporate inquiry into its landscape. With all the activities associated with developments in virtual learning environments it is appropriate that research should assume an important role in looking at challenges and future considerations. Several chapters have been included to represent some recent research work that provides a sense of the diversity in the application of technologies to collaborative learning settings. Sosnoski and colleagues present a fascinating description of the development of "Virtual Harlem", a collaborative learning environment that models the subject of life in the Harlem, NY of the 1920's and 1930's. It represents an achievement of a variety of scholars in the sciences and arts that has salience for both teaching and research purposes. Its importance lies in the development of a networked environment whose ongoing research utilizes video, audio and database technologies to provide collaborative learning environments for design, interactive art and data visualization. It's an excellent example of a curriculum in action, one that brings together an integration of the curriculum commonplaces. Pea's work specifically concentrates on the development of a digital video collaboration for research communities. He describes some of the theoretical and technological considerations in creating the Diver Project, a unique software system for capturing, annotating and sharing perspectives (which he labels as dives) on activities video-recorded IRL. In the world of virtual learning environments, this represents a movement away from a broadcast-centric and asymmetric use of video and has important implications for elaborating knowledge building in the life sciences from application of video sources and for practical consumer video communication applications. Both possibilities address a constructivist vision of future learners moving from the role of consumer to one of active participation.

A different example of the integration of technology with social activity is the development of ePresence Interactive Media System, a virtual learning environment created through application of webcasting. Zijdemans and her colleagues describe an early example of its use in supporting live interactions of experts and others in an early childhood education forum. ePresence demonstrates how knowledge media differs from traditional media in the ability to make major modifications in the medium through reasonably non-complicated software changes. Several changes in the technology have made its use as a VLE much more user and research friendly. Among these characteristics is ability for attendees at an event to participate with remote viewers, using Voice Over Internet Protocol (VOIP) that allows for voice contributions from remote viewers, sophisticated archive searching after the event, and linking online course settings with the live events and archives, an invaluable teaching-learning tool.

Previous mention was made of the concept of the "invisible college", a limited community of scholars, and how the digital age has been transforming the communication patterns of academia. Wellman and his colleagues provide useful information about previous research of networked scholarship in academic communities. They discuss how the application of social network analysis procedures to computer-supported networks: determine how different kinds of relationships interrelate, detect structural patterns, and analyze the implications of these structural patterns for behaviors of network members. They include a research analysis of TechNet, a scholarly network that has developed into a community of practice for academics from the humanities, sciences and social sciences. An important future implication of this work is that curriculum designers of online educational communities and other forms of virtual learning environments should consider the social networks of community members, and how various media usage and network structures impact upon mutual peer-to-peer learning.

Bruckman offers a very different example of research into the behaviors of users in online communities. What is special about her work is that she collected physical data on the actual activities that users engaged in while online. The virtual learning environment she studied, MOOSE Crossing, a text-based MUD, offered the opportunity to collect log file data, a comprehensive record of all commands typed by users. This raises the question of the kinds of data and methods of data collection that are most compatible with trying to inquire into the digital world. Much of the previous research has been similar to that conducted using procedures from real-life settings, such as the use of face-to face interviews. Are there features of the digital world which require different types of data and data collection procedures in order to learn as much about life “in the screen” as life “on the screen”? Bruckman’s research offers data procedures collected on the interaction between the user and the computer screen. She blends both quantitative and qualitative techniques, uses both manual and automated methods of analysis, and recognizes the importance of ethical considerations in recording and analyzing log file data. Issues of potential invasion of privacy and rights of human subjects research is an important curriculum area that needs to be more fully developed for researchers investigating virtual learning environments.

The issue of the digital divide, disparities in who has access to the virtual world, is a refrain that cuts across past, present and future moments. Each of the next three chapters presents diverse approaches to discussing and inquiring into aspects of this divide. Very different classes of learners are discussed: women, those from developing countries, and ordinary citizens in a democracy. Dwight, Boler and Sears contribute an imaginative piece looking at the visual images that shape our interpretations leading to myths about the ways in which women are perceived to be disadvantaged in the digital world. They inquire into the ways that the popular discourses generated by advertising and Hollywood shape the public imaginary of cultural stereotypes around gender and power in education and technology. Rather than accepting these ‘taken-for-granted’ stereotypes, their work demonstrates alternative possibilities for how women inhabit and re-define cyberspace through the development of creative spaces. This has very important implications for the curriculum about virtual learning for educators, and how representations of alternative imaginaries should be infused into the curriculum of their students.

Dicum offers an important discussion of the expectations for the developed world's digital technology as an ingredient in ameliorating the digital divide represented in less and least developed areas of the world. Using information from several examples of the use of such technology in community development projects in these areas, she reports that not enough attention has been paid to local ecological issues. The centralizing tendency of globalization efforts in the use of the internet needs to consider discourses about the important theories, principles and knowledge gleaned from the "development" field. If the internet and other technologies are to have a positive influence on these areas, respect must be given to the needs, resources and other factors that help to define a local community's reality. This requires that assumptions from the developed world be questioned, and that consideration be given to complex curriculum interactions of learner, milieu, type of pedagogy and the nature of the required content in less and least developed communities.

A different issue about the digital divide is discussed in Allen's chapter. It concerns the potential impact of the development of broadband technology on Australian citizens. The issue is how the audience for this technology is being shaped, often well before the technology is either developed or available. This addresses the possible creation of a digital divide between those who may, and those who may not, have access to this technology. Allen looks beneath the proposed claims for a broadband future that allows for distributed, audio-visually enhanced rich virtual learning environments and demonstrates the importance of understanding the setting for such developments. He illustrates the influence of political, economic and social forces to create an "imaginary' about a technology and its perceived future usefulness. This raises important questions about how forces in a setting may help to shape images of the learner.

Zizek's "The Matrix, or, the two sides of perversion" is deliberately placed as the penultimate contribution to this section, and indeed, The Handbook. His exploration of the real and the virtual juxtaposes the complexities of the mind/body relationship. This provides a dramatic introduction to the final contribution, Mann's description of the reality of the individual as cyborg. He describes his experiences of constructing himself as a computer-based learning environment over a thirty-year period as an inventor, builder and user of several wearable computing and personal technological systems. The importance of this life's work is in a conception of "being" at one with technology, developing an epistemology of choice, "existemology", and constructing an in-real-life curriculum for students to transform themselves into virtual learning environments. In addition to the imagery offered by Zizek, readers may also interpret this extreme view of virtual learning environments through the prisms offered by other authors in this Handbook. We have come full circle in

The Handbook: from Burbules who questions the concept of virtual learning to Mann who has become a VLE.

It also makes one wonder about how much we have traveled since the Allegory of the Cave:

> Will he not fancy that the shadows which he formerly saw are truer than the objects which are now shown to him? (Plato, 1963, 547)

SOME FINAL THOUGHTS BEFORE BEGINNING

This volume represents a kaleidoscope of ideas, topics, points of view- brought together as one way of providing coherence to the evolving concept of virtual learning environments. My brief introduction is but a mere sketch compared with the richness of the words and worlds of the authors, both individually and collectively that the reader will engage with in the following chapters. Although many perspectives are included, The Handbook has been created through a particular prism of interpretation, one that emanates from educational and curriculum discourses. However, any prism offers a narrow range, one subject to the concept of the null curriculum. By including this set of material, we obviously have excluded other worthy possibilities for expanding our elucidation of this area. Our expectation is that the current project will stimulate others to contribute their voices in that quest.

To that end, I will offer a few suggestions that emanate from a consideration of both the actual, and the null curricula, of The Handbook. First, if there is merit in using a learning and curriculum prism, perhaps others will re-work it to include ideas and perspectives not necessarily included in my current vision. Other prisms could be used to explore other facets of the kaleidoscope of virtual learning environments. This may require a transciplinary approach, one that honors eclecticism in bringing together viewpoints regarding knowledge, media, design from the arts, humanities, social sciences and sciences. (A good example already exists in pioneering work by Turkle (1984, 1995) on looking at issues of the self and identity in the computer age.) There should be recognition that issues of learning require dialogue involving the theoretical and practical arts.

A second consideration is that the examples and references to technology included in this project are but a tip of the iceberg of past and present developments, let alone a future imaginary of what may be possible. Developments in the wired and wireless worlds, and the ways that different technologies can and may be integrated only hint at the possibilities for learning environments. Thus, some of this present and future technology should be creatively developed within the concept of the VLE. However, if there is one theme that emerges as a constant refrain from our authors, and represents a third , and crucial, suggestion, is that the technical is inextricably integrated with the social milieu. Since technology doesn't operate in a vacuum, the social context in all its complexity is an essential ingredient in any technological considerations in the virtual learning environment equation.

As a fourth consideration, the curriculum commonplaces suggest that this VLE equation represents a set of complex interactions among images of the learner, content, teaching strategy, and the milieu. The importance of the learner and its' interactions with the others should be highlighted in future work, and might include a more detailed delineation from a constructivist perspective of the many roles possible for learners (student, teacher, developer, researcher, citizen) in all facets of virtual learning. This is especially so if the digital age is to bring about a sense of agency in dealing with issues arising from hidden curricula. Finding innovative ways for learners to participate in the various curricula of virtual learning environments might be a useful strategy for bridging the many digital divides.

A fifth suggestion is the exploration of the implications of the conceptual distinction between virtual learning and learning virtually for an understanding of the roles of fantasy, imagination and creativity in developing learning environments. What can we learn from the best practices of learning virtually that provides examples for how the digital environment should go beyond the fairly traditional, indeed pedestrian, applications that just mimic rote learning models? Equally as well, can exemplary forms of newer technology enhance the more successful visions of learning virtually?

Progress in any field is enriched and transformed by the appropriate application of procedures of inquiry. A sixth consideration is how research in, and about, virtual learning environments can be transformative. How can research guide the determination of appropriate questions to formulate, especially for the different locations of IRL, digital and virtual? Does the virtual world require methods of inquiry different from in-real-life situations? Although there is excellent material available about research in this setting (for example, Jones, 1998) most of the studies have been conducted IRL, typically using face-to-face procedures. How can we develop and use procedures for looking at the digital location of computer-mediated interactions between the user and the computer screen? Even more ambitious would be the development and use of procedures for VLE's in virtual locations, such as MOO's and Massive Role-Playing Games (MRPG), where life is constructed in the screen itself. In addition to the important issues about techniques and their applications, attention must be paid to the daunting ethical challenges that arise in creating and studying VLE's in both digital and virtual locations.

A final suggestion (but by no means exhaustive of many more possible) relates to the larger milieu of how our many worlds will continue to change as a result of the virtual environment. What previously had been relatively impermeable, socially constructed boundaries in our lives (work, home, school, play) has radically been altered in many cultures so that the screens surrounding role, space, place and activity have become quite porous. This has important implications for how the various, previously segmented learning environments which we inhabit have shifted to a more holistic, larger unit of 'the curriculum of life'. This potentially alters how we conceive of, construct and re-construct learning environments for personal, family, institutional, local community, national and global levels. What possibilities hold for developing VLE's for crafting public and personal imaginaries for all facets of life, that are just and fair, and enable learners to create diverse forms of knowledge through the transformation of their experiences?

> . . . transcendence, the conscious experience of hierarchic integration where what was before our whole world is transformed into but one of a multidimensional array of worlds to experience. (Kolb, 1984, 222)

Part I

Foundations of Virtual Learning Environments

Chapter 1: Rethinking the Virtual

NICHOLAS C. BURBULES
Department of Education Policy Studies, University of Illinois, Urbana/Champaign

1. THE VIRTUAL

The term "virtual reality" (VR) was reputedly first coined by Jaron Lanier, head of Virtual Programming Language, Inc.[1] It is usually taken to refer to a computer-mediated simulation that is three-dimensional, multisensory, and interactive, so that the user's experience is "as if" inhabiting and acting within an external environment. A few typical definitions emphasize these main elements:

> The illusion of participation in a synthetic environment . . . VR relies on three-dimensional, stereoscopic, head-tracked display, hand-body tracking, and binaural sound.[2]
>
> A combination of computer and interface devices (goggles, gloves, etc.) that present a user with the illusion of being in a three-dimensional world of computer-generated objects.[3]
>
> VR is minimally defined as a computer-generated experience consisting of stereoscopic, real-time, viewer-centered computer graphics. A VR experience may be further and significantly enriched by the inclusion of spatially located sound, haptics, and smell.[4]
>
> A computer system used to create an artificial world in which the user has the impression of being in that world and with the ability to navigate through the world and manipulate objects in the world.[5]
>
> A VR is a computer world that tricks the senses or mind.[6]

There are two main characteristics revealed by these definitions, which, I will argue, inhibit a deeper understanding of "virtuality" or "the virtual" (terms I will prefer here to "VR"). The first assumption is to put the matter of technology at the forefront: VR is computer generated; it involves the use of goggles, gloves, or head-tracking devices, etc. *Yet the key feature of the virtual is not the particular technology that produces the sense of immersion, but the sense of immersion itself (whatever might bring it about), which gives the virtual its phenomenological quality of an "as if" experience*[7]. When we think of the virtual in this way, we see that all sorts of things can create this sense of "as if": watching a film, reading a book, listening to music, or just being caught up in a reverie or conversation, for example; all of these can trigger engrossing experiences of multisensory worlds which, when we are immersed in them, fill our experiential horizons. There is nothing necessarily

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 37–58.

computer-based about such immersive experiences: some writers characterize science fiction literature as a VR; others, shopping malls.[8]

The second assumption of most of these definitions is to characterize VR as a substitute for reality, as an "illusion" or a "trick". Terms often used in place of "VR" include "simulated reality" or "artificial reality". The problem with this view is that it assumes an overly sharp separation between the "virtual" and the "real"—the real seems to be a simple, unproblematic given that we perceive and interact with directly while the virtual means something more like "synthetic" or "illusory".[9] Yet any reality we inhabit is to some extent actively filtered, interpreted, constructed, or *made*; it is not merely an unproblematic given while the virtual is not merely imaginary. *The virtual should not be understood as a simulated reality exposed to us, which we passively observe, but a context where our own active response and involvement are part of what gives the experience its veracity and meaningfulness*. Hence, the virtual is better seen as a *medial* concept, neither real nor imaginary, or better, both real *and* imaginary. In this sense "VR" is a misnomer.

For many critics of technology, this contrasting of the "synthetic" world with a more immediately sensible "real" or "authentic" world begins with arguments derived from Martin Heidegger's "The Question Concerning Technology".[10] Heidegger contrasts two ways of interacting with the natural world. From the technological standpoint, nature is revealed as a "standing reserve" (*Bestand*) a potential resource for humans to control, reshape, and exploit for their purposes. In this context, "technology" is not a thing, but an attitude toward and relation to the world. We regard natural things in terms of what we can do with them: a river is a potential source of electrical power; a tree is a potential table; a canyon a potential tourist attraction. This attitude and relation, this "enframing" (*Gestell*), in Heidegger's phenomenology, already transforms the world, even prior to any actions: the tree is changed into a thing-that-can-be-used and is never again simply a tree, a thing-in-itself. A canyon that you have to pay to go see is in an important sense no longer the same canyon that it was before. On this highly influential view, "technology" is something intrinsically damaging, even insidious, because it robs us of the capacity to apprehend and appreciate the world simply as it is. This inverts the understanding of technology as something useful and beneficial—even if it may have dangerous side effects (pollution, say)—to something inevitably destructive. On this view, it is an all-consuming, all-inclusive mindset that attempts to draw everything into its utilitarian frame of reference. Heidegger's anti-technological views, although not referring to computers at all, have been widely cited in the work of those suspicious of the rise of digital culture.[11]

Heidegger contrasts with the technological attitude a more direct, immediate, and in some ways almost mystical engagement with the natural world, in which its being becomes apparent to us on its own terms, not on ours. The world that presents itself *to* us, not as a potential object *for* us, is the authentic, natural reality that grounds all being. Here again, we see an influential idea that has shaped environmental movements and other back-to-nature trends—and at a broad level, the dichotomy Heidegger is drawing makes some sense: we know that there are real-estate developers who look over a wooded valley and see it only as a potential site for a new sub-division; or engineers who boat down rivers looking only for a good place to build a dam. We have seen the decimation that occurs when society begins consuming non-renewable natural resources, when humans regard the world as a domain somehow given to them for their exclusive use, as opposed to an ecological system of which humans, like all natural beings, are a part, and to which we must be ultimately responsible.

At the same time, it must be said, this dichotomy is overdrawn. Heidegger's view of technology is too encompassing, too deterministic, and his view of nature too romantic. The origin of human culture is itself grounded in the first tools, the first attempts to harvest and later to grow food, the first attempts to build shelter. If this is inherently an assault on nature, then there never was a pure, authentic engagement with it—nor ever could be (because on this view, the "technological" attitude is just as much expressed in "renewable" resource use, low-energy-consuming lifestyles, the adoption of "natural" foods and fibers, etc.). On the other side, whenever Heidegger does try to explain what a non-technological engagement with nature would look like, his language becomes allusive and quasi-mystical. Nearly all of us have a sense of those moments when a sunset, a surging river, a breathtaking vista, overwhelm us with their purity and power, but presumably even real-estate developers and engineers can experience these too (and then get back to work planning their next ground-breaking).

In the context of computers and digital culture, this bifurcation of the synthetic and the real has obscured a deeper understanding of what is changing in the ways that we make and explore our worlds, mediated by and through new technologies. Very rarely, if ever, is there a "direct perception" of anything; we actively observe, select, filter, and interpret our experiences in all sorts of ways that construct distinct and sometimes idiosyncratic versions of the world. Some of these mediations are overtly technological in nature: eyeglasses, cameras, telescopes—or, more subtly, concepts, categories, theories, and assumptions. The world we perceive is always already a world we "make" to some extent.[12] This understanding, then, complicates the picture expressed in quotes like, "the more completely 'virtual', the more completely 'made' our lives become, the more obsessively we search to rediscover something simply given, something authentic".[13] There is something to this view, of course; but matters are not so simple. As I noted, the virtual is a *medial* concept, between the patently made and the apparently real.

I do not think I need to review here all the recent theoretical work that challenges the easy distinction between representation and reality.[14] The boundaries of our "real" selves, "real" lives, "real" experiences are already fluid and contingent. An excellent discussion of some of these issues in the context of new technologies is Sherry Turkle's book, *Life on the Screen*, published in 1995.[15] For many of the people she interviewed, the internet is a place they inhabit, not simply a tool they use; some users spend so much of their day working, playing, interacting, exploring, and creating online that this becomes their primary mode of existence—what we call "ordinary life" or "real life" is not what is most important or "real" to them. Plugged in, logged on, immersed in what they are doing for hours at a stretch, for these folks it is no exaggeration to say that they *live* in a virtual world. What is most striking in reading these accounts is how these people report their *preference* for the online world; they say it is more "real" to them, more important to them, and where they feel their authentic selves get expressed. One important dimension of this change is how people inhabit the virtual space; often by constructing online identities ("avatars") that are different—sometimes dramatically different—from their ordinary selves (a man representing himself as a woman; a shy woman representing herself as sexually aggressive; a black person "passing" as white, or vice versa; a soft-spoken dweeb posing as a heavily muscled superhero). These are not in any simple sense "substitutes" for their "real" selves—performances, fantasies, or role playing—because these people often say that they *prefer* their online selves, and even say that these avatars are *more truly* who they are, or feel themselves to be, than their apparent identities. As Turkle notes, this trend is part and parcel of broader social and cultural trends that highlight the constructed and non-essentialist nature of personal identity.[16] Either one can discount these people's views as deluded or pathological, or one must acknowledge that something new and different is happening for them. I will return to this theme later.

In this chapter, I build theoretically off this conception of the virtual, through a series of steps. First, I explore four processes of engagement through which immersion happens (interest, involvement, imagination, and interaction); these will prove especially important for understanding the educational potential of virtuality. Second, I apply this conception of the virtual to a discussion of virtual space and time, suggesting that as virtual spaces become familiar and significant, they become virtual *places*. Two ways in which this transformation can take place are *architecture* and *mapping*, and I suggest that in educational contexts these processes broadly relate to the perspectives of teacher and learner, respectively. Architecture and mapping represent the structures or design elements in which the four aspects of immersion are guided toward learning goals; when these structures are successful, the process of immersion involves students strongly in the activities of learning. In this sense, then, it is not an exaggeration to suggest that all successful learning environments are, to some extent, "virtual". One way to think of this project is as an attempt to rethink virtuality outside of an exclusively technological domain, and to see it as a central *educational* concept.

It needs to be explained *how* the virtual sustains the sense of "as if"—what some call telepresence, and what I am calling here immersion.[17] I gave several examples previously of experiences that can sustain a sense of immersion—and which are to this extent *virtual experiences*: watching a film, reading a book, listening to music, or being caught up in a reverie or a conversation. What gives such virtual experiences this quality of immersion? I define four inter-related factors at work here: interest, involvement, imagination, and interaction.[18]

An experience is *interesting* to us when it is complex enough to allow us to pick out new elements, even with repeated encounters. We can shift focus and notice things we had not noticed before. An interesting experience presents a kind of puzzle that is challenging enough to engage us in actively trying to work out what is going on. Even rereading a book or hearing a piece of music that is very familiar can have the capacity to interest us anew if there is enough to it that we can pick out something that we had not noticed before, allowing us to appreciate it or understand it in a new way. Interest is one of the qualities that can sustain the sort of engrossment that makes us immersed in a virtual experience. But, of course, interest is not an intrinsic quality of experiences; what is interesting to me may not be interesting to you. Something that lacks interest cannot sustain a truly immersive experience.

An experience is *involving* when we have a reason to care about what we are experiencing: we pay attention to it because it concerns us in some way. Perhaps there is a narrative structure involved, or a goal or aim that *matters* to us, even if the goal or aim is not intrinsically valuable (games can be like this, for example, as we lose ourselves in the playing of them). In some cases, there may be an esthetic component to involvement, because we enjoy the experience and this is what makes us care—at other times, the experience may not be particularly enjoyable, but it involves us because it is important for other reasons (hearing a sad story recounted by a friend, for example).

An experience engages our *imagination* when we can interpolate or extrapolate new details and add to the experience through our own contributions. We may be interpreting what is going on, making guesses about things that are not immediately present to us (visualizing the face of a character in a novel, wondering what her inner thoughts might be; conjuring a mental image to go along with a piece of music we are hearing; thinking about what the unseen interior of a house we see in a painting might look like); or we may be anticipating what will happen next in some sequence or development. Actively going beyond the given is part of what engages us deeply in it.

An experience is *interactive* when it provides us with opportunities to participate in it, not only perceptually or intellectually, but also through embodied action and responses. Many theorists put interactivity at the forefront of what makes "VR" so vivid and plausible, where we are able to act upon an environment, see the effects of our actions, and react to them. This deeper engagement of our body's movement, activity, and sensations triggers unconscious responses that make us *feel* "this is really happening", below the level of conscious analysis (for example, how the perceptual field of a technological "VR" environment moves as you move your head wearing goggles or a helmet). But, again, it is a mistake to think of this as a factor only in such technological "VR" environments. When watching a film or hearing a story, our posture, body tension, and startle responses—or, to take another example, our relaxation, rhythmic movement, and kinesthetic sensations listening to music—are a key dimension of the quality of immersion that makes the virtual seem or feel "real" to us at the moment it is happening.

These four qualities, as described here, are not meant to be exhaustive of all the factors that constitute the virtual; and they are not entirely discrete from each other—one could consider imagination in the sense defined here as a kind of interactivity; interest and involvement clearly can have a lot to do with one another. But I think they are helpful in clarifying the processes through which immersion happens, and they help us understand why immersion can be such a powerful mode of response. They push our understanding of the virtual beyond simply thinking of it in terms of vividness or verisimilitude ("it seems so real"!); and they decouple what makes the virtual, virtual, from the issue of technology and the specific media through which engagement happens. All of these qualities (interest, involvement, imagination, and interactivity) could be true, for example, of an intense conversation with a friend recounting a traumatic event, say, an accident or an assault: for long stretches, the conversation could sustain an immersive, virtual experience, in which we are not only listening, but actively engaged with what they are telling us; all four of the factors described here could be involved as we identify with the event and even, in some sense, virtually re-experience it with them—we may even *feel* as if it were happening to us (we may feel a sympathetic ache, for example). These four factors are outgrowths of the *relation* between observer and observed: qualities of response to an experience (in this they might be characterized in John Dewey's terms as *transactional* elements).[19] While grounded in characteristics and qualities of the virtual environment, this analysis makes clear that immersion is a consequence of our active response and engagement with them—it is not something that happens "to" us.

This analysis also makes it possible to see some of the ways in which virtuality can be abused: as a method of deception or manipulation, for instance. I have already described people who state that they *prefer* their virtual experiences and identities, consider them "more real", as far as they are concerned. For some of these people, it may truly be a concern that they become addicted to virtual experiences or can no longer differentiate the virtual from other modes of experience. Countless science fiction stories and films (most recently, and perhaps most famously, *The Matrix*) have been premised on the idea that a person may permanently inhabit the virtual and lose awareness of the context that gives the virtual experience its boundaries. Here, the illusion/reality dichotomy seems to re-emerge, but in my view, it is more accurate to say that these are different kinds of realities, made worlds, some of which are more susceptible to questioning about how and why they are made the way that they are (a vivid memory that may or may not recall an event which really happened; an historical text versus a "truthful" fiction; and so on). It is the lack of an ability to ask such questions, to regard the context of any experience as potentially problematic, that is a concern here. The whole point of "immersion" is that for periods of time we forget that we are watching a film, wearing goggles, sitting in a symphony hall, etc. But if we *perpetually* forget this, abuses and dangers can arise.

On the other hand, turning this question around, I would argue that this analysis of immersion, and how it happens, has strong positive implications for the design of educational environments and experiences. Interest, involvement, imagination, and interactivity, as I have defined them here, are essential educational resources if we mean to engage and motivate active student learning: in this sense, any truly educational experience is immersive, or in other words, *virtual*. A virtual learning environment is not necessarily a technologically based one, I have stressed, and other modes of teaching can promote the quality of immersion. But I do mean to upset the assumption that face-to-face classroom interactions are necessarily more authentic, more meaningful, or more educationally productive than technologically mediated ones. For a digital generation, the qualities of interest, involvement, imagination, and interactivity are to some extent shaped by their engagements with technology and the media (computer games, videos, cell phones and handheld PDAs, etc.) and educators seeking to attract and retain student attention will have to learn from what makes those environments so immersive for youth. Yet neither am I arguing the superiority of the technological over the face-to-face. Each domain has its own unique qualities and advantages; for this reason, the question, to me, is not a matter of "Which is better?" or which should substitute for the other, but, "What is the distinct capability of each to support immersive learning experiences"? (For example, in my experience, based on several online courses, there often is more, and more varied, student interaction and participation in online discussions than in many regular classroom seminars—and for particular students a great deal more.) The virtual, as I am describing it here, is not a new fad or a gimmick, but a very concrete way of rethinking the nature of learning spaces—spaces where creativity, problem-solving, communication, collaboration, experimentation, and inquiry can happen.

3. VIRTUAL SPACE AND TIME[20]

People tend to think about the online environment as a *medium*; a path of point-to-point communication. People use the network like a telephone or mail system to exchange messages or to retrieve and download documents, web pages, and other resources. To the extent that it is a medium or pathway, however, it is not *neutral*—it affects the form of information and the communication that occur within it. As many have noted, online text-based communication has features of both writing and speech; it is written, of course, but it is often spontaneous and unedited, like speech. Online communication is affected by whether it is synchronous or asynchronous and is shaped also by the degree of anonymity provided by not being in immediate, face-to-face contact with one another. It can make people more frank and honest, perhaps, but also less sensitive to the effects of what they say upon others. This degree of impersonality can also make participants oblivious to irony, sarcasm, or intended humor. In all of these ways, the online medium is not a neutral medium.

But it is also useful, and more directly relevant to my purposes here, to think of the online environment as a *space*, a place where people spend time, interact, and *do* things—for example, collaborating with others on a shared project. The fact that they inhabit a shared space is essential for this collaboration to work. I do not mean the medium/space distinction as a sharp or overly broad dichotomy; different technologies are designed with one or the other sort of purpose predominantly in mind. But to the extent that this is a useful distinction, it helps us see that the online, networked environment supports community-building, communication, and the sharing of resources in ways that are impossible to explain simply as a series of point-to-point exchanges. When this online environment is seen as a space people occupy, and through which they *move*, new ways of thinking about it come to the fore.

First, start with the idea of mobility itself: movement defines, and is defined by, both space and time, transiting distance d in length of time t. Online mobility has a different character, since what "moves" are electrons through cables, chips, wires, and screens—but what they carry (voices, images, information, etc.) has the quality of *virtual movement* that defines, and is defined by, *virtual space and time*. This is why "distance education", for example, is becoming an anachronism: distance is not a primary factor in how such teaching and learning are accessed and experienced. The symbol "@"—normally transliterated as "at"—is colloquially used as both a spatial ("meet Bob @ café") and temporal ("meet Bob @ 2:00") shorthand. But in the online environment, such as an e-mail address, "@" does not necessarily mean "at": my e-mail address may appear to be "at University of Illinois"; but someone else is not in the same sense "at yahoo.com" (*where is* "yahoo.com"?)[21]

The nature of our experience in networked environments is frequently of a *kind* of movement: the most obvious example is exploring the World Wide Web.[22] In following hyperlinks, we do have a sense of moving across different semantic spaces: we can trace a kind of trail or pattern to our path; sometimes, we may feel lost. We might wonder, How did I get here? It is interesting, and significant in my view, that these links and pathways have both semantic as well as navigational characteristics.[23] Here, I want to foreground the question of mobility: we interact with these networked environments with the language, the subjective sensibility, and sometimes even the embodied feeling of movement.

This is dramatically true of certain technological VR systems: a room-sized VR space at my university called "the Cave" features a virtual roller coaster ride. I have seen people almost fall over while "riding" it, even though they are standing upright in an empty, unmoving room, two feet firmly planted on the floor. (I have not personally seen instances of how this simulation earned its colloquial name, "Vomit Mountain".) I will return later to the nature of embodiment in such contexts, but I want to reiterate that this embodied sense of movement is not unique to VR settings; we might experience something similar, and just as powerful, listening to music, watching a film, or surfing a series of websites. Are we "really moving"? The question of virtuality wants us to see that question in a new light: *we are really moving through virtual space and time*. You ride the roller coaster and sway, stumble, and feel dizzy and nauseous. Is that "real" enough for you? The experience of movement is one of the primary dimensions underlying the sense of immersion which, I have suggested, defines the "virtual".

But this roller coaster example puts a rather negative spin on the virtual (though people do seem to like riding roller coasters, even when it terrifies them or makes them feel dizzy and nauseous). In many networked settings, this experience of movement is part of the pleasure of discovery. (Why else do we label web browsers with intrepid names like "Explorer", "Navigator", and "Safari"?) It is not just that one can be a virtual tourist and go visit websites featuring the sights and sounds of sub-Saharan Africa; it is that even in looking for good barbecue recipes or checking sport scores or sending birthday greetings to a cousin or reading an e-book there is a fluidity and flexibility and "timelessness" to the way one can browse sites, or meander through texts, that feels liberating (Note: I am not saying here that space, time, or embodiment—of the "real" varieties—disappear or become irrelevant when we are in virtual environments; but they do not constitute fundamental constraints on how we inhabit and explore such environments).

Second, online mobility is related to certain things that we can do in virtual space (and time): we can communicate, interact, observe, and even act upon objects "from a distance". The virtual, Paul Virilio writes, has the quality of simultaneity.[24] This idea of the extension of our senses and physical capabilities suggests, to some, the emergence of a "cyborg" self, a "human+technology" entity that is both more and less than the fully enclosed and self-sufficient human self. This is not my main concern here, though I would point out that prostheses, pace-makers—or for that matter eyeglasses and telescopes—carried us over this bridge a long time ago. I am concerned with the experience of this extension as a transformation of space and time.

These transformations are not only matters of distance; in the Cave at the University of Illinois, you can observe the development of a fertilized chick embryo in an egg, *from the inside*. When we look at a web-cam, watching our child at play in pre-school or checking the current weather in Lillehammer, Norway; when we turn off our coffee maker with a coded beep from our cell phone while we are driving toward work two miles away; when we have a synchronous ("real time", we like to say) conversation with a colleague from halfway around the world, discussing and simultaneously revising a draft book chapter we have posted in a shared writing space, we are, as I said earlier, doing more than just sending and receiving a series of electronic messages back and forth. We are inhabiting and doing things as actors in a virtual space (and time), and our *expectations*, our *habits*, our *relationships*, and our *values* are reshaped by the fact that we are actors in virtual space and time. "Real" space and time do not disappear or become irrelevant. For one thing, they provide the experiences and the vocabulary that we carry over to the virtual domain as a way of making sense of it. Furthermore, they provide a context that gives the sense of movement within virtual space and time part of its force (the fact that we *know* the colleague is halfway around the world; that the websites we move between have been developed by people who never will meet each other; that we can "fast forward" the stages of development of the chick embryo, etc.). But it is also true that for many people, their activities in virtual space and time provide a set of experiences and vocabulary for how they make sense of "real" space and time too.

Third, our engagement with virtual space and time is linked to the fact of our embodiment.[25] We may have virtual identities and experiences, but these are not set against our "real" embodied identities and experiences; on the contrary, by basing the concept of the virtual on *immersion*, and showing how our embodied selves, in interaction with a situation or set of experiences, are *part of* what creates this sense of immersion, what makes it seem or feel "real" to us (for example, *that* the field of view shifts as we turn our heads), the two domains cannot be understood apart from each other, or even less in opposition to each other.

Another way in which our bodies do not disappear or become irrelevant is that while their internal "clocks", their needs for rest and for food, may move into the background of our awareness when we are in an immersive experience, these needs have a way of intruding themselves upon us whether we like it or not—and, of course, without attention to such "real" needs none of the rest would matter anyway.

One might even say that our bodied selves are the sites on which the real and the virtual play off each other (for instance, it is the disjunct between what our eyes seem to be telling us and the feedback from our own inner ears that makes the roller coaster ride in the Cave so disorienting). We feel an interaction with a virtual world because we *feel* it; immersion is, revealingly, itself a bodily metaphor.

This intimate connection is even more apparent with the growing interest in *haptics*: the use of touch and feel as the basis for a human/machine interface. Control gloves were one of the first areas explored in this domain: one can, wearing a glove containing sensors, move, pick up, and manipulate objects in a virtual world (remember the scene in the movie *Disclosure* where the character is rifling though folders in a digital file drawer); or to control robotic machines that translate one's movements into a distant location. One dimension of haptics is to strengthen the sense of "action at a distance": imagine being able to pick up a rock on the lunar surface, heft its weight, feel its texture, and so on.[26] Another dimension of haptics is to exploit the particular sensitivity of our sense of touch as the locus of experiencing a virtual domain, providing feedback not just through visual and audial cues but through a tap on the shoulder, a vibration or change in temperature, or, for example, through a seat that allows us to "move" through a virtual domain through movements of our body or shifts of our weight, while communicating back to us a subtle sense of movement or location that provides us with a way of orienting ourselves within a complex domain. Here again our embodied selves do not become irrelevant, quite the contrary.

Finally, there are questions of embodiment and identity, which I introduced earlier in discussing Turkle's *Life on the Screen*. For Turkle, the internet is a zone of enormous creativity and experimentation in forming virtual identities. Decoupled from the apparent one-to-one association of body and identity, participants online are exploring identities, perspectives, and modes of interaction that are not constrained by their "real" selves: pretending to be a character of the opposite gender in a chat room, putting out provocative opinions that are not necessarily one's own, just to see where the discussion will take them, and so on. For many people, these can be tremendously liberating experiments. These are not necessarily *false* identities; they may in fact involve exploring aspects or extrapolations of one's actual identity that cannot be enacted without disapproval, harm, or other consequences in one's ordinary life. So, again, "real" versus "false" identities is too neat a dichotomy, which does not capture the ways in which these can be different *versions* of one's identity. People sometimes say that these virtual identities are in fact more truly who they feel themselves to be. These identities often become the basis on which *interaction* and *involvement* take place in virtual contexts; and they support a sense of significance related to how *interest* and *imagination* get triggered. Hence, they can be fundamental to the process of how immersion takes place.

To be sure, these experiments in identity can be subject to abuses—where playing with an alternative identity can become impersonation or deception (the legendary "Alex" affair, in which a male psychiatrist posed in a women-only chat room as a character named Joan),[27] or where playful online interactions can have dire real-world consequences (a rape in cyberspace),[28] or where participants cannot integrate their various selves into a coherent identity (that is, a form of schizophrenia), or where they can no longer differentiate between the real and the virtual.[29]

An MCI commercial once said, when you're online, there is no race, no gender, no disability. This is not really true: all of these factors clearly impinge on who is participating online, who is not (the digital divide), and on how those who are online interact with each other—many claim they can identify gender just by others' speech patterns, for example. People do not *lose* their embodied identities when they act anonymously or pretend to be other than they are. But the relative anonymity of online interaction can suppress the effects of prejudice or discrimination. Others are forced to deal more with the content of what one says or does, not necessarily with what one looks like. It is important to remember that the embodied experience for many people is seriously limited: by disability, infirmity, illness, chronic pain, isolation, or a physical appearance that leads others to prejudge, ignore, or despise them. For many of these people, their virtual identities expand their opportunities and sense of efficacy. Here as elsewhere in these sorts of arguments, claims about which mode of interaction is "better" must always be tempered by asking, "better for whom?"[30]

In the end, it is not the existence of new technologies that has raised questions about the necessity of our bodies for our sense of identity; it is a much larger cultural shift that foregrounds the "performative" rather than "essential" character of our embodied selves. Every day people play at other roles in relation to gender, race, sexuality, etc., regardless of their "bodily" facts. For others, I have tried to make clear, the embodied self is seen as an artificial constraint, falsely prioritizing *one* dimension of identity (which is itself a changeable social construction) over others. For the different, the hybrid, the disabled, and others, it is experienced as tremendously liberating *not* to allow an embodied physical "fact" to be so determining; and the virtual is proving a fascinating zone of experimentation in how people can move beyond these embodied physical facts, not necessarily for the sake of "escaping" them or denying them, but for *changing what they mean to themselves and to others*.

In this section I have been asking, If immersion is the basis of virtual experience, what are we immersed "in"? The dynamics of interaction, imagination, interest, and involvement that create the sense of immersion in virtual space and time, I have argued, are closely tied to experiences of mobility, inhabitance, action at a distance, haptic sensitivity, and performative identities that each, in various ways, engage our embodied selves. In this context, it is important to see, *virtual* movement, *virtual* identities, *virtual* action at a distance, and so on are not simulated or illusory experiences: they are real in the context of virtual space and time—as real as can be. And their sense of veracity, their "as if" quality, is intimately tied to the fact that these experiences are implicated in our actual embodied selves, and vice versa; they should not be seen as separate from or in opposition to them.

But there is another stage of transformation. Eventually, the sense of inhabitance, familiarity, and comfort people feel in virtual space and time—especially when these are experienced in conjunction with the similar engagements of other people—achieve a further qualitative shift: from virtual *spaces* to virtual *places*.

4. VIRTUAL PLACES

Calling the online environment a space captures the idea of movement and activity within it, the possibility of discovering meaningful connections between elements found there; but it does not capture the distinctive ways in which people can make a space familiar, make it *their* space—make it a *place*. This shift from thinking in terms of spaces to places reflects an important theoretical and practical difference. A place is a socially or subjectively meaningful space. It has an objective, locational dimension: people can look for a place, find it, move within it. But it also *means* something important to a person or a group of people, and this latter, more subjective, dimension may or may not be communicable to others. When people are in a *place*, they know where they are, and what it means to be there. Place also has an important temporal dimension, because places emerge, change, and develop diachronically: a space may be a place at one point in time, but not earlier or later; or it may become a different kind of place.[31]

The transactional elements of interest, involvement, interaction, and imagination, as I have defined them here, are not just qualities of response to an experience: they actively shape and change the experience. We might not just visit a space; after a while we move in, start to rearrange the furniture, so to speak, and make it comfy. Spaces are transformed by such activities. And, as I have mentioned, this is not necessarily an individual endeavor, but can be a collective one—indeed, it is often the quality of a space as a *shared space* that plays a crucial role in its development into a *place*. Things happen there, memorable things (whether pleasant or unpleasant, but *important*), which mark the space as a place ("this is where it happened"). Places become familiar, acclimated to us as we are to them. They become marked by various social conventions (rules, norms, customs, vocabularies). They become, in many cases, a locus of community. In all of these respects, a relatively objective space and time, a pre-transformative given, becomes something marked, signified, *important*: and in this both the space and those inhabiting it are changed in relation to each other. A place is a special, important kind of space; but those occupying it also stand in a different relation to the space, and to each other, because they are there. In this description, I have purposely not emphasized whether these must be *virtual* spaces becoming *virtual* places; this dynamic is true of spaces and places generally (a crossroads, a battlefield, a classroom, a lovers lane). Or perhaps it is more accurate to say that insofar as spaces become places, there is *always* an element of the virtual to them (in other words, there is a quality of immersion, supported by the elements of interest, involvement, interaction, and imagination).

It is possible to theorize more broadly what is going on here. There are two distinctive ways in which we turn spaces into places.[32] One is by *mapping*: by developing schemata that represent the space, identify important points within it, and facilitate movement within it. A map is never an exact replica (as the story goes, the only map that would be identical would be an exact copy of the original, which would be useless as a map)—a map always simplifies, selects, and schematizes the original, and it is the particular way in which this simplification, selection, and schematization occur that makes this version of the space a place. These are pragmatic activities; we make certain, and not other, choices because they allow us to do things in the space that are meaningful and important to us. There can be multiple maps, and in this sense they constitute different *places*, even when they refer to the same space.

There are also maps that represent patterns of use. Trails that are worn by many feet tramping through forests, or across campus greens, are maps of a sort. Again, they simplify, select, and schematize a space: they identify what is important to people, they mark out key places, they facilitate movement. They also indicate another important characteristic of maps: how their use can also shape and transform the space they represent. This can be seen at work in the World Wide Web, for example, through frequency indicators: page counters, for example, as well as ratings of "most frequently visited" sites. Such representations tend to influence patterns of future use, because they influence how search engines pick out and identify sites, which sites get selected for indexes, and so on. Viewed pragmatically, the representation is not discrete from the thing represented; it acts upon and is acted upon by it.

Yet another kind of map is one showing relations of relative centrality and relative periphery, from some point or points of reference. The repetitiveness of "relative" here is not accidental: there can be no absolute center of a space that is any more necessary than any other—in fact, it is as true to say that a center is *defined* by the map, as to say that the map begins from a center. And a more rhizomic map may have no single center at all. But a map of relative centrality and periphery can still provide a way of simplifying, selecting, and schematizing the pragmatic relation of what is more or less useful or relevant to a given purpose, or set of purposes. This sort of endeavor can be highly useful even though there is nothing necessary about this particular mapping, even if others would map it differently—indeed, we should expect this to be true in order for such maps of relative centrality and periphery to be useful to different people (because their purposes and criteria will differ).

In sum, a map does two things as once: it marks significant places, and it makes places significant by marking them. To return again to the four elements of immersion: mapping is a process that makes manifest our *involvement* with a space, the places we care about; it is an expression of *interest*, as mapping is a kind of problem-solving (how do we find our way about); it entails an act of *imagination*, because mapping is a process of selecting what is judged to be significant enough to include, and of adding a structure of association and organization for what is selected (in other words, it is both less and more than the original); and finally, mapping is a process of *interaction*, changing what is mapped, from space to place, in the process of trying to describe it.

The second distinctive way in which spaces become places is through *architecture*. A space becomes a place when we build into it enduring structures. Often, we live in these structures, work in them, observe or admire them. We are changed by these things we create as we change them—the relation runs both ways. Architecture here is not only the initial design or building, but also the transformation of it over time; in this sense, we always help build the structures we occupy, and the structures are not fully finished until they have been used for a while (in one sense, then, they are never "finished"). Here, I do not mean architecture only in the literal sense of buildings and bridges; there are architectures also of language, of customs, of complex practices and activities (games, for example); all of these can play a role in transforming a space into a place.

Architectures transform not only a space, but also the patterns of activity for those who occupy them. I think that these patterns can be viewed along five polarities:

(1) movement/stasis;
(2) interaction/isolation;
(3) publicity/privacy;
(4) visibility/hiddenness;
(5) enclosure/exclusion.

These inter-related dynamics shape the ways in which participants operate within a space, and the particular constellation of them gives a space its distinctive character as a certain kind of place: for example, structures along the polarity of isolation, hiddenness, and privacy, versus those emphasizing visibility, interaction, and publicity.

(1) Architectures facilitate, direct, or inhibit movement. They anticipate the way in which people are likely to navigate a space, but by making this assumption they also tend to direct it. In an art museum, for example, this is reflected in choices such as what exhibits to put near each other, and where to put doorways. Where will people want to pause, and which paintings will they want to linger over? Yet there are substantive assumptions at work here as well: say one wants to learn about historical periods in art, but finds that the rooms have been organized by subject matter or styles of painting; all the information is there the visitor might want, but not in a pattern that supports the inferences he or she is trying to make. Which room to start with? Where to go next? The visitor's confusion and uncertainty may also be a kind of

paralysis, even though the design of the museum is, on its own terms, quite clear and easily navigated.

(2) The design of spaces also communicates assumptions and expectations about social interaction. Architectures, by directing movement, create avenues to bring people together or barriers to keep them apart. Where will crowds tend to congregate, for example? Architectures also make assumptions about the kinds of things people will be doing in a space, and whether they want to be doing it with others or alone. Again, these assumptions also shape behaviors: if a telephone booth is only big enough for one person, three girl friends cannot all talk to their friend at the same time; they have to decide who gets to talk first, which may start an argument.

(3) Publicity and privacy constitute a slightly different issue, which is the extent to which an architecture allows or inhibits the disclosure of the participants' selves, their activities, and not only their words and ideas, to others (and vice versa). Are walls transparent; or are there walls at all? Can you be seen, or do you always know you might be seen, and how does this tend to encourage or discourage certain things you might do? Can you *choose* when you can be seen, and when you do not want to be?

(4) Visibility and hiddenness, here, refer to the transparency of architectures, to what they disclose or conceal within, and to what they disclose or conceal about themselves. This is not quite the same as publicity and privacy, because here what is exposed or hidden are characteristics of the architecture itself. Does a wall close off a room that only some people know how to get to? Where does this doorway lead, and who is allowed through it?

(5) Architectures also operate through enclosure and exclusion; what (or who) is counted in and what is counted out. Some structures are intended to define a community made special in its own eyes by its privileged access and made to feel safe so that others viewed as less worthy will not interfere. The very attractions of such a partitioned space give rise to its limitations: the risk of complacency and numbing homogeneity. If we assume that certain kinds of change and development can only come from encounters with new and challenging ideas, this architecture of enclosure and exclusion may seem less like a protective shell, and more like a self-built prison.

There is much more to be said about architecture and the dynamics of shaping spaces into places; but here again, I want to return to the dynamics of virtuality. I have tried to indicate how specific design features express assumptions about social dynamics, values, knowledge, and substantive subject matter; in this, I have tried to enlarge the concept of "architecture" to mean much more than just the design of rooms and buildings. Architectures reveal and conceal; they facilitate and discourage; they welcome and exclude; they direct and redirect and inhibit certain choices. In all this, architectures assume particular modes of interest, involvement, interaction, and imagination—and in these assumptions tend to bring them about (or to suppress other modes).

In summary, I have explained two different ways in which spaces become places. The first is mapping, which is in some ways a more reactive process; a process of representing a space in order to be able to move and work within it. A mapped space takes on the character of a place for those who understand and can use the map. The second way in which spaces become places is through architectures; enduring structures that reconfigure spaces. This is in some ways a more active process, in which the space is not only represented (mapped), but also transformed. There are at least five ways, I have suggested, in which this transformation affects not only the configuration of space, but also the activities and the persons who operate within it. These dimensions determine the kind of place it is. I do not mean to argue that the activities of mapping and architecture are utterly unrelated or dichotomous: sometimes a map is prefatory to designing a structure (a blueprint is a kind of map, in fact); sometimes a large, complex architectural layout includes maps or directional markers within it as a way of helping people get around; trails, as I describe them here, have features of both. But the ways in which mapping and architecture influence navigation and meaning-making are different; and they suggest something important, I think, about virtual learning environments.

5. VIRTUAL LEARNING ENVIRONMENTS

Earlier, I described virtual learning environments as spaces where creativity, problemsolving, communication, collaboration, experimentation, and inquiry can happen.[33] But now we can give greater specificity to how they happen. Let me suggest that mapping indicates, on the whole, the perspective of the learner while architecture indicates more the perspective of the teacher (though again, I am not trying to separate these entirely). A learner is asking, How do I find my way about? A teacher is asking, How do I design this learning space in such a way that my students will explore and use it in the way I intend for them to? Mapping and architecture are both ways of turning spaces into places, generally; but in the context of this chapter, I am interested in how they turn virtual spaces into virtual places—and more specifically, virtual *learning* spaces into meaningful, hospitable virtual learning places. They do this by guiding the dynamics of interest, involvement, imagination, and interaction in ways that are judged to be productive (in this case, educationally productive); when they are successful, the learning space becomes immersive—the learner is engaged, actively relating to the subject matter, seeing (and I will add here *feeling*) its importance. As I mentioned before, a place (as opposed to a space) always entails, to some extent, the quality of the virtual; and so in this sense it is no exaggeration to say that a successful learning space, as it becomes a learning place, is in a wider sense *by definition* virtual.

Now, I think you can see the larger purpose of my discussion here: to remove the virtual from a fundamentally technological domain and situate it at the core of educational theory and practice. How do we make learning *immersive*? What role do interest, involvement, imagination, and interaction play as dimensions of active engagement between a learner and a learning environment? In what ways are these activities linked with *mapping*? How can we theorize teaching as the design of *architectures* of learning spaces—architectures that allow learners to inhabit and experience them as places of interest and familiarity? How do these structures of the virtual express (and thereby reinforce) deeper assumptions about social community, value, equity, and the nature of knowledge? Do they assume standardized models of engagement, or tolerate, even encourage, the expression and exploration of alternative identities? Each of these important questions needs to be elaborated in further studies.

This rethinking of the virtual as an educational concept[34] poses a sharp contrast to much current practice: in highlighting the centrality of choice, decision, and exploration as important dimensions of learning; in thinking in terms of learning spaces (learning places), rather than "delivery systems"; in seeing these learning places as potential sites of collaboration and communities of learners, and not just individual achievement; and in recognizing that the face-to-face classroom, as it is currently constituted, is by no means necessarily more humane or authentic than alternative learning spaces. One can see these issues arising in how new information and communication technologies are being thought about and used in schools—but as should be apparent they raise much larger questions about the ways that we think about teaching and learning in general.

I hope to have laid the groundwork for a reconception of the virtual, and to have engaged in an exercise in virtuality here: beginning the design of a theoretical architecture that invites engagement and exploration. If I have been successful in some measure, you have moved into this space yourself and begun to make it a place of your own. It may not be the same as mine. But an academic article can also be a virtual environment—one that you complement through your own interest, involvement, imagination, and interaction.

ACKNOWLEDGMENTS

Previous versions of some parts of this chapter were presented in "Dialogue in Virtual Spaces" at the Didactics and Technology Conference, Lillehammer University (Norway); in "Virtual Spaces as Places of Teaching and Learning" at Ohio State University, Columbus Ohio; and in "On Virtual Learning Environments" at the Wisconsin Library Association, Milwaukee, Wisconsin. The manuscript was completed during a sabbatical hosted at the American College of Thessaloniki, and has been supported in part by the endowment of the Grayce Wicall Gauthier Professorship. I want to thank Megan Boler and Vincent Müller for helpful feedback on earlier drafts.

Chapter 2: A History of E-learning: Shift Happened

LINDA HARASIM
School of Communication, Simon Fraser University, Vancouver, BC, Canada

However, the very genesis of e-learning as based on human collaboration in knowledge work and innovation, can be traced to the development of network communication in the late 1960s, with the invention of e-mail and computer conferencing over packet-switched networks in 1971. Historically, these technological innovations introduced an unprecedented opportunity whereby people could communicate and collaborate despite differences in time and place, and they became key to a social, economic, and especially educational paradigmatic shift.

The telecommunications revolution both enabled and required fundamentally new forms of societal and economic activity, leading to the knowledge economy. The resultant demands and opportunities impacted and transformed education.

The 1980s and 1990s represented a period of intense innovation and expansion in e-learning and networking throughout public schooling as well as in tertiary, professional, workplace, and adult education. The 21st century thus unfolded with new attitudes toward e-learning, and the emergence of new pedagogical models, technological affordances, and mindsets. A paradigm shift became apparent, subtle yet ultimately profound. A fundamental shift in understanding of the very nature of learning and hence the definition, design, and delivery of education characterized the late 1990s and early 21st century, and this shift became civilizational and global as educators and learners worldwide adopted networked e-learning.

This chapter addresses that paradigmatic shift. It begins by presenting an overview of the history of online education as a context and framework for understanding the state of the art of e-learning today, especially the use of network technologies for collaborative learning. The chapter outlines how the early pioneers contributed to the educational paradigm change and how the theory and practice of learning has been advanced into new learning theories and models, modes of delivery, instructional roles, instructional designs, and learning processes and outcomes. The goal of the chapter is to provide an overview of the highlights of the early days of e-learning, a sense of the accomplishments, the challenges, and the adventure. The author recognizes that there are many more dots to be added and linked into creating a comprehensive history. I apologize to the many individuals, teams, and projects omitted. Let us keep working at documenting our history. The field and its future deserve it.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 59–94.

1. HISTORY AND OVERVIEW

The Communication Revolution launched in the late 19th century with the invention of the telegraph (1861) and the telephone (1876) and advanced in the 20th century with the Network Revolution (1969–) has fundamentally impacted our social, economic, cultural, and personal lives, ultimately on a planetary level.

Large-scale adoption of telecommunication technologies invented over the past 150 years have created a world profoundly different in terms of human collaboration and communication than was hitherto ever conceivable. Up until the mid-1800s, telecommunications had been the same for millennia: non-existent except for highest levels of royal or religious use. Queen Victoria had available to her basically the same means of communication as did the Egyptian Pharaohs: mail carried by beast (horse, camel, etc.) or by ship. The village was a closed unit, with communication limited to local face-to-face conversation, or transmitted by peddler/traveler passing through, or by such technologies as smoke signal or talking drum. By the 18th century, mail carriages and variations of the Pony Express enabled some distance communications by the public.

It was the invention of the telegraph and then the telephone in the late 19th century, however, that opened the floodgates of public telecommunications. And the Network Revolution, launched in the mid-20th century with the invention of the Net, e-mail, the internet, the web, etc. triggered a global revolution in human communications, community, and especially their application to education.

The timeline below (Figure 1) identifies key moments in the development of e-learning modalities, which typically employed peer communication and interaction. This chapter focuses on e-learning based on online collaborative learning (OCL) which was the dominant form until the 1990s when the invention of the internet made online distance education (ODE) more viable, and in 1993 when the web made online computer-based training (OCBT) more publicly accessible. Nonetheless, historically, the invention and dissemination of e-learning has been largely based on collaborative learning approaches.

Below is a brief timeline of the history of e-learning.

2. HISTORY OF THE FIELD OF E-LEARNING

Educational adoption of computer networking began in the mid-1970s, following closely upon the very invention of packet-switched networks in 1969 and of e-mail and computer conferencing in 1971 (Hafner & Lyon, 1996; Hiltz & Turoff, 1978). Many of the scientific researchers involved in early networking

YEAR		EXAMPLE
1861	*Telegraph is Invented*	
1876	*Telephone is Invented*	
1969	*Computer data networking is Invented (ARPANET)*	*DARPANET/ARPANET*
1971	*Email is Invented*	
1971	*Computer Conferencing is Invented*	*1971*
Mid 70's	University Courses are Supplemented by Email and Conferencing	
Mid 70's	Virtual Communities of Practice	Scientists use EIES to colaborate
1981	First Totally Online Courses (Nonformal, Adult Education)	The Source; EIES
1982	First Online Program (Executive Education)	• WBSI Executive Education (EIES)
1983	Networked Classroom Model Emerges (Primary and Secondary Schools)	• ICLN Research Project in 4 Countries • RAPPI: Canada X-Cultural Project I Countries • SITP (1990)
1986	First Totally Online Undergraduate Classroom	• Virtual Classroom (NJIT)
1985	First Totally Online Graduate Courses	• Connect-Ed (New School of Social Research) • OISE (University of Toronto)
1985	First Totally Online Labour Education Network	• Solinet (Canadian Union of Public Employees)
1986	First Online Degree Program	• Connect-ED (1986) • 1989 University of Phoenix
1986	Online Professional Development Communities Emerge	• OISE Ontario Educators Online Courses
1989	*Internet launched*	
1989	First Large Scale Online Courses	• Open University (U.K)
1992	*World Wide Web is invented*	• *CERN (Switzerland)*
1993	First National Educational Networks	• 1993 SchoolNet (Canada) •
1996	First Large-Scale Online Education Field Trials	• Virtual-U Research Project

Figure 1. Brief history of e-learning.

experiments were also academics. As these faculty introduced e-mail and computer conferencing into their academic curricula, they discovered expanded opportunities for student communication, interaction, and collaboration. Beyond what anyone anticipated, a sea change in education would emerge.

It is difficult to convey the *tabula rasa* that early e-learning pioneers confronted in conceptualizing their vision of educational applications of computer communications. The technology was unprecedented: What was e-mail? What was computer conferencing? How to use one or the other technology? How to value them? Design them for education? Turoff (and cohorts such as Jacques

Vallee) played an immense role in both inventing and championing computer conferencing as a group communication system, in contrast to e-mail, which is a one-to-one or one-to-many communication mode (Vallee, 1982). What role did group interaction play in education? Was there any value added at all? These were not only mind-boggling questions but coming in the shadow of the disappointments and criticisms of educational television, any application of technology or computers in education was greeted with skepticism at best and derision most often.

Nonetheless, scattered throughout the U.S.A., Canada, and the U.K., handfuls of individuals and small teams pursued their vision of online educational applications. While many e-learning early adopters in the 1980s focused on electronic mail (e-mail), computer conferencing increasingly became recognized as key to facilitating collaboration and interaction in educational discourse and teamwork.

What follows is a sample of some of the highlights and key contributions, and selected exemplars.[1] The accounts are organized by type of education and level of education—and by educational application. Some specific technological advances are noted but the intent is to focus on the *educational* rather than the *technological* transformation.

2.1. Organization of the Content: Definitions and Categories

This section defines key educational terms that have come to be associated with e-learning, and which are used to organize the content of the chapter. Three different categories, each with three sub-categories, are identified.

The first set of terms or definitions is that of the Educational Approach: how is the e-learning application designed in terms of pedagogical model? The Educational Approach emphasized in this chapter is that of OCL, which was historically the first and remains the major approach to e-learning.

2.1.1. Educational Approach (Pedagogy)

Educational Approach refers to the pedagogical models that an application is based on. E-learning has in recent years come to represent a myriad of different even contradictory educational approaches. The term e-learning is often applied without differentiation by the news media, and even by vendors to any use of online activity, regardless of educational model. This confounds research results related to e-learning and confuses the practitioners. Here, we provide a brief definition of three major models (Harasim, 2003):

a) *Online collaborative learning* emphasizes the use of collaborative discourse and group projects (such as debates, simulations, role plays, case analyses) in the online activities. OCL is the educational approach emphasized in this chapter.
b) *Online distance education* refers to the use of e-mail rather than postal mail for the mailing and receipt of distance education materials and assignments. Pedagogically, it relies predominantly on the traditional correspondence or one-to-one, one-to-many model.
c) *Online computer-based training* refers to the use of the web for access to online courseware or individualized learning modules. There is typically neither peer collaboration nor communication with an instructor or tutor; the major interaction occurs between the learner and the software.

It should also be stated that the applications in this chapter refer to asynchronous types of e-learning (use of e-mail, computer conferencing, forums), and not synchronous (i.e., real-time chats, videoconferencing, etc.) e-learning.

2.1.2. Educational Form

In order to understand the design and implementation of e-learning, it is essential to recognize the types of education likely to occur in various settings. Educators and researchers have increasingly come to distinguish among three types of education: formal, non-formal, and informal settings first described by Coombs and Ahmed (1974) that proposed to equate learning and education.

Coombs and Ahmed define these educational types as follows:

- formal education is the "institutionalized, chronologically graded, and hierarchically structured educational system, spanning lower primary school and the upper reaches of university";
- non-formal education is "any organized, systematic, educational activity carried on outside the framework of the formal system to provide selected types of learning to particular sub-groups of the population, adults as well as children"; whereas
- informal education is "the lifelong process by which every person acquires and accumulates knowledge, skills attitudes and insights from daily experiences, and exposure to the environment".

A major difference between the first two processes and the third is that the deliberate instructional and programmatic emphases in formal and non-formal education are absent in informal education. Hence, given the very experiential and amorphous nature of informal education, it will not be discussed in this chapter.

2.1.3. Educational Mode

Various applications of e-learning, regardless of discipline, can also be organized along quantity/quality dimensions (Harasim, 1993). Three key categories are

a) *Adjunct mode*: In which online networking is used to supplement a traditional face-to-face classroom or distance education approach.
b) *Mixed (blended) mode*: In which online networking is used as a significant component of the curriculum and course grade.
c) *Totally online mode*: In which online networking is the major form of discourse and course delivery (although other formats such as text books, phone calls) may be used to supplement the course.

2.2. History of E-Learning Applications

This section of the chapter explores the emergence and development of e-learning applications in the 1970s, 1980s, and 1990s. The applications are categorized by Educational Form/Type (non-formal, formal); the formal categories are further sub-categorized by Educational Mode (Adjunct, Mixed, and Totally Online Mode) in the order below:

1. Non-formal education applications
   a. Virtual communities of practice (first launched in mid-1970s)
   b. Executive education (first launched in 1982)
   c. Labor education (1985)
   d. Teacher networking and professional development (1986)
2. Formal education post-secondary applications
   a. Adjunct mode course delivery (mid-1970s)
   b. Totally online undergraduate course delivery (1984)
   c. Totally online graduate course delivery (1985)
   d. Totally online program delivery (1985, 1989)
3. Formal education K-12 school applications
   a. Adjunct mode applications (networked classrooms) (1983)
   b. Mixed mode applications (1990)
4. E-learning research: communities, projects, and theory

2.2.1. Non-Formal Education Applications

2.2.1.1. First Virtual Communities of Practice

Murray Turoff, credited as the father of computer conferencing, designed the first computer conferencing system in 1971 as a Delphi System (EMISARI). By 1974 he was at New Jersey Institute of Technology, following his “dream of developing and evaluating computer mediated communication technology to facilitate group decisions so that groups might act with their collective intelligence instead of the lowest common denominator" (Turoff, 1999: 39). There he created the Electronic Information Exchange System (EIES) for scientific research communities.

> In the early 1970's the research group I direct at NJIT started an R&D program in the area of Computer Mediated Communication, conceived as the use of computers to facilitate group communications by tailoring the communication structure and protocol to fit the nature of both the application and the group. Our first effort, sponsored by the National Science Foundation, was dedicated to the study of scientific communications and the working of "invisible colleges" or research communities. We were also looking at decision support applications and the use of the technology to facilitate project groups developing software. In 1976 we went online across the nation with the first version of EIES, the Electronic Information Exchange System. We were using Telenet as well as Arpanet and grew our user population to many hundreds of professional users in a short space of time. By the mid eighties we had a few thousand users in one system.
>
> (Turoff, 1999: 39)

The book, *Network Nation: Human Communication via Computer* (Hiltz and Turoff, 1978) is highly recommended reading as a thorough overview of the state of the art of online communication in the mid-1970s, and the authors' vision of the use of technology to support "invisible colleges" of scientists building knowledge together and applying "collective intelligence" to decision making and problem solving, the catalysts that resulted in the first Virtual Communities of Practice, linking scientists via computer conferencing.

2.2.1.2. Executive Education (1982–)

In 1982, the Western Behavioral Sciences Institute (WBSI), based in La Jolla, California, launched an innovative educational program to deliver online courses, taught by prominent university faculty, to highly placed executives. WBSI targeted executives who needed access to state-of-the-art intelligence and discourse but who could not afford to leave their jobs for long periods of time. It was a 2-year program of four six-month sessions online, with an initial face-to-face seminar.

> The real problems began when the participants returned home. Since no one had ever been taught on a computer network before, there were no models. The first courses consisted of either professorial monologues

> that made interesting reading but were unsatisfactory as computer conferences or telegraphic questions followed by days of inactivity while the teachers waited for responses. Meanwhile, various technical problems inhibited the participants from joining in the conversation, such as it was.
>
> Recall that these were the early days of the personal computer. We used modified Apple IIE's with 48K of RAM and 300 baud Hayes modems—donated by Dennis Hayes who was himself a participant—to access the Electronic Information exchange System (EIES) network at the New Jersey Institute of Technology. . . . This setup was so complex, it took a full page of instructions just to sign on and many more pages to list the basic EIES commands.
>
> (Feenberg, 1993: 187)

Feenberg reports that "WBSI's first attempts at online teaching were disastrous. Great teachers were helpless in front of a class of sympathetic but skeptical students scattered between Caracas, Philadelphia, and San Francisco". (*ibid.*: 191). Yet despite the problems, student numbers grew. Students engaged in a "frontier solidarity" that increased their engagement to the program and to building a virtual support community. Moreover, the WBSI program offered participants a unique opportunity to extend their intellectual reach: "where else could they hope to find professors from Harvard, Yale, and the University of California, a Jonas Salk, a Carl Rogers and a Steward Brand, all available in an information-age setting?" (*ibid.*: 187).

Through trial and effort the WBSI program faculty, students, and consultants (especially consultants Peter and Trudy Johnson-Lenz) worked through various pedagogical approaches to ultimately settle on the online group discussion model.

2.2.1.3. Labor Education (1985–)

SoliNet (Canada's Solidarity Network) began in 1985, launched by Marc Belanger originally for the members of the Canadian Union of Public Employees. As a technology organizer he was responsible for "the installation of Canada's first Local Area Network (LAN) and the development of the country's first national, bilingual, computer conferencing system (note all the qualifiers there). The conferencing system, SoliNet, was the first labor-education computer communications system in the world" (Belanger, 1999: 58).

Belanger defines his role (and that of other e-learning pioneers) as "technology organizing": "the bringing together of people and tools to create new forms of technology. Like community organizing it encourages people to take charge of their situation and use what is at hand to increase their social, political, and economic influence. It squeezes out of the technical maelstrom democratic possibilities". (*ibid.*: 58).

The curiosity and drive to "squeeze" democratic possibilities out of the new communications technologies led Belanger to explore the early uses of microcomputers and, in 1983, to find a technician who helped install the first LAN in Canada (with the assistance of a small Utah firm called Novell). Belanger pursued new online communication oppertunities:

> But if microcomputers could be used to communicate within a building why could they not be used by other unionists to communicate nationally, even internationally? Couldn't we use microcomputers to involve unionists in online educational activities? I thought that it would be possible but was completely baffled about how it could be done. Then I read an ad in the New York Times. An organization called Connected Education, headed by Paul Levinson, was teaching online courses in conjunction with the New School for Social Research in New York. I enrolled and Paul taught me the basics of computer conferencing and how to use the medium for educational purposes.... I was able to earn a Master's in Media Studies completely online. There had to be a way, I hoped, to provide the same sort of educational opportunities to working people who could not afford to leave their jobs or take the time away from their families to attend night classes.
>
> (*Ibid.*: 58–59)

Around 1983, the University of Guelph in Canada was developing the CoSy conferencing system, and a few faculty were involved in using it for course applications. As CUPE required a bilingual (English/French) system, Belanger worked with the CoSy team to produce a French and English interface for CoSy. The system, SoliNet, was opened to the labor community in 1985. The pedagogical model was based on collaborative learning: group discussions, seminars, and workshops.

> SoliNet was used to teach courses and conduct workshops. These included conferences on technological change, pay equity, employment equity, health and safety, shop stewarding and other labour-oriented subjects. In 1991 SoliNet became the first labour-conferencing system to teach university credit courses....
>
> One of the conferences on SoliNet was called the Lounge. It was the central conference, which people could use to chat about anything on their minds. Early in SoliNet's history I tried to shut down the Lounge and steer people to a number of topic-specific conferences. Big mistake. My e-mail in-box was filled with messages objecting to what I was

proposing and my office was picketed! (Unionists are not shy people). It was then I realized that SoliNet had grown into a real community.

(*Ibid*.: 59)

2.2.1.4. Teacher Networking and Professional Development: (1983–)

This author's own involvement with e-learning began in the early 1980s, through research and the implementation of several projects that built on my previous efforts and commitment to collaborative learning and building knowledge communities globally (albeit in face-to-face contexts). Writing my doctoral dissertation at the Ontario Institute for Studies in Education (OISE) (the Graduate School of Education at the University of Toronto), I began to use e-mail in the 1970s and computer conferencing in the early 1980s. In 1983, I was hired to design and implement training for Ontario educators using the Canadian educational computer, the ICON. The ICON was a networked computer and enabled computer communications among the local users. These experiences showed me that teachers valued the opportunity to communicate, interact, and share ideas and resources beyond the classroom walls. And that computer networking suggested powerful potential for teacher professional development. How to design and apply computer networking for educational purposes was still very unclear, although the experiences with the networked ICON computers provided rudimentary promise.

The literature on e-learning was non-existent. Any book or article on networking that I could find focused on "networking" as the linking of one's computer to the printer—but nothing at all about linking users with other users.

> In 1984, I obtained funding to study the potential of educational networking for teachers from the Ontario Ministry of Education. This project enabled me to research the literature, conduct needs assessment with teachers regarding their professional communication and networking problems and interests, obtain information on computer conferencing, and thereby to develop a framework for how computer networking could be used to advance educator needs and effectiveness (Harasim and Johnson, 1986). It also helped me to begin making connections in the fledgling area of educational computer networking and conferencing.
>
> That year I also discovered the book *Network Nation* by Hiltz and Turoff (1978) while browsing in a Toronto bookstore. Reading it was a pivotal experience. I found substantiation, experience, history, and applications that directly addressed my interests in the potential for human communication and collaboration via computer networks.
>
> (Harasim, 1999: 25)

In late 1984, Dr. Dorothy Smith and I undertook a project with the Ontario Ministry of Education, entitled: "Research into Developing Computer Networks for Women Educators". Building on this research, in 1985 I sought and obtained funding from the Federation of Women Teachers Associations of Ontario (the FWTAO) to develop and implement "The Ontario Women Educators' Computer Network: Online Participatory Research Project".

The first Teacher Network project was launched in January 1986. Twenty female teachers from all the regions of Ontario (to respect geographical equity, even at a time when packet-switched networks did not) were selected by the teachers' union to participate in a 12-week totally online course, together with 20 graduate students from OISE. The network of 20 teachers represents the first or one of the first online teacher and professional development networks.

Dorothy Smith collaborated with me on the design and implementation. My interest in collaborative learning complemented her own commitment to feminist pedagogy, and the first online non-formal course was based on a variety of small and large group activities such as discussion groups, plenary sessions, small project teams, and debates.

The results were very positive: both the teachers and the graduate students participated actively and regularly. Moreover, the distribution of communications was surprisingly evenly distributed: most people participated, and they participated more or less equitably. There was little or no domination by a few individuals. And potential differences (such as those between students taking the course for credit while teachers did not receive credit) did not create an imbalance in engagement, participation, or completing tasks. All participants were active 7 days a week, 24 hours a day. We used 150 or 300 bps modems. Today it sounds extremely primitive, but then it felt like rocket science (especially as one by one, each teacher decoded the bizarre formula for linking to the data network which was then still not public advertised or accessible). Nonetheless, even teachers living in remote regions of Ontario persevered, gained access and were highly active, with participants each sending at least five messages per week.

It was a tremendous learning experience for all involved, and helped to build credibility for online course delivery at the Institute. And in this case, the technological innovation was designed, launched, conducted, and employed by female educators.

2.2.2. Formal Education: Post-Secondary

2.2.2.1. Enhanced or Adjunct Mode Application

Around the mid-1970s, soon after the invention of e-mail and of computer conferencing, DARPANET and NSF scientists—including Murray

Turoff—began introducing these technologies into their university classrooms as part of the subject matter. But they soon discovered the potential value of CMC as not only content but also educational process.

> Because we had the technology in operation a few of us who were involved with the research decided to use it to improve communications with our face-to-face classes. Much to our amazement we found that the technology allowed us to have insightful, reflective, and fascinating discussions with our classes that had never been possible in the face-to-face classroom. We were teaching technical courses in the areas of Computer Science and Information Systems. There was always so much to cover in lectures that very little discussion time was available. Furthermore, it was always the same, small percentage of the class that spoke up. Even though these are technical courses there is a great deal of pragmatic content in many of the upper division and graduate courses that deal with design tradeoffs. We found that when every student had a chance to reflect on their views and to compose their thoughts, the resulting discussion was fairly equally distributed.
>
> (Turoff, 1999: 39)

Enhanced or adjunct mode e-learning (the use of the Net to enhance conventional f2f or distance education) was historically the first use of educational computer communications (e-mail and conferencing), and remains today the most typical entry point for faculty adopting e-learning.

Starr Roxanne Hiltz notes that a decade of experimentation with EIES as enhancement to the traditional classroom (TC) prefaced her work on the Virtual Classroom (VC) project in 1986 as a totally online course delivery application. "Before this formal field trial, we experimented with the use of computer conferences and messages to enhance the delivery of college-level courses, but 'mixed' it with 25% to 75% of the usual face-to-face classes". (Hiltz, 1994: xvii).

2.2.2.2. First Totally Online Undergraduate Courses

Starr Roxanne Hiltz, a pioneer of e-learning in post-secondary education, describes how she first came to visualizing and then realizing the VC.

> The term (now trademarked by the New Jersey Institute of Technology) and the concept was first a gleam in its creator's eye during a graduate seminar on the Sociology of Architecture, led by Professor Suzanne Keller at Princeton University in 1977. The final assignment was to design 'an ideal classroom' for the 21st century. First I sat down and started sketching a set of inter-connected physical spaces for different forums of interaction among people and knowledge resources. In this imagined learning environment there was a multi-media lecture hall, where

> the Professor pronounces words of Truth and Knowledge, and students try to absorb this and take notes. In a sumptuously furnished circular "conversation pit" with leather couches and marble coffee tables, the Professor as Discussion Leader and Socrates would conduct seminar-type sessions, moderating discussions and presentations in which the majority of the talking was done by students. There was also a "learning resources" area, with reference materials, computer hardware and software, and perhaps laboratory equipment, where individuals and small groups of students might do research and prepare their assignments. There were obvious problems. How could you create a comfortable, upholstered discussion space for say, 30 people, without having to put in microphones so that participants could be heard across the huge circle without shouting? How could you possibly provide an adequate amount of computer and other resources, so that they would always be available to students in assignments, whenever they wanted them, without the endowment of a Princeton or Harvard?
>
> Suddenly it came to me. A teaching and learning environment did not have to be built of bricks and boards. It could be constructed in software. It could be Virtual! In an era when many teachers and students have their own computers, it was no longer necessary for them to travel to a classroom. . . . The classroom could come to them. Over their telephone lines and through their computer.
>
> (Hiltz, 1999: 31)

2.2.2.3. First Totally Online Graduate Courses

Our efforts in online graduate course delivery at OISE (University of Toronto) occurred without knowledge of or collaboration with Hiltz's VC activities or Levinson's Connected Education efforts. Recall that e-learning activities in the early- to mid-1980s were very much independent and isolated efforts. There was unfortunately little or no educational confirmation, evidence or interest in educational computer networking, except by a few. One exception was a handful of researchers and faculty at OISE, working in different areas and on different perspectives of networking, who ultimately contributed major perspectives in educational networking.[2]

In launching the first graduate courses in 1985, there was neither literature nor models available. With one exception: I was able to find and invite Ward Deutchsmann, then a Dean at New York Institute of Technology who had in 1984 integrated computer conferencing as adjunct mode into distance education courses. I invited Prof. Deutchsmann to visit OISE in late 1985; a snowstorm reduced his visit to a few hours in the afternoon, but one major consequence was his enthusiasm for educational networking. Educational design of totally online courses was still unclear. But Deutchsmann's presentation offered his professional judgement and experience that online education had value, which further fueled our resolve to explore and experiment with this new modality. One of the major outcomes and contributions was focus on our online delivery of graduate courses at OISE (rather than adjunct mode as in the NYIT example), and, in my own case, an totally continue emphasis on the design of learning activities and online environments to support various collaborative learning pedagogies.

The design of the online educational applications into different virtual spaces, each with specific functions and characteristics to support collaborative learning activities is one of the achievements that has been associated with my own theory and practice. I write this in hindsight based on feedback from other researchers and practitioners.

The online courses that I first designed and implemented in 1985, until today, use a variety of activities based on collaborative learning. For example, a totally online course may start and end with a set of plenary activities, to build the sense of group identity and community. Seminars, small group discussions, and small group assignments might comprise the core curriculum, each lasting for one online week or for a set number of online weeks. Courses designed and offered in the mid- to late 1980s at the OISE, illustrate this approach (Harasim, 1993). The courses were graduate level credit courses, with a limit of about 25 students to a course (although some were considerably smaller and a few significantly larger). The first activities were plenary group discussions. Topics included a conference for "Self-introductions", a conference for setting personal and class "Learning Objectives", and a conference for engaging in a "Great Debate". And there was also the very important "Café" for socializing and a conference entitled "Mutual Assist" for peer technical help. The graduate courses employed the following types of group learning activities: Seminars (plenary and small group); Dyads; and Project Teams. The 12-week course was organized into 4 weeks of seminar activity, followed by 2 weeks of a dyad assignment; 4 weeks of project work and class presentations and concluded with 2 weeks of debates structured around dyad interaction. Between 35 and 60 computer conferences and sub-conferences were used to create the environment. The shape of the environment changed each week, as some topical conferences were closed, while new ones were opened.

Learning Task. The tasks and the groups changed, from plenaries to dyads to small group activities. The online course environment included perhaps 10 conferences for core discussions (plenary and small group); 10 for small work group presentations (with an equal number of work spaces); 10–15 conferences for dyad presentations (with an equal number of work spaces); 10–15 conferences for debating teams; and 6–10 spaces for informal conferences.

Group Size. Conference spaces were also defined by the size of learning group. The graduate courses that I designed and taught employed a fairly complex instructional design, involving plenaries, seminars, dyads, and small group activity. Plenary (full class) sessions were employed for group building, especially for initial and concluding course activities. All the informal conferences were also designed as plenaries, to enable the entire course to "meet". In a large-sized class (more than 20 students) or where there were distinct special interest or work groups, small group discussions helped manage the volume of online discussion. A conference for small group discussion typically had 8–15 students each; seminars might have 18–22 students. Group assignments and tasks were organized around small groups, usually with two to four persons per group. Dyads or learning partnerships are another design for online group work. In this design, two students are partnered either for a specific task/assignment or for peer support. Users were active in generating ideas and information: analysis of the online courses at OISE shows that graduate students averaged between 5 and 10 conference messages per week per person (electronic mail notes were not tracked, but were prolific). Thousands of messages were generated in the conferences over the 12 weeks online, representing a significant database of ideas and perspectives on various topics.

The online courses were distinguished by active peer-to-peer discussion and exchange. In the OISE online courses, students contributed 85–90% of messages, a level of student participation and interaction high even for face-to-face graduate seminars. The collaborative nature of the conferences is illustrated not only by the quantity of participation but by the quality of the interaction as well. Analysis of selected contents of the online courses indicates that learners formulated positions and responded to their peers with active questioning, elaboration, and/or debate. Transcript analysis of online seminars and small group activities showed that students build on one another's ideas by posing and answering questions, clarifying ideas, expanding on or debating points raised by others. Message map analysis of interaction patterns in selected online discussions demonstrated that students refer to one another's messages, adding on and building to the ideas posed (Winkelmans, 1988). Peer interaction, in which students are exposed to multiple perspectives on a particular topic as well as to being challenged by a question or expansion of their own ideas, offered a valuable opportunity for knowledge building and developing critical thinking skills (webb, 1989). Online activities facilitate such collegial exchange. Online interaction thus displayed fewer of the extremes typical of face-to-face class activity such as excessive or dominating input by a few and little or no participation by everyone else in the class. Online environments such as educational computer conferencing do not entirely eliminate domination by a few more vocal participants. What is new and different is that conferencing ensures that dominance by a few does not exclude the ability of others to have their say.

Post-secondary Totally Online Programs (UoPhoenix Online). Terri Hedegaard-Bishop was the major force behind putting complete degree programs online.[3] In the 1980s her employer, the University of Phoenix (UOP), began searching for new methods of providing greater access to education for its growing population of working adult students. The search was for new pedagogical methods of distance delivery that were both institutionally altruistic (preserving the UOP model of highly collaborative and interactive learning and small class size), as well as enabling increasing access, outreach, and growth. In 1987, she encountered OCL.

> As the new Vice President for Curriculum and Product Development, the search for an appropriate distance-learning model fell to me. I had rejected a series of technologies available at the time (satellite, video, CDROM), either because they were not cost-effective over the short shelf life of our courses, or because they were supportive of primarily didactic teaching methods. It was important to me and others that the University preserve its highly collaborative and interactive learning model, which included small class sizes and the extensive use of study-groups.
>
> Sitting in a hotel room in Detroit Michigan while on a business trip, I received a call from my boss—the founder of the University of Phoenix Dr. John Sperling. He had heard about a person doing pioneering research on the use of computer mediated communication for educational delivery and he thought that I should take a flight up to Ontario, Canada "while I was in the neighborhood" and talk to this person. I called Linda Harasim and arranged to see her at the University of Toronto (Ontario Institute for Studies in Education) the very next day, having no idea of what I was about to discover.
>
> (Hedegaard-Bishop, 1999: 20)

Hedegaard notes that while waiting for our meeting, she began to read my research papers.

> So I sat there and began reading about the work she had been doing teaching graduate students using online computer mediated communication and found myself growing increasingly intrigued. I immediately recognized the strong convergence between UOP's adult collaborative teaching/learning model and Linda's online education model. Over lunch I fired question after question at Linda, searching for a "loop hole" or some indication that this learning model wouldn't work on a larger scale. However, her confidence was contagious and convincing. It appeared to be the perfect match for the University of Phoenix.
>
> (*Ibid.*)

As a next step, in 1988, Hedegaard formed a committee to design the online learning project,[4] exploring the concept, selecting a software program, designing the curriculum model, and testing theories by experimenting with the new online learning system. She introduced several innovations in her 1989 program, which still remain valuable lessons for the field:

a) The degree program should be entirely online, not simply piece meal as in individual courses or parts of courses.
b) Focus on and emphasize what is pedagogically possible and important. Some aspects of the f2f program, such as focus on oral presentation skills, were abandoned. "I didn't see how it could be done in a truly effective way. The decision was to remove the objective entirely rather than doing it poorly". (*Ibid.*: 20).

Hedegaard was a pioneer in her vision of quality education and student needs, taking difficult but important decisions regarding what she considered to be most possible, and most effective in online educational delivery. She committed to effective change, educational transformation, and success regardless of rocking the traditional academic boat. Her commitment was based on pedagogical principles, such as active collaborative learning, rather than the tradition of one-many (lecture hall or correspondence) education, a new pedagogical and programmatic model, which ultimately succeeded.

2.2.3. Formal Education: K-12 School Applications

2.2.3.1. Enhanced Mode Applications (Networked Classrooms)

In the early 1980s, scarcely a decade after the invention of e-mail and of computer conferencing, teachers and students in public schools began to experiment with these exciting but still very complex telecommunications innovations. Their efforts resulted in a new modality of learning that can be termed the "Networked Classroom", in which educational applications of computer networking are used to enhance the course curriculum.

In 1983, at the Versailles Economic Summit in France, Canada proposed to create an educational conferencing project linking selected public schools in Canada, the U.S.A., England, France, and Italy into online discussion groups related to geography, history, social and cultural issues, etc. The project, called RAPPI, was a breakthrough and success in that for the first time in human history classrooms (local, national, and international) were linked by computer communications, and online student relationships and group projects were facilitated. Electronic pen pals between schools and countries were created. A few classroom-to-classroom collaborations were also initiated. Some linkages were better than others, whereas several failed to materialize. Interestingly, among the most successful were linkages between schools in Canada and in Italy.

Reasons for the success are not clear. Since RAPPI was not a research project there was unfortunately little analysis or even documentation of the activities or their implications. My own casual observation of some of the activities suggests that success stories resulted from significant teacher commitment and pedagogical structure. The development of "class projects" with clear goals and structures (such as group projects that involved class-based questionnaires or interviews, or structured history projects) seemed to characterize the most successful efforts.

In 1983, a group at the University of California, San Diego, began to use university networking equipment to link schools in various locations to form the InterCultural Learning Network.[5] "The goal was to explore how computer networking could be used to create new contexts for learning for elementary and secondary students and their teachers. The communication systems we used were difficult, expensive, and incredibly slow". (Riel, 1999: 54). The ICLN was not linked in any way to RAPPI and neither group knew of the other. However, they each encountered similar challenges (as well as success) with the electronic pen pal approach.

> Like many others, our first notions of how to use telecommunications in the classroom was to match students in one-to-one writing pairs with distant "computer-pals". This task was difficult to manage with unequal numbers of students in each class in different locations. It was time consuming and frustrating as some, but not all, students heard from their partners. Most importantly, these friendly exchanges did not have extensive or sustained educational benefits. Personal communication did not stretch students capabilities and most letters, even from very distant places, carried very similar content. The few messages that did contain insightful views, cultural contrasts or valuable learning were narrowly directed to a single student. Telelearning needed educational structure.
>
> (Riel, 1999: 54)

The lessons experienced by RAPPI reverberated in the ICLN activities and subsequent classroom network applications. Electronic pen pals were an interesting but naïve approach. They were certainly the major application that many teachers and schools attempted when first adopting e-learning during the 1980s and the early 1990s. Nonetheless, the complexity of the technology, the tremendous organizational effort required, and the ultimately disappointing outcomes of geographically distributed dyads led to the demise of this approach as a major educational application.

The ICLN began to incorporate a clearly defined educational research component and thus generated more clearly articulated lessons from the front lines of public school computer networking. Riel writes

> We wanted to design models of cross-classroom communication that would help students participate in learning and teaching, sharing their diverse experiences, and reflect on both similarities and differences.

> Learning tasks would have to integrate with differences in curriculum, fit into different school schedules, and work with students of different ages. Struggling with these constraints, we began to structure teaching and learning environments that made use of cross-classroom collaboration and group-to-group communication.
>
> [1999: 54]

The ICLN activities began creating a newswire service, The Computer Chronicles, to which students could contribute and retrieve stories. Classrooms were able to contribute to an international school newspaper, with stories written on location around the world. The focus of the ICLN activities and research studied the value of an audience for student writing and a communicative purpose for writing.

> Early research on this writing and editing process demonstrated remarkable student gains as a result of cross-classroom collaboration. These findings appeared on holistic scoring of writing and on standardized tests of reading and writing. We had found a meaningful context for promoting language art instruction. We also found that it provided for teachers a rich network of professional peers for thinking about different instructional practices and educational theories often in relation to the use of technology.
>
> (Riel, 1999: 54)

2.2.3.2. Mixed Mode Applications: The Southern Interior Telecommunications Project

Mixed mode (or blended mode) applications of e-learning refer to the integration of networking as a significant component of Traditional Classroom (or distance) education. The Southern Interior Telecommunications Project (SITP) of British Columbia, Canada, was designed to integrate computer networking with the school curriculum, rather than provide it as an "add-on activity". The SITP project was launched in 1990 to link teachers and students in 50 primary and secondary schools of the Southern Interior of British Columbia. At that time the web did not yet exist and communication was done via text-only asynchronous conferencing. Teachers in primary and secondary schools integrated their curriculum with teachers in other schools, creating a networked classroom expanded over a wide geographical area. Students participating in the networked classroom did assignments and projects together, all related to the school curriculum and grade structure.

Among some of the exemplary networked classroom projects created by SITP teachers were the "Salmonids Online" and "Legal Beagles". In these projects new ideas for online curriculum integration were explored, reformulating face-to-face pedagogical formats such as mentorship, cognitive apprenticeship, ask-an-expert, peer interaction, role play, and collaborative learning into new e-learning processes.

The SITP project introduced new pedagogic and scientific approaches to classroom learning. The Salmonids Online project, for example, used peer interaction and "ask-an-expert" formats to expand the science of classroom salmon hatcheries in which students raised salmon eggs to the fry stage of development, and released them in the spring. The project was organized into three phases, fall, winter, and spring, following the natural salmonid activities that occur in the southern interior area. Through regular access to salmonid experts such as "Dr. Fish" (a world expert who volunteered his time and energy) and engagement in online peer conferences for sharing and analysis of data, student-based discussions such as *Salmon Around the World*, *Idea Spawning Bed*, and *Salmonid Chums* encouraged and enabled students to participate in high level scientific discourse and debate. A significant portion of the course grade was related to this online project.

A related but somewhat different approach to mixed mode e-learning was that of the Law 12 (Civic Education) course offered to Grade 12 students in the southern interior of BC. This course created the *Legal Beagle* space, designing online environments as settings for a variety of key class-related collaborative activities: online seminars, debates, and role plays (i.e., online trials, in which students were assigned roles such as judge, plaintiff, witness, etc.). Students were supported by a team of three lawyers who volunteered to assist the online project. What is of especial interest is that the online component, involving student collaboration and legal experts, was employed to compensate for the lack of a legal textbook for the course, thus providing a new model for student interaction and knowledge building with the knowledge community (Teles and Duxbury, 1991, 1992).

It is historically noteworthy that the SITP experiences and reports also served as the model for one of the first national educational networks. The SITP networked classroom models and reports were subsequently used to launch Canada's Schoolnet project to connect all schools in Canada in 1993 (http://www.schoolnet.ca).

3. E-LEARNING RESEARCH: COMMUNITIES, PROJECTS, AND THEORY

3.1. Research Communities

A key characteristic of e-learning practice, since the beginning of this new field, has been investment in research. The field moved from obscurity in the 1980s to skeptical recognition in the 1990s, to rapid acceptance in the 2000s. A significant contribution to e-learning's growth, credibility, adoption, and general success has been the evidence base that grew out of the research that accompanied its emergence.

E-learning pioneers and practitioners by and large were active in the study and research of this new paradigm and educational domain. And this investment has provided a powerful and essential base of educational evidence for what works, what does not, for whom, and under what circumstances. Certainly e-learning is not a panacea; but then no e-learning pioneer has ever claimed as much. Traditional education (lecture halls, classrooms) has never fully addressed the effectiveness issue and there is little baseline evidence regarding learning processes, intellectual progress, or collaborative interaction and cognitive change in the f2f classroom or lecture hall.

The creation of e-learning research communities was a critical component to building the field, both in terms of providing the relevant evidence, the methodologies, and also in developing the knowledge community of experts. E-learning research has also made major contributions to learning theory and practice. Below are examples of early initiatives that helped to build a community of researchers and specialists in e-learning, particularly those focusing on post-secondary education.

3.1.1. Guelph Symposia on Computer Conferences

One of the earliest contributions to building a research base and community on computer conferencing was the Guelph Symposia on Computer Conferences. Three major Conferences in the 1980s attracted an international gathering of researchers, developers, educators, philosophers, and scientists from fields such as computer sciences, social sciences, and learning sciences. Participants came from Canada, the U.S.A, and Europe, catalyzing an incredibly vibrant and interdisciplinary "meeting of minds" in terms of the exposure to new communication approaches, technologies, disciplines, and perspectives. Participants had an opportunity to listen to and meet with the gurus in the field, as well as to encounter state-of-the-art experiments or work in very different fields.

The University of Guelph was a pioneer in computer conferencing, having built the CoSy (COnferencing SYstem) in 1983, and then promoting the sharing of technical, theoretical, research, and practical knowledge in the field. Three major conferences were held: the First Guelph Symposium on Computer Conferences (January, 1985); the Second Guelph Symposium on Computer Conferencing (June, 1987); and the Third Guelph Symposium on Computer-Mediated Communications (May, 1990).

3.1.2. American Educational Research Association

A major venue for e-learning research was the American Educational Research Association (AERA). Beginning in the mid-1980s, a small number of educational researchers dedicated to e-learning [under such titles as educational computer-mediated communication (CMC), educational computer conferencing, network learning, etc.] began to present their research at the annual AERA conferences and soon formed a community. These sessions were initially small panel and poster presentations, mostly to kindred spirits. During the 1980s those of us in e-learning were by and large lone rangers who encountered colleagues and relevant data at these venues. We came to know one another, and to create a mental map [and connection to] researchers and implementers of e-learning in K-12 and [to a lesser extent, post-secondary] environments in North America and Europe.

It may seem surprising, but in the mid- to late 1980s it was possible to know about most of the e-learning experiments and efforts in the U.S.A., Canada, and Europe. We were so few in number, that when a group came together, between those present and their own connections, it was possible to map out many if not most of the e-learning activities in existence.

3.1.3. Online Education: Perspectives on a New Environment

In the mid-1980s, this author recognized the need to advance the field of online education "by presenting theoretical, design, and methodological perspectives that can help us to better understand, use, and benefit from computer-mediated communication (CMC). Online education already exists as a field of practice; there is an urgent need, now, to build a research discipline and knowledge base to guide research, practical and technical developments in the new field". (Harasim, 1990, xv).

The need to establish and set down foundations was clear. The mechanism identified was to develop an online community of e-learning experts, who would each lead an online seminar on a topic of their expertise which would then form the kernel of a chapter for an edited book: *Online Education: Perspectives on a New Environment*, published in 1990.

> *Online Education* is itself the product of an online educational collaboration. The need to build a scholarly community and discipline for studying, developing, and promoting online education was acknowledged in 1986–87 in the "Online Educational Research Workshop," which brought "together," on a computer conferencing system, twenty educators from Canada, the United States, and the United Kingdom. Over a period of almost three months, participants explored and developed ten perspectives on online education. These ten topics have been refined into the chapters that make up this book."
>
> (Harasim, 1990: xv)

The book was published and another link in the community was established. The community did not remain an ongoing set of online seminars, but for many of us became an important professional and social network that continued to share and to communicate and to help build the field, using online and face-to-face conferences and meetings.

3.1.4. Mindweave: Communication, Computers, and Distance Education

An initiative that was somewhat similar to the *Online Education* seminars and book was the face-to-face conference on CMC in Distance Education, organized at the British Open University's main campus in Milton Keynes, launched in October 1988. The result was a book (*Mindweave*) based on the plenary presentations and the poster sessions. And also a further building of the community and the field. Half of the chapter authors from Harasim's *Online Education*, were again featured in Mason and Kaye's *Mindweave*, further building the community and the dialogues/debates.

A quote from *Mindweave* evinces the newness of the field and the need for community and both theoretical and practical analyses. The book addresses both existing practitioners, but especially those new to the field. Consider the infancy of the field when an asynchronous conversation among five learners is highlighted.

> For those readers who are wondering why we believe computer-mediated communication will have such an important role to play in distance education, we recommend the Prologue. This is a transcript of a 'conversation' on the Open University's CoSy conferencing system between five of the most enthusiastic users of CMC on this course—students based respectively in London, Cambridge, Birmingham, Preston, and Troon (in Scotland). Without CoSy, they would never have met each other, 'electronically' or otherwise. We believe they are among the pioneers in the use of this technology for learning at a distance. *Mindweave* is dedicated to an exploration of the ways in which benefits of computer-mediated communication, as experienced by these students, can be made more widely available to adult distance learners.
>
> (Kaye and Mason, 1989: vii)

3.2. Research Projects

Beginning in the 1980s, a handful of major research projects were launched that helped to scope out the field and to provide a knowledge base, and a landscape of data that could influence policy, contribute to practitioner knowledge transfer, and help to build the field. While many conferences and research activities began to populate the field, here we identify three key examples.

3.2.1. Virtual Classroom Project (1986–1987; 1987–1992)

The Virtual Classroom (VC) research project was the first set of significant large studies of e-learning, especially in post-secondary education. And as such it provided an important touchstone for e-learning researchers and practitioners. The project offered valuable methodological contributions to the study of e-learning: at that time, the need to "prove" that the VC was "as good as" the Traditional Classroom (TC) for mastery of facts and information called for a traditional evaluation based on experimental and quasi-experimental design (comparing courses matched with the same teacher, texts, and tests in VC and TC modes) (Hiltz, 1994). In addition, the evaluation instruments were made available to other investigators. The project also contributed valuable data about e-learning software and teaching techniques, providing a base of empirical evidence that significantly helped to advance the field.

It is perhaps surprising to recall that as recently as late 1980s, the big question was whether it was even possible to use computer communication for educational access and effectiveness. In 1990, Hiltz, the VC Project Leader, wrote

> The primary goal of the project "Tools for the Enhancement and Evaluation of a Virtual Classroom" is to explore whether it is possible to use communication systems to improve access to and effectiveness of postsecondary educational delivery. The most important "product" of the project is knowledge about the advantages and disadvantages of this new technology, as they may be influenced by variations in student characteristics and implementation techniques and settings. Evaluation is as important as software development for the Virtual Classroom project. The two key questions are the following:
>
> 1. Is the Virtual Classroom a viable option for educational delivery? That is, are outcomes, on the whole, at least as good as outcomes for traditional face-to-face courses?
> 2. What variables are associated with especially good and especially poor outcomes in this new teaching and learning environment?
>
> (Hiltz, 1990: 133)

3.2.2. Virtual University Project, TeleLearning Network of Centers of Excellence (1996–2002)

The Virtual-U field trials were the first large-scale field studies of online post-secondary education. Over 1500 students, 250 faculty and 500 totally online and mixed mode courses were involved in the study of e-learning in Canadian, American, and European universities who adopted the Virtual-U LMS system between 1996 and 2002. The focus was on the pedagogical implications rather than specific technological features.

The results of these field studies provided a profile or overview of the state of the art in the post-secondary e-learning in the late 1990s and the early 2000s. Data on levels of participation, interaction, completion, learner and faculty satisfaction, pedagogic approaches employed, assessment strategies used, and academic disciplines helped to create a kind of map of e-learning: who was doing it? How were they doing it? And what were the results?

The results of these field studies offered a glimpse into the new online world that was unfolding in education, and contributed to knowledge about what it was about. Not in a great deal of granularity but nonetheless, as in the 15th century maps of China and Europe, the Virtual-U field studies began to identify some of the e-learning landscape that might lay ahead and thus provide educators, administrators, and policy makers with some navigational landmarks and tools. And like other pioneering efforts, helped to demonstrate that the world was not flat.

3.2.3. Sloan-C

The Alfred P. Sloan Foundation became active in promoting the adoption and advancing the effectiveness of e-learning in 1992, with its program in Learning Outside the Classroom. One of the major mechanisms has been the Sloan Consortium (also known as Sloan-C) and the provision of large grants to institutions to catalyze the adoption of e-learning [or in their terms Asynchronous Learning Networks (ALN)] as well as providing financial support for e-learning research and dissemination of results. Since 1999, a series of case studies and empirical research by selected faculty and researchers has been published in a special set of monographs (that present the case studies plus peer reviews) and also in special issues of the *Journal of Asynchronous Learning Networks*. Research is conducted within what Mayadas, the Sloan Program Director identifies as the "Five Pillars of ALN" (http://www.aln.org/publications/books):

- Learning effectiveness
- Faculty satisfaction
- Student satisfaction
- Cost effectiveness
- Access

In addition, the Sloan Foundation funded the WebCenter for Learning Networks Effectiveness Research (http://www.alnresearch.org/index.jsp), a series of online knowledge bases available to researchers, faculty, the press, and the public. The goal of this research program has been to increase the quality, quantity, and dissemination of results of research on the effectiveness of ALN. It does this by synthesizing existing knowledge and creating new knowledge about the methods and findings of research on the determinants of effectiveness of ALN. A secondary goal of the site is to build and strengthen the ALN evaluation research community to create and share improved research methods, theoretical frameworks, and instrumentation for assessing the outcomes of online learning.

3.3. Research Theory

The principle of collaborative learning may be the single most important factor for online networked learning, since it is this principle which provides the strong socio-affective and cognitive power of learning on the web. It may be argued that the online asynchronous environment of the web both enables and requires collaborative learning: collaboration provides the motivation and social glue of a community that engages learners and encourages them to participate and contribute to common goals. Instructional models where faculty "present" or publish information on the web are less engaging and have resulted in higher drop out rates.

Educational applications of computer networking have led to major insights in collaborative learning, knowledge communities, and knowledge construction. Hiltz and Turoff (1978) pioneered the use of computer conferencing and networking in linking communities of scientists into online discussion and workgroups. By the early 1980s, educational networking based on collaborative learning was launched and became the basis for future models: totally online short courses, networked classrooms in schools, online programs for executives, online university courses, virtual classrooms, online training programs, etc. (Harasim et al., 1995). Related fields such as online communities of practice (Lave & Wenger, 1991), computer-supported co-operative work and collaborative learning (Koschmann, 1996), knowledge building networks (Scardamalia and Bereiter, 1993), virtual classrooms (Hiltz, 1994), and learning networks (Harasim et al., 1995) have flourished.

Online network models tend to be constructional or conversational, with discourse and teamwork motivating a sense of commitment. Engaging learners in a co-operative pursuit of knowledge requires new instructor roles. Cognitive growth and the development of problem-solving skills depend on epistemic conflict, that is, the collision of adverse opinion. Students encounter opportunities to experience and resolve academic controversies in the online discourse environment.

Bruffe (1999) describes collaborative learning as a process that helps students become members of knowledge communities, where by they

> learn to construct knowledge as it is constructed in the knowledge communities they hope to join after attending colleges and universities: the knowledge communities of industry, business, finance, government, academic disciplines, and public professions such as medicine, accounting and public law. With no loss of respect for the value of expertise, they learn to depend on one another rather than depending exclusively on the authority of experts and teachers. Most important, in collaborative learning students learn the craft of interdependence.
>
> (Bruffee, 1999: xiii)

Harasim's (1990, 2002) model of conceptual change focuses on collaborative learning in the online (web-based) discourse environment, identifying three processes/phases that describe the path from divergent to convergent thinking. Collaboration is viewed as a key process in conceptual change. Although identified and developed in the online context, it resonates with Bruffee's theoretical position that intellectual convergence through collaborative discourse is key and suggests a framework for understanding discourse in online seminars.

The three cognitive phases involved in intellectual development and collaborative learning are

1) *Idea generating*: Idea generating implies divergent thinking, brainstorming, verbalization, and thus sharing of ideas and positions. Participants engage and contribute. Indicators include verbalization, offering input, generating information, and generally democratic participation. It involves multiple monologs as each participant presents her or his view on the topic.
2) *Idea linking*: The second process, idea linking, provides evidence of conceptual change and intellectual progress as new or different ideas become clarified, identified, and clustered into various positions (agreement/disagreement; questioning/elaboration), based on access to resources linked to the knowledge community such as the readings and/or input from the instructor. This is an early form of convergence, a mutual contribution to and construction of shared knowledge and understanding advancing from opinions to the use of analytical concepts. This phase involves organizing and elaborating various ideas into intellectual positions or clusters, demonstrating intellectual progress through recognizing multiple perspectives and how these relate or not to one another.
3) *Intellectual convergence*: The third phase, intellectual convergence, is typically reflected in shared understanding (including agreeing to disagree) and is especially evident in co-production, whether the product is a theory, a publication, an assignment, a work of art, or a similar output authored by the group or sub-group. Idea structuring, through gradual convergence, reaches a level of intellectual synthesis, understanding and consensus, and employs and applies the analytical framework of the knowledge community on that topic

These three phases can also be applied as categories for the study of learning and intellectual progress in online discourse. Transcript analysis of student discourse in online courses can study the existence of intellectual progress and conceptual change over time, and under particular conditions (pedagogical design? role of the instructor? etc.). A major and unprecedented advantage of e-learning is the existence of the verbatim archive of student discourse (especially in totally online courses) which is an artifact of student understanding. Over the course of an online course, it is expected that students would progress from individual opinions (Phase 1) to begin to grasp and apply the theoretical and analytical terms when discussing problems (Phase 2), to actually applying these analytical terms in problem solving or knowledge building of new solutions (Phase 3) (Harasim, 1990).

4. LESSONS LEARNED: EMERGENT MODES AND MODELS

One of the major "lessons learned" through the first three decades of e-learning is its potential to be more than "as good as" TC learning but to provide far superior quality of learning. Well designed and implemented collaborative e-learning represents powerful gains in key indicators such as learning effectiveness, educational access, satisfaction by instructors and learners, completion rates, and institutional and workplace innovation.

4.1. Learning Effectiveness

A common approach to examine the quality of learning effectiveness is whether the quality of learning in the e-learning environment has been demonstrated and perceived to be *at the same level of quality or better* than non-e-learning (i.e., TC or distance education) environments. Certainly the goal is that e-learning would provide a better environment for learning (Mayadas, 2002). Hence, a key research question is what are the indicators of success for e-learning environments? What does a knowledge economy require in terms of learning processes and outcomes? Clearly an e-learning environment should be designed to be *more effective,* not less, than what is traditionally available. Traditional success indicators have included such measures as data on completion rates, grades, faculty reports, and learner reports. And as major research studies have reported, the findings have been very positive.

New indicators such as level, volume, and patterns of interactivity and participation are illuminating patterns of participation, under various contexts (pedagogic approaches, disciplines, instructor roles, etc.), and over time.

Potentially more powerful are the insights into advanced learning effectiveness and intellectual progress generated by analyses of transcripts of student discourse in online seminars and group activities whereby researchers and instructors can study conceptual change and improvement over time by individual and group participants. Transcript analysis enables scientific study of what occurs, both to deepen learning sciences, and to provide feedback on intellectual progress under various conditions and contexts. Moreover, analyses of usage data/participation records provide additional empirical evidence of such indicators as active reading, active writing, level of participation and interaction, distribution of communication, referencing other messages, etc.

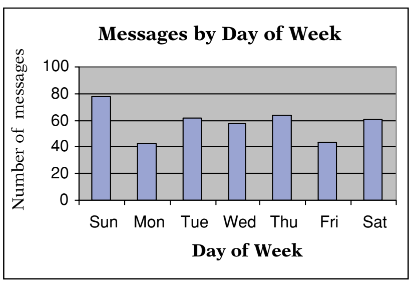
4.2. Access: Geographical and Temporal

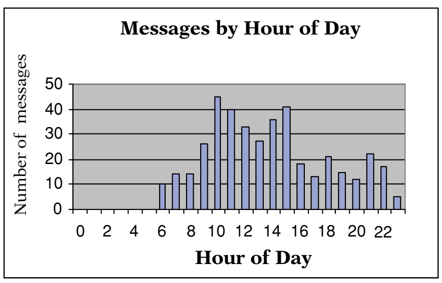
Student access is a critical goal of education and has a number of aspects. One aspect is geographical: here e-learning has shown a tremendous advantage. Today the internet is available virtually worldwide, although politics more than economics remains a challenge to equitable access. One important goal or indicator of e-learning success is that all students who are able and motivated can obtain a course and/or degree program in their area of choice online.

Another key aspect is temporal or asynchronous access. Asynchronous (24/7) access enables a number of benefits for effective learning, enabling mindful composition of input, access to references, ability to reflect on or reread messages, and a more equitable distribution of communication since everyone has access to the air time that they need. Students do in fact access the learning activities 24 hours a day, 7 days a week.

This leads to highly active participation and interaction. An analysis of 64 courses in the Virtual-U field trials found that:

- 77% of the classes had active students, who log in at least 10 times per week on average;
- 85% of the students in all classes logged in regularly, at least five times per week; and
- 81% of the students in all classes posted regularly, writing at least three messages per week.





4.3. Satisfaction Rates: Faculty and Learners

Faculty satisfaction refers to experiences of faculty who engage in e-learning: do they feel engaged and more involved as a result of this experience? Do they experience increased fulfillment as educators? Would they continue to teach online? Will they incorporate e-learning approaches into their f2f classes? Encourage other educators to become e-learning faculty? A recent study of 255 faculty using collaborative e-learning in 31 colleges in the State University of New York system examined the effects of conceptualizing, developing, and teaching a complete online course and found:

- 96% of faculty expressed general satisfaction;
- 74% believed that learning online is equivalent to or better than in other modes;
- 88% believe that interaction among students was equivalent or higher online; and
- 62% believe that they know their students as well or better online. (Shea et al., 2002: 103).

There is frequently a change in instructional approaches and roles by instructors who begin to teach online. Many begin to adopt collaborative learning approaches. In a study of 100 online courses in the Virtual-U field trials (offered by universities in Canada, Europe, and the U.S.A.), it was found that 100% of the instructors had introduced some form of collaborative learning activity (typically group discussions or group projects or both) into their course. Many instructors reported that teaching online improved their teaching approaches in f2f classes as well, and that the positive experiences in online teaching lead to "teacher revitalization".

Students are very positive about online courses with collaborative learning approaches: in the Virtual-U trials, 85% of students in 32 totally online classes reported that the learning experience offered by online courses was as positive or more positive than the classroom experience (Harasim, 2000).

4.4. Completion Rates

Completion rates are viewed as one, very strong indicator of academic success, of user satisfaction, and of the quality of the education offered, particularly in post-secondary (university and college) and corporate training. Research has identified high completion rates of e-learning based on OCL, at all educational levels and sectors. At the post-secondary level, the Virtual-U field studies identified completion rates of 92% completion rates in the 64 online courses studied (Harasim, 2000); Pace University reports 90% completion (Sachs, 2003), and the larger Sloan-C Post-secondary Consortium has 85% completion rates for e-learning courses (Sloan-C). E-learning delivery of post-secondary degrees to the workplace (NACTEL) resulted in 96% completion rates (Sachs, 2003). The Concord Consortium Virtual High School (VHS) notes an 80% completion rate, with the following qualitative comments:

> VHS students consistently report feeling closer to and better acquainted with their online teachers than with their local teachers. I have heard similar reports from higher education faculty who teach online courses. We also have had reports that VHS has kept potential dropouts interested in school. VHS teachers say that their online teaching experiences have positively affected their face-to-face teaching. On the other hand, asynchronous course delivery, which is the VHS model, consistently has a 20% dropout rate which needs to be investigated.
>
> (Rose, 1999)

In contrast, the use of online networks to facilitate correspondence education (ODE) results in completion rates of around 60%, while the use of the OCBT model typically results in a completion rate of 20–30% (Carr, 2000; Diaz, 2002).

4.5. Pedagogical, Institutional and Workplace Innovation

A key lesson regards the encouragement of pedagogical renewal and enhancement through the introduction of networked technologies, to provide students and faculty with opportunities for 21st century skills like knowledge work, collaborative learning, etc. E-learning is already becoming such an enabler in Canada, the U.S.A., Europe, and Latin America. The Minister of Education, Mexico, referred to e-learning as a "Trojan Horse": faculty who adopted e-learning become motivated to adopt new pedagogical practices, and as a result of this experience, transform their curriculum from knowledge transmission (lecture mode) to collaborative learning and knowledge work modes.

The introduction of new technologies and new educational practices also provides important opportunities for institutional renewal, which will be critical to maintaining its reputation and for survival in an increasingly competitive marketplace.

CONCLUSION: SHIFT HAPPENED

This chapter has provided a brief overview of the early history of e-learning, identifying some highlights and experiences of this period and outlining the changing educational paradigm as the use of computer networking shifted from being experimental to becoming the educational NORM.

E-learning was invented in the mid- to late 1970s, a few short years after the development of packet-switched e-mail and computer conferencing. Within two decades, profound transformations in the field of education itself were evident as e-learning became not only a new educational option to that of TC or distance education, but was also integrated into these traditional forms of education, thereby transforming the entire field. Some examples of the shift.

1. Changing Educational Models: Passive Competitive to Active Collaborative. The invention or emergence of e-learning has transformed the basic model of education, emphasizing new educational principles, and practice based on *active, collaborative learning*. The educational models of the 19th and 20th century, based on *principles of passive and competitive approaches* to education have been transformed into models of *active collaborative learning* where students engage in group discourse and team projects. The traditional model of *knowledge transmission*, in which the instructor is seen as the sole or primary font of knowledge that is to be transmitted to the students (didactic approaches), is now being replaced by a *knowledge building model* in which learners engage in problem solving and decision making to innovate new solutions. Learners are increasingly encouraged to learn by participating in small and large group discussions, to employ the terms and analytical methods of their chosen fields to solving problems and making decisions increasingly akin to the methods of their knowledge community. The role of the professor is to not simply ensure student memorization of the analytical terms and approach, but the ability to apply these appropriately, thereby facilitating the student's membership in the knowledge community of his/her choice. Furthermore, learner-centered educational models and pedagogies are thus replacing the teacher-centered models of the past.

2. Changing Educational Environments: Closed Individualized to Open Networked. A second transformation or shift is a major change in the educational "environment" that learners and educators inhabit. The introduction of networking technologies into the public sphere, globally, has transformed personal, social, and economic reality. And has transformed education from the traditional *closed community* of the classroom or lecture hall (or the individualized workspace for distance learners) into a porous interactive *knowledge network*, where online resources, expertise, and peers are routinely sought.

Moreover, *e-learning environments* (also referred to as Learning Management Systems) that explicitly support new educational models and principles, are being developed to provide frameworks, tools, scaffolds, etc. to support and/or assess collaborative learning, knowledge building, problem solving, intellectual progress, etc. A relatively recent technological innovation, *Open*

Source, is contributing to the development of a new range of learning environments and tools that are free and which encourage ongoing development and refinement by the open availability of the source code to all users. Such initiatives have the potential to offer the educational community with much needed new tools and resources, as well as encourage innovation and input from users worldwide.

3. Changing Educational Role: Supplementary to Integral. The educational role of e-learning shifted dramatically during its early decades, moving from being viewed and used as supplementary (at best) to becoming an integral component of all or most learning activities.

Despite the pioneering applications of totally online classrooms for undergraduate, graduate, executive, and labor education in the 1980s, the vast majority of e-learning applications in the 1980s and 1990s could be classified as "adjunct (enhanced) mode". School-based applications emphasized such e-learning activities as "electronic pen pals", electronic field trips, "ask-an-expert", and Q&A forums. University applications tended to focus on student e-mail to professors, online submission of assignments, web searches for research data, online quizzes, or grade books.

By the late 1990s, the use of e-learning had matured from *supplementary* to being *an integral part* of the course or program curriculum. The use of networking is increasingly a significant portion of the curriculum and grade, and most importantly, the use of e-learning moved from being the effort of a single professor or teacher (a lone ranger) to the institutionalization of e-learning, involving online courses, online degree or professional programs, and virtual universities in which the educational administration allocates a permanent budget line for training, software, and support, thereby representing an institutional commitment to quality e-learning.

4. Changing Societal Role: Peripheral to Mainstream. The major shift has occurred in e-learning's changing societal role and status. E-learning has moved from a position on the periphery of social recognition, which it occupied in the 1980s and 1990s, to mainstream acceptance and demand. Indeed, the availability of e-learning pedagogies and technologies is becoming an indicator of state-of-the-art education. Students, parents, professionals, and educators have come to view the level and commitment to e-learning as an indicator of success for educational providers.

Today, e-learning impacts all educational sectors, from formal (primary, secondary, and tertiary education) to non-formal (professional development, workplace training, corporate education) and increasingly informal lifelong experiential learning.

E-learning has become an integral, valuable, and highly valued component of education, and standard-bearer for state-of-the-art learning and teaching as we advance into the 21st century.

As a recent study of e-learning in the United States reported

> From the Ivy League to tiny community colleges, a majority of institutes of higher education say online learning is just as good as traditional, face-to-face classroom instruction. Nearly three out of four academic leaders say learning online may be better within three years. A comprehensive survey . . . concludes that online learning is at historically high levels and will continue to grow at a rate of nearly 20%.
>
> (Allen and Seaman, 2003: http://www.aln.org/resources/survey.asp)

The 2003 Sloan Survey of Online Learning polled academic leaders and was weighted to allow for inferences about all degree-granting institutions open to the public. When asked to compare the online learning outcomes with those of face-to-face instruction a majority said they are equal. Two out of every three also responded that online learning is critical to their long-term strategy.

The field of e-learning, born a mere 25 years ago in the mid- to late 1970s with the very invention of computer networking and communications has become a major force in education and society, engaging over 10% of post-secondary education students in the U.S.A. It is in the midst of transforming education, shifting the educational paradigm, as we have known it for the past three centuries.

As recently as 10–15 years ago, e-learning was unknown or dismissed. Today it is transcending the goal of being "as good as" traditional education to demonstrating the possibility and effectiveness of educational approaches and processes far better and beyond was has hitherto been possible or anticipated.

ENDNOTES

1. The chapter highlights some of the key pioneering applications in elearning. The author is grateful for suggestions on missing links.
2. This included cutting edge research and practice in online graduate level course delivery (Harasim and Smith, Davie), as well as online hypertextual design (Wolfe, 1990), and knowledge building (Scardamalia and Bereiter, 1993).
3. Paul Levinson's Master's program, Connected Education, begun in 1985 and offered through the New School of Social Research, was the first totally online graduate program. The program however was small in student numbers and relatively short lived.
4. Initial team members were Eileen Aranda, Beth Aguiar, Gerry Bedore, Linda Harasim, and Richard Housley.
5. The ICLN researchers included Margaret Riel (USA), Jim Levin (USA), Moshe Cohen (Israel), and Naomi Miyake (Japan), each of whom were studying/working at UCSD at that time.

Chapter 3: Towards Philosophy of Technology in Education: Mapping the Field

MICHAEL A. PETERS
Department of Educational Policy Studies, University of Illinois at Urbana-Champaign, 360 Educational Building, 1310 South Sixth Street, Champaign, IL 61820

1. INTRODUCTION

Technology has become the new star ship in the policy fleet for governments around the world. While often conceptually inchoate and ill-defined, technology studies figures as a new subject in national curricula, often as part of the new core. Also technology as a subject is promoted in higher education, including teacher education programmes, as part of a thrust to develop links with industry and business in a series of new venture partnerships. The emphasis on technology in education also accords with initiatives to promote greater entrepreneurial skills and activity within so-called national systems of innovation. What is more, technology planning often is now part of national knowledge foresight programmes and science policy, designed to promote sunrise industries and knowledge and technology transfer. In short, technology is seen to be a key driver towards the knowledge economy.[1]

The public policy focus on technology, in part, reflects a growing consensus in macroeconomics of "new growth" or "endogenous growth theory", based on the work of Solow, Lucas, and Romer, that the driving force behind economic growth is technological change (i.e., improvements in knowledge about how we transform inputs into outputs in the production process). On this model technological change is *endogenous*, "being determined by the deliberate activities of economic agents acting largely in response to financial incentive" (Snowdon & Vane, 1999: 79). The neo-classical growth model developed by Solow assumed technology to be exogenous and therefore available without limitation across the globe. Romer's endogenous growth model, by contrast, demonstrates that technology is not a pure public good for while ideas are *non-rivalrous* they are also partially *excludable* through the legal system and patents. The policy implication is twofold: knowledge about technology and levels of information flow are critical for economic development and can account for differential growth patterns. Knowledge gaps and information deficiencies can retard growth prospects of poor countries, while technology transfer policies can greatly enhance long-term growth rates and living standards.[2]

My purpose is not to explain the recent increase in the public profile of technology in economic and education policy, but rather to begin to develop

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 95–116.

a mapping of the field of philosophy of technology and its significance for education.[3] At a general level, this is important because philosophy of technology addresses general questions concerning the nature of technology, its impact on society and, for the purposes of this paper, specifically on education. Philosophy of technology, therefore, promises the possibility of an understanding of technology that may be important not only to public policy but also in helping to conceptualize intellectual approaches to the study of technology and, indeed, to shaping new fields of knowledge and research. These approaches to the study of technology, clearly, have a significant role to play in curricularizing technology at all levels. Philosophy of technology may also have a role to play in relation not only to structuring a largely disparate and inchoate field but also more directly in teaching and learning about technology. These are only promissory notes to be redeemed, if at all, at the end of the paper after our investigation.

We might make even grander claims for philosophy of technology. Just as economic growth theory now postulates an endogamous model where technology is considered as a factor intrinsic to development, in society and education the notion that technology is an autonomous system operating neutrally has come under increasing scrutiny. Rather than considering technology as something separate from daily life and from society at large, philosophers and sociologists now contemplate the way in which technology structures our institutions and impacts upon all aspects of our existence. Clearly, technology has permanently altered the labour process and our conception of labour in post-industrial service-oriented societies and it continues to transform our notions of intellectual labour. With the environmental movement, as Feenberg (1999) comments, technology entered the charmed circle of democracy. The very technical transformation of government and democracy is a subject in its infancy, with various thinkers beginning to explore the possibilities of joined-up-government and cyberdemocracy (e.g., Poster, 1995). The technological revolution demands new types of media and multimedia literacies, just as print technology transformed the public sphere, and makes possible the radical restructuring of education as a key to democracy and active citizenship within the global economy (Kellner, 2001). With the discoveries of biotechnology and the prospects of the human genome project, the very stuff of life and its reproduction, is now a matter of urgent ethical and political concern. The possibilities for dealing with so-called learning disabilities genetically or as part of biological planning and regulatory regimes is as yet unrealized. Furthermore, advances in information and communications technologies and in related telecommunications technologies have already transformed our practices of reading and writing, of communicating, of viewing, and of the transmission, storage and retrieval of information, thereby, also changing the nature of our knowledge practices and institutions (Peters & Roberts, 1998). New information and communication technologies raise complex ontological, epistemological, ethical, and identity issues; they at one and the same time present exciting educational possibilities but also grave dangers (Burbules, 2001).[4] At the experimental psychological level, it is obvious that the computer has stimulated the development of models of the mind, providing not only a computational analogue for the brain but also research programmes for the so-called revolution in cognitive psychology now in its third generation (Bruner, 1996; Harré & Gillet, 1994). Philosophy of technology is a field that defines what it is to be human in terms of technology; in short, technologies shape and produce our subjectivities.

Yet as a field, philosophy of technology is both a recent and a poor cousin to philosophy of science. Philosophy of science has had little time for either technology or the relation between science and technology. Technology was not seen as philosophically interesting. Traditionally, in standard accounts, technology often has been seen as synonymous with industrial technology that came into existence on the back of Enlightenment science and flourished in the 19th century to develop exponentially and in a myriad of different directions in the 20th century. On this conception it was seen as the handmaiden of science, a kind of applied knowledge that put into practice the pure theory of science. This standard liberal "engineering" account is now being questioned, modified, refined, and alternative theories are being developed. Some scholars who read the present situation critically want to talk of the conglomeration "technoscience", indicating a dramatic historical shift in the nature of knowledge (e.g., Lyotard, 1984); others contemplate reversing the traditional relationship, suggesting that technology is the ground out of which science came to be and that modern technology rather than science is the all embracing and pervading ethos defining the modern *zeitgeist* (Heidegger, 1977).

2. WAYS OF MAPPING THE FIELD

Carl Mitcham (1994) makes a distinction in *Thinking Through Technology* between an engineering and humanities tradition. The former takes technology as a good or positive value and is oriented to technological development, whereas the latter interprets technology more broadly in relation to culture and history. Where the former tends towards a kind of technicity and materiality, the latter views technology as something more than material, embodying cultural practices and symbolic forms. The former tends to treat political and ethical aspects of technology, insofar as these questions arise, only retroactively as a way of responding to the worst excesses of technology, whereas the latter treat them as central. The engineering tradition is indebted to nineteenth German philosophy (neo-Kantians and neo-Hegelians, and especially Marx, Kapp, and Dessauer, although is not restricted to them. See also Pitt, 2000). The humanities tradition in the 20th century owes its shape to Mumford, Ortega, Dewey, Jonas, Heidegger, and Ellul who turn to cultural critique and tend to investigate the interface between technology and culture, emphasizing the instrumental nature of technology and its essence in control and efficiency functions.[5]

For the sake of this essay I shall be focusing on the humanities tradition and what has been called the classical philosophy of technology (Achterhuis, 2001) and, in particular, mainly I shall be considering what I call the Heideggerian research programme in philosophy of technology, construed Lakatosian terms, even although without empirical testing it is difficult to know what might constitute a progressive as opposed to a degenerating problem-shift. I consider in terms of the Heideggerian programme not only Heidegger himself, beginning with his famous late essay *The Question Concerning Technology* (1977), but also Herbert Marcuse, Heidegger's student, and his major work *One-Dimensional Man* (1964), Michel Foucault and his *Technologies of Self* (1977), and, finally Hubert Dreyfus, especially his latest work *On the internet* (2001). When I use the term "programme" I do not mean to suggest that subsequent thinkers slavishly imitate Heidegger or even subscribe to the same basic ontological commitments. Rather I mean to suggest that each of these thinkers in their own way have developed out of Heidegger's work their own distinctive orientations. Against these thinkers indebted to the Heideggerian programme, as I put it, I will offer two contrasts, the socialist feminist programme developed by Donna Haraway and the social constructivist programme offered by Andrew Feenberg. I offer the work of Haraway because, first, she is one of the few theorists working in philosophy of technology who takes questions of gender seriously, and, second, she focuses on the twin fields of communications and biotechnologies. I refer to Feenberg because he takes the constructivist programme the further than any other thinker.

Before embarking on this task, let me suggest, first, that it is possible to carry through similar programme for Marx, Dewey, Mumford, Ortega, Jonas, and Ellul. A full mapping of the field would at least configure the main contours of each programme, sourcing main texts and noting major theorists. It would be an additional endeavour then to indicate where these programmes have been picked up and developed in relation to education. Second, I should make it clear that I do not believe that this is the only way to map the field. Indeed, there are other useful ways of proceeding, including what we might call the approach through national traditions. Here we might talk of the British empiricist tradition beginning with Francis Bacon's *Novum Organum*, or the German tradition, including many of the classical approaches from Marx to Heidegger, or the recent Dutch tradition, focusing on Hans Achterhuis and his colleagues, who published *De maat van de techniek* (*The Matter of Technology*) in 1993, followed by *Van stoommachine tot cyborg: denken over techniek in de nieuwe wereld* (*From the Steam Engine to Cyborg: Thinking Through Technology in the New World*) in 1997. Achterhuis' (2001) recent *American Philosophy of Technology: The Empirical Turn* clearly fits into this category, with pen nail sketches of the work of Albert Borgmann, Hubert Dreyfus, Andrew Feenberg, Donna Haraway, Don Ihde, and Langdon Winner.

As an example of this approach, Achterhuis (2001: 3) distinguishes between the classical thinkers of technology and the American philosophers of technology, maintaining

> The classical philosophers of technology occupied themselves more with the historical and transcendental conditions that made modern technology possible than with the real changes accompanying the development of technological culture.

Achterhuis (2001) suggests that American philosophy of technology can be broadly characterized by an empirical turn that took a constructivist direction that opened up the black box, analyzing the formation of technological processes and describing the social forces acting upon them. Technology was no longer considered autonomous or monolithic but rather comprised of many distinct technologies that needed to be analyzed separately. Rather like the empirical turn that philosophy of science took after Kuhn, so too American philosophers of technology began to investigate in actual contexts the ways in which technology and society influence one another. The terms "technoculture" and "technosociety" on the one hand speak to the way classical philosophers had disembedded processes of technology, while on the other, recognizing how technology itself is a social activity, which is given a particular cultural form. American philosophy of technology also distinguishes itself from classical philosophy in their approach to nature, no longer necessarily holding to the technological disenchantment of nature subscribed to by Jonas, Ellul, and Heidegger but exhibiting a greater sensitivity to ideological constructions of nature.

Finally, I should mention a conceptual approach to distinguishing varieties of theory in technology developed by Andrew Feenberg. Figure 1, as Feenberg (1999: 9) indicates, sets out the theoretical variety that has unfolded over time according to two axes:

> The theories differ with respect to the role of human action in the technical sphere, and the neutrality of technical means. Common sense assumes both the possibility of human control and the neutrality of technology. Deterministic theories, such as traditional Marxism, minimize our power to control technical development, but consider technical means to be neutral insofar as they merely fulfil natural needs. Substantivism share determinist scepticism regarding human agency but denies the neutrality thesis. Ellul, for example, considers ends to be so implicated in the technical means employed to realize them that it makes no sense to distinguish means from ends. Critical theories, such as Marcuse and Foucault's left dystopianism, affirm human agency while rejecting the neutrality of technology. Means and ends are linked in systems subject to our ultimate control.

Technology is:	*Autonomous*	*Humanly Controlled*
Neutral (complete separation of means and ends)	**Determinism** (e.g. traditional Marxism)	**Instrumentalism** (liberal faith in progress)
Value-laden (means form a way of life that includes ends)	**Substantivism** (means and ends linked in systems)	**Critical Theory** (choice of alternative means-ends system)

Figure 1. The varieties of theory. Source: Feenberg (1999).

David Blacker's (1994) discussion of the ontologies underlying various ways in which technology is discussed in a representative sampling of the education literature indicates how these conceptual distinctions might work. Yet he only employs two implicit ontologies—the substantive and the instrumental, i.e., only two squares of Feenberg's grid. Yet within these categories he suggests we might talk of "pro" and "con" attitudes. For example, he labels the work of C. A. Bowers (1982, 1988) as an educational theorist that proposes a form of substantivism. For Bowers the "technological mindset" is so pervasive that every school reform and aspect of contemporary pedagogy is unwittingly contained within it. It is the Herculean task of a radical pedagogy to step outside this enframing to recover what is truly human. As Blacker (1994) comments a subtler version of this view derives from the Frankfurt's critique of instrumental reason and is evident in the educational theory of Broughton (1985). Educational substantivist or what Blacker calls "radical instructional design" (RID) theory—the computer romanticists—constitute the pro-technology lobby, holding that technology holds the key to effective leaning and successful school reform (e.g., Heinrich, 1984, 1985; McClintock, 1988; see also Winn, 1989).

There is also an educational pro-technology that takes the form of instrumentalism. The most celebrated example of this way of thinking, Blacker claims, is the work of Seymour Papert (1980) whose *Mindstorms* lay the pattern for a computer instrumentalism that argued that LOGO (and other computer programmes) offer children "powerful ideas" for problem-solving (see also Davy, 1985; Franz and Papert, 1985; Papert, 1987). Educational anti-technology instrumentalism often takes a Marxist form or a form of socio-political critique evident in critical theory of technology, stated most carefully by Feenberg. In education this position is ascribed to Bowles' and Gintis' (1976) *Schooling in Capitalist America*, where the guiding idea for educational reform is the necessary transformation of social relations rather than a new technology.

Blacker (1994) argues that a proper theory of technology in education ought to take account of both positions and he begins to outline such a theory in terms of an appeal to the thought of Dewey and the early Heidegger. It might be called "double aspect" theory of technology for on this theory technology is both concealing and revealing (see also Blacker, 1993).

The advantage of Feenberg's and Blacker's approach is that it provides a way of classifying theories of technology according to their underlying theoretical commitments, but as can be seen from my discussion (below) it is clearly the case that a programme may cut across these lines, so that the Heideggerian programme, for instance, can run across forms of substantivism (Heidegger) and critical theory (Marcuse and Foucault). Feenberg's position is that of critical theory, although he works it out somewhat differently.

3. OUTLINING THE HEIDEGGERIAN PROGRAMME: HEIDEGGER, MARCUSE, FOUCAULT, DREYFUS

3.1. Heidegger

Heidegger delivered four lectures comprising *The Question Concerning Technology* in 1949—over 50 years ago. It remains one of the most profound statements concerning technology that has been made and established a tradition of thought, remaining an important source of inspiration for a generation of philosophers writing of the nature of technology. Heidegger (1977: 4) poses the question quite forthrightly:

> According to ancient doctrine, the essence of a thing is considered to be what the thing is. We ask the question concerning technology when we ask what it is. Everyone knows the two statements that answer our question. One says: Technology is a means to an end. The other says: Technology is a human activity.

Two definitions: the instrumental and the anthropological. Heidegger goes on to question the instrumental and the will to mastery that such a conception entails. This is the source, in part, for the notion of instrumental rationality, a purely technical reason, that the Frankfurt School contrast strongly to practical reason.

For Heidegger, "technology's essence is nothing technological" (1977: 4). It is a system—*Gestell*—an all-encompassing view that describes a mode of human existence. Heidegger's account relates technology back to a critique of the Western metaphysical tradition and focuses upon the way *machinic* technology can alter our mode of being, distorting our actions and aspirations.

In terms of the received view technology is something that stands in a subsidiary, instrumental, and temporal relation with modern science. Modern physical science begins in the 17th century, historically it is seen as achieving a kind of take-off by 1750, and its institutionalization through royal societies and universities also dates from that period. *Machinic* technology, by contrast, chronologically speaking, begins in the 18th century and comes to fruition in the 19th century. It is pictured essentially as the "handmaiden" to science and it is regarded as an application of "pure" science or applied science.

Heidegger reverses the chronological order of the received view. He distinguishes technology in its various manifestations from its essence that is not technological and describes this essence by returning to the Greek concept of *techné*, which relates not only to the activities and skills of the artisan but also to the arts of the mind and fine arts. *Techné* is a word linked to *episteme*. It is a form of knowing in the widest sense. The essence of technology, Heidegger maintains, is a *poiesis* or "bringing forth" which is grounded in revealing (*aletheia*). He writes: "Technology is a mode of revealing. Technology comes to presence in the realm where revealing and unconcealment take place, where *aletheia*, truth, happens" (Heidegger, 1977: 13).

Heidegger distinguishes modern technology from its ancient form: "The essence of modern technology shows itself in what we call Enframing . . . It is the way in which the real reveals itself as standing-reserve" (Heidegger, 1977: 23). He observes: "The revealing that rules in modern technology is a *challenging*, which puts to nature the unreasonable demand that it supply energy that can be extracted and stored as such" (Heidegger, 1977: 14). Heidegger describes this *challenging* as a demand and a *setting upon*. As he indicates: "modern technology sets upon nature challenging forth the energies of nature, unlocking and exposing them but always directed toward furthering something else (maximum yield at the minimum expense)" (Heidegger, 1977: 15). Heidegger uses the term *setting-in-order* and suggests: "Everywhere everything is ordered to stand by, to be immediately at hand, indeed to stand there just so that it may be on call for a further ordering. Whatever is ordered about in this way has its own standing. We call it the standing-reserve [*Bestand*]" (Heidegger, 1977: 17). Enframing endangers "man" in his relationship to himself and to everything that exists. Its destiny is to banish humankind into a kind of revealing which is an ordering and where this ordering holds sway, it drives out every other possibility of revealing. Thus, Enframing conceals that form of "revealing which, in the sense of *poiesis*, lets what presences come forth into appearance" (Heidegger, 1977: 27).

Modern technology thus is seen in terms of "productionist metaphysics" where the concept of "standing reserve" refers to resources, which are stored in anticipation of consumption. Ingrid Scheibler (1993: 116) explains that modern technology, for Heidegger, "is linked to a particular mode of conceiving our relation to the world—of bringing forth—through a process that objectifies the world". For Heidegger the essence of technology is part of the broader project of understanding the relation of this mode of objectifying experience to the tradition of Western metaphysics, which means that the question concerning modern technology cannot be thought apart from the critique of Western metaphysics or, indeed, the critique of modernity.

Heidegger's account of technology has been criticized on a number of grounds. First, it is "essentialist" in that it ascribes an *essence* to technology and thus cannot differentiate among different types or levels of technology. It can only describe technology as part of an evolving cultural system that becomes ever more efficient in ordering the world. While Heidegger acknowledges, quoting Hölderlin, that where the danger is, so too lies the "saving power" it is not clear in what the "saving power" consists. It may consist in a kind of poetic reflection which characterized an ethos and aesthetic sensibility in early Greece that was *techné*—"a single, manifold revealing" that revealed the true nature of things that exist and was responsible for "the safekeeping of truth" (Heidegger, 1977: 34). As he writes: "The poetical thoroughly pervades every art, every revealing of coming to presence into the beautiful" (Heidegger, 1977: 34). Second, therefore, Heidegger's essentialism is aimed at a kind of primordiality only recoverable, it seems, by returning to early Greek aesthetic sensibility. This sensibility that is the possible basis of a spiritual renewal is, for some, too abstract and too theological to inform a new technological practice. In short, it offers us no guidelines for reform of technology in the present era. Third, by ontologizing technology in the way that he does and by linking it to the critique of Western metaphysics and especially the critique of modernity (via Nietzsche) he leaves no room for a future-oriented practice of reform or human agency reforming or changing or democratizing the apparently autonomous cultural system of ordering that modern technology has become.

3.2. Marcuse

Heidegger's commitments stand in marked contrast on these points to Marcuse, Foucault, and Dreyfus. Marcuse, who was Heidegger's student, in *One-Dimensional Man* (1964) runs together a humanist Marxism—the young "rediscovered" Marx of the *Economic and Philosophical Manuscripts* —with a Heideggerian thesis. He clearly continues the Heideggerian programme in insisting that technology is the source of most of the difficulties that advanced industrial societies face. Indeed, technology and technological rationality (which has become a form of political rationality) has contained social change, especially progress that comes from the struggle of classes, and extends a system of domination that co-opts all possibility of protest. He also carries through Heidegger's argument that technology can no longer be regarded as neutral:

> In the face of the totalitarian features of this society, the traditional notion of the "neutrality" of technology can no longer be maintained. Technology as such cannot be isolated from the use to which it is put; the technological society is a system of domination which operates already in the concept and construction of techniques.
>
> (Marcuse, 1964: xvi)

Yet as he argues in *One-Dimensional Man* (1964) while advanced industrial society is capable of containing qualitative change there are "forces and tendencies exist which may break this containment and explode the society" (p. xv). Here, Marcuse, under the influence of a humanist Marxism, departs from Heidegger to emphasize historical theory and practice, the possibilities of transformation, and historical alternatives based on subversive tendencies and forces. Marcuse borrows a Marxist utopianism based on a concept of human collective agency, although he is quick to point out that the kind of struggles will no longer be necessarily class-based because technical progress has "abolished labour" and transcended the realm of necessity, where it serves as an instrument of domination, to become "subject to the free play of faculties in the struggle for the pacification of nature and society" (p. 16). He still holds on to the thesis that the processes of production transform labouring classes but in advanced industrial society mechanization and occupational stratification has led to a change in attitude and conscious of labourers, weakening the negative position of the working class and rendering them docile. As he argues in Marxian theory "the social mode of production, not technics is the basic historical factor. However, when technics becomes the universal form of material production, it circumscribes an entire culture; it projects a historical totality—a 'world' " (Marcuse, 1964: 154). It is not surprising that Marcuse became the hero of the New Left and student movement in the 1960s and 1970s. In a highly prophetic way he had anticipated the political significance of new social movements and their railing against technological enframing.

3.3. Foucault

Foucault learns from both Heidegger and Marcuse. Like Marcuse, he departs from Heidegger's essentialism to focus on historical ontologies established through Nietzschean genealogical investigations. For him there are no universal necessities in human nature but only different *technologies* through which the subject is created or by which (s)he creates him- or herself. Following both Nietzsche and the later Heidegger, Foucault rails against the phenomenological and humanist subject to emphasize modes of subjectivation and the way that human beings become subjects. Thus, he transforms Heidegger's essentialism into an historical inquiry and he distances himself from Heidegger's universalism. From Heidegger he accepts the relationship between subjectivity and technology, although he gives it an historical cast. With Marcuse, he wants to locate questions of power at the centre of his inquiry, but this is not a Marxist notion of power, construed either individually or collectively. Rather it is a kind of power that springs directly from the will to knowledge and truth—a conception of power as positive, productive, and capillary, very different from either Marxist or liberal accounts.

Foucault had spoken of a new book in "Technologies of the Self", shortly before his death, based on a seminar presented at University of Vermont in 1982. Throughout his work Foucault had been concerned with technologies of power and domination, whereby the self had been objectified through scientific inquiry. By 1981, he became interested in how a human being turns him- or herself into a subject. In particular, he became interested in those practices whereby individuals, by their means or with the help of others, acted on their own bodies, souls, thoughts, conduct, and way of being in order to transform themselves and attain a certain state of perfection or happiness. At this late period of his life he became interested in the Kantian question "what are we today" and, he indicates that his project on the self was suggested by Christopher Lash's the *Culture of Narcissism* (1978). In particular, he became interested in techniques of self-formation and how the roots of the modern concept of the self could be located in 1st and 2nd century Greco-Roman philosophy and in 4th and 5th century Christian spirituality. As he says in the interview "Truth, Power, Self": "All my analyses are directed against the idea of universal necessities in human existence. They show the arbitrariness of institutions and show which space of freedom we still can enjoy and how changes can still be made" (p. 11).

Foucault may be disappointing for philosophers of technology who are looking for an account of technology per se for he emphasizes the relation between technique and subjectivity or self-development rather than investigates anything about the nature of technology. And yet what Foucault does is to draw our attention to the ways in which technologies have always been part of culture and society and instrumental in questions of self-formation. In his essay "Technologies of the Self" he aims

> to sketch a history of the different ways in our culture that humans develop knowledge about themselves . . . [and] to analyze these so-called

> sciences as very specific "truth games" related to specific techniques that human beings use to understand themselves (p. 17).

He then outlines four major types of technologies, "each a matrix of practical reason":

(1) technologies of production, which permit us to produce, transform, or manipulate things;
(2) technologies of signs systems, which permit us to use signs, meanings, symbols, or signification;
(3) technologies of power, which determine the conduct of individuals and submit them to certain ends or domination, an objectivizing of the subject;
(4) technologies of the self, which permit individuals to effect by their own means or with the help of others a certain number of operations on their own bodies and souls, thoughts, conduct, and way of being, so as to transform themselves in order to attain a certain state of happiness, purity, wisdom, perfection, or immortality (p. 18).

Foucault explains that in antiquity there were two major ethical principles—"know yourself" and "take care of yourself". The former came to displace and obscure the latter because the tradition of Christian morality made self-renunciation the condition for salvation. By contrast, taking care of oneself became presented as an immorality. Also, knowledge of the self, as Foucault explains "takes on an ever-increasing importance as the first step in the theory of knowledge" (p. 22). Foucault then proceeds to investigate the theme of "taking care of oneself" in Antiquity, focusing first on Plato's *Alcibides 1* and second, on the Hellenistic period and the Stoics, four to five centuries later, including Seneca and Plutarch. He investigates techniques employed by the Stoics—the disclosure of the self through letters to friends and the examination of self and conscience—and the truth games of early Christianity, that led finally to the whole apparatus of confession.

3.4. Dreyfus

Hubert Dreyfus is influenced strongly by Heidegger's work (Dreyfus, 1991) and, in addition, he has written and drawn on the work of Merleau-Ponty (Dreyfus, 1998) and Foucault (Dreyfus & Rabinow, 1983).[6] Beginning with *What Computers Can't Do* (Dreyfus, 1972) first published over 20 years ago, Dreyfus develops a non-reductionist account of the relation between minds and brains at a point historically when the computer-mind analogy has dominated for decades. He has been an early and consistent critic of artificial intelligence (AI). As Phillip Brey (2001: 39) notes:

> A remarkable aspect of Dreyfu's critiques is that they are motivated by a philosophical tradition—phenomenology—which at the same time was not often associated with science and technology and seemingly far removed in its concerns. Phenomenology, as it appears in the work of Martin Heidegger and Maurice Merleau-Ponty, applies itself to describing the interrelationships between human beings and the world, and uses the first-person experiences of human beings as a point of departure. And while Heidegger, Merleau-Pony, and other phenomenologists have quite specific things to say about the nature of human perception, thinking and behavior, their pronouncements about science and technology tend to be rather general and abstract. Dreyfus, however, was able to apply their ideas skilfully in his critique of AI to reach quite specific and concrete conclusions.

It is precisely this orientation and his non-reductive account of the relation between minds and brains that makes his work of the first order of importance to educational thought and to educational philosophy. It should come as no surprise that the intersection of his interests in psychology, cognitive science, ethics, entrepreneurship, and expert systems, should profile Dreyfus as one of the most important and yet unrecognized philosophers who speaks to educational questions. In *Mind over Machine* (1982), written with Stuart Dreyfus, Dreyfus provided a detailed account of the phenomenology of skill acquisition; an approach utilized and developed in a series of papers, including most recently, "Intelligence without Representation—Merleau-Ponty's Critique of Mental Representation: The Relevance of Phenomenology to Scientific Explanation" (Dreyfus, 1998), where Dreyfus outlines in summary the stages of an adult acquiring skill by instruction from the novice, through advanced beginner, competence, and proficiency, to expertise.

On the internet (2001), in a sense, represents the culmination and synthesis of much of his work with direct application to education, bringing together, as it does his interests in Nietzsche, Merleau-Ponty, Heidegger, and Kierkegaard as their work impacts on contemporary questions concerning the body, self, and skill acquisition. He begins: "The internet is not just a new technological innovation; it is a new type of technological innovation; one that brings out the very essence of technology" (p. 1), and ends: "as long as we continue to affirm our bodies, the Net can be useful to us in spite of its tendency to offer the worst of a series of asymmetrical trade-offs: economy over efficiency in education, the virtual over the real in our relation to things and people, and anonymity over commitment in our lives. But, in using it, we have to remember that our culture has already fallen twice for the Platonic/Christian temptation to try to get rid of our vulnerable bodies, and has ended in nihilism" (p. 106) (see Peters, 2002).

4. HARAWAY'S *MANIFESTO FOR CYBORGS* AND FEENBERG'S CONSTRUCTIVISM

4.1. Haraway

Donna Haraway's project is distinctive of the socialist tradition and marked by its concern for feminist issues in relation to technology. I include Haraway here partly because the question of the gendered nature of technology is not a topic that has been taken up by male theorists. The feminist emphasis alone warrants her inclusion. Yet Haraway is also a highly original thinker who brings her analysis to bear on information and reproductive technologies. Like all the theorists so far discussed Haraway wants to question the alleged neutrality of technology, especially its alleged neutrality in the face of gender. Haraway sees not only technology and technological rationality as gendered but also what Foucault calls technologies of the self. Indeed, the very concept of "biopower" is gendered.

Haraway is professor in the History of Consciousness department at the University of Santa Cruz where she teaches feminist theory and science studies. She is the author of *Crystals, Fabrics and Fields: Metaphors of Organicism in Twentieth-Century Biology* (1976), her PhD thesis, *Primate Visions: Gender, race, and Nature in the World of Modern Science* (1989), *Simians, Cyborgs, and Women: The Reinvention of Nature* (1991) and *Modest_Witness@Second_Millenium.FemalMan©MeetsOncoMouseTM* (1997). For the purposes of this essay I shall focus briefly on her most famous essay "Manifesto for Cyborgs" that originally appeared in *Socialist Review* in 1985. An early version, from which I shall work is entitled "The Ironic Dream of a Common Language for Women in the Integrated Circuit: Science, Technology, and Socialist feminism in the 1980s or a Socialist Feminist Manifesto for Cyborgs". The complete version appears in Haraway (1991). In the paper Haraway looks at electronics and biotechnology "to suggest the scope of social reformations which socialist feminists and other progressive groups must face". She goes on to write:

> I want to be able to show how we can generate new political imaginations and practices that might empower us in the permanently fractured, reconstituted world in which we are placed and place ourselves. My traditional and starting point of the partial but rich ground of socialist, especially Marxist, feminism . . . Without arguing for a theoretical or practical hierarchy among class, race, or sex . . . how might a politics proceed which aims for our material and imaginative empowerment in the social relations produced by and producing science and technology? (p. 2).

Haraway characterizes the emerging world system "as a movement from an organic, industrial society to a polymorphous, information system" (*pace*

Heidegger) and she examines "women in the integrated circuit" in relation to two universes of science and technology: communications technologies, and biotechnologies. These technologies are "tools for recrafting our bodies"; they "embody social relations" and are "instruments for enforcing meanings". Haraway maintains that boundaries are very fluid between tool and myth, instrument and concept, social relations and anatomies of possible bodies (p. 2). She argues:

> Communications sciences and modern biologies are constructed by a common move—the translation of the world into a problem of coding, a search for a common language in terms of the common coin through which all resistance to instrumental control disappears and all heterogeneity can be submitted to disassembly, reassembly, investment and exchange. I like to term the logic of this kind of knowledge and practice an informatics of domination. The world become a game plan; everything is only a move; to win is to stay in the game; to persist is to communicate successfully, to reproduce favourably, to replicate faithfully enough (p. 3).

Immediately one can pick up the resonances to the work of Heidegger and Foucault, especially the ways in which they point us toward the complex relations between technology and subjectivity, between technologies and identities. Yet at the same time there are clear echoes of Marx and Marcuse. Yet the tools for analysis that we might use—Marxist, psychoanalytic, and feminist—are all problematic. Humanist Marxism asserts an essentialism that suggests we can only come to know the subject through labor. It thus relies on a Western sense of self and erases the polyvocal and inassimilable difference made visible in anti-colonial discourse. Psychoanalysis, at least the Freudian and Lacanian discourses, rely on the category of women as other, that is unable to escape the familial narrative or the birth of the "self" drama. Feminism imposes a false unity whereas there is nothing about being female that naturally unites women.

It is for these reasons that Haraway chooses the figure of the cyborg. As she writes:

> A cyborg is a cybernetic organism, a hybrid of machine and organism, a creature of social reality as well as a creature of fiction. Social reality is lived social relations, our most important political construction, a world-changing fiction. The international women's movements have constructed "women's experience", as well as uncovered or discovered this crucial collective object. This experience is a fiction and fact of the most crucial, political kind. Liberation rests on the construction of the consciousness, the imaginative apprehension, of oppression, and so of possibility. The cyborg is a matter of fiction and lived experience that

> changes what counts as women's experience in the late twentieth century. This is a struggle over life and death, but the boundary between science fiction and social reality is an optical illusion . . .
>
> By the late twentieth century, our time, a mythic time, we are all chimeras, theorized and fabricated hybrids of machine and organism; in short, we are cyborgs. Ths cyborg is our ontology; it gives us our politics. The cyborg is a condensed image of both imagination and material reality, the two joined centres structuring any possibility of historical transformation. In the traditions of "Western" science and politics—the tradition of racist, male-dominant capitalism; the tradition of progress; the tradition of the appropriation of nature as resource for the productions of culture; the tradition of reproduction of the self from the reflections of the other—the relation between organism and machine has been a border war. The stakes in the border war have been the territories of production, reproduction, and imagination.
>
> (Haraway, 1991: 140–150)

"Cyborg replication is uncoupled from organic reproduction" (p. 150); "The cyborg does not dream of community on the model of the organic family" (p. 151). It does not aspire to "organic wholeness" and "is not afraid of joint kinship with animals and machines . . . of permanently partial identities and contradictory standpoints" (p. 154). As Carolyn Keen (2002: 1–2) observes:

> The cyborg thus evades traditional humanist concepts of women as child-bearer and raiser, of individuality and individual wholeness, the hetero-sexual marriage-nuclear family, transcendentalism and Biblical narrative, the great chain of being (god/man/animal etc.), fear of death, fear of automatism, insistency of consistency and completeness. It evades the Freudian family drama, the Lacanian m/other, and "natural" affiliation and unity. It attempts to complicate binary oppositions, which have been "systematic to the logics and practices of domination of women, people of color, nature, workers, animals" (177).

The cyborg, then, becomes the figure by which Haraway investigates the creation myth of genetic engineering and the relations among genetic engineering, sex, and reproduction.

4.2. Feenberg

Feenberg's (1999) *Questioning Technology* is, perhaps, the most comprehensive introductory text in philosophy of technology. It is the third book in a trilogy dealing with technology, including *Critical Theory of Technology* (1991) and *Alternative Modernity* (1995). In *Questioning Technology* Feenberg takes the constructivist turn against all forms of essentialism. As he writes:

> The "essence" of actual technology, as we encounter it in all its complexity, is not simply an orientation toward efficiency. Its many roles in our lives cannot be captured so simply. This is the burden of constructivist sociology of technology, which affirms the social and historical specificity of technological systems, the relativity of technical design and use to the culture and strategies of a variety of technological actors. Constructivism, in short, has introduced difference into the question of technology.
>
> (Feenberg, 1999: x)

Feenberg argues against both essentialism and its cousin—determinism—to put forward a political theory of technology which embraces the social dimensions of technological systems, including their impact on the environment and workers' skills and their role on the distribution of power. Feenberg wants to encompass the technical dimension of our lives and to provide a social account of the essence of technology which enlarges our democratic concerns.[7] Feenberg suggests that his philosophy of technology comprises four major elements, which I have abridged for the purposes of this essay.

1. *Hermeneutic Constructivism*. Technology is not the product of a unique technical rationality but of a combination of technical and social factors. The study of these factors must include not only the empirical methods of social science but also the interpretive methods of the humanities in order to get at the underlying meaning of technical objects and activities for participants. Meaning is critically important insofar as technical objects are socially defined.
2. *Historicism*. In recent years technology studies has benefited greatly from the adoption of a historicist approach derived from the work of Thomas Kuhn in the history of science. Instead of regarding technological progress as a deterministic sequence of developments, we have learned to see it as a contingent process that could lead in many different directions.
3. *Technical Democracy*. A technological society requires a democratic public sphere sensitive to technical affairs. But it is difficult to conceive the enlargement of democracy to technology through procedures such as voting . . . Nevertheless, local publics do become involved in protests over technical developments that concern them. Hence the widespread recourse to protests and public hearings in domains such as environmentalism . . . we are witnessing the slow emergence of a technical public sphere but that it has been largely overlooked because of its unfamiliar concerns and fragmented form.

4. *Meta-Theory of Technology*. There have been many attempts in philosophy to define the essence of technology and to distinguish the specific difference of modern and premodern technologies . . . these various theories are unilateral and fail to grasp the full complexity of their object. I distinguish two levels of technical "instrumentalization" . . . At the primary level technology reifies its objects, i.e., decontextualizes them and manipulates them. At the secondary level various compensations are introduced to recontextualize technical objects once again, for example, by providing them with ethical and aesthetic dimensions (http://www-rohan.sdsu.edu/faculty/feenberg/Method1.htm).

CONCLUDING NOTE

In this paper I have been concerned to map approaches in philosophy of technology, focusing on how we might address this question, and also the importance of the field for education. I mapped the humanities versus the engineering traditions and within the former, indicated what the Heideggerian programme might look like through the work of Heidegger, Marcuse, Foucault, and Dreyfus. There is a question of how we determine a research programme in philosophy, left unresolved, and whether, in fact, it is correct to construe Marcuse, Foucault, and Dreyfus as Heidggerian, especially when they all jettison Heidegger's essentialism and his post-humanism. I then contrasted the Heideggerian programme with Haraway's socialist–feminism project and Feenberg's sociological constructivism. Philosophy of technology is an exciting emerging field of interest. It has crucial significance for education for education is not only a discipline often conceived as the study of education with an accent on its improvement, it is also a giant enterprise, increasing the centre of the knowledge economy, where such improvements are now driven by both economic theories concerning the importance of technology and technical innovations touted to transform its development. In relation to the economic and technical transformation of education I believe that the humanities tradition and, in particular, the Heideggerian programme of philosophy of technology offers a necessary corrective and critique to theories of educational modernity.

ENDNOTES

1. See, for instance, the US National Academies 1997 report in the series *Preparing for the 21st Century*, "Technology and the Nation's Future" at http://www.nas.edu/21st/technology/; see also the report in the same series "The Educational Imperative" at http://www.nas.edu/21st/technology/. For a European perspective see the OECD's science and

technology policy at http://www1.oecd.org/dsti/sti/s_t/index.htm. See also *Research and Knowledge Transfer in Scotland*, Report of the Scottish Higher Education Funding Council and Scottish Enterprise Joint Task Group (2002) available at http://www.shefc.ac.uk.

2. Neoclassical economics does not specify how knowledge accumulation occurs. As a result there is no mention of human capital and there is no direct role for education. Further, in the neo-classical model there is no income "left over" (all output is paid to either capital or labour) to act as a reward or incentive for knowledge accumulation. Accordingly, there are no externalities to knowledge accumulation. By contrast, new growth theory has highlighted the role of education in the creation of human capital and in the production of new knowledge. On the basis it has explored the possibilities of education-related externalities. In short, while the evidence is far from conclusive at this stage there is a consensus emerging that education is important for successful research activities (e.g., by producing scientists and engineers) which are, in turn, important for productivity growth, and; education creates human capital, which directly affects knowledge accumulation and therefore productivity growth. (See Report 8, "Externalities in Higher Education", *The Dearing Report*, 1997).
3. My interest was initially stimulated by reading Heidegger's work (see Peters, 2002). In 2001 I organized and taught a graduate level course entitled "Technology, Culture and Value" across two institutions in New Zealand: the University of Auckland (AU) and Auckland University of Technology (AUT). I held the course for explicit reasons as I wanted to institutionalize philosophy of technology as a pedagogical intervention at AUT. Any university of technology needs to reflect on the nature of technology as part of its fundamental mission. The course of twelve 3-hour lectures, with 4 of the 12 taught by staff from AUT, focused on Heidegger, Marcuse, Foucault, and Haraway, before focusing on issues (including the political technology of freedom, virtual learning, and technologized cultures) and disciplinary approaches (architecture, visual arts, higher education, media studies). See the website at: (http://www.aut.ac.nz/faculties/arts/summer_school/about.shtml), especially the links to theorists, web resources, essays, and journals.
4. Burbules (2001) mentions as exciting possibilities new opportunities for learning involving constructivist, problem-oriented, social learning as well as the benefits of visualization and virtualization, simulations, and distance education. He mentions five dangers: the creation of an information caste society; commecialization of education as a for-profit enterprise; the rise of edutainment and other hybrid products; the deregulation and decentralization of public education; and the greater interpenetration of public/private spheres; and finally deinstitutionalization of education leading to the demise of a public schooling system.

5. One might also attempt an institutional analysis of philosophy of technology, an approach implicitly suggested by Don Ihde (1996) in providing a retrospective of the Society for Phenomenology and Existential Philosophy (SPEP), founded in 1962, the Society for Women in Philosophy (SWIP) and the Society for Philosophy and Technology (SPT), whose origins date from the same time.
6. Dreyfus has a new book *Heidegger and Foucault on the Ordering of Things*, forthcoming from University of California Press.
7. For symposia on Feenberg's latest book see his homepage at (http://www-rohan.sdsu.edu/faculty/feenberg/symposia.html), including the article by Iain Thomson "From the Question Concerning Technology to the Quest for a Democratic Technology: Heidegger, Marcuse, Feenberg" that also appears in Peters (2002). See also his list of publications and comments on distance education and online community.

Chapter 4: A Cyborg Manifesto: Science, Technology, and Socialist-Feminism in the Late 20th Century*

DONNA HARAWAY
History of Consciousness Program, University of California, at Santa Cruz

1. AN IRONIC DREAM OF A COMMON LANGUAGE FOR WOMEN IN THE INTEGRATED CIRCUIT

This chapter is an effort to build an ironic political myth faithful to feminism, socialism, and materialism. Perhaps more faithful as blasphemy is faithful, than as reverent worship and identification. Blasphemy has always seemed to require taking things very seriously. I know no better stance to adopt from within the secular-religious, evangelical traditions of United States politics, including the politics of socialist-feminism. Blasphemy protects one from the moral majority within, while still insisting on the need for community. Blasphemy is not apostasy. Irony is about contradictions that do not resolve into larger wholes, even dialectically, about the tension of holding incompatible things together because both or all are necessary and true. Irony is about humor and serious play. It is also a rhetorical strategy and a political method, one I would like to see more honoured within socialist-feminism. At the center of my ironic faith, my blasphemy, is the image of the cyborg.

A cyborg is a cybernetic organism, a hybrid of machine and organism, a creature of social reality as well as a creature of fiction. Social reality is lived social relations, our most important political construction, a world-changing fiction. The international women's movements have constructed "women's experience", as well as uncovered or discovered this crucial collective object. This experience is a fiction and fact of the most crucial, political kind. Liberation rests on the construction of the consciousness, the imaginative apprehension, of oppression, and so of possibility. The cyborg is a matter of fiction and lived experience that changes what counts as women's experience in the late 20th century. This is a struggle over life and death, but the boundary between science fiction and social reality is an optical illusion.

Contemporary science fiction is full of cyborgs—creatures simultaneously animal and machine, who populate worlds ambiguously natural and crafted. Modern medicine is also full of cyborgs, of couplings between organism and machine, each conceived as coded devices, in an intimacy and with a power that was not generated in the history of sexuality. Cyborg "sex" restores some of the lovely replicative baroque of ferns and invertebrates (such nice

organic prophylactics against heterosexism). Cyborg replication is uncoupled from organic reproduction. Modern production seems like a dream of cyborg colonization work, a dream that makes the nightmare of Taylorism seem idyllic. And modern war is a cyborg orgy, coded by C3I, command-control-communication-intelligence, an $84 billion item in 1984s US defence budget. I am making an argument for the cyborg as a fiction mapping our social and bodily reality and as an imaginative resource suggesting some very fruitful couplings. Michael Foucault's biopolitics is a flaccid pre-monition of cyborg politics, a very open field.

By the late 20th century, our time, a mythic time, we are all chimeras, theorized, and fabricated hybrids of machine and organism; in short, we are cyborgs. This cyborg is our ontology; it gives us our politics. The cyborg is a condensed image of both imagination and material reality, the two joined centers structuring any possibility of historical transformation. In the traditions of "Western" science and politics—the tradition of racist, male-dominant capitalism; the tradition of progress; the tradition of the appropriation of nature as resource for the productions of culture; the tradition of reproduction of the self from the reflections of the other—the relation between organism and machine has been a border war. The stakes in the border war have been the territories of production, reproduction, and imagination. This chapter is an argument for pleasure in the confusion of boundaries and for responsibility in their construction. It is also an effort to contribute to socialist-feminist culture and theory in a post-modernist, non-naturalist mode and in the utopian tradition of imagining a world without gender, which is perhaps a world without genesis, but maybe also a world without end. The cyborg incarnation is outside salvation history. Nor does it mark time on an oral symbiotic utopia or post-oedipal apocalypse. As Zoe Sofoulis argues in her unpublished manuscript on Jacques Lacan, Melanie Klein, and nuclear culture, Lacklein, the most terrible and perhaps the most promising monsters in cyborg worlds are embodied in non-oedipal narratives with a different logic of repression, which we need to understand for our survival.

The cyborg is a creature in a post-gender world; it has no truck with bisexuality, pre-oedipal symbiosis, unalienated labor, or other seductions to organic wholeness through a final appropriation of all the powers of the parts into a higher unity. In a sense, the cyborg has no origin story in the Western sense—a "final" irony since the cyborg is also the awful apocalyptic *telos* of the "West's" escalating dominations of abstract individuation, an ultimate self untied at last from all dependency, a man in space. An origin story in the "Western", humanist sense depends on the myth of original unity, fullness, bliss, and terror, represented by the phallic mother from whom all humans must separate, the task of individual development and of history, the twin potent myths inscribed most powerfully for us in psychoanalysis and Marxism. Hilary Klein (1989) has argued that both Marxism and psychoanalysis, in their concepts of labor and of individuation and gender formation, depend on the plot of original unity out of which difference must be produced and enlisted in a drama of escalating domination of woman/nature. The cyborg skips the step of original unity, of identification with nature in the Western sense. This is an illegitimate promise that might lead to subversion of its teleology as star wars.

The cyborg is resolutely committed to partiality, irony, intimacy, and perversity. It is oppositional, utopian, and completely without innocence. No longer structured by the polarity of public and private, the cyborg defines a technological *polis* based partly on a revolution of social relations in the *oikos*, the household. Nature and culture are reworked; the one can no longer be the resource for appropriation or incorporation by the other. The relationships for forming wholes from parts, including those of polarity and hierarchical domination, are at issue in the cyborg world. Unlike the hopes of Frankenstein's monster, the cyborg does not expect its father to save it through a restoration of the garden; that is, through the fabrication of a heterosexual mate, through its completion in a finished whole, a city and cosmos. The cyborg does not dream of community on the model of the organic family, this time without the oedipal project. The cyborg would not recognize the Garden of Eden; it is not made of mud and cannot dream of returning to dust. Perhaps that is why I want to see if cyborgs can subvert the apocalypse of returning to nuclear dust in the manic compulsion to name the Enemy. Cyborgs are not reverent; they do not remember the cosmos. They are wary of holism, but needy for connection—they seem to have a natural feel for united front politics, but without the vanguard party. The main trouble with cyborgs, of course, is that they are the illegitimate offspring of militarism and patriarchal capitalism, not to mention state socialism. But illegitimate offspring are often exceedingly unfaithful to their origins. Their fathers, after all, are inessential.

I want to signal three crucial boundary breakdowns that make the following political-fictional (political-scientific) analysis possible. By the late 20th century in United States scientific culture, the boundary between human and animal is thoroughly breached. The last beachheads of uniqueness have been polluted if not turned into amusement parks—language, tool use, social behavior, mental events, nothing really convincingly settles the separation of human and animal. And many people no longer feel the need for such a separation; indeed, many branches of feminist culture affirm the pleasure of connection of human and other living creatures. Movements for animal rights are not irrational denials of human uniqueness; they are a clear-sighted recognition of connection across the discredited breach of nature and culture. Biology and evolutionary theory over the last two centuries have simultaneously produced modern organisms as objects of knowledge and reduced the line between humans and animals to a faint trace re-etched in ideological struggle or professional disputes between life and social science. Within this framework, teaching modern Christian creationism should be fought as a form of child abuse.

Biological-determinist ideology is only one position opened up in scientific culture for arguing the meanings of human animality. There is much room for radical political people to contest the meanings of the breached boundary.[1] The cyborg appears in myth precisely where the boundary between human and animal is transgressed. Far from signaling a walling off of people from other living beings, cyborgs signal disturbingly and pleasurably tight coupling. Bestiality has a new status in this cycle of marriage exchange.

The second leaky distinction is between animal-human (organism) and machine. Pre-cybernetic machines could be haunted; there was always the spectre of the ghost in the machine. This dualism structured the dialogue between materialism and idealism that was settled by a dialectical progeny, called spirit or history, according to taste. But basically machines were not self-moving, self-designing, autonomous. They could not achieve man's dream, only mock it. They were not man, an author himself, but only a caricature of that masculinist reproductive dream. To think they were otherwise was paranoid. Now we are not so sure. Late 20th-century machines have made thoroughly ambiguous the difference between natural and artificial, mind and body, self-developing and externally designed, and many other distinctions that used to apply to organisms and machines. Our machines are disturbingly lively, and we ourselves frighteningly inert.

Technological determination is only one ideological space opened up by the reconceptions of machine and organism as coded texts through which we engage in the play of writing and reading the world.[2] "Textualization" of everything in post-structuralist, post-modernist theory has been damned by Marxists and socialist-feminists for its utopian disregard for the lived relations of domination that ground the "play" of arbitrary reading.[3] It is certainly true that post-modernist strategies, like my cyborg myth, subvert myriad organic wholes (for example, the poem, the primitive culture, the biological organism). In short, the certainty of what counts as nature—a source of insight and promise of innocence—is undermined, probably fatally. The transcendent authorization of interpretation is lost, and with it the ontology grounding "Western" epistemology. But the alternative is not cynicism or faithlessness, that is, some version of abstract existence, like the accounts of technological determinism destroying "man" by the "machine" or "meaningful political action" by the "text". Who cyborgs will be is a radical question; the answers are a matter of survival. Both chimpanzees and artifacts have politics, so why shouldn't we? (de Waal, 1982; Winner, 1980).

The third distinction is a subset of the second: The boundary between physical and non-physical is very imprecise for us. Pop physics books on the consequences of quantum theory and the indeterminacy principle are a kind of popular scientific equivalent to Harlequin romances as a marker of radical change in American white heterosexuality: They get it wrong, but they are on the right subject. Modern machines are quintessentially microelectronic devices: They are everywhere and they are invisible. Modern machinery is an irreverent upstart god, mocking the Father's ubiquity and spirituality. The silicon chip is a surface for writing; it is etched in molecular scales disturbed only by atomic noise, the ultimate interference for nuclear scores. Writing, power, and technology are old partners in Western stories of the origin of civilization, but miniaturization has changed our experience of mechanism. Miniaturization has turned out to be about power; small is not so much beautiful as pre-eminently dangerous, as in cruise missiles. Contrast the TV sets of the 1950s or the news cameras of the 1970s with the TV wrist bands or hand-sized video cameras now advertised. Our best machines are made of sunshine; they are all light and clean because they are nothing but signals, electromagnetic waves, a section of a spectrum, and these machines are eminently portable, mobile—a matter of immense human pain in Detroit and Singapore. People are nowhere near so fluid, being both material and opaque. Cyborgs are ether, quintessence.

The ubiquity and invisibility of cyborgs is precisely why these sunshine-belt machines are so deadly. They are as hard to see politically as materially. They are about consciousness—or its simulation.[4] They are floating signifiers moving in pickup trucks across Europe, blocked more effectively by the witch-weavings of the displaced and so unnatural Greenham women, who read the cyborg webs of power so very well, than by the militant labor of older masculinist politics, whose natural constituency needs defence jobs. Ultimately the "hardest" science is about the realm of greatest boundary confusion, the realm of pure number, pure spirit, C^3I, cryptography, and the preservation of potent secrets. The new machines are so clean and light. Their engineers are sun-worshippers mediating a new scientific revolution associated with the night dream of post-industrial society. The diseases evoked by these clean machines are "no more" than the minuscule coding changes of an antigen in the immune system, "no more" than the experience of stress. The nimble fingers of "Oriental" women, the old fascination of little Anglo-Saxon Victorian girls with doll's houses, women's enforced attention to the small take on quite new dimensions in this world. There might be a cyborg Alice taking account of these new dimensions. Ironically, it might be the unnatural cyborg women making chips in Asia and spiral dancing in Santa Rita jail[5] whose constructed unities will guide effective oppositional strategies.

So my cyborg myth is about transgressed boundaries, potent fusions, and dangerous possibilities which progressive people might explore as one part of needed political work. One of my premises is that most American socialists and feminists see deepened dualisms of mind and body, animal and machine, idealism and materialism in the social practices, symbolic formulations, and physical artifacts associated with "high technology" and scientific culture. From *One-Dimensional Man* (Marcuse, 1964) to *The Death of Nature* (Merchant, 1980), the analytic resources developed by progressives have insisted on the necessary domination of technics and recalled us to an imagined organic body to integrate our resistance. Another of my premises is that the need for unity of people trying to resist worldwide intensification of domination has never been more acute. But a slightly perverse shift of perspective might better enable us to contest for meanings, as well as for other forms of power and pleasure in technologically mediated societies.

From one perspective, a cyborg world is about the final imposition of a grid of control on the planet, about the final abstraction embodied in a Star Wars apocalypse waged in the name of defence, about the final appropriation of women's bodies in a masculinist orgy of war (Sofia, 1984). From another perspective, a cyborg world might be about lived social and bodily realities in which people are not afraid of their joint kinship with animals and machines, not afraid of permanently partial identities and contradictory standpoints. The political struggle is to see from both perspectives at once because each reveals both dominations and possibilities unimaginable from the other vantage point. Single vision produces worse illusions than double vision or many-headed monsters. Cyborg unities are monstrous and illegitimate; in our present political circumstances, we could hardly hope for more potent myths for resistance and recoupling. I like to imagine LAG, the Livermore Action Group, as a kind of cyborg society, dedicated to realistically converting the laboratories that most fiercely embody and spew out the tools of technological apocalypse, and committed to building a political form that actually manages to hold together witches, engineers, elders, perverts, Christians, mothers, and Leninists long enough to disarm the state. Fission Impossible is the name of the affinity group in my town. (Affinity: Related not by blood but by choice, the appeal of one chemical nuclear group for another, avidity.)[6]

2. FRACTURED IDENTITIES

It has become difficult to name one's feminism by a single adjective—or even to insist in every circumstance upon the noun. Consciousness of exclusion through naming is acute. Identities seem contradictory, partial, and strategic. With the hard-won recognition of their social and historical constitution, gender, race, and class cannot provide the basis for belief in "essential" unity. There is nothing about being "female" that naturally binds women. There is not even such a state as "being" female, itself a highly complex category constructed in contested sexual scientific discourses and other social practices. Gender, race, or class-consciousness is an achievement forced on us by the terrible historical experience of the contradictory social realities of patriarchy, colonialism, and capitalism. And who counts as "us" in my own rhetoric? Which identities are available to ground such a potent political myth called "us", and what could motivate enlistment in this collectivity? Painful fragmentation among feminists (not to mention among women) along every possible fault line has made the concept of *woman* elusive, an excuse for the matrix of women's dominations of each other. For me—and for many who share a similar historical location in white, professional middle-class, female, radical, North American, mid-adult bodies—the sources of a crisis in political identity are legion. The recent history for much of the US left and US feminism has been a response to this kind of crisis by endless splitting and searches for a new essential unity. But there has also been a growing recognition of another response through coalition—affinity, not identity.[7]

Chela Sandoval (n.d., 1984), from a consideration of specific historical moments in the formation of the new political voice called women of color, has theorized a hopeful model of political identity called “oppositional consciousness”, born of the skills for reading webs of power by those refused stable membership in the social categories of race, sex, or class. “Women of color”, a name contested at its origins by those whom it would incorporate, as well as a historical consciousness marking systematic breakdown of all the signs of Man in “Western” traditions, constructs a kind of post-modernist identity out of otherness, difference, and specificity. This post-modernist identity is fully political, whatever might be said abut other possible post-modernisms. Sandoval’s oppositional consciousness is about contradictory locations and heterochronic calendars, not about relativisms and pluralisms.

Sandoval emphasizes the lack of any essential criterion for identifying who is a woman of color. She notes that the definition of a group has been by conscious appropriation of negation. For example, a Chicana or US black woman has not been able to speak as a woman or as a black person or as a Chicano. Thus, she was at the bottom of a cascade of negative identities, left out of even the privileged oppressed authorial categories called “women and blacks”, who claimed to make the important revolutions. The category “woman” negated all non-white women; “black” negated all non-black people, as well as all black women. But there was also no “she”, no singularity, but a sea of differences among US women who have affirmed their historical identity as US women of color. This identity marks out a self-consciously constructed space that cannot affirm the capacity to act on the basis of natural identification, but only on the basis of conscious coalition, of affinity, of political kinship.[8] Unlike the “woman” of some streams of the white women’s movement in the United States, there is no naturalization of the matrix, or at least this is what Sandoval argues is uniquely available through the power of oppositional consciousness.

Sandoval’s argument has to be seen as one potent formulation for feminists out of the worldwide development of anti-colonialist discourse; that is to say, discourse dissolving the “West” and its highest product—the one who is not animal, barbarian, or woman; man, that is, the author of a cosmos called history. As orientalism is deconstructed politically and semiotically, the identities of the occident destabilize, including those of feminists.[9] Sandoval argues that “women of colour” have a chance to build an effective unity that does not replicate the imperializing, totalizing revolutionary subjects of previous Marxisms and feminisms which had not faced the consequences of the disorderly polyphony emerging from decolonization.

Katie King has emphasized the limits of identification and the political/poetic mechanics of identification built into reading "the poem", that generative core of *cultural* feminism. King criticizes the persistent tendency among contemporary feminists from different "moments" or "conversations" in feminist practice to taxonomize the women's movement to make one's own political tendencies appear to be the *telos* of the whole. These taxonomies tend to remake feminist history so that it appears to be an ideological struggle among coherent types persisting over time, especially those typical units called radical, liberal, and socialist-feminist. Literally, all other feminisms are either incorporated or marginalized, usually by building an explicit ontology and epistemology.[10] Taxonomies of feminism produce epistemologies to police deviation from official women's experience. And of course, "women's culture", like women of color, is consciously created by mechanisms inducing affinity. The rituals of poetry, music, and certain forms of academic practice have been pre-eminent. The politics of race and culture in the US women's movements are intimately interwoven. The common achievement of King and Sandoval is learning how to craft a poetic/political unity without relying on a logic of appropriation, incorporation, and taxonomic identification.

The theoretical and practical struggle against unity-through-domination or unity-through-incorporation ironically not only undermines the justifications for patriarchy, colonialism, humanism, positivism, essentialism, scientism, and other unlamented -isms, but *all* claims for an organic or natural standpoint. I think that radical and socialist/Marxist-feminisms have also undermined their/our own epistemological strategies and that this is a crucially valuable step in imagining possible unities. It remains to be seen whether all "epistemologies" as Western political people have known them fail us in the task to build effective affinities.

It is important to note that the effort to construct revolutionary standpoints, epistemologies as achievements of people committed to changing the world, has been part of the process showing the limits of identification. The acid tools of post-modernist theory and the constructive tools of ontological discourse about revolutionary subjects might be seen as ironic allies in dissolving Western selves in the interests of survival. We are excruciatingly conscious of what it means to have a historically constituted body. But with the loss of innocence in our origin, there is no expulsion from the Garden either. Our politics lose the indulgence of guilt with the *naiveté* of innocence. But what would another political myth for socialist-feminism look like? What kind of politics could embrace partial, contradictory, permanently unclosed constructions of personal and collective selves and still be faithful, effective—and, ironically, socialist-feminist?

I do not know of any other time in history when there was greater need for political unity to confront effectively the dominations of "race", "gender", "sexuality", and "class". I also do not know of any other time when the kind of unity we might help build could have been possible. None of "us" have any longer the symbolic or material capability of dictating the shape of reality to any of "them". Or at least "we" cannot claim innocence from practicing such dominations. White women, including socialist-feminists, discovered the non-innocence of the category "woman". That consciousness changes the geography of all previous categories; it denatures them as heat denatures a fragile protein. Cyborg feminists have to argue that "we" do not want any more natural matrix of unity and that no construction is whole. Innocence, and the corollary insistence on victimhood as the only ground for insight, has done enough damage. But the constructed revolutionary subject must give late 20th-century people pause as well. In the fraying of identities and in the reflexive strategies for constructing them, the possibility opens up for weaving something other than a shroud for the day after the apocalypse that so prophetically ends salvation history.

Both Marxist/socialist-feminisms and radical feminisms have simultaneously naturalized and denatured the category "woman" and consciousness of the social lives of "women". Perhaps a schematic caricature can highlight both kinds of moves. Marxian-socialism is rooted in an analysis of wage labor which reveals class structure. The consequence of the wage relationship is systematic alienation, as the worker is dissociated from his [*sic*] product. Abstraction and illusion rule in knowledge, domination rules in practice. Labor is the pre-eminently privileged category enabling the Marxist to overcome illusion and find that point of view which is necessary for changing the world. Labor is the humanizing activity that makes man; labor is an ontological category permitting the knowledge of a subject, and so the knowledge of subjugation and alienation.

In faithful filiation, socialist-feminism is advanced by allying itself with the basic analytic strategies of Marxism. The main achievement of both Marxist-feminists and socialist-feminists was to expand the category of labor to accommodate what (some) women did, even when the wage relation was subordinated to a more comprehensive view of labor under capitalist patriarchy. In particular, women's labor in the household and women's activity as mothers generally (that is, reproduction in the socialist-feminist sense), entered theory on the authority of analogy to the Marxian concept of labor. The unity of women here rests on an epistemology based on the ontological structure of "labor". Marxist/socialist-feminism does not "naturalize" unity; it is a possible achievement based on a possible standpoint rooted in social relations. The essentializing move is in the ontological structure of labor or of its analogue, women's activity.[11] The inheritance of Marxian-humanism, with its pre-eminently Western self, is the difficulty for me. The contribution from these formulations has been the emphasis on the daily responsibility of real women to build unities, rather than to naturalize them.

Catherine MacKinnon's (1982, 1987) version of radical feminism is itself a caricature of the appropriating, incorporating, totalizing tendencies of Western theories of identity grounding action.[12] It is factually and politically wrong to assimilate all of the diverse "moments" or "conversations" in recent women's politics named radical feminism to MacKinnon's version. But the teleological logic of her theory shows how an epistemology and ontology—including their negations—erase or police difference. Only one of the effects of MacKinnon's theory is the rewriting of the history of the polymorphous field called radical feminism. The major effect is the production of a theory of experience, of women's identity, that is a kind of apocalypse for all revolutionary standpoints. That is, the totalization built into this tale of radical feminism achieves its end—the unity of women—by enforcing the experience of and testimony to radical non-being. As for the Marxist/socialist-feminist, consciousness is an achievement, not a natural fact. And MacKinnon's theory eliminates some of the difficulties built into humanist revolutionary subjects, but at the cost of radical reductionism.

MacKinnon argues that feminism necessarily adopted a different analytical strategy from Marxism, looking first not at the structure of class, but at the structure of sex/gender and its generative relationship, men's constitution and appropriation of women sexually. Ironically, MacKinnon's "ontology" constructs a non-subject, a non-being. Another's desire, not the self's labor, is the origin of "woman". She therefore develops a theory of consciousness that enforces what can count as "women's" experience—anything that names sexual violation, indeed, sex itself as far as "women" can be concerned. Feminist practice is the construction of this form of consciousness; that is, the self-knowledge of a self-who-is-not.

Perversely, sexual appropriation in this feminism still has the epistemological status of labor; that is to say, the point from which an analysis able to contribute to changing the world must flow. But sexual objectification, not alienation, is the consequence of the structure of sex/gender. In the realm of knowledge, the result of sexual objectification is illusion and abstraction. However, a woman is not simply alienated from her product, but in a deep sense does not exist as a subject, or even potential subject, since she owes her existence as a woman to sexual appropriation. To be constituted by another's desire is not the same thing as to be alienated in the violent separation of the laborer from his product.

MacKinnon's radical theory of experience is totalizing in the extreme; it does not so much marginalize as obliterate the authority of any other women's political speech and action. It is a totalization producing what Western patriarchy itself never succeeded in doing—feminists' consciousness of the non-existence of women, except as products of men's desire. I think MacKinnon correctly argues that no Marxian version of identity can firmly ground women's unity. But in solving the problem of the contradictions of any Western revolutionary subject for feminist purposes, she develops an even more authoritarian doctrine of experience. If my complaint about socialist/Marxian standpoints is their unintended erasure of polyvocal, unassimilable, radical difference made visible in anti-colonial discourse and practice, MacKinnon's intentional erasure of all difference through the device of the "essential" non-existence of women is not reassuring.

In my taxonomy, which like any other taxonomy is a re-inscription of history, radical feminism can accommodate all the activities of women named by socialist feminists as forms of labor only if the activity can somehow be sexualized. Reproduction had different tones of meanings for the two tendencies, one rooted in labor, one in sex, both calling the consequences of domination and ignorance of social and personal reality "false consciousness".

Beyond either the difficulties or the contributions in the argument of any one author, neither Marxist nor radical feminist points of view have tended to embrace the status of a partial explanation; both were regularly constituted as totalities. Western explanation has demanded as much; how else could the "Western" author incorporate its others? Each tried to annex other forms of domination by expanding its basic categories through analogy, simple listing, or addition. Embarrassed silence about race among white radical and socialist-feminists was one major, devastating political consequence. History and polyvocality disappear into political taxonomies that try to establish genealogies. There was no structural room for race (or for much else) in theory claiming to reveal the construction of the category woman and social group women as a unified or totalizable whole. The structure of my caricature looks like this: Socialist-feminism—structure of class // wage labor // alienation labor, by analogy reproduction, by extension sex, by addition race radical feminism—structure of gender // sexual appropriation // objectification sex, by analogy labor, by extension reproduction, by addition race.

In another context, the French theorist, Julia Kristeva, claimed women appeared as a historical group after the Second World War, along with groups like youth. Her dates are doubtful; but we are now accustomed to remembering that as objects of knowledge and as historical actors, "race" did not always exist, "class" has a historical genesis, and "homosexuals" are quite junior. It is no accident that the symbolic system of the family of man—and so the essence of woman—breaks up at the same moment that networks of connection among people on the planet are unprecedentedly multiple, pregnant, and complex. "Advanced capitalism" is inadequate to convey the structure of this historical moment. In the "Western" sense, the end of man is at stake. It is no accident that woman disintegrates into women in our time. Perhaps socialist feminists were not substantially guilty of producing essentialist theory that suppressed women's particularity and contradictory interests. I think we have been, at least through unreflective participation in the logics, languages, and practices of white humanism and through searching for a single ground of domination to secure our revolutionary voice. Now we have less excuse. But in the consciousness of our failures, we risk lapsing into boundless difference and giving up on the confusing task of making partial, real connection. Some differences are playful; some are poles of world historical systems of domination. "Epistemology" is about knowing the difference.

3. THE INFORMATICS OF DOMINATION

In this attempt at an epistemological and political position, I would like to sketch a picture of possible unity, a picture indebted to socialist and feminist principles of design. The frame for my sketch is set by the extent and importance of rearrangements in worldwide social relations tied to science and technology. I argue for a politics rooted in claims about fundamental changes in the nature of class, race, and gender in an emerging system of world order analogous in its novelty and scope to that created by industrial capitalism; we are living through a movement from an organic, industrial society to a polymorphous, information system–from all work to all play, a deadly game. Simultaneously material and ideological, the dichotomies may be expressed in the following chart of transitions from the comfortable old hierarchical dominations to the scary new networks I have called the informatics of domination:

Representation	Simulation
Bourgeois novel, realism	Science fiction, post-modernism
Organism	Biotic Component
Depth, integrity	Surface, boundary
Heat	Noise
Biology as clinical practice	Biology as inscription
Physiology	Communications engineering
Small group	Subsystem
Perfection	Optimization
Eugenics	Population Control
Decadence, Magic Mountain	Obsolescence, *Future Shock*
Hygiene	Stress Management
Microbiology, tuberculosis	Immunology, AIDS
Organic division of labor	Ergonomics/cybernetics of labor
Functional specialization	Modular construction
Reproduction	Replication
Organic sex role specialization	Optimal genetic strategies
Biological determinism	Evolutionary inertia, constraints
Community ecology	Ecosystem
Racial chain of being	Neo-imperialism, United Nations humanism
Scientific management in home/factory	Global factory/Electronic cottage
Family/Market/Factory	Women in the Integrated Circuit
Family wage	Comparable worth
Public/private	Cyborg citizenship
Nature/culture	Fields of difference
Co-operation	Communications enhancement
Freud	Lacan

Sex	Genetic engineering
Labor	Robotics
Mind	Artificial Intelligence
Second World War	Star Wars
White Capitalist Patriarchy	Informatics of Domination

This list suggests several interesting things.[13] First, the objects on the right-hand side cannot be coded as "natural", a realization that subverts naturalistic coding for the left-hand side as well. We cannot go back ideologically or materially. It's not just that "god" is dead; so is the "goddess". Or both are revivified in the worlds charged with microelectronic and biotechnological politics. In relation to objects like biotic components, one must not think in terms of essential properties, but in terms of design, boundary constraints, rates of flows, systems logics, costs of lowering constraints. Sexual reproduction is one kind of reproductive strategy among many, with costs and benefits as a function of the system environment. Ideologies of sexual reproduction can no longer reasonably call on notions of sex and sex role as organic aspects in natural objects like organisms and families. Such reasoning will be unmasked as irrational, and ironically corporate executives reading Playboy and anti-porn radical feminists will make strange bedfellows in jointly unmasking the irrationalism.

Likewise for race, ideologies about human diversity have to be formulated in terms of frequencies of parameters, like blood groups or intelligence scores. It is "irrational" to invoke concepts like primitive and civilized. For liberals and radicals, the search for integrated social systems gives way to a new practice called "experimental ethnography" in which an organic object dissipates in attention to the play of writing. At the level of ideology, we see translations of racism and colonialism into languages of development and under-development, rates and constraints of modernization. Any objects or persons can be reasonably thought of in terms of disassembly and reassembly; no "natural" architectures constrain system design. The financial districts in all the world's cities, as well as the export-processing and free-trade zones, proclaim this elementary fact of "late capitalism". The entire universe of objects that can be known scientifically must be formulated as problems in communications engineering (for the managers) or theories of the text (for those who would resist). Both are cyborg semiologies.

One should expect control strategies to concentrate on boundary conditions and interfaces, on rates of flow across boundaries—and not on the integrity of natural objects. "Integrity" or "sincerity" of the Western self gives way to decision procedures and expert systems. For example, control strategies applied to women's capacities to give birth to new human beings will be developed in the languages of population control and maximization of goal achievement for individual decision-makers. Control strategies will be formulated in terms of rates, costs of constraints, degrees of freedom. Human beings, like any other component or subsystem, must be localized in a system architecture whose basic modes of operation are probabilistic, statistical. No objects, spaces, or bodies are sacred in themselves; any component can be interfaced with any other if the proper standard, the proper code, can be constructed for processing signals in a common language. Exchange in this world transcends the universal translation effected by capitalist markets that Marx analyzed so well. The privileged pathology affecting all kinds of components in this universe is stress—communications breakdown (Hogness, 1983). The cyborg is not subject to Foucault's biopolitics; the cyborg simulates politics, a much more potent field of operations.

This kind of analysis of scientific and cultural objects of knowledge which have appeared historically since the Second World War prepares us to notice some important inadequacies in feminist analysis which has proceeded as if the organic, hierarchical dualisms ordering discourse in "the West" since Aristotle still ruled. They have been cannibalized, or as Zoe Sofia (Sofoulis) might put it, they have been "techno-digested". The dichotomies between mind and body, animal and human, organism and machine, public and private, nature and culture, men and women, primitive and civilized are all in question ideologically. The actual situation of women is their integration/exploitation into a world system of production/reproduction and communication called the informatics of domination. The home, workplace, market, public arena, the body itself—all can be dispersed and interfaced in nearly infinite, polymorphous ways, with large consequences for women and others—consequences that themselves are very different for different people and which make potent oppositional international movements difficult to imagine and essential for survival. One important route for reconstructing socialist-feminist politics is through theory and practice addressed to the social relations of science and technology, including crucially the systems of myth and meanings structuring our imaginations. The cyborg is a kind of disassembled and reassembled, post-modern collective and personal self. This is the self feminists must code.

Communications technologies and biotechnologies are the crucial tools recrafting our bodies. These tools embody and enforce new social relations for women world-wide. Technologies and scientific discourses can be partially understood as formalizations, i.e., as frozen moments, of the fluid social interactions constituting them, but they should also be viewed as instruments for enforcing meanings. The boundary is permeable between tool and myth, instrument and concept, historical systems of social relations and historical anatomies of possible bodies, including objects of knowledge. Indeed, myth and tool mutually constitute each other.

Furthermore, communications sciences and modern biologies are constructed by a common move—*the translation of the world into a problem of coding*, a search for a common language in which all resistance to instrumental control disappears and all heterogeneity can be submitted to disassembly, reassembly, investment, and exchange.

In communications sciences, the translation of the world into a problem in coding can be illustrated by looking at cybernetic (feedback-controlled) systems theories applied to telephone technology, computer design, weapons deployment, or data base construction and maintenance. In each case, solution to the key questions rests on a theory of language and control; the key operation is determining the rates, directions, and probabilities of flow of a quantity called information. The world is subdivided by boundaries differentially permeable to information. Information is just that kind of quantifiable element (unit, basis of unity) which allows universal translation, and so unhindered instrumental power (called effective communication). The biggest threat to such power is interruption of communication. Any system breakdown is a function of stress. The fundamentals of this technology can be condensed into the metaphor C^3I, command-control-communication-intelligence, the military's symbol for its operations theory.

In modern biologies, the translation of the world into a problem in coding can be illustrated by molecular genetics, ecology, sociobiological evolutionary theory, and immunobiology. The organism has been translated into problems of genetic coding and read-out. Biotechnology, a writing technology, informs research broadly.[14] In a sense, organisms have ceased to exist as objects of knowledge, giving way to biotic components, i.e., special kinds of information-processing devices. The analogous moves in ecology could be examined by probing the history and utility of the concept of the ecosystem. Immunobiology and associated medical practices are rich exemplars of the privilege of coding and recognition systems as objects of knowledge, as constructions of bodily reality for us. Biology here is a kind of cryptography. Research is necessarily a kind of intelligence activity. Ironies abound. A stressed system goes awry; its communication processes break down; it fails to recognize the difference between self and other. Human babies with baboon hearts evoke national ethical perplexity—for animal rights activists at least as much as for the guardians of human purity. In the US gay men and intravenous drug users are the "privileged" victims of an awful immune system disease that marks (inscribes on the body) confusion of boundaries and moral pollution (Treichler, 1987).

But these excursions into communications sciences and biology have been at a rarefied level; there is a mundane, largely economic reality to support my claim that these sciences and technologies indicate fundamental transformations in the structure of the world for us. Communications technologies depend on electronics. Modern states, multinational corporations, military power, welfare state apparatuses, satellite systems, political processes, fabrication of our imaginations, labor-control systems, medical constructions of our bodies, commercial pornography, the international division of labor, and religious evangelism depend intimately upon electronics. Microelectronics is the technical basis of simulacra; that is, of copies without originals.

Microelectronics mediates the translations of labor into robotics and word processing, sex into genetic engineering and reproductive technologies, and mind into artificial intelligence and decision procedures. The new biotechnologies concern more than human reproduction. Biology as a powerful engineering science for redesigning materials and processes has revolutionary implications for industry, perhaps most obvious today in areas of fermentation, agriculture, and energy. Communications sciences and biology are constructions of natural-technical objects of knowledge in which the difference between machine and organism is thoroughly blurred; mind, body, and tool are on very intimate terms. The "multinational" material organization of the production and reproduction of daily life and the symbolic organization of the production and reproduction of culture and imagination seem equally implicated. The boundary-maintaining images of base and superstructure, public and private, or material and ideal never seemed more feeble.

I have used Rachel Grossman's (1980) image of women in the integrated circuit to name the situation of women in a world so intimately restructured through the social relations of science and technology.[15] I used the odd circumlocution, "the social relations of science and technology", to indicate that we are not dealing with a technological determinism, but with a historical system depending upon structured relations among people. But the phrase should also indicate that science and technology provide fresh sources of power, that we need fresh sources of analysis and political action (Latour, 1984). Some of the rearrangements of race, sex, and class rooted in high-tech-facilitated social relations can make socialist-feminism more relevant to effective progressive politics.

3.1. The "Homework Economy" Outside "The Home"

The "New Industrial Revolution" is producing a new worldwide working class, as well as new sexualities and ethnicities. The extreme mobility of capital and the emerging international division of labor are intertwined with the emergence of new collectivities, and the weakening of familiar groupings. These developments are neither gender- nor race-neutral. White men in advanced industrial societies have become newly vulnerable to permanent job loss, and women are not disappearing from the job rolls at the same rates as men. It is not simply that women in Third World countries are the preferred labor force for the science-based multinationals in the export-processing sectors, particularly in electronics. The picture is more systematic and involves reproduction, sexuality, culture, consumption, and production. In the prototypical Silicon Valley, many women's lives have been structured around employment in electronics-dependent jobs, and their intimate realities include serial heterosexual monogamy, negotiating childcare, distance from extended kin or most other forms of traditional community, a high likelihood of loneliness and extreme economic vulnerability as they age. The ethnic and racial diversity of women in Silicon Valley structures a microcosm of conflicting differences in culture, family, religion, education, and language.

Richard Gordon has called this new situation the "homework economy".[16] Although he includes the phenomenon of literal homework emerging in connection with electronics assembly, Gordon intends "homework economy" to name a restructuring of work that broadly has the characteristics formerly ascribed to female jobs, jobs literally done only by women. Work is being redefined as both literally female and feminized, whether performed by men or women. To be feminized means to be made extremely vulnerable; able to be disassembled, reassembled, exploited as a reserve labor force; seen less as workers than as servers; subjected to time arrangements on and off the paid job that make a mockery of a limited work day; leading an existence that always borders on being obscene, out of place, and reducible to sex. Deskilling is an old strategy newly applicable to formerly privileged workers. However, the homework economy does not refer only to large-scale deskilling, nor does it deny that new areas of high skill are emerging, even for women and men previously excluded from skilled employment. Rather, the concept indicates that factory, home, and market are integrated on a new scale and that the places of women are crucial—and need to be analyzed for differences among women and for meanings for relations between men and women in various situations.

The homework economy as a world capitalist organizational structure is made possible by (not caused by) the new technologies. The success of the attack on relatively privileged, mostly white, men's unionized jobs is tied to the power of the new communications technologies to integrate and control labor despite extensive dispersion and decentralization. The consequences of the new technologies are felt by women both in the loss of the family (male) wage (if they ever had access to this white privilege) and in the character of their own jobs, which are becoming capital-intensive; for example, office work and nursing.

The new economic and technological arrangements are also related to the collapsing welfare state and the ensuing intensification of demands on women to sustain daily life for themselves as well as for men, children, and old people. The feminization of poverty—generated by dismantling the welfare state, by the homework economy where stable jobs become the exception, and sustained by the expectation that women's wages will not be matched by a male income for the support of children—has become an urgent focus. The causes of various women-headed households are a function of race, class, or sexuality; but their increasing generality is a ground for coalitions of women on many issues. That women regularly sustain daily life partly as a function of their enforced status as mothers is hardly new; the kind of integration with the overall capitalist and progressively war-based economy is new. The particular pressure, for example, on US black women, who have achieved an escape from (barely) paid domestic service and who now hold clerical and similar jobs in large numbers, has large implications for continued enforced black poverty *with* employment. Teenage women in industrializing areas of the Third World increasingly find themselves the sole or major source of a cash wage for their families, while access to land is ever more problematic. These developments must have major consequences in the psychodynamics and politics of gender and race.

Within the framework of three major stages of capitalism (commercial/early industrial, monopoly, multinational)—tied to nationalism, imperialism, and multinationalism, and related to Jameson's three dominant aesthetic periods of realism, modernism, and post-modernism—I would argue that specific forms of families dialectically relate to forms of capital and to its political and cultural concomitants. Although lived problematically and unequally, ideal forms of these families might be schematized as (1) the patriarchal nuclear family, structured by the dichotomy between public and private and accompanied by the white bourgeois ideology of separate spheres and 19th-century Anglo–American bourgeois feminism; (2) the modern family mediated (or enforced) by the welfare state and institutions like the family wage, with a flowering of a-feminist heterosexual ideologies, including their radical versions represented in Greenwich Village around the First World War; and (3) the "family" of the homework economy with its oxymoronic structure of women-headed households and its explosion of feminisms and the paradoxical intensification and erosion of gender itself.

This is the context in which the projections for worldwide structural unemployment stemming from the new technologies are part of the picture of the homework economy. As robotics and related technologies put men out of work in "developed" countries and exacerbate failure to generate male jobs in Third World "development", and as the automated office becomes the rule even in labor-surplus countries, the feminization of work intensifies. Black women in the United States have long known what it looks like to face the structural underemployment ("feminization") of black men, as well as their own highly vulnerable position in the wage economy. It is no longer a secret that sexuality, reproduction, family, and community life are interwoven with this economic structure in myriad ways which have also differentiated the situations of white and black women. Many more women and men will contend with similar situations, which will make cross-gender and race alliances on issues of basic life support (with or without jobs) necessary, not just nice.

The new technologies also have a profound effect on hunger and on food production for subsistence world-wide. Rae Lessor Blumberg (1983) estimates that women produce about 50% of the world's subsistence food.[17] Women are excluded generally from benefiting from the increased high-tech commodification of food and energy crops, their days are made more arduous because their responsibilities to provide food do not diminish, and their reproductive situations are made more complex. Green Revolution technologies interact with other high-tech industrial production to alter gender divisions of labor and differential gender migration patterns.

The new technologies seem deeply involved in the forms of "privatization" that Ros Petchesky (1981) has analyzed, in which militarization, right-wing family ideologies and policies, and intensified definitions of corporate (and state) property as private synergistically interact.[18] The new communications technologies are fundamental to the eradication of "public life" for everyone. This facilitates the mushrooming of a permanent high-tech military establishment at the cultural and economic expense of most people, but especially of women. Technologies like video games and highly miniaturized televisions seem crucial to production of modern forms of "private life". The culture of video games is heavily orientated to individual competition and extraterrestrial warfare. High-tech, gendered imaginations are produced here, imaginations that can contemplate destruction of the planet and a science fiction escape from its consequences. More than our imaginations is militarized; and the other realities of electronic and nuclear warfare are inescapable. These are the technologies that promise ultimate mobility and perfect exchange—and incidentally enable tourism, that perfect practice of mobility and exchange, to emerge as one of the world's largest single industries.

The new technologies affect the social relations of both sexuality and of reproduction, and not always in the same ways. The close ties of sexuality and instrumentality, of views of the body as a kind of private satisfaction- and utility-maximizing machine, are described nicely in sociobiological origin stories that stress a genetic calculus and explain the inevitable dialectic of domination of male and female gender roles.[19] These sociobiological stories depend on a high-tech view of the body as a biotic component or cybernetic communications system. Among the many transformations of reproductive situations is the medical one, where women's bodies have boundaries newly permeable to both "visualization" and "intervention". Of course, who controls the interpretation of bodily boundaries in medical hermeneutics is a major feminist issue. The speculum served as an icon of women's claiming their bodies in the 1970S; that handcraft tool is inadequate to express our needed body politics in the negotiation of reality in the practices of cyborg reproduction. Self-help is not enough. The technologies of visualization recall the important cultural practice of hunting with the camera and the deeply predatory nature of a photographic consciousness.[20] Sex, sexuality, and reproduction are central actors in high-tech myth systems structuring our imaginations of personal and social possibility.

Another critical aspect of the social relations of the new technologies is the reformulation of expectations, culture, work, and reproduction for the large scientific and technical work-force. A major social and political danger is the formation of a strongly bimodal social structure, with the masses of women and men of all ethnic groups, but especially people of color, confined to a homework economy, illiteracy of several varieties, and general redundancy and impotence, controlled by high-tech repressive apparatuses ranging from entertainment to surveillance and disappearance. An adequate socialist-feminist politics should address women in the privileged occupational categories, and particularly in the production of science and technology that constructs scientific-technical discourses, processes, and objects.[21]

This issue is only one aspect of enquiry into the possibility of a feminist science, but it is important. What kind of constitutive role in the production of knowledge, imagination, and practice can new groups doing science have? How can these groups be allied with progressive social and political movements? What kind of political accountability can be constructed to the women together across the scientific-technical hierarchies separating us? Might there be ways of developing feminist science/technology politics in alliance with and-military science facility conversion action groups? Many scientific and technical workers in Silicon Valley, the high-tech cowboys included, do not want to work on military science.[22] Can these personal preferences and cultural tendencies be welded into progressive politics among this professional middle class in which women, including women of color, are coming to be fairly numerous?

4. WOMEN IN THE INTEGRATED CIRCUIT

Let me summarize the picture of women's historical locations in advanced industrial societies, as these positions have been restructured partly through the social relations of science and technology. If it was ever possible ideologically to characterize women's lives by the distinction of public and private domains—suggested by images of the division of working-class life into factory and home, of bourgeois life into market and home, and of gender existence into personal and political realms—it is now a totally misleading ideology, even to show how both terms of these dichotomies construct each other in practice and in theory. I prefer a network ideological image, suggesting the profusion of spaces and identities and the permeability of boundaries in the personal body and in the body politic. "Networking" is both a feminist practice and a multinational corporate strategy—weaving is for oppositional cyborgs.

So let me return to the earlier image of the informatics of domination and trace one vision of women's "place" in the integrated circuit, touching only a few idealized social locations seen primarily from the point of view of advanced capitalist societies: Home, Market, Paid Work Place, State, School, Clinic-Hospital, and Church. Each of these idealized spaces is logically and practically implied in every other locus, perhaps analogous to a holographic photograph. I want to suggest the impact of the social relations mediated and enforced by the new technologies in order to help formulate needed analysis and practical work. However, there is no "place" for women in these networks, only geometries of difference and contradiction crucial to women's cyborg identities. If we learn how to read these webs of power and social life, we might learn new couplings, new coalitions. There is no way to read the following list from a standpoint of "identification", of a unitary self. The issue is dispersion. The task is to survive in the diaspora.

Home: Women-headed households, serial monogamy, flight of men, old women alone, technology of domestic work, paid homework, re-emergence of home sweat-shops, home-based businesses and telecommuting, electronic cottage, urban homelessness, migration, module architecture, reinforced (simulated) nuclear family, intense domestic violence.

Market: Women's continuing consumption work, newly targeted to buy the profusion of new production from the new technologies (especially as the competitive race among industrialized and industrializing nations to avoid dangerous mass unemployment necessitates finding ever bigger new markets for ever less clearly needed commodities); bimodal buying power, coupled with advertising targeting of the numerous affluent groups and neglect of the previous mass markets; growing importance of informal markets in labour and commodities parallel to high-tech, affluent market structures; surveillance systems through electronic funds transfer; intensified market abstraction (commodification) of experience, resulting in ineffective utopian or equivalent cynical theories of community; extreme mobility (abstraction) of marketing/financing systems; inter-penetration of sexual and labour markets; intensified sexualization of abstracted and alienated consumption.

Paid Work Place: Continued intense sexual and racial division of labour, but considerable growth of membership in privileged occupational categories for many white women and people of colour; impact of new technologies on women's work in clerical, service, manufacturing (especially textiles), agriculture, electronics; international restructuring of the working classes; development of new time arrangements to facilitate the homework economy (flex-time, part-time, over-time, no time); homework and out work; increased pressures for two-tiered wage structures; significant numbers of people in cash-dependent populations worldwide with no experience or no further hope of stable employment; most labour "marginal" or "feminized".

State: Continued erosion of the welfare state; decentralizations with increased surveillance and control; citizenship by telematics; imperialism and political power broadly in the form of information rich/information poor differentiation; increased high-tech militarization increasingly opposed by many social groups; reduction of civil service jobs as a result of the growing capital intensification of office work, with implications for occupational mobility for women of colour; growing privatization of material and ideological life and culture; close integration of privatization and militarization, the high-tech forms of bourgeois capitalist personal and public life; invisibility of different social groups to each other, linked to psychological mechanisms of belief in abstract enemies.

School: Deepening coupling of high-tech capital needs and public education at all levels, differentiated by race, class, and gender; managerial classes involved in educational reform and refunding at the cost of remaining progressive educational democratic structures for children and teachers; education for mass ignorance and repression in technocratic and militarized culture; growing and-science mystery cults in dissenting and radical political movements; continued relative scientific illiteracy among white women and people of colour; growing industrial direction of education (especially higher education) by science-based multinationals (particularly in electronics- and biotechnology-dependent companies); highly educated, numerous elites in a progressively bimodal society.

Clinic-hospital: Intensified machine-body relations; renegotiations of public metaphors which channel personal experience of the body, particularly in relation to reproduction, immune system functions, and "stress" phenomena; intensification of reproductive politics in response to world historical implications of women's unrealized, potential control of their relation to reproduction; emergence of new, historically specific diseases; struggles over meanings and means of health in environments pervaded by high technology products and processes; continuing feminization of health work; intensified struggle over state responsibility for health; continued ideological role of popular health movements as a major form of American politics.

Church: Electronic fundamentalist "super-saver" preachers solemnizing the union of electronic capital and automated fetish gods; intensified importance of churches in resisting the militarized state; central struggle over women's meanings and authority in religion; continued relevance of spirituality, intertwined with sex and health, in political struggle.

The only way to characterize the informatics of domination is as a massive intensification of insecurity and cultural impoverishment, with common failure of subsistence networks for the most vulnerable. Since much of this picture interweaves with the social relations of science and technology, the urgency of a socialist-feminist politics addressed to science and technology is plain. There is much now being done, and the grounds for political work are rich. For example, the efforts to develop forms of collective struggle for women in paid work, like SEIU's District 925 (Service Employees International Union's office worker's organization in the US), should be a high priority for all of us. These efforts are profoundly tied to technical restructuring of labor processes and reformations of working classes. These efforts also are providing understanding of a more comprehensive kind of labor organization, involving community, sexuality, and family issues never privileged in the largely white male industrial unions.

The structural rearrangements related to the social relations of science and technology evoke strong ambivalence. But it is not necessary to be ultimately depressed by the implications of late 20th-century women's relation to all aspects of work, culture, production of knowledge, sexuality, and reproduction. For excellent reasons, most Marxisms see domination best and have trouble understanding what can only look like false consciousness and people's complicity in their own domination in late capitalism. It is crucial to remember that what is lost, perhaps especially from women's points of view, is often virulent forms of oppression, nostalgically naturalized in the face of current violation. Ambivalence towards the disrupted unities mediated by high-tech culture requires not sorting consciousness into categories of clear-sighted critique grounding a solid political epistemology' versus "manipulated false consciousness", but subtle understanding of emerging pleasures, experiences, and powers with serious potential for changing the rules of the game.

There are grounds for hope in the emerging bases for new kinds of unity across race, gender, and class, as these elementary units of socialist-feminist analysis themselves suffer protean transformations. Intensifications of hardship experienced worldwide in connection with the social relations of science and technology are severe. But what people are experiencing is not transparently clear, and we lack sufficiently subtle connections for collectively building effective theories of experience. Present efforts—Marxist, psychoanalytic, feminist, anthropological—to clarify even "our" experience are rudimentary.

I am conscious of the odd perspective provided by my historical position—a PhD in biology for an Irish Catholic girl was made possible by Sputnik's impact on US national science-education policy. I have a body and mind as much constructed by the post-Second World War arms race and cold war as by the women's movements. There are more grounds for hope in focusing on the contradictory effects of politics designed to produce loyal American technocrats, which also produced large numbers of dissidents, than in focusing on the present defeats.

The permanent partiality of feminist points of view has consequences for our expectations of forms of political organization and participation. We do not need a totality in order to work well. The feminist dream of a common language, like all dreams for a perfectly true language, of perfectly faithful naming of experience, is a totalizing and imperialist one. In that sense, dialectics too is a dream language, longing to resolve contradiction. Perhaps, ironically, we can learn from our fusions with animals and machines how not to be Man, the embodiment of Western logos. From the point of view of pleasure in these potent and taboo fusions, made inevitable by the social relations of science and technology, there might indeed be a feminist science.

5. CYBORGS: A MYTH OF POLITICAL IDENTITY

I want to conclude with a myth about identity and boundaries which might inform late 20th-century political imaginations. I am indebted in this story to writers like Joanna Russ, Samuel R. Delany, John Varley, James Tiptree, Jr., Octavia Butler, Monique Wittig, and Vonda McIntyre.[23] These are our storytellers exploring what it means to be embodied in high-tech worlds. They are theorists for cyborgs. Exploring conceptions of bodily boundaries and social order, the anthropologist Mary Douglas (1966, 1970) should be credited with helping us to consciousness about how fundamental body imagery is to world view, and so to political language.

French feminists like Luce Irigaray and Monique Wittig, for all their differences, know how to write the body; how to weave eroticism, cosmology, and politics from imagery of embodiment, and especially for Wittig, from imagery of fragmentation and reconstitution of bodies.[24]

American radical feminists like Susan Griffon, Audre Lorde, and Adrienne Rich have profoundly affected our political imaginations—and perhaps restricted too much what we allow as a friendly body and political language.[25] They insist on the organic, opposing it to the technological. But their symbolic systems and the related positions of ecofeminism and feminist paganism, replete with organicisms, can only be understood in Sandoval's terms as oppositional ideologies fitting the late 20th century. They would simply bewilder anyone not pre-occupied with the machines and consciousness of late capitalism. In that sense they are part of the cyborg world. But there are also great riches for feminists in explicitly embracing the possibilities inherent in the breakdown of clean distinctions between organism and machine and similar distinctions structuring the Western self. It is the simultaneity of breakdowns that cracks the matrices of domination and opens geometric possibilities. What might be learned from personal and political "technological" pollution? I look briefly at two overlapping groups of texts for their insight into the construction of a potentially helpful cyborg myth: Constructions of women of color and monstrous selves in feminist science fiction.

Earlier I suggested that "women of colour" might be understood as a cyborg identity, a potent subjectivity synthesized from fusions of outsider identities and, in the complex political-historical layerings of her "biomythography", Zami (Lorde, 1982; King, 1987a, 1987b). There are material and cultural grids mapping this potential. Audre Lorde (1984) captures the tone in the title of her *Sister Outsider*. In my political myth, Sister Outsider is the offshore woman, whom US workers, female and feminized, are supposed to regard as the enemy preventing their solidarity, threatening their security. Onshore, inside the boundary of the United States, Sister Outsider is a potential amidst the races and ethnic identities of women manipulated for division, competition, and exploitation in the same industries. “Women of colour” are the preferred labor force for the science-based industries, the real women for whom the worldwide sexual market, labor market, and politics of reproduction kaleidoscope into daily life. Young Korean women hired in the sex industry and in electronics assembly are recruited from high schools, educated for the integrated circuit. Literacy, especially in English, distinguishes the “cheap” female labor so attractive to the multinationals.

Contrary to orientalist stereotypes of the “oral primitive”, literacy is a special mark of women of color, acquired by US black women as well as men through a history of risking death to learn and to teach reading and writing. Writing has a special significance for all colonized groups. Writing has been crucial to the Western myth of the distinction between oral and written cultures, primitive and civilized mentalities, and more recently to the erosion of that distinction in “post-modernist” theories attacking the phallogocentrism of the West, with its worship of the monotheistic, phallic, authoritative, and singular work, the unique and perfect name.[26] Contests for the meanings of writing are a major form of contemporary political struggle. Releasing the play of writing is deadly serious. The poetry and stories of US women of color are repeatedly about writing, about access to the power to signify; but this time that power must be neither phallic nor innocent. Cyborg writing must not be about the Fall, the imagination of a once-upon-a-time wholeness before language, before writing, before Man. Cyborg writing is about the power to survive, not on the basis of original innocence, but on the basis of seizing the tools to mark the world that marked them as other.

The tools are often stories, retold stories, versions that reverse and displace the hierarchical dualisms of naturalized identities. In retelling origin stories, cyborg authors subvert the central myths of origin of Western culture. We have all been colonized by those origin myths, with their longing for fulfilment in apocalypse. The phallogocentrie origin stories most crucial for feminist cyborgs are built into the literal technologies—technologies that write the world, biotechnology and microelectronics—that have recently textualized our bodies as code problems on the grid of C^3I. Feminist cyborg stories have the task of recoding communication and intelligence to subvert command and control.

Figuratively and literally, language politics pervade the struggles of women of color; and stories about language have a special power in the rich contemporary writing by US women of color. For example, retellings of the story of the indigenous woman Malinche, mother of the mesdzo “bastard” race of the new world, master of languages, and mistress of Cortes, carry special meaning for Chicana constructions of identity. Cherríe Moraga (1983) in *Loving in the War Years* explores the themes of identity when one never possessed the original language, never told the original story, never resided in the harmony of legitimate heterosexuality in the garden of culture, and so cannot base identity on a myth or a fall from innocence and right to natural names, mother's or father's.[27] Moraga's writing, her superb literacy, is presented in her poetry as the same kind of violation as Malinche's mastery of the conqueror's language—a violation, an illegitimate production, that allows survival. Moraga's language is not "whole"; it is self-consciously spliced, a chimera of English and Spanish, both conqueror's languages. But it is this chimeric monster, without claim to an original language before violation, that crafts the erotic, competent, potent identities of women of color. Sister Outsider hints at the possibility of world survival not because of her innocence, but because of her ability to live on the boundaries, to write without the founding myth of original wholeness, with its inescapable apocalypse of final return to a deathly oneness that Man has imagined to be the innocent and all-powerful Mother, freed at the End from another spiral of appropriation by her son. Writing marks Moraga's body, affirms it as the body of a woman of color, against the possibility of passing into the unmarked category of the Anglo father or into the orientalist myth of "original illiteracy" of a mother that never was. Malinche was mother here, not Eve before eating the forbidden fruit. Writing affirms Sister Outsider, not the Woman-before-the-Fall-into-Writing needed by the phallogocentric Family of Man.

Writing is pre-eminently the technology of cyborgs, etched surfaces of the late 20th century. Cyborg politics is the struggle for language and the struggle against perfect communication, against the one code that translates all meaning perfectly, the central dogma of phallogocentrism. That is why cyborg politics insist on noise and advocate pollution, rejoicing in the illegitimate fusions of animal and machine. These are the couplings which make Man and Woman so problematic, subverting the structure of desire, the force imagined to generate language and gender, and so subverting the structure and modes of reproduction of "Western" identity, of nature and culture, of mirror and eye, slave and master, body and mind. "We" did not originally choose to be cyborgs, but choice grounds a liberal politics and epistemology that imagines the reproduction of individuals before the wider replications of "texts".

From the perspective of cyborgs, freed of the need to ground politics in "our" privileged position of the oppression that incorporates all other dominations, the innocence of the merely violated, the ground of those closer to nature, we can see powerful possibilities. Feminisms and Marxisms have run aground on Western epistemological imperatives to construct a revolutionary subject from the perspective of a hierarchy of oppressions and/or a latent position of moral superiority, innocence, and greater closeness to nature. With no available original dream of a common language or original symbiosis promising protection from hostile "masculine" separation, but written into the play of a text that has no finally privileged reading or salvation history, to recognize "oneself" as fully implicated in the world, frees us of the need to root politics in identification, vanguard parties, purity, and mothering. Stripped of identity, the bastard race teaches about the power of the margins and the importance of a mother like Malinche. Women of color have transformed her from the evil mother of masculinist fear into the originally literate mother who teaches survival.

This is not just literary deconstruction, but liminal transformation. Every, story that begins with original innocence and privileges the return to wholeness imagines the drama of life to be individuation, separation, the birth of the self, the tragedy of autonomy, the fall into writing, alienation; that is, war, tempered by imaginary respite in the bosom of the other. These plots are ruled by a reproductive politics—rebirth without flaw, perfection, abstraction. In this plot women are imagined either better or worse off, but all agree they have less selfhood, weaker individuation, more fusion to the oral, to Mother, less at stake in masculine autonomy. But there is another route to having less at stake in masculine autonomy, a route that does not pass through woman, primitive, zero, the mirror stage and its imaginary. It passes through women and other present-tense, illegitimate cyborgs, not of Woman born, who refuse the ideological resources of victimization so as to have a real life. These cyborgs are the people who refuse to disappear on cue, no matter how many times a "western" commentator remarks on the sad passing of another primitive, another organic group done in by "Western" technology, by writing.[28] These real-life cyborgs (for example, the Southeast Asian village women workers in Japanese and US electronics firms described by Aihwa Ong) are actively rewriting the texts of their bodies and societies. Survival is the stakes in this play of readings.

To recapitulate, certain dualisms have been persistent in Western traditions; they have all been systemic to the logics and practices of domination of women, people of colour, nature, workers, animals—in short, domination of all constituted as others, whose task is to mirror the self. Chief among these troubling dualisms are self/other, mind/body, culture/nature, male/female, civilized/primitive, reality/appearance, whole/part, agent/resource, maker/made, active/passive, right/wrong, truth/illusion, total/partial, God/man. The self is the One who is not dominated, who knows that by the service of the other, the other is the one who holds the future, who knows that by the experience of domination, which gives the lie to the autonomy of the self. To be One is to be autonomous, to be powerful, to be God; but to be One is to be an illusion, and so to be involved in a dialectic of apocalypse with the other. Yet to be other is to be multiple, without clear boundary, frayed, insubstantial. One is too few, but two are too many.

High-tech culture challenges these dualisms in intriguing ways. It is not clear who makes and who is made in the relation between human and machine. It is not clear what is mind and what body in machines that resolve into coding practices. In so far as we know ourselves in both formal discourse (for example, biology) and in daily practice (for example, the homework economy in the integrated circuit), we find ourselves to be cyborgs, hybrids, mosaics, and chimeras. Biological organisms have become biotic systems, communications devices like others. There is no fundamental, ontological separation in our formal knowledge of machine and organism, of technical and organic. The replicant Rachel in the Ridley Scott film *Blade Runner* stands as the image of a cyborg culture's fear, love, and confusion.

One consequence is that our sense of connection to our tools is heightened. The trance state experienced by many computer users has become a staple of science-fiction film and cultural jokes. Perhaps paraplegics and other severely handicapped people can (and sometimes do) have the most intense experiences of complex hybridization with other communication devices.[29] Anne McCaffrey's pre-feminist *The Ship Who Sang* (1969) explored the consciousness of a cyborg, hybrid of girl's brain and complex machinery, formed after the birth of a severely handicapped child. Gender, sexuality, embodiment, skill: All were reconstituted in the story. Why should our bodies end at the skin, or include at best other beings encapsulated by skin? From the 17th century till now, machines could be animated—given ghostly souls to make them speak or move or to account for their orderly development and mental capacities. Or organisms could be mechanized—reduced to body understood as resource of mind. These machine/organism relationships are obsolete, unnecessary. For us, in imagination and in other practice, machines can be prosthetic devices, intimate components, friendly selves. We don't need organic holism to give impermeable wholeness, the total woman and her feminist variants (mutants?). Let me conclude this point by a very partial reading of the logic of the cyborg monsters of my second group of texts, feminist science fiction.

The cyborgs populating feminist science fiction make very problematic the statuses of man or woman, human, artifact, member of a race, individual entity, or body. Katie King clarifies how pleasure in reading these fictions is not largely based on identification. Students facing Joanna Russ for the first time, students who have learned to take modernist writers like James Joyce or Virginia Woolf without flinching, do not know what to make of The *Adventures of Alyx* or *The Female Man*, where characters refuse the reader's search for innocent wholeness while granting the wish for heroic quests, exuberant eroticism, and serious politics. *The Female Man* is the story of four versions of one genotype, all of whom meet, but even taken together do not make a whole, resolve the dilemmas of violent moral action, or remove the growing scandal of gender. The feminist science fiction of Samuel R. Delany, especially *Tales of Neveyon*, mocks stories of origin by redoing the neolithic revolution, replaying the founding moves of Western civilization to subvert their plausibility. James Tiptree, Jr., an author whose fiction was regarded as particularly manly until her "true" gender was revealed, tells tales of reproduction based on non-mammalian technologies like alternation of generations of male brood pouches and male nurturing. John Varley constructs a supreme cyborg in his arch-feminist exploration of Gaea, a mad goddess-planet-trickster-old woman-technological device on whose surface an extraordinary array of post-cyborg symbioses are spawned. Octavia Butler writes of an African sorceress pitting her powers of transformation against the genetic manipulations of her rival (*Wild Seed*), of time warps that bring a modern US black woman into slavery where her actions in relation to her white master-ancestor determine the possibility of her own birth (*Kindred*), and of the illegitimate insights into identity and community of an adopted cross-species child who came to know the enemy as self (*Survivor*). In Dawn (1987), the first instalment of a series called *Xenogenesis*, Butler tells the story of Lilith Iyapo, whose personal name recalls Adam's first and repudiated wife and whose family name marks her status as the widow of the son of Nigerian immigrants to the US. A black woman and a mother whose child is dead, Lilith mediates the transformation of humanity through genetic exchange with extra-terrestrial lovers/rescuers/destroyers/genetic engineers, who reform earth's habitats after the nuclear holocaust and coerce surviving humans into intimate fusion with them. It is a novel that interrogates reproductive, linguistic, and nuclear politics in a mythic field structured by late 20th-century race and gender.

Because it is particularly rich in boundary transgressions, Vonda McIntyre's *Superluminal* can close this truncated catalogue of promising and dangerous monsters who help redefine the pleasures and politics of embodiment and feminist writing. In a fiction where no character is "simply" human, human status is highly problematic. Orca, a genetically altered diver, can speak with killer whales and survive deep ocean conditions, but she longs to explore space as a pilot, necessitating bionic implants jeopardizing her kinship with the divers and cetaceans. Transformations are effected by virus vectors carrying a new developmental code, by transplant surgery, by implants of microelectronic devices, by analogue doubles, and other means. Lacnea becomes a pilot by accepting a heart implant and a host of other alterations allowing survival in transit at speeds exceeding that of light. Radu Dracul survives a virus-caused plague in his outerworld planet to find himself with a time sense that changes the boundaries of spatial perception for the whole species. All the characters explore the limits of language; the dream of communicating experience; and the necessity of limitation, partiality, and intimacy even in this world of protean transformation and connection. Superluminal stands also for the defining contradictions of a cyborg world in another sense; it embodies textually the intersection of feminist theory and colonial discourse in the science fiction I have alluded to in this chapter. This is a conjunction with a long history that many "First World" feminists have tried to repress, including myself in my readings of *Superluminal* before being called to account by Zoe Sofoulis, whose different location in the world system's informatics of domination made her acutely alert to the imperialist moment of all science fiction cultures, including women's science fiction. From an Australian feminist sensitivity, Sofoulis remembered more readily McIntyre's role as writer of the adventures of Captain Kirk and Spock in TV's *Star Trek* series than her rewriting the romance in *Superluminal*.

Monsters have always defined the limits of community in Western imaginations. The Centaurs and Amazons of ancient Greece established the limits of the centerd polis of the Greek male human by their disruption of marriage and boundary pollutions of the warrior with animality and woman. Unseparated twins and hermaphrodites were the confused human material in early modern France who grounded discourse on the natural and supernatural, medical and legal, portents and diseases—all crucial to establishing modern identity.[30] The evolutionary and behavioral sciences of monkeys and apes have marked the multiple boundaries of late 20th-century industrial identities. Cyborg monsters in feminist science fiction define quite different political possibilities and limits from those proposed by the mundane fiction of Man and Woman.

There are several consequences to taking seriously the imagery of cyborgs as other than our enemies. Our bodies, ourselves; bodies are maps of power and identity. Cyborgs are no exception. A cyborg body is not innocent; it was not born in a garden; it does not seek unitary identity and so generate antagonistic dualisms without end (or until the world ends); it takes irony for granted. One is too few, and two is only one possibility. Intense pleasure in skill, machine skill, ceases to be a sin, but an aspect of embodiment. The machine is not an *it* to be animated, worshipped, and dominated. The machine is us, our processes, an aspect of our embodiment. We can be responsible for machines; *they* do not dominate or threaten us. We are responsible for boundaries; we are they. Up till now (once upon a time), female embodiment seemed to be given, organic, necessary; and female embodiment seemed to mean skill in mothering and its metaphoric extensions. Only by being out of place could we take intense pleasure in machines, and then with excuses that this was organic activity after all, appropriate to females. Cyborgs might consider more seriously the partial, fluid, sometimes aspect of sex and sexual embodiment. Gender might not be global identity after all, even if it has profound historical breadth and depth.

The ideologically charged question of what counts as daily activity, as experience, can be approached by exploiting the cyborg image. Feminists have recently claimed that women are given to dailiness, that women more than men somehow sustain daily life, and so have a privileged epistemological position potentially. There is a compelling aspect to this claim, one that makes visible unvalued female activity and names it as the ground of life. But *the* ground of life? What about all the ignorance of women, all the exclusions and failures of knowledge and skill? What about men's access to daily competence, to knowing how to build things, to take them apart, to play? What about other embodiments? Cyborg gender is a local possibility taking a global vengeance. Race, gender, and capital require a cyborg theory of wholes and parts. There is no drive in cyborgs to produce total theory, but there is an intimate experience of boundaries, their construction, and deconstruction. There is a myth system waiting to become a political language to ground one way of looking at science and technology and challenging the informatics of domination—in order to act potently.

One last image organisms and organismic, holistic politics depend on metaphors of rebirth and invariably call on the resources of reproductive sex. I would suggest that cyborgs have more to do with regeneration and are suspicious of the reproductive matrix and of most birthing. For salamanders, regeneration after injury, such as the loss of a limb, involves regrowth of structure and restoration of function with the constant possibility of twinning or other odd topographical productions at the site of former injury. The regrown limb can be monstrous, duplicated, potent. We have all been injured, profoundly. We require regeneration, not rebirth, and the possibilities for our reconstitution include the utopian dream of the hope for a monstrous world without gender.

Cyborg imagery can help express two crucial arguments in this essay: First, the production of universal, totalizing theory is a major mistake that misses most of reality, probably always, but certainly now; and second, taking responsibility for the social relations of science and technology means refusing an anti-science metaphysics, a demonology of technology, and so means embracing the skilful task of reconstructing the boundaries of daily life, in partial connection with others, in communication with all of our parts. It is not just that science and technology are possible means of great human satisfaction, as well as a matrix of complex dominations. Cyborg imagery can suggest a way out of the maze of dualisms in which we have explained our bodies and our tools to ourselves. This is a dream not of a common language, but of a powerful infidel heteroglossia. It is an imagination of a feminist speaking in tongues to strike fear into the circuits of the supersavers of the new right. It means both building and destroying machines, identities, categories, relationships, space stories. Though both are bound in the spiral dance, I would rather be a cyborg than a goddess.

ENDNOTES

1. Useful references to left and/or feminist radical science movements and theory and to biological/biotechnical issues include: Bleier (1984, 1986), Fausto-Sterling (1985), Gould (1981), Harding (1986), Hubbard et al. (1982), Keller (1985), Lewontin et al. (1984), *Radical Science* journal (became *Science as Culture* in 1987), 26 Freegrove Road, London N7 9RQ; *Science for the People*, 897 Main St, Cambridge, MA 02139.
2. Starting points for left and/or feminist approaches to technology and politics include: Athanasiou (1987), Cohn (1987a, b), Cowan (1983), Edwards (1985), Rothschild (1983), Traweek (1988), Weizenbaum (1976), Winner (1977, 1986), Winograd and Flores (1986), Young and Levidow (1981, 1985), Zimmerman (1983). *Global Electronics Newsletter*, 867 West Dana St, no. 204, Mountain View, CA 94041; *Processed World*, 55 Sutter St, San Francisco, CA 94104.

3. A provocative, comprehensive argument about the politics and theories of "postmodernism" is made by Fredric Jameson (1984), who argues that postmodernism is not an option, a style among others, but a cultural dominant requiring radical reinvention of left politics from within; there is no longer any place from without that gives meaning to the comforting fiction of critical distance. Jameson also makes clear why one cannot be for or against postmodernism, an essentially moralist move. My position is that feminists (and others) need continuous cultural reinvention, post-modernist critique, and historical materialism; only a cyborg would have a chance. The old dominations of white capitalist patriarchy seem nostalgically innocent now: they normalized heterogeneity, into man and woman, white and black, for example. "Advanced capitalism" and post-modernism release heterogeneity without a norm, and we are flattened, without subjectivity, which requires depth, even unfriendly and drowning depths. It is time to write *The Death of the Clinic*. The clinics methods required bodies and works; we have texts and surfaces. Our dominations don't work by medicalization and normalization any more; they work by networking, communications redesign, stress management. Normalization gives way to automation, utter redundancy. Michel Foucault's *Birth of the Clinic* (1963), *History of Sexuality* (1976), and *Discipline and Punish* (1975) name a form of power at its moment of implosion. The discourse of biopolitics gives way to technobabble, the language of the spliced substantive; no noun is left whole by the multinationals. These are their names, listed from one issue of Science: Tech-Knowledge, Genentech, Allergen, Hybritech, Compupro, Genen-cor, Syntex, Allelix, Agrigenetics Corp., Syntro, Codon, Repligen, MicroAngelo from Scion Corp., Pencom Data, Inter Systems, Cyborg Corp., Statcom Corp., Intertec. If we are imprisoned by language, then escape from that prison-house requires language poets, a kind of cultural restriction enzyme to cut the code; cyborg heteroglossia is one form of radical cultural politics. For cyborg poetry, see Perloff (1984); Fraser (1984). For feminist modernist/postmodernist "cyborg" writing, see HOW(ever), 871 Corbett Ave, San Francisco, CA 94131.
4. Baudrillard (1983). Jameson (1984: 66) points out that Plato's definition of the simulacrum is the copy for which there is no original, i.e., the world of advanced capitalism, of pure exchange. See *Discourse* 9 (Spring/Summer 1987) for a special issue on technology (cybernetics, ecology, and the post-modern imagination).
5. A practice at once both spiritual and political that linked guards and arrested anti-nuclear demonstrators in the Alameda County jail in California in the early 1980s.
6. For ethnographic accounts and political evaluations, see Epstein (1993); Sturgeon (1986). Without explicit irony, adopting the spaceship

earth/whole earth logo of the planet photographed from space, set off by the slogan "Love Your Mother", the May 1987 Mothers and Others Day action at the nuclear weapons testing facility in Nevada none the less took account of the tragic contradictions of views of the earth. Demonstrators applied for official permits to be on the land from officers of the Western Shoshone tribe, whose territory was invaded by the US government when it built the nuclear weapons test ground in the 1950s. Arrested for trespassing, the demonstrators argued that the police and weapons facility personnel, without authorization from the proper officials, were the trespassers. One affinity group at the women's action called themselves the Surrogate Others; and in solidarity with the creatures forced to tunnel in the same ground with the bomb,they enacted a cyborgian emergence from the constructed body of a large, non-heterosexual desert worm.

7. Powerful developments of coalition politics emerge from "Third World" speakers, speaking from nowhere, the displaced centre of the universe, earth: "We live on the third planet from the sun"—*Sun Poem* by Jamaican writer, Edward Kamau Braithwaite, review by Mackey (1984). Contributors to Smith (1983) ironically subvert naturalized identities precisely while constructing a place from which to speak called home. See especially Reagon (in Smith 1983: 356–68). Trinh T. Minh-ha (1986–87).
8. Hooks (1981, 1984); Hull *et al*. (1982). Bambara (1981) wrote an extraordinary novel in which the women of color theatre group, The Seven Sisters, explores a form of unity. See analysis by Butler-Evans (1987).
9. On orientalism in feminist works and elsewhere, see Lowe (1986); Mohanty (1984); Said (1978); Many Voices, *One Chant: Black Feminist Perspectives* (1984).
10. Katie King (1986, 1987a) has developed a theoretically sensitive treatment of the workings of feminist taxonomies as genealogies of power in feminist ideology and polemic. King examines Jaggar's (1983) problematic example of taxonomizing feminisms to make a little machine producing the desired final position. My caricature here of socialist and radical feminism is also an example.
11. The central role of object relations versions of psychoanalysis and related strong universalizing moves in discussing reproduction, caring work and mothering in many approaches to epistemology underline their authors' resistance to what I am calling postmodernism. For me, both the universalizing moves and these versions of psychoanalysis make analysis of "women's place in the integrated circuit" difficult and lead to systematic difficulties in accounting for or even seeing major aspects of the construction of gender and gendered social life. The feminist standpoint argument has been developed by: Flax (1983), Harding (1986), Harding and Hintikka (1983), Hartsock (1983a, b), O'Brien (1981), Rose (1983),

Smith (1974, 1979). For rethinking theories of feminist materialism and feminist standpoints in response to criticism, see Harding (1986, pp. 163-96), Hartsock (1987) and H. Rose (1986).

12. I make an argumentative category error in "modifying" MacKinnon's positions with the qualifier "radical", thereby generating my own reductive critique of extremely heterogeneous writing, which does explicitly use that label, by my taxonomically interested argument about writing which does not use the modifier and which brooks no limits and thereby adds to the various dreams of a common, in the sense of univocal, language for feminism. My category error was occasioned by an assignment to write from a particular taxonomic position which itself has a heterogeneous history, socialist-feminism, for *Socialist Review*. A critique indebted to MacKinnon, but without the reductionism and with an elegant feminist account of Foucault's paradoxical conservatism on sexual violence (rape), is de Lauretis (1985; see also 1986a, b, pp. 1–19). A theoretically elegant feminist social-historical examination of family violence, that insists on women's, men's and children's complex agency without losing sight of the material structures of male domination, race and class, is Gordon (1988).
13. This chart was published in 1985. My previous efforts to understand biology as a cybernetic command-control discourse and organisms as "natural-technical objects of knowledge" were Haraway (1979, 1983, 1984). The 1979 version of this dichotomous chart appears in Haraway (1991), Ch. 3; for a 1989 version, see Ch. 10. The differences indicate shifts in argument.
14. For progressive analyses and action on the biotechnology debates: *GeneWatch, A Bulletin of the Committee far Responsible Genetics*, 5 Doane St, 4th Floor, Boston, MA 02109; Genetic Screening Study Group (formerly the Sociobiology Study Group of Science for the People), Cambridge, MA; Wright (1982, 1986); Yoxen (1983).
15. Starting references for "women in the integrated circuit": D'Onofrio-Flores and Pfafflin (1982), Fernandez-Kelly (1983), Fuentes and Ehrenreich (1983), Grossman (1980), Nash and Fernandez-Kelly (1983), Ong (1987), Science Policy Research Unit (1982).
16. For the "homework economy outside the home" and related arguments: Burr (1982); Collins (1982); Gordon (1983); Gordon and Kimball (1985); Gregory and Nussbaum (1982); Microelectronics Group (1980); Piven and Coward (1982); Reskin and Hartmann (1986); Stacey (1987); S. Rose (1986); Stallard et al. (1983); *Women and Poverty* (1984), which includes a useful organization and resource list.
17. The conjunction of the Green Revolution's social relations with biotechnologies like plant genetic engineering makes the pressures on land in the Third World increasingly intense. AID's estimates (*New York Times*,

14 October 1984) used at the 1984 World Food Day are that in Africa, women produce about 90% of rural food supplies, about 60–80% in Asia, and provide 40% of agricultural labor in the Near East and Latin America. Blumberg charges that world organizations' agricultural politics, as well as those of multinationals and national governments in the Third World, generally ignore fundamental issues in the sexual division of labor. The present tragedy of famine in Africa might owe as much to male supremacy as to capitalism, colonialism and rain patterns. More accurately, capitalism and racism are usually structurally male dominant. See also Bird (1984); Blumberg (1981); Busch and Lacy (1983); Hacker (1984); Hacker and Bovit (1981); International Fund for Agricultural Development (1985); Sachs (1983); Wilfred (1982).

18. See also Enloe (1983a, b).
19. For a feminist version of this logic, see Hardy (1981). For an analvsis of scientific women's story-telling practices, especially in relation to sociobiology in evolutionary debates around child abuse and infanticide, see Haraway (1991), Ch. 5.
20. For the moment of transition of hunting with guns to hunting with cameras in the construction of popular meanings of nature for an American urban immigrant public, see Haraway (1984–5, 1989b), Nash (1979), Preston (1984), Sontag (1977).
21. For guidance for thinking about the political/cultural/racial implications of the history of women doing science in the US see: Haas and Perucci (1984); Hacker (1981); Haraway (1989); Keller (1983); National Science Foundation (1988); Rossiter (1982); Schiebinger (1987).
22. Markoff and Siegel (1983). High Technology Professionals for Peace and Computer Professionals for Social Responsibility are promising organizations.
23. An abbreviated list of feminist science fiction underlying themes of this essay: Octavia Butler, *Wild Seed, Mind of My Mind, Kindred, Survivor*; Suzy McKee Charnas, *Motherliness*; Samuel R. Delany, the Nevérÿon series; Anne McCaffery, *The Ship Who Sang, Dinosaur Planet*; Vonda McIntyre, *Superluminal*, *Dreamsnake*; Joanna Russ, *Adventures of Alix, The Female Man*; James Tiptree, Jr, *Star Songs of an Old Primate, Up the Walls of the World*; John Varley, *Titan, Wizard, Demon*.
24. French feminisms contribute to cyborg hetcroglossia. Burke (1981); Duchen (1986); Irigaray (1977, 1979); Marks and de Courtivron (1980); *Signs* (Autumn 1981); Wittig (1973). For English translation of some currents of francophone feminism see *Feminist Issues: A Journal of Feminist Social and Political Theory*, 1980.
25. But all these poets are very complex, not least in their treatment of themes of lying and erotic, decentred collective and personal identities. Griffin (1978), Lorde (1984), Rich (1978).

26. Derrida (1976, especially part 11); Lévi-Strauss (1961, especially "The Writing Lesson"); Gates (1985); Kahn and Neumaier (1985); Ong (1982); Kramarae and Treichler (1985).
27. The sharp relation of women of color to writing as theme and politics can be approached through: Program for "The Black Woman and the Diaspora: Hidden Connections and Extended Acknowledgements", An International Literary Conference, Michigan State University, October 1985; Carby (1987); Christian (1985); Evans (1984); Fisher (1980); *Frontiers* (1980, 1983); Giddings (1985); Kingston (1977); Lerner (1973); Moraga and Anzaldúa (1981); Morgan (1984). Anglophone European and Euro-American women have also crafted special relations to their writing as a potent sign: Gilbert and Gubar (1979), Russ (1983).
28. The convention of ideologically taming militarized high technology by publicizing its applications to speech and motion problems of the disabled/differently abled takes on a special irony in monotheistic, patriarchal, and frequently anti-semitic culture when computer-generated speech allows a boy with no voice to chant the Haftorah at his bar mitzvah. See Sussman (1986). Making the always context-relative social definitions of "ableness" particularly clear, military high-tech has a way of making human beings disabled by definition, a perverse aspect of much automated battlefield and Star Wars R & D. See Welford (1 July 1986).
29. James Clifford (1985, 1988) argues persuasively for recognition of continuous cultural reinvention, the stubborn non-disappearance of those "marked" by Western imperializing practices.
30. DuBois (1982), Daston and Park (n.d.), Park and Daston (1981). The noun monster shares its root with the verb *to demonstrate*.

Chapter 5: Teaching and Transformation: Donna Haraway's "A Manifesto for Cyborgs" and Its Influence in Computer-Supported Composition Classrooms

ERIN SMITH AND CYNTHIA L. SELFE
Department of Humanities, Michigan Technological University, Houghton, MI, U.S.A.

In an increasingly global and post-modern world marked by rapid technological, political, and social change, teachers at all levels face the difficult if not impossible challenge of preparing a coming generation for a world that they, themselves, have never seen or experienced (Mead, 1970). Within this context, Donna Haraway's "Manifesto for Cyborgs" has offered a broad range of humanist teachers and scholars a challenge and the possibility of hope.

In part, it is Haraway's interdisciplinary background in philosophy, biology, and English that has made her work so important to such a wide range of scholars. She earned her Ph.D. in biology from Yale in 1976 and has since helped to articulate and explore the interconnections among language, science, and technology both as a scholar and as a teacher in the History of Consciousness program at the University of California Santa Cruz. Her major works include *Crystals, Fabrics and Fields: Metaphors of Organicism in Twentieth-Century Developmental Biology* (1976), *Primate Visions: Gender, Race, and Nature in the World of Modern Science* (1989/1992), *Simians, Cyborgs, and Women: The Reinvention of Nature* (1991a), and *Modest_Witness@Second_Millennium.FemaleMan©MeetsOncoMouse*™ (1997). Haraway's theory of "situated knowledges" (1991b), however, has also proven instrumental to feminist, post-colonial, and technology studies, emphasizing an approach to scientific inquiry that assigns agency to our "objects of knowledge" and refuses to view them as "a screen or ground or a resource, never finally as slave to the master that closes off the dialectic" (1991b: 198). Her critique of objectivity has extended to Marxist/socialist feminist and cultural theories that provide totalizing or essentializing explanations of self and society. For Haraway, "partiality" as opposed to "universality" (1991b: 195), ambiguity as opposed to certainty, provide more productive ground for both feminist theory and epistemology.

Although Haraway's scholarship has been *broadly* influential in the humanities, however, there is no discipline it has shaped more *specifically*, and more fundamentally than that of computers and composition studies as it is practiced in the United States. Part of what has made Haraway's work so appealing to teachers and scholars in this area is her preoccupation with language and the

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 159–188.

skillful deployment of metaphor. She writes "Like all neuroses, mine is rooted in the problem of metaphor, that is, the problem of the relation of bodies and language" (1991b: 185). This focus made both Haraway's approach and her insights of particular interest to composition scholars and literacy colleagues who began to grapple in the early 1980s with helping students communicate responsibly and effectively in digital contexts. Importantly, however, Haraway's work—and the work of scholars she influenced—challenged many of the nascent approaches to computer-supported composition in the United States, especially those that employed computers simply to teach skill and drills, but did not adequately address the critical dimensions of new technology or its possibilities to support more broadly transformative social and communicative relationships. For those scholars and teachers who imagined more radical possibilities for composing and communicating within electronic environments, Haraway's debt to the liberatory literacy work of Paulo Freire,"the inescapable ancestor" proved inspiring. As she noted, "I think of him as one of my fathers, or one of my brothers. I inherited his work; *we* who try to link writing and freedom projects inherited his work, collectively" (Olson, 1996).

For all of the teachers and scholars who read Haraway's germinal work—both in the specific area of computers and composition studies, as well as in the broader disciplines of social sciences and English—"*A Manifesto for Cyborgs: Science, Technology, and Socialist Feminism in the 1980s*" (1985) presented the challenge of recognizing and honoring the contradictory nature of cyborgs, to participate in building and sustaining an "ironic, political myth" (p. 65), a blasphemic, socialist-feminist identity that resists many of the negative influences of contemporary technological society and, instead, embraces "partial, contradictory, permanently unclosed constructions of personal and collective selves" (p. 75). As "a hybrid of machine and organism, a creature of social reality as well as a creature of fiction" (1985: 65) Haraway's cyborg is a metaphor of resistance, specifically opposed to the destructive social formations of racism, sexism, poverty, capitalism, violence, ecological degradation, and domination that grow out of male dominance, capitalism, and a delusional faith in the related modernist projects of science and technology. These forces, among others, Haraway notes, have helped support and construct a series of progressively problematic dualisms (nature/culture, humans/machines, and men/women) that artificially separate members of the global ecosystem, masking the fact that they are actually related by a series of complex actions and effects. This false separation, in turn, serves as both a foundational and continuing basis for increasingly destructive social, material, and industrial practices, and the related beliefs that average human beings have little responsibility to control the technologies they create and limited ability to change the technological systems within which they participate for the better.

Haraway argued that the notion of a closed, organic body is especially detrimental to women with regard to technological agency: "Only by being out of place could we take intense pleasure in machines, and then with excuses that this was organic activity after all, appropriate to females" (p. 99). Her closing declaration, "I would rather be a cyborg than a goddess" (p. 101), succinctly (and ironically) summarized her critique of essentialist feminist theories and initiated a new discourse that enabled scholars and teachers of composition—particularly feminist scholars and teachers—a very fruitful means by which to engage classroom technology issues and to approach pedagogy in computer-mediated environments from a feminist and socially conscious critical framework.

Many contemporary educators—particularly those who use computer technology to carry out their teaching and are critically aware of the difficulties that such teaching poses—have come to adopt the activist political agenda that Haraway assigned to cyborgs in 1985. Haraway's work has been central to emerging pedagogies that stress our responsibility for helping students attend to the ways in which humans are implicated in technological systems, as well as our need to understand and respond to the increasingly close relationship between computer technology and literacy—between computers and human efforts to make meaning, to code culture and to construct social systems through their signifying practices (linguistic, depictive, aural, and multimodal) in digital contexts and environments. This chapter identifies several important aspects of this transformative agenda, drawing directly from Haraway's essay—and subsequent works that have built on that germinal piece.

1. UNDERSTANDING HUMANS AND THEIR RELATIONSHIP TO TECHNOLOGICAL SYSTEMS IN LOCAL AND GLOBAL CONTEXTS

At the time that Donna Haraway's "Manifesto" was published in 1985—and for sometime thereafter as the implications of this important contribution and related works percolated through the academic communities of the social sciences and humanities—most public educators in highly industrialized countries such as the United States and Canada understood computers and computer networks in relatively simple instrumental terms as effective teaching, learning, and communication environments. Relatively few educators during this period recognized the importance of exploring with students the critical and complex responsibilities humans have for understanding and shaping such environments. Relatively few were engaged in exploring with students the ways that humans are related to, and implicated in, the global spread of computer technology—or in making students aware of the larger social, cultural, political, and economic systems of which technology is a key part. But it was just this kind of critical awareness—of "taking responsibility for the social relations of science and technology" (p. 100) and understanding technology to be "completely without innocence" (p. 67)—that formed a central tenant of the cyborg politics Haraway described in the "Manifesto".

In part, the recognition of the "Manifesto's" import was slow to take root in educational settings because industrialized nations such as the United States and Canada—the only countries in the early 1980s that could afford the large-scale integration of computers in public school classrooms—generally subscribed to a common, powerful, ideological parable—a story that linked advances in science and technology to progress in education, society, and politics. Contributing to the effects of this dominant narrative were other related fictions, historically framed in Western cultures by words like *progress*, *democracy*, and *capitalism*; as well as the common practice of appropriating "nature as a resource for . . . production," and the habit of composing Western identities and ideas of "self" in opposition to "reflections of the other" (p. 66). Given the mythic status of these intersecting narratives and their accompanying practices, it was not surprising that so many educators in the United States and Canada, especially in the first decade of computer use in public school classrooms—understood computers as instructional tools that had a great deal of potential (Hawisher et al., 1996; Selfe, 1999).

This central and unified fiction—in shorthand, Scientific + Technological Progress = Social + Economic + Educational Progress—was deeply sedimented in both public and official discourses about computer technology during the 1980s, the decade that marked the emergence of the first fully assembled microcomputers in U.S. markets. A brief look at the history of that period shows why this fiction was so dominant.

When Ronald Reagan assumed the U.S. presidency on 20 January 1981, the country was deeply mired in a stubborn recession at home. Abroad, the country was occupied with fighting a troublesome, multifront Cold War and confronting a troubling loss of economic sovereignty (Johnston & Packer, 1987).

Internationally, the political battles of the Cold War raged on in Libya, the former Soviet Union, Nicaragua, Italy, and Granada (*Annals of America, Vol. 21*, 1987: xxx–xxxvi). These Cold War political struggles were mirrored by, and actually related to, international economic battles the United States found itself waging around the world. After World War II, as industrial Japan, Germany, and Brazil recovered and began to flex their political and economic muscles, the global scene became increasingly populated by nations who had their own opinions about American politics and financial policies, and, moreover, felt justified in challenging the United States in both areas. By the end of the 1970s, then, the increasingly competitive global economic picture had become at least as disturbing to many Americans as the contested political landscape: The American standard of living was threatened; the competitive status of the domestic steel, automobile, textiles, consumer electronics, and other manufacturing industries had begun to erode; and Americans had begun to express a "growing crescendo of support for trade restrictions", (Johnston & Packer, 1987: 13).

By the end of the 1980s, the effects of these international wrestling matches were being felt more directly. The oil cutoffs by OPEC, for example, convinced many Americans that these struggles were serious, indeed, and that the United State's former sovereignty over global economic matters had ended. By 1987, when the famous Hudson Institute report, *Workforce 2000*, was published, a disturbing picture of economic decline had begun to dominate the American consciousness:

> Between 1975 and 1980, [productivity] output per hour in U.S. manufacturing rose by an average of 1.7 percent per year, compared to 3.8 in West Germany and 8.6 percent in Japan .... U.S. steel production dropped by more than one-fourth between 1975 and 1983, and the U.S. share of the world steel production declined from 16 percent to 12 percent; for autos, the drop in volume was 22 percent, as the U.S. share of world production fell from 27 to 17 percent.
>
> (Johnston & Packer,1987: 15)

America's domestic growth was now "inextricably intertwined with world growth" (Johnston & Packer, 1987: 3) and this linkage was not going America's way:

> Between 1960 and 1985, the world economy grew at an average rate of 3.9 percent per year, while U.S. growth averaged 3.1 percent annually. As a result of this lower growth, the U.S. share of the world economy ... dropped from 35 percent in 1960 to 28 percent in 1985 .... The U.S. share of the economy will fall further by the year 2000. (p. 6)

Given this political and economic environment, the American national mood was increasingly tense and defensive. On the 23rd of March, in 1983, President Reagan delivered a televised address to Americans in which he described a space-based, missile-defense system that the media called "Star Wars". And, although many scientists were skeptical about whether or not such a system could succeed, the first and second voyages of the space shuttle *Challenger*—concluded on 9th April and 24th June, respectively—helped convince many Americans that the Star Wars project might actually work (*Annals of America*, *Vol. 21*, 1987: xxxiv–xxxvi).

Other frontiers and challenges also provided a positive vision of what Americans were capable of accomplishing if the national resources could be organized effectively. In March of 1983, for instance, after 112 days as the first recipient of an artificial heart, Barney Clark died. In May of 1983, the United States declared AIDS as the nation's top medical priority, and in October of 1984, Baby Fae had a baboon's heart transplanted into her chest cavity in an attempt to save her life (*Annals of America*, *Vol. 21*, 1987: xxxiv–xxxvi).

A combination of macro-level historical, political, economic, and social factors—the global struggles of the Cold War and America's fading economic status, the domestic recession, the ongoing race for the domination of space, and the technological challenges associated with medical research—converged to fuel America's national investment in technology and the resultant explosion in technological innovation that was to characterize the decades of the 1980s and the 1990s. As the national thinking went, such an investment could help revitalize a flagging domestic economy and stop America's downward spiral in global political and economic arenas as well (Johnston & Packer, 1987). This investment was enacted, on a practical level, by a range of social agents: Among only a few of these, members of the military-industrial complex, medical researchers, industry leaders, and educators.

Technology was certainly a primary focus of the nation's military-industrial complex during the Reagan presidency (Levidow & Robins, 1989). In particular, the military's need for increasingly sophisticated technological weaponry and the domestic industrial sector's need for lucrative contracts proved an extremely potent combination. By 1983, for instance, the military and the private sector—represented by large research universities and major technology companies—had begun collaborating on The Defense Advance Research Projects Agency's (DARPA) Strategic Computing Initiative, a "major program for research in microelectronics, computer architecture, and AI [artificial intelligence]" (Kurzweil, 1990: 480). In Michigan, the DARPA effort inspired a related statewide project—the Michigan Educational Research Information Triad (MERIT)—which would link major universities conducting technology research to both the National Science Foundation and corporate sponsors such as IBM and MCI ("Merit's History," 1998).

By 1987, similar collaborations among military, industrial, and educational partners were underway on AI vision systems for military aircraft and AI support for remotely piloted aircraft (Kurzweil, 1990: 255). These projects exploited the country's Cold War concerns about foreign aggression and its increased willingness to fund military efforts. During the two terms of the Reagan Presidency, from 1981 to 1989, national defense spending increased from $167.5 billion to $303.4 billion (Council of Economic Advisors, 1990: 295). With such resources available to support military projects, private industries, and public universities participated willingly and vigorously in defense-based research and development efforts—most of which involved technology (Noble, 1989).

The needs of medical and health researchers also fueled the demand for increasingly sophisticated technologies and a workforce capable of both using and manufacturing such technologies. By the early 1980s, for example, the medical research team that had worked on an early diagnosis project named MYCIN had also produced two more expert systems for disease diagnosis: NeoMYCIN and ONCOCIN, both of which used newly designed hierarchical database structures. By 1982, CADUCEUS, a computer program based on the expert knowledge of internists, was able to make more than "100,000 associations between symptoms and diseases" and to cover 70% of that field's knowledge. And, by 1986, the development of computer-based imaging systems allowed doctors to see "inside our bodies and brains" (Kurzweil, 1990: 471–499).

The Reagan administration hoped that the increasing numbers of industries undertaking such technology-rich projects would need to hire large numbers of technologically savvy workers—thus, creating an employment trend that would reduce high-unemployment figures and boost America out of the current recession. To grease the skids for this recovery dynamic, Reagan began a program of industry de-regulation (Council of Economic Advisors, 1985: 119–126)—an approach that, along with other factors, contributed to the rapid growth of the computer industry during the 1980s and 1990s.

By mid-decade, the expansion of the technology industry was well underway, and Americans had begun to recognize its value as a key to both the country's domestic *and* global difficulties. If America could develop advanced technologies faster than other countries, the thinking went, it could recapture its rightful share of global and economic power—but to accomplish this task, the country had to continue down a high-tech path. Thus, when Japan formed the ICOT consortium to develop a new "Fifth Generation" of computers in 1982 and funded it with a billion dollars of government and private monies, the Americans undertook, in short order, a similar project. By 1984, Ronald Reagan had signed legislation paving the way for the Microelectronics and Computer Corporation, an American-based consortium of more than 20 companies that shared a goal of developing intelligent computers and a budget of $65 million a year. By 1986, the revenue of the American AI industry alone reached $1 billion, growing to 1.4 billion by 1987 (Kurzweil, 1990: 479–480).

The vigor of all these converging trends led to astonishing growth in the computer industry during the 1980s, and not only in the manufacturing of large mainframe computers for advanced research and development. In the late 1970s, the invention of integrated microcircuit technologies—such as Motorola's 68,000 16-bit microprocessor containing 680,000 transistors (*Timeline of Computing History*, 1996)—fed into the rapid and far-reaching development of personal computers. And the invention of these handy, relatively affordable machines was to prove transformative for many aspects of American life.

In 1981, for example, the IBM PC was launched, and its open architecture system, in turn, invited additional industry collaborations and partnerships (*Timeline of Computing History*, 1996). Among the first of these, in 1982, was Microsoft's release of *DOS 1* (Polsson, 2000) and WordPerfect Corporation's release of *WordPerfect 1.0* (*Timeline of Computing History*, 1996). Indeed, as Paul LeBlanc has noted, within a year of the IBM PC's release, IBM was supporting 12 new Microsoft products, and 30 other companies had announced the development of DOS-based software programs (Hawisher et al., 1996: 41). Also in 1982, the word "internet" was used for the first time (*PBS Life on the internet*, 1997), *Time* magazine named the computer "Man of the Year", and the first commercial e-mail service linked 25 cities. In 1983, the Apple Lisa was launched; and in 1984, the Apple Macintosh followed. By the end of 1984, computers were so much a part of our national consciousness that William Gibson invented the term "cyberspace" in his novel *Neuromancer* (*Timeline of Computing History*, 1996). The software industry grew in tandem with the personal-computer hardware industry: The 300 software companies in existence in 1970 skyrocketed to over 2000 companies in 1983; sales in this industry went from $750 million in 1977 to $475 billion in 1983 (Hawisher et al., 1996: 96).

3. EDUCATIONAL CONTEXT

The American educational system was quick to understand the implications of these related national trends—especially for new, technologically rich curricula. A successful global superpower needed increasingly sophisticated technologies—to manufacture goods more efficiently, to wage war more effectively, or to conduct medical research on new and threatening viruses. And to invent and operate these new technological systems, increasing numbers of technologically savvy citizens were needed.

The Condition of Education (1980) described the new national dynamic as it was to affect American education during the coming decade:

> The 1980's are expected to be a period of new assessments of our scientific capabilities, as National concerns shift to such areas as energy, the environment, and health. . . . Our Nation's continued advancement in technology is dependent to a large extent upon its supply of science and engineering personnel. The persons who can make up this manpower base conduct basic research to advance the understanding of nature, perform applied research and development in a variety of areas such as health, energy, and the environment, and train the nation's future scientists and engineers. (p. 6)

In support of this national project to expand technology use—and technological education—in schools, as Hawisher et al. note, a powerful coalition of social forces aligned themselves:

> Computer industry giants like IBM, Control Data Corporation, and Mitre Corporation were rushing to explore the educational marketplace [for computer applications]. Government agencies like the National Science Foundation, the U.S. Office of Education, and the Defense Advanced

> Research Projects Agency (DARPA) were seeking to inform and enlist American education in response to Cold War politics (Thurston, 1994). Private foundations like the Carnegie Corporation and the Annenberg/CPB Project were funding new answers to old educational questions.
>
> (Hawisher et al., 1996: 34)

In this milieu, the newly invented personal computer promised to be an exceptionally powerful educational ally. These small, affordable machines offered a cost-effective way of helping educators produce a technologically savvy citizenry, and the relative ease of programming personal computers appealed to teachers in a number of disciplines unrelated to computer science. Personal computers made it relatively easy for faculty to create their own computer-assisted instruction (CAI) packages for mathematics, social studies, and importantly, English—where personal computers quickly became popular environments for literacy and communication instruction.

It was during this period of innovation—framed by a growing national investment in technology as a response to the challenges posed by the Cold War, raging economic battles at home and around the globe, the need for new energy sources, and the call for medical and health innovations—that Donna Haraway's "Manifesto" was first published in 1985.

4. ACADEMIC CONTEXTS: HUMANITIES AND THE SOCIAL SCIENCES

Haraway's publication presented educators in the humanities and social sciences with a challenging new role. The cyborg political agenda described in the "Manifesto" charged educators not with simply *using* computers and teaching students to do so—a task which had proven difficult enough in public school classrooms during the previous 5 years—but also with acknowledging their own participation in, and responsibility for, the technological systems that supported national and international systems of domination. Teachers and scholars were asked, moreover, to *become* cyborgs: To assume the role of "monsters" (p. 99) responsible for blaspheming the powerful mythic system surrounding computers in the increasingly technological U.S. culture and to create new, resistant "world-changing fictions" (p. 65) that would help students and the public gain some critical perspective on technology as a part of social systems and formations that supported the politics of domination and inequity. These new fictions were needed to tell different truths, to show different perspectives—in Haraway's words, to give voice to the "imaginative apprehension, of oppression, and so of possibility" (p. 66) that escaped the masking and naturalizing effects of the nationalistic narratives perceived as common sense.

Given the public enthusiasm for computer technology during the 1980s and 1990s—as well as the potency, ubiquity, and coherence of the social and discursive formations surrounding computer use in educational settings—the impact of the "Manifesto" on U.S. educational practice and the diffusion of ideas from this publication took considerable time to unfold. Despite this delay, however, the "Manifesto" proved itself to be an important intellectual forerunner of a vigorous movement to establish critical perspectives on technological systems and their relation to existing social, political, ideological, cultural, and economic formations (cf. Feenberg, 1999; Gray, 1995; Grossberg et al., 1992; Turkle, 1995). During the 1980s, the intellectual trajectory described by these works—especially as influenced by the "Manifesto"—grew in strength and gave rise to work in four important areas of the academy: Historically and philosophically informed studies of the relationship between science, technology, and society; literary studies of cyborgs and their antecedents; cultural studies of cyberspace; and gender and technology studies.

A number of cyborg educators and scholars, for instance, were involved in extending agenda related to those in the "Manifesto"—tracing for students and the public the historical and philosophical roots of Western narratives about science and ideologically determined belief that science and technology would always yield a better world for the human species. Gergen (1991), for instance, pointed out, that a broad public faith in Science gained potency with the emergence of modernity near the end of the 19th century. During this period, as Gergen noted, Science as a waxing social and cultural influence was linked to the waning of Romanticism and its adherence to "passion, purpose, depth, and personal significance" (p. 27). Scientific discovery—sketched in simple terms as the outcome of applied truth and reason, and associated with an accompanying faith in the power of systematic observation, rigorous reason, and rationally designed technological tools—exerted increasing cultural influence in various fields over the next century (Gergen, p. 27).

As the "Manifesto" suggested, technological invention played a crucial role in the rise of science in the 19th and 20th centuries, and many scholars who read Haraway's work were prompted by such thinking to outline the specific historical and philosophical connections between technology and various "longstanding social and cultural practices" in both highly industrialized and less industrialized countries. After the publication of the "Manifesto", scholars such as Bruno Latour (1993), Arturo Escobar (1994), Andrew Feenberg (1999), and Chris Hables Gray (1989, 1995) among many others, studied the sustained connections between technology and the social formations of positivism, rationality, instrumentality, capitalism, democracy, and militarism. Bruno Latour (1988, 1993) traced ways in which the philosophical tenets of modernism shaped understandings of technology, agency, and human relationships to technology within social contexts. J. MacGregor Wise (1997) examined the ways in which Western cultural formations have historically shaped epistemic understandings of technology. Haraway's cyborg metaphor has also been taken up by Chéla Sandoval (1995) who argued that for the past 300 years colonized peoples have been using "cyborg skills" and "cyborg consciousness" to survive "techno-human conditions" (p. 408). She outlined a "methodology of the oppressed", (p. 409), using Haraway's metaphor to think through configurations of "U.S. Third World Feminism".

A second group of educators found it fruitful to explore Haraway's cyborg as a textual and literary phenomenon, as Haraway herself does on numerous occasions. These educators focused on cyborgs and their literary forerunners as rendered in works of literature (especially science fiction) and film by authors such as Mary Shelley, cyberpunk writers such as William Gibson and Neil Stephenson, and comic books by superhero and supervillian artists (Oehlert, 1995). Katherine Hayles, whose early work on scientific discourse and language (1984) influenced Haraway's (1991a, b) analysis of biopolitics, has consistently explored the cyborg and its implications for literature and writing in "post-human" contexts (1995, 1999, 2002). David Tomas (1989) cited Haraway in his examination of William Gibson's cyberpunk fiction—*Neuromancer*, *Count Zero*, and *Mona Lisa Overdrive*—claiming that such literary works could help further Haraway's agenda by "sensitiz[ing] us to the possibility of explosive social/biological mutations produced by rapidly changing technoscapes" (p. 129). In related work, Mark Oehlert (1995) used Haraway's work to explore images of cybernetic heroes and villains in comic books, maintaining that the graphic representation of such characters revealed our own ambivalence to the merger of biology and technology. Alison Landsberg (1995) cited Haraway as she explored the prosthetic nature of human memories in an analysis of the films *Total Recall* and *Blade Runner*.

A third group of scholars, influenced by a combination of popular culture and cultural studies, took up the challenges of Haraway's "Manifesto" by examining popular conceptions of cyborgs and cyberculture. Diana Gromala (1996), for instance, suggested that medical imaging transformed humans into cyborgs—beings in which "social, political, economic, and technological forces flow and collide" (p. 236); and Alluquere Rosanne Stone (1992) described a community of individuals who conversed so consistently and actively online that they created a "social space in which the divide between nature and technology" was "thoroughly unrecognizable" (p. 82). Many of the scholars interested in cyberculture focused on Haraway's call for a "cyborg world" that was informed by radical feminist, socialist, and transformative values—one that might be informed by "lived social and bodily realities in which people are not afraid of their joint kinship with animals and machines, not afraid of permanently partial identities and contradictory standpoints" (p. 72). These scholars, committed to the "Manifesto's" call for "fictions" that resisted the dominant utopian narratives about technology, remained wary of the dangers posed by a "salvation history" (p. 67). Working in this arena, for instance, Lisa Nakamura (1995a, b) extended the agenda of Haraway's work by critiquing the racist practices of "identity tourism" (p. 181), the appropriation and colonization of minority identities in online chat rooms and commercial advertisements about technology; Vivian Sobchack accused the *Mondo 2000* subculture of the "God trick" (Haraway, 1991a, b: 189) of plugging into "dangerous forms of holism" and a "dizzying pro-technology rhetoric" (that was "neither progressive nor democratic, … [and] hardly communitarian" (Sobchack, 1994: 22–24) in nature. In a similar vein, Chris Hables Gray (1995), in "The Cyborg Soldier", extended Haraway's agenda by exploring the ways in which computer technologies were implicated in the specific agenda of U.S. militarism and aggression.

Finally, feminist scholars undertook critical projects closely related to those in the "Manifesto", both extending and, at times, influencing Haraway's own work on technology and gender. Judith Wajcman (1991) surveyed feminist approaches to technology and science, advocating that feminists develop theories and models that reveal technology's connection to structures of power and knowledge production. At the same time, she argued, like Haraway (1991b), that a monolithic theory would not suffice. Anne Balsamo (1996) examined intersections of the discursive and the material in representational practices such as female bodybuilding, plastic surgery, reproductive technologies, and cyberspace. Other feminists considered the boundaries between gendered bodies and identity in cyberspace, emphasizing the fluidity of personality (Turkle, 1995), the diverse configurations of gendered participation (Miller, 1995), or communication styles in computer-mediated environments (Herring, 1996; Kramarae, 1988; Kramarae & Taylor, 1993). Sadie Plant (1997) argued that women have always played essential roles in the development and use of technology, focusing as an example on Ada Lovelace's involvement in Charles Babbage's "Difference Engine" project. In 1997, Lynn Hershman Leeson wrote and directed the film, *Conceiving Ada*, in which a pregnant modern-day mathematician makes contact with Ada Lovelace through her computer and transfers the memories and, ostensibly, the DNA of Lovelace to her unborn child. Directly or indirectly, Haraway's incisive "Manifesto" became a touchstone for virtually all considerations of gender, technology, and science that followed it.

5. UNDERSTANDING THE RELATIONSHIP BETWEEN COMPUTER TECHNOLOGY AND LITERACY

If Haraway's "Manifesto" influenced work in key areas of social sciences and literature, however, much of its impact was limited to academic scholarship published in professional journals and theoretical discussions in graduate-level classrooms. Relatively little of this scholarship found its way into the undergraduate collegiate curricula (women's studies programs providing an exception) and even less into actual secondary classrooms. In English composition studies, however, the ideas contained within the "Manifesto" shaped not only the scholarship of educators, but, importantly, teaching practices as well—both at the undergraduate and graduate levels. For the many teachers and scholars who, by 1985, were researching and teaching composition in digital environments, Haraway's work had become mandatory reading.

6. HISTORICAL CONTEXT

In part, composition teachers and scholars found Haraway's thinking in the "Manifesto" so compelling because she acknowledged that writing in digital contexts was an important new literacy practice that had strong potential for political agency. "The silicon chip", as Haraway acknowledged, had become a politically charged "surface for writing" (p. 70), and one that had "special significance" for transformative efforts. Within this space, many composition teachers agreed with Haraway, the "contemporary political struggle" was being played out, and with "deadly serious" (p. 93) consequences that would affect citizens not only in the United States, but in many other countries as well.

The importance of Haraway's insight on this point was especially significant to educators—many of whom were influenced by the work of Paulo Freire—who were increasingly dissatisfied with the inequitable literacy practices that characterized U.S. schools and classrooms in an age considered so rich with technological promise. A brief review of the historical context can help explain the persistent problems that these educators considered so disturbing. When the first fully assembled microcomputers began entering American classrooms early in the 1980s, hopes for computers were high. Teachers and scholars hoped not only that computers could serve as effective instructional tools, but also—in a broader and more important context—that these machines could actually help democratize American classrooms. As the culturally informed reasoning went during that period, if the nation could put enough computers into enough schools, then all students—regardless of socio-economic status, race, or gender—would have access to technology and, thus, to success through the technologically supported power structures of our culture. This reasoning was based on a series of important cultural realizations: First, that U.S. society would be increasingly dependent on technology in the decades to come; second, that all citizens could benefit from rapid technological development and a vigorous computer sector; third, that schools would be responsible for the education of an increasingly savvy, high-tech workforce; and, fourth, that the current educational system had not yet been successful in providing equitable opportunities to all students.

The context within which these realizations were articulated was influenced by an increasingly acute set of social and educational tensions. As Mary Louise Gomez (1991) explained

> United States classrooms are increasingly filled with children who are poor (Kennedy et al., 1986), children who have limited English proficiency (Hispanic Policy Development Project, 1988), and children who are not white (National Center for Education Statistics, 1987a, b). For example, estimates of the growth of the nonwhite school population includes a rise from 24% in 1976 to 30–40% in the year 2000 (Center for Education Statistics, 1987a, b). . . . Currently, 2.5 million school-age children speak a language other than English or come from homes where English is not spoken (Romero et al., 1987), and these numbers will increase as the non-English language background (NELB) population is expected to grow to 39.5 million by the year 2000.
>
> (Gomez, 1991: 319)

These changing demographics of ethnicity and race, moreover, could not be separated from the changing demographics of the U.S. economy in the 1980s. Many of the populations, as Gomez noted, lived in poverty. As she further explained

> data show that one in four children in the U.S. lives in poverty. A breakdown of these figures for race shows much higher rates of poverty for blacks (50%) and for Hispanics (40%). Of the 80 million school-age children in the U.S. in 1988, nearly 10 million came from homes headed by a single, female parent (Strong, 1989). For children living in female-headed households, rates of poverty are high, rising to 47.6%, 68.5%, and 70.5% for whites, blacks, and Hispanics (Kennedy et al., 1986). . . . Of students who were enrolled as sophomores in our public secondary schools in 1980, 12.2% of whites had dropped out of school by the autumn of 1982; while in the same period, 17% of black students, 18% of Hispanic students, and 29.2% of Native American students left school.
>
> (Gomez, 1991: 319; Wheelock & Dorman, 1989)

Educators clearly recognized these inequities, and they hoped that personal computers would help the U.S. educational system address them by providing children with an entre into high-tech, high-paying jobs and subsequent economic prosperity. Within this context, the mass integration of personal computers into U.S. classrooms during the decade of the 1980s happened rapidly—especially in courses involving fundamental literacy instruction, such as English composition. According to the National Center for Educational Statistics, for instance, although only 23.4% of Grade 4 reported using a computer in school to write stories or papers in 1984, this number grew to 39.6% by 1988, 48.6% by 1990, 56.9% by 1992, and 68.3% by 1994 (*Condition of Education 1997*, 1997: 56).

The rapid large-scale integration of computers into U.S. classrooms continued throughout the 1980s and 1990s despite a disturbing lack of evidence that technology provided any help at all for long-standing educational and literacy problems, and even evidence to the contrary (Cole & Griffin, 1987; *Falling Through the Net*, 1995, 1998, 1999, 2000; Sheingold et al., 1987). Teachers, parents, school administrators, and community members, continued to believe that increasing the numbers of computers in schools would result in more citizens from all races and classes who could secure high-tech, high-paying jobs; re-invigorate the computer sector of the nation's economy; and, ultimately, help the United States establish an expanded role in a competitive global marketplace. In part, this belief persisted because it was articulated with what Haraway recognized as a complex "historical system" that "structured relations" (p. 85) between the United States and other peoples of the world.

An important part of this system was the commonly held belief that the United States had the responsibility of ensuring prosperity domestically while creating conditions conducive to the spread of democracy and free-market economic trade so that other nations could benefit from the same advantages on an international basis (Selfe, 1999). Integral to this understanding was a related belief in the superiority of democracy and the conviction that the world would be a better place if the concept of democracies were to spread around the globe. Within such a global system, U.S. citizens reasoned, individuals around the world could exercise freedom of speech and religion; make their own independent choices about local, state, and national issues of importance; and engage in representative forms of government.

At an ideological level, the agenda to extend democracy on a global scale was linked to the success of free-market capitalism, as Haraway pointed out in the "Manifesto". Capitalism was understood to provide an open stage for individuals—regardless of their current position in society—to work hard, invest their own capital and labor, and reap both the rewards and the risks that accrued from such activities. Hence, the freedoms represented by democracy, according to this linked set of beliefs, required an appropriately unregulated economic environment within which to flourish.

Computer technology, in this belief system, was understood as an important vehicle for the expansion of both capitalism and democracy. The Global Information Infrastructure (GII), for instance, was identified by the Clinton administration in 1993 as a primary means of supporting the spread of democratic ideas and free-market capitalism to the rest of the world. Vice President Gore, for example, noted that computer network technologies were designed to provide individuals around the globe access to increasing amounts of information so that they could make "incredibly accurate and efficient decisions" (1991: 150) as literate and responsible citizens.

Of course, this national focus on technology, as Haraway had pointed out in the "Manifesto", was far from innocent. Both the technology and the equipment for creating the GII were to come from the U.S. computer industry—a sector that would be revitalized by supporting increased levels of export, advanced technological research, and the development of new technological products, and the infusion of knowledgeable employees. A government report in 1993 described the benefits of this domestic dynamic, explaining how the National Information Infrastructure (NII) would provide the springboard for the larger GII:

> In an era of global markets and global competition, the technologies to create, manipulate, manage, and use information are of strategic importance for the United States. Those technologies will help U.S. businesses remain competitive and create challenging, high-paying jobs. They will also fuel economic growth which, in turn, will generate a steadily increasing standard of living for all Americans. . . . The development of a national information infrastructure (NII) that enables all Americans to access information and communicate with each other using voice, data, image or video at any time, anywhere. By encouraging private sector investment in the NII's development, and through government programs to improve access to essential services, we will promote U.S. competitiveness, job creation, and solutions to pressing social problems.
> (*The National Information Infrastructure*, 1993: 5)

If the Clinton Administration was to build a viable NII and GII, however, a large proportion of Americans had to be educated to use, design, and manufacture sophisticated technologies in increasingly effective ways. The education of the population on such a large-scale constituted, *de facto*, a national project of enormous proportions, especially because it included efforts in all areas of the curriculum. Americans not only had to be able to design and manufacture technology, they had to be able to program, create software products, market technologies, and use electronic networks for communication, among many other tasks.

7. EDUCATIONAL CONTEXT

To jump start this effort, in 1996, the Clinton administration allocated $109 billion (*Getting America's Students Ready*, 1996: 6) to the Technology Literacy Challenge. This national literacy project had the goal of creating a citizenry comfortable in using computers *not only* for the purposes of calculating, programing, and designing, but also for the purposes of *reading, writing, and communicating*. The project's sponsors claimed, further that it would provide *all* Americans equal access to an education rich in opportunities to use and learn about technology. With such an education, it was believed, graduates would be able to gain the qualifications needed for high-tech, high-paying jobs, and thus, to the means of achieving upward social mobility and economic prosperity within an increasingly technological culture (*Getting America's Children Ready*, 1996: 3).

As a result of this funding and the broader national investment in digital literacy that it represented, the proportion of younger American school children who used computers as a literacy tool increased rapidly during the last half of the 1990s. As of 1994, for example, 68.4% of 4th grade students, 82.3% of 8th grade students, and 86.9% of 11th grade students were writing stories or papers on computers (*The Condition of Education 1997*, 1997: 56). By 1999, 98% of all schools owned at least some computers, and the ratio of computers to students, at 1–10, was at an all time low (Coley et al., 1997: 3).

Given this context, enthusiasm for technology use in educational contexts remained generally high during both the 1980s and 1990s. But as Haraway points out, in the "Manifesto", totalizing narratives of progress and technology never tell the entire story. Even by mid-1980s, educators (Cole & Griffin, 1987; Sheingold et al., 1987) were noting alarming trends in connection with race and poverty associated with computers. Mary Louise Gomez (1991), for example, summarized the findings of a 1987 report authored by Cole and Griffin:

- more computers are being placed in the hands of middle- and upper-class children than poor children;
- when computers are placed in the schools of poor children, they are used for rote drill-and-practice instead of the "cognitive enrichment" that they provide for middle- and upper-class students (pp. 43–44).

Pioneering teacher-scholars such as Richard Ohmann (1985) and David Livingstone (1987) also began to connect the dots between early efforts to expand computer-supported literacy, the forces of monopoly capitalism, and intergenerational patterns of poverty and illiteracy. As Livingstone (1987) noted

> Throughout the past 150 years of industrial capitalism, advocates of the extension of public schooling have repeatedly emphasized two basic themes, solidly grounded in technological rationalist and progressive individualist precepts respectively: the importance of formal schooling in upgrading the labor force and ensuring upward social mobility among the disadvantaged.
>
> The essence of the upgrading theme has been the assumption that continual societal progress requires a more socially competent and technically knowledgeable populace, and that such qualities can best be assured through formal schooling. The mobility theme is founded on the belief that individuals control their own destinies, and that schooling can provide equal opportunities for each individual to develop his or her abilities. (p. 127)

Supporting the insights of such scholars was the fact that, despite the money invested in the President's Technological Literacy Challenge during the next decade, the same persistent problems of racial and class inequities were proving embarrassingly persistent. By the end of the 1990s, in the American schools system as a whole, and in the culture that this system reflected, computers—and, thus, technological literacy—continued to be distributed differentially along the related axes of race and socio-economic status. And this uneven distribution continued to contribute—as Haraway's "Manifesto" had foreshadowed—to ongoing patterns of racism, domination, and to the continuation of poverty.

By 1997, for instance, educational researchers noted that schools primarily serving students of color and poor students continued to have less access to computers, and access to less sophisticated computer equipment than did schools primarily serving more affluent students or white students. Moreover, schools primarily serving students of color and poor students were reported to have *less* access to the internet, *less* access to multimedia equipment, *less* access to CD-ROM equipment, *less* access to local area networks, and *less* access to videodisk technology than did schools primarily serving more affluent and white students (Coley et al., 1997: 3).

These data, which were profoundly disturbing, became all the more problematic when linked to the situation in the country's workplaces and homes. There, too, census figures indicated a strong correlation between race and socio-economic status: Black employees were *less* likely than White employees to use a range of computer applications in their workplace environments; employees who had not graduated from high school were *less* likely to use a range of computer applications than were employees who had a high school degree or had some college experience (*The Digest of Educational Statistics 1996*, 1996: 458); families of color and families with low incomes were *less* likely to own and use computers than were white families and families with higher incomes (cf. *The Condition of Education 1997*, 1997: 212; *The Digest of Educational Statistics 1996*, 1996: 458; *Getting America's Children Ready*, 1996: 36).

In other words, within the system of domination that Haraway had identified in the "Manifesto", the poorer individuals were and the less educated they were—both conditions that continued to be closely correlated with race—the less likely they were to be technologically literate and to have access to computers and to high-paying, high-tech jobs. In these terms, then, the national project to expand technological literacy had *not r*esulted in a better life or more democratic opportunities or an enriched educational experiences for *all* U.S. citizens, as many believed—or hoped—it might. Rather, it had served to improve the education only for *some* citizens. Moreover, this specific project—and the more general social forces and formations that sustained it, many of which Haraway had identified specifically in the "Manifesto"—had substituted a value on competition and consumerism for a commitment to equal opportunity, democratic cooperation, and a public education that served the common good of this country's peoples.

Partly as a result of these converging forces, by the last decade of the 20th century, the findings of educators who had expressed early reservations about the educational benefits of technology (Coley et al., 1997; Livingstone, 1987; Ohmann, 1985) began to resonate with the activist intellectual trajectory described by Haraway's "Manifesto". In 1992, for instance, Cynthia Selfe wrote

> [O]ne way of working toward the goals of radical democracy—in the spirit of Gilles Deleuze and Felix Guattari (1987) and Donna Haraway (1991a, b)—involves thinking, and trying to act, as what I am going to call nomadic, feminist, cyborg guerillas: nomadic beings (Deleuze & Guattari, 1987) who can inhabit *both* virtual and non-virtual landscapes; contentious, "protean," feminist (Haraway, 1990: 125) beings possessed of attributes both human and machine; disruptive, *oppositional* beings created continually by the technology that we ourselves continually create. By thinking in these terms, I suspect we can come to an increasingly realistic understanding of what is entailed in operating effectively within virtual spaces. We can learn how to balance or restore our own electronic ecology, recognizing that we define in virtual spaces—simultaneously and in continually contradictory ways—both official and anti-official territories. We can explore where we are now standing as educators, from what perspectives we are now seeing and not seeing; we can struggle with our own implication in the very inequities we work to critique or eradicate.
>
> (Laclau & Mouffe, 1987; Selfe, 1992: 16)

In addition to these convergences, many compositionists—even those unfamiliar with Haraway's work when the "Manifesto" was first published—shared with her an understanding of the importance of discourse and rhetoric within specific social contexts; an appreciation of the explanatory power of Marxism, cultural studies, feminism, and post-modern theories; and a belief in social justice and the need to enact productive social change—even if only temporary, partial, and fragmentary. Like Haraway, moreover, many composition and literacy scholars also had a first-hand understanding of the difficulties associated with achieving social justice, enacting change, and resisting the tendential forces associated with stasis. Many of these educators shared a general commitment to enacting productive social change—especially in the venues of educational settings (including classrooms, schools and institutions, writing centers, educational sites in workplaces, and community literacy program) as potential venues for enacting productive social change. Paradoxically, this commitment was shaped by a sense of hope and optimistic pragmatism, even while it was tempered by the skepticism. Much like Haraway, for instance—although these educators did not focus directly on technology studies—critical pedagogists such as Berlin (1994, 1996), Cooper (1986, 1999), Faigley (1992, 1996, 1999), Giroux (1991, 1992a, b), Knoblauch and Brannon (1993), and Ohmann (1985), who were familiar with and influenced by the work of Paulo Friere, possessed a keen understanding of the role that institutions played in reproducing inequities along the related axes of race, class, gender, and orientation.

8. ACADEMIC CONTEXTS: HARAWAY IN COMPUTER-SUPPORTED COMPOSITION CLASSROOMS

Composition and literacy scholars whose work did focus on computer use in classrooms shared with Haraway a complex understanding of technology and technological systems and recognized the contradictory potential of technology. These educators saw technology both as a possible vector for enacting productive change and a powerful force for resisting such change and exacerbating inequitable practices. Their understanding rested on two related insights: That technology consisted not only of machines—of computers, for instance—but also of a complexly articulated set of social formations and that technology and power and literacy practices were linked at fundamental levels (Faigley, 1996, 1999; Kolko et al., 2000; Selfe, 1999). Eventually, the work that these educators undertook went far beyond the use of computers as transcription devices, machines that made revision easier, or mechanisms that supported drill-and-practice approaches to grammar. Inspired by Haraway's vision, scholars in computers and composition studies assumed increasing responsibility for establishing important critical perspectives on the relationship between computers and humans and for shaping computers networks in ways that helped authors think transformatively about their work, and their exchanges with others.

Given this intellectual context, it was little wonder that cyborg politics and scholarship emerged as such a vigorous force in composition studies and had such an impact in computer-supported composition classrooms. At least four major threads of composition studies were strongly influenced by the "Manifesto's" challenge. They included

- implementing computer-based pedagogies in literacy classrooms;
- identifying social justice and equity issues as they affect technological literacy;
- tracing literacy practices and values in post-modern contexts;
- examining how individuals represent themselves in digital literacy environments.

Haraway's "Manifesto" helped ensure that the work of composition scholars and teachers was, wherever possible, mutually informed by pragmatic, theoretical, and political concerns.

Perhaps the most immediate exigency for paying attention to the ideas contained within Haraway's "Manifesto" had to do with the pragmatic material reality of the U.S. educational system. Within this system, during both the 1980s and 1990s, increasing numbers of students and teachers were being asked to use computers and networked systems in English studies, language arts, and composition classrooms; in writing centers; in educational institutions; in workplace education sites; and in community literacy programs. It became increasingly clear during this period that literacy and technology were inextricably intertwined, at least within American culture, and that, as a result, individuals were no longer considered literate unless they knew how to communicate in the officially sanctioned form of Standard English and within electronic contexts (Selfe, 2000).

Given this context, many of the educational projects carried out in computer-supported composition classrooms during the decade of the 1990s had to do with discovering and designing effective instructional approaches that were based on sound theory and practice, and critically reflecting on—and assessing—the efficacy of such approaches on different populations of students. In this work, compositionists saw computers much as did Haraway in the "Manifesto"—as "coded texts through which we engage in the play of writing and reading the world" (p. 69). Compositionists who believed that critical technology literacy was an essential component of composition pedagogy in computer-supported environments began to write new narratives of pedagogical possibility. These scholars cited Haraway, and often the "Manifesto", directly, in their explorations of composition pedagogy (Duin and Hanson, 1996; Johnson, 1997; Joyce, 1999; Porter, 1997; Selber, 1997; Sloan, 2000; Wahlstrom, 1997).

Working from this foundation, composition teachers continued to explore and critique the liberatory instructional potential of a wide range of computer-based environments: Among them, computer networks and conferences (Gruber, 1999; Romano, 1999); MOOs, particularly, those designed specifically for language exchanges (Haynes, 1999; Sanchez, 1998); chat rooms (Boese, 1999); listservs (Hocks, 1999; Kolko, 1998a); the web (Hawisher & Sullivan, 1999); e-mail (Grigar, 1999; Monroe, 1999); and computer-based classrooms and labs (Covino, 1998; Snyder, 1996). Pedagogical approaches in these environments were aimed at helping students explore the relationship between writing and identity in virtual environments (DeVoss & Selfe, 2002, Selfe & Selfe, 1994; Takayoshi et al., 1999), made use of chat and MOO transcripts where students could critically examine talk about writing during peer review (Haynes & Holmevik, 1998), and asked students to reflect on their experiences with technology in technology autobiographies (Kitalong et al., 2003). The latter activity helped students interrogate the connection between literacy practices and the development of new technologies. In each of these cases and more, educators resisted the notion that computers were simply tools that transparently facilitated writing and helped students imagine the broader implications of writing practices in technological environments.

Composition teachers also took up Haraway's agenda for social justice and equity—focusing on the issues of race, class, gender, and sexuality as they seemed to be linked to computer-based literacy. These scholars and teachers composed new "ambiguous" (Haraway, "Manifesto", p. 69) narratives that acknowledged the paradoxes associated with social justice efforts and technological systems. This particular strand of inquiry recognized, as did Haraway, competing discourses of optimism and skepticism, enthusiasm, and critical awareness. Citing Haraway directly or indirectly (by including references to works that *had* cited Haraway) compositionists interrogated claims that computer-based learning environments could encourage increasingly democratic or egalitarian contexts for literate exchanges (Daisley & Romano, 1999; Taylor & Ward, 1998); and questioned the discursive possibilities for women and other under-represented groups practicing literacy in online contexts (Taylor, 1997; Addison & Hilligoss, 1999; Aschauer, 1999; Kolko et al., 2000; Sloan, 1999).

Many compositionists who worked on issues of social justice and equity were influenced by the "Manifesto's" attention to the complex and thorny social and cultural issues associated with technology. These educators often looked at large-scale literacy practices and contexts, focusing, for instance, on inequities related to the differential distribution of—and access to—computers within the American culture, especially along the related axes of race, class, age, or gender (Braun, 2001; Selfe, 1999). Composition teachers and scholars have also found Chéla Sandoval's (1994) theory of "oppositional technologies of power" (p. 409) useful as they questioned constructions of whiteness in critical pedagogy practice (Trainor, 2002) and interrogated the production of traditional and non-traditional (technology-based) academic work (Gruber, 2000).

Compositionists interested in the use of computers also focused, like Haraway, on the dynamic conditions of post-modernity and the changing nature of discursive practices generated within—and sometime in resistance to—these conditions. This work has produced particularly productive examinations of the post-modern values that shape communications in digital and online environments (Bolter & Grusin, 2000; Johnson-Eilola, 1994; Sloan, 1999). Haraway, among others, provided Johndan Johnson-Eilola (1997) with a means by which to question the seemingly transparent and "angelic" operations of hypertext, while at the same time offering teachers strategies for "inhabit[ing] and appropriat[ing], if only partially and rarely, the technologies of literacy" (p. 186). Haraway also proved to be an active influence on the theoretical and pedagogical considerations of multimedia composing. When Jay David Bolter and Richard Grusin examined how new technologies "re-mediate" perceptions of "the real", for instance, both Haraway and Anne Balsamo were central to their insights about remediation and "technologies of the gendered body" (Balsamo, 1996). Other scholars working in this area explored the claim that conventional forms of discourse, especially those authorized by modernism, functioned to "imprison" the imagination in various ways. These scholars looked at the possibility that writing in the radically new post-modern environments of computer-based environments might provide ways of "cut[ting] the code" to achieve new kinds of "cyborg heteroglossia", of engaging in a "radical cultural politics" (Haraway, 1985: 70). Among these, some examined how conventional alphabetic forms constrained communication (Barber & Grigar, 2001; Vielstimmig, 1999). Other educators in this arena explored how new computer-based literacy forms like hypertext might affect both students' and scholars' patterns of reading and writing, and, thus, thinking (LeCourt & Barnes, 1999; Snyder, 1996; Vitanza, 2001).

Finally, among the most vigorous intellectual work in composition studies over the past two decades has been that occurring in the area of representation—both graphic and text-based representation—within computer-based literacy environments. This work was often shaped—albeit not always—by concerns of social justice and frequently focused on problematic representations of gender, race, class, and sexuality. Computers and composition scholars working in this arena cited Haraway and other feminist scholars (Kramarae, 1988; Plant, 1997; Turkle, 1984, 1988, 1995; Wahlstrom, 1994; Wajcman, 1991) directly as they tried to identify pedagogical approaches that would help students recognize and resist conventional print and visual representations of women used in cyberspace and in connection with computer technology (Balsamo, 1996; Blair & Takayoshi, 1999; DeVoss & Selfe, 2002; Grigar, 1999; Hawisher & Selfe, 1999, 2001; Hawisher & Sullivan, 1999; Haynes, 1999; Hocks, 1999; Selfe, 1999; Takayoshi, 1994; Takayoshi et al., 1999). Representation projects also focused on resistant identity narratives involving race (Knadler, 2001) and the politics of the body (Kolko, 1998b; Monroe, 1999; Sanchez, 1998).

IN LIEU OF A CONCLUSION: THE VALUE OF AMBIGUITY, THE MATERIALITY OF DISCOURSE AND THE NATURE OF CYBORG RESPONSIBILITY

In his analysis of the "manifesto technologies" of Marx, Marinetti and Haraway, Steven Mentor (1996) has observed that, "Haraway's cyborg manifesto contains a cyborg writing that joins the reader to different prosthetic rhetorical machinery". Or, as Haraway has put it, "I will never finally say what I mean . . . not because I'm of bad faith[, but] because I'm committed to the proposition that this is neither possible nor a good idea" (Olson, 1996). Haraway's willingness to embrace the indeterminacy of language seems in some ways at odds with the agenda of the traditional writing classroom where teachers ostensibly help students say what they mean. However, as Marilyn Cooper (1999) has observed, the role of teachers and students in post-modern classrooms may more accurately be characterized by the extent to which students can learn to mean what they say. Allowing students to explore language in electronic environments gives them "the chance to consciously consider and take responsibility for the effects their actions have on others" (p. 157). Moreover, teachers must be willing to shift the terms of their authority rather than finding new ways to regulate student voices. Haraway's "cyborg writing" has offered compositionists ways to envision and teach new writing technologies that resist these potentially over-determining effects in order to actively engage with the materiality of language: "Cyborg writing is about the power to survive, not on the basis of original innocence, but on the basis of seizing the tools to mark the world that marked them as other" (1985: 175). Through her fluent and wide-ranging analysis of science, technology, and their rhetorics, Haraway has permanently joined class, race, sexuality, and gender to technology discourse and left her own lasting mark on contemporary composition classrooms.

Chapter 6: The Political Economy of the Internet: Contesting Capitalism, the Spirit of Informationalism, and Virtual Learning Environments

JEREMY HUNSINGER
University of Toronto, Koku University of Toronto,
Hunsinger Virginia Polytechnic Institute and State University

In Neal Stephenson's *Diamond Age* the world is transformed by a series of events surrounding the creation of a virtual learning environment in the form of a book, *The Young Lady's Illustrated Primer*. It is a story of power, liberation, social division, and transformation. It is a fable of information technology and virtual learning environments in which the dustpan world of Stephenson's novel is overcome. The social structures that create the virtual learning environment are transformed by its creation, creating a population that are critically aware of their situation and what they can do to change it. Similarly, virtual learning environments are transforming learning and thus transforming the world and our understanding of it. Inherently these environments, like all technological environments, contain systemic, ideological biases, and assumptions. We need to be critically aware of these environments, their biases and assumptions and the world that creates, endorses, and in the end supports them, so that we have the ability to understand our responsibilities toward not merely their usage, but their creation, and what is built into them, the biases, values, and ideological positions.

For virtual learning, it is clear that human interests and social structures are politicized and embedded in the relationships of power found in the era of informational capitalism. The power is merely embedded not only in the social world, but also in our technics, our institutions, and our ecology. Informational capitalism has transformed the world and made it a more interesting and problematic place to live. In its moment, informational capitalism has transformed the landscape of education, brought about the advent of the virtual learning environments, a new contestation surfaces involving the manifold roles of information and knowledge, their centralization and distribution through society. In attempting to come to grips with these issues for virtual learning environments, I confront the spirit of informationalism as conceived by Manuel Castells. I question the explicit ideas for it in the context of online education as network enterprises.

> "The spirit of informationalism" is the culture of "creative destruction" accelerated to the speed of the opto-electronic circuits that process its

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 189–206.

signals, Schumpeter meets Weber in the Cyberspace of the Network Enterprise".

(Castells, 2000: 215)

Castells sees the recreation of the digital world through the Schumpeterian idea of creative destruction, this is a conception of innovation and labor, where an old set of institutions is destroyed and a new one is created to take its place. But I argue, the old set of institutions, the old forms, and clearly the old powers, are implicit in the new network enterprises; they are not destroyed as much as they are recreated in the informational arena. Through this continue recreation of old forms into new combined with the ongoing capitalist enterprise, there becomes new centralizations of information, new places that hold power, and want to retain power.

Informational capitalism requires us to accept the perspective that information transforms the central systems of our economy, and with that has ripple effect to everything that depends on those systems. To understand one of those ripples, virtual learning environments, we have to understand what information is in the context of learning and learning's goal—knowledge.

1. INFORMATION AND KNOWLEDGE

Our everyday life is enmeshed in information. From its physical manifestation in computer-aided design of toasters and cars to its purely digital form constituting the monetary flows of capitalism, internet broadcasted lectures, and the textual flows of e-mail, information is ubiquitous. These digital goods constitute a significant part of our economic, social, and political milieu. "Digital goods—by which I mean things we produce, such as this book in its original form, that can be reduced to 1's and 0's—are materially different from other goods, mainly in that they are material-less and have economic lives of their own" (Mckenzie, 2003: 2). The 1s and 0s fill our everyday existence, constructing and signaling everything from traffic signals to art. These fundamental reductions seem to have lives of their own because they are informational signaling systems that control parts of our lives and occasionally interact in unexpected ways. Information's core conception is that it contains meaning. Meaning is constructed and reconstructed through interaction. Humans and machines interact with it and are left changed. That information can impart change is very important to it as a concept, because it explains its importance for our economy and society and as such why control of information is transforming our lives and institutions. Information causes change, and the ability to control that change is a significant power in our everyday lives. The moments of informational capitalism are inscribed in these digital goods and the implications for this are not dissimilar to the effects of prior revolutions in material culture on everyday life and as such learning.

In the context of learning, information is not synonymous with knowledge as Lively indicates, "Information is knowledge in any form" (Lively, 1996). Contrarily, one type of information is encoded knowledge, knowledge abstracted and removed from the subject and encoded into any of a myriad of forms. Other types of information may encode the values, norms, ideologies, and other meaningful abstract systems, which may be embedded in knowledge, but may also be externalized in other meaningful parts of our ecology. Knowledge though, when it is encoded, is transformed into information. The encoding process varies, and with it, the usefulness of the information it produces varies. Digitalization, for instance, transforms knowledge into zeros and ones, making it, giving it some use in digital technologies, such as computers or the internet. "Digitalization shifts human agency and structure to a register of informational bits from one of manufactured matter" (Luke, 1995). Digitalization transforms knowledge from its analogue whole to its digitalized parts, fragmenting it, and allowing less meaningful parts to be forgotten altogether. It creates an informational representation of the analogue, abstracted at a definable level, losing richness and completeness for the sake of control, ubiquity, and efficiency, shifting the registers of subjectivity with it. While digitalization is conceivably a manual activity, it usually requires an immense amount of human labor, machinics, and informatics to enable its functional use in society. This labor is in part of our subjectivity that we are embedding through the labor process into the digital object. Combining the embedded labor with the embedded knowledge the digital, informationalized object contains the moment of informationalization to a form of alienation of subjectivity. This alienation of subjectivity has been seen in the industrial age as a normalized function of production. However, in digitalization, the informationalized object no longer is objectified as physical artifacts, books, papers, etc., but it is informational, which entails that with the proper tools, we can make infinite copies and distribute them without cost. This mode of production and distribution transforms the value structure of the artifact transforms the value structure surrounding our subjectivity, and with that transforms the structures surrounding knowledge, devaluing and to some extent delegitimizing them (Lyotard, 1984).

Similarly to books and traditional instructional materials, information forms and requires an infrastructure. The infrastructure contains implicit and explicit biases about labor, subjectivity, and power, just like the infrastructures of material culture. The infrastructures themselves also encode norms, traditions, and modes of use, distribution, and production. "While design intentions can be evaded or subverted, as most hacking practices indicate, the infostructures raised in cyberspace also begin to conventionalize how and why they are used by most of their clients (Luke, 1995). This conventionalization is normalization. As new digital tools are created, they recreate the environments that their creators use to create them, thus the cultural systems embedded in these tools are not only distributed as product by consumed by their creators.

This creates contested spaces of cultural production that parallels and constitutes the mode of production of the digital artifacts. There is a "hacker" space, that many think countervenes but in most places eventually sublimates itself into informational capitalism (Castells, 2002; Himmanen, 2001). The subversion found in hackers and their alternative mode of production, which seems to be a subaltern, is actually a substructure of the hegemony. The creative practice of coding in informational capitalism is always integrated into the larger whole.

The codification of knowledge and the architecting of its infrastructures is clearly an immense, ongoing project that is encapsulating both the past and seeks to encapsulate the future. The institutions pursuing this encapsulation and their corresponding norms and traditions surrounding information are just as important as the information itself. This might be why some metaphors and ideas carry well in the provision of information; the library, the encyclopedia, and the journal have their metaphorical relation in digital space. It might also be why builders of informational spaces structure them similarly to their own experiences in the classroom or elsewhere. They want to pass on their traditions, real or imagined, in this digital environment. The old physical form is made new in digital form to conventionalize and normalize the way people use the information provided by technocrats and through their infotechnics.

The information itself, to be used, must be interpreted either by a human or machine. These interpreters are nodes that make the knowledge available. Once available, information tends to flow either as knowledge amongst humans or socio-technical networks like the internet to reach another node of translation. These networks are the central institutional structures of the information society, and the manifold ways that they order and structure our world is still being understood. These networks can be understood to operate on many levels, from the interpersonal network, to the global information superhighway, to the massive networks of economies, monetary exchange, and capital flows. They can be seen along the whole spectrum of analysis, from the atomic like digital subjectivity to the molar like integrated world informational capitalism (Guattari, 2000). With these networks we have interactions and interchanges, and transformations at all levels, they are always in flux, and so, along with the information they contain, must be interpreted, and must be converted into knowledge through interpretation. These networks require human and machinic capacity to operate, and in that requirement they require certain knowledges and ideas to be inculcated into future generations of the network and the culture surrounding it, until such a point as it becomes apparent that they do not apply and then we have a change, paradigm shift, or minor revolution (Fleck, 1981; Kuhn, 1996; Lakatos, 1980).

Castells believes the transformation from the industrial age to the information age is revolutionary. In that revolution, there is another relationship between information and knowledge that is transformed by thinking about information. "What we think, and how we think, become expressed in goods, services, material and intellectual output, be it food shelter, transportation and communication systems computers, missiles, health, education, or images" (Castells, 31). If the goods, services, and productive outputs structure the way we think then information itself structures the way we think. What we believe about information, such as "information wants to be free", structures our worldview. Our knowledge about information may be true or not, but in either case; it structures our relationship to information. If we believe the learning environment to be a marketable good in all cases, then institutions and tools will reflect that belief and with that, you have changed the premises of education and educational institutions toward a market mentality and in that transformed the future.

2. INFORMATIONAL SPACE AND INFORMATIONAL POWER

While there are many forms of power operating on many levels of analysis in informational capitalism, informational power is one of the defining forms of power within the spaces it inhabits. Lefebvre indicates this in his conclusion of *The Production of Space*:

> Historical formations flow into worldwide space much like rivers debouching into the ocean: some spread out into a swampy delta, while others suggest the turbulence of a great estuary. Some, in democratic fashion, rely on the force of inertial to insure their survival; others look to power and violence (of strategic—and hence military and political—kind).
>
> (Lefebvre, 1991: 417)

Power flows through and inhabits space through the social presences of human beings and the technologies they create and use in that space. Power is a subjective and universal part of human experience. It is embedded in language, and operates as much through discursive formations as through physical force. For the first time in history, the human mind is a direct productive force, not just a decisive element of the production system (Castells, 2000: 31). There is a very real aspect of all forms of power, and it can be analyzed in a variety of ways. With the recognition of information all around us, the recognition of power operating in and through information, as much as through any other interaction or artifact, becomes manifest. Much like the physical power of arms and armies, informational power is about spaces or territories, and what is allowed to pass through those spaces.

Comprehending the nature of this power perhaps can be aided by Foucault's description:

> Power is not something that is acquired, seized, or shared, something that one holds on to or allows to slip away; power is exercised from innumerable points, in the interplay of non-egalitarian and mobile relations . . . Power comes from below; that is, there is no binary and all encompassing opposition between rulers and ruled at the root of power relations, and serving as a general matrix—no such duality extending from the top down and reacting on more and more limited groups to the very depths of the social body.
>
> (Foucault, 1978)

In short, power is not purely the dominating power of armies, but it is also exists as dispersed and pastoral. It is a power of control, but it is not limited to the manipulation of base emotion, like fear based in inequities in the means of production and their control, it is habituated and constructed into the very subjectivity of the individual and populace, through the establishment of norms, traditions, and similar systems. This power governs populations as much as any other, and it is through its operations that governance that a political economy of the internet are made possible.

The spaces of power though need not be real spaces, though real spaces have much the same characteristics. The construction of virtual spaces whether perceived or imagined also holds and sustains power

> Software and networks do more than structure and present information; they also generate and sustain spaces, or hyperreal estates, which need to be rethought and reenacted as spatial domains with their own unique properties of accessibility/inaccessibility, boundedness/unboundedness, underdevelopment/overdevelopment, security/insecurity, publicity/privacy, openness/enclosure or commodification/collectivization for the cybersubjectivies now beginning to inhabit them in groupware, thoughtware, mediaware formations as digital beings.
>
> (Luke, 1995)

Hyperreal, virtual spaces construct another area of informational power as Luke indicates. Functionally, they operate as real loci of power for users and creators, like any space does. It has the power of the territory and the power of flows that occur in it. Capillary power flows through these spaces as distributed interests are pursued, contesting the very structure and presentation of the information involved. These virtual territories are places of recruitment and enclosure (Latour, 1988, 1993; Callon, 1998). The imagination of the virtual learning environment is commonly an imagination of a virtual space, like a virtual library, a virtual classroom or a virtual lecture hall. It is the imagination of a simulation of a classroom, frequently lacking the other secondary systems supporting the existence of classrooms, and in that partial simulation it amplifies all of the structures of power that we can identify with classroom.

Is there anything more than simulation and power in these environments? There must be because they are informational, they possess the perpetually reconstructed artifactuality of the digital artifact, which can be created and manipulated in real time according to programmers or others wishes. This is part of informational power, the power of immediate control via infotechnics. In short, these virtual territories are spaces that are controlled by infotechnics that are built by programmers and designers. This array of infotechnics and communities establish a defensible territory, a community of knowledge and practice that provides the productive capacity for the future development of informational spaces.

This community is at the core of any notion of informational power because its members control the means of production and reflexively structure the mode of production. They are sub-political in that the decisions they make are directly political, but our outside of the public sphere. "Sub-politics, then, means shaping society from below. Viewed from above, this results in the loss of implementation power, the shrinkage and minimization of politics," (Beck, 1995, 23). The state, the social apparatus as a whole, becomes less powerful because the sub-political exists within it, and transforms it. The meta-politics involved in sub-politics is where the politics of the information age plays out. It is a politics without choice, determining what will be within or outside of political decision-making depending on many variables, but driven by economic concerns. Even though many state and institutional policies exist as official political apparatus, they do not change the institutions as a whole. Information producers and users are altering the rules of virtual learning environments and transforming the very environment in which they operate. They are providing an external system, a different set form of governance, with a different form of power, a sub-political power of transformation and depolitization, that may be liberating for certain economic interests, but even if not liberating is encapsulating to the greater population because they are the ones that learn the values, norms, and rules built into the information systems.

3. INFORMATIONAL POWER AND THE PARALOGICS OF CONTROL

There is a question of governance and economy in the sense that people and machines control information and inversely, according to Norbert Wiener, information can control people and machines in a variety of ways (Wiener, 1965). Through the creation of informational goods, people create value, and then they have the choice of what to do with this valuable object, and when they make those choices, they are in fact governing the relationships surrounding this informational good. So we can think of informational power about the control or management of informational goods in a given territory. A political understanding of the contestation of informational power provides us with an understanding of the informational power as a power of control, a power of territories, a power of flows, and a power of institutions and artifacts/objects. Informational power is thus a power of space, both real and virtual, where issues of who owns, who governs, and in the end, who controls information are contested.

This definition of information power helps us to understand what is at stake in the digital world. The technical assemblage of information surrounding learning in later modernity and the power and culture constituting it already are surrounded with monumental institutions for their production and distribution. One of those institutions is a school, which is usually part of a large system of nodes and networks governing the production and distribution of education. The materiality of education stored in schools, libraries and increasingly in virtual learning environments, clearly must contain valuable information if their management is so costly in comparison to their production.

Inherently the architecture surrounding informational artifacts varies significantly along several spectrums. The difference between the book as it sits on a students desk and the book as it exists on someone's computer for future reading on their Personal Digital Assistant is the difference between the physicalized information and information in its digital form, letters and words versus bits and bytes. From physical artifact to digital artifact is one spectrum of analysis, but there are others. Value is another significant area of analysis. When virtual learning environments become points of translation, and points of negotiation, where they become partial subjects or actants, and thus possess power, they become valuable (Latour, 1993). In that they hold value, and come to embody values, they become political spaces and spaces of governance.

These quasi-objects need not be like any artifact that we currently know (Latour, 1993). Ted Nelson for instance frequently argues that in fact these informational artifacts should not be limited by physical form or the metaphor thereof, but should be as open as the human mind allows (Nelson, 1987). However, we are burdened by familiarity and tradition, though there are processes of detraditionalization certainly removing some of our boundaries, norms, and expectations over time, leaving us with new forms for digital artifacts which will have to some extent, new ways of expressing informational value (Lash, 2002; Luke, 1989). Nelson's *Computer Lib/Dream Machines* clearly realizes the concretization of traditions and tried to break the paradigmatic structures implicit in the page and book. But as we can learn from his efforts, fighting the behemoth of traditionalized capitalist institutions may not in the end bring you to the desired result.

It is clear that informational artifacts seemingly possess the qualities Nelson identified, it is also clear that most information systems are not built to handle empowered, fluxing, compound, actants, such as mutable hypertexts, wikis or related interactive digital media. Those are aberrations of the normal institutions and call for new institutions to be imagined. Because of their fluxing nature, and the number of people using them at any point in time, some digital objects can take on a life of their own and be very hard to control and archive.

Most archived media reproduces media in earlier forms, media that is fixed, and closed. The reasons for this are varied, but control and encapsulation of the artifacts should not be dismissed as one of the possible motivations.

These quasi-objects take on significance in our culture whether we want them to or not because they have value (Latour, 1993). With the social construction of value, we always have the social construction of means to control its value. Overtime we develop norms, laws, rights, and similar social technologies to manage these things and their affects. Copyrights, patents, Digital Rights Management, even computer operating systems are being built to control and manage what people do with information that they may have created, transformed, or otherwise interacted with to create value. Even when people want to make their materials publicly accessible, they might face impediments based on the systems of control, which are built into our socio-political economic system. These paralogics of control: the laws, norms, and instruments are part of informational power because it is centered on the access and use of information, the control of information, and the limitations put upon that by a variety of institutions.

Informational power then is not unlike any other power; it involves the creation of artifacts, their transmission, and their control. It involves subjects, their construction, and their control through norms, traditions, laws, and other means. Informational power then is a social power as much as it is technical. It is not just a power based in contestation, but it is a power of enculturation, transformation, and everything that implies. This is why informational power as the control of information, its distribution, and its access is a core issue in the informational capitalism.

4. BUSINESS MODELS AS CULTURAL MODELS FOR VIRTUAL LEARNING

There is a tension widely described between normal, shared, cultural production and its capitalization. The tension exists between some content producers and content commodifiers (Lessig, 2001). The tension centers on the concept of ownership, and as such control of information. For our purposes, this is a question of provision, and in capitalist structures collection of payment, but provision is the central question. We have a problem because for a few hundred years there were commodities that were heavily imbued with value through their initial production, and then imbued with other values through their reproduction (Benjamin, 1985). The transformation from individual and guild craft production to industrial production changed the value structure of production. Likewise, when the costs of replication of the digital object become infinitesimally close to zero, commodity structures change, and this changes business and culture.

The normal, communal sharing of knowledge in science and education is somewhat contrary to the privatization accompanying commodification

(Merton, 1942). We can see the transformation of knowledge production and provision toward a commodification model in current events. Systems and forms of knowledge are rapidly changing, as knowledge becomes more business centered than science centered. With businesses such as Blackboard moving into teaching, Pearson's digital publishing providing digital only materials too classrooms, and the rise of for profit universities providing online content, the traditional forms of knowledge that science and human development requires are moving from the public to the private sphere. This extensive privatization and rapid transformation of education makes knowledge provision an increasingly costly service, one that states and nations are slowly vacating. Instead of knowledge provision being of a shared cost between colleagues, educational institutions, teachers, and students, it is a matter of massive contracts between capitalist institutions and occasionally other forms. This service model drives further privatization of public knowledge in a strange circularity, where the privatization of knowledge encourages the further privatization of knowledge, and packages of related knowledge are sold together. By packaging private knowledge with public knowledge, the ownership of the knowledge in the public domain becomes unclear, and if they are bundled in certain ways, such as in a database in the United States, the public knowledge then becomes private knowledge. This vicious circle is happening throughout the educational enterprise, and with the market ballooning to tens of billions of dollars in the next decade, it is hard to see where it might stop.

The institutional apparatus that allow this privatization and commodification of knowledge are manifest in our everyday life. They are justified in part by a claim that the production of a digital artifact within a proprietary system under license gives the proprietor some property rights toward the artifact, whether or not, it can be directly shown to be derived from their product or not. However, ownership of these tools is a key strategy for the informational world.

> Productivity and competitiveness in information production are based on the generation of knowledge and information processing. Knowledge generation and technological are key tools for competing between firms, organizations of all kinds, and, ultimately countries.
>
> (Castells, 2000: 124)

We have to be careful when, like Castells, we assign the outcomes of production and processing to the firm, organization, and country, because it need not be so. When we think about it this way though, we automatically put information, no matter what its intent, into the realm of profit and capital. This move imports significant ideological commitments about ownership and control that do not hold for all digital artifacts.

We have a choice between the open models of shared knowledge versus a closed model of owned, proprietary knowledge. However, it is not really a binary opposition, but a spectrum of virtue and vice. Some knowledge will be owned and some will be shared. It will become an asset not just of individuals and corporations, but also of nations and part of national security and trade policy. We see this today already with certain computers being classified as weapons in the U.S. to prevent them from being used by certain nations to decode transmissions. These instruments of control are being used as weapons against loss of "intellectual property". "This is an age in which ownership of ideas—copyright—can create international trade crises and lead publishing houses to fight the electronic revolution with all their might" (Chodorow, 2001: 5). The technologies developed to handle this will then determine the future of knowledge, if we design computers with implicit Digital Rights Management for music and movies, and people habituate themselves in their contexts, then those habits over time will likely territorialize other habits, practices, and assumptions in their everyday life.

In the end, as Lessig indicates in *The Future of Ideas*, we have choices. One choice we can make is to have a system of control that allows for all to define their own roles instead of having them being defined for us. The default choice seems to assume the current system of centralization of systems into corporations, and information provision in pursuit of economic incentives will rule the day. If we look virtual learning environments, it seems as if many of their chief promoters have made the choice similarly to Castells' spirit of informationalism. They assume the rampant progress of informational capitalism, and frame the situation in that context instead of framing it in terms such as social or public goods.

Traditionally, models based on public goods are put forth as the motivation for education, such as sharing of knowledge, providing for the education of the public, or similar social goals. While there need not be tensions between the commercial interest and the public good, in this case the tension is clear, especially if the commercial interests impedes the public good as it might if the commercial spirit of informationalism holds forth. If our knowledge is embedded within payment structures that require our schools to submit to and in the end participate fully in the realm of privatized, commoditized knowledge, then what are we teaching about public goods, and how do we legitimize the functions of government in that respect? The crisis of legitimation surrounding public goods is clear. If learners do not participate in the public sphere in schools, where will they participate in it? As our educational institutions are detraditionalized from their roots in information and knowledge as public goods, toward the privatization of knowledge, the students are learning the values of privatization, corporations, and similar interests, which certainly have private, not public interests at their core.

The forms and values that educational institutions take force real understandings of the way they work and should world onto their users, from the student, to the instructor, to the woman off the street. "Users and Doers may become the same" (Castells, 2000: 31). The development of this multiplicity and its transition into a fully fledged digital knowledge space will take on aspects of the traditional forms as much as they will become something new. However, the traditional role of educational institutions is more significant. Like early churches, educational institutions seed a territory with specific forms of knowledge and structures of control. It is a pastoral knowledge closely related to the pastoral power of feudalistic institutions. In libraries and universities, knowledge is housed not only in books, but in the buildings, structures, traditions, and people themselves. They combine as the institutions to provide a portal to the forms of knowledge that has become the their role to provide such as books, newspapers, movies, and music, and in that are a place of power.

They are not merely local nodes in the network of information though. They are global networks and the nodes are global too, though they are local to some users. Chodorow states "Librarians and collections are now serving an increasingly global public and serving it globally" (Chodorow, 2001: 11). This is clearly true for libraries and educational institutions, but the global public that they serve should not be mistaken for a utopian universalization of access to education and information. In becoming networked enterprises, these institutions take the dispositions that information and its owner's puts on access and use. They cannot give access to information without overcoming social, economic, and technological barriers embedded in information technology. This means that the traditional public institutions may no longer serve for the public at large, but will only serve in formational public, which implicitly has a different demographic than the universal public, much as the televisual public is a different demographic than newspaper reading publics (Baudrillard, 1983).

Different publics consume and thus require different information, and that perpetuates the differentiation of the public into individual consumers and the eventual collapse of the public sphere. In a recent issue of Educause Review, Cass Sunstein warns higher education of the problems of the individualized market in higher education (Sunstein, 2002). The argument, which parallels one in his book *Republic.com*, is that one of the aspects of learning in our current environment is the exposure to and tolerance of the ideas of others. He sees this tolerance and the trust of the good of plural views collapsing under the wait of individualized filters and the ignorance of others. This collapses of the public into not merely publics and counterpublics, but to a non-public is one of the risks of moving from the universal public with a unified public sphere. The death of the public sphere and the collapse of the social are not new theoretical constructs. They are historically issues involved with the growth of a legitimation crisis in late capitalism (Habermas, 1975). This legitimation crisis is tied intrinsically to educational institutions as public goods and the rise of the information society according to Lyotard (1984). Between Sunstein, Habermas, and Lyotard, there is reason to view that as the publics collapse and are transformed, there are spaces of power where informational institutions are aiding in the devolvement of the universal public into the informational, filtered, individual consumer. This structural change transforms the cultural models of information that business models use and lessens the resistance toward the commoditization of public goods.

The idea that educational institutions will benefit from the new efficiencies of virtual learning is clear in the public rhetoric, but we have to wonder about how the system will end up and who will benefit from that and why. In fact, if we look at the transition to the informational mode of production that will be required, we quickly see there are other issues at stake. When we move from industrial production to informational production, the infrastructure required is different. No longer do you need factories, presses, and large institutions maintaining them. "The production of services and other informational commodities (legal contracts, product promotions, movie showings, scientific papers, etc.), however, can be conducted almost entirely on the Net through shareware packages or on-line services" (Luke, 1995). The one benefit of the fordist, factory-based production had was that it provided for a new arena for collectivity, for people to work together in a common goal, and learn to be effective in organizing themselves toward that goal, which then translates into political effects that sought new power for the workers and producers of these objects, both the creative class, technocrats, and the capitalists.

But the diverse interests of these competing classes and their technocratic constructs have implications for society much like fordism transformed and unified subjects into classes, post-fordism, and late capitalism, ruled by technocratic producers and systems breaks the collectivities and transforms the public sphere, which traditionally contains the learning environments as Beck indicates:

> Technocracy ends with the alternatives which break open the techno-economic process and polarize it. These alternatives become fundamental and detailed, professional and profitable, found careers, open markets and perhaps even global markets. They divide up the power bloc of the economy in this way and thereby make possible and enforce new conflicts and constellations between and inside the institutions, parties, interest groups and public spheres of all types, and as far and as soon as this occurs, the image of the indifferent self-referentiallity of social system shatters.
>
> (Beck, 1995: 48)

As the economy is divided and transformed by information, the new constellations of technocrats in institutions gain power, and subvert some of the institutions interests to their own, and with that the imagination, the norms, and traditions embodied in that institution loses the self-referential possibility of identity and the collectivity and its politics fails. Likewise, with online education and distributed, online production, you no longer require the physical location, the factory or its functional equivalent, that produces this politicized collectivity.

In fact, informationalized production deterritorializes production, distributing power, and control across many individuals and institutions that do not seem to have the same political effect. This is paralleled in the decentralization of users, and their individualization in education that Sunstein describes as possible in virtual learning environments. Unlike most educational institutions, where you might meet, socialize, and coproduce knowledge and power, virtual learning environments like Blackboard have few communal facilities that allow the normal interaction of the anonymous and social public. They focus on the user and the service, this transforms the potentialities of production from communal and shared to one of limited potentialities where one person and one screen with their own digitized experience, individualized and customized to limit. With digital rights management regimes in place, these functions will be reterritorialized and recentralized, to be controlled by different interests.

It can be imagined to be otherwise of course.

> In the fluid world of the electron, the body of scholarship in a field may become a continuous stream, the later work modifying the older, and all of it available to the reader in a single database or a series of linked databases. In such a world, scholarship would progress in a perennial electronic conference or bulletin board. Contributions and debates would occur on the internet and be continuous. The browser would become the catalog to the collection of knowledge.
>
> (Chodorow, 2001: 7)

Chodorow envisions an information intensive interactive communal system, perhaps one like Wikipedia. However, wikipedia is a communal, open project and not a closed learning environment. It is an encyclopedia of sorts as claimed by its presentation at wikipedia.org (Wikipedia.org, 2004). But it is still distributed, and in some ways heavily contested instead of a collective domain. It is an encyclopedia of negotiated knowledge, not of universal agreement, and is still mediated through the internet, its controls, and interfaces. Similarly, the social constructivist, open source learning system developed at Curtin University of Technology called Moodle might be a point of resistance against the corporatization of education and the privatization of knowledge found in informational capitalism. However, both Moodle and Wikipedia are late arrivals to informational capitalism, and both are facing increasing problems with the capital requirements of information provision, such as funding of bandwidth, providing easy access, and openness in the face of the barrage of the normalized culture of commodification.

The processes involved in virtual learning are always involved in the creation and distribution of informational power, the control over information, in all its dimensions. The strategies and tools available to them are the ones that are built into the institutions in which they exist, such as ownership, rights management, software production, etc. These tools and strategies are being vested into knowledge spaces in a variety of ways, and are producing systems that have significantly different social effects than their predecessors and namesakes.

CONCLUSIONS

Manuel Castells in *The Rise of the Network Society* argues that there is a spirit of informationalism that provides an ethical foundation of the network enterprise (Castells, 2000: 214). This parallels Weber's argument in *The Protestant Ethic and the Spirit of Capitalism*, in which the normative framework of Protestant Christianity is put forth as the core driving force and the ethical justification of capitalism and capital accumulation.

Inarguably, Castells is talking about a business network, but the education is in fact more and more becoming a form of networked enterprise, and more often than not is a business venture of itself in these the days of academic capitalism. "These business networks that form the new network enterprise are built on technological tools and attempt to compete globally and resist to some extent the idea of the state" (Castells, 2000: 212). They are very much transnational institutions or if not stand a high likelihood of becoming one. But they are the same sort of institutions we find in our everyday lives, the old forms, and the old powers, are inherent in the Castells network enterprises; they are not destroyed as much as they are recreated in the informational arena.

We should not forget that these transnational institutions are technologically enabled. This is what allows them to reach their audiences and investors equally well and convince them of their relative merit in comparison the wide array of competing services. This as Castells notes, is part of their historical development, they arose with these tools and moved into the informational arena by strategically implementing information services within their organizations. These arose in specific historical context though.

> The informational, global, economy is organized around command and control centers able to coordinate, innovate, and manage the intertwined activities of networks of firms. Advanced services, including finance, insurance, real estate, consulting, legal services, advertising, design, marketing, public relations, security, information gathering, and management of information systems, but also R&D and scientific innovation, are at the core of economic processes, be it manufacturing, agriculture, energy, or services of different kinds. They can all be

> reduced to knowledge generation and information flows. Thus, advanced telecommunication systems could make possible their scattered location around the globe.
>
> (Castells, 2002: 410)

The context is the firm and the service sector business for Castells, that is the locus of the information network and control. However, as we have seen, it need not be so. The publicly funded school provides a counter example, a public good, that while like a firm was occasionally provided for by states, and non-business groups. As a category for reference and ground for traditional expectations, educational culture provides an alternative to the grounding of the spirit of informationalism, while always being immersed in its contexts.

Information systems are scattered in one context, the geographic, but concentrated in another, the informational. Relatedly informational power is concentrated where information combines with institutions, both new and old. This concentration is aided by the social development of new technologies strategically supporting the goals of the social groups that consume them. The combinations of possible institutions and information technology are nearly endless. It is clear that many groups strategically seek some goal in relation to informational power, either concentration or diffusion of it. Many things will happen, some people will win, and some people will lose. Will our world be like Stephenson's socially fragmented, informational dystopia, or will there be a revolution or a point of balance where we can balance the tendencies of informational capitalism with the provision of public goods such education and knowledge? Depending on what happens in the near future, either the spirit of informationalism will align with Castells' conception or not, and this has implications for the future of virtual learning environments.

Chapter 7: The Influence of ASCII[1] on the Construction of Internet-Based Knowledge

JASON NOLAN
School of Early Childhood Education, Ryerson University

1. PROGRAM OF INQUIRY

The intention of this chapter is to engage the deep structures of the hegemony of the digital technology revolution as represented by the internet, levels beneath those addressed by most of the contemporary critical discourses. I am not working with more obvious barriers that constitute the "digital divide" such as the relationship of access to safe drinking water and basic rights of women's education to global attempts to bridge the digital divide (Nolan, 2000), the future of educational technology in North America (Nolan and Hogbin, 2001), or the potential for zero-cost computing and telephony technologies and indigenous language software environments. The goal is to extend the dialogue to a consideration of the locations of control over which disadvantaged groups of users of communication technologies have little or no control, and even less information or understanding. I am looking not at the content/information/data that is presented through the various media of the internet, but at the bias inherent in the medium itself (Jones, 2000).

The internet is first and foremost a learning environment in both formal and informal learning (Nolan and Weiss, 2002). It is one that presents itself as value neutral; a manifestation of McLuhan's global village where bias and difference all meld into a stream of bits (McLuhan, 1995). There is a great deal of pedagogy and curriculum about the internet that both challenges and reinforces difference (Cummins and Sayers, 1995; Harasim et al., 1995; Haynes and Holmevik, 1998). But there is very little curriculum or curriculum theorizing that engages the software, code, discourse, and metanarrative of the internet itself, leaving current pedagogy to function in a sea of assumptions about what can be done and said and accomplished online. There is an "anti-intellectualism" similar to what Giroux describes as present in the classroom, or lack of interest in the sub-surface discourse of the code and software of the internet (Giroux, 1992: 116; Gray, 2001).

McLuhan's *medium is the message* mantra is ever current as we are infected with the latest rash of technological developments. However, as educators and researchers confront the dominant and subversive ideologies presented online, very few are willing or aware of the need to critique the imposition of the

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 207–220.

locations of power that have brought the internet into existence. There is a need for us all to be aware of the levels of implicit colonialization that accompanies the proliferation of internet-informed culture (Said, 1993). There are a variety of layers that must be unpacked and brought into the light of inquiry, "to know as much as possible about the house that technology built, about its secret passages and its trapdoors" (Franklin, 1992: 12). First and foremost is the foundation and genesis of the internet itself, located in the Cold War desire for a computer network designed to withstand nuclear war (Krol, 1992). Who made the internet? Who are its informal architects? What culture was this creation located in? Second, we have to look at the software that runs the internet, the servers that move information, and the software that extends its purview to our desktops at home and in our workspaces. Third, there is the post-1994 World Wide Web which opened this brave new world to both the general public and to the commercial influences that followed them (Berners-Lee, 1998). Fourth, we are faced with the internet representing technology and discourse as the informing metanarrative of the new global economy. Fifth, we need to envision strategies to help educators encounter difference in our pedagogy, practice, and inquiry. These will serve to point to locations, the potential avenues, for radical repositioning of the discourse at the nexus of the educator and her performative/transformational capacity as creator of learning environments (Nolan, 2001).

2. THE FOUNDATION AND GENESIS OF THE INTERNET

Most of us are aware of the genesis of the internet at the hands of the Advanced Projects Research Group, of the US Department of Defense which, in late 1960s founded research that led to the linking of computers at universities in the Western U.S. (Cailliau, 1995; Gray, 2001; Krol, 1992; Mitchell, 1998). This foundation has morphed into an ostensibly uncontrolled and uncontrollable global phenomenon that has exploded the opportunities for voice and communication around the world. It has gone down in Western history alongside Gutenberg and Caxton's moveable type revolutions which propelled text out of the Medieval modes of production and privilege (McLuhan, 1995). And just as the print revolution was about the technology of the printing press, the internet is as much about the software code and Internet Protocols (originally TCP/IP, Telnet, SMTP, FTP, and recently HTTP) that bring the internet into existence as it is about what we do on it. Those who controlled the printing presses still controlled what could be and was said. Someone needed to control a printing press in order to have voice; as time went on more people had access, and differing voices could make themselves heard. Of course, concomitant with this means of production, one needed to have access to networks of distribution, a limitation that still restricts the diversity of voices that are heard both in media-rich and media-poor cultures/languages. Today, access to public consciousness via the medium of print is seen as widespread, but in many situations individuals and groups are still voiceless (OECD, 2000).

The internet stands now as a force within our collective worlds. But control is still located in corporate and government institutions. In 1992, the U.S. government released the rules governing acceptable use of internet resources, opening the internet up to business, and since then corporations have taken over much of the internet (Cerny, 2000; Hochheiser and Ric, 1998). Individuals must purchase or rent time on expensive machines made by an ever-shrinking number of multinational corporations. Organizations such as the various Freenets (Scott, 2001), FIDOnet (Vest, 2001) and the Free Software Foundation (Stallman, 1999) are still challenging the hegemony of institutional and corporate interests, but their influence is small and localized.

3. TECHNOLOGIES OF RESISTANCE

The internet is not the free-for-all anarchic space that business, the media, Libertarians, and cyborgs would have us believe (Gray, 2001). Though chaotic and anarchic activities do exist, and these are very important locations of resistance, every act of resistance or conformity occurs under the graces of the protocols of the internet. These protocols are governed by various institutions, governments, and administrative agreements. The most fundamental of these it the TCP/IP protocol, invented by Vinton Cerf and Bob Kahn. Almost all internet traffic must conform to the TCP/IP protocol or it is rejected by the servers that pass information from computer to computer. How that information is encoded is governed by standards developed and maintained by various groups such as WC3 (World Wide Web Consortium), ICANN (Internet Corporation for Assigned Names and Numbers), IEEE (Institute for Electrical and Electronic Engineers), and JPEG (Joint Photographic Experts Group) (Champeon, 2001). These regulatory bodies, organizations, and protocol standards control what can and is done on the internet. Many of these groups are transnational, but they contain a very narrow selection of interests that are contiguous with the goals of the West.

There is no question that the software and hardware we use is primarily informed by multinational corporations; Microsoft, Sun Microsystems, Intel, Google, AOL Time Warner, Apple Computer, IBM, Yahoo, Hewlett-Packard, Sony, etc., along with their support companies and organizations, control at the most basic level how we communicate online. Their software is not value-neutral. It is culturally and linguistically embedded in a technologically positivist metanarrative that sees the technology itself, and those who create it and use it, at the apogee of human cultural experience (Lyotard, 1984). This predisposition is encoded in the software itself.

There are a number technologies and movements that challenge the consumerist/corporatist profit driven models of the internet, positing a somewhat prosumerist[2] model; “As prosumers we have a new set of responsibilities, to educate ourselves. We are no longer a passive market upon which industry dumps consumer goods but a part of the process, pulling toward us the information and services that we design from our own imagination” (Finely, 2000). The open source movement is the key idea that brings otherwise competing interests together; it is one of the most important in computing in the late 1990s, and will probably be one of the dominant forces into the next century (Scoville, 1998; Raymond, 1998; O’Reilly & Associates, 2000). Open Source Initiative and the GNU Project are two organizations influenced by specific individuals; GNU by Richard Stallman, and Open Source by Eric Raymond (Scoville, 1998). In general terms, they both want to promote software that is free, freely available, and open to the Hacker community. These projects both support the traditional notion of sharing resources among members of a community.

The Free Software Foundation is clearly immersed in the Hacker philosophy that information wants to be free. The Free Software Foundation’s GNU General Public License (GPL) was first brought forth in 1991: “The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software—to make sure the software is free for all its users” (Stallman, 1999).

The Linux operating system builds on this open source philosophy. It is both a software and a conceptual revolution that has changed computing in a way that we cannot have imagined. Because of its success, it is also an important pedagogical signpost, showing an alternative direction from the commercialization of online exploration of learning. “Linux is a free Unix-type operating system originally created by Linus Torvalds with the assistance of developers around the world. Developed under the GNU General Public License, the source code for Linux is freely available to everyone” (Online 1994–2000). As such, it represents a movement that critical education can follow, through vehicles such as the GNU, to allow individuals and organizations to maintain ownership, while freely sharing of their work with a larger community.

The rise in importance of Linux (www.linux.org) is predicated on the fact that it is an open source operating system. The dynamic potential of the CVEs (Collaborative Virtual Environments) I work with is fundamentally due to their open source existence. This means that the raw source code of the system is publicly available under a license that allows anyone to use it and modify it for their own purposes under relatively flexible conditions as laid out in the license (Nolan, 2001; Nolan and Weiss, 2002). The result is that thousands of users are motivated not only to modify and add to open source software for their own purposes, but also to share what they have created with the entire community. The strength comes from the openness of the system and the community that surrounds it.

4. CULTURAL PRODUCTION

These initiatives do not challenge the Western bias outlined in this chapter. They do, however, challenge the multinational corporations' ability to control what software we use, and how software can be modified. Open source initiatives offer individuals and groups interested in social justice not only valuable allies who are often underutilized, but most importantly a model of resistance that seeks to transform debates and relocalize them within social, as opposed to corporate, purviews.

Hackers are the first community of the internet. Many of the original members are the programmers who hacked the internet together in the first place. They were the first to subvert the dominant discourse of the internet to human, communicative, social ends (Ruffin, 2001; Sterling, 1993). Hackers are not the malicious Crackers and virus programmers that strike fear into corporations and are vilified in the popular media (e-cyclopedia, 1999; Raymond, 2000; Stoll, 1989). They are not destroyers, but travelers, seekers, and creators of alternatives and solutions to barriers to accessing knowledge and information. Their mantra is that information wants to be free (Gray, 2001). They are also predominately ultra-privileged young educated heteronormative white males, but they are philosophically opposed to the hegemony of corporate and governmental interests. I work with queer Hackers, cyborgwomen, and cybergirls, and the work of Stone on the transgendered body (Stone, 1992), and Harraway's cyborg (Harraway, see chapter 4), and Hayles post-human (Harraway, see chapter 4; Hayles, 1999) collectively reveal how the interfacing of women and technology are relocalizing the discourse of hacking in gendered spaces. As the technologies and influence of technology on the body are engaged by women, they are staking territory in the realm of the Hacker. The roots of the community, however, are located in this opposition to institutions that want to control information and access to resources.

There are social learning environments, collectively called Collaborative Virtual Environments (CVEs) such as MOOs, where individuals and groups construct/program/hack out virtual spaces and communities (Cicognani, 1998; Fanderclai, 1995; Rheingold, 1993; Schank et al., 1999; Turkle, 1995). I have been involved in CVEs since the late 1980s, and developed two MOOs. MOO is an acronym for Object Oriented MUD, itself an acronym often unpacked as Multi-User Domain/Dungeon/Discourse (Curtis, 1992; Curtis and Nichols, 1993). My MOOs are virtual places where participants from as far away as Taiwan, Iceland, Brazil, and Russia "create representations of people, places and things and share them with others" (Nolan, 2001). The key to these constructionist, polysynchronous[3] (integrated synchronous and asynchronous communication) spaces is that people not only communicate online in a multimedia, open source software environment, but that they can collaboratively create and program these spaces according to whatever criteria they choose to conceptualize and describe (Davie et al., 1998; Davie and Nolan, 1999). Though MOOs still suffer from their English-only roots, we can and have worked simultaneously in English, Chinese, Japanese, Russian, Icelandic, and we are conceiving a MOO dedicated to polylingual communication. A polylingual space, versus multilingual, suggests that not only can many languages be accommodated, but that no one language reigns supreme; that multiple, intersecting language events and spaces can be created, and participants can work within the language(s) of their choice without being mediated by an overall dominant language.

5. THE INTERNET IS WRITTEN IN ENGLISH

The internet infrastructure, corporations, and technologies/groups that challenge them are primarily English/male/Western dominated discourses. All strands are Western in voice. More importantly, software is written in programming languages such as C, C++, ObjectC, Java, and/or scripting/markup languages like Perl, PHP, HTML, XML. Though it is possible to use these languages to express written languages other than English through various encodings, these languages were created by speakers of English to be used by English speakers. You cannot participate in the creation of software without *using* English in the programming, scripting, or markup of content, without participating in the hegemony of English, even if you do not have the ability to speak or write English.

What does this mean in terms of education and technology? Simply put, it means that it is practically impossible to participate in the world of technology without privileging English. The internet is written in English. A programmer who wants to write a word processor for Icelandic writes the word processor in English using a language like Java or C++. The software is installed into, say, a Windows, Linux or Apple operating system that has been *localized* into Icelandic. And files created still require, in most instances, a .doc .txt .html suffix; all derived from English. These *localized* versions are localized as an afterthought. The major operating systems, and the various software packages, are most all written for English consumers first, tested and made available to English consumers, and then *ported* to other languages, *if* the software company feels that it is profitable to do so. In 1997, Microsoft was pressured into porting one of their versions of windows to Icelandic by the

Icelandic government, highlighting the fragility of languages in the face of English and corporate interests (Ford, 2001).

Though many operating systems, such as Macintosh's OSX and Linux, now are sufficiently international to ship with multi-language package options, and has localized versions for a few major language markets, there is very little available that is not Anglo-centric. The hegemonic influence of English in the computer languages running the internet, however, means that concerted effort by educators of difference who are willing to work towards the creation of alternative language spaces is required.

The 26 letters of the English alphabet form the basis of how most content moves across the internet, encoded as ASCII (American Standard Code for Information Interchange) text. The internet functions primarily using the 94 printable characters that make up the ASCII character set:

abcdefghijklmnopqrstuvwxyz
ABCDEFGHIJKLMNOPQURSTUVWXYZ
0123456789
!"#$%&'()*+,-./:;<=?@[\]^_`{!}~ (Lunde, 1993: 36)

And when Japanese is displayed on your computer, the characters look and act like Japanese, but the encoding method still involves ASCII characters in the background.

か	な	漢	字
82A9	82C8	8ABF	8E9A

In this example the two groups of characters, *ka na* and *kan ji*[4], are presented with ASCII characters shown below.[5] These *characters* which represent words that describe the two main writing scripts in Japanese (*ka na* and *kan ji*) are each represented by four hexadecimal digits; digits which are part of the ASCII character set.[6] That is, the Japanese language is represented by characters that make up the American Standard Code for Information Interchange. And Japanese is often encoded using methods that represent data based on ASCII in order to be to be communicated to another computer, even within Japan.

When you write a program, script, or electronic document, it must be written using an English-based programming language, such as Java, C, Perl, HTML. This following example from MOOca.java describes connecting to our MOO and setting the parameters for encoding non-English characters:

```
outputWriter = new OutputStreamWriter(mSocket.getOutputStream(),
   mRequestedEncoding);
s = new String(inputBuffer, 0, byteCount, getEncoding());
```

> Where mRequestedEncoding is taken from the applet parameters and is a string such as “SJIS” “ASCII” “UTF8” [Unicode] which tells Mooca how it should encode the characters to send it to the Moo. Where getEncoding() usually is the same as mRequestedEncoding above. The only time it would be different is if someone tried to ask for an encoding that didn’t exist, such as “japlish”, in which case it would fall back to the user’s default encoding (Nolan and Goulden, 1996–2001).
>
> (Goulden, 2001)

It is possible to see this form of encoding as unproblematic. A minor price to pay for global communication, but the hegemony of English is even more profound: “*Does the interiorization of media such as letters alter the ratio among our sense and change mental processes?*” (McLuhan, 1995: 119). When you send an e-mail message, regardless of the language in which you compose your text, your e-mail program must talk to a server. A message is sent to a server on port 25 and the first message it says is “HELO”, an abbreviation of “hello”, in order to initiate a process that gets your e-mail moving on its way (commands sent to initiate communication are in **bold**):

telnet achieve.utoronto.ca 25
Trying 128.100.163.xxx... Connected to achieve.utoronto.ca.
Escape character is '^]'. 220 achieve.utoronto.ca ESMTP Sendmail 8.9.3/8.9.3; Tue, 6 Nov 2002 14:36:15 -0500
helo achieve.utoronto.ca 25
achieve..utoronto.ca Hello envvirtual.utoronto.ca [128.100.163.xxx], pleased to meet you

This means that every e-mail ever sent on the internet by anyone in any language to any country, is couched in, or bracketed by, English. Communication is initiated in English and concluded in English. As Steiner notes: “So far as language is the mirror or counter statement to the world, or most probably an interpretation of the reflective with the creative along an ‘interface’ of which we have no formal model, it changes as rapidly and in as many ways as human experience itself” (Steiner, 1998: 468). Steiner’s ideas suggest that what we can do and think with technology is forever informed by a language that, though in flux itself, forces the expression of human experience to conform to the influence of a single language and perhaps the metanarrative of those who thus situated it. The phenomenon that is the internet has come upon the human species fast and unanticipated. Educators are playing catch up in their critical awareness of the foundations of the internet, with the result that aspects of this revolution that should be challenged and problematized have slipped by, perhaps unnoticed.

I am writing this chapter in English, as it is the only language to which I can claim fluency, but I choose to code this chapter in raw html, the hidden background scripting language that forms the background of most web pages. What I have written looks to me like this:

```
</blockquote>
<p><b>The educator as a Creator of Learning Environments</b></p>
<blockquote>
<p>
I am writing this . . .
```

I am also writing using programs such PICO and BBEditLite, free word processors. These choices remove, even if just temporarily, a level of commercial influence over the production of text, and a level of isolation from what goes on behind the location of the presentation of text. In order to participate in the publication of this book, however, I will have to convert my text into Microsoft's Word program. These vaguely symbolic acts do highlight how an educator can position herself within alternatives to corporatist agendas, and model a practice that can be both emulated by students and stimulate awareness and inquiry into alternatives.

These are, however, the most superficial locations of resistance, and an entire volume such as this would be required to engage the possible examples and experiences of CVEs, MOOs, Cyborgs, and Hackers (Gray, 2001; Stone, 1992). Technology and computer literacy as it is taught rarely takes even this stance. Review any curriculum, and you will see that it is largely infused with corporate technologies and corporate interests. The goal of technology-based curriculum is that of teaching users to be consumers of products in the name of global competitiveness and efficiency. Often the technologies are no more than computer assisted learning and evaluation tools. Teaching is limited to what is proscribed in the manual. Rarely do even the most pedagogically aware educators, informed by critical pedagogy and aware of the need to promote alternative voices, critique the technologies in which the voices are located. And if/when they are aware, they lack the time or resources to really explore the options that are hidden away by security-conscious systems administrators (Nolan, 2001). Today most decisions as to what technologies are used in learning environments are made by technology specialists and administrators, and are given to educators with little or no consultation. There is even less awareness on the part of the educators and students that alternatives exist.

This is an untenable position. If valid and sustained strides are to be made to embed alternative choices in the global culture, they must be found within the technologies we use. These technological alternatives are something that cannot be done for us either. They must be done by us in community with our peers and students. To control the conceptualization, creation, development, implementation, co-habitation, and governance of these spaces we must learn to code, program, create our own software and environments that reflect our diverse needs and goals, and we must share them freely with others; allowing others to revise and relocalize what we share according to their own criteria and needs. For if we do not actively participate in the creation of our discursive spaces, they are created by someone else, and we are at the most disempowered end of the power relationship (Foucault, 1991; Illich, 1970). If we do not govern our own spaces, teaching and learning is open to commodification, and we are no longer creators, but consumers.

As a first step, transforming ourselves from consumers into prosumers where we are involved in communities of discourses, technologies, and narratives that we co-create and inhabit, allows us to share and interact with our stories. The much vaunted virtual community becomes a potential reality when we are able to (re)construct and embrace both collective and infinitely differentiating representations of ourselves, as we see ourselves, and reflect upon how we see others and are seen by them (Fernback and Thompson, 1995; Rheingold, 1993). The potential dialogues are, however, only realizable when we control the means of our own representation. The situation is hazardous simulation when dialogues are mediated by technologies over which we have minimal understanding and scant influence (Baudrillard, 1988; Fernback & Thompson, 1995; Stone, 1992).

The influence of the internet on diverse languages and cultures, those represented and under-represented by technology, is an act of relocalization of culture(s) from the real to the virtual. Cultural topologies are (re)constructed, and cultural experience must find new strategies of expression and resistance to survive and thrive (Ostrom, 1990; Rheingold, 1993). But more importantly, this relocalization is an act of translation of cultural experience (Steiner, 1998). And without the concerted effort of educators informed by the ideas of the pedagogies of difference—educators who are able to engage and dialogue with the Englishness of the internet below the surface level of written texts, down to the level of the code and encodings that make the internet happen—we are situating struggles within colonializing dialogues, aware of whose hands we are playing into, but unaware of how deeply the cards are stacked against us (Giroux, 1992). Where Steiner hypothesizes that “the proliferation of mutually incomprehensible tongues stems from an absolutely fundamental impulse in language itself [and] that the communication of information, of ostensive and verifiable ‘facts’, constitutes only one part, and perhaps a secondary part, of human discourse” I think that we are not only engaged in a struggle to liberate internet discourses from the hegemony of English, but are engaged in a struggle fundamental to the defense of all aspects of difference (Steiner, 1998: 497). Little can be done to exorcise English as the fundamental language informing internet communication, but it is important that educators struggle to demarginalize communities of difference to extend their program of inquiry and resistance to an engagement of how language and cultural influences inherent in the structure of the internet translate/encode discourse and experience within a dominant cultural ideology.

ENDNOTES

1. ASCII stands for American Standard Code for Information Exchange, and is the encoding method by which most text-based information moves around the internet.
2. Prosumer, in general, is an individual who partakes in both production and consumption.
3. Polysynchronous is a term coined to describe the nature of MOOs where communication is an embedded combination of both synchronous and asynchronous communication (Davie and Nolan, 1999; Nolan, 1998). An IRC chat group is completely synchronous. Users communicate in real time, and there is usually no record kept of the communication unless one member personally creates a transcript of the interaction as a log. Asynchronous communication refers to the what happens on bulletin boards and via e-mail where a message is composed and transmitted to another individual or group. In a MOO, communication can be synchronous or asynchronous, but it can also be a combination of both. A conversation can be encoded into an object for others to read. MOO objects can be programed to listen to conversations between members and generate responses that become part of the MOO-space itself for other participants to listen to later. As well, a conversational interaction may take the form of direct synchronous speech *and* the co-manipulation of MOO objects. It is possible to talk with another person, hand her virtual objects for her to look at, co-program MOO objects, and record the conversation for a third party to read later. This type of polysynchrony is particular to MOO-type environments, but reflects the direction that collaborative virtual environments are anticipated to follow in the future (Nolan, 2001).
4. The *ka na* and *kan ji* characters and their encodings have been created by Ken Lunde for this publication.
5. For more information on Japanese language and computers, please see Jun'ichiro Kida's web site "Japanese in the Age of Technology" (http://www.honco.net/japanese/). Of particular relevance to this paper is the section "Inputting Text with Two-Byte Characters" (http://www.honco.net/japanese/05/page4.html).
6. Dave Goulden (2003) notes that Japanese characters are more properly identified as having been encoded into hexadecimal digits, rather than ASCII characters. Hexadecimal is a base-16 numbering system used by programers for, among other things, representing binary data. The hexadecimal character set (1, 2, 3, 4, 5, 6, 7, 8, 9, 0, A, B, C, D, E, F) can, for the purposes of this discussion, be characterized as a subset of ASCII.

Chapter 8: Interaction, Collusion, and the Human–Machine Interface

MIZUKO ITO
University of Southern California

In contrast with instructional media such as videos and books, the computer has held out the promise of instruction that is learner-centered and engaged, with the machine providing immediate and situationally responsive feedback. The early 1980s saw interaction with computers expand from drill-and-practice into action video gaming as well as the instructional adventure and simulation formats that we now associate with commercial edutainment. By the1990s, multimedia had become a new buzzword in educational media, promising to rival popular culture with its fast-paced and attention-grabbing graphics and sound. These interactive qualities and multiple forms of media representation have given birth to interactive entertainment and instructional media that have proven to capture the attentions of children. At the same time, these media forms have introduced new complexities in media design and our understandings of learning with computers. Interactive media not only rely on a layering of technical, narrative, and interactive qualities that expand opportunities for engagement with media, but also make these engagements difficult to predict and determine. This indeterminacy provides unique challenges for those seeking to create and analyze learning with computers. Drawing from a more extended study of the production and consumption of children's software (Ito, 1998; 2003), this chapter works to fill in one piece of this puzzle, by analyzing some of the basic interactional dynamics between a child and educational software.

The interaction between a child and a piece of computer code differs in important ways from interpersonal interaction and interaction with other forms of media. Not only must analytic attention be trained to the particular rhythms of human–computer interaction, but also research must pay attention to the design and symbolic content of the computer's "voice" as it is packaged and distributed through the software. Consumer software is often designed to imitate situationally responsive aspects of human interaction while at the same time partially replicating other kinds of media that concretize culture in a relatively inflexible way.[1] Accordingly, study of human–computer interaction must poach from frameworks derived from cultural studies of media (looking at how meanings are packaged into texts that travel) and human interaction studies (looking at how meaning is constituted through interaction).

Study of computational media is enabled by the ability to observe interactions in ways not available to researchers of non-interactive media: mouse

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 221–240.

clicks and keystrokes are accessible ways of observing the act of "reception" (use) of computational media. The challenge, however, is that the meanings of computational media are often less effectively explored outside of the actual context of use (i.e., through subsequent conversation or testing). Since there are multiple and contradictory pathways that one can take through many of the new forms of computer games, it is difficult to unpack the consumption-side meanings instantiated by a game without looking at the activity context. For example, a child might play a city simulation game for hours, treating it as a palette for drawing blobs on a grid, without ever engaging in the game as a representation of a developing city. This contrasts to, say, film, where viewers of a given movie might reasonably be expected to have journeyed through a similar set of images, albeit with different interpretations. In the case of interactive media, our understanding of what children get out of their engagement benefits from conversation with users as well as direct observational studies of use in order to capture the particular kinds of interactions and understandings that a particular software title affords.

This chapter takes some first steps towards describing the unique qualities of interaction with computational instructional media through analysis of a videotaped interaction with one educational multimedia title where a child works on a simple word-matching game with an adult helper. The case describes the space of possibility with an interactive title as indeterminate due to the multireferential quality of the interface. Alignment with the designed uses of the game is a contingent process of negotiation between child, game, and others in the local play context. Two analytical lenses are proposed for the study of children's interactions with educational multimedia. One is the asymmetric interactional capabilities of human and machine, where the strength of machine interaction is in its inflexibility and reproducibility, and the human's is in flexibility, indexicality, and situational responsiveness. The other is an idea of human–machine interface that extends beyond objects on the screen and the keyboard to include other people and contexts of play. After first describing the analytic framework for this study, I turn to the interaction case.

1. INTERACTION, GAMES, AND MEDIA

Studies of the details of interpersonal interaction, including conversation, gestures, and proxemics, have amply demonstrated the intricacies of the alignment work that goes into the construction and instantiation of a shared set of interpersonal understandings (e.g., Duranti & Goodwin, 1992; Garfinkel, [1967] 1994; Goodwin, 1990; Kendon, 1990; Lynch, 1985; McDermott & Tylbor, 1984; Schegloff, 1992). These studies have demonstrated how the structure of language and meaning are played out and engaged with in historically specific, context dependent, dynamic, and ongoing activity. In their essay on "the necessity of collusion in conversation", McDermott and Tylbor (1984) describe how the meaning of an utterance can only be fully understood as part of an ongoing set of interpersonal and institutional negotiations, and that analytic attention should be trained not to meaning sealed within the "inside" of an utterance, but rather meaning as it is achieved through the collusion of multiple actors in complex social relations.

> Collusion derives from a playing together (from the Latin *com plua ludere*). Collusion refers to how members of any social order must constantly help each other to posit a particular state of affairs, even when such a state would be in no way at hand without everyone so proceeding. Participation in social scenes requires that members play into each other's hands, pushing and pulling each other toward a strong sense of what is probable or possible, for a sense of what can be hoped for and/or obscured. In such a world, the meaning of talk is rarely contained on the "inside territory of an utterance"; proposition and reference pale before the task of alignment, before the task of sequencing the conversation's participants into a widely spun social structure (219).

McDermott and Tylbor thus insist on a relational view of language, not only in the semiotic sense of relation and difference in signification (Saussure, 1959), but also in the interactionist sense of meaning as a product of historical, relational, interpersonal, practice. In line with other interaction based studies of language use, McDermott and Tylbor describe how even the most mundane human activities are a product of constant and subtle acts of interpretation and alignment, which both index and utilize a wealth of structuring resources, linguistic, material, and institutional.

Given an interactional view of meaning production, media artifacts present particular analytic problematics. Mass media and computer games have a set of semiotic and material relations "hardwired" into a material substrate, whether this is a page, film, or a floppy disk, but these meanings acquire social significance through engagement in everyday practice. An interactional view of language has much in common, conceptually though not methodologically, with ethnographic work on how mass media texts are interpreted at local sites of consumption (Mankekar, 1999; Morley, 1992; Radway, 1991). The attention, again, is on how a text is made meaningful through its embeddedness in and indexing of the ongoing activity of everyday life. A mass media text, as a stabilized or "encoded" configuration of meaning, mechanically reproduced and distributed across wide distances, is socially meaningful only to the extent that it is rendered sensible in particular, local, circumstances of consumption. In contrast to analytic positions that locate meaning only in the "inside" of a text and read a determinate set of meanings based on the text itself, ethnographic approaches to mass media have looked at how these artifacts are part of the ongoing flow of social life and acquire meaning through their location in social and historical contexts. The same is true for games, as particular "texts", or standardized, rule-governed systems. In her analysis of girls' play with hopscotch, Marjorie Goodwin describes gaming as a meaningful activity, determined, not by the formal rules of the game and the parameters of the hopscotch grid, but rather by the interplay between these structuring resources and the embodied practices of play:

> In hopscotch, a player systematically moves through a grid of squares drawn in chalk or painted on the sidewalk, street, playground, or other flat surface. The marks on the grid construct a relevant visible field for action, which orients those who know how to read it to the sequence of moves through space that must be traversed while playing the game . . . the grid makes possible the forms of action and local identities that are constitutive of the game: for example, stepping on or outside a line count as a consequential event, an "out" in which the hapless player loses her turn. Of central importance to the conduct of the game are not simply internal representations (e.g., an abstract rule set of some sort), but rather a dynamic interplay between the player's body and visible marks in a structured external environment (1995: 263).

Computer games, as a particular kind of text, based on a rule-driven model of interaction, engage varied and indeterminate interactions and relationships with the daily lives of children, institutions, and other interlocutors. Like a game of hopscotch, a computer game embodies a stabilized set of rules and meanings that are locally engaged with in various and flexible ways by children, and acquires social meaning through these ongoing engagements. The meaningfulness of a game is thus an interaction between the stabilized sets of meanings and rules "coded" in the game, and the active sense-making processes of children in local situations of play. This is not to say that human activity is governed by a set of abstractable rules, but rather, on the contrary, that games, rules, and stabilized texts are malleable resources in the production of meaningful action, and that in turn, rules and structure are produced as a result of these ongoing practices.

In the case of both people and interactive texts, language and meaning are necessarily indexical and situated within a set of common cultural understandings, but the different embodiments of human and machine make for an asymmetric interagentive encounter. The computer game relies on a set of pre-programmed semiotic relations animated by a standardized and mass-produced configuration of computer circuitry. The success of a piece of software is predicated on its stability and inflexibility across situations, its ability to reliably produce the same responses and interpretations based on standard inputs. We want our word processors to reliably save and format our documents, and we want our games to respond consistently when we input answers to certain questions. For people, stable and common understandings are interactional achievements, based on ongoing collusion between people with unique life histories and richly embodied sensory awareness of the world. Conversation analysts have demonstrated that even moments as simple as asking for the time or saying a greeting are occasions for widely variable and situationally responsive negotiations. In contrast to the interpretive inflexibility of machine understanding, human understanding indexes a richly indeterminate set of meanings and interpretive resources. Computer games, no matter how sophisticated, are based on a freezing or standardization of meanings in order for them to function translocally, as mass produced objects. In contrast, while people certainly share a common set of cultural resources, these meanings are constantly in flux, idiosyncratic, and situationally responsive.

The result of this asymmetry in interactional resources is that human–machine interaction has a peculiar rhythm and structure, where the person is continuously compensating for the inflexibility of the machine, as well as trying to guess at the underlying structure internal to the machine. In actor-network terms (Latour, 1987; 1990), this is the sense in which stabilized technologies enlist people into their sociocultural network, as durable and inflexible objects in the social landscape. It is the interaction between this stabilized sets of meanings, and the dynamic and heterogeneous contexts of human play, that is the topic of this chapter. The remainder of this chapter outlines a theoretical departure point for this work in Lucy Suchman's analysis of human–computer interaction and then analyzes one example of game play as a way of drawing from this framework and extending it into the particular domain of computational media.

2. THE PROBLEM OF HUMAN–MACHINE COMMUNICATION

In her book, *Plans and Situated Actions: The Problem of Human–Machine Communication*, Suchman (1987) analyzes the interactions between people and a function-loaded copier with a computerized, interactive interface. Drawing from ethnomethodological frameworks and previous studies of face-to-face interaction between people, Suchman posits a basic asymmetry in the interaction between people and machines: " (P)eople make use of a rich array of linguistic, nonverbal, and inferential resources in finding the intelligibility of actions and events, in making their own actions sensible, and in managing the troubles in understanding that inevitably arise" (180–181). In contrast, machines "rely on a fixed array of sensory inputs, mapped to a predetermined set of internal states and responses" (81). Through close analysis of interactional sequences of copier use captured on videotape, Suchman demonstrates some of the interactional outcomes of this asymmetric communication. Of particular interest are breakdown situations, where the responses of the machine, as anticipated and pre-programmed by systems designers, are not appropriate to the specific needs and situations of the users, and human and machine are unable to engage in mutually intelligible action. For example, Suchman has documented many instances when the user and machine have been unable to orient to a task, such as making double-sided copies of a document, because of the mutual unintelligibility of their respective actions.

Suchman's analysis points to the differences between the semiotic and material capabilities of a human and machine, and some of the peculiarities of interaction and communication across this divide, the most salient of which is the asymmetry between pre-determined and situationally informed response. What is curious about computer software, however, are its multiple layers of signification, mediating between "internal" computer code at one end, and visible interface encodings at the other, only the latter of which is directly available to and interpretable by the user of a machine or the player of a computer game. Unlike non-interactive media, computer software embeds within its internal operation the force of interpretation, the ability, albeit a primitive one, to associate a set of symbolic elements, associations that are often unexpected to the user. A computer takes user input and performs operations based on the user input, in ways that are invisible to the user or only partially represented at the interface. It is this sense of opacity, the distance between human and machine interpretive stances and capabilities, which can be both a problematic and enabling feature of interaction with computers.

Examples from Suchman's study are illuminating of this sense of mutual opacity, of this distance between human and machine codes and interpretive capacities. In many of her examples, users of the copier are attempting to complete a complex task with multiple steps, such as making a set of double-sided copies from a single-sided, bound document. Through the course of a task of this sort, the copier communicates to the user through a display that provides instructions such as "place your original face down on the glass", or "close the document cover". The machine is able to gain knowledge of the user's status and activity through a limited set of sensory inputs, such as the closing of the document cover, the selection of the number of copies, or the pushing of the start button. Progress along a multistep task is made through the fulfillment of if—then conditions that speculate as to the status of user activity (e.g., if the document cover is closed, this means that the user has placed an original on the glass, then give the next instruction to the user). Situationally, relevant information, such as whether the user has a bound or unbound document, or whether the user knows what a "document cover" is, is systematically unavailable to the copier.

This opacity, however, goes both ways. The user, too, is lacking situationally relevant information about the internal states of the copier and the semantic relations of its encoding. While the interface provides the user with information about each step in a pre-programmed procedure for action, the user lacks access to the actual logic of the copier's sequential operation, the conditions it needs to fulfill to move along the multiple steps of a complex task, and an understanding of the machine language that drives these procedures. When the designer has successfully anticipated a user's sequence of action, human and machine action are mutually comprehensible, the task is completed without incident, and the user leaves the interaction with a sense that he/she has engaged with an "intelligent" machine. In situations of breakdown, however, the machine is frozen into a set of pre-programmed procedures and interpretations that are out of alignment with the particular situation of the user, and whose logic is incomprehensible and inaccessible to the user.

As with any media, whether it is print, film, radio, or television, computer software ventriloquizes for its creators through the body of a material technology—a page, a screen, a mouse, or a keyboard. While this is, in a sense, a form of highly mediated interpersonal interaction, the process of producing consumer software strips the content creators of access to the settings of consumption or play. As reception studies of media have amply demonstrated, a representation acquires meaning as an effect of human interpretation and decoding of meaning, rather than through the force of its own internal operation or the creator's intentions (Hall, 1993). To the extent that the relatively circumscribed settings of software creation and the manifold settings of use are socially and culturally disjunctive, we can expect that the meanings encoded at the moments of production and the meanings instantiated at moments of consumption will diverge. In a related vein, de Certeau (1984) has theorized how the practices of everyday life are structurally disjunctive from the "proper" spaces of authoritative cultural production, producing meanings that poach from and refigure those centrally produced while also being dependent and subordinate to authoritative texts.

Standing behind Suchman's description of an asymmetric encounter between human and machine is a communicative breakdown between content creators and consumers, the structurally over-determined failures of programmers to anticipate all of the situations in which software might be used. In more recent work, Suchman (2000) has critiqued the stance of "design from nowhere", where technical commodities are designed with the goal of being "stabilized and cut loose from the sites of their production long enough to be exported *en masse* to the sites of their use". These relations of technology production and use mean that usage contexts are often systematically invisible from the point of view of designers, since the settings of design are separated from the settings of use through multiple distancing mediations. These are forms of distancing that Suchman (2003) seeks to challenge by crossing boundaries between settings of design and use and insisting on a view of humans and artifacts as mutually constituted across these settings. It follows that the necessary inflexibility of machine response has to do with the material structure of software and machine, as well as particular relations of production and consumption; a product coded and designed at a singular and relatively controlled site of production is mechanically reproduced and disseminated to a wide and indeterminate set of settings of consumption.

Computer games, as a form of mass media with an increasingly complex set of interactional possibilities, are a far cry from Suchman’s copier, in terms of the activity that they invite, the computational complexity of their encodings, and the narrative meanings mobilized. Suchman’s insights on the disjuncture between human and machine (and design and use) understandings still, however, provide a useful lens for analyzing some of the basic dynamics of how children engage with computer games. The starting point, in an analysis of interaction involving computational devices, is the peculiarity of the communicative encounter between human and machine.

3. EXPLORING LANGUAGE WITH A COMPUTER GAME

My research on play with children’s software was conducted as part of a three-year, collaborative ethnographic evaluation effort examining the Fifth Dimension After-School Club (5thD) reform effort,[2] where we analyzed field-notes and videotape from three 5thD clubs. The 5thD is an activity system where elementary-aged children and undergraduates from a local university come together to play with educational software in an afterschool setting. The clubs are located at community institutions such as Boys’ and Girls’ Clubs, schools, or libraries and vary considerably depending on the local context and institution. What is common across the settings is a commitment to a collaborative and child-centered approach to learning, the non-hierarchical mixing of participants of different ages, and the use of personal computers running software designed for children.

One example of play in the 5thD with a game with a simple interface and functionality illustrates the relationship between pre-determined code and indeterminate local meaning, and some of the texture of human–machine interaction with interactive media. In this bit of activity, a graduate student and an 8-year old are playing together with a game called *Language Explorer*. The task is a simple one. The machine presents a set of words, with blanks above them, and a set of pictures that correspond with the words. The goal of the game is to click on and drag the pictures into the proper blanks. The pictures can be dragged to any part of the screen, but will only stick in the blanks above the words. Once all the pictures are placed, the computer will drop any incorrectly placed pictures back down to the starting position. If the pictures are all placed correctly, they will stay in position and animate.

The semiotic and functional relations encoded in this game are relatively simple and thus provide a useful starting point for understanding the basic structures of interaction with educational software and games. The content of the game can be understood based on a simple means-end model, where there is a starting state, an ending state, and a limited set of interactional possibilities to move from the one to the other. The cultural knowledge embedded in the system is one of simple signification between word and picture, where a designer has determined that one corresponds to the other. Interactionally, the only available form of human communication with the machine is through the dragging of pictures into spaces. From a starting state with blanks and pictures in a random jumble at the bottom of the screen, the player is invited to fill in the blanks. The machine has two possibilities for communicative response (only after all blanks have been filled): drop some pictures back to the bottom or leave pictures in the spaces. The responses signify, respectively, a disjuncture and a match between the semiotic relation programmed into the machine, and the one instantiated by the player. The desired end-state, from the point of view of the designers/educators, is correspondence between the signification relations encoded in the machine, and the signification relations instantiated through the activity of the player.

Although this game is simpler than most educational software on the market today, similar interactional tensions between the intentionalities of designers and the maneuverings of players still hold. Games are cultural resources that explicitly provide narrative content and interactive capabilities that players can take up in flexible ways. Despite this flexibility, however, the following case illustrates a stubbornness of machine response that encourages gradual alignment to the relations instantiated by the machine rather than flexible interpretation of the narrative elements, particularly when there is an adult present who orients a child in a more goal-directed way. In other words, even the most sophisticated media technologies embed certain cultural and interactive relations that have persuasive force, in part because of the inflexible nature of the technology, and in part, because other users share similar cultural frameworks. The industrial relations that bring a piece of software to the hands of a child are a highly mediated form of interpersonal communication that works through the body of a machine to instantiate the vision of the designer and programmer. The voices of software creators are privileged ones even at these distanced sites of play because they have enlisted stubborn technologies and local adults with a shared interest in merging education and play. The educators at the 5thD and the educationally minded programmers of *Language Explorer* culturally collude across a social divide to deliver a vision of learning that is active and playful, but remains focused on the mastery of academic content.

While the structure of the *Language Explorer* software is simple and seemingly transparent, the actual dynamics of use can be quite complex, especially when they involve a young child who does not necessarily orient to the suggested associations between a word and a picture. In the example to follow, the interpretation of the game is further complicated by the participation of an English-speaking adult, a bilingual child who is an early reader, and a Spanish language game. Sonia is a regular participant at one of the bilingual 5thD sites and is one of the younger kids at the site, known for her sassy charm. The adult working with her is a graduate student who is involved with the 5thD project, and makes occasional visits to Sonia's club. While the semiotic relations between game elements are fixed within the parameters of game functionality and interaction, at local sites of use, the meanings of these elements are indeterminate and subject to a wide range of interpretive flexibility.

In the interactional sequence below, collusion with the meanings encoded in the machine is achieved only as the result of an extended series of interactions, where the machine provides repetitive feedback and an adult works to orient the child to what the machine is designed to communicate. This case is presented in order to illustrate the dynamic between the interactional capabilities of a game, a child and adult, when they engage in joint activity. The child begins by flexibly interpreting the narrative elements on the screen in a playful and open-ended way. The adult and the machine gradually orient her to the learning task of matching words to pictures. In contrast to the inflexible responses of the machine, the adult is able to provide nuanced and situationally responsive interaction that eventually cements a common space of understanding and goals. This is a microcosm of processes of cultural reproduction through media artifacts. The three players of child, adult, and game have aligned themselves to a set of meanings that the game and adults sought to "teach". Far from being a result of transparent "decoding" at sites of play, cultural reproduction, in this example, is about highly contingent and ongoing alignment between multiple social and technological actors.

This first sequence of activity opens with the computer booting up the game, and a title splash screen appearing, with the words: "Language Explorer".

S = Sonia

A = Adult

1. S: OK, You know how to play this?
2. A: No, uh-huh. What do you do?
3. S: (Picks up a picture and starts to move it around the screen as she talks.) Try to find the name, the name that says—Hmmmm. Do we put it up here? Over here? (Places first picture in top left space.)
4. A: The name that fits with the picture?
5. S: Look we got to put it right here in the blanks, OK? (Places a second picture in space immediately below first picture.)
6. A: OK. What's that one? (Points to screen.)
7. S: *Martillo*
8. A: This is ahhhh?
9. S: *Nina*. (Places third picture below the second, completing one column of pictures.)
10. A: What is that?
11. S: *Naranja*. (Places another picture at top of next column.) See what I'm doing? (Places another picture below the previous one.) And then I take them off, and then I do it again. OK.
12. A: Ahh.
13. S: *Pajaro*, *pajaro*. (Places another picture below the previous one, completing second column.)
14. A: Ahhh.
15. S: Let's do this.
16. A: But . . .
17. S: You see what I'm doing? (Places another picture in new column.)
18. A: Isn't the name supposed to go with the picture?
19. S: You can do it any way you want to.

When the game screen comes up, the child begins by determining the adult's knowledge of the game: "You know how to play this"? (line 1). When the answer is negative, she explains and exhibits her state of understanding of the game. She begins to explain the relevance of "the name" to the game, but interrupts her own exposition, "hmmmm", and orients toward the interactional choice of where to put the picture: "Do we put it up here? Over here"? (line 3). The adult, in the meantime, has decoded the game rules and explicates them for her in light of her seeming confusion: "The name that fits with the picture" (line 4). Taking a contrary and didactic tone, Sonia insists, "Look, we've got to put it right here in the blanks, okay?" (line 5). The adult again orients to the task of naming, that is, establishing the signifying relation that ties together word and picture (lines 6 and 8). Sonia then starts to move pictures into the blanks, in sequence from right to left, top to bottom, while calling out names (lines 7, 9, 11, and 13). These names refer to elements in the pictures—*martillo* (hammer), *nina* (girl), *pajaro* (bird)—they are not the words that are written below the blanks. For example, the picture that Sonia identifies as "*martillo*", which depicts a hammer shattering an object, is identified by the game as "*romper*" (to break). As she busily fills in the blanks, explaining, to the adult, the task at hand, the adult protests—"But"—and finally cuts in—"Isn't the name supposed to go with the picture"?—again trying to establish the relation between the two game elements (lines 16 and 18). She responds, "You can do it any way you want to" (line 19). In short, Sonia is operating from knowledge about the interactional capabilities of the game (move pictures, fill blanks, repeat) and certain narrative meanings available at the interface (a hammer, a girl, a bird) while the adult tries to orient her to the semiotic relations between game elements (the match between a written word and a picture). She goes on to demonstrates her knowledge of how the pictures only will stick in the blanks, and not in other parts of the screen (lines 20 and 22):

20. S: Look. (Drags a picture to a space between two blanks, and it drops back down to the bottom of the screen.)
21. A: Oh, OK.
22. S: See, look. Look what happens. (Again, drags a picture to a space between two blanks, and it drops back down to the bottom of the screen.)
23. A: So it doesn't go there.
24. S: Yeah, it goes. Yeah so we put it right here. (Places a picture.) See, and that one goes over here. (Places a picture.)
25. A: And that fits there.
26. S: Get up here, get up here. There. (Places last picture in final blank, and most of the pictures fall back to the bottom of the screen.)
27. A: Whoa.
28. S: You see? Magic. You see? Magic.
29. A: Magic. Yeah, pretty good.

    Some transcript omitted where she continues to place pictures in spaces at random.

30. A: So what does it, what are you supposed to do? I still don't, I mean like you put the pictures in the places, but –
31. S: And then, then some stay OK?
32. A: Some stay. OK.

A few minutes later, Sonia has filled in all the blanks, and most of the pictures fall back down to the bottom of the screen. "You see"? She exclaims, "Magic. You see? Magic" (line 28). She sees the pictures dropping to the bottom of the screen as an example of a fun special effect, and an indication of playful narrative meaning, rather than an indication of an incorrect answer. In this sequence, Sonia displays an alternative set of meanings that can be brought to bear on the game, which are fully "explanatory" of (i.e., make sense of) game elements, but which mobilize a set of associations that are not coded into or intended by the game design. For Sonia, a graphic representation calls forth multiple associations—a hammer, something breaking, a bright color—and interaction with the machine is about exploration of a space of possibility—some things go in some places and not in others; and some things migrate while others do not. Sonia has interpreted game responses as *ad hoc* rather than rationalistic and pre-determined, game syntax as associative rather than syntagmatic, and game narrative as whimsical rather than evaluative. Sonia has a wide range of interpretive resources that enable her to take pleasure in the visual and spectacular features of the game, even as adults try to orient her to educational goals. She is a confident and regular participant in the 5thD and is comfortable talking back to an adult. Her interpretation of the game is robust, has held up through at least one other instance of her play of this game, and holds ground for some time despite the adult's persistent though gentle interference pattern.

In alliance with the game, the adult does eventually succeed in displacing Sonia's interpretation of the game interface. He begins to read, in halting Spanish, the words below the blanks. "*Detras de* means . . . "? he asks. "What"?! Sonia responds, turning to look at him in surprise. He repeats himself, pointing to the screen, and Sonia begins to orient rapidly to the designed goal of the game, to match the words to the pictures. They arrive at an interactional dynamic where he will read a word, she will translate for him, and they will work together to figure out which picture corresponds to the word. They proceed in this manner until all of the spaces are filled, and the computer responds by dropping a substantial number of the pictures down to the bottom of the screen. In contrast to her earlier delight at the "magic" of this computer response, now Sonia is dismayed, and responds with a loud "What?!" (line 33). She then orients immediately toward working out the correct answers with the adults help:

33. S: WHAT? OK, let's do this. Tell me what this is. (Points to blank.)
34. A: That one? (Points to blank.)
35. S: Uh-huh.
36. A: *Deba . . . debah*.
37. S: *Debajo*.
38. A: *Debajo de. Esto*. (Points to picture.)
39. S: OK this one. (Puts picture in blank.)

This example illustrates some of the interactional and interpretive dynamics involved in play with an interactive informational technology. The basic asymmetry that Suchman identified is clearly exhibited here: a child with a rich set of imaginative and interpretive resources, and a game that responds to her activity with simple, formulaic responses, based on a narrow set of interpretive resources. The game's responses are in marked contrast to that of the adult, who repeatedly engages the child in multiple ways, in response to the nuances and timing of her utterances and actions. The first characterization of this interaction, then, follows directly from Suchman's analysis; in contrast to interpersonal interaction, where people are constantly molding their responses in collusion with another's, human–machine interaction is characterized by an asymmetric relation of a person with a wide interactional range, and a machine with a small set of interactional resources.

A related feature of this interaction is the contrast between the range of meanings produced on either side of the human–machine interface. Sonia and *Language Explorer* exchange the same limited set of tokens across the same graphical user interface—information about whether a picture has been moved into one location or another. And both Sonia and the game process the exchange of these tokens as meaningful "social" acts (i.e., acts that provide relational information). The contrast is between the game, which interprets a token based on conformity to a simple binary logic (a correct or incorrect match), and a child, who is able to produce meaning out of not only the location or a picture in or out of a grid, but also of the dynamic quality of its motion, the varied nuance of the graphical form, and the relation to other experiences (i.e., "magic"). In other words, there is a disjuncture between the semiotic logic of the software's interactional algorithms (if this, then that), and the semiotic logic of the narrative elements (multiple associative networks of meaning), as represented at the user interface. This disjuncture is exploited in game design as a way of infusing game characters with evocative and multidimensional qualities despite the fact that they may only have a limited set of pre-programmed responses.

The graphical aspects of the media form also point to some particular features of multimedia that distinguish them from more "functional" computational objects such as copiers, or text-based drill-and-practice exercises. The narrative logic of the game affords multiple meaningful interpretations that are pleasing to Sonia but not significant to the game play mechanism—the way the pictures move and how the characters and objects are represented at the interface. While *Language Explorer* has a very thin set of narrative elements, they are still interpretable as meaningful by Sonia apart from the goal-oriented logic of the underlying machine functionality. The animation and graphics are experienced as "magical" special effects that elicit delight apart from any goal-directed aspect of play. The case of Sonia is a schematic microcosm of these particular game features and aspects of kid–game interaction.

The two people in this interaction collude in shifting, resourceful, and complicated ways, organized in part by the inflexible task set up by the machine.

While the machine doggedly reproduces the same sets of meanings—a set of meanings that would not be comprehensible to a young girl with limited reading skills and an adult with limited Spanish knowledge—the two players are able to orient quickly to both their respective capabilities, as well as the capabilities of the software. Sonia and the adult have thus demonstrated superior interpretive and practical flexibility, which has enabled them to move ahead in the task, but it is the meaning intended by the game designers, rather than Sonia's idiosyncratic readings, that were, in the end, reproduced. This triumph of the meanings generated through the game production is due in part to the stubbornness of the machine, as well as the adult's alignment with these meanings. This particular interaction, in addition to providing an illustration of the asymmetric interactional dynamics between human and machine, is also a microcosm of processes of cultural reproduction, where people and artifacts engage in a complex collusional dance, which serves to instantiate a set of meanings that are locally, and at least momentarily, hegemonic. These hegemonies are the result of an alignment of multiple factors such as the presence of guiding adults and peers, as well as the design of the technology. They need to be instantiated moment by moment, situation by situation in order to retain their hold on children's imaginations.

This case could also be considered an instance of genre ambiguity. Sonia initially reads the game as an entertainment title, designed for fleeting pleasures read primarily through the idiom of children's visual culture. Part of the adult's work in this interaction is to facilitate genre recognition, orienting Sonia to the fact that the game is not only about enjoying brightly colored animations, but also about progressing along a set of discrete progress-oriented tasks. One could imagine Sonia continuing to engage with the software as an entertainment title if playing within a peer group setting. The adult eventually orients her to the software as an educational genre; he is stubborn in his resistance to Sonia's modality of play, and the software is stubborn in its preprogrammed responses. Both the adult and the game display the dispositions of responsible and progress-directed educators.

Even the more graphically sophisticated educational titles that are currently on the market (and which were analyzed as part of the broader research project framing this study) generally exhibit interactional building blocks similar to those found in Sonia's case. Play-minded children orient to whimsical and entertainment-oriented graphical hooks, often engaging repetitively with what adults call "eye candy". In an educational setting, they tend to be guided through the collusion of on-screen cues, characters, and local adults toward the underlying academic goals and functionality of the game. In Sonia's case, as in many others, the 5thD has succeeded in inflecting a reading of the game to align with the educational orientation of the software creators, a small but clear shift in the micropolitics of representation and social reproduction, a translocal handshake across a highly mediated set of social relations.

Beginning with the recognition of an asymmetric relation between human and machine, and complemented by a notion of multiple technical and narrative layers of interactive media, the human–machine interface becomes a crucial analytic focus, the site where meanings are translated across a fundamentally disjunctive divide. In the case of a copier, an interface is largely valued based on the transparency of its translations, the ability to provide the user with relevant information about machine functionality, and the ability to translate user intentions into a form clearly intelligible to the machine. In the case of games, this relation is more complex, due to their multimedia interfaces, their more developed narrative qualities, and their interactive range. Most significantly, interactive multimedia rely on the production of a vivid fantasy environment, and deliberate obfuscation of the technical substrate that produces this fiction as its special effect.

Regardless of how transparent, the human–machine interface is a site of mutual mystification between person and technology, a meeting point of incommensurable regimes of value (Appadurai, 1986), where one coin of the realm is exchanged for a different currency. The interface, while still the site of translation between human and machine understandings, is also the site of meaningful opacity. Just as in film, where the suspension of disbelief is based on a technical apparatus of digital special effects, artful editing, and tricks of lighting, all of which are invisible to the spectator, the fantasy effect of multimedia is also dependent on the (at least partial) invisibility of the technical substratum, and a propped up illusion of a simulated environment. Suchman demonstrated that copier interfaces produce certain interface fantasies and obfuscations that were seen as failures in translation rather than as productive fictions. In the case of games, functional transparency of interactive elements is valued in addition to the graphical and auditory qualities that evoke a narrative and fantasy elements that exceed the functional encodings of the game.

In contrast to much of the common usage of the term interface, this study suggests an interactional and socially contextualized view. Some in the software design community have suggested that a notion of interface be expanded out from a narrow view of buttons and windows on a screen to include the broader social relations (i.e., technical support staff, manuals, etc.) that make software intelligible to users. In his study of the history of the term in computer design, Grudin (1990a, b) traces how the notion of computer interface grew out of the growing separation between production and use. Owing to the esoteric nature of early computational practice, the first computer users were almost inevitably also programmers and were comfortable with and relied on the visibility of machine language in their computer use. As computers became more widespread and more complex, designers and programmers needed to represent machine functionality in ways accessible to non-programmers, and the notion of interface represented these more accessible representations that were distanced from basic machine language. Grudin's work suggests that, as computers become embedded in more complicated social networks, designer's notions of computer interface need to be expanded out from this narrowly technical usage.

The growing distance and layering between machine code and functions and the interface thus mirrors the growing sense of mediation and distance between software design and use (Suchman, 2000). From a somewhat different angle, Turkle (1995) has described how the post-Macintosh user interface has co-constructed modes of engagement with computers that center on the manifestations of the interface rather than on underlying machine algorithms. While recognizing the distancing and fixity of certain aspects of current consumer interfaces, this study has suggested that the relations between user and code are not determinate; interface should be understood as an interactive process, constantly under negotiation, rather than a static set of encoded relations or structural positions. The case of Sonia illustrates how there are multiple interfaces and entry-points to a given piece of software, relations that extend beyond the co-present encounter to include the processes of coding and designing the software, engaging with particular elements of the software, and alternative narrative and functional interpretations.

The human–machine interface is importantly the site not only of happy mutual understanding and successful alignment between human and machine actors, but also the site of conflict, tension, confusion, complaint, and misunderstanding. As with face-to-face interaction, human–machine interaction is the occasion for relationships to be instantiated, relationships that carry the usual weight of social conflict, power relations, and institutional imperatives. In their discussion of "macro-actors", Callon and Latour (1981) describe the particular kind of power that comes from stabilizing and fixing a set of relations into a durable network of actors. This conglomerate, which they call a macro-actor, is defined by its durability and translocal reach, as well as by its ability to bend the will of others around the space that it occupies, by the sheer force of its stubbornness and size. What Latour and Callon describe is the power of the machine (as a stabilization and black-boxing of the interests of multiple actors) to insist on an inflexible set of meanings and demand, invite, and cajole human alignment. No matter how many times Sonia tries to get the machine to see her point of view, the machine will persist in dropping pictures to the bottom of the screen until they are exactly the way it wants them. This asymmetry is indicative of a power differential that legitimizes and embodies a certain model of educational and software design into mass-produced and durable artifacts, rather than the whimsical readings that Sonia brings to bear on the situation.

In contrast, interactional studies of human action describe a different source of strength and resilience, one based on the ability to index flexibly a wide range of meanings, and to work around the stubbornness of any particular object. Sonia can create meaningful play out of a relatively simple toy, bending the meanings suggested by the machine into something that is personally evocative, a source of amusement, and an occasion to have some fun with a friendly adult. As de Certeau suggests, she can inflect and exploit the given cultural resources she has on hand to something of her own local manufacture. She is also empowered by her superior ability to figure out the machine's point of view; for all we know, Sonia could grow up to become a computer game programmer and code her own view of the world into a machine. In the larger scheme of things, Sonia can also get bored and walk away, unless she is called into alignment with the machine by a greater institutional power (i.e., a teacher), or by an undergraduate playmate. The machine enlists Sonia into a stubbornly defined set of relations, but Sonia, in turn, enlists the machine as a peripheral element in the overall fabric of her life. The power dynamic at the interface, between the hegemony of a set of encoded meanings and their reinterpretation, is a constant feature of play with computational media.

The interface is also the site at which children form relationships with machines. While certainly different, in both depth and range, from interpersonal relationships, relationships with computational media are important factors in the learning and identity formation of many children. Children's relation to computers, both in terms of technical literacy and their orientation to the broader cultural codes embedded in computer games, is a dynamic site of identity work, where children pit their skills and wills against the game goals and the deliberate opacity of the interface. Much of the work of "beating" a computer game is about decoding the peculiar nature of machine communication and delving below the visible clues of the interface to work out the underlying logic of machine semantics. Continued engagement with computer games is also importantly about progressive alignment with the semiotic relations that are encoded into the game, as well as the concomitant social and institutional subject positions implied by those relations.

When looking at interactive multimedia as a particular computational form, the interface emerges as uniquely layered based on the relations between narrative and functional encodings. The goal of this chapter has been to lay out a working framework for understanding some of the foundational features of children's engagement with interactive multimedia, drawing on existing theories of narrative engagement, on one hand, and interpersonal and human–machine interaction on the other. Through the case of Sonia and *Language Explorer*, the work has been to apply these existing theories and extend them into the domain of interactive multimedia. In contrast to most human–computer interactional approaches, which focus on computational tools or communications, interaction analysis of computer games needs to pay more attention to narrative meanings, goals, and competition, as they are coded into a mass media form. In short, the interactive aspects of computer games demand interaction and activity-based understandings of media consumption as well as understandings of interpretive process and narrative meaning. The responsive and narrative qualities of interactive multimedia present us with new analytic puzzles that demand attention to a widely spun social structure co-constituted by people and machines encountering one another across an increasingly complex set of interface conventions, as well as the relations of production and consumption that bring these actors together.

ACKNOWLEDGMENTS

Research for this chapter was conducted as part of a project funded by the Mellon Russell-Sage Foundation, and located at the Institute for Research on Learning, the University of California, San Diego, and Whittier College. The overall 5thD effort is immense, but I would like to acknowledge those in my immediate research team: my academic advisors, Ray McDermott, Michael Cole, James Greeno, Don Bremme, and Shelley Goldman, fellow graduate students Vanessa Gack and Katherine Brown, and research assistants Dena Hysell, Natasha Royer, Joy Yang, Raquel Ramirez, and Alla Cherkassky. Writing was funded in part by a Spencer Dissertation Fellowship and the Annenberg Center for Communication and the University of Southern California. This chapter is excerpted from two dissertations at Stanford University, one at the School of Education, entitled *Interactive Media for Play,* and the other at the Department of Anthropology, entitled, *Engineering Play.* This chapter has benefited from readings and comments by Jason Nolan, Carol Delaney, Joan Fujimura, Shelley Goldman, James Greeno, Purnima Mankekar, Ray McDermott, Susan Newman, Lucy Suchman, and Sylvia Yanagisako.

ENDNOTES

1. By this, I am not referring to interpretive inflexibility on the part of viewers, but rather the fact that users cannot easily reconfigure the texts themselves, or design customized pathways through the representations.
2. For more information on the 5thD clubs, see Cole (1997) and Vasquez et al. (1994).

Chapter 9: Technological Transformation, Multiple Literacies, and the Re-visioning of Education[1]

DOUGLAS KELLNER
Philosophy of Education, University of California, Los Angeles

The dramatic multiplication of computer, information, communication, and multimedia technologies has been changing everything from the ways people work, to the ways they communicate with each other and spend their leisure time. This technological revolution is often interpreted as the beginnings of a knowledge or information society, and therefore ascribes education a central role in every aspect of life. It poses tremendous challenges to educators to rethink their basic tenets, to deploy the new technologies in creative and productive ways, and to restructure schooling to respond constructively and progressively to the technological and social changes currently underway. At the same time, important demographic and socio-political changes are taking place throughout the world. Emigration patterns have created the challenge of providing people from diverse races, classes, and backgrounds with the tools and competencies to enable them to succeed and participate in an ever more complex and changing world.

In this chapter, I argue that educators need to cultivate multiple literacies for contemporary technological and multicultural societies, that teachers need to develop new literacies of diverse sorts, including a more fundamental importance for print literacy, to meet the challenge of restructuring education for a hi-tech, multicultural society, and global culture. In a period of dramatic technological and social change, education needs to help produce a variety of types of literacies to make current pedagogy relevant to the demands of the contemporary era. As new technologies are altering every aspect of our society and culture, we need to comprehend and make use of them both to understand and transform our worlds. In particular, by introducing multiple literacies to empower individuals and groups traditionally excluded, education could be reconstructed to make it more responsive to the challenges of a democratic and multicultural society.

1. TECHNOLOGY AND THE RE-VISIONING OF EDUCATION

To dramatize the issues at stake, we should consider the claim that we are now undergoing one of the most significant technological revolutions for education since the progression from oral to print and book-based teaching (Best & Kellner, 2001; Castells, 1996; 1997; 1998). Just as the transition to print

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 241–268.

literacy and book culture involved a dramatic transformation of education (Illich & Sanders, 1988; McLuhan, 1962; 1964; Ong, 1988), so too does the on-going technological transformation demand a major restructuring of education today with novel curricula, pedagogy, literacies, practices, and goals. Furthermore, the technological developments of the present era makes possible the radical re-visioning and reconstruction of education and society argued for in the progressive era by Dewey and in the 1960s and the 1970s by Ivan Illich, Paolo Freire, and others who sought radical educational and social reform.[2]

A re-visioning education requires a thorough examination and critique of dominant institutions of schooling, pedagogical practices, and the goals and ends of teaching. Technological change, globalization, and multicultural expansion all demand looking at things in novel ways and looking back at how the world was before dramatic changes have occurred. Re-vision involves both critically seeing the past and the present and imagining a different future. It implies as well reconstructing education, using informed theory to guide novel pedagogical practices and to fundamentally restructure educational institutions. Re-visioning education also involves another way of seeing and doing grounded in historical practices of the present and looking toward a different and better future.

Put in historical perspective, it is now possible to see modern education as preparation for industrial civilization and minimal citizenship in a passive representative democracy. Modern education, in short, emphasizes submission to authority, rote memorization, and what Freire called the "banking concept" of education in which learned teachers deposit knowledge into passive students, inculcating conformity, subordination, and normalization. Today, these traits are somewhat undercut in certain sectors of the global post-industrial and networked society with its demands for new skills for the workplace, participation in emergent social and political environs, and interaction within novel forms of culture and everyday life.

A more flexible economy, based on an ever-evolving technological infrastructure and more multicultural workforce demands a more technically literate, interactive, culturally sensitive, and educated workforce, while revitalizing democracy requires the participation of informed citizens.[3] Yet, while on one hand, the demands of the expanding global economy, culture, and polity require a more informed, participatory, and active workforce and citizenship, on the other hand, a docile workforce and service industry is still the norm in many sectors of work, society, and culture. Although for a time, ideologues of the new technologies argued that information and communication technology (ICT) would of themselves dramatically reorganize and democratize the workplace, schooling, the polity, and everyday life (Gates, 1996; Kelly, 1995; 1999, it is by now clear the supposed liberating effects of new technologies were greatly exaggerated. But while globalization and technological multiplication have highly ambiguous effects (Best & Kellner, 2001), they provide educational reformers with the challenge of whether education will be restructured to promote democracy and human needs, or whether education will be transformed primarily to serve the needs of business and the global economy.

To some extent, constant technological transformation renders necessary the sort of thorough restructuring of education that radicals have demanded since the Enlightenment of Rousseau and Wollstonecraft through Dewey, all of whom saw the progressive reconstruction of education as the key to democracy. Today, however, intense pressures for change now come directly from technology and the economy and not ideology or educational reformist ideas, with an expanding global economy and novel technologies demanding innovative skills, competencies, literacies, and practices. It is therefore a burning question as to what sort of restructuring of education and society will take place, in whose interests, and for what ends. More than ever, we need philosophical reflection on the ends and purposes of education, on what we are doing and trying to achieve in our educational practices and institutions. In this situation, it may be instructive to return to Dewey and see the connections between education and democracy, the need for the reconstruction of education and society, and the value of experimental pedagogy to seek solutions to the problems of education in the present day. A progressive reconstruction of education will urge that it be done in the interests of democratization, ensuring access to ICTs for all, helping to overcome the so-called digital divide and divisions of the haves and have nots, so that education is placed, as Dewey (1997 [1916]) and Freire (1972; 1998) propose, in the service of democracy and social justice.

Yet we should be more aware than Dewey of the obduracy of divisions of class, gender, race, and work self-consciously for multicultural democracy and education. This task suggests that we valorize difference and cultural specificity, as well as equality and shared universal Deweyean values such as freedom, equality, individualism, and participation. Theorizing a democratic and multicultural reconstruction of education forces us to confront the digital divide, that there are divisions between information and technology have and have nots, just as there are class, gender, and race divisions in every sphere of the existing constellations of society and culture. The latest surveys of the digital divide, however, indicate that the key indicators are class and education, as well as race and gender, hence the often-circulated argument that new technologies merely reinforce the hegemony of upper class white males must be questioned, at least for some contemporary societies.[4]

Rob Shields has argued that the concept of the "digital divide" serves as a marketing device for the benefit of technology disseminators and that on the whole the development of new technologies helps increase the divide between haves and have nots (2001). While no doubt hi-tech corporations and affiliated government institutions have promoted the challenge of a digital divide the concept points to some serious problems and challenges. It is clear by now that providing access and computers alone without proper training and pedagogy does not advance education or social justice. Thus, more broadly conceived, the notion of a digital divide points to disparities in terms of access, training, skills, and the actual use of technologies to improve education and promote social justice.

With the proper resources, policies, pedagogies, and practices, educators can work to reduce the (unfortunately growing) gap between haves and have nots by promoting broad training in information and computer literacy that embraces a wide range of projects from providing technical skills to engaging students in the production of media projects. Although technology alone will not suffice to democratize and adequately reconstruct education, in a technological society providing proper access and training can improve education if it is taken as a supplement.[5] That is, technology itself does not necessarily improve teaching and learning, and will certainly not of itself overcome acute socio-economic divisions. Indeed, without proper re-visioning of education and without adequate resources, pedagogy, and educational practices, technology could be an obstacle or burden to genuine learning and will probably increase rather than overcome existing divisions of power, cultural capital, and wealth.

In the following reflections, I focus on the role of computers and information technology in contemporary education and the need for new pedagogies and an expanded concept of literacy to respond to the importance of ICTs in every aspect of life. I propose some ways that ICTs and new literacies can serve as efficacious learning tools which will contribute to producing a more democratic and egalitarian society, and not just provide skills and tools to privileged individuals and groups that will improve their cultural, capital, and social power at the expense of others. How, indeed, can education be re-visioned and reconstructed to provide individuals and groups with the tools, the competencies, the literacies and social practices, to overcome the class, gender, and racial divides that bifurcate our society and at least in terms of economic indicators seem to be growing rather than diminishing?

First, however, I wish to address the technophobic argument against ICT *per se*. I have been developing critical theories of technology that call attention to uses or types of technology as tools of domination, and that rejects the hype and pretensions of techno-utopias and techno-fixes to the problems of education and society. A critical theory of technology thus sees the limitations of pedagogy and educational proposals based primarily on technology without adequate emphasis on classroom pedagogy, and on teacher and student empowerment. It insists on developing educational reform and restructuring to promote multicultural democracy, and calls for appropriate restructuring of technology to democratic education and society. Yet a critical theory also sees how technology can be used, and perhaps redesigned and restructured for positive purposes such as enhancing education, democracy, and overcoming the divide between haves and have nots, while enabling individuals to democratically and creatively participate in a new global economy, society, and culture (see Feenberg, 1991; 1999; Best & Kellner, 2001).

The late Ivan Illich's post-industrial model of education contains a radical critique of existing schooling and alternative notions like webs of learning, tools for conviviality, and radically reconstructing education to promote learning, democracy, and social and communal life, thus providing salient alternatives to modern systems (1971, 1973). Illich's "Learning Webs" (1971) and "Tools for Conviviality" (1973) anticipate the internet and how it might provide resources, interactivity, and communities that could help revolutionize education. For Illich, science and technology can either serve as instruments of domination or progressive ends. Hence, whereas big systems of computers promote modern bureaucracy and industry, personalized computers made accessible to the public might be constructed to provide tools that can be used to enhance learning. Thus, Illich was aware of how technologies like computers could either enhance or distort education depending on how they were fit into a well-balanced ecology of learning.

"Tools of conviviality" for Illich are appropriate, congenial, and promote learning, sociality, and community (1973). They are tools in which ends dictate means and individuals are not overpowered or controlled by their technologies (as say, with assembly lines, nuclear power plants, or giant computer systems). Convivial tools produce a democratic and convivial society in which individuals communicate, debate, participate in social and political life, and help make decisions. Convivial tools free individuals from dependency and cultivate autonomy and sociality. They provide individuals and society with the challenge of producing convivial tools and pedagogies that will create better modes of learning and social life.

Conviviality for Illich involves "autonomous and creative intercourse among persons, and the intercourse of persons with their environment" (1973: 27). Illich proposes a normative dimension to critique existing systems and construct alternative ones using values of "survival, justice, and self-defined work" as positive norms (1973: 13). These criteria could guide a reconstruction of education to serve the needs of varied communities, to promote democracy and social justice, and to redefine learning and work to promote creativity, community, and an ecological balance between people and the Earth. Indeed, Illich was one of the few critics working within radical pedagogy in his period who took seriously ecological issues and critically appraised institutions like schooling, medicine, transportation, and other key elements of industrial society within a broad social, political, economic, and ecological framework. His goal was nothing less than a critique of industrial civilization and a project of envisaging post-industrial institutions of learning, democratization, and social justice.

Illich saw that a glaring problem with contemporary educational institutions was that they become fixed in monomodal instruction with homogenized lesson plans, curricula, and pedagogy, and neglect to address challenging political, cultural, or ecological problems. The development of tools of conviviality and radical pedagogies enable teachers and students to break with these models and to engage in Deweyean experimental education. A reconstruction of education could help create subjects better able to negotiate the complexities of emergent forms of everyday life, labor, and culture, as contemporary life becomes more multifaceted and dangerous. More supportive, dialogical, and interactive social relations in learning situations can promote co-operation, democracy, and positive social values, as well as fulfill needs for communication, esteem, and learning. Whereas modern mass education tended to see life in a linear fashion based on print models and developed pedagogies which broke experience into discrete moments and behavioral bits, critical pedagogies could produce skills that enable individuals to better navigate the multiple realms and challenges of contemporary life. Deweyean education focused on problem-solving, goal-seeking projects, and the courage to be experimental, while Freire developed alternative pedagogies and Illich oppositional conceptions of education and learning and critiques of schooling. It is this sort of critical spirit and vision to reconstruct education and society that can help produce new pedagogies, tools for learning, and social justice for the present age.

At a time when many were enamored of the autonomous power and emancipatory potential of the school, Illich insisted on seeing schools as part and parcel of industrial society and one of the major instruments of its social reproduction. One of Illich's enduring contributions is to see relationships between modern industrial institutions like schooling, production, medicine, transportation, and other major sectors of industrial society. In order to engage with how what goes on in educational institutions we must have far better and more critical self-understandings of what specific institutions like schooling do in their institutional structure within the broader society, their hidden curriculum and how they engage in social reproduction. Understanding schooling beyond its institutional sites also requires grasping its dialectical relationships to the public pedagogies of media and the street, and the networked civic and social space of the internet, as well as how schooling relates to the oppressions and operations of workplaces, government institutions, and corporations.

Illich thus provides concrete analyses and a critique of how schooling reproduces the existing social order and is flawed and debased by the defects and horrors of the industrial system. Illich also recognizes that post-industrial society requires certain competencies and that a major challenge is to construct convivial technologies that will improve both education and social life. While he resolutely opposed neo-liberal agendas and was critical of encroaching corporate domination of the internet and information technologies, Illich's notion of "webs of learning" and "tools of conviviality" can be appropriated for projects of the radical critique and reconstruction of education and learning in the contemporary era.

It is interesting that one of the godfathers of critical pedagogy, Paulo Freire, was positive toward media and new technologies, seeing technologies as potential tools for empowering citizens, as well as instruments of domination in the hands of ruling elites. Freire wrote that: "Technical and scientific training need not be inimical to humanistic education as long as science and technology in the revolutionary society are at the service of permanent liberation, of humanization" (1972: 157).[6] Some critical pedagogues, however, are technophobes, seeing new technologies solely as instruments of domination. Certainly, both Illich and Freire also had concerns about the internet and globalization. In a world inexorably undergoing processes of globalization and technological transformation, one cannot, however, in good conscience advocate a policy of clean hands and purity, distancing oneself from technology and globalization, but must intervene in the processes of economic and technological revolution, attempting to deflect these forces for progressive ends and developing new pedagogies to advance the project of human liberation and well-being.

Re-visioning technology, literacy, and education should avoid both technophobia and technophilia, rejecting technological determinism, while being critical of the limitations, biases, and downsides of new technologies, but wanting to use and redesign technologies for education for democracy and for social reconstruction in the interests of social justice. This project is also, in the Deweyean spirit, pragmatic and experimental, recognizing that there is no agreed upon way to deploy new technologies for enhancing education and democratization. Critical educators should be prepared to accept that some of the attempts to use technology for education may well fail, as have no doubt many of our own attempts to use computer-mediated technologies for education. Different parts of the world and varying groups will have different projects that computers can help them with, different needs and problems, and thus varied pedagogical projects.

A critical theory of technological literacy is aware that technologies have unforeseen consequences and that good intentions and seemingly good projects may have results that were not desired or positive. Indeed, there are ecological consequences concerning the production, use, and discarding of computer technologies, dangers of over and misuse of computers for individual health and well-being, and costs and downsides of organizing so many activities ranging from work to communication to research around information technologies. A critical pedagogy will thus contextualize the production and use of multimedia and information technologies within social relations and contexts, criticize negative aspects and effects, and attempt to transform technologies into positive environments of education and social transformation.

Thus, the question is not whether computers and multimedia technologies are good or bad in the classroom or more broadly for education. Rather, it is a question of what multimedia and computers can do and cannot do toward helping to produce a more democratic and equalitarian society and what their limitations are for producing more active and creative human beings and a more just society. Crucially, we must ask: What sort of skills do students and teachers need to effectively deploy computers and information technology, what sort of effects might ICTs have on learning, subjectivities, and social relations, and what new literacies, forms of education, and social relations do we need to democratize and improve education today?

2. MEDIA LITERACY: AN UNFULFILLED CHALLENGE

Literacy involves gaining the skills and knowledge to read and interpret the text of the world and to successfully navigate and negotiate its challenges, conflicts, and crises. Literacy is thus a necessary condition to equip people to participate in the local, national, and global economy, culture, and polity. As Dewey argued (1997), education is required to enable people to participate in democracy, for without an educated, informed, and literate citizenry, strong democracy is impossible. Moreover, there are crucial links between literacy, democracy, empowerment, and participation, and without developing adequate literacies differences between haves and have nots cannot be overcome and individuals and groups will be left out of the emerging economy, networked society, and culture.

To reading, writing, and traditional print literacies, one could argue that in an era of technological revolution, we need to develop robust forms of media literacy, computer literacy, and multimedia literacies, thus cultivating “multiple literacies” in the restructuring of education. Computer and multimedia technologies demand novel skills and competencies, and if education is to be relevant to the problems and challenges of contemporary life it must expand the concept of literacy and develop new curricula and pedagogies.

Both traditionalists and reformists would probably agree that education and literacy are intimately connected. “Literacy” in my conception comprises gaining competencies involved in effectively using socially constructed forms of communication and representation. Learning literacies requires attaining competencies in practices in contexts that are governed by rules and conventions. Literacies are socially constructed in educational and cultural practices involving various institutional discourses and pedagogies. Literacies evolve and shift in response to social and cultural change and the interests of elites who control hegemonic institutions.

I would resist, however, extreme claims that the era of the book and print literacy is over. Although there are discontinuities and novelties in the current constellation, there are also important continuities. Indeed, in the emergent information-communication technology environment, traditional print literacy takes on increasing importance in the computer-mediated cyberworld as people need to critically scrutinize and scroll tremendous amounts of information, putting increased emphasis on developing reading and writing abilities. For instance, internet discussion groups, chat rooms, e-mail, blogs, wikis, and various internet forums require writing skills in which a new emphasis on the importance of clarity and precision is emerging.[7] In this context of information saturation, it becomes an ethical imperative not to contribute to cultural and information overload, and to concisely communicate thoughts and feelings.

In the emergent multimedia environment, *media literacy* is arguably more important than ever. Cultural studies and critical pedagogy have begun to teach us to recognize the ubiquity of media culture in contemporary society, the growing trends toward multicultural education, and the need for media literacy that addresses the issue of multicultural and social difference.[8] There is expanding recognition that media representations help construct our images and understanding of the world and that education must meet the dual challenges of teaching media literacy in a multicultural society and sensitizing students and publics to the inequities and injustices of a society based on gender, race, and class inequalities and discrimination. Recent critical studies see the role of mainstream media in exacerbating or diminishing these inequalities and the ways that media education and the production of alternative media can help create a healthy multiculturalism of diversity and more robust democracy. They confront some of the most serious difficulties and problems that currently face us as educators and citizens.

Yet despite the ubiquity of media culture in contemporary society and everyday life, and the recognition that the media themselves are a form of pedagogy, and despite criticisms of the distorted values, ideals, and representations of the world in popular culture, media education in K-12 schooling has never really been established and developed in most contemporary societies. The current technological revolution, however, brings to the fore more than ever the role of media like television, popular music, film, and advertizing, as the internet rapidly absorbs these cultural forms and creates novel cyberspaces and forms of culture and pedagogy. It is highly irresponsible in the face of saturation by internet and media culture to ignore these forms of socialization and education; consequently a critical reconstruction of education should produce pedagogies that provide media literacy and enable students, teachers, and citizens to discern the nature and effects of media culture.

Media culture is a form of pedagogy that teaches proper and improper behavior, gender roles, values, and knowledge of the world (Kellner, 1995a, b). Individuals are often not aware that they are being educated and constructed by media culture, as its pedagogy is frequently invisible and subliminal. This situation calls for critical approaches that make us aware of how media construct meanings, influence and educate audiences, and impose their messages and values. A media literate person is skillful in analyzing media codes and conventions, able to criticize stereotypes, values, and ideologies, and competent to interpret the multiple meanings and messages generated by media texts. Media literacy helps people to use media intelligently, to discriminate and evaluate media content, to critically dissect media forms, and to investigate media effects and uses.

Within educational circles, however, a debate persists over what constitutes the field of media pedagogy, with different agendas and programs. A traditionalist "protectionist" approach would attempt to "inoculate" young people against the effects of media addiction and manipulation by cultivating a taste for book literacy, high culture, and the values of truth, beauty, and justice, and by denigrating all forms of media and computer culture (see Postman, 1985; 1992). A "media literacy" movement, by contrast, attempts to teach students to read, analyze, and decode media texts, in a fashion parallel to the advancement of print literacy. Media arts education in turn teaches students to appreciate the esthetic qualities of media and to use various media technologies as instruments of self-expression and creation. Critical media literacy builds on these approaches, analyzing media culture as products of social production and struggle, and teaching students to be critical of media representations and discourses, but also stressing the importance of learning to use the media as modes of self-expression and social activism where appropriate (Kellner, 1995a).

Developing critical media literacy and pedagogy also involves perceiving how media like film or video can also be used positively to teach a wide range of topics like multicultural understanding and education. If, for example, multicultural education is to champion genuine diversity and expand the curriculum, it is important both for groups excluded from mainstream education to learn about their own heritage and for dominant groups to explore the experiences and voices of minority and excluded groups. Thus, media literacy can promote multicultural literacy, conceived as understanding and engaging the heterogeneity of cultures and subcultures that constitute an increasingly global and multicultural world (Courts, 1998; Weil, 1998).

Critical media literacy not only teaches students to learn from media, to resist media manipulation, and to use media materials in constructive ways, but is also concerned with developing skills that will help create good citizens and that will make them more motivated and competent participants in social life. Critical media literacy can be connected with the project of radical democracy and concerned to develop skills that will enhance democratization and participation. Critical media literacy takes a comprehensive approach that would teach critical skills and how to use media as instruments of social communication and change. The technologies of communication are becoming more and more accessible to young people and ordinary citizens, and can be used to promote education, democratic self-expression, and social progress. Technologies that could help produce the end of participatory democracy, by transforming politics into media spectacles and the battle of images, and by turning spectators into cultural zombies, could also be used to help invigorate democratic debate and participation (Kellner, 1990; 1998).

Indeed, teaching critical media literacy could be a participatory, collaborative project. Watching television shows or films together could promote productive discussions between teachers and students (or parents and children), with emphasis on eliciting student views, producing a variety of interpretations of media texts, and teaching basic principles of hermeneutics and criticism. Students and youth are often more media savvy, knowledgeable, and immersed in media culture than their teachers, and can contribute to the educational process through sharing their ideas, perceptions, and insights. On the other hand, critical discussion, debate, and analysis ought to be encouraged with teachers bringing to bear their critical perspectives on student readings of media material. Since media culture is often part and parcel of students' identity and most powerful cultural experience, teachers must be sensitive in criticizing artifacts and perceptions that students hold dear, yet an atmosphere of critical respect for difference *and* inquiry into the nature and effects of media culture should be promoted.

One of the most effective ways of teaching critical media literacy is involving students themselves in the production of media texts (see Hammer in McLaren et al., 1995; Kellner and Share, 2005). Learning to produce different forms of media texts teaches codes, formal features, and the role of technology in constructing media artifacts. In becoming literate in semiological and ideological codes of media culture, students not only can read and critique dominant modes of cultural hegemony, but also can produce oppositional forms of culture, subverting the dominant codes and ideologies and providing alternatives.

A major challenge in developing critical media literacy, however, results from the fact that it is not a pedagogy in the traditional sense with firmly established principles, a canon of texts, and tried-and-true teaching procedures. Critical media pedagogy is in its infancy; it is just beginning to produce results, and is more open and experimental than established print-oriented pedagogy. Moreover, the material of media culture is so polymorphous, multivalent, and polysemic, that it requires sensitivity to different readings, interpretations, perceptions of the complex images, scenes, narratives, meanings, and messages of media culture which in its own ways is as complex and challenging to critically decipher as book culture.

Teaching critical media literacy involves occupation of a site above the dichotomy of fandom and censor. One can teach how media culture provides significant statements or insights about the social world, empowering visions of gender, race, and class, or complex esthetic structures and practices, thereby putting a positive spin on how it can provide significant contributions to education. Yet critical educators should indicate also how media culture can advance sexism, racism, ethnocentrism, homophobia, and other forms of prejudice, as well as misinformation, problematic ideologies, and questionable values, accordingly promoting a dialectical approach to the media that aims at critical and discriminating readers.

3. COMPUTER LITERACY: AN EXPANDED CONCEPT

To fully participate in the hi-tech and global society, teachers and students should cultivate forms of computer literacy in ways that go beyond standard technical notions. Critical computer literacy involves learning how to use computer technologies to do research and gather information, as well as to perceive computer culture as a terrain containing texts, spectacles, games, and interactive multimedia which call for cultivating new literacies. As technologies like computers, telephones, televisions, and emergent multimedia devices converge, computer-mediated culture will increasingly provide an encompassing environment in which people work, play, relate, learn, and interact. Becoming computer-literate in this broad sense thus requires expanding notions of literacy and learning how to communicate, interact, and create in novel cybercultures.

The emergent cybercultures can be seen as a discursive and political location in which students, teachers, and citizens can all intervene, engaging in discussion groups and collaborative research projects, creating Websites, producing innovative multimedia for cultural dissemination, and engaging in novel modes of social interaction and learning. Computer culture enables individuals to actively participate in the production of culture, ranging from dialogue concerning public issues to creation of their own cultural forms. However, to take part in this culture requires not only accelerated skills of print literacy, which are often restricted to the growing elite of students who are privileged to attend adequate and superior public and private schools, but also demands multiple forms of literacy.

To respond intelligently to the dramatic technological revolution of our time, we need to begin teaching computer literacy from an early age. Computer literacy, however, itself needs to be theorized. Often the term is synonymous with technical ability to use computers, to become proficient in the use of existing programs, and maybe undertake some programming. I suggest expanding the conception of computer literacy from using computer programs and hardware to a broader concept of information and multimedia literacy. This necessitates promoting more sophisticated abilities in traditional reading and writing, as well as the capability to dissect and read cultural forms taught as part of critical media literacy and multimedia pedagogy.

In my expanded conception, computer literacy involves learning how to use computers, access information and educational material, use e-mail and list-serves, and construct Websites. Computer literacy comprises the accessing and processing of diverse sorts of information proliferating in the so-called "information society". It encompasses learning to find sources of information ranging from traditional sites like libraries and print media to new Internet Websites and search engines. Computer-information literacy involves learning where information is found, how to access it, and how to organize, interpret, and evaluate the information that one seeks.

One exciting development in the current technological revolution is that library materials and information are accessible throughout the world. To some extent, the internet is potentially the all-encompassing library, imperfectly constructed in Alexandria, Egypt, that would contain the great books of the world. Yet while a mind-boggling amount of the classics are found on the internet, we still need the local library to access and collect books, journals, and print material not found on the internet, as well as the essential texts of various disciplines and the culture as a whole. Information literacy, however, and the new tasks for librarians, also involve knowing what one can and cannot find on the internet, how to access it, and where the most reliable and useful information is at hand for specific tasks and projects.

Information literacy also requires learning how to distinguish between good and bad information, identifying what Burbules and Callister (2000) identify as misinformation, malinformation, messed-up information, and mostly useless information. In this sense, information literacy is closely connected with education itself, with learning where information is found, how to produce knowledge and understanding, and how to critically evaluate and interpret information sources and material. It also raises questions of power and knowledge, concerning who decides that privileged information is, who gets to produce and valorize various modes of information, and whose ideas get circulated and discussed, and who gets marginalized.

Computer and information literacies also involve learning how to read hypertexts. This involves learning how to traverse the ever-changing fields of cyberculture, and to participate in a digital and interactive multimedia culture that encompasses work, education, politics, culture, and everyday life. Hypertext was initially seen as an innovative and exciting new mode of writing which increased potentials for writers to explore novel modes of textuality and expression (Joyce, 1995; Landow, 1992).[9] As multimedia hypertext developed on the internet, it was soon theorized as a multisemiotic and multimodal form of culture. This mode is now increasingly seen as the dominant form of a new hyperlinked, interactive, and multimedia cyberculture (see Burbles & Callister, 1996; 2000; Snyder, 1996; 1997; 2002).

Genuine computer literacy involves not just technical knowledge and skills, but refined reading, writing, research, and communicating ability. It involves heightened capacities for critically accessing, analyzing, interpreting, processing, and storing both print-based and multimedia material. In a novel information/entertainment society, immersed in transformative multimedia technology, knowledge and information come not merely in the form of print and words, but through images, sounds, and multimedia material as well. Computer literacy thus also involves the ability to discover and access information and intensified abilities to read, to scan texts and computer data bases and Websites, and to access information and images in a variety of forms, ranging from graphics, to visual images, to audio and video materials, to good old print media. The creation of new multimedia Websites, databases, and texts requires accessing, downloading, and organizing digitized verbal, imagistic, and audio and video material that are the current building blocks of multimedia culture.

Within multimedia computerized culture, visual literacy takes on increased importance. On the whole, computer screens are more graphic, multisensory, and interactive than conventional print fields, and disconcerted many of us when first confronted with the new environments. Icons, windows, mouses, and the various clicking, linking, and interaction involved in computer-mediated hypertext dictate new competencies and a dramatic expansion of literacy. Visuality is obviously crucial, compelling users to perceptively scrutinize visual fields, perceive and interact with icons and graphics, and use technical devices like a mouse to access the desired material and field. But tactility is also important, as individuals must learn navigational skills of how to proceed from one field and screen to another, how to negotiate hypertexts and links, and how to move from one program to another if one operates, as most now do, in a window-based computer environment. And as voice and sound enter multimedia culture, refined hearing also becomes part of the esthetics and pedagogies of an expanded computer literacy.

In my conception, computer literacy thus involves technical abilities concerning developing basic typing skills, mastering computer programs, accessing information, and using computer technologies for a variety of purposes ranging from interpersonal communication to artistic expression to political debate and struggle. There are ever more hybrid implosions between media and computer culture as audio and video material becomes part of the internet, as CD-ROMs, DVDs, and multimedia develop, and the evolving technologies become part and parcel of the home, school, and workplace. Therefore, the skills of decoding images, sounds, and spectacle learned in critical media literacy training can also be valuable as part of computer literacy.

Moreover, with ever-expanding internet subcultures and on-line communities, more and more people have the possibilities of participating in cultural production and expression. New web forms of design, such as blogs and wikis,[10] have emerged as important new developments of the Net's hypertextual architecture and provide opportunities for new voices, alternative on-line communities, and political activism (Kahn & Kellner, 2003). Participation in this new cultural and political environment accordingly requires the cultivation of multiple literacies.

4. MULTIMEDIA AND MULTIPLE LITERACIES: THE NEW FRONTIER

The emergent multimedia environments necessitate a diversity of types of multisemiotic and multimodal interaction, involving interfacing with words and print material and often images, graphics, and audio and video material. As technological convergence develops apace, individuals need to combine the skills of critical media literacy with traditional print literacy and new forms of multiple literacies to access, navigate, and participate in the current multimedia hypertext environments. Literacy in this conception involves the abilities to engage effectively in socially constructed emergent and novel forms of culture and communication. Reading and interpreting print was the appropriate mode of literacy for books, while critical multiple literacies entail reading and interpreting discourse, images, spectacle, narratives, and the forms and genres of media culture. Forms of multimedia communication involve print, speech, visuality, and audio, in a hybrid field that combines these forms, all of which involve skills of interpreting and critique.

The term "multiple literacies" points to the many different kinds of always proliferating literacies needed to access, interpret, criticize, and participate in the emergent multimedia forms of culture and society.[11] The key root here is the "multiple", the proliferation of media and forms that demand a multiplicity of competencies and skills and abilities to access, interact, and help construct a new semiotic terrain. Multiple literacies involve reading across varied and hybrid semiotic fields and being able to critically and hermeneutically process print, graphics, moving images, and sounds. Perpetually multiplying media provide the challenge for multiplying uses, always recreating and reconstructing media forms and practices.

The term "hybridity" suggests the combination and interaction of diverse media and the need to synthesize the various forms in an active process of the construction of meaning. Reading a music video, for instance, involves processing images, music, spectacle, and sometimes narrative in a multisemiotic activity that simultaneously draws on diverse esthetic forms. Interacting with a Website, DVD, or CD-ROM often involves scanning text, graphics, moving images, and clicking onto the fields that one seeks to peruse and explore, looking for appropriate material. This might lead individuals to draw upon a diversity of materials in novel interactive learning or entertainment environments, whereby they must simultaneously read and interpret images, graphics, animation, and text.

While traditional literacies concern practices in contexts that are governed by rules and conventions, the conventions and rules of multiliteracies are currently evolving so that their pedagogies comprise a fresh although bustling and competitive field. Multimedia sites are not entirely new, however. Multisemiotic textuality was first evident in newspapers (consider the difference between *The New York Times* and *U.S.A. Today* in terms of image, text, color graphics, design, and content) and is now evident in textbooks that are much more visual, graphic, and multimodal than the previously linear and discursive texts of old. But it is CD-ROMs, DVDs, Websites, and new multimedia that are the most distinctively multimodal and multisemiotic forms. These spaces are the new frontier of learning and literacy, the great contemporary challenge to education. Critical educators need to theorize the literacies necessary to interact in these emergent multimedia environments and to gain the skills that will enable individuals to learn, work, and create in emergent cultural spaces and domains.

Cultivating multiple literacies and reconstructing education for democratization will also involve reconstructing traditional pedagogies and social relations. Emergent multimedia technologies enable group projects for students and more of a problem-solving pedagogy in the spirit of Dewey and Freire (1972 and 1998) than traditional transmission top-down teaching models. To enable students to access information, engage in cultural communication and production, and to gain the skills necessary to succeed in the global economy and culture, they need to acquire enhanced literacies, abilities to work co-operatively with others, and to navigate emergent cultural and social terrains. Such group activity may generate more egalitarian relations between teachers and students and more democratic and co-operative social relations. Of course, it also demands reconsideration of grading and testing procedures, rethinking the roles of teacher and student, and constructing projects and pedagogies appropriate to the new cultural and social environments.

Moreover, critical educators are soon going to have to rethink SATs and standard tests in relation to the new media and technologies; having the literacy and skills to successfully access material sought after, communicate, work, and create within computer and multimedia culture is quite different from reading and writing in the mode of print literacy. While traditional skills of reading and writing continue to be of utmost importance in cyberculture, they are sublated within multiliteracy, so eventually an entirely different sort of test is going to need to be devised in order to register individuals' multiple literacy competencies and to predict success in a new technological and educational environment. In this mutating global and technological world, it becomes increasingly irrational to focus education on producing higher test scores on exams that themselves are becoming obsolete and outdated by the changes in the economy, society, and culture.[12]

Critical pedagogies of the future must also confront the issue of on-line education, of how the new cultural terrain of cyberspace produces new sites of information, education, and culture, as well as novel on-line forms of interaction between students and teacher. In addition, possibilities of students developing their own spaces, cultural forms, and modes of interaction and communication should be promoted. The challenge will also arise of how to balance classroom instruction with on-line instruction, as well as sorting out the strengths and limitations of print versus on-line multimedia material (see Feenberg, 1999). Indeed, the emergent ICTs and cultural spaces require us to rethink education in its entirety, ranging from the role of the teacher, teacher—student relations, classroom instruction, grading and testing, the value and limitations of books, multimedia, and other teaching material, and the goals of education itself.

On-line education and virtual learning also confronts us with novel problems such as copyright and ownership of educational materials; collaborations between computer programmers, artists and designers, and teachers and students in the construction of teaching material and sites; and ascertaining the role of federal and local government, the community, corporations, and private organizations in financing education and providing the skills and tools necessary for a global economy and culture. Furthermore, the technological revolution forces a rethinking of philosophical problems of knowledge, truth, identity, and reality in virtual environments. Both philosophy and philosophy of education most be reconstructed to meet the challenges of democracy and a new hi-tech economy (Kellner, 2003).

Finally, adequately meeting the challenges of ever-multiplying technologies raise the question of design and reconstruction of technology itself. As Feenberg (1991, 1995, 1999) has long argued, democratizing technology often requires its reconstruction and re-visioning by individuals. Within the technology world, "hackers" have redesigned technological systems and much of the internet itself is the result of individuals contributing collective knowledge and making improvements that aid various educational, political, and cultural projects. Of course, there are corporate and technical constraints in that dominant programs impose their rules and constraints on users and the open source movement has challenged users to participate in alternative computer programs and sites, freely providing new innovations, programs, and content of various modes. There has been an on-going struggle within computer world between corporations and users with governments usually intervening on the side of major corporations.

Critical educators, however, should help teach students and themselves to become producers as well as consumers, thus helping to redesign and reconstruct the very forms and programs of computers. There are, of course, restrictions on what those without highly developed technical knowledge can do, but within limits more creative and reconstructive uses of ICTs can be devised and implemented. This leads to some final considerations on the revision and reconstruction of education.

5. RE-VISIONING AND RECONSTRUCTING EDUCATION IN THE CONTEMPORARY ERA

In sum, individuals should be helped to develop the competencies to understand, critique, and transform the social and cultural conditions in which they live, gaining the ability to be creative and transformative subjects and not just objects of domination and manipulation. This requires developing abilities for critical thinking, reflection, and the capacity to engage in discourse, cultural creation, and political action and movements. Active and engaged subjects are produced in social interaction with others, as well as with tools and techniques, so social skills and individual capacities for communication, creativity, and action must be part of the multiple literacies that a radical reconstruction of education seeks and cultivates.

Crucially, developing multiple literacies and alternative pedagogies must become reflective and critical, aware of the educational, social, and political assumptions involved in the restructuring of education and society currently underway. In response to the excessive hype concerning ICTs and education, it is important to maintain the critical dimension and to reflect upon the nature and effects of new technologies and the pedagogies developed as a response to their challenge. Many advocates of ICTs, however, eschew critique for a purely affirmative agenda. For instance, after an excellent discussion of new modes of literacy and the need to rethink education, Kress (1997) argues that we must move from critique to design, beyond a negative deconstruction to more positive construction. But rather than following such modern logic of either/or, critical pedagogues should pursue the logic of both/and, perceiving design and critique, deconstruction and reconstruction, as complementary and supplementary rather than as antithetical choices. Certainly, we need to design alternative technologies, pedagogies, and curricula for the future, and should attempt to design more democratic and egalitarian social and pedagogical relations as well, but we need to criticize misuse, inappropriate use, overinflated claims, and exclusions and oppressions involved in the introduction of ICTs into education. The critical dimension is needed more than ever as we attempt to develop improved teaching strategies and pedagogy, and design more emancipatory and democratizing technologies and curricula. In this process, we must be constantly critical, practicing critique, and self-criticism, putting in question our assumptions, discourses, and practices, as we experimentally develop novel and alternative literacies and pedagogy (see Kellner, 2003).

In all educational and other experiments, critique is indeed of fundamental importance. From the Deweyean perspective, progressive education involves trial and error, design and criticism. The experimental method itself comprises critique of limitations, failures, and flawed design. In discussing new technologies and multiple literacies, we also need to constantly raise the questions: Whose interests are emergent technologies and pedagogies serving? Are they helping all social groups and individuals? Who is being excluded and why? We also need to raise the question both of the extent to which multiplying technologies and literacies are preparing students and citizens for the present and future and producing conditions for a more vibrant democratic society, or simply reproducing existing inequalities and injustice.

Further, creating multiple literacies must be contextual, engaging the life-world of the students and teachers participating in the new adventures of education. Learning involves developing abilities to interact intelligently with the environment and other people, and calls for vibrant social and conversational environments. Education requires doing and can be gained from practice and social interaction. One can obviously spend too much time with technologies and fail to develop basic social skills and competencies. As Rousseau, Wollstonecraft, and Dewey argued, education involves developing proficiencies that enable individuals to successfully develop within their concrete environments, to learn from practice, and to be able to interact, work, and create in their own societies and cultures. In the dynamically evolving and turbulent global culture, multiple literacies require multicultural literacies. Communicating and interacting with different groups and individuals demands being able to understand and work with a heterogeneity of people and spaces, acquiring literacies in a multiplicity of media and gaining the competencies to participate in a democratic culture and society (see Courts, 1998; Weil, 1998).

From the policy perspective, it seems clear that it is the duty of the federal, state, and local government, as well as other interested parties, to provide the necessary equipment and tools to teachers, students, and schools in order to make it possible for education to cultivate the skills necessary for participation in the emergent global economy, networked society, and cyberculture. Second, it is important that teachers have proper training to make use of the technology in their classrooms and that there are labs with training or support people who have the proper skills and can ensure that teachers and students can effectively deploy the new media and technologies.[13] Recent studies have indicated that without proper teacher training the technology itself will not do the teaching and may be a source of frustration, thus blocking the educational goals desired (see Rawls, 2000; Zimmerman, 2000). Consequently, teacher training and intelligent computer lab design and use, as well as development of more intelligent and user-friendly software, is necessary to improve education in the contemporary era.

But, as I have argued in this paper, teachers and students need to develop new pedagogies and modes of learning in the emergent information and multimedia environment. This could involve a democratization and restructuring of education such as was envisaged by Dewey, Friere, and Illich in which education is seen as a dialogical, democraticizing, and experimental practice. ICTs encourage the sort of experimental and collaborative projects proposed by Dewey (1997 [1916]) as important for progressive education. This could also involve the more dialogical relations between student and teachers envisaged by Freire (1972, 1998) in which teachers learn from students and promote collaborative, dialogical and non-authoritarian teaching methods, and Illich's conceptions of "webs of learning" and "tools for conviviality" (1971 and 1973).

This re-visioning of education involves that recognition that teachers can learn from students and that often students are ahead of teachers in various technological literacies and technical abilities. Many of us (and this is true of myself) have learned much of what we know of computers and new media and technologies from students. We should also recognize to extent to which young people helped invent the internet and have grown up in a cyberculture in which they may have cultivated technological skills from an early age.[14] Peer-to-peer communication among young people is highly sophisticated and developed and democratic pedagogies should build upon and enhance these resources and practices.

One of the challenges of contemporary education is to overcome the disconnect between students experiences, subjectivities, and interests rooted in the emergent multimedia cyberculture in contrast to the classroom situation grounded in print culture and traditional learning and disciplines (see Luke & Luke, 2002). Already in the 1960s, McLuhan (1964) pointed to the disconnect between students raised on radio, television, and popular culture confronted with print materials. Today, the disconnect is even more striking in the contrast between an interactive and multimedia cyberculture and traditional forms of authoritarian lecturing and problematic print materials, thus suggesting a generational divide as well as a digital divide.

The disconnect and divides can be overcome, however, by more actively and collaboratively bringing students into interactive classrooms or learning situations in which they are able to transmit their skills and knowledge to fellow students and teachers alike. Such a democratic and interactive reconstruction of education thus provides the resources for democratic social reconstruction, as well as cultivating the multiple skills and literacies needed for the global economy and cyberculture. So far, arguments for restructuring education mostly come from the hi-tech and corporate sector who are primarily interested in new media and literacies and the reconstruction of education for the workforce and economy. But restructuring can serve the interests of democratization as well as the global economy. Following Dewey, we should accordingly militate for education that is aimed at producing better democratic citizens, as well as providing skills for the workplace and social and cultural life.

Further, to cultivate multiple literacies for democratizing education and society in the contemporary era, we need the Deweyan experimental method of trying out and testing ideas in how computers and new information technology can aid reading, research, and teaching traditional material. This involves trial and error, attempting to discern what works and what does not in using ICTs to democratize and enhance education. Thus, like Dewey, we need to perceive the interconnection of science, technology, education, and democracy in the present conjuncture. To have an enlivened democracy, we must have educated and informed citizens who require training in science and technology, and acquisition of new multiple literacies. Cultivating multiple literacies involves the scientific method of trial and error, seeking collaborative solutions to problems, and working together to democratically reconstruct education and society. As Dewey noted, this experimental and collaborative method is also the ethos of democracy, which involves dialog, co-operation, and working together, as well as designing and properly using voting machines.[15]

It appears that technology will certainly drive the reconstruction of education, but we should make sure that it works to enhance democracy and empower individuals and not just corporations and a privileged techno-elite. Producing democratic citizens and empowering the next generation for democracy should be a major goal of the reconstruction of education in the present age. Moreover, as Freire reminds us (1972, 1998), critical pedagogy comprises the skills of both reading the word and reading the world. Hence, multiple literacies include not only media and computer literacies, but also a diverse range of social and cultural literacies, ranging from ecoliteracy (e.g., understanding the body and environment) to economic and financial literacy to a variety of other competencies that enable us to live well in our social worlds. Education, at its best, provides the symbolic and cultural capital that empowers people to survive and prosper in an increasingly complex and changing world and the resources to produce a more co-operative, democratic, egalitarian, and just society. Thus, with Plato, Rousseau, Wollstonecraft, Dewey, Freire, and others, I see philosophy of education as reflecting on the good life and the good society and the ways that education can contribute to creating a better world. But as the world changes, so too must education that will be part of the problem or part of the solution as we enter negotiate an ever more precarious and insecure present and future.

The project of transforming education will take different forms in different contexts. In the overdeveloped countries, individuals should be empowered to work and act in a hi-tech information economy, and should learn skills of media and computer literacy to survive in the evolving social environment. Traditional skills of knowledge and critique should also be enhanced, so that individuals can name the system, describe and grasp the changes occurring and the defining features of the emergent global order, and can learn to engage in critical and oppositional practice in the interests of democratization and progressive transformation. This process challenges us to gain vision of how life can be, of alternatives to the present order, and of the necessity of struggle and organization to realize progressive goals. Languages of knowledge and critique must be supplemented by the discourse of hope and praxis.

In much of the world, the struggle for daily existence is paramount and meeting unmet human and social needs is a high priority. Yet everywhere education can provide the competencies and skills to improve one's life, to create a better society, and a more civilized and developed world. Moreover, as the entire world becomes part of a global and networked society, gaining the multiple literacies discussed in this chapter becomes important everywhere as media and cyberculture become more ubiquitous and the world economy demands ever more sophisticated technical skills.

This is a time of challenge and a time for experiment. It is time to put existing pedagogies, practices, and educational philosophies in question and to construct more democratic and progressive ones. It is a time for pedagogical experiments to see what works and what does not work. It is a time to reflect on our goals and to discern what we want to achieve with education and how we can achieve it. Ironically, it is a time to return to classical philosophy of education which situates reflections on education in reflections on the good life and society at the same time that we reflect on how we can transform education to become relevant to a hi-tech society and global economy and culture. It is time to return to John Dewey to rethink that intimate connection between education and democracy at the same time we address the multicultural challenges that Dewey in the midst of a still vital melting pot ideology and liberal progressivist optimism did not address. Most saliently, it is time to take up the Deweyean attitude of pragmatic experimentation to see what it is that the new technologies can and cannot do in order to see how they can enhance education.

In the current turbulent situation of the global restructuring of capitalism and worldwide struggles for democratization, we have a chance to reconstruct education and society. In this conjuncture, technology is a revolutionizing force, whereby all political parties and candidates pay lip service to education, to overcoming the digital divide, and to expanding literacy. The time is ripe to take up the challenge and to move to reconstruct education and society so that groups and individuals excluded from the benefits of the economy, culture, and society may more fully participate and receive opportunities not possible in earlier social constellations.

ENDNOTES

1. An earlier and substantially different version of this study appeared in *Educational Theory* (Kellner, 1998) and I am grateful to its editor Nicholas Burbules for helpful criticism and on-going discussion of technology and literacy. Yet another version was presented at UCLA in February 26, 1998 at my Kellner Chair Inaugural Lecture and I thank members of the audience for discussion of the issues developed here. The paper was also presented at the Philosophy of Education Society convention in Toronto on April 1, 2000 and I appreciate this audience for vigorous polemic and to commentator Nicholas Burbules for constructive critique and discussion. I was also able to refine ideas in this paper at the October 2000 Pac-Bell/UCLA conference on information literacy and at the California Association for the Philosophy of Education (CAPE) meetings at UCLA the same month and am also thankful to audiences at these events for constructive commentary and discussion, especially Aimee Dorr and Howard Besser who organized the

Pac-Bell/UCLA conference and participated in CAPE discussions. Later versions were published in a Routledge volume on multiculturalism, edited by George Katsiaficas and Teodros Kiros, and Silicon Literacies, edited by Ilana Snyder (Kellner, 1999; 2002) and I am thankful to the editors for comments and discussions which helped with clarification of my position on multiculturalism and education and on "silicon literacies". For continuing discussions of the issues in this paper I am especially grateful to Rhonda Hammer, Allan and Carmen Luke, and Richard Kahn.

2. For materials pertaining to the educational reform proposed by Dewey and Freire and the broader conceptions of relating education to creation of the good life and good society advanced by Plato, Rousseau, Wollstonecraft, and others which inform this paper, see my philosophy of education Website, accessible from www.gseis.ucla.edu/faculty/kellner/kellner.html. See also my Education and Technology Website, which contains materials pertinent to this study.
3. Studies reveal that women, minorities, and immigrants now constitute roughly 85% of the growth in the labor force, while these groups represent about 60% of all workers; see Duderstadt (1999–2000: 38). In the 1990s, the number of Hispanics in the United States increased by 35% and Asians by more than 40%. Since 1991, California has had no single ethnic or racial minority and half of the high school students in the state are now African-American or Latino. Meanwhile, a "tidal wave" of children of baby boomers are about to enter college; see Atkinson (1999–2000: 49–50). Obviously, I am writing this study from a U.S. perspective, but would suggest that my arguments have broader reference in an increasingly globalized society marked by a networked economy, increasing migration and multiculturalism, and a proliferating internet-based cyberculture. There is by now a tremendous amount of books and articles on the global economy, technological revolution, new cultural spaces, and the implications for every aspect of life from education to war. See, for example, the monumental studies by Castells (1996, 1997, 1998), and the analyses of the restructuring of capital, technological revolution, and the post-modern turn in Best and Kellner (2001).
4. The "digital divide" has emerged as the buzzword for perceived divisions between information technology have and have nots in the current economy and society. A U.S. Department of Commerce report released in July 1999 claimed that digital divide in relation to race was dramatically escalating and the Clinton administration and media picked up on this theme (See the report "Americans in the Information Age: Falling Through the Net" at http://www.ntia.doc.gov/ntiahome/digitaldivide/). A critique of the data involved in the report emerged, claiming that it was outdated; subsequent studies by Stanford University, Cheskin Research, ACNielson, and the Forester Institute claim that education

and class are more significant factors than race in constructing the divide (see http://www.clickz.com/stats/big-picture/demographics for a collection of reports and statistics on the divide; see also http://nces.ed.gov/pubsearch/pubsinfo.asp?pubid=2004011). Earlier and more recent research both make clear that there is a gaping division between information technology haves and have nots, that this is a major challenge to developing an egalitarian and democratic society, and that something needs to be done about the problem. My contribution involves the argument that empowering the have nots requires the dissemination of new literacies and thus empowering groups and individuals previously excluded from economic opportunities and socio-political participation.

5. See the Ph.D. dissertations by two of my UCLA students, Rawls (2000) and Zimmerman (2000). See also Bernard Warner, "Computers for Youth: Spreading the Net", *The Standard*, March 27, 2000 which reports: "A study conducted recently by Denver-based Quality Education Data showed school districts across the country spent $6.7 billion on technology in the 1998–1999 school year, up almost 25% from the previous year. But the same study revealed that an equally crucial funding component—computer training for teachers—was startlingly low, rising just 5.2% over the same period". In June 2000, however, President Bill Clinton argued for increased funding for teaching training to use new technologies so it appears that there is growing recognition of the problem.
6. Freire also stated that: "It is not the media themselves which I criticize, but the way they are used" (1972: 136). Moreover, he argued for the importance of teaching media literacy to empower individuals against manipulation and oppression, and using the most appropriate media to help teach the subject matter in question (114–116).
7. On the novel forms of internet culture and on-line communities, see Kahn and Kellner (2003).
8. For an earlier and expanded discussion of media literacy, see Kellner (1998). Carson and Friedman (1995) contains studies dealing with the use of media to deal with multicultural education. Examples of teaching media literacy which I draw on include Masterman (1985), Kellner and Ryan (1988), Schwoch, White, and Reilly (1992), Fleming (1993), Giroux (1992, 1993, 1994, 1996), Giroux and McLaren (1994), Sholle and Denski (1994), McLaren et al. (1995), Kellner (1995a, b), Luke (1996, 1997a, b), Giroux and Shannon (1997), Potter (1998), Semali and Pailliotet (1999) and Kellner and Share (1995). See also the work of Barry Duncan and the Canadian Association for Media Literacy (Website: http://www.nald.ca/province/que/litcent/media.htm) and the Los Angeles based Center for Media Literacy (www.medialit.org). It is a scandal that there are not more efforts to promote media literacy

throughout the school system from K-12 and into the University. Perhaps the ubiquity of computer and multimedia culture will awaken educators and citizens to the importance of developing media literacy to create individuals empowered to intelligently access, read, interpret, and criticize contemporary media and cyberculture.

9. Some early advocates of hypertext attacked the emergence of the World Wide Web as a debased medium which brought back into play the field of earlier media, like television, forcing the word to renegotiate its power against the image and spectacles of sight and sound, once again decentering the written word [see, for instance, Joyce (1995) and the discussion in Landow (1992, 1997); see also their more recent reflections in Snyder (2002)]. As the internet becomes a multimedia hypertext, however, it is clear that contemporary education must teach reading a multimodal hypertext as a basic skill and mode of literacy.
10. On blogs and wikis, see Kahn and Kellner (2003). "Blogs" are hypertextual web logs which people use for new forms of journaling, self-publishing, and media/news-critique. For examples, see our two blogs: BlogLeft: Critical Interventions, <www.gseis.ucla.edu/courses/ed253a/blogger.php> (accessed November 2005). Vegan Blog: The (Eco)Logical Weblog, <getvegan.com/blog/blogger.php> (accessed November 2005). "Wikis" (from the Hawaiian word for "quick") are popular new forms of group databases and hypertextual archives. See http://en.wikipedia.org/wiki/Main_Page.
11. For other recent conceptions of multimedia literacy that I draw upon here, see the discussions of literacies needed for reading hypertext in Burbules (1997); Burbules and Callister (1996, 2000); the concept of multiliteracy in the New London Group Cazden et al. (1996) and Luke (1997a, b); the papers in Snyder (1997, 2002); Semali and Pailliotet (1999); and books being published in David Barton's Routledge series "literacies" that include Illana Snyder's "silicon literacies", as well as books on "city literacies", "situated literacies", "multiliteracies", and "global literacies and the World Wide Web".
12. On the centrality of preparation for exams in contemporary education and the role of standardized tests in the U.S. educational and social system, see Lemann (1999). While I have not myself researched the policy literature on this issue, in the many discussions of SAT tests and their biases which I have read, I have not encountered critiques that indicate the obsolescence of many standardized tests in a new technological environment and the need to come up with new testing procedures based on the new cultural and social fields that we are increasingly immersed in. I would predict that proposals for devising such tests will emerge and that this issue will be hotly debated and contested in the future.
13. It was at one time encouraging that computers and new technologies were getting into the schools in the U.S. and elsewhere at an impressive rate.

The September 25, 2000 *U.S. News & World Report* notes that in 1994 when President Clinton vowed to connect every school to the information superhighway, only one in three schools, and just 3% of the classrooms, were wired to the internet. But by 1999, according to the National Center for Education Statistics, 95% of schools and 63% of classrooms had internet access. A survey then showed that 76% of the public polled believed that U.S. government should support efforts to train teachers to use new technologies in their classrooms, and that those surveyed said that they saw new technologies and gaining necessary literacies and skills as essential to their own professional and personal advancement, that 71% thought that the internet could enhance their own educational level, while 86% thought that the net could help their children learn more and that 71% claimed that they had gone online for educational reasons—up from 36% when same group was polled in 1999. Yet it is discouraging that the Bush administration has not continued the progressive technology and education policies of the previous administration and has reverted to conservative schooling based on training for tests and centering on traditional forms of literacy and curricula.

14. For instance, Mosaic, Netscape, and the first browsers were invented by young computer users, as were many of the first Websites, list-serves, chat rooms, and so on. A hacker culture emerged that was initially conceptualized as a reconfiguring and improving of computer systems, related to design, system and use, before the term became synonymous with theft and mischief, such as setting loose worms and viruses (see Levy, 1991). On youth and internet subcultures, see Kahn and Kellner (2003).
15. I am, of course, ironically pointing to the non-functioning of voting technology and the system of democracy in the 2000 U.S. Presidential election, suggesting a massive disconnect between the hi-tech economy and cyberculture and traditional voting machines and practices that helped the Bush machine to gain the presidency (see Kellner, 2001).

Chapter 10: Cyberpedagogy

CARMEN LUKE
Centre for Critical and Cultural Studies,
University of Queensland, Australia

1. INTRODUCTION

In the last two decades, everyday life in post-industrial societies has shifted from a wired to an increasingly wireless world. Cell phones have given us a new kind of mobility and freedom to send messages or talk to anyone from anywhere, to check our e-mail, access the web, or locate others by activating global tracking systems. Online shopping, banking, entertainment and travel reservations, and educational courses—they are all just a click away whether on the wired or wireless keyboard or cell phone touchpad. Anyone, anywhere, can now communicate and access information as long as the user has a computer and access codes to wireless networks (WLAN), or a modem, electricity and a cable or phone line which, needless to say, excludes two-thirds of the world's population. In the brave new digital world, everyone is said to have access to more information than ever before, which many ICT enthusiasts herald as the democratization of knowledge and information. Interactivity has broken the tyranny of the passive user (whether of magazines, books, or TV), as the cybernaut is now in charge of when and what is viewed and read. Connectivity has broken the tyranny of distance and time as instant electronic access to information and people located anywhere around the globe shrinks time and space. ATMs, internet, and phone banking have liberated us from the drudgery and "time waste" of banking queues. Online education courses enable students any time and from anywhere to log on and move through menued choices at their own pace and leisure. Wired or wireless—our everyday routines, social relations, cultural activities, and frames of reference have been irrevocably changed by digital technologies and global connectivity.

2. MULTIMODAL MULTILITERACIES

In the midst of all this, educators have tried to come to terms with the contradictions between industrial model schooling based on static print/book culture and competitive individualism, and the collaborative learning possibilities and deterritorialized meaning-making and knowledge configurations enabled by new technologies. Digital technologies have remediated traditional text genres and forms (Bolter, 2002; Bolter & Grusin, 2000), and have given us a new

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 269–277.

kind of immediacy (e-mail and chat; www shopping, searches or e-ticketing; virtual reality, webcams, etc.). When learning is no longer geographically tied to a desk, the school library, the book, or the teacher who demands "all eyes up front", then old-style transmission and surveillance pedagogy is destabilized and increasingly unworkable. Throughout the last decade, notions of a singular print-based literacy have been reconceptualized into hyphenated or multiple literacies that acknowledge the diversity of information sources and media that people access, negotiate, and redeploy in everyday contexts.

Partially influenced by constructivist theories of learning and pedagogy (Bruner, 1990; Vygotsky, 1978), and post-structuralist theories of knowledge as socially constructed, critical educational theorists have been arguing for the need to reconceptualize traditional teaching and learning relations in light of technologically mediated access to and relations with knowledge that have changed literacy practices and produced new kinds of social relations among learners/students in their engagements with IT (Snyder, 2002). A social constructivist view of knowledge and learning implies that learning occurs in situated sociocultural contexts and that knowledge is apprehended and appropriated in social interaction, dialogue, negotiation, and contestation. In the contemporary blend of "old" and "new" information environments, learning and information exchange or knowledge production occur in socially interactive communities as people draw on diverse sources of information, modes of communication, and (virtual) community engagements. Solitary and silent desk-bound (or library-bound) reading and writing, pencil and paper testing are being replaced by interactive group work around, with and "through" the computer interface.

In turn, collaborative and constructivist theories of pedagogy and learning complement emerging interest in problem-based learning (Savin-Baden, 2000) seen as more responsive to the diverse experiences and background knowledge of students, and able to provide "richer" and more "authentic" situated learning experiences that demand interdisciplinary thinking and learning. Together, collaborative, constructivist, and problem-based learning is a powerful conceptual antidote to pedagogy as transmission, and knowledge as parceled facts and objects. Instead, knowledge acquisition and production are seen as process, as design, as contextual, situational, and contestable. That is to say, the joint formulation of a solution to a problem is necessarily a design process—a process of harnessing diverse information "bits" into new relations in response to the situated context of a given problem. This locates knowledge and learning, rather than technology, at the center of pedagogy. Knowledge as design implies and much more adequately describes the intrinsic relational aspects of knowledge, the mix-and-match characteristics of hybrid, intertextual, and multimodal knowledge and communication exchanges, and the inherent transformative nature of all knowledge as people apprehend, use, contest or reproduce it in situated contexts.

As more texts become available in digital form, users are forced to access information in different ways that have profound ramifications for reading and writing. Although the fundamental principles of reading and writing have not changed, the process has shifted from the serial cognitive processing of linear print text to parallel processing of multimodal text-image information sources. Longhand pencil and paper writing has been replaced by keyboarding and, increasingly, iconic writing (button clicks). Text and meaning are no longer embedded exclusively in a linear sequence of alphabetic characters combined in a "logical" sequence of phrase, sentence, paragraph, and narrative units dictated by author intent or formatting demands of a page or book. Instead, hypertext embeds text-image and (potential) meaning in a web-like pattern of links that readers can pursue or ignore. The hypertext author designs an "editorial" structure of potential meanings through links, but readers too structure their own transitions from one part of the text to another, moving from one set of emerging meanings to another (Kaplan, 2000). The process of the link pathways chosen and those passed by demands a particular kind of reading, a cognitive mapping and pathway navigation that is radically different from the relatively choice less linearity of book-based print.

Yet hypertext reading is also hypertext viewing of the semiotic cartography of software interfaces, graphics, link patterns, images, color, and sound. The cultural discourses subtending these symbols, images, and metaphors are extra-textual yet an integral component of an emerging "grammar" of knowledge and communication that students are enculturated into from an early age through electronic story books, games, and toys (Holloway & Valentine, 2000; Luke, 1999). Since students not only learn important social and cultural lessons from such texts and objects, but reshape and re-incorporate them into their own play, social relations, and (hyper)textual productions, it thus seems crucial that students develop a critical understanding of the cultural stories they consume and produce. Arguably, then, the need for a critical ICT literacy is as important in the use and study of new media as it is of "old" (broadcast) media (Johnson-Eilola, 1997; Luke, 2002).

Having grown up in a world of connectivity and immediacy, of "digital fun and games" (Nixon, 1998), children's entry into knowledge-in-boxes curriculum, into disciplined "on task" cognition and a school culture of hyperindividualism and "deferred gratification" (e.g., "testing", grades) can create the kind of generational divide that Green and Bigum (1993) have referred to as "aliens in the classoom". Students see their teachers as aliens from another time: trained in the culture of the book, monologic literacy, specialists in one disciplinary content area, and many struggling with the new technologies. Teachers, in turn, see today's students as alien digi-kids—wired and plugged in, speaking a "foreign language" of ICT acronyms and insider technical know-how. Connectivity invokes clichés of a borderless world and in that immaterial "white" space there is a new sense of spatiality that defies the sorts of modernist understandings of knowledge, of place, of sociality that is so foundational to our own schooling experience and the normative social science and teacher training most of us underwent at some time in the last several decades.

Offline–online distinctions are increasingly untenable in relation to young people's use of ICTs and in terms of media convergence. Today's youngster is a savvy citizen of the digital age. She has seen *Harry Potter* the movie, read the book, has the DVD and several *Potter* e-toys, and Hogwarts mosey across the screensaver on her personal digital assistant (PAD). Perhaps for adults, going "online" to do the banking or a bit of web browsing is something that happens, say, in the study, after a "real" social event like the family dinner. For kids who have grown up with Walkman, Gameboy, cell phones, kiddie PADs, internet, and console gaming, "real life" is online. Net, TV, and radio can be accessed while doing e-mail on one screen, chat on another, and text messaging on the cell phone. Magazines emulate webpage layouts, most are accessible online, and product advertisements whether on the subway, billboard, or TV provide the ubiquitous dot.com website of the product or service. Information, ideas, cultural icons, social connections cross-reference, and flow into one another in an intertextual multimedia and multimodal network in which (middle class) kids' experience and knowledge of the world, their identities, literacy practices, and learning are largely shaped.

Industrial-era collection code curriculum delivered through chalk-and-talk pedagogy measured academic outcomes and success on the accumulation and reproduction of isolated facts in discrete content area domains. In digitalized knowledge and networked environments, an understanding of the relations among ideas is as if not more important than mastery of the bare facts. The conceptual shift here is one from *collection* to *connection*. Thinking laterally across associations, developing a meta-awareness of the links or paths taken and those passed over, backtracking along paths, reading and viewing mix-and-match old and new blended media genres and forms—these are the very rhizomatic conceptual and cognitive maps required to read through and think through localized branchings of larger global knowledge units (disciplinary or otherwise). Thinking across associations, accessing, and integrating knowledge laterally are the very cognitive, socially situated repertoires we use to negotiate everyday life and are core requirements for hypertext navigation. In that regard, hyptertext's multimedia and multimodal interface and gateways to laterally connected and further embedded information sources and/or knowledge domains comes much closer to an authentic representation of the interdisciplinarity, connectedness, and multimodality (Kress & Van Leeuwen, 2001) of knowledge as we experience and enact it in the contexts of everyday life.

Since all meaning is situated relationally—connected and cross-referenced to other genres, media and related meanings in other social and cultural contexts—an intertextual understanding of how meanings shift across media, genres, and cultural frames of reference is crucial. Meaning-making from the multiple linguistic, audio, and symbolic visual graphics of hypertext means that the cyberspace navigator must draw on a meta-knowledge of traditional and newly blended genres or representational conventions, cultural, and symbolic codes, as well as linguistically coded and software driven meanings. The dynamics of lateral and cross-linked information of hypertext requires and generates a cognitive orientation akin to what is often termed lateral thinking—the very skills many educators aim to instill in students. That is to say, instead of learning and thinking "vertically"—deductively or inductively—within the root structures of disciplinary boxes, connectivity and hypertext environments demand horizontal or lateral cognitive mobility across disciplines, genres, modalities and, indeed, cultural zones. The global cross-cultural information flow on the internet and the global composition of many virtual communities (whether chat, gaming, special interest, or classroom communities) requires new ways of thinking about transcultural communication: our "readings" of and interaction with others from culturally diverse backgrounds. Intertextuality, transcultural communication, metamedia (Lemke, 1998), multimedia or "intermediality" (Semali, 1999), and multimodal multiliteracy (Luke, 2000) are features of the "new communicative order" (Kress & van Leeuwen, 1996; Snyder, 2001) in which young people's orientations to "life online", information, knowledge, learning and communication, time and space, are shaped.

4. PEDAGOGY

In just two decades educational wisdom has shifted from 1980s assumptions about the need for a computer in every classroom, in the early 1990s to have a computer on every students' desk, by the late 1990s to have every classroom wired and every computer network capable, and today to plan for the wireless school. We know now that students prefer collaborating around the screen, problem solving, and information sharing as a group rather than working individually in isolation (Bruce, 2002; Holloway & Valentine, 2000). The social group habits that kids establish during the years of out-of-school console or web-based gaming and "play" have been transposed into the classroom and they engage with screen-based information and learn in very different ways that involve risk and play: "let's click here and see what happens" or "playing around" with MP3s, identities, digital scanners, or cameras (cf. Beavis, 1997). What, then, might a "cyberpedagogy" based on collaborative and constructivist learning principles look like?

Too often collaborative learning may merely mean co-operative learning as in a group task. Collaborative learning by contrast implies not only co-operative group work but, importantly, aims to develop students' mastery (or meta-awareness) over their own learning skills and styles. This self-reflective understanding of one's learning, in turn, informs collaboration with others (via face to face, chat, bulletin boards, or e-mail) to (dis)confirm if one is on the right track in terms of situational understanding, meaning-making, design of new knowledge, and perceptions of multiple problem-solving options. Collaboration is about "sound checks" on one's learning and understanding in the context of peers, and in consultation with and guided by the teacher or instructor. In higher education contexts, however, where courses are often exclusively online without real-time face-to-face contact with instructors, the disadvantages are that there is no guided "instructional conversation", no mediating "authority" or expert to pull a group back on track, or to suggest alternatives. In totally unmediated online groups, students often find that some are doing all the work while others only marginally contribute which can create interpersonal and intragroup tensions and conflicts that militate against the very principles of a collaborative and co-operative learning environment. Moreover, when communication is solely via chat, bulletin boards (e.g., WebCT), or e-mail, replies from other students or an instructor may take days and discussions languish because members fail to log in. Clearly, a balance between face-to-face real time and online learning encounters is optimal.

Despite common fears among educators of the demise of the teacher role in the face of a rapid and global rollout of e-education programs, courses, and software, IT is but one resource among a platform of critical, learner-centered, constructivist, and collaborative pedagogy. Teachers are an indispensable component in this mix. Their role as mediators, as tele-guides and mentors, as craft experts with specialized expertise who induct new learners into communities of practice is as central as is their role in shaping and supporting pedagogies that assist and immerse student learning in authentic and relevant activities. High-tech and visually seductive webpages, courseware, and graphic interfaces are no substitute for teachers' specialized expertise at scaffolding learning, working with and alongside groups around the screen, engaging students through probing, guiding, and prompting, simplifying or expanding a concept or approach, and ensuring a productive, cultural, and ability inclusive real-time and online environment. Teachers and curriculum, "old" media and "new" media resources, parents and other community stakeholders, academic or community experts, together constitute the broader platform of mixed resources on which learners draw and which collectively shapes students' intellectual growth and learning environments.

Yet despite general agreement among many educators over the "fit" between constructivist approaches to learning and the new ICTs, we still find ourselves in an historical moment where institutional infrastructures, teacher skills, student access to and facility with ICTs are uneven. Moreover, given that K-12 and higher education sectors remain immersed in residual book-print culture along with a very powerful legacy of teacher centered pedagogy, and a psychologized and individualized model of learning, assessment, and achievement, many educators have become experts at bricolage pedagogy. Teachers are grafting "new" onto "old" models of learning and teaching, trying out innovative pedagogies while also answering state or federally mandated calls for outcomes-based instruction, individualized assessment, and grades. And yet, in this current backwash of rapid ICT innovation, wired into bricks and mortar educational paradigms, teachers nonetheless have been constructing innovative hybrid pedagogies in the cracks between industrial model schooling and cyberschooling (Bruce, 2002; Chris Bigum, 2001; Hawisher & Seife, 2000; Windschitl & Sahl, 2002). Whether teachers incrementally develop a more collaborative and student-centered pedagogy as a result of the introduction of IT into classrooms, or whether teachers' established pedagogical knowledge and philosophy are grafted onto technology remains unclear. What is certain is that teachers' attitudes toward and uses of technology and pedagogical change remain uneven and variable (Bigum et al., 1997; Meredyth et al., 1999; Windschitl & Sahl, 2002).

Some studies have suggested that the more adept teachers become with technology over time, the more likely they will reshape their orientation toward a more constructivist pedagogy (Becker & Ravitz, 1999; Mehlinger, 1996; Schofield, 1995). Yet as Windschitl and Sahl (2002) found in their study of instructional change among teachers in a laptop school, availability of technology in and of itself does not appear to "initiate teachers' movements toward constructivist pedagogy" (p. 198). The re-shaping of teacher practice seems to depend on the variable intersections between teachers' attitudes and beliefs about IT and pedagogy, and a host of contextual and situational factors such as the extent to which teachers use technology in out-of-school settings, the kinds of technologies available in schools, levels of technical support, access to ongoing professional development, and levels of collaborative and collegial relations among teachers.

CONCLUDING COMMENT

Although hypertext and the internet are placeless and "immaterial" in a literal sense, the user–reader–viewer interacts with the interface to the virtual from an embodied space, a material place (home, school, office), reads and writes in real time. The materiality of interaction among teachers and students at and through the screen requires a new way of looking at the temporal and spatial presence in the disembodied and immaterial spaces of flows. So, on one hand the importance of old-style ethnographic studies of real bodies in real-time connected to new forms of immaterial but nonetheless "real" spatialities located *within institutionalized educational contexts* remains crucial. On the other hand, the bigger challenge is to devise flexible and innovative analytic tools with which to track the fluidity and mobility of "travel" across the semioscape of links, knowledge fields, webpages, chat rooms, e-mail routes, intersubjective and intercultural relationships, and so on. Capturing the idea and practices of mobility and flows—of the subject's circuits and trajectories, semantic-semiotic production and consumption—across the internet's global terrain of signification which operates in real time but nearly instantaneously and yet "never stops" (Jordan, 1999), is probably at present beyond what electronic transcript analysis, interview, observational or survey data, electronic site logging, or even critical discourse analysis can reveal. As Burbules (2001) has argued, learning with and on the web is not just about information access, retrieval or even critical hyperreading. Rather, we should conceptualize "learning in the context of the web as the achievement of a certain kind of *mobility* . . . to move within . . . across . . . against the pathways that seem to determine users' options for navigation and for meaning-making" (p. 83). The challenge for educational theorizing and research, then, is to devise a flexible conceptual and methodological mix based on an equally flexible, indeed provisional and transformational, epistemology with which to capture the dynamics of mobility and "travel" across media, modalities, information nodes, communities, link pathways, and networks which demand and generate new kinds of learning, (meta)cognitive routing, multisemiotic literacy, identity construction and performance, community ethics, and sociality.

Chapter 11: Re-situating Constructionism

JOHN W. MAXWELL
Centre for the Study of Curriculum and Instruction, University of British Columbia, Vancouver, BC, Canada

1. INTRODUCTION

Over the past few decades, much has been written and said about the use of computers in education. But despite the incredible advances in computing power and software sophistication in that time, the application and integration of technology in educational settings have remained confused and troublesome for many educators. For all the energy expended in creating and marketing computing technologies, the ways in which educators have used technology in teaching and learning have developed little over the past 20 years. While there are certainly more computers in classrooms today than ever before, the "big ideas" that shape how we interpret and use these technologies have been few and far between.

One of these "big ideas" is the school of thought called *constructionism*, which emerged from the Epistemology and Learning Group at the MIT Media Lab in the 1980s. Constructionist theorists hold that learning happens best when children are engaged in creating personally meaningful objects and sharing them with their peers. Probably, its most famous manifestation has been the Media Lab's work with children and the Logo programming language. The computer was seen as an expressive tool that allowed children to manipulate objects (the Logo "turtle" is the classic example) in a computer "microworld", and through exploration and reflection to come to more formal understandings of relationships, say, in geometry. The constructionist researchers saw educational technology in the sense of "objects to think with" that facilitate novel ways of thinking.

Since the Logo research of the 1980s, the world of computers and high technology has seen enormous—if not revolutionary—change. The personal computer has become an integral part of how most people communicate, work, write, learn, and play. The advent of global networks and ubiquitous connectivity has caused us to consider computing technology as a mass medium alongside television and the press. The emergence of the "information economy" and e-commerce spawned a new period of economic growth—one that has looked at times like a gold rush. But this incredible social transformation brings with it much confusion about what's really going on, where things are really heading, and what will really be important over the long run. A casualty of this confusion has been, I believe, the field of educational technology,

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 279–298.

which is sorely fragmented and insecure today. This is not surprising, for how can we hope to understand educational technology when our understanding of technology itself is constantly being challenged?

I believe that it is worthwhile to re-examine constructionism as a guiding philosophy in educational technology in the light of some significant recent contributions in the fields of situated learning, media theory, and science and technology studies. My aim here is to re-situate constructionism within contemporary thought as a way of re-defining its relevance to the integration of education and technology today.

This chapter is in three parts. In the first, I will examine the literature on situated learning, situated cognition, and ecologies of knowledge. In the second, I will explore some significant contributions to thinking about media, science, and technology. In the third and final part, I will focus on the literature of constructionism itself, from the early 1980s to current works, and attempt to trace some trends in the thinking around it. Ultimately, I will attempt to elaborate an *ecological* approach to understanding educational technology and educational media, an approach that brings together the three areas covered in this chapter. By ecology, I mean a dynamic, evolving system in which actor and environment are inseparable and mutually constitutive, in which both people and cultural artifacts are considered, and in which responsibilities and ethics are emergent and situated. In looking for these qualities in approaches to knowledge, culture, learning, and technology, I believe, we can begin to develop a critical stance with respect to a confusing world.

2. SITUATED LEARNING AND ECOLOGIES OF KNOWLEDGE

A good place to begin the examination of situated learning is an article by Brown et al. (1996 [1989]) called "Situated Cognition and the Culture or Learning". This article, which largely introduced the concepts and vocabulary of situated cognition to the educational community, expressed the authors' concern with the limits to which "conceptual knowledge can be abstracted from the situations in which it is situated and learned" (Brown et al., 1996: 19)—as is common practice in classrooms. Building upon the experiential emphasis of pragmatist thinkers like John Dewey and on the social contexts of learning of Russian activity theorists like Vygotsky and Leontiev, Brown and his colleagues proposed the notion of "cognitive apprenticeship". In a cognitive apprenticeship model, knowledge and learning are seen as situated in practice

> The activity in which knowledge is developed and deployed, it is now argued, is not separable from or ancillary to learning and cognition. Not is it neutral. Rather, it is an integral part of what is learned. Situations

> might be said to co-produce knowledge through activity. Learning and cognition, it is now possible to argue, are fundamentally situated. (p. 20)

Cognitive apprenticeship takes as its model the "evidently successful" (p. 22) authentic activities of craft apprenticeship, and extends it to include the kinds of cognitive-domain learning that one might find in a mathematics classroom. Brown, Collins, and Duguid explore several examples from mathematics education in which the apprenticeship model has been applied to "thinking mathematically" in a variety of authentic and situated contexts. Brown and his colleagues go on to argue that all knowledge is like language in that it is "indexical". Indexicality in language is seen in pronouns, articles, and dependent references, where the meaning of an utterance is very directly linked to the context of the discourse, as in the statement, "I will be here tomorrow". Extending this notion to knowledge itself, Brown suggests: "its constituent parts index the world and so are inextricably a product of the activity and situations in which they are produced" (p. 22). This idea is carried forward to an examination of tools and the way in which they are learned and used

> Learning how to use a tool involves far more than can be accounted for in any set of explicit rules. The occasions and conditions for use arise directly out of the context of activities of each community that uses the tool, framed by the way members of each community see the world. The community and its viewpoint, quite as much as the tool itself, determine how a tool is used. (p. 23)

Brown is thus critical of the de-contextualized quality of classroom learning—or rather, its artificially contextualized nature, since classroom activity is of course situated within the social and cultural context of the school. But this is significantly distant from the way actual practitioners of math, science, history, and so on work. The assumption underlying traditional classroom teaching is that abstracted conceptual representations are self-sufficient as an approach to knowledge. Brown, Collins, and Duguid challenge this assumption at its root:

> A theory of situated cognition suggests that activity and perception are importantly and epistemologically prior—at a nonconceptual level—to conceptualization and that it is on them that more attention needs to be focused. (p. 42)

This phenomenological stance is significant. Brown, a cognitive scientist at Xerox PARC, was undoubtedly influenced at the time by trends in computing and artificial intelligence (AI) research—trends that pointed to a de-centered, situated view of cognition, in contrast to the rationalist, representational focus of previous decades. Two important books appeared in the late 1980s that describe the AI community's movement away from a cognitive model that is based on internal representations of external reality: Winograd and Flores' *Understanding Computers and Cognition*, and Suchman's *Plans and Situated Actions*.

In *Understanding Computers and Cognition: A New Foundation for Design*, Winograd and Flores (1986) attempt to orient the field of AI research and intelligent systems design in a new direction. Instead of a rationalist, rules-based computational model of mind, Winograd and Flores take a de-centered and situated approach. Winograd and Flores draw on the phenomenological thinking of Martin Heidegger, the biology of perception work of Humberto Maturana and Francisco Varela, and the speech-act theory of philosophers John Austin and John Searle. These influences lead them to call for a situated model of mind-in-the-world, composed of a self-sustaining system that is capable of continual transformation, capable of commitment, and intentionality in real relationships.

Winograd and Flores' work raises significant questions about the assumptions of a functionalist, rationalist, representational model of cognition, arguing that such a view is based on highly questionable assumptions about the nature of human thought and action. In a parallel and almost contemporaneous book, *Plans and Situated Actions: The Problem of Human-Machine Communication*, Suchman (1987) examines the difference between rational, purposive "plans", and circumstantial, negotiated, "situated actions". As her argument develops through examples of each, it becomes clear that rather than situated actions being imperfect copies of rational plans, plans are *idealized* representations of real-world actions. Research in cognition and intelligent systems design needs to take the latter seriously:

> A basic research goal for studies of situated action, therefore, is to explicate the relationship between structures of action and the resources and constraints afforded by physical and social circumstances.
>
> (Suchman, 1987: 179)

Both Winograd and Flores' and Suchman's work point to the emergence in the AI and intelligent systems communities of theories of situated, distributed knowledge, embodied in real-world contexts, rather than functionalist, abstract models of cognition. The implications for education and learning theories are significant.

The work that brings the situated perspective firmly home to education is Lave and Wenger's (1991) *Situated Learning: Legitimate Peripheral Participation*. This small, simple book has more to say than most of the rest of the literature combined. Coming a year or two after Brown, Collins, and Duguid's article, it presents a view of situated learning substantially more developed. One of Lave and Wenger's starting points—Brown's "cognitive apprenticeship"—becomes a point of some departure. Lave and Wenger are wary that privileging apprenticeship over other forms of teaching and learning misses the point: while the apprenticeship model may be an example of situated learning in action, they argue, situated learning cannot help but occur in all contexts of practice:

> In our view, learning is not merely situated in practice—as if it were some independently reifiable process that just happened to be located somewhere; learning is an integral part of generative social practice in the lived-in world. . . . Legitimate peripheral participation is proposed as a descriptor of engagement in social practice that entails learning as an integral constituent.
>
> (Lave & Wenger, 1991: 35)

This perspective flips the argument over: it is not that learning happens best when it is situated (as if there were learning settings that are not situated), but rather, learning is an *integral part* of all situated practice. So, rather than asking, "How can we create authentic learning situations?" they ask, "What is the nature of communities of practice?" and "How do newcomers and old-timers relate and interact within communities of practice?". They answer these questions through elaborating the nature of communities of practice in what they term "legitimate peripheral participation".

> By this we mean to draw attention to the point that learners inevitably participate in communities of practitioners and that mastery of knowledge and skill requires newcomers to move toward full participation in the sociocultural practices of a community. (p. 29)

The terminology is intentionally elusive; there is really no such thing as "illegitimate" or "central" participation; legitimate peripherality refers to the dynamics of membership in a real community of practice. A member of a community is *legitimate,* in that the community forms the context for practice in a real way; *peripherality* refers to the notion that he or she is inevitably on a trajectory from newcomer to old-timer within a community. "*Peripherality* is also a *positive* term, whose most salient conceptual antonyms are *unrelatedness* or *irrelevance* to ongoing activity" (p. 37).

Lave and Wenger warn against understanding legitimate peripheral participation as a technique or a form of learning environment, one that can be designed or created. Rather, they argue, it is an "analytical viewpoint on learning, a way of understanding learning" (p. 40), and as such it forms a framework for looking at the dynamics of learning in all situations of practice, even those which at face value appear to be anti-thetical to learning. Included in this latter category is their example of butchers' apprentices (pp. 76–79) in which newcomers feel intimidated and are kept apart from the experienced meat cutters, confined to tasks that have little to do with professional practice. Nevertheless, learning takes place, and the dynamics of this community of practice produce new generations of butchers. In a later work, Brown and Duguid (1996a) explore the idea of learning as "stolen knowledge", and ask how one can "legitimize theft". Their answer is a reference to Lave and Wenger's book.

Core to Lave and Wenger's work is the idea of knowledge as distributed across a community of practice—what Gavriel Salomon refers to as the "radical situated" perspective (Salomon, 1993). This idea stands opposed to conceptions of learning and cognition that emphasize individuals' internalization of knowledge. Lave and Wenger instead re-emphasize the ways a community of practice reproduces itself through its individuals:

> This pivotal emphasis, via legitimate peripheral participation, on relations between the production of knowledgeable identities and the production of communities of practice, makes it possible to think of sustained learning as embodying, albeit in transformed ways, the structural characteristics of communities of practice.
>
> (Lave & Wenger, 1991: 55)

This is indeed an ecological perspective, for it describes the shaping of the environment by the actors within it, and the reciprocal shaping of the actors by the environment. Neither one nor the other is privileged as the locus of action or learning. It is impossible to consider one without considering the other.

Interestingly, this has implications for traditional notions of "abstract" versus "concrete" thinking and learning, which might previously have been thought of as constituting (or *not* constituting, as it were) situated learning. Some forms of practice may be disconnected or bracketed from others. "*Abstraction* in this sense stems from the disconnectedness of a particular cultural practice. Participation in that practice is neither more nor less abstract or concrete, experiential or cerebral, than in any other" (p. 104).

Lave and Wenger also elaborate on the involvement of cultural artifacts and technologies within communities of practice. As knowledge is stretched across a community of practice, it is also embodied in the material culture of that community, both in the mechanisms of practice and in the shared history of the community:

> Participation involving technology is especially significant because the artifacts used within a cultural practice carry a substantial portion of that practice's heritage. . . . Thus, understanding the technology of practice is more than learning to use tools; it is a way to connect with the history of the practice and to participate more directly in cultural life. (p. 101)

Artifacts and technology are not just instrumental in embodying practice; they also help constitute the structure of the community. Peripheral participation can involve differential access to various areas of community knowledge. Lave and Wenger refer to the relative *transparency* and *opacity* of systems and technologies, in terms of the degree to which members of the community have access to them.

Knowledge, power, history, and identity are all constituted through the structures and interstices of communities of practice. Lave and Wenger's success at turning the situativity of learning upside down gives us a perspective on learning as integral to situated practice, instead of the other way around. The result is a theory of knowledge that is not limited to the individualistic conceits of a Cartesian epistemology. It is a theory of knowledge that will stand us in good stead when we need to relate it to a world rich with electronic media and technology.

The sociologist of science Susan Leigh Star, in the introduction to her book, *Ecologies of Knowledge*, writes, "Our memories are in families and libraries as well as inside our skins; our perceptions are extended and fragmented by technologies of every sort" (Star, 1995: 19). It is to the world of technology and media that I will turn next.

3. ECOLOGIES OF ACTORS AND ARTIFACTS

In *Abstracting Craft: The Practiced Digital Hand*, Harvard architecture professor McCullough (1998) offers the following definition of *tool*, *medium*, and *artifact:*

> Tools are means for working a medium. A particular tool may indeed be the only way to work a particular medium, and it may only be for working that medium. Thus, a medium is likely to distinguish a particular class of tools . . . . Sometimes a medium implies such a unique set of tools that the whole is referred to without differentiation. Painting is a medium, but it is also the use of specific tools and the resulting artifact: a painting. The artifact, more than the medium in which or tools by which it is produced, becomes the object of our work . . . . Artifact, tool, and medium are just different ways of focusing our attention on the process of giving form.
> (McCullough, 1998: 62–63)

In his exploration of the subtleties of craft—and particularly handcraft—McCullough moves from tool to medium to artifact seamlessly, drawing his attention to the spaces of tension and grain within each, letting his attention fall away where it is not needed. Making a point reminiscent of Winograd and Flores' notions of distributed cognition, McCullough writes, "If a medium is a realm of possibilities for a set of tools, then any immediate awareness of the tools may become subsidiary to a more abstract awareness of the medium" (McCullough, 1998: 63).

The idea of abstract awareness is key to McCullough's analysis. His goal is to demonstrate how digital technologies are now reaching the point of sufficient sophistication that practices previously in the domain of traditional handcrafts—sculpture, drawing, and painting—can now be used with the computer. "Formal notation invites the study of structure", McCullough writes, and the elaboration of structure is what digital technologies are all about; the sophistication and richness of any digital medium is a reflection of the sophistication and richness of its underlying structures. The analog, in his terminology, is *grain:*

> Objects have a grain, as if they might as well have cracks and wrinkles. This grain consists of internal hierarchies and classifications, external formats and displays, and accumulations of specially modified generic formal vocabulary elements. Understanding these constructive frameworks is at the heart of digital form-giving expertise. (p. 166)

Awareness of tool and medium is about knowledge of this grain or structure. McCullough writes, "Acute knowledge of a medium's structure comes not by theory but through involvement" (p. 196). This awareness or knowledge has two faces: one is the falling away of intermediaries to allow consciousness of the medium or artifact itself. The other is the traces of culture, knowledge, and history that become wrapped up in our tools, media, and artifacts. The guitar may disappear from the consciousness of the musician, such that she becomes aware only of the music, but over time, the instrument will bear the marks of her playing, will show wear from her hands, be stained by the moisture from her skin. In a sense, our tools, media, and artifacts are as situated as we are, and they share the temporality of our existence. They have history, or historicity, or horizons that we merge with our own.

Perhaps, a more everyday example of this notion is the ubiquitous document. In a recent article, "The Social Life of Documents", by Brown and Duguid (1996b)—not talking about situated learning this time—the social and artifactual role of documents is discussed. Documents are more than texts, because they have a kind of material form that embodies them in social reality. This material or artifactual incarnation is socially important "because it mediates and temporizes, records traces and fixes spaces, and demands institutions as well as technologies of distribution". Brown and Duguid continue, "We need to see the way documents have served not simply to write, but also to underwrite social interactions; not simply to communicate, but also to co-ordinate social practices".

Documents, say Brown and Duguid, perform a number of important social roles. One is the constitution (in both senses of the word) of communities and nations. Another is the maintenance and construction of the boundaries between communities. Still another is bridging and negotiation between distinct communities. In a document-literate society, we are quite used to these phenomena; because we are familiar—intimate, even—with the structure or "grain" of documents as tools, media, or artifacts, our world is richly constituted and structured by the distribution, historicity, and inter-relations of documents.

A complementary argument is made by the literary critic Fish (1980) in his book, *Is There a Text in this Class?*. Fish describes how interpretive communities create texts, or at least the readings of them. As a literary critic, he is concerned with the interpretation of texts. Going beyond the idea that the meaning of a text is in the reader or in the reading, Fish holds that the meaning of a text is not centered in the individual, but in the community:

> [Interpretive strategies] proceed not from [the reader] but from the interpretive community of which he is a member; they are, in effect, community property, and insofar as they at once enable and limit the operations of his consciousness, he is too. (p. 14)

The appropriateness or authority of any interpretation is a function of the interpretive community within which it is read. What constitutes interpretive communities themselves seems to be the historicity of readers and readings and texts and interpretations; again, a distributed, ecological perspective. Fish continues:

> The fact of agreement, rather than being a proof of the stability of objects, is a testimony to the power of an interpretive community to constitute the objects upon which its members (also and simultaneously constituted) can then agree. (p. 338)

Brown and Duguid's conception of documents managing community structures—inside, between, and across communities—fits nicely with Fish's account of how interpretive communities constitute disagreements as well as agreements. Fish writes provocatively, "Disagreements are not settled by the facts, but are the means by which the facts are settled" (p. 338).

Stanley Fish's turning upside-down of facts and disagreements almost perfectly pre-figures the work of French sociologist of science Bruno Latour. Latour makes almost the exact same inversion that Fish does, and does so in a similar spirit to the shift in focus Lave and Wenger made regarding the situatedness of learning.

Latour's concern is with how science is made. His influential work, *Science in Action* (1987), paints a picture of science as the working through of disputes via the "mobilization of collectives"—that is, through gathering and arranging an army of allies: natural, social, human, non-human, political, technical, and so on. Latour's argument is that it makes little sense to spend time dividing up the world along these axes, since what makes science effective is the skill by which these allies are orchestrated and directed to a common goal. The business of arranging such diverse actors along coherent networks so that disparate forms and voices speak as one is what Latour calls "translation", and it is this activity that western science has become very good at.

Latour's actor network theory traces science in the making, watching not for the emergence of reliable facts and "black boxes", but rather for the mobilization of forces to resolve disputes, and thus to construct valid ways of representing reality. According to Latour, the practice of science is all about translating potential allies (human and non-human, "natural" and "social") into useful ones by getting them to speak the same language. In the tradition and culture of western science, there are a variety of accepted ways of doing so; ways of "inscribing" phenomena in such a way that they are mobilizable in scientific texts. Latour (1987: 227) refers to such inscriptions as "immutable, combinable mobiles", because they are translated into a fixed form that is combinable and comparable with other inscriptions, and because they are then able to be carried from their original contexts to other applications. Latour gives the example of the maps that European explorers made of the coast of Asia (p. 215ff): inscriptions which were fixed and thus reliable, which shared their form with other maps of other places, and which were capable of being rolled up and taken back to Europe. This translation and inscription of hydrographic features gave European nations immense power over trade relations in Asia. Latour's immutable, combinable mobiles are very similar to Brown and Duguid's documents, defining communities, drawing boundaries, and making bridges between disparate groups.

While it may be tempting to identify Latour's immutable mobiles with the distilling of abstract knowledge from the concrete, Latour is careful to warn that translation and inscription are not occult cognitive processes. In a similar movement to Lave and Wenger's denigration of the abstract-concrete divide, Latour writes:

> The concrete work of making abstractions is fully studiable; however, if it becomes some mysterious feature going on in the mind then forget it, no one will ever have access to it. This confusion between the refined product and the concrete refining work is easy to clarify by using the substantive "abstraction" and never the adjective or the adverb. (p. 241)

This questioning of sacred either—or divisions is key to Latour's work, and reaches its peak in his book, *We Have Never Been Modern* (1993), in which Latour deconstructs the totalizing myths upon which the modern world has been built: the divisions between nature and society, science and politics, and the distinction between modern and pre-modern cultures. Latour critiques modernity's belief in the separateness of these categories by pointing out the *hybrid* nature of almost all cultural forms, despite our best intentions in believing that natural things are purely natural and social things are purely social. Latour's project is to refocus the sociology of science and technology (and contemporary society) on a more faithful account of the constitution of the world, one in which the objects of study are both natural and cultural, human and non-human, and scientific and political—a "parliament of things" (p. 142). Latour calls for anthropology to come home from the tropics; anthropologists, he argues, have never had any trouble in portraying the complex blend of spiritual, natural, and cultural aspects of "pre-modern" societies as holistic systems. Why then do we have such trouble viewing our own systems as similarly intermeshed?

This anthropological challenge informs Latour's (1995) own studies of science. In his article "Mixing Humans and Non-humans: The Sociology of a Door-Closer", Latour writes under the pseudonym Jim Johnson, a technologist from Columbus, Ohio (thereby inscribing a convenient "non-human" delegate for his instructive purposes), to conduct an ethnographic treatment of the broken-down hydraulic door spring at the sociology department of Walla Walla University. Latour (as Johnson) approaches the collection of hydraulic cylinder, spring, door, sociology building, cold weather, and warm sociologists as an integrated whole, each participant in the system acting in ways that anticipate and expect the actions of others in the system. The door spring is banal, yet essential to Latour's argument. He writes:

> The bizarre idea that society might be made up of human relations is a mirror image of the other no less bizarre idea that techniques might be made up of non-human relations. We deal with characters, delegates, representatives, or, more nicely, lieutenants (from the French *lieu tenant*, i.e., holding the place of, for, someone else), some figurative, others nonfigurative, some human, others nonhuman, some competent, others incompetent.
>
> (Latour, 1995: 273)

Latour, it seems, is calling for an ecology of actors and artifacts, and suggesting that it is foolish to try to see the world otherwise. We are engaged in communities of practice that are not made up of people alone. The ways in which we work have everything to do with the non-human presences we construct (tools, media, and artifacts, as McCullough might point out) and with whom we are in constant dialogue. To recognize this is to adopt a theory of human action that is inclusive of its technological and artifactual extensions; one not limited to the mind/body reductivism of a Cartesian worldview.

4. RE-SITUATING CONSTRUCTIONISM

The school of constructionism comes from MIT researcher Seymour Papert, who, in the 1970s and 1980s, led a groundbreaking series of projects that brought computing technology to schoolchildren through the Logo programming language. As described in Papert's (1980) landmark book *Mindstorms: Children, Computers, and Powerful Ideas*, the Logo project puts children in charge of computational objects—originally, a mechanical "turtle" that drew a line on paper as it moved around, but later a virtual turtle that moved on the computer screen. Papert, a protégé of famous developmental psychologist Jean Piaget, was concerned with children's difficult transition from Piaget's concrete to abstract stages. Papert saw the computer as the tool that could make the abstract concrete:

> Stated most simply, my conjecture is that the computer can concretize (and personalize) the formal. Seen in this light, it is not just another powerful educational tool. It is unique in providing us with the means for addressing what Piaget and many others see as the obstacle which is overcome in the passage from child to adult thinking.
>
> (Papert, 1980: 21)

Papert's work made computer programming accessible to children, not through "dumbing down" computer science, but by carefully managing the relationship between abstract and concrete. Logo gave children the means to concretize mathematics and geometry via the computer, which made them into explorers in the field of math. Papert believed that since the best way to learn French is not to go to French class, but to France, the best way to learn mathematics would be in some sort of "Mathland" (p. 6). Logo provided a "microworld" operating in terms of mathematical and geometric ideas. By experimenting with moving the turtle around, children had direct, concrete experience of how mathematical and geometric constructs work. Through reflection on their experiments, they would then come to more formalized understandings of these constructs. Papert saw children as *epistemologists*—thinking about their thinking about mathematics.

By the late 1980s, Papert's work with children and Logo was one of the most influential forces in educational technology. The MIT Media Lab's Epistemology and Learning Research Group ran extensive research projects in schools, studying all manner of phenomena around the experience of schoolchildren and Logo-equipped computers. A snapshot of this research is found in Harel and Papert's (1991) book *Constructionism*, which covers the perspectives of 16 different researchers. In the book's introductory essay, "Situating Constructionism", Papert outlines how *constructionism* differs from Piaget's *constructivism*:

> Construction*is*m—the N word as opposed to the V word—shares constructivism's connotation of learning as "building knowledge structures" irrespective of the circumstances of the learning. It then adds the idea that this happens especially felicitously in a context where the learner is consciously engages in constructing a public entity, whether it's a sand castle on the beach or a theory of the universe.
>
> (Papert, 1991: 1)

There are two main features of the theory. The first, building on Piaget's constructivism, is that knowledge is not transferred whole from person to person, but rather is constructed by individuals in practice. Papert's playful essay notes the irony of explaining what constructionism is, rather than letting the reader construct her own idea of it. The second feature is that this knowledge construction does not exist purely within the head of the individual, but is embodied in the creation of a "public entity". There is something of the ecological stance in this, especially as Papert draws our attention to the necessary *pluralism* that comes from the interplay of different people engaged in constructing their own knowledge. The importance of the public, shared nature of what is constructed implies that there is communication and shared culture that is built in the process. Papert writes

> We can come to agreement about theories of learning . . . only by groping in our disorderly bags of tricks and tools for the wherewithal to build understandings. (p. 2)

The emphasis on pluralism in constructionist practice is a major theme to emerge from the Media Lab in the 1980s. Sociologist Sherry Turkle's ethnographies of computing cultures emerge from this work. Her hugely popular 1984 book, *The Second Self: Computers and the Human Spirit*, explored the different "styles of mastery" that she observed in boys and girls in Logo classrooms. In her 1991 article with Papert, "Epistemological Pluralism and the Revaluation of the Concrete", Turkle outlines two poles of technological mastery: "hard" and "soft". Hard mastery, identified with top–down, rationalist thinking, they observed in a majority of boys. Soft mastery, identified with relational thinking and Claude Lévi-Strauss' notion of *bricolage*, they observed in a majority of girls (Turkle & Papert, 1991: 167–168).

The identification of soft mastery and *bricolage* in programming was very important for Papert and Turkle, for a number of reasons. This relational, negotiated approach to understanding systems has much in common with Piaget's constructivist theory and is also very much in line with how Papert saw children working with Logo, exploring the features of a microworld, and building an intimate awareness of it. Papert and Turkle's agenda was to "revalue the concrete", which they saw as woefully undervalued in contemporary life, and especially in math and science education. Turkle wrote

> The development of a new computer culture would require more than technological progress and more than environments where there is permission to work with highly personal approaches. It would require a new and softer construction of the technological, with a new set of intellectual and emotional more like those we apply to harpsichords than hammers.
>
> (Turkle & Papert, 1991: 184)

I find it particularly interesting to note the tension in Papert and Turkle's writings between an ecological perspective—which seems so near amid discussion of *bricolage*, relational approaches, pluralism, the construction of public entities, and so on—and the centered, cognitive science perspective from which their work derives. Papert's work with Jean Piaget, not to mention his long-standing relationship with the MIT AI Lab, can be credited with supplying the cognitivist paradigm he seems to write from. Sherry Turkle too, with a background in psychoanalysis and body of work studying computer scientists at MIT, is concerned with what is going on inside people's heads. Their work on *epistemological* pluralism clearly reveals this cognitivist perspective: both Papert and Turkle are working from a deep desire to understand *how mind works*—rather than how knowledge and understanding are constituted in communities, or what I have been calling an ecological approach.

It may not be fair to criticize the thinking of a particular period in hindsight, but I believe the cognitivist stance was limiting for constructionist theory in the 1980s. Roy Pea, in his article "Practices of Distributed Intelligence and Designs for Education" (1993) offers a critique of Papert's constructionism from the standpoint of distributed intelligence:

> Papert described what marvelous machines the students had built, with very little "interference" from teachers. On the surface, the argument was persuasive, and the children were discovering important things on their own. But on reflection, I felt this argument missed the key point about the "invisible" human intervention in this example—what the designers of LEGO and Logo crafted in creating just the interlockable component parts of LEGO machines or just the Logo primitive commands for controlling these machines.
>
> (Pea, 1993: 65)

Pea's insight draws attention to the fact that what is going on in the Logo project exists partly in the minds of the children, and partly in the Logo system itself; that they are inseparable. This is, I think, a more distributed stance than Papert and Turkle take.

Interestingly, the major work of the Media Lab in the 1980s was contemporaneous with a sea change in the thinking of AI researchers, such as described in the work of Winograd and Flores, described earlier. Sherry Turkle later acknowledged the significance of the newer trends of "connectionism" and "emergent AI" in her 1995 book, *Life on the Screen: Identity in the Age of the Internet* (Turkle, 1995: 137).

It would be the next generation of Media Lab researchers who would move constructionist research to a more distributed footing. Mitchel Resnick was probably influential in this trend, with his work with parallel computing: Logo microworlds with hundreds or thousands of turtles that allowed children to play with populations and complex systems (Resnick, 1991: 205–214). However, while Resnick's work explored ecologies of turtles, it did not really address ecologies of learners. But Resnick's student Amy Bruckman took constructionism and situated it in the MUD.

The internet had emerged as a revolutionary technology for many in the early- to mid-1990s. During this time, educational technology, and practically everything else having to do with computers, suddenly became about the internet. Amy Bruckman was interested in MUDs—*Multiuser Dungeons*—multiplayer text-based virtual reality games on the internet. Bruckman watched the dynamics of communities in internet MUDs and made the connection: "MUDs are a constructionist playground", she wrote in 1995 (Bruckman & Resnick 1995). While Bruckman's work is not heavily theoretical, she succeeded in merging the constructionist and situated learning perspectives. In her doctoral dissertation, *MOOSE Crossing*, she wrote:

> Analyses of individuals interacting with stand-alone computer systems such as those in Sherry Turkle's *The Second Self* often focus on the individual's quest for mastery (Turkle, 1984). That quest takes on added dimensions when the activity is strongly situated in a supportive community context. (p. 122)

The idea of supportive community is key to Bruckman's work. *MOOSE Crossing* describes a MUD she created for a community of pre-adolescent kids. Her work is an ethnographic portrait of a subset of the community there, a community situated in a very real place, and with very real interpersonal dynamics.

> Calling a software system a "place" gives users a radically different set of expectations. People are familiar with a wide variety of types of places, and have a sense of what to do there... Instead of asking "What do I do with this software?", people ask themselves, "What do I do in this place?" The second question has a very different set of answers than the first. (Bruckman 1997, p. 49)

Bruckman's thesis is that community and constructionism go hand in hand. Her ethnography reveals very close, very personal bonds emerging between children in the process of designing and building software in the virtual environment. "The emotional support", she writes, "is inseparable from the technical support. Receiving help from someone you would tell your secret nickname to is clearly very different from receiving help from a computer program or a schoolteacher" (p. 128). Bruckman's ethnography underscores dynamics clearly recognizable from Lave and Wenger's description of legitimate peripheral participation:

> Sometimes the best teachers are not experts, but learners only one step ahead of you who are excited about sharing what they themselves just learned. (p. 132)

As close as Bruckman's ethnography of MOOSE Crossing comes to an ecological approach to constructionism, I feel it still falls short. Bruckman emphasizes the importance of role models in the virtual environment and points out many cases in which the personal creations of children in the virtual environment were instrumental in helping establish relationships. But they remain just that: the artifacts in the virtual world are projections of their creators and remain mere instruments, secondary to the more important interpersonal connections. Bruckman does not fully acknowledge the ecology of people, virtual artifacts, and environment that emerges in MOOSE Crossing.

Constructionism reaches what I consider a more complete ecological perspective in the work of Ricki Goldman-Segall. Part of the Media Lab's second generation, Goldman-Segall's approach is that of an ethnographer and a media theorist, rather than a cognitive scientist or a hacker. This difference is significant, I think, because it allows Goldman-Segall to move into a phenomenological perspective in her analysis of ecologies of learning. In her book, *Points of Viewing Children's Thinking*, she writes:

> [A] medium opens up a path for a different set of partnerships among viewer, author, and text—a set of partnerships that revolves around, and is revolved around, our constant recognition of culture. A video segment (in text form), for example, is the representation of a cultural moment in the making of cultures. A video object is a cultural object, something to turn around and reshape. And, just as we change it through our manipulation, so it changes both us and our cultural possibilities.
>
> (Goldman-Segall, 1998: 10–11)

Goldman-Segall's central metaphor is the *constellation:* a configuration of stars that takes its shape—its essence—from the point of view of the subject. The majority of Goldman-Segall's work has dealt with ways of embodying the constellation metaphor in collaboratively authored hypermedia documents, so that several participant authors can configure texts according to their own points of view, and to layer the resulting configurations. This layering leads to what Goldman-Segall calls "configurational validity" (Goldman-Segall, 1995; 1998), the idea that we can construct more valid interpretations by layering and comparing the perspectives of others. This is somewhat reminiscent of Stanley Fish's notion of interpretive communities, but draws more influence from "post-modern" anthropologist Stephen A. Tyler's notion of ethnographic 'authority' via *polyphony* and *evocation* (Tyler, 1986).

Moreover, Goldman-Segall directly challenges the work on "epistemological styles" developed by Turkle and Papert (1991), in favor of much more dynamic ideas of "frames" and "attitudes". Framing is a notion of perspective used in many contexts: Marvin Minsky's AI, Howard Gardner's theory of multiple intelligences, Erving Goffman's everyday sociology, architecture, and cinematography. The important thing about frames—in contrast to the essentialist notion of "styles"—is that they implicate the framer as well as that which is left out of the frame.

> I have become less comfortable with the notion of styles, which is the term my colleagues Sherry Turkle, Seymour Papert, and others have asked us to consider over the last decade. I now choose a different kind of framing—one that is conscious of the precariousness of any framing of others' lives. The kind of frames I now choose open the possibility for both those who are being portrayed and those who view them to become partners in framing.
>
> (Goldman-Segall, 1998: 244–245)

Goldman-Segall's notion of epistemological "attitudes" emerged as a dynamic response to the more essentialist notion of "styles" in Turkle's hard and soft mastery. Attitudes imply positionality and orientation and are situated in time and place. The idea that dynamic epistemological attitudes may run at odds with the gender breakdown of hard and soft mastery led Goldman-Segall to suggest that "gender-flexing" may occur: that boys may take on attitudes that are traditionally associated with girls' styles and vice versa. The underlying theme here is the primacy of situated "points of viewing", rather than essential qualities. Goldman-Segall sees learners more as *ethnographers* than epistemologists.

This *meta*-ethnographic approach, in which Goldman-Segall creates texts of learners creating texts, is key to what I see as the ecological perspective of Goldman-Segall's work. She makes the children into ethnographers, into videographers, and in so doing, the lines of research methodology, ethnographic authority, subject, and object, are blurred, for the ecology of texts is polyvocal and collaboratively authored. The researcher's traditional authoritative stance is de-centered. Furthermore, the texts and constructions of the participants become part of the ecology of texts that constitutes their community—become constellations—encouraging still further configuration and layering, in an ongoing process.

> We can now form more permeable partnerships with those we study and with our readers, creating a digital commons . . . Readers of our socially constructed texts can either be silent lurkers or decide to make their presence known to us. Layers build, patterns emerge, friendships and enmities grow, and digital inquiry becomes a reflexive practice—with an emphasis on flexing, stretching, and strengthening our inquiry. (pp. 268–269)

CONCLUSION: DISTRIBUTED CONSTRUCTIONISM

In this review, I have attempted to draw together three traditions of research—from situated learning, media and technology, and constructionism—to assemble a more sophisticated arrangement. This layering creates a whole that is greater than the sum of its parts. I believe that situated learning becomes richer when viewed from the point of view of media and technology studies, that media and technology are better understood from the point of view of constructionist learning theory, and that constructionism itself benefits greatly from the light shed by situated and distributed learning theories. I have presented the work of a variety of thinkers, drawing together the commonalities, and pointing out the paths to more ecological awarenesses of action, inquiry, and learning.

These perspectives have important implications for educational analysis and practice: Lave and Wenger made it clear that their description of legitimate peripheral participation was not in itself a recipe or model for the design of educational systems, but it is not too hard to think forward to such designs, with their analysis in mind. Latour's sociology of science is first and foremost an analysis, but he is careful not to distance himself or his work too much, not to deconstruct capriciously or irresponsibly, and as such provides a model for honest intellectual practice. Goldman-Segall's outright blurring of methodological boundaries is certainly a call to follow suit, to be a participant learner. I am fond of this passage from Goldman-Segall's book, in which she relates her reaction to Ryan, a 13-year-old educational researcher, in a profoundly de-centered moment:

> I sit in my seat, rendered speechless by his idea that learning is a result of layering others' views with our own, and his broad understanding about how we make sense of the living world around and inside us.
>
> (Goldman-Segall, 1998: 232)

I am seeking an ecological perspective on constructionism, one that takes seriously the distributed nature of cognition, intelligence, and learning across a community of practice; that includes the tools, media, and artifacts themselves as part of that community; and that recognizes the interdependent evolution of individual and context.

Part II

Schooling, Professional Learning and Knowledge Management

Chapter 12: Realizing the Internet's Educational Potential

J. W. SCHOFIELD
Learning Research and Development Center and Psychology Department, University of Pittsburgh

Internet access is increasingly widespread in primary and secondary schools around the world, just as it is in society at large. Ninety-nine percent of public schools in the United States had internet access by 2001, as did 87% of their classrooms (National Center for Education Statistics, 2001). Many other countries, including Australia, Canada, England, Finland, Iceland, New Zealand, Singapore, and Wales, also have very high levels of school internet access and numerous others, including Korea and Israel, have more modest but still substantial levels of access (Organization for Economic Cooperation and Development, 2002a; Pelgrum & Anderson, 2001). Indeed, the development of the idea of virtual schools and the growth in the availability of distance education opportunities (E-defining education, 2002; Orange & Hobbs, 2000; Trotter, 2002; Virtual Schools Forum Report, 2002; Zehr, 1997; Zucker & Kozma, with Yarnall, Marder & Associates, 2003) have begun to challenge the very notion of a school as a specific geographic place in which teachers and students congregate for the purpose of teaching and learning. Furthermore, the growing popularity of laptop computers and hand-held computing devices and the increasing presence of the internet at home, work and in other settings have also blurred the boundaries between schools and other places by facilitating rapid communication and collaboration between those who are not in the same location at the same time (Kozma & Shank, 1998).

Internet access has grown so quickly in schools because it is seen as a way of substantially, even dramatically, improving students' education. Countries around the world have set national goals and policies reflecting the belief that the use of this information and communication technology will improve their school systems (Jones, 2003; Pelgrum & Anderson, 2001; Plomp et al., 2003). Consistent with glowing, sometimes utopian, predictions made about the impact of other earlier computer applications (Kling, 1994), expectations tend to be very high. For example, Mambretti (1999: 17) argues that "Not since the invention of movable type and the printing press has a technology held such potential for transforming the learning process . . . the internet is a revolutionary technology that is bound to change every aspect of society and, in particular, the education system". Similarly, Carlitz (1991: 26) asserts that the internet "has the potential to become the foundation on which all educational programs and material are developed and distributed".

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 301–327.

Faith in the power of the internet to improve education is not limited to scholars and visionaries. It can be seen in public opinion polls in the U.S., Canada and elsewhere which suggest that parents believe that technology is "very important" for their children's education (Media Awareness Network, 2000; Turow, 1999). It is also apparent in the public support in many countries for "Net Days" when parents, educators, community members, vendors, and others work together to help bring internet access to large numbers of schools simultaneously (Süss, 2001). Such faith is most likely strengthened by advertising campaigns, run by those with a commercial interest in fostering internet access in schools and elsewhere, that link the use of educational technology to improved learning. It is also most likely connected to the growing ubiquity of internet use for both work related and personal purposes in many countries around the globe, which exposes millions of individuals to the internet's power and reach. Finally, there is a growing research-based consensus that many different kinds of computer applications do indeed have positive educational outcomes (Hattie et al., 1996; Kulik & Kulik, 1991; Murphy et al., 2002; President's Committee of Advisors on Science and Technology and Panel on Educational Technology, 1997; Waxman et al., 2002; Wenglinsky, 1998), although not all studies of the issue are consistent with this conclusion (Angrist & Lavy, 2002). This emerging consensus may also play a role in encouraging educational policy makers to adopt yet another such application, the use of networking technologies.

Indeed, the internet does appear to have the potential to be very useful for students and teachers (Bransford et al., 1999; Means et al., 2001; Owston, 1997). First, and most obviously, it has the potential to provide access to an extraordinary amount and variety of information. Thus, it can put students and teachers in touch not only with far more information than school libraries are likely to be able to supply, but also with a wider variety of kinds of information and experiences than would be available otherwise (video clips, graphics, databases, government documents, foreign language newspapers, specialized web pages designed for educational purposes, etc.). Second, it provides a convenient and rapid means of communication between teachers, students and those beyond the walls of their schools or the confines of the communities in which they are located (Penuel et al., 2002). This creates many opportunities for professional growth for teachers (Renninger & Shumar, 2002; Schlager et al., 2002; Schofield & Davidson, 2002), although teachers' use of such opportunities may be more problematic than it is often assumed to be (Hunter, 2002). It also opens up the possibility of involving those with specialized expertise in students' education, of allowing students to enroll in on-line classes that can not be taught in their schools because of limitations related to demand, resources, or expertise, of allowing collaboration between individuals who would have no practical means of working together otherwise, and of providing students with a wider audience for their work.

1. INTERNET'S CURRENTLY LIMITED SCHOOL USE BY AND EDUCATIONAL IMPACT ON STUDENTS

Yet, it is unwise to assume that school or classroom internet access, in and of itself, will promptly result in substantial student internet use, let alone substantial student use that will transform educational environments and improve educational outcomes. Almost as common as the theme of high expectations in the research literature on computer technology in schools is that of relatively low levels of use. Studies indicate that computers in schools are employed less frequently than might be expected (Cuban, 2001; Loveless, 1996; Schofield, 1995; U.S. Congress, Office of Technology Assessment, 1995; U.S. Department of Education, 1993). Accounts of computers sitting virtually unused for long periods of time, boxed or gathering dust in a corner, are numerous (Piller, 1992; Schofield, 1995). Broken or outdated computers are also quite common in schools (Pelgrum & Anderson, 2001). Indeed, Hollands (2003) found that middle school students in New York City reported being much more likely to use a computer in a public library than at a school library, an interesting finding in light of the vastly greater time students spend in school and the fact that many of these students' schools had large numbers of computers.

Although more and more classrooms have internet connections, studies suggest that student internet use is nonetheless often relatively low. For example, Süss (2001) reports that, as of late 1998, only 13% of over 4000 European students who used computers in school reported using the internet there, although the proportion of those reporting such use varied markedly by country and age, with Nordic countries and older students showing much higher than average levels of internet use. Furthermore, Becker's (2000) large-scale study of internet use in classrooms in the U.S. found that only one-quarter of teachers with modem-based classroom access and 30% of teachers with direct high speed connections indicated that they had asked students to do World Wide Web research on ten occasions or more over the course of the school year. A more recent study of U.S. students, selected because of high self-reported levels of internet use, including home use, reported that these students perceived numerous serious barriers to their use of the internet at school, including a variety of kinds of school-imposed limitations on access. Indeed, many of these students reported using the internet for school work more at home than in school because of such limitations in school (Levin & Arafeh, 2002). Consistent with this, a study of middle and upper SES Israeli high school students found that the most commonly reported educational use of the internet was to do homework, that the preferred location for internet use was the home (82%) rather than the school (17%), and that only 7.4% of these students reported learning to use the internet in school (Nachmias et al., 2000).

In addition, there are at least some indications that when internet use does occur in schools it often does not realize its full educational potential, or even begin to have the kind of impact that many expect. Although parents are very positive about internet access as a means of gathering information, the very large majority do not think that it has any effect on their children's grades (The UCLA Internet Report, 2003). Interestingly, a survey of nearly 6000 Canadian students and over 1000 Canadian parents found that whereas 66% of the parents of students in 7th–11th grade reported educational benefits as the biggest benefit gained from their children's internet use, only 24% of the students agreed (Environics Research Group, 2001). Students were more likely to highlight benefits related to their social life (36%), to convenience (31%), and to entertainment (27%). Further, Levin and Arafeh (2002) found that the internet-using students they interviewed reported that the quality of their internet-based school assignments was poor, complaining about rote activities, like filling out worksheets, that do not make full use of the internet's potential. Yet another study found that whereas teachers "felt they are making dramatic leaps in their ability to harness the power of technology to create stimulating, engaging and challenging learning experiences for students, the students themselves have seen few changes in classroom instruction" (Power to Teach, 2003: 1).

2. THE IMPORTANCE OF FIT IN REALIZING THE INTERNET'S EDUCATIONAL POTENTIAL

The main argument presented in this chapter is that several important issues above and beyond merely connecting schools to the internet must be dealt with if internet use in schools is even to begin to realize its full potential for improving education. Specifically, this chapter focuses on four issues that have the potential to impede internet use, to undercut the utility of such use for teachers and students, and/or to raise problems for schools attempting to make use of the internet to improve the education they provide for students. Unless careful thought is devoted to dealing with these issues, internet use is likely to be less frequent and less productive than it could be. Given the very high hopes that typically accompany the introduction of the internet to schools and classrooms and the major financial investment already made in many countries to provide teachers and students with access (Anderson & Becker, 2001; Coley et al., 1997; Department of Education and Skills, 2003; Pelgrum & Anderson, 2001), finding ways to maximize the internet's contribution to education seems crucial. Ironically, given existing rhetoric about the ways in which the internet will revolutionize education, the issues that must be dealt with to facilitate productive internet use in schools can readily be conceptualized as issues of alignment or fit with the existing educational system and the context in which it is embedded. These issues include fit between teachers' goals and those that internet use is likely to facilitate, fit between teachers' existing skills, expectations, and practices and those needed to take full advantage of internet access, fit between the values and norms of the communities in which schools are embedded and those of the world to which the internet connects them, and fit between existing assessment systems and the student outcomes most likely to be influenced by internet use. Each of these issues will be explored in turn.

2.1. Fit Between Teachers' Goals and Those for Which the Internet Provides a Comparative Advantage over Other Resources

It has become increasingly clear during the past two decades that merely placing computers in schools does not guarantee their use, let alone their effective use (Collis et al., 1996; Cuban, 2001; Schofield, 1994, 1995). Research on the use of numerous kinds of computer applications suggests that such use depends on many factors including the extent to which teachers believe the use of this technology is likely to meet their needs and to help them reach valued goals (Cohen, 1988; Cuban, 1986). The same appears to be true with regard to use of the internet.

Specifically, Becker (2000) reports a positive relationship between teachers' judgments about the value of the internet in their work and their professional use of it. In addition, he and his colleagues found a clear link between teachers' objectives and their use of various kinds of computer-based applications. For example, teachers who considered finding out about ideas and information to be one of their main objectives for students were much more likely to use the World Wide Web than were those who did not. In addition, those who considered mastering basic skills or the remediation of skills as among their main objectives for students were much less likely to use the World Wide Web than other teachers (Becker et al., 1999). Similarly, Schofield and Davidson (2002) found a link between the internet's facilitation of teachers' goals and internet use. Specifically, use of the internet was relatively high when teachers believed it helped them reach goals that they had been striving to reach before the introduction of the internet and low when this was not the case. Thus, for example, use was high in classes whose teachers had decided that it was important to expose their foreign language students to the words of native speakers of the languages being studied, which the internet does readily by providing access to foreign language newspapers, web sites, and chat rooms. In contrast, use was often low when it did not lend itself in such an immediate and obvious way to achieving ends for which teachers were already striving. These findings are consistent with Hunter's (2002) conclusion that many teachers tended not to use the resources available through an extremely rich internet project called the Math Forum because they saw the materials presented there as outside of the curriculum they were trying to teach, that is, as not consistent with the goals they were trying to reach.

Many teachers believe that internet use will help further attainment of their goals, both personal and professional (Schofield et al., 1997). For example, Becker (2000: 85) reports that roughly half of the teachers surveyed in a large study in the U.S. saw having access to e-mail and the World Wide Web as essential to their work, and nearly 90% thought it was either valuable or essential for their work. However, the most common type of teacher internet use is very consistent with the traditional goal of having teachers' present students with information to be assimilated. Specifically, Becker (2000) reports that teachers in the U.S. most commonly use the internet to find information for use in lessons, many doing so weekly. This use of the internet influences students only by first influencing teachers, a less direct route to changing student experiences or outcomes than internet use by students themselves. Another large-scale survey of technology decision-makers in districts in the U.S. also suggests that teacher research is a very common use of the internet, with 72% of respondents mentioning it (National School Boards Foundation, 2002).

Use of the internet in this way may well importantly increase the timeliness or richness of the information that teachers present to their students. Thus, it is likely to contribute to students' education. However, it is not likely to foster the kind of major change that proponents of internet use in schools often foresee. Indeed, the kinds of activities that would more clearly reflect changed goals, such as the use of the internet for extended student projects, were reported in fewer than 10% of school districts in the U.S. (National School Boards Foundation, 2002). This finding is consistent with that of a study of use of the internet in Europe, which concluded that the most common student use in most countries studied was for finding information, a task quite traditional for students. Uses that implied greater change in classroom goals or practice, such as internet use for group projects or for the dissemination of materials produced by the students, were much less common (Pelgrum & Anderson, 2001). Interestingly, another large-scale, multinational project designed specifically to study innovative uses of the internet concluded that fewer than 20% of these projects reported using information and communication technology to foster curricular change or other educational reform efforts (Kozma, 2003).

In sum, there seems little reason to expect that teachers will make substantial use of the internet in their work unless they believe that it will help them achieve the goals for which they are already striving better than the resources they have traditionally used. The fact that the internet is very commonly referred to as a tool in discussions of its use in education emphasizes this point. Just as individuals are unlikely to use a hammer sitting at hand unless they have something that they wish to pound, they are unlikely to use the internet unless they have something they wish to accomplish for which it seems well suited. Indeed, since learning how to use the internet in their work involves time and effort for many teachers, it is only logical that educators must believe it will help them achieve their goals better than existing tools in order to justify that investment.

Of course, those who study the history of technology use point out that it often takes a while for individuals to realize just what pre-existing goals they can accomplish with a new technology and how a tool can be used (Bruce, 1993). This fact is especially important with regard to the use of the internet in schools since, unlike some kinds of computer applications such as computer assisted instruction or computer-based tutors, the internet was not developed to serve as an educational tool. Thus, it takes considerable effort and thought on the part of the user to understand thoroughly the capabilities of the internet and the ways in which these capabilities can be used to foster given educational goals. Although more and more resources, located both on the internet and elsewhere, are available to help with these tasks, it nonetheless takes time and effort to locate them and to reflect on how the internet might be useful in specific situations to achieve pre-existing educational goals.

Although fit with existing goals is very important in influencing internet use in schools, the development of new technologies can sometimes lead people to adopt new goals over time as they become aware of possibilities they did not envision before because the means to achieve them were not at hand (Bruce, 1993; Mehan, 1989). As will be discussed later in this chapter, there is some reason to think that internet use may sometimes foster a gradual change in educational goals and practices by opening up new possibilities. For example, Dexter, Anderson and Becker (1999) found that computer-using teachers who used progressive teaching practices saw their reflections on such experiences as a source of change in their teaching. Similarly, Kozma and McGhee (2003) conclude that use of information and communication technology can foster significant change in a range of classroom practices. However, in order to make maximally effective use of the internet in schools, it will be necessary to explore carefully how it can help teachers reach their existing goals while at the same time focusing close attention on the issue of what new possibilities internet access brings with it that may ultimately end up changing current understandings of what it is reasonable and desirable to strive for in schools.

2.2. Fit Between Teachers' Skills, Expectations, and Longstanding Practices and Those Conducive to Productive Internet Use

As Bruce (1993: 9) points out, "The linking of new technology to a vision of transformed pedagogy is a distinguishing feature in many proposed innovations in education. It is rare that the developer of an innovation would adopt the goal of simply facilitating current practices with a new technology". Consistent with this, those who advocate internet use in schools typically see it as a mechanism for change in goals or practice (Bransford et al., 1999; Feldman et al., 2000; Sheingold & Frederiksen, 2000). More specifically, internet use is often seen as facilitating constructivist practices, which are consistent with research in cognitive science suggesting the importance of students' active involvement in creating their own understandings. For example, the internet is often seen as useful in helping teachers shift from reliance on a didactic approach to the use of more student-centered practices. In the immediately preceding section of this chapter, I argue that internet use is likely to be relatively low when the goals it readily facilitates are not consistent with those of teachers. Here, I argue that internet use is also likely to be relatively low when it requires skills that teachers do not have or when its productive use seems to call for practices that do not fit well with those with which teachers are familiar.

The importance of fit between teachers' skills and those required for effective internet use is widely acknowledged. Awareness that lack of such fit may well lead to underutilization of this relatively expensive resource has led to increasing recognition of the importance of professional development activities related to technology use in countries in which large investments have been made for internet use in education (CEO Forum, 1999; National Grid for Learning, 2003; National School Boards Foundation, 2002; Pelgrum & Anderson, 2001; President's Committee of Advisors on Science and Technology and Panel on Educational Technology, 1997).

However, in spite of awareness of the importance of such fit, this fit is often not achieved. For example, after conducting a survey of internet use in schools in roughly two-dozen countries around the world, Pelgrum and Anderson (2001) concluded that providing teachers with the skills they need to make effective use of information and communication technology is still a major problem in most countries. Solving this problem is important in order to realize value from the money spent on internet access in schools since both empirical evidence (Anderson & Becker, 2001; Hollands, 2003) and logic suggest that appropriate support and skill development for teachers is related to technology use in schools. Consistent with this point, Becker, Ravitz, and Wong (1999) found that teachers' computer expertise is related to their use of the World Wide Web in a substantial number of subject matter areas, although generally speaking the relation between skills and the teacher's own professional use of technology was greater than the relation between their skills and their instructional use of technology. Not surprisingly, teachers' computer expertise appears to be related to at least some degree to professional development experiences (Pelgrum & Anderson, 2001).

Providing appropriate professional development experiences is likely to be especially complex and expensive with regard to internet use for several reasons. First, in addition to learning various technical skills, teachers need to develop a vision of how the internet can be used productively in their work and to develop ways to implement this vision in the context of their classroom environments (Feldman et al., 2000; Levin & Arafeh, 2002; Means et al., 2001). Developing such a vision is a much more complex task than allowing or encouraging students to use a piece of software designed specifically to develop various skills or to help them learn about a particular topic. Furthermore, finding effective ways to implement such visions is made more difficult by that fact that many educators have relatively little experience with curriculum development. In addition, the most effective kinds of internet use may be quite different from grade to grade and from subject to subject, further complicating the task of professional development. Finally, those charged with the responsibility for providing professional development experiences to teachers relating to information and communication technology are generally more proficient with regard to technical matters than with regard to pedagogical and curricular issues (Feldman et al., 2000; Pelgrum & Anderson, 2001). There are more and more software tools, web sites, on-line curricula, and books designed to help educators figure out how to make productive use of the internet for themselves or with their students, but these are much more readily available in some languages than in others (Hogenbirk, 2000). In addition, many teachers may not have the time or the inclination to make use of these resources, especially if they do not receive support for this effort from related professional development activities.

Even if teachers develop the requisite technical skills to use the internet effectively and the capacity to envision how they can use the internet to enrich and improve students' experiences in school, issues regarding fit with long-standing expectations and practices and with the constraints existing in the larger school environment are still likely to limit internet use. Two common expectations are particularly problematic with regard to internet use. The first is the expectation that teachers will know more than their students. The second is the expectation that teachers will function quite autonomously within their classrooms. Each of these expectations and its potential impact on internet use will be discussed in turn.

An important part of the teacher's role is the exercise of authority, that is, legitimate power over the students (Bierstedt, 1970). Teachers' authority has a number of bases, one of which is their expertise, or more precisely the gap between their expertise and their students' level of expertise (Benne, 1970). Events that undermine a teacher's image as knowledgeable and competent in comparison to students have implications not only for the teacher's sense of self but also for the functioning of the classroom.

There is little doubt that a substantial number of students, especially in secondary schools where issues of authority are often the most problematic, know more about internet use than many of their teachers (Schofield & Davidson, 2002). Sometimes schools make good use of students' technical expertise (Means et al., 2001). For example, in the U.S. over 50% of school districts report having students provide technical support in at least some of their schools (National School Boards Foundation, 2002). Interestingly, it appears that the disparity between students' and teachers' technical knowledge can sometimes even improve teacher–student relations when teachers discover new-found respect for students they had not thought very well of before, and students react positively to feeling valued (Schofield & Davidson, 2003). However, some teachers see the likelihood that students may know more than they do regarding the internet as a problem, fearing that it will undermine their authority, increase the difficulty they have managing their classes, or provide students with an opportunity to use the internet inappropriately with impunity (Schofield & Davidson, 2002). For these teachers, the disparity between their own and students' knowledge serves as a deterrent to the instructional use of the internet.

Yet another common expectation in many countries that is often inconsistent with internet use is that teachers will function quite autonomously in their classrooms. It is true that schools, school districts, or even national policy may set rules about many important aspects of teachers' work, including things such as the textbooks to be used, curricular objectives to be pursued, and acceptable disciplinary practices. However, once teachers have closed their classroom doors and begun to interact with their students they are often more or less on their own as long as they stay within the bounds of professional behavior (Hargreaves, 1993; Little, 1990; Lortie, 1975). Many kinds of use of the internet can interfere with the teacher's expectation of being able to work fairly autonomously. For example, collaborative activities between students and others at a distance, which many see as having great promise for enhancing students' educational experiences, raise a host of issues connected to the need to negotiate goals and coordinate schedules. Although such issues may appear minor, in practice often they are not, at least partly because collaborators in different school systems or in other kinds of settings may be working within larger organizational contexts that differ in important ways from that of any given teacher trying to initiate or maintain a collaboration. Further, collaboration puts teachers and their students at the mercy of the collaborators. If the latter fail to carry out the activities they agreed to by the time agreed on, or if the others' efforts do not work out as expected, the result may be wasted time and effort, which is likely to discourage further collaborative undertakings. Perhaps such issues account for the finding in a recent study of innovative uses of information and communications technology in many countries that very few such projects involve connection and collaboration with others outside of the classroom (Kozma & McGhee, 2003).

Not only are deeply held expectations often rather inconsistent with internet use, so too are some longstanding classroom practices. Such inconsistency may well limit use. For example, Schofield and Davidson (2002) found that internet use was high in classroom situations in which use readily fit with longstanding practices and procedures and low when it did not. So, for example, teachers with a small number of computers with internet access in their classroom were likely to have students make use of those connections if they were used to having students work in small groups. In contrast, teachers with similar computer set-ups who were more used to and comfortable with whole class instruction had their students make relatively little use of the internet.

Whole class instruction is common, most likely because teachers in many countries typically have over twenty students to work with at any given time

(Organization for Economic Cooperation and Development, 2002b). Teachers used to whole class instruction are faced with a dilemma if they wish to have the students in their classes use the internet unless they have a classroom equipped with a very large number of internet-connected computers, a highly unusual situation. [Even in such atypical situations, clashes between internet use and traditional practices arise because web sites may be overwhelmed when large numbers of students try to access them simultaneously (Power to Teach, 2003; Schofield & Davidson, 2002)]. Given the student–computer ratios common in countries whose schools are characterized by internet connections (Pelgram & Anderson, 2001), a much more common situation is for a teacher with classroom internet access to have a small number of internet connected computers. This creates a challenge to traditional whole class instruction. Unless the internet connection is used with a LCD projector and screen, which many classrooms do not have, there is no way for all or even most students to see the computer's monitor or to work on the internet simultaneously. Rather, the internet must sit unused or a small number of students must break off from the larger class to pursue an internet-related task. To the extent students need assistance from others, including their teacher, to use the internet productively, their internet use is potentially disruptive to the larger class. Further, the question arises of how the internet-using students will learn the material being covered by the rest of the class, unless such use is restricted to students who have already completed their work, which raises important issues related to equity.

Such issues of fit between traditional practices and internet use do indeed often limit use markedly (Schofield & Davidson, 2002). Indeed, as mentioned earlier, many of those who most enthusiastically advocate the instructional use of the internet do so precisely in the hope that such use will encourage teachers to adopt different kinds of classroom practices (Feldman et al., 2000). Given the foregoing, it should come as no surprise that Becker (2000) found that the more teachers espouse constructivist goals and report constructivist practices, the more they value the internet, use it themselves, and have their students use it for research and for projects and publication. Furthermore, these differences are large in magnitude. For example, the most constructivist teachers were likely to report using the internet roughly three times as much as the most traditional teachers. Indeed, pedagogical beliefs and practices were the third most important predictor of internet use in this study, right after classroom access and the teacher's computer expertise.

In sum, lack of fit between teachers' technical and curriculum development skills and those required for productive internet use can limit such use. Use is often further limited both by pre-existing expectations about teachers' roles that are not always consistent with internet use and by traditional practices. Further, fit between pedagogical goals and practices and those conducive to internet use seems not only to influence how readily individual teachers make use of the internet, as discussed above. It also influences how quickly and easily the new practices pioneered by innovative teachers are adopted by their peers (Hunter, 2002; Owston, 2003) as do the structural conditions under which teachers work (Schofield & Davidson, 2002).

However, the fact that disjunctions between existing skills, expectations, and practices and those conducive to internet use often limit internet use does not mean that some change is not possible or likely. For example, in the United States the last twenty years have seen a major change in conceptions of what good teaching looks like. Constructivist approaches, which many see as very consistent with various affordances provided by the internet, are now quite widely accepted by teachers there, at least at a philosophical level (Ravitz et al., 2000). The availability of internet access may provide teachers who would like to adopt such practices with a means to do so. Furthermore, there is some evidence that the availability of technology for instruction may encourage teachers to move in new directions, at least to some degree (Becker, 1999a). Thus, at the same time that lack of fit inhibits internet use, such lack of fit can serve as a force for change, as it surely has in the last decade with regard to teachers' computer-related skills in many countries.

2.3. Fit Between the Values and Norms of the Community in which the School is Embedded and Those of the Larger World Accessible via Internet

One of the primary benefits of the internet is that it can connect students to information resources and people all around the world (Cummins & Sayers, 1995; Garner & Gillingham, 1996; Koizumi et al., 2000; Starkey, 1998). This opens up an extraordinary variety of potentially useful educational possibilities, as mentioned earlier. However, the very access to people and resources that would not otherwise be available that gives the internet so much potential as an educational tool raises an important issue—whether it also exposes students to individuals and to written, auditory, or graphic content that is unacceptable within their communities, especially within the context of an educational institution.

Norms, values, and behaviors vary markedly from culture to culture. In addition, the internet has a kind of culture of its own because it is a place where those whose interests or behaviors are not mainstream can make themselves and their views known as readily as those who are more conventional. Furthermore, they can do so anonymously if they wish to. Thus, those who are part of educational systems in different parts of the world are likely to find some of the behavior and content found on the internet disturbing, offensive, or unacceptable, although exactly what is seen as problematic may vary from culture to culture. To take just one example, controversy about internet content in the context of U.S. schools tends to focus around access to explicit sexual material (Schofield & Davidson, 2002). In much of Europe, in contrast, there is less concern about certain kinds of sexual material and more concern about hate speech (Thornburgh & Lin, 2002). In other countries, such as China and Saudi Arabia, concern runs high in influential sectors of society about the dissemination of Western political thought and popular culture because it is seen as incompatible with existing political structures or influential world views (Rand Review, 2002).

When internet content is inconsistent with the interests of the local power structure, or with local values and norms, use can be curtailed in schools due to concerns about the impact of such material on students or about controversy within the community regarding the materials to which students should have access at school (Thornburgh & Lin, 2002). For example, these concerns had a very marked impact on the way the internet was used in a U.S. school district studied in detail as it introduced the internet to its classrooms (Schofield & Davidson, 2002). The primary impact seemed to be to limit internet use in a variety of ways. Specifically, many teachers did not let students use the internet unless the students were closely supervised. Often, this supervision consisted of the teacher keeping an eye on the computer monitor to see what kinds of material the students were accessing. Since many classrooms had just a few computers in the back and it was difficult for a teacher to both teach the other students and supervise those using the internet, this sometimes curtailed internet use dramatically. Concerns about supervision also inhibit computer use elsewhere. This is not surprising in light of the fact that many books written for educators emphasize the importance of close supervision, as illustrated by Valauskas and Ertel's (1996: 111) admonition to teachers to "Watch your students like a Doberman watches the mailman when they have internet access". Lankshear, Snyder and Green (2000) report that students in a school in Australia lost their lunchtime and recess access to the internet when physical changes in their school meant that teachers could no longer observe them from the staff room. In Switzerland and Spain most students have no independent internet access, with such access typically being limited to students doing schoolwork under the supervision of a teacher. Much less frequently, as in Finland, are students free to use the internet without supervision, such as in computer rooms open after school hours (Süss, 2001).

Use may not only be curtailed by concerns about students' exposure to certain kinds of content. In addition, the kinds of use allowed can be so circumscribed that a substantial portion of the possible educational value of internet use can be undermined. For example, due to fears about inappropriate material, some teachers allow students to visit only pre-approved web sites, which dramatically reduces the resources students can access using the internet as well as undermining the development of many kinds of internet-related skills (Schofield & Davidson, 2002). As another example, the same study found that a high school librarian kept the computer keyboard behind her desk and only let students check it out for use after she had approved the search terms they planned to use, again because of fear about what material students might seek or encounter inadvertently if left to their own devices. This procedure markedly discouraged student searches and constrained students from making useful changes in search terms in response to seeing what their initial search produced. Interestingly, such procedures reflect a much broader trend in U. S. school districts, 48% of which report some sort of restriction of access (in addition to filtering) as a mechanism used to deal with security, privacy or safety (National School Boards Foundation, 2002).

Of course, strategies have been developed to try to deal with incompatibility between local values and those of the world accessible via the internet (National Research Council and Institute of Medicine, 2001). For example, acceptable use policies, which parents and/or students in some countries sign as a condition of students' internet access, lay out the kinds of materials that students are permitted to seek and the kinds of internet behaviors in which they are allowed to engage (Thornburgh & Lin, 2002). In addition, filters that block many kinds of content can be used. Finally, many efforts have been made to create educational resources that students and teachers can use to help students learn how to avoid danger or exploitation by individuals they may encounter on the internet who may not have their best interests at heart (Thornburgh & Lin, 2002). However, each of these approaches to handling possible clashes between the norms and values of the local community and those of the larger world outside has its own problems and complications.

Acceptable use policies are one reasonable way of trying to make sure that students use the internet in ways consistent with the norms of their schools and the community in which they are embedded while they are in school. However, use of these policies, which is widespread in the U.S. (National School Boards Foundation, 2002), raises numerous potentially complicated and difficult issues. First, of course, the signing of such a policy as a condition of access creates at least some administrative burden, especially in districts in which the student population is very mobile. Second, the issue arises of how teachers adjust their curricula and assignments so that students who have not signed the policy can be accommodated. Third, a similar issue arises regarding students who may have lost access due to behavior inconsistent with the policy. Of course, somewhat similar issues arise when schools have policies relating to suspension of students for unacceptable behavior. However, suspended students are not in the classroom, whereas those without internet access are, which creates a more complicated situation with regard to how assignments can be structured. Specifically, it creates a situation in which use for all may be restricted or diminished because some students do not have internet access. Finally, acceptable use polices both become harder to enforce and more complex to construct when schools have programs that provide students with internet access during non-school hours, such as the increasingly common programs that provide students with laptop computers for home access. In such cases, the common expectation that internet use will be restricted solely to educational activity becomes unreasonably limiting and close supervision becomes impossible without software designed to monitor student activity. The use of such software raises difficult issues related to privacy, especially since other family members may use the computer. Furthermore, it adds to cost since someone needs to decide if violations of the acceptable use policy have occurred and to follow up on such violations.

Filters that block access to content that the school or community finds objectionable can also be used to minimize any potential harm that might come to students through exposure to such material and to help prevent controversy about their access to such materials. Indeed, filters are widely used in schools in some countries. For example, roughly 90% of school districts in the U.S. use some kind of filtering (National School Boards Foundation, 2002). Filters are typically designed to block very specific kinds of materials, which may or may not overlap completely with the ones that would concern a particular community.

Although many filters are flexible and allow districts to influence the kinds of things that are blocked, there is no guarantee that they will be structured in a way that meets every community's desires. Further, given the increasing diversity in many countries due to immigration, there is no guarantee that there will be any significant consensus within the community from which a school draws its students regarding what, if anything, should be filtered and what should not be. Many school systems have longstanding procedures for the selection of educational materials such as textbooks or library books. For example, the American Library Association has a workbook on educational materials selection procedures that is used by many school districts in the U. S. However, procedures for deciding whether and how to use filters often need to be developed, and this process is complicated by the fact that at least some filters will not provide information on the specific sites that they block (Thornburgh & Lin, 2002).

Finally, there is no doubt that filters block at least some materials that they were not intended to block, making internet access less useful to students than it would otherwise be (Digital Chaperones for Kids, 2001). If filters are set appropriately, the amount of unintended blocking can be markedly reduced (Rideout et al., 2002). However, schools and school systems may well err on the side of over blocking in order to avoid controversy. For example, interviews with school district personnel in several communities in the U.S. found that the avoidance of controversy was a much more frequently mentioned reason for filtering than concerns about actual harm to students from exposure to unfiltered material (Thornburgh & Lin, 2002). Further, some teachers expressed specific concerns about their legal liability if students under their supervision accessed certain kinds of objectionable materials, ranging from the explicitly sexual to information on topics such as suicide or bomb construction. Such concerns also seem likely to lead to over blocking because the consequences of lawsuits pertaining to such issues could potentially be very serious for both teachers and school systems.

Students frequently complain about the blocking of access to internet materials for which they feel they have a legitimate educational need, suggesting that over blocking is more than a theoretical possibility (Levin & Arafeh, 2002; Thornburgh & Lin, 2002). Thus, it appears that the institutional needs of educational organizations to maintain public support and to avoid problems may well be given priority over the educational needs of students when decisions are made about if and how to use filters, creating yet another way in which the lack of fit between materials available on the internet and local values and norms can limit access to internet resources.

The use of educational resources to help students learn how to avoid danger or exploitation by individuals they may encounter on the internet is yet another mechanism for protecting students from experiences that might harm them or that are inconsistent with local values (Thornburgh & Lin, 2002). Such resources have proliferated in recent years, and many schools have found ways to ensure that students are exposed to them. For example, some schools require internet safety certification before students are provided with access. This is one approach to dealing with part of the potential misalignment between the norms of the local community and those of the larger world to which students are exposed via the internet that does not tend to undercut internet use. However, schools often have difficulty fitting internet safety information into the already crowded curriculum, especially if there is no formal computer literacy or media literacy course that students take before gaining internet access.

Of course, as a tool that facilitates information access and communication, the internet not only allows students to find information they might otherwise not have access to or to be contacted by individuals that they might not otherwise meet. It also allows students to provide information to others and to initiate contact with others. Interestingly, issues of fit arise with regard to these activities that also impede student internet use, although not as strikingly as with the concern about information the students might access. For example, numerous teachers in one district felt that they should monitor whatever material students sent out over the internet, partly to make sure that students did not give out personal information such as their home addresses, and partly to ensure that the students' messages did not somehow embarrass the school by dealing with topics or using language seen as inappropriate in the school environment (Schofield & Davidson, 2002). This undercut the rapidity with which messages were exchanged, which is significant in light of the fact that speed is often cited as one of the primary advantages of using the internet for correspondence. Further, it also allowed teachers to control the content of the messages when such messages were inconsistent with teachers' understandings of community norms or the image of the school they wished to present to the local community. For example, in one case a teacher changed the content of an e-mail that was part of an exchange designed to foster understanding between white and African-American elementary students in nearby but very different communities. A specific invitation from one student to another to meet in person to go the movies was transformed without the students' knowledge into a more general observation about how nice it would be to meet. In another case, teachers reviewing a web site required a student to remove comments critical of their colleagues (Schofield & Davidson, 2002). Although such behaviors do not actually limit internet use, they do undercut the internet as an agent for change.

2.4. Fit Between Existing Assessment Systems and Student Outcomes Most Likely to be Influenced by Internet Use

Another major factor likely to influence internet use is the alignment between the assessment mechanisms that school systems and teachers use and the kinds of experiences and skills that internet use is likely to foster. In many countries there are national or regional exams that play an extremely important role in determining individual students' and educational institutions' reputations and futures. For example, in the United States schools whose students do not perform adequately run the risk of being required to replace staff, to allow student transfers, and even of being taken over by the state or by a private management contractor. Furthermore, in some states students who do not pass a minimum competency test do not receive high school diplomas even though they have taken the required set of courses. Given such facts, it should not be surprising that tests often shape what is taught and that they have real power, both as agents of change and as inhibitors of change, depending on how they are aligned with newly emerging and traditional practice (National Research Council, 2003; Sheingold & Frederikson, 2000).

As mentioned previously, there is good reason to believe that use of many kinds of computer technology does foster educational outcomes that have traditionally been valued. Thus, such use may well produce the kind of learning that is evidenced on standardized tests, in spite of the numerous factors that can interfere with measuring such change when it occurs (Herman, 1994). However, there is no reason to assume that the internet use will necessarily do the same. Indeed, the internet is so new that strong evidence about its effectiveness in fostering various kinds of traditionally valued and measured outcomes is not readily available in large and convincing quantity, although studies of this issue have begun to emerge (Songer, 1996). Furthermore, the internet is such a flexible application that there is no reason to expect it will normally be used in one or two ways with predictable outcomes. Indeed, Kozma and McGhee's (2003) study of innovative internet use in twenty-eight countries concluded that there are eight different common patterns or clusters of use and that different patterns of use produce different kinds of outcomes. Although it is clear that many teachers value internet use highly (Becker, 2000; Schofield & Davidson, 2002), and there are indications that some of its uses may be helpful in developing long-valued skills such as writing (Cohen & Riel, 1989), it is far from clear how various kinds of internet use are likely to influence scores on many existing influential standardized tests.

There are several problems in the fit between traditional tests and internet use that lead to the prediction that internet use may well not result in marked positive change on many of the kinds of high-stakes tests currently used in schools within the relatively short time periods that policy makers usually desire to see results from change efforts. First, as mentioned previously, unlike many kinds of computer-based educational applications, the internet itself was not designed specifically to foster learning. It came into being for purposes quite unrelated to education. Thus, finding ways to use it effectively is an uncertain evolutionary process. The speed and success of this process is influenced by a broad array of factors including how students' existing skill levels are suited to making good use of the content available, teachers' familiarity with the internet and their level of technical skill, the overall quality of the information available on the internet, and the quality of various tools, resources, and professional development experiences created to help teachers use the internet effectively. Perspectives that expect rapid improvement in student performance on traditional tests stemming from internet use are most likely unrealistic, given that it is widely acknowledged that teachers may take from three to five years to learn how to use even less challenging kinds of educational technology (Hadley & Sheingold, 1993; Honey, 1994; Kerr, 1991; Sheingold, 1990; Stearns et al., 1991).

Second, many of the kinds of change that the internet seems most likely to bring about in classrooms are not necessarily ones that will produce better scores on the kinds of tests that are traditionally used to measure students' and schools' performance. For example, one of the great advantages of the internet is that it can individualize learning and allow students to pursue their own interests more than is often the case when the internet is not used (Hollands, 2003; Schofield & Davidson, 2002). However, standardized exams, almost of necessity, presuppose a common set of knowledge and skills that are tested. To the extent that the internet leads to more diverse and individualized learning opportunities for students, there is at least the possibility that such use will not be reflected on many high-stakes examinations and that this will ultimately discourage teachers and educational institutions from taking maximum advantage of internet access.

Indeed, it is important to note that the kinds of changes in classroom experiences and outcomes that are readily facilitated by internet use are not ones that seem likely to presage better performance on the kinds of standardized tests that are widely used (Means et al., 2001). For example, Means, Penuel, and Quellmalz (2000) describe an innovative technology-supported project called Hands-On Universe in which high school students use software tools similar to those used by actual scientists to help search for super nova and asteroids. They point out that this project has many of the characteristics that current theory and research (Bransford et al., 1999) suggest facilitate learning, such as a real world context and interaction with experts. However, they also suggest that the skills learned in conjunction with projects of this type are not likely to be measured by standardized tests.

Problems in fit between internet use and longstanding classroom practices discussed earlier also contribute to making internet use unlikely to improve standardized test scores. Specifically, such problems contribute to the practice of teachers using the internet for "enrichment" or other peripheral activities rather than as part of the core curriculum (Schofield & Davidson, 2004). Typically, enrichment or peripheral activities are not the focus of teachers' classroom testing, which can lead to students taking them less seriously than they would otherwise and thus undermine learning that might otherwise occur (Means et al., 2000). Further, Wallace, Kupperman, Krajcik, and Soloway's (2000) study of internet use in science classrooms concludes that students use the internet simplistically and that developing students' understanding of science through use of the World Wide Web is a challenge for students and teachers. In addition, Schofield and Davidson (2002) discuss the fact that many students tend to drift to recreational and entertainment sites when they are supposed to be using the internet for schoolwork.

There is yet another issue relating to fit between assessment practices and internet use that is likely to impact both what is learned from internet use and whether tests reflect this. Typically, in addition to the standardized high-stakes tests that students take at widely spaced intervals, students often take other everyday tests covering materials their teachers consider central to their courses. These tests are commonly developed by teachers or supplied by textbook publishers. To the extent that these tests reflect teachers' past experiences, traditional views of achievement, and the kinds of standardized tests that are important in a particular school system, they are not likely to measure internet-related computer skills or the kinds of capabilities with regard to information seeking, collaboration, or the like that many feel can be fostered by well-structured internet use (Owston, 1997). Furthermore, they may not be well-aligned with the specific content students' learn in internet activities. This leads to two problems. First, as Young, Haertel, Ringstaff, and Means' (1998) study of classes using the Global Lab Curriculum suggests, students may not be tested on either the content they are intended to learn during activities involving the internet or on the kind of skills they might develop in the course of such activities, leading them to see these activities as unimportant "fun" even when they are intended to be a part of the curriculum (Means et al., 2000). In addition, in such cases, teachers get relatively little feedback on whether students are learning what they are intended to learn through these activities. Thus, students' learning or the lack thereof may go unnoticed and activities that do not promote learning may be left in place because they are assumed to be useful.

Another reason why it is unrealistic to assume that internet use will improve academic achievement as it is commonly measured is that study after study suggests that teachers do not use the internet with students primarily to improve academic achievement. For example, Pelgrum and Anderson (2001) found that teachers in over a dozen countries most commonly rated improving academic achievement seventh or eighth out of eight possible instructional objectives for their use of information and communications technology. Much more commonly ranked high were objectives like making learning more interesting and preparing students for jobs. Schofield and Davidson (2002) also found that teachers in an urban district in the U.S. were more likely to mention using the internet in order to do things like preparing students for a world in which technology plays an important role than as a means for improving their academic achievement.

Although it is possible that internet use intended to achieve such alternative purposes could result in increased learning that would be reflected on standardized tests, it does not seem likely. Furthermore, even if such increases in learning as it is traditionally measured were demonstrated, they might not capture the most important contributions that internet use has made to students' education. However, without ways to measure other outcomes it is hard to gauge the extent to which internet use actually influences them. Thus, it seems vitally important to develop assessment tools appropriate for the outcomes that are expected to come from various kinds of internet use (Means et al., 2000; National Research Council, 2003). Unless this is done, schools face two serious risks. The first is that the positive impact of internet use on students will be under-estimated, thus setting up a situation in which the spread of effective internet use may be inappropriately undermined because of disappointment regarding its apparent lack of impact on students. The second is that the impact of this relatively expensive resource will be incorrectly assumed to be positive. This might well divert resources from other potentially more valuable activities. In addition, it makes it less likely that teachers will have feedback needed to help them determine how to make the most productive use of this resource.

3. CONCLUDING THOUGHTS

This chapter has argued that lack of fit between the world of the internet and teachers' goals, skills, expectations, their longstanding educational practices, community norms, and valued assessment systems create impediments to potentially productive instructional use of the internet in schools. Furthermore, the contention that lack of fit often leads to low levels of utilization and to utilization in a manner that is unlikely to change education in fundamental ways suggests that conceptualizing the internet as an agent of rapid educational transformation may be mistaken. However, this does not mean that the internet has no useful place in schools. Furthermore, it does not mean that, over time, the internet will not serve as an agent of constructive, if not fundamental, change.

There are many ways in which the internet can make important contributions to education without transforming it. For example, like many other computer applications, internet use appeals strongly to many students, and there is reason to believe that it may increase motivation, class attendance and the like (Schofield & Davidson, 2002). There is also no doubt that its use provides teachers and students with access to a world of resources and opportunities that would not be otherwise available or that would be so inconvenient to access that they would not be used. Furthermore, its extraordinary scope and its remarkable flexibility of use means that it can serve administrators, teachers, and students in a variety of ways, from providing educators with opportunities for professional development, to putting students in touch with mentors, to helping link schools more closely with their communities. Thus, its potential to improve education as it is currently conducted depends largely on the imagination and creativity of those who use it, the wisdom and flexibility of those who create the conditions under which students and teachers work, and the resources that are devoted to providing a technical and social environment in which constructive internet use can flourish.

In addition, it appears likely that internet use may well, at least under some conditions, lead to changes that take a step toward transforming certain aspects of education as we presently know it. For example, the contention that fit between teachers' goals and the internet's affordances influences use suggests that teachers who wish to change their practices in significant ways may do so when internet use supports such change. Consistent with this observation, the work of Becker (1999b: 30) and his colleagues (Becker & Ravitz, 1999) suggests that internet use may have "an emancipating effect on teachers who believe in project-based teaching and other constructivist-compatible strategies". To the extent constructivist beliefs become widespread, as research suggests is beginning to be the case in the United States and elsewhere (Pelgrum & Anderson, 1999; Ravitz et al., 2000), the potential for major change is substantial. For example, Law, Yuen, Ki, Li, Lee, and Chow (2000) found that Hong Kong teachers who wished to change their teaching strategies toward more constructivist and problem-based approaches were able to do so using information and communication technology.

Furthermore, internet use sometimes seems to lead unexpectedly to potentially important changes in schools. For example, Schofield and Davidson (2003) found that internet use led to increased student independence, even in the classrooms of teachers who did not set out to achieve this goal. This is consistent with other research suggesting that the internet leads to greater individualization of instruction (Hollands, 2003) and that students often take on valued and constructive roles in supporting their schools' use of information and communications technology (National School Boards Foundation, 2002). Further, Schofield and Davidson (2003) found that internet use rather unexpectedly appeared to improve student–teacher relations in many classrooms and that, over time, some teachers evolved constructive uses of the internet which they had not been able to envision before they had some experience working with it. There is no reason to assume that all potentially significant unplanned changes relating to internet use will be positive. However, awareness of the potential power of this resource to change students' educational experiences in unexpected ways may make it possible to find ways to enhance those changes which seem constructive and to find ways to minimize those than are unconstructive.

In sum, existing social arrangements, including commonly shared educational goals, expectations and practices, community values, and existing assessment systems will play a major role in determining the amount and nature of internet use in schools around the globe. In the near term, such factors seem likely to importantly constrain internet use and the subsequent impact of that use on schools and the students in them. Thus, in the near future, it is unrealistic to expect internet use to transform schools and those in them in fundamental ways. However, just as the social environment of schools influences technology use, so too technology and the affordances it brings is likely, over time, to influence schools and those in them by opening up new possibilities and helping them envision and realize new ways of teaching and learning.

Chapter 13: Virtual Schools: Reflections on Key Issues

GLENN RUSSELL

1. INTRODUCTION

A VLE can be understood as a computer-accessible cognitive context where students interact with mediated representations rather than their experiential equivalent. For students of school age, an emergent variation is the Virtual School, where the internet is used to deliver some or all of the courses that would traditionally be offered in a "bricks-and-mortar" school in face-to-face mode with a teacher. Increasingly, Virtual Schools are an available alternative to conventional schools. Unlike their physical counterparts, Virtual Schools are, for the most part, not restricted by the restraints of timetables, bells, uniforms, or other organizational characteristics of face-to-face teaching.

Virtual Schools have shown considerable growth in recent years, particularly in the U.S.A. (Clark, 2001) and Canada (SAEE, 2002). They are seen as having identifiable advantages. Mittleman (2001) refers to a Virtual School in Israel as "breaking barriers of time and place" (p. 84), while Florida High School in the U.S.A. uses the motto "any time, any place, any path, any place" (Florida Virtual School, 2003). Virtual Schools have been described in quite glowing terms. Berman (1999) sees virtual learning in the following way:

> Imagine classrooms without walls, where students are able to attend their classes at any time they wish, 24 hours a day, seven days a week. Imagine a nearly limitless selection of courses that are innovative, timely and technologically rich. Imagine students working collaboratively and on-line with students from a wide variety of geographic locations. What you are imagining is becoming a reality . . . (p. 12)

Virtual Schooling shares some similarities with Home Schooling, but it can be differentiated from it by the responsibility that parents accept for the education of their children. While both variations can involve students using online technology at home, Virtual Schools usually provide a course of instruction from a more distant site, and a teacher or tutor accepts some responsibility for student assessment. Despite this distinction, the boundaries between Home Schooling and Virtual Schooling can be indistinct. There are indications from the World Wide Web that some Home Schoolers are quite comfortable with technology, and that they use online materials including those of Virtual Schools when they feel that they are appropriate. In both the online interpretation of

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 329–343.

Home Schooling and Virtual Schools, students are educated through a Virtual Learning Environment (VLE).

2. REASONS FOR THE EMERGENCE OF VIRTUAL SCHOOLS

Virtual Schools have become an attractive option for some students and parents in recent years. Several factors account for the growth of Virtual Schools, including increased technological capability, the acceptance of technology in school education, the modeling effect provided by online alternatives in daily life, dissatisfaction with existing schools, the desire for increased flexibility in learning, economic rationalism, globalization, and vested interests.

Technological capability, in the context of online learning, refers to the potential for online computers to deliver educational programs in a timely, motivating and interactive way. While there have been forms of distance education for more than a hundred years, students' ability to interact with peers, teachers, and educational materials was reduced by the ways that predecessor technologies such as print, radio, and television relied on top-down publication or broadcast of materials. The development of the World Wide Web has meant that students can access online learning environments wherever there is a computer and phone line, and they are not usually constrained by the synchronous data transmission that have characterized radio and television. These environments can contain animations, movies, sounds, graphics, and interactive components. They are likely to prove interesting for students who have been conditioned by fast-paced mass media to expect dynamic presentations in their daily lives.

A related issue is access to the technology and acceptance of its use in school education. Virtual Schools can be accessed from homes, existing schools, or other areas where students can obtain an internet connection. internet connections are more common in industrialized countries where there is a sophisticated telecommunications network. It is not surprising that leading adopters of Virtual Schools should include the U.S.A., Canada, Australia, the U.K., and Israel. The widespread availability of such a network has contributed to the adoption of the internet in U.S. schools. Ninety-nine percent of public schools in the U.S.A. had access to the internet in 2002, an increase from 35% in 1994 (NCES, 2002). Where internet technology is commonplace in the community, it is likely that increased acceptance of its use in education will follow.

Daily life in the early 21st century provides numerous examples of online alternatives to conventional hands-on or non-mediated experiences. Mitchell (1995), in his book *City of Bits: Space, Place and the Infobahn*, discussed the ways in which digital spaces have provided alternatives to traditional locations:

> I discovered—as did many others—that I no longer had to go to work. Not that I suddenly became idle; it's just that the work now came to me.

> I did not have to set out every morning for the mine (as generations of my forebears had done), the fields, the factory, or the office; I simply carried a lightweight laptop computer that gave me access to the materials on which I was working, the tools that I required, and the necessary processing power . . . More and more of the instruments of human interaction, and of production and consumption, were being minimised, dematerialised, and cut loose from fixed locations. (pp. 4–5)

There are now online alternatives to the bricks-and-mortar places that have been part of our daily lives for hundreds of years. Banks, travel agents, bookshops, meeting places, libraries, and businesses all have an online presence. Virtual universities can also be added to this list. Dunn (2000) argues that there are now hundreds of university degrees available through distance education, and suggests that by 2025 the virtual university will be the predominant mode of higher education. Collectively, the online alternatives provide a modeling effect when people choose how they will live their lives. There is a reassurance that online activities are normal, and a reasonable choice that can be made. In the case of virtual universities, they provide additional evidence that education does not require attendance at a physical campus. As more students graduate from virtual universities, or complete online courses from a more conventional university, it can be expected that many households will contain parents with personal experience of online learning. Consideration of a Virtual School for students becomes more likely in this context.

In some countries a contributing factor to an interest in Virtual Schools can be dissatisfaction with the conventional school system. Concerns can include fear for students' safety or moral development, the apprehension that students are disadvantaged through under-resourcing, and inflexibility of curriculum. As Wellburn (1999) suggests, declining confidence in the public school system in the U.S.A. has led to the development of charter schools, and to parents taking their children out of the public school system altogether. It has also contributed to the popularity of the Home Schooling movement in the U.S.A., where as many as one million school children were home schooled in the period 1997–1998 (Stevens, 2001).

Devine (1996), discusses examples of inner-city New York schools where there are uniformed security guards, weapons searches, and violence is seen as normal. Less obvious are the concerns raised by Epp (1996), where schools are complicit in exclusionary practices, tolerate abuse, and are involved in other practices that hinder student learning.

Student dissatisfaction with conventional schools can result from a range of factors including a dislike of the institutional nature of schools and unsatisfactory academic progress. Thompson (1998) points out that school staffs are asked to take on a range of academic and social missions with insufficient staff and diminishing resources. When parents believe that classes are too large for effective learning, the school is poorly maintained, or the nature of school organization hinders learning, they may be more inclined to consider the alternative of Virtual Schools. There are critics such as Tiffin and Rajasingham (1995), who believe that schools can be seen as part of a former industrial era, and those who accept this view might believe that existing schools are not always appropriate for the 21st century.

Organizational constraints also contribute to the perception that traditional forms of schooling are inflexible, and this can make Virtual Schools attractive in comparison. Conventional schools require timetabled classes if face-to-face teaching is to occur, and this means that, for other than elementary schools, the full range of classes may be unavailable for students. A hypothetical example illustrates this point. If a large senior high school contained students who wanted to study a range of foreign languages, but only a small number of students wanted to enroll for each language, it is likely that the school would be unable to afford a teacher for each language, even if timetabled rooms could be found. A Virtual School, in contrast, would be able to enroll students from a wide geographical area, and classes could be offered in asynchronous mode to enable students to complete their classwork when they wanted to.

Economic rationalism also contributes to the spread of Virtual Schools because, as Smith and Sachs (1995) argue, economic rationalism puts a premium on productivity, efficient use of resources, and value for money. One interpretation of how this theory can be applied to school education is, as Rutherford (1993) suggests, the perception that deregulation, private provision, and commercialization is preferable to government provision of goods and services. When some observers are able to view conventional schools as an inefficient use of resources, Virtual Schools can seem an attractive alternative. For administrators and politicians who have to budget for the infrastructure and buildings required for new schools, the possibility that a Virtual School will reduce these costs by allowing students to work from home can be tempting. Economic rationalism also promotes the commercial aspects of Virtual Schools because it encourages the provision of non-government schools, and it enables vendors to sell the software, which the teachers and administration at the school will use.

Globalization is also a contributory factor in the rise of Virtual Schools because the same use of online computers that enables globally oriented businesses to bypass geographical boundaries in order to access markets enables students to access a Virtual School from anywhere in the world. Students are no longer restricted in their choice of schools to those that they can physically travel to each day. Moreover, while it is likely that there will continue to be certification requirements for identifiable school districts, states, and areas, it is also true that the materials that students draw on to satisfy these requirements will increasingly be drawn from the internet. Increasingly, it will be possible for students to connect to their Virtual School from a number of countries, and they will not be restricted to the print-based texts in their community.

The extent to which vested interests are involved in the spread of Virtual Schools is difficult to estimate. Understandably, when Virtual Schools are introduced there is a corresponding need for administrators and teachers with expertise in online learning. The market for online modules, and for related hardware and software, will also develop. In short, Virtual Schools can advance the careers or commercial interests of those who promote them. As it is likely that the Virtual Schools will also satisfy an identified need for learners, self-interest will be difficult to untangle from public announcements concerning the reasons for a school's introduction.

A number of the factors identified in this chapter may apply to the introduction of a Virtual School. Variation can be expected depending on the cultural, educational, economical, and historical patterns that influence school education. Such variations also help to explain the differing ways that countries have introduced VLEs, or even why they have not been adopted at all. Dutton (2003) has observed that complex social processes can result in many different outcomes for the same technology, depending on choices made by people in the production, use, consumption, and governance of information and communication technologies. Hence, for Virtual Schools, the technological capability of users and administrators is not the sole determinant of adoption, and it helps to explain why some technologically sophisticated countries have shown little interest in the introduction of Virtual Schools. In addition, such explanations provide part of the answer to the question of why countries with similar online capabilities can introduce versions of Virtual Schools that are quite dissimilar.

In trying to understand the ways in which these social processes affect the characteristics of Virtual Schools, it is important to ask why students and parents would prefer a Virtual School to a conventional equivalent. Senior high school students who wanted employment during the school day would find the out-of-school variety of virtual school attractive. This situation is also likely to be true for students who are concerned with problems of violence and bullying in conventional schools, for students who live at a considerable distance or for those who are unable to travel to school because of inhospitable weather conditions. In contrast, the Virtual Schools which Brown and Weiss (2005) refer to as bricks-and-mortar schools with elements of virtual schooling, offer a less radical solution. Although the need to conform to timetables and geographic place suggests reduced flexibility, advantages including socialization and supervision can be identified.

3. MODELS OF VIRTUAL SCHOOLING

Several variations (or models) of Virtual Schools can be identified. The choice of school or home as learning site and the relative proportion of face-to-face and mediated interactions are among the distinguishing characteristics. In this chapter, two contrasting models of Virtual Schooling are discussed, and this approach allows the exploration of relative advantages, disadvantages, and educational outcomes. The two models referred to are the *in-school* and *out-of-school* models, respectively.

The *in-school* model is exemplified by the Virtual Schooling Service (2003), in Queensland, Australia. This system uses a synchronous delivery system, primarily based on audiographics (Prendergast et al., 2002), with some additional support provided by asynchronous websites. Lessons are timetabled, with delivery schools providing a service to receiving schools. A Study Coach provides both an administrative function and student guidance.

Schnitz and Young (2002) refer to the type of Virtual School, which does not require school buildings as the *out-of-school* model. The Florida Virtual School is probably the most well-known example of this type. The Florida High School Evaluation (2002) notes that "there is no Florida High School building and students and teachers can be anywhere in the world" (p. 12). Florida Virtual School uses the slogan "Any Time, Any Place, Any Pace" (Johnston, 2004) and the approach emphasizes flexibility.

4. KEY ISSUES IN VIRTUAL SCHOOLING

Russell (2004a) identifies a number of issues critical to an understanding of Virtual Schools, including flexibility, industrial models of schooling, socialization, student suitability for online environments, and teacher training and professional development. These concerns are explored in this section of the chapter, together with other consequences that might result from the adoption of a new educational paradigm.

5. FLEXIBILITY

An advantage of Virtual Schools is the flexibility that results from the spatial and/or temporal separation of students, teachers, and learning materials. For both the in-school and out-of-school models a valuable aspect of this flexibility is the provision of teachers. The author's research to date has not identified any Virtual Schools that have replaced teachers. The use of online computers has changed the ways that teachers work (Russell & Russell, 2001), and the application of them to Virtual Schools has enabled existing pools of teachers to be used more effectively. The *in-school* model allows schools to timetable subjects where there is no trained teacher available in the receiving school. However, the *out-of-school* model provides additional flexibility in this respect because it is not constrained by synchronous technology, and the organizational characteristics of bricks-and-mortar schools. Hence, a senior high school student in the *out-of-school* model could be employed during the day and study missed high school subjects in the evening. Similarly, a student could attend a conventional school during the day and enroll for one subject in a Virtual School, which could be studied at a time convenient for the student.

6. INDUSTRIAL MODELS OF SCHOOLING

One of the reasons why parents or students may choose the out-of-school model of Virtual Schools is that conventional bricks-and-mortar schools can seem unattractive or inappropriate. Existing schools may be unable to meet student needs, and provide adequate skills for employment or tertiary entrance. There can also be concerns about pedagogy, resourcing, and safety. Schools as we know them may be remnants of a former industrial era, where it was appropriate to treat students as though they were part of a factory system. In this understanding of schooling, the organizational model required students to attend timetabled classes on a physical site, and undergo regimented procedures as they were processed through the system. For Perelman (1992), traditional schools are irrelevant and ought to be replaced with "a brand new high-tech learning system" (p. 20).

Virtual Schools can be seen as one solution to the problems arising from an educational design that has its origins in the factory era of the 19th and early 20th centuries. However, although schools usually retain industrial era characteristics, their organizational nature is more complex than might first appear. Beare (2001) argues that we are now in a post-industrial period where the concepts of market economy, increased responsibility, and reduced centralization and management teams are more likely to prevail. Consequently, the *in-school* model of Virtual Schooling retains all of the advantages and disadvantages of traditional schools. Virtual classes are timetabled within its organizational and physical constraints, but there may also be some benefits arising from face-to-face interactions. The *out-of-school* model, in contrast, can be seen as a more radical alternative in which the organizational problems of traditional schools are largely eliminated, but problems arising from reduced unmediated interaction are likely to increase.

7. SOCIALIZATION AND VIRTUAL SCHOOLS

The question of whether students are adequately socialized in virtual and conventional schools prompts a reflection on a more basic underlying question. What is the purpose of schools? The answer to this question is likely to reflect the role, position, and perspective of the respondent. While many would mention the development of skills and knowledge, or stress related certification and employment, others could refer to custodial functions while parents earn a living, the importance for the economy, or appropriate attitudes needed for future life. The development of student attitudes and values has been a continuing educational theme in conventional schooling, and it has been reinforced both by the teaching of appropriate school subjects, and the ways in which learning experiences have been provided in schools.

Students will learn the norms and values of society by interacting with people, artifacts, and representations in a variety of contexts. This will include schools, mass media, the internet, and physical environments such as shopping malls. Public education, according to Moll (1998), has become the primary vehicle for the transference of national narratives, and of humanistic and democratic values. If students were to transfer from a traditional school to an out-of-school model of a Virtual School, the ways in which these values would be taught is uncertain. It is unlikely that a value-free school could ever exist. Consequently, students enrolled in an *out-of-school* model of Virtual School will interact with others online, and when they are not involved in school activities it is likely that they will meet with peers and others for social activities. The principles of honesty, respect for self and others, responsibility, and citizenship have been identified by Wagner (1993) by the use of school focus groups. With traditional schools, these principles are often reinforced by face-to-face relationships between students and teachers, and between students, in combination with institutionalized procedures such as assemblies and awards.

With the *out-of-school* model of Virtual Schooling, the mediating technology reduces the teacher's ability to support this traditional schooling role. With asynchronous technologies such as e-mail, teachers have a restricted ability to monitor students' affective responses because cues such as body language and facial expressions are absent.

If students were prejudiced against a particular group in society, the teacher of a virtual class in the *out-of-school* model might never become aware of it. Indeed, a student who does not want to respond to an online teacher can simply turn off the computer. Some Virtual Schools are aware of these problems. Odyssey Charter School (2003) offers a range of extra-curricular activities to supplement its academic program, including field trips, skate nights, holiday events, and choir. Children are also required to attend assigned group science class twice per month. While there is no guarantee that the provision of these activities will solve students' socialization problems, by planning for face-to-face activities it is likely that students will continue to be able to relate to others.

The socialization problem is less pronounced with the *in-school* model of Virtual Schools because it takes place within a conventional school. As such, the usual support structures provided by face-to-face teachers and peers, and by school organizational procedures, will continue to be available. The Virtual School component of the student's day is likely to be synchronous, providing the teacher with immediate feedback on a student's understanding. In addition, there are likely to be Study Coaches or other designated support teachers who can discuss the implications of online lessons with students.

It might be possible to argue that the in-school variety of Virtual Schools are inferior because they offer face-to-face classes, and that this was one element of schooling that proponents of the out-of-school model of Virtual Schools usually avoid. The objection, however, misses the point. The worth of a virtual school, or any other school, is determined by the congruence between the educational environment, curriculum, and the objectives of those involved. It is more appropriate to consider whether the interests of students, parents, and the community are being addressed than it is to compare an individual school against a theoretical framework.

8. STUDENT SUITABILITY FOR ONLINE ENVIRONMENTS

Students' success in Virtual Schools is related both to the nature of the online learning provided and to the students' characteristics. Findings from a study by Del Litke (1998), based on an *out-of-school* model of Virtual Schooling, indicated that self-motivation, persistence, intelligence, and supportive parents were important factors. Some Virtual Schools offer online questionnaires for students, asking them about their independent learning abilities, motivation, and time management skills.

The problems are likely to be more pronounced in the *out-of-school* model of Virtual Schooling, because students are not constrained by teacher presence and timetabled classes. While students have the freedom to choose when they will complete their online schoolwork, they will still need the self-discipline to meet deadlines. Parental support is likely to be particularly important. If parents accept responsibility for supervising their child in an out-of-school model of Virtual School, they will need to provide adequate assistance.

Students involved in the *in-school* model of Virtual Schooling are less likely to suffer from this problem because the usual support structures should be in place, and the online sessions will often be timetabled in the expectation that the student will attend. Much, however, will depend on what assistance is provided. There may be a shortage of subject teachers for the area that the student is enrolled in, and this presumably is one reason why the course has been offered. However, the school will still need to provide assistance in areas such as counseling, time management, and information technology.

9. TEACHER TRAINING AND PROFESSIONAL DEVELOPMENT

Teaching in a Virtual School requires both the acquisition of new skills and a reduced emphasis on some traditional skills. The teaching practices and class management skills used in face-to-face classrooms will differ from their online equivalents. Because Virtual Schools constitute only a very small proportion of available schooling, there has been little modification by teachers' colleges and other providers of teacher education to existing courses, although teacher trainees will increasingly use online methods for some components of their courses. Training is likely to highlight teachers' professional development, rather than pre-service education.

Some evidence for this proposition is provided by the California Virtual School Report (2002). This report describes the use of online modules for teachers at Durham Virtual High School, in Canada, a 15-week teacher training program in Fairfax County School District, and professional development options at Virtual High School. There is also a mentoring program operating at Florida Virtual School, and a training program operating at the Cyber Schoolhouse associated with the Clark County School District in Nevada, U.S.A.

Although it is possible to identify characteristics of both *in-school* and *out-of-school* Virtual Schooling models, it is likely that teachers in both environments would benefit from tailored professional development. Prendergast et al. (2002: 35) have identified the characteristics for virtual teachers as including technoliteracy, flexibility, dynamism, grasp of subject content, experience as a classroom teacher, awareness of student learning styles, ability to use a variety of teaching strategies, enthusiasm, and confidence. A more specific response is suggested by Erlbaum et al. (2002) who outline a 26-week online course, which trains secondary teachers in online teaching practices and prepares them to design and deliver their own online course.

10. VIRTUAL LEARNING ENVIRONMENTS: NEW PARADIGMS AND TENSIONS

The perception that the predominant mode of school education required students' collective attendance at a designated place, where trained teachers would educate them, has its origins in the 19th century. The adoption of universal education through the 19th and 20th centuries led to changes in educational practice. In earlier times, it was likely that either children would receive little education, or some instruction would be provided at home, by parents or tutors. The emergence of the in-school variety of Virtual Schools constitutes a potential paradigm shift that substantially returns the focus to the home as the instructional center. Thomas Kuhn (1970), in *The Structure of Scientific Revolutions*, noted that paradigms were examples of practice, and that these provided models from which particular coherent traditions were derived (pp. 10–11). Conventional schooling has coalesced into such a paradigm, and, as Von Dietze (2001) argues, it is consistent with the conformity of paradigms that the community involved seeks to suppress competing views.

Consequently, the opponents of Virtual Schools will include those who find it difficult to imagine any system other than that which they have always accepted. Conversely, Virtual School proponents would argue that the existing paradigm is inadequate. This explanation can include the notion that the society for which students are to be educated has changed radically. Daily life combines unmediated and digital experiences, and the preparation of students involves a wide variety of functions that schools can address only with great difficulty.

Tension arises for educators in both conventional and Virtual Schools when they attempt to resolve the tensions that arise from the resolution of competing alternatives. Festinger (1959) argued that humans try to establish consistency among opinions, and that the decision between two or more alternatives leads to dissonance. In conventional schools, this can lead to questions such as the inclusion of digital literacies in the curriculum, or exploration of online environments. A school curriculum is a perpetually contested arena, where competing interest groups struggle to maintain their share of available instructional time. For Virtual School educators, critical issues are likely to be associated with the acceptance of Virtual Schools as an appropriate learning pathway. This can include the effectiveness of online environments in socializing students, or in providing online education that will provide the equivalent of experiential or face-to-face contact between teachers, students, and instructional materials. Some schools, such as the Fraser Valley Distance Education Centre (2002), invite students to complete their science work at home and send digital pictures or movies of their project to a supervising teacher. A number of Virtual Schools outline their curriculum offerings on related websites, and an examination of these websites indicates that some schools have resolved this issue by not offering face-to-face activities or subjects.

11. VIRTUAL SCHOOLS AND THE REDUCTION OF EMPATHY

Virtual Schools can also be criticized because they represent a form of VLE where fewer information channels are used to transmit information than in a corresponding face-to-face class. Parks (1996) has argued that that the cues emanating from physical settings are missing in online contexts. In contrast, the bandwidth available in conventional classes allows for the transmission of cues related to body language, and social and relational cues. The consequence of the reduction of these cues in Virtual Schooling contexts is that much of the information relating to the emotional and psychological states of teachers and learners is lost or misunderstood.

In the unmediated world, a continuing theme is that an increase in geographical distance between people can lead to a distancing effect. This can make it harder for one person to feel sympathy for another. Joseph Wiezenbaum (1972) believed that technology was implicated in the psychological distance between a bomber pilot and his victims. Similarly, in the online world, teachers and students may also suffer from a distancing effect. The long-term result may be that students in Virtual Schools may have a reduced ability to appreciate the concerns of others.

12. DISSIMILAR VALUES IN ONLINE AND UNMEDIATED ENVIRONMENTS

The problems arising from distancing can be better understood by considering the ways that values are transmitted or promoted in both conventional and Virtual Schools. Traditional schools promote values that they consider important, by overt and less obvious means. Teachers can see when students do not understand their work, or do not seem to appreciate the values that the school supports. As a result, teachers can adjust their teaching practices. In addition, the organizational nature of schools serves to support value formation, by practices such as school assemblies to reward students, attendance at chapel for religious schools, recognition of sporting achievements, and opportunities for community involvement. By these means, conventional schools promote qualities such as community and group cohesion. Schools' ability to encourage desirable attitudes is further strengthened by the greater ability to exercise power and control that is characteristic of face-to-face contexts.

In contrast, Virtual Schools rely on online interactions that often involve students using the internet from their homes. However, the values characteristic of the internet may be inappropriate. It is a global consumer culture where most people speak English (Ess, 2001). The web is also permeated by many websites, which implicitly support identifiable interpretations of democracy, individual freedom, sexuality, capitalism, individualism, and consumerism. However, some cultures can be expected to oppose these values. In addition, the ways in which media environments condition users are probably still not well understood. McLuhan and Hoskins (1989) once argued that the ways that media alter perception are more important than the content of media, and that we are not aware of these changes. The application of this argument to Virtual Schools suggests that the nature of the online environment itself will be an important factor in how students perceive the world. In addition, they may be unaware that their worldview is likely to differ from those of their conventional school counterparts.

13. RESEARCH AND VIRTUAL SCHOOLS

Much of the research on Virtual Schools is still speculative. Individual schools have published evaluations available over the internet, including the California Virtual School Report (2000), the Florida High School Evaluation (2002), and Virtual High School (Kozma et al., 2000). Others, however, provide few details of their operations. The problem is further compounded because some traditional schools and distance education centers offer online courses, and the identification of them as "Virtual Schools" is sometimes problematic. The reliable identification of trends over time is also difficult, as programs can change, and Virtual Schools can appear, or disappear. One recent survey of Virtual Schools (Russell, 2004b) provides an indication of some virtual schooling trends, but the associated study was limited by the number of respondents. It is however, likely that the imperative to demonstrate educational quality will lead to schools publishing evaluations and reports as a matter of course. At present, there is a tendency for some Virtual Schools to promote their schools through websites that use student testimonials, advertizing slogans, and sophisticated web elements to impress potential students.

14. CONCLUSION

Virtual Schools are one example of a VLE. Their emergence in the closing years of the 20th century and subsequent growth can be attributed to a complex combination of technological changes, economics, and views of learning. Although some characteristics of Virtual Schools can be identified, they are undergoing constant change. Consequently, the ways in which students can gain an online education are also changing. Although a number of advantages can be identified, there are still several disadvantages that will need to be overcome before Virtual Schools become more widely accepted. It is likely that as online computers become more powerful, interactive, and mobile, VLEs will become increasingly attractive for school students and their parents. This is likely to lead to an increased focus on the characteristics of online environments and a deeper understanding of the purposes of school education.

Chapter 14: Time, Space, and Virtuality: The Role of Virtual Learning Environments in Time and Spatial Structuring

ROBERT S. BROWN* AND JOEL WEISS†

*Research & Information Services, Toronto District School Board, Toronto, Canada;
†OISE/UT

There is no lack of speculation and theorization on the current and future roles of virtual schools. However, when one looks at virtual schools through the prism of the role of calendars—the chronological superstructure of schools—a different, rather less theoretical picture emerges. Many e-learning institutions call themselves virtual schools, but there is a continuum from "bricks-and-mortar" schools with elements of virtual schooling, to true virtual schools where all educational teaching and learning occurs in the virtual environment. At this time, more tend to have elements of virtual schooling than to be true virtual schools. Because of this situation, we will mainly refer to virtual schooling except for those situations where a true virtual school is in view. Much of the discussion of virtual schooling is ahistorical: From documents extolling virtual schools one would think virtual schooling dates from the widespread growth of personal computers and the World Wide Web in the mid- 1980s, whereas much of the structure is directly attributable to distance education which has existed for nearly two centuries.

There are three main types of time structuring in modern schools: The school calendar or chronological superstructure (usually used to describe the duration of study throughout the year, but also including the number of days in the week and the number of hours in the day); attendance and absenteeism of students (the degree to which students show up to school and to classes), and the organization of the school day (into classes, lunch, study periods, etc.). Each of these topics has received a fair bit of study. The key direction at this time in current calendar research is around the advantages or disadvantages of the full-year school versus the importance of the summer vacation (Gold, 2002; Weiss & Brown, 2003). Attendance has been examined both as a sociological phenomenon and for its role in student achievement (e.g., Brown, 1999). The importance of the organization of the school day was recognized by the authors of *Prisoners of Time*, the 1994 report of the National Education Commission on Time and Learning (1994). However, in a virtual environment, it is difficult to differentiate time structures: Therefore, an examination of the school calendar will look at all three of these issues. Given its key role in an understanding of virtual schooling, we believe it necessary to briefly discuss the concept of the "calendar".

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 345–364.

1. CALENDAR EVOLUTION

The calendar is a social invention. In his examination of the history of the modern calendar, Duncan (1998) noted, "We take the mechanism of the calendar for granted, as we do breathing and the force of gravity". Yet this current, unexamined part of our lives is the result of a turbulent evolution that has had an important role in the development of today's society.

For thousands of years the effort to measure time and create a workable calendar was one of the great struggles of humanity, a conundrum for astronomers, mathematicians, priests, kings, and anyone else who needed to count the days until the next harvest, to calculate when taxes were due, or to figure out the exact moment a sacrifice should be made to appease an angry god. A case can be made that science itself was first sparked by a human compulsion to comprehend the passing of time, to wrestle down the forward motion of life and impose on it some sense of order.

Likewise, the calendar of school is something that tends to be taken for granted. However, today's elementary, secondary, and post-secondary time structures have been stable for only the past century or so. Contemporary universities proudly trace their descent to medieval institutions. In the High Middle Ages and early Renaissance, most elements of the university were still evolving and the time structures of the university year also changed substantially. According to the Catholic Encyclopedia, lectures were given throughout the year, with short recesses at Christmas, Easter, and Pentecost, and a longer vacation in summer. Throughout the High Middle Ages university calendars across Europe varied considerably.

In Germany, there was considerable difference between the calendars of the various universities and even between those of the faculties at the same university. In general, the year began about the middle of October and closed about the middle of June. But at Cologne, Heidelberg, and Vienna there was a break from the end of August to early October. The vacation, however, was not a complete suspension of academic work; the extraordinary lectures, given for the most part by bachelors, were continued, and credit was given to students who attended them. About the middle of the 15th century, the division of the year into two semesters, summer and winter, was introduced at Leipzig, and eventually was adopted by the other German universities (Catholic Encyclopedia, 1914).

Our research in Ontario, Canada (Weiss & Brown, 2003) as well as the work of Gold (2002) in Michigan, Virginia, and New York in the U.S., chronicles a similar fluidity in the evolution of the summer vacation in North American public schools as they evolved in the 19th and early 20th centuries. Looking at Ontario and Toronto historical documents, we found that legislation established the first minimum school holidays for Ontario elementary schools in 1850—a short two-week break between terms, the same as at Christmas. It would appear that, at this time, Ontario authorities were most interested in ensuring that the new Ontario schools remained open long enough to ensure an education to those students who could actually attend. The 2-month long holiday we know today evolved between 1850 and 1913, when it was universally mandated across all schools. Although reasons for the growth of the summer holiday are not totally entirely apparent, the impetus clearly came from cities and urban areas; and rather than being the cause of the Ontario summer holiday, the farming communities were in opposition to it. Data for other jurisdictions suggests similar patterns of calendar development.

That the current academic calendars were most stable over the last century—the height of modern industrial technology—may be more than coincidence. And it is recent technology that has been instrumental in raising questions about the structure of the calendar through the possibilities associated with virtual schooling. In this chapter, for the most part, we discuss these issues for formal schooling, but we briefly touch upon some aspects of non-formal education, including the important area of professional development. Finally, we speculate on how the development of another learning environment, the library, may intersect with future activities in virtual learning.

2. FROM VIRTUAL SCHOOLING TO VIRTUAL SCHOOLS

There are a number of unresolved issues around day-to-day organization, such as the role of attendance (time on task, task completion, time on computer, versus time in the classroom) the roles and responsibilities of teachers and students, communication in a virtual environment, and what "success" means in such a context. The ability of current educational structures to absorb changes has been impressive, and at this time, the structure of electronic virtual schooling tends to resemble that of standard educational institutions. Yet the increasing popularity of virtual schooling is bound to lead to changes over time for both standard and virtual educational structures. Ultimately, these changes could redefine what is meant by public education, as the distinctions among virtual schooling and schools, charter schools, and home schooling becomes blurred, as does the distinction between formal and non-formal courses.

When one looks at virtual schooling as it relates to organizational structure, most examples can be segmented into four categories: Virtual elements as a supplement to already existing courses; virtual courses that grew out of the distance education tradition; virtual courses; and finally, virtual schools. As we have earlier suggested, the difference between, on the one hand, the labels of virtual courses and virtual schooling, and on the other, the label of virtual schools, is rather blurred. Many so-called "virtual schools" are actually intended for students attending regular "bricks-and-mortar" schools, and so are parts of schools in the traditional sense. An actual virtual school is physically unlike traditional schools, although there are features such as planning, curriculum, and financing activities, all of which may be shared with bricks-and-mortar structures.

3. VIRTUAL ELEMENTS AS A SUPPLEMENT TO ALREADY EXISTING COURSES

Over the last number of decades, developments in various technologies have been integrated into instructional environments. Halyard and Pridmore (2000) outline the changes they have observed in the teaching of science, going from 8 mm film loop projectors in the 1960s; through overhead projectors, videotapes, and audiotapes; into the 1970s and 1980s with mainframe computers providing drill and practice through computer-assisted instruction (CAI); entering cyberspace in the early 1990s with CD-ROMs and low-cost computers introducing simulated labs; and, finally, the internet of the late 1990s as an intrinsic part of science instruction. The internet has become the student's "third hand".

But for most courses, this "third hand" remains a supplement to regular instruction—albeit one that, as Halyard and Pridmore speculate, is fundamentally changing and will continue to change this instruction. Thus, Witham et al. (2002/3) outline the use of WebCT, a multipurpose software package, to create an online supplement to their Earth Science course. Uses include class e-mail, hyperlinks, an online calendar, an online discussion board, and online handouts.

Using virtual elements in a course may also lead to the course becoming entirely virtual. Clark (2001: 3) found that a quarter of self-described virtual schools had been operating in 1995 or before. Many of these early start dates "appear to be referring to pilots of early internet-based instruction, or dial-up client server applications. Some of these organizations previously offered CAI as part of independent study packages, and gradually transitioned to online or internet delivery".

4. VIRTUAL COURSES THAT GREW OUT OF THE DISTANCE EDUCATION TRADITION

We have previously suggested that much of the discussion of virtual schools is ahistorical, and owes much of the structure to the earlier era of distance education, which has existed for nearly two centuries, and with CAI, which became fairly prevalent in the 1960s.

Formal distance education started in 1840 when Isaac Pitman began to teach by correspondence. In 1850, the University of London offered distance courses to students in British colonies, like India and Australia. In 1889, Queen's University in Kingston, Ontario first started offering post-secondary correspondence courses. These 19th-century courses used writing and the mail service, but distance educational institutions have been among the first to utilize new technologies. In 1922, Pennsylvania State College and Columbia University began radio courses. In 1968, Stanford University created a television network. By the 1980s, TVOntario and the University of Guelph were experimenting with computer-based courses, including electronic e-mail systems, one of several such pilots taking place across the world.

Having the tradition of adapting new technologies to their already existing structures meant that the internet was easily folded into distance education courses in the 1990s. An example is Ryerson Polytechnic Universities' Open College distance education program, founded in 1969, and inspired by Britain's Open University. Ryerson offered its first credit course—via radio—in 1971.

Norquay (1993), the first Director of the Open College, stated that Ryerson had to fight the assumption that any course offered outside the bricks-and-mortar classroom was academically suspect. Therefore, it was thought necessary that the Open College courses were to be like Caesar's wife—not only did they have to be academically demanding, they also had to be *seen* to be academically demanding. This lead to "extraordinary" efforts to match Ryerson's bricks-and-mortar academic structure.

> Ryerson's standard full credit course in the Faculty of Arts called for two semesters, each semester consisting of three contact hours per week for thirteen weeks, for a total of 78 hours (less three or four when a holiday or special event intervened). Open College hours, therefore, were carefully planned to total 76, on the basis that radio hours were a full sixty minutes, not the classroom fifty minutes. There would be 48 hours of radio programming and two study weekends (one per semester), each with fourteen hours of lectures and discussion . . . ten television programs were planned as "enrichment", but they were not regarded as crucial for course content. In addition to listening to 48 broadcast hours and attending two study weekends, the students completed thirteen assignments, a minor and a major essay, a mid-term, and a final examination. These requirements, more rigorous than those required of regular classroom students, were built into the course to assure that it would be regarded as academically worthy.
>
> (Norquay, 1993: 75–76)

By the late 1980s, Ryerson was offering 27 courses through a combination of radio, audiocassette, and correspondence. The current (2003/4) course calendar shows that the number of courses has dramatically increased (to over 100). Courses are offered in print, on the internet, or on audiocassette. Students submit assignments in person, by mail, by fax, or by e-mail. The courses (many of which can be applied to a degree or certificate program) are still located within the regular Ryerson academic calendar.

There are no references to "virtual reality" in the Ryerson calendar. In fact, it is easy to miss the references to the internet altogether. Ryerson has clearly added the internet to its already-existing distance education system; a system in itself consciously modeled on the structure of the mother university—itself a modified version of a medieval institution. It is difficult to find a clearer illustration of the resiliency of institutional organizations.

Britain's Open University reiterates the difference between distance education and virtual schooling. In "E-learning at the Open University" available through the Open University's main web page, the Open University states that it "has always been a world leader in the use of new technologies to improve the quality of education for students and to broaden their access to it", and that it is regarded as Britain's major e-learning institution. However, the document also notes that the Open University does not strive to become an "online university". Instead, the University believes that "the best outcomes for learning are usually achieved by striking a balance between using traditional and new media, individually selecting and developing the products that are best suited for each purpose". It is essential to provide the right balance of text, audio, video, interactive simulations, database resources, IT tools, and communication environments.

5. SOME THOUGHTS ABOUT LIBRARIES

Libraries have traditionally been closely associated with schooling as an important learning resource. Both the school library and the public library system have been used to augment classroom teaching–learning activities. The public library is always available for those situations like virtual schooling, home-schooling, and charter arrangements that may bypass the formal school structure. The development of the e-library (see chapter by Brophy in this volume) potentially magnifies the importance of virtual learning sites.

The library is in some ways the ultimate institution of self-directed learning. Perhaps in the best of all worlds, the properly educated person should be able to take advantage of the guidance and facilitation of a library (through the library's organization, its support materials, and the expertise of its staff) to be able to design and implement his or her learning, whether this be in the context of a specified curriculum or research project. Although this guidance and facilitation has not traditionally taken the form of courses in the formal educational system, it is possible that it might in the future, given how the format of "virtual courses" are becoming more common in aspects of professional development, and in various forms of schooling. How would this change the time structures of schooling? One reason for the growth of virtual libraries has been their ability to facilitate and provide quick response to interactive inquiry. Such a dynamic could ultimately lead to a change in the way courses are organized—and it is a safe bet that this change will be different from whatever we can speculate about now.

Much of this speculation is dependent on changes in the school calendar in the form of year round schooling, growth in charter schools, and home schooling, as well as any realistic notion that virtual schooling will become more feasible, not to mention "true" virtual schools. There are many issues that are necessary to be resolved before there is realistic expectations for major influx of the "true" virtual school: Politics, resource availability, technological advances, a trained and willing teacher complement, as well as resistance to radical change in one of our most conservative institutions. We are starting to see changes in higher education, and in the workplace, but formal schooling, as we know it might be more resistant to such a radical development.

6. VIRTUAL COURSES AND VIRTUAL SCHOOLS

The number of virtual schools appears to be growing; according to the 2003 Tech Trends survey done for Education Week (Ansell & Park, 2003) U.S. 16, states had virtual schools and 24 allowed cyber charter schools. It should be noted that the Tech Trends survey looked at elementary and secondary virtual schools only. Researchers looking at California's e-line learning potential felt that the virtual educational system should be designed for all levels of education, serving students from kindergarten through graduate school (Trotter, 2002). Currently, this is a distant ideal. The discussion of "cyber schools" tends to revolve around the elementary and secondary levels; post-secondary courses are more likely to be offered through already-existing universities and colleges, and often reflect the pre-existing "distance education" dialogue. However, there are post-secondary institutions such as the University of Phoenix, which specialize in online programs, including the granting of degrees.

Elementary/secondary and post-secondary schools appear to be separated in virtual reality as they are in regular education, or in real time. In part, this may be due to organizational structure, with elementary and secondary schools having entirely different systems of certification and authority and funding. The evolution of many distance education courses in post-secondary institutes prior to the growth of the internet may have heightened the divide. Of course, we cannot overlook the fact that these types of institutions operate on different calendars: An 8–9 month university school year versus a 10-month elementary/secondary organizational structure.

Clark (2001) provides one of the most comprehensive examinations of virtual schools to date. He lists several categories of virtual schools: State-sanctioned; state-level (sanctioned by the state government to act as the state's own virtual school); college and university based; consortium and regionally based; local education agency based (created by local public school and school districts); charter schools; and private schools.

At this time, most so-called cyber schools offer only a selection of courses rather than the full range of educational requirements. For example, the Virtual School of the Toronto District School Board offered twenty-three secondary school courses in 2003, a fraction of the total available credit courses in the district.

Clark (2001) notes that the majority of students are taking courses from virtual schools that are supplemental to their "regular" high schools—that is, they attend bricks-and-mortar high schools, and use virtual courses as additional options. These students (and courses) would be following the traditional school calendar: Regular school year semesters, or summer school.

There are some interesting exceptions, although these appear to demonstrate the dynamic tension of providing "regular" courses within a virtual environment, and how calendar may allow flexibility. The Virginia Internet High School offers 90-day courses, although some remedial 45-day courses are also available (Rutkowski, 1999). The Florida Virtual High School (FLVS) is the largest virtual school in the U.S., and is regarded as an industry leader. The motto of FLVS was learning at "any time, any place, any path, any pace". However, the school found that large numbers of students in "any pace" courses were not completing them. As a result, the school modified its "any pace" pledge to adopting three time frames: The standard 9-month schedule; an accelerated 6-month schedule if students feel comfortable with the course material; or an extended, year-long schedule, if they think they need more time (Doherty, 2002). The COOLSchool of Eugene, Oregon allows students to work on courses at each student's own pace—but within the 10-month school year.

7. ISSUES OF VIRTUAL SCHOOL ORGANIZATION

Although the overall structure of virtual schooling tends to resemble that of standard educational institutions, there are a number of issues around day-to-day organization that bear discussion. These issues may define the differences between the time structure of "bricks-and-mortar", and that of virtual, schools.

7.1. What is Meant by Attendance in a Virtual School?

What is written about attendance in a virtual school is not especially consistent, perhaps because virtual schools are at an early enough stage of evolution that there is limited consistency in their composition and characteristics. As noted earlier, at this time most students taking virtual courses are actually attending "bricks-and-mortar" schools and taking virtual courses as a supplement, so "attendance" in the virtual school would only refer to working on one or a few courses. Schools usually have legal penalties aimed at students physically absent from the school for a certain amount of time (truancy requirements for those below the age of school leaving, deletion from the school rolls for those at or above the school leaving age). It is unclear how overall school attendance is calculated for those students taking both face-to-face and virtual classes.

According to Clark (2001) many virtual courses were developed for primary use within regular instructional time in public K-12 schools (for example, for students wishing to take courses not available at the school). Thus, these students are (or may be) physically present in the school while taking the virtual course. Students can always work at these courses during non-school hours, presuming they have online access. Of course, this is no different from students spending time on non-virtual courses outside of school hours.

Moreover, looking specifically at course attendance rather than attendance at the school, the term is still unclear. In a physical environment, class or course attendance simply means that the student is in the general vicinity of the teacher, regardless of whether learning takes place (as many teachers can testify). In the virtual environment there is no clear replacement for this physical link, since many or most students are working on the course after school, in the evenings, late at night, or on weekends (Doherty, 2002). Educational providers do try to monitor and/or enforce attendance. Some courses monitor attendance using the number of "hits" (Witham et al., 2002/3). Others have logs that are verified by the parent (Bowman, 2003). Both have issues of validity. Numbers of "hits" may merely show that the student (or, someone signed on as the student) has made a connection to the course, but with today's multitasking computers that may well be like a student signing into their homeroom class in the morning and never attending any actual courses. Hurley's account of attendance at a virtual school shows some of the problems of both logs and self-paced courses:

> Flexibility regarding when work could be done led to problems for some students. It was common for a portion of the week's work to be put off to the weekend, resulting in long hours on Saturday and/or Sunday to meet the time quota. Also, because a learner-level user [in the PLATO system] cannot effectively call up a record of time logged on, some students found that they had trouble remembering to record their sessions properly. Those who failed to log the minimum hours were warned, counseled, set up with schedules to log extra hours, and, when necessary, removed from the program.
>
> (Hurley, 2002: 34)

Ultimately, the concept of "attendance" in a virtual course or virtual school may have to be fundamentally modified. Many post-secondary institutes do not have clear attendance and absenteeism requirements. Students are expected to hand in assignments and attend exams, without necessarily attending classes. This is the ultimate direction, a "laissez faire" approach to schooling pioneered by Robert Hutchins of the University of Chicago in the middle of the 20th century. However, since there is a clear, linear relationship between absenteeism and secondary school success in "brick-and-mortar" schools, such a process (and the lack of monitoring for signs of "at risk" absenteeism) may dramatically increase the number of course non-completers (Brown, 1999).

Perhaps virtual schools will agree on some sort of compromise attendance process, combining time-on-task and task completion. Currently this does not appear to even be at the discussion stage, but the issue has the potential to be a divisive problem as virtual instruction becomes more widespread in school systems.

7.2. What is Communication and Instruction in a Virtual Course?

It is all very well to talk about "24/7" as an advantage of virtual schooling, but if this means the ability of the student to get onto the computer and work on assignments, there is little difference from completing pen-and-paper assignments. However, the difference may be in the roles that teachers play. There appears to be a wide range of roles undertaken by the teacher in the virtual setting, and in the methods of the virtual teacher in interacting with the students.

According to Clark (2001), a majority of virtual schools appear to be using web or internet instruction as their only distance learning method. However, this does not mean that virtual schools are entirely "virtual". As noted above, the philosophy of many schools that call themselves "distance education" providers (such as the Open University) is to use whatever technology is best for the match of learner and instruction, including the internet but with many other possible directions. In addition, Clark points out that many schools are part of organizations that offer conventional, face-to-face education; that traditional independent study programs sometimes have web-based courses as a parallel offering to traditional independent study methods; that some require on-site meetings or offer optional activities like field trips; and that print-based study guides traditionally associated with independent study are used by some schools (Clark, 2001: 7).

Three of the schools profiled by Joiner (2002) illustrate the potential range of structures. Courses in the Virtual High School in Hudson, Massachusetts have no live meeting times. But with the CCS Web Academy of North Carolina, students must meet with online instructors at a pre-determined date and time. Students from the Basehor–Linwood Virtual Charter School complete assignments at their own pace but submit weekly progress reports, and exams are proctored at specific locations.

Also, classes can be taken at any time (asynchronous) or teachers and students might be required to log in at the same time each day (synchronous), or, a combination (Vail, 2002). Synchronous classes are very similar in structure to the regular school calendar, but they also reduce the flexibility that is supposed to be one of the key advantages of the virtual course.

Several articles on virtual schools stress the difference between face-to-face teaching and virtual teaching (e.g., Vail, 2002). Among some of the differences outlined by Melnick (in Owen, 2002) are:

- With no face-to-face time between teachers and students, all interactions must take place and be supported by technology. If the technology fails, so does the learning.
- Teachers need to become experts in myriad technologies, often without benefit of formal training.
- Courses need to be continually modified by teachers as links to existing resources change and new online resources become available.
- Curriculum has to be written with consideration given to the specific technology that will be used for delivery.

There are some types of activities that may never make the transition to an entirely virtual environment. Bowman (2003) looks at the physical education course offered through the Florida Virtual High School. Students are required to exercise, but the ultimate usefulness of the course has its critics. Halyard and Pridmore (2000) wonder about the absence of the "wet" nature of science labs in the virtual environment, and whether this provides the opportunity to "really" experience the exercise. Perhaps technology may ultimately make this distinction meaningless, as portrayed in the world of Arthur C. Clarke's science fiction classic *The City and the Stars* (Clarke, 1968).[1] But at least for the immediate future some experiences cannot be replaced in cyberspace, and these will need to be integrated into the time structure of virtual schools.

7.3. Time Structure and Governance

What "time" means in cyber schools also brings up a host of issues related to school governance. As Payne (2002: 48) points out, "one of the biggest drawbacks to online education is that no standards currently exist, meaning a school district could have to pay for cyber education without the slightest knowledge that the student is learning anything except how to log on to a computer".

It might be worthwhile to recall how the supervision of curriculum in the public system evolved. In 19th century Ontario (a fairly typical example), prior to post-secondary education there were no "credits" or formal courses of the sort we take for granted today. A reasonably small proportion of students wrote exit exams (for the end of elementary school and secondary school) and entrance exams (for entering high school and university). The quality of instruction in schools was validated by a complicated hierarchy of regional school "inspection" (hence, the name of the official in charge was usually "Inspector"). One role of the Inspector was to physically visit schools to ensure that instruction was both standardized and of sufficiently high quality. This was complemented by having a reasonably consistent (some might consider as rigid) curriculum and to have a standardized time structure, both throughout the day, and throughout the year. In addition, public "success" in an educational system meant the degree to which the system could get students to come to school and stay throughout the year; this also increased the importance of the time structure of the calendar. Over the century, inspection and external validation of education has to a degree been replaced by standardized tests; entrance and exit exams have been replaced by credit completion requirements (and in some cases, re-instituted in the form of school-leaving competency examinations); the concepts and practices of teaching has changed out of all recognition; and courses have dramatically increased in both scope and variety).

Yet in spite of all of this, the time structure of schools has remained remarkably unchanged—perhaps, in part, because it adds consistency in the governance of a rather large and unwieldy set of institutions. In general, the more formal the governance structure, the more rigid the time structure. When looked at this way, the virtual school's evolving use of time may provide yet another challenge to bringing acceptance by mainstream education.

8. ALTERNATIVES TO TRADITIONAL COURSES

From the above description of the format of virtual schooling, it is likely that although the technology used in the formal virtual environment has changed, the fundamental morphology of the courses has not. Courses are nearly always offered within the calendar of the mother institution—usually semesters over the regular school year, with additional options for summer school. (The limited exceptions, as with the FLVS, may be exceptions that prove the rule.)

However, when most people think of "courses" they tend to think only of those offered in the formal education system: Instruction by accredited educational authorities as a component of graduation, whether the graduation is from elementary school, secondary school, or post-secondary institute. In addition to traditional credit courses, there are also courses for professional development in a variety of fields, and non-formal or self-directed learning courses. These appear to have a much wider range of calendar options, in both bricks-and-mortar and virtual environments.

8.1. Formal Courses for Professional Development

In the 19th and 20th century, accredited instruction in such fields as medicine, architecture, and law came from various apprenticeship and certification practices recognized by tradition. The "articles" of law practiced by Dickens's David Copperfield in his employer's workplace, which would have led to Copperfield becoming a lawyer after several years of clerkship, is a well-known literary example. In late 19th-century Manitoba, this "consisted of five years of apprenticeship (three in the case of university graduates) under articles of clerkship to a practicing lawyer. At the end of the period of articles, each student had to pass an examination prescribed by the Bar Society" (*Historical Sketch of Legal Education in Manitoba*, http://webapps.cc.umanitoba.ca/calendar99/faculties/law/history.asp).

Most of these programs evolved into training and accreditation through formal and standardized university fields of study. In Manitoba, a provincial law school was established in the early 20th century under the joint authority of the Law Society and the University of Manitoba, which became the Faculty of Law in 1962. One can see this process today in the requirements for certification by various accounting societies such as the Certified Management Accountants association. Today, professions are more likely to provide courses for upgrading or maintaining skills and practice. The courses are provided (or at least regulated) by the professional organization rather than the formal education system.

Not surprisingly, many of these professional development or upgrading courses have evolved into the virtual environment. Thus, Microsoft offers a certification program where courses can be completed entirely online. The size and influence of Microsoft, and the effort provided by Microsoft to regulate the courses, have provided this certification by a private company a similar "cachet" to certification by professional organizations.

And unlike formal school credits, these courses may not have a set calendar—they do not necessarily start and end on a standardized and relatively inflexible date. There is more likely to be a set of chronological conditions, e.g., that the requirements must be completed by a certain time after the (often arbitrary) start date. In Ontario between 2000 and 2003, certified teachers were required to complete an average of three professional courses a year. The courses were regulated, although not provided, by a provincial authority, the Ontario College of Teachers. There was a range of course providers, often Ontario school boards. In the Toronto District School Board, the Staff Development department provided half day, one day or multiple day conferences on selected topics; it also provided virtual courses where teachers could register at any time and complete on a completely open basis.

8.2. Non-Formal/Self-Directed Learning Courses

These courses are taken for the interest of the learner, whether for professional reasons or for pleasure. As with distance education, non-formal courses have a long tradition, for example, with the "Mechanics" and "Workers" institutes that became prominent across Ontario during the mid-19th century. These types of courses have also utilized "new" technologies as they became developed. For example, starting in the 1970s, TVOntario started to provide non-formal learning "telecourses" that consisted of a television component, along with support materials that always included print (usually a textbook and/or a viewers guide) and sometimes included audio tapes, CAI, and human contact such as telephone tutors.

Participants sometimes signed up for the courses in a rather casual manner (often on a whim) but their use of the materials was focused: Rather than using materials according to the organizational plan of the course designers, they strategically located and synthesized the information they needed. Participants also noted that they signed up for TVO telecourses rather than bricks-and-mortar courses because they found telecourses more convenient, or they were too "busy" to take a regular course, or they preferred to learn at their own pace (Brown & Constantin, 1992).

In other words, these learners preferred telecourses because of characteristics that tend to be consistent with the virtual environment. The internet has provided verdant ground for the growth of non-formal courses (e.g., the online non-credit courses offered through Louisiana State University in Shreveport).

The difference between non-formal and formal courses for professional development may in some cases have to do with the intent of the learner than the actual structure of the course. In 2001, the Ontario Ministry of Education had mandated that teachers take an average of three professional courses a year, in order to maintain their certification. The requirement was extremely contentious and was opposed by the teaching associations (and ultimately was abolished in May 2004 following a change in provincial government). Offering these mandated courses put professional development suppliers such as the TDSB into a bind. As a result, the courses were offered, but whether they would be taken for certification, or taken for professional (but informal) interest was left to the discretion of the student. Thus, the only difference between a formal course taken by one student, and a non-formal course taken by another, would be a decision by the first student to submit the course to the Ontario College of Teachers. Furthermore, the submission to the College of Teachers could be made after the course had ended—no one would know at any given time during the course which student was taking it as formally, and which was taking it non-formally.

The time structure of self-directed courses—always broad—has become extremely elastic with recent technological changes. Initially, TVO telecourses had the limitation of their broadcast schedule. With the increased availability of videocassette technology in the 1980s, even this structure became irrelevant. On the internet, the calendar of self-development courses becomes more philosophical: The calendar is dependent upon when the student is engaged in his/her inquiry of knowledge, balanced by some loose technological and administrative constraints: How long the course is available through internet access, how long the student is allowed to log on to gain access to course material or to work on tutorials. If the student is accessing a course through CD-ROM rather than through the internet, even these limitations may be irrelevant.

9. FUTURE DIRECTIONS

While virtual schools may have greater similarities to their technological predecessors than some virtual school proponents would like to believe, differences are major enough that they should lead to some very new structures in education. There is a possible analogy of how the virtual school may change school calendars, with now the sorting of students into age-based grades evolved between the 19th and 20th centuries. The later was a compromise of administrative consistency and pedagogical efficiency.

9.1. Time on Task: a Proviso

Elsewhere in this volume, Russell (2004) makes the point that virtual instruction is quite different from regular instruction, and many instructors tend to find it more "time consuming" than comparable instruction for regular "bricks-and-mortar" schooling. The same might be said of the experience of many students. It is a common finding of distance education research that distance students tend to have higher achievement than regular students. This may be because they are a self-selected group—are voluntarily seeking further education, are older, and are highly motivated and self-disciplined (see http://www.uidaho.edu/eo/dist9.html). Such self-discipline is often needed because a distance education course may require more time than a comparable on-campus course (e.g., http://www.regent.edu/acad/schedu/defaq.html for a brief overview of this).

Looked at optimistically, the possibility that virtual education students and curriculum designers will spend more time than their "bricks-and-mortar" equivalents suggests that virtual learning environments motivate students to spend more time at schooling. Less optimistically, it could be a limitation on the potential growth of virtual classes. There appears to be little discussion about how an increase in "time on task" would change virtual time structure (perhaps because theoreticians may be happily assuming that virtual schooling will decrease time on task). Since students have only so many hours in the day to spend on school, would the number of courses decrease? Would homework decrease? Would the number of school days in the school year increase? It will be interesting to see how this plays out.

9.2. The Blurring of Spatial Boundaries

In January 2004, the Wisconsin Education Association Council filed a lawsuit challenging the legality of the Northern Ozaukee School District's online charter school, the Wisconsin Virtual Academy. The suit contents that the district violated state law by enrolling students from outside its boundaries (the academy is run by the school district in conjunction with K12 Inc., the company led by former U.S. Education Secretary William J. Bennett) (Johnston, 2004).[2] In this example, we have the intersection of several organizational possibilities: A virtual school, run as a charter school at public expense, for children being home schooled.

Perhaps what is most telling about this lawsuit is the fact that it occurred at all. Not too long ago, it was taken for granted that "regular" public education, home schooling, and charter schools were separate institutions. The lawsuit shows that the distinctions are starting to blur. The possible modification of school attendance areas may introduce another element of uncertainty into the time structures of virtual schools. Although the written documentation of many virtual schools use "24/7" as a catchword, the fact remains that most virtual schools had tended to be locally based—in the city (or, at best, state/province) in which the physical plant of the virtual school is located. Slowly, things may be changing. The TDSB Virtual School is intended for students living in Toronto, but it also includes students from outside Canada (including several from China).

Such cases—where physical attendance even for introductory meetings becomes impossible, and where teachers are living in a different day than their students—are infrequent enough at this time that they have not challenged thinking about the time structure of schooling. This may not be the case in the future. It is telling that the Wisconsin lawsuit raises some issues on the structure of "out of area" attendance, since physical catchment areas are irrelevant. It has been wryly observed that money will change an educational issue from vaguely abstract to immediate and urgent. Perhaps public educational systems may have greater incentive to emphasize virtual schooling in their regular curriculum and structures in response to perceived funding shortfalls. Enrolling "virtual students" potentially represents additional revenues, but more information is needed about the costs of virtual schooling before judgments of financial viability can be made. These issues—finances, charter schools, private provisioning of education—in conjunction with virtual schooling, may well help to elevate time structural issues into mainstream discussions.

9.3. The Blurring of School Institutional Boundaries

Earlier, the LSU Shreveport online courses were pointed to as an example of non-credit courses being offered through the internet. However, a closer examination of these courses show that many are components of professional certification in such fields as travel, IT and health sciences (see http://www.lsus.edu/ce/online_courses/gatlin_online_courses_2003.htm). Thus, doctors can use these courses for professional development; software engineers can maintain or upgrade their Microsoft certification. Some of the course providers appear to be "for profit" enterprises; others are professional associations. By "non-credit", LSU presumably means non-credit for its own post-secondary degree requirements.

Although exact figures are hard to come by, there is no question that these types of professional development courses are becoming more common as the use of the internet has become commonplace in so many areas of society. As the LSU Shreveport example shows (and has been seen elsewhere in this chapter) the difference between formal and non-formal study is becoming blurred at times.

To put this in historical context, there has been fluidity in the relationship between professional societies and formal post-secondary institutions: Many faculties of medicine, dentistry, nursing, law, business, and teaching started as institutions outside the formal university structure that were gradually integrated (or, perhaps, assimilated). For example, the School of Dentisty for Ontario was founded in 1875 by Ontario's professional governing body of dentists, the Royal College of Dental Surgeons, who had responsibility for professional training and education. Between 1888 and 1925 the school gradually changed from control of the College of Dental Surgeons to that of the University of Toronto (see http://www.utoronto.ca/dentistry/abouttheschool/aboutback.html).

A difference at this time is that many, perhaps most of the associations now offering internet upgrading and certification courses are aiming their "product" (to use the current nomenclature) at people who are already working professionals or, at least, working full time. As the trend continues, there are many different possibilities. The widespread nature (or, at least, quantity) might modify the time structure of the virtual university structure—although the fabled ability of the university structure to resist change may make this a challenge. It is just as likely, based on previous historical developments, that professional associations will adapt themselves into the current virtual university structure.

In April 2004, MIT announced a new course-management platform called Caddie.net, designed to give educational institutions more flexibility in managing both on-campus and distance education programs. According to an online article in e-School News,

> . . . the framework—which schools can download free of charge—supplies basic applications for course management and scheduling, while enabling users to build customized portals designed to meet the specific needs of a particular class or campus organization.
>
> Developers are touting the program as more versatile and easier to use than leading commercial course management solutions, such as those provided by Blackboard Inc. and WebCT. What's more, they say, the program will save schools money by cutting down on IT costs and streamlining the process of updating web services applications such as campus events calendars, class schedules, and student rosters.
>
> (Murray, 2004)

This particular technological innovation may or may not succeed; but the article clearly shows that this is one of several software innovations that, collectively, could be an important step in the evolution of virtual schools and schooling. Yet so far, such innovations appear to have had a comparatively limited influence on the time structure of virtual schooling, which appears much closer to "bricks-and-mortar" scheduling than one might expect from the current rhetoric around e-learning.

The school calendar is a social construct that been taken for granted, but has tended to be extremely variable in the past. The North American elementary and secondary school calendars have provided a dizzying series of permutations throughout the 19th and early 20th century, before stabilizing into the format we tend to regard with the agelessness of the pyramids. Yet currently, there appears to be limited experimentation by virtual schooling and schools with elementary, secondary, and even post-secondary academic calendars.

This lack of calendar variation may be a consequence of the relatively small number of truly virtual schools. Many of what are called virtual schools actually are virtual schooling components to existing schools. They are not truly different institutions, but consist of some layer of virtuality to already-existing regular school structures—the assigning, research, and marking of assignments through the internet, for example, or the offering of a range of courses designed as a supplement to a student's regular curriculum. There simply may not be enough truly virtual schools, operating consistently for several years, to observe recognizable modifications to the traditional time structures.

But it is likely that there will be some sort of systemic change, if for no other reason than simple economics. Although many think that the advantage of virtual school as currently organized is that they will lower the costs of education, they may not be cheaper to operate than traditional schools. Several have reported financial difficulties and some states are tightening up their auditing requirements ("Virtual-School Costs Under Siege", Gartner, 2004). "Necessary as the mother of invention" is one cliche with much truth behind it, and the time structures of virtuality will doubtless evolve in consequence. This can already be seen in a limited way with professional development courses and schooling.

Speculating on what directions this evolution will take may be fun and intriguing but will doubtless be at least in part inaccurate. A central premise of Tenner's "Why Things Bite Back: Technology and the Revenge of Unintended Consequences" (1996) is that technological advances will often lead to developments entirely different from their original intentions. The final (or, at least, stable) time structures of virtual schools will probably follow this pattern.[3]

ENDNOTES

1. This brilliant 1953 tale outlined a world of virtual reality in the far future. Like other of Clarke's works, it also showed the ultimate sterility in relying entirely on computers.
2. According to the January 21, 2004 *Education Week* article, the suit also charged that because the charter school's students are typically directed by their parents or another adult, the virtual school violates a state law requiring public school students to be licensed instructors: Another potential issue as virtual schools, and their association with charter instruction, becomes more widespread.
3. "Intensive antibiotic therapy has removed the horror of some of the nineteenth century's most feared infections, yet it has also promoted the spread of even more virulent bacteria. Massive shielding of beaches from the energy of waves has deflected their intensity to other shores or robbed these beaches of replenishing sand" (Tenner: 255).

Chapter 15: Motivational Perspectives on Students' Responses to Learning in Virtual Learning Environments

MARY AINLEY* AND CHRISTINE ARMATAS†
*University of Melbourne, Melbourne, Vic., Australia
†Deakin University, Melbourne, Vic., Australia

Virtual learning environments are of special interest to educators because it is the province of educators to create, select, and provide environments that encourage learning. This is true whether the educator is concerned with very young children who have a very limited range of knowledge and skills, or mature learners whose experience has equipped them with extensive knowledge and well-developed learning strategies. It is the way environments set the framework or context for experiences that make them key tools whereby educators influence the direction of learning. Learning happens with or without the educator. However, the yardstick for evaluation of any educational endeavor is the degree that learning approximates the goals and outcomes valued by learners, educators, educational institutions, and educational systems. The chapters in this volume acknowledge that throughout history humans have used a wide range of technologies to design and construct environments to encourage the development of knowledge and skills in their young. However, the power of environments to promote learning has been accentuated by electronic information technologies as they offer an ever-increasing range of digital and virtual forms. These virtual learning environments have the potential to provide opportunities for active, flexible, and increasingly individualized learning experiences. Our examination of motivational perspectives will range widely across the electronic information technologies that are used in creating virtual learning environments, from the simplest forms of computer-aided instruction through to complex virtual reality environments.

An important factor influencing the widespread interest in electronic information technologies is the seemingly limitless possibilities they provide for the construction of virtual learning environments. Each new virtual learning environment comes with its implicit assumptions, and often explicit claims offering enhanced student learning outcomes. The idea that electronically created environments will open the doors of learning for everyone has been embraced enthusiastically to the extent that it is not uncommon to read claims such as "ICT can be used to provide new, authentic, interesting, motivating and successful educational activities" (Kelleher, 2000: 37). In particular, it is the motivating power of virtual learning environments that we will examine.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 365–394.

In this chapter we present a perspective that gives central place to identifying the character of the relationship or interactive process that connects learner and learning environment. More specifically our analysis will identify motivational processes that characterize how students engage with technologically based learning environments. In this way our approach will differ from other reviews of learning and virtual learning environments and will address what some have referred to as a "neglected factor in instructional design" (Spitzer, 1996). Our focus is not on any one form of virtual learning environment but rather we explore how the set of learner characteristics known as motivation might influence educational experiences and outcomes across a range of virtual learning environments. As Hartley and Bendixen (2001) have suggested the role of learner factors is likely to become more pronounced as learning environments become more open-ended.

The editors have adopted for this series a perspective that treats learning experiences as "participation in an interconnected series of learning environments". Our approach is to focus on the motivational processes that influence "participation". Motivation is about movement, energy, selectivity and direction in behavior, and so motivation is an essential component of participation. We examine how some psychological factors (e.g., curiosity, interest, goals, anxiety) influence what happens when specific objects or events within electronic environments impact students' personal information processing systems. This is one of a number of perspectives on learning in virtual learning environments that emphasize functional qualities of the interactive learning system. For example, another way to look at learning in virtual learning environments is represented in a Gibsonian perspective. As Flach and Holden (1998) note, the Gibsonian view of design principles as applied to virtual environments highlights the link between perception and action. They argue that the dynamic interplay between the environment and the learner determines the quality of the simulation and therefore the quality of the experience. In this way, the yardstick for measuring experience in virtual environments lies not in the quality of the images, but with what can be done, "the reality of experience is defined relative to functionality, rather than to appearances" (p. 94). In contrast, we address the issue of learning in virtual learning environments by considering ways that students react to and interact with (i.e., are curious about, have their interest triggered by, become anxious about, want to master, want to avoid) virtual learning environments.

We have adopted a broad conception of virtual learning environments and include computer-mediated and computer-assisted learning programs that model traditional classroom practices, as well as electronic environments that simulate real-world situations in which students can interact and influence the environment. An important characteristic of virtual learning environments is their degree of veridicality with real-world environments. As societies have developed ways of transmitting adaptive understandings of the culture to developing members of the social group, so they have constructed learning environments that are more or less veridical with the real-world environments which the developing young will need to navigate. These learning environments can also be classified according to whether learners experience them as being equivalent to the real world. Some learning environments represent the real world on a two-dimensional page. Throughout the history of education in western, literate societies, environments of this type have made up a large proportion of children's educational experiences. The critical features of real-world experience are abstracted and represented in either two- or three-dimensional form on the two-dimensional surface. At the same time there have always been educators who have argued the need for a closer match between the learning environments that make up formal schooling and the "real-world environments" for which schooling is preparing students. In the electronic age this issue is again brought into focus through the potential of computer environments to both *be* learning environments and *to simulate* real-world learning environments. Contemporary learning environments range on a continuum of immediacy. Towards one end of the continuum is the two-dimensional page or screen with its symbolic representations of the real world, abstracted from the environment and formally presented in a range of ways thought to assist learning. Currently at the other end are the virtual reality worlds created through digital means where students are active contributors to the life of the environment. The history of education shows clearly that across the full range of these learning environments students have reported experiences of being curious about, being interested in, wanting to understand, as well as being bored, being confused and frustrated, and being anxious. We will consider elements of learners' experiences within a range of these learning environments by giving special focus to what we can discover about the characteristics of students' motivational processes and how they contribute to what happens in the encounter between learner and virtual learning environment.

The specific approach we have taken to understanding learning in virtual environments can be illustrated by reference to a recent review of educational research technology. Winn (2002) identified four successive perspectives associated with the development of educational technology. The underlying theme for these perspectives has at its core the increasing sophistication of learning technologies. Early research according to Winn focused on learning content. Research questions were framed in terms of task analysis identifying effective instructional design. As more sophisticated presentation features were developed there was a shift to consideration of how format and individual student characteristics interact. Then development of media technologies that supported simulations heralded opportunities for vastly enhanced student control and more constructivist learning approaches. The latest stage has been the use of technological advances to generate learning environments that potentially can transcend limitations of time and space in what they offer to communities of learners. Seen in this way, the underlying theme associated with changes in learning environments is increasing sophistication of technology. However, learning does not take place without a learner, and although the learner is never absent in the perspectives presented by Winn, his analysis gives technological change center stage. While acknowledging the importance of the technological changes described by Winn, we will turn the spotlight onto the psychological processes, more particularly the motivational processes that color the relationship between learner and environment. In doing so we will identify how these relationships contribute to the quality of the learning outcome.

Our motivational perspective on virtual learning environments will take as its central tenet that if we wish to understand learning we need to consider the subjective experience of the learner (Hickey, 1997). Curiosity, interest, anxiety, and achievement goals are just some of the motivational processes that describe the interactive relationship between learner and learning environment. We will examine evidence on the effectiveness of virtual learning environments to identify where motivational processes are essential for the quality of learning outcomes.

1. MOTIVATION, LEARNING, AND ACHIEVEMENT

Questions about motivation arise from the selectivity of human behavior. At any given point in time every person is surrounded by a vast array of stimulation, some we notice, some we ignore, and some never impinge on our awareness. Every person also has a history that they bring with them to any new situation as a psychological organization incorporating values, interests, emotions, and attitudes. When two people are in the same situation what is novel and puzzling for one person may be familiar and valued, or familiar and trivial for others. Sometimes what is selected for attention and further investigation is a function of specific properties of the stimulus. At the simplest level this may be the brightest light, the strongest color, or maybe the loudest sound. Brightest, strongest, and loudest all imply appraisal of the selected stimulus relative to others that might have attracted attention. Sometimes what is selected and investigated is a function of personal expectation or valuing. Most people have at some time had their attention drawn away from their own conversation at a party or social event by hearing their name mentioned in a conversation across the room.

When the prominent or predictable in a virtual learning environment is ignored and a less predictable path chosen, the selectivity typical of human behavior becomes an especially critical issue invoked to understand learner behavior. Knowing how learners typically respond to particular properties of instructional experiences provides important knowledge that can be used to guide instructional design. What stimulus qualities prompt curiosity and interest, trigger specific achievement goals, or create anxiety? Of course this is only the typical pattern and individual learner characteristics can intervene and reduce the precision of predicted effects. There is also pattern within the personal factors that influence selectivity.

All of the major motivational dimensions associated with learning and achievement command a literature exploring situational triggers as well as a literature exploring individual differences. Sometimes these are framed as situational and individual perspectives and at other times as state and trait perspectives. As background to our review of the contribution of motivational processes in virtual learning environments, we will outline how both of these perspectives have been applied to some key motives associated with learning and achievement; namely curiosity, interest, achievement goals, and anxiety.

1.1. Curiosity

Curiosity refers to the motivational processes that result in a person approaching a novel situation. Probably the most well known of curiosity researchers is Berlyne, who found that the motive curiosity and its consequences, exploratory behavior, were associated with situations that were characterized by what he called *collative variability* (Berlyne, 1960; 1978). This referred to properties such as ambiguity, complexity, and incongruity. From his research findings we know that most people will approach novel situations that have high collative variability. They will then explore the situation to reduce the uncertainty generated by its ambiguity, its complexity, or its incongruity. From the perspective of individual or personal variability, a number of theorists (Beswick, 1971; Day, 1971) have proposed that there are also individual differences in the degree that people generally approach novel situations. For example, some individuals may have their curiosity aroused by a wide variety of novel situations, whereas for others there is a much narrower range of situations that arouse curiosity and result in exploratory behavior. Some may have their curiosity aroused by novel and puzzling situations that offer new knowledge and understanding, others by situations that offer new experiences and sensations (Ainley, 1987; 1998).

1.2. Interest

Interest is a related construct that has also been used to explain the impact of motivation on learning. Schiefele (1996) reviewed a number of studies that have quantified influences of interest on learning suggesting that about 10% of the variability in learning can be accounted for by interest factors. Maximize student interest in what is to be learned and typically learning will improve. The roles of both situational (Hidi, 1990; Hidi & Berndorff, 1998; Hidi & Harackiewicz, 2000) and individual interest (Krapp, 2002; Krapp et al., 1992) as they contribute to learning have been explored extensively. Recent studies have attempted to identify how both situational and individual factors together contribute to learning (Ainley et al., 2002a, b). These studies have shown that students bring to their learning well-developed individual interests and that simultaneously specific learning topics trigger different levels of interest. In addition they have explored some of the processes through which interest has its effect on learning. For example, positive effect is involved in maintaining students' engagement, thereby providing an opportunity for learning to occur.

1.3. Achievement Goals

Achievement goals refer to students' purposes in learning. Typical models refer to a range of specific purposes. On the one hand purpose can be defined as whether students want to master, to understand, or to improve competency (mastery or learning goals). Another purpose students have for their learning is to do well (performance goals). This may take the form of wanting public acknowledgement of achievement, of wanting to outperform peers, or to maintain face and "not appear dumb" in front of family or friends. At the other end of the spectrum, work avoidance goals indicate that students' purpose is to reduce learning to a minimum (Dweck, 1986; Elliot & Harackiewicz, 1996; Nicholls et al., 1985). The major emphasis in this research has been to consider the individual perspective, and achievement goals have been measured as personal orientations. Some research has adopted a situational perspective and has considered goals and purposes for learning that are salient in specific classroom environments (Ames, 1992; Ames & Archer, 1988). Most recently, research into the contribution of achievement goals to learning has expanded the focus to consider combinations of social and achievement goals represented. Every learning situation is also a social situation and so both sets of goals contribute to learning outcomes (Urdan & Maehr, 1995; Wentzel, 1992; 1999).

1.4. Anxiety

Undoubtedly the most widely known effects of motivation on learning have come from the literature on anxiety (Pekrun, 2000). The debilitating effects of anxiety on learning have been well documented. Equally well known is the inverted U-curve describing the relationship between anxiety and performance. Up to a point anxiety can improve learning. But as the level of anxiety gets higher the anxiety symptoms such as increased heart rate, or quickened breathing divert attention from the task and the quality of performance declines. When students experience a learning exercise as an easy task, anxiety focuses attention and facilitates performance. When experienced as a difficult task, anxiety is likely to interfere with performance. In the anxiety literature the situational perspective has been prominent through measurement of *state* anxiety and investigation of the relationships between state anxiety and performance. The individual perspective is represented in studies of *trait* anxiety, that is the degree to which individuals generally have a tendency to feel threat in a wide variety of situations (Spielberger & Krasner, 1988).

We have briefly sketched some prominent research directions in the study of motivation and learning. It is not exhaustive. What is critical for a consideration of the contribution of motivation in virtual learning environments is an acknowledgment that both situation and person contribute to the actual learning experience. Instructional design for virtual learning environments should be cognizant of the knowledge that has been generated from both situational and individual perspectives on motivation and learning. The learner perceives, appraises, and interacts with the virtual learning environment. In each of the processes that make up perception, appraisal, and interaction there is a contribution of both what is triggered in the person by the situation and what the selective processing of learners' personal psychological organization detects as salient.

2. STUDENT REACTIVITY TO ELECTRONIC LEARNING ENVIRONMENTS

The most common medium for accessing virtual learning environments is the personal computer. How students use computers and their attitudes toward the place of computers in education is critical to understanding student motivation and interactivity within virtual learning environments. One of the most recent studies shedding light on the extent of computer use amongst students in western industrialized countries is the OECD's Programme for International Student Assessment (PISA)[1]. Fifteen-year-old students were asked about their familiarity with computers as part of their learning environment. The questions consisted of self-assessments in response to items on interest in computers, attitudes and ability to work with computers, and use and experience with computers (OECD, 2001). Each self-report rating was made on a scale specifying response categories of "disagree", "disagree somewhat", "agree somewhat", and "agree". Summaries of these data for 16 OECD countries have been published and are informative for the insights they offer into national variations in access to computers.

While on average 60% of 15-year-olds in OECD countries use a computer at home almost every day, or at least a few times per week, there is considerable variability between countries. For example, this figure ranges from 21% in Mexico, 40% and 45% in Hungary and the Czech Republic, to more than 70% in Australia, Canada, Norway, and Sweden. In contrast, only 36% of students in this age group in OECD countries use a computer at school every day or at least a few times per week. Again there is considerable variability across countries, with proportions ranging from 15% in Germany to 55% or more in Denmark, Hungary, and the United Kingdom. Internet use across all OECD countries is high, with 42% of students on average using a computer for electronic communication almost every day or at least a few times per week, with school-related use high at 30%.

Analysis of the particular familiarity issues (interest, comfort, and perceived ability) across national samples demonstrates some of the complexity of students' responses to computers as learning environments. Patterns of familiarity are related to factors such as computer availability and school organization, and also reflect cultural beliefs and lifestyles that determine the amounts of time spent in work, school, and leisure by children and adolescents around the world (Larson & Verma, 1999).

The PISA (OECD, 2001) measure of student interest in using computers was based on responses to questions dealing with using computers for reasons of importance, fun, being interested, and involvement. Students' comfort and perceived ability with computers consisted of self-ratings on questions about specific tasks including writing a paper and taking a test. They were also asked to compare their own computer ability with what they thought to be the computer skills of the average 15-year-old. When these indices of students' responses to computers were considered in relation to measured reading achievement there was a positive association between interest in computers and reading literacy scores. The authors caution that this association does not allow interpretations of directional effects, nor does it allow for the operation of other factors such as socio-economic status. However, these data are available for closer inspection and some of the more detailed patterns within this general finding are particularly informative for understanding students' reactivity to electronically mediated learning environments. Students from Finland and from the U.S.A. demonstrated contrasting patterns. Overall, Finnish students scored lower than average across the OECD respondents for interest in computers and scored very high on the reading literacy index. For these students there was a negative association between interest in computers and literacy scores. In contrast, students from the U.S.A. reported the highest level of interest in computers coupled with a strong positive association between interest in computers and reading. Australian, New Zealand, and Canadian students whose reading levels were comparable showed only slight variations in reading literacy scores across the quartiles of interest ratings. Students from all three countries showed lower than average interest in computer scores. It is of note that for all three of these countries, the lower than average interest in computers index was coupled with high comfort and computer ability scores. Countries such as Germany, the Czech Republic, and Denmark, who also demonstrated little difference in the reading literacy scores across the four quartiles of interest in computers, showed a range from high interest (Germany), close to average interest (Czech Republic), and low interest (Denmark). Clearly the patterns of association between the various aspects of familiarity with electronically mediated learning environments and student achievements is complex and requires more understanding of how students within specific socio-cultural contexts are reacting to those learning environments. Most of the research that is reviewed in this chapter was conducted in countries where computer availability is high. Students are familiar with computers, are generally interested in them, and expect them to be part of their learning environment. The findings cannot necessarily be applied to students in countries where computer availability is low.

3. SITUATIONAL FACTORS INFLUENCING REACTIVITY TO VIRTUAL LEARNING ENVIRONMENTS

A widely used approach to evaluating the role of situational factors in virtual learning environments compares learning outcomes using some form of electronic instruction medium (e.g., CAI or Web) and traditional learning environments. A second approach directs attention to specific components within the learning environment supported by newer learning technologies and explores their effectiveness in terms of cognitive processing characteristics of the learner. Each specific component is tested for its contribution to learning in controlled experiments. A third approach focuses on the motivational conditions required for effective learning and from this perspective identifies features of virtual learning environments that optimize motivation. We will consider the contribution of each of these approaches in turn.

4. VIRTUAL AND TRADITIONAL LEARNING ENVIRONMENTS COMPARED

Virtual learning environments have commonly been evaluated by asking whether students' learning is enhanced when some form of electronic medium delivers that learning. The basic research design involves comparison of an electronic medium with some form of more traditional learning medium. Because of their longer history and the relative ease of implementing the experimental design, CAI learning environments have featured prominently in the large numbers of these studies reported over the last three decades. More recently results have been synthesized using meta-analysis. For example, one meta-analysis of studies involving secondary students (Christmann et al., 1997) indicated that overall there was a slight improvement in achievement associated with the CAI treatment groups. However, the size of this effect varied considerably. Of the studies that met their strict criteria for inclusion (i.e., a CAI treatment group compared with a traditional instruction group and the effect of the treatment on measured achievement outcomes reported), approximately half reported positive findings in favor of the CAI groups, some reported no difference, and others negative findings. Effect size varied across subject areas. The largest positive effect sizes were reported in studies concerned with science instruction and the largest negative effect sizes in studies concerned with English instruction. Two examples of this type of study will be detailed here to illustrate the findings and interpretations that are generated using this approach.

Using instructional material from a Biology course on reproduction in plants and animals, Soyibo and Hudson (2000) compared the pre- and post-instruction scores of Jamaican grade 11 students. One group of students had the typical lecture and discussion methods of instruction supplemented with access to commercially produced software called the *Virtual Body* (made by Time-life, IVI Publishing Inc., 1995). The attractive elements of this package for the teaching of animal reproduction were the attention given to issues of "learner control, feedback, interactivity, and flexibility". Other material that did not have strong interactivity features was used for the plant reproduction section of their course. At the end of the 4 weeks instructional period Soyibo and Hudson found that students in the *Vitual Body* experience group significantly outscored the control group. The outcome variable in this study was a score on a 30-item multiple-choice biology knowledge test. Studies of this general type have sometimes reported significant learning advantages for the virtual learning experience groups, sometimes no differences and sometimes negative results, although the latter might be expected to have more difficulty in getting published (Christmann et al., 1997). In other studies comparisons of learning outcomes across learning environments based on media allowing for a range of learner participation are reported. For example, Ricci and Beal (2002) compared children's story memory following use of interactive story software, narration (audio-only), and a television-like audio-visual. A second form of the interactive-computer story software consisted of a passive computer condition where the student "observed but did not control" the story. Measures of story memory following these four modes of presentation indicated that the audio-only group had the poorest performance, but there were no significant differences between memory response scores for the other three presentation modes.

In terms of the range of virtual learning environments available in the first decade of the 21st century these studies have investigated relatively simple learning environments. However, it is important to note that both studies go beyond the basic achievement findings and report aspects of students' reactivity to the learning experience. Soyibo and Hudson (2000) reported changes in students' attitudes to biology and to computer-aided instruction following their learning experience, and more importantly that the post-instruction attitudes to biology showed a "positive statistically significant but weak relationship" with the post-test biology achievement scores. Changes in students' responsiveness to both the medium of instruction and to the content of the instruction were reported. In the Ricci and Beal (2002) study, children's enjoyment ratings for the story were high and did not differ between any of the four media conditions. However, when all of the children reported their preferences across media types, there was a significant preference for computer-based media. Radio was least preferred.

The difficulty of comparing and synthesizing findings from these types of studies is compounded by a number of factors. As pointed out earlier, there are very different socio-cultural environments in which the students are located. Soyibo and Hudson's (2000) study was conducted in Jamaica in direct response to educational authority initiatives seeking to increase the low base of computer use in Jamaican primary and secondary schools. In contrast, Ricci and Beal (2002) described their school context as one where "computer access and use by children is becoming increasingly important, both at home and in school settings" (p.138). There are also complexities for interpretation and generalization of results from these studies associated with the age of the students. Ricci and Beal conducted their study with 6–7 year olds and suggested that the children were highly engaged with material no matter what the medium. Contrast this with the situation provoking a lot of studies like those of Soyibo and Hudson where the computerized instruction medium has been adopted in response to falling motivation for learning (generally dealing with adolescent/secondary or high school populations). In the latter, electronically mediated learning environments are often seen as a way of addressing issues of engagement and motivation.

On balance, comparisons between the effectiveness of learning using various forms of virtual learning environments and learning using more traditional methods have shown that virtual learning environments can produce higher learning outcomes. However, across the studies results are variable and often the interpretation of group differences has to be qualified with reference to the influence of students' interest, enjoyment, or attitudes. Motivational factors such as interest, enjoyment, and clear goals are important influences on students' responsiveness in virtual learning environments.

5. COMPONENTS OF VIRTUAL ENVIRONMENTS SUPPORTING LEARNING

A second way of assessing virtual learning environments is to focus on the key factors of the learning environment in relation to the cognitive abilities of the learner. In response to the large body of research comparing electronic and traditional learning environments, Mayer has argued that "the most important factor in producing cognitive outcomes is not the medium that is used but rather the quality of the instructional message" (Mayer, 1997: 7). Quality is determined by the way instruction is tuned to the cognitive processing capacities of student users. In this he is supported by a range of reviews directing attention to the characteristics of instructional materials as they facilitate or inhibit learning, rather than the more global approach that credits the medium *per se* as the facilitator of learning (Clark, 1994; Kozma, 1994a, b). The work of Mayer and his colleagues (Cordova & Lepper, 1996; Mautone & Mayer, 2001; Mayer, 1997; Mayer & Chandler, 2001; Mayer et al., 2002; Mayer et al., 1999; Mayer et al., 2000; Moreno & Mayer, 2002) has made a substantial contribution to this field. Their research program is built on insights from a number of contemporary theories about learning processes. For example, citing Wittrock's (1989) generative theory, Mayer argues that the learner is a constructor of knowledge, actively selecting from within the available information, building their own representation of the selected information, and then integrating it with their existing representational system. From Pavio's (1986) dual coding theory he points to the possibility that separate visual and verbal systems will be involved in the extraction of information from multimedia displays. All of this occurs within the constraints on the information processing system set by the capacity of short-term working memory (Chandler & Sweller, 1991). These and other theories of human information processing have been applied by Mayer and colleagues in their experiments evaluating the instructional potential of specific media components in multimedia learning environments.

In all Mayer's experiments, individual components of multimedia learning environments have been isolated to test their effects on two types of learning, retention and transfer. A relatively consistent picture has emerged showing that these two types of learning are differentially affected by the learner's experience with specific kinds of instructional components. The participants in many of these studies have been college-age students and they have been asked to learn concepts and principles from physical science. A number of these studies will be described in detail to illustrate the important features of this approach.

Interactivity is a key component of multimedia learning environments. Mayer and Chandler (2001) used narrated animation to assess the role of "simple interactivity" in the form of the learner being able to control the flow of the presentation. The experimental design involved narrated animation being presented to each student twice and incorporated different degrees of student control over the "pace of a narrated animation". Some students had a mixed experience. They controlled the pace for the first presentation but on the second presentation had no control over pace. For other students the order of these two experiences was reversed. Still other groups of students either controlled the pace for both presentations or had no control over the pace in either presentation. In this experiment there were two levels at which the effects of the medium of learning might operate: the actual processing of information during learning and the amount of information able to be retrieved. In terms of the processing of information, any learning exercise puts a certain level of cognitive load on students' working memory. Too much cognitive load on working memory interferes with learning. At the same time the structure of the learning exercise may facilitate or impede students' construction of a coherent mental model of the specific learning task. In many of Mayer's experiments the learning task consisted of explaining the formation of lightning (Mayer &

Chandler, 2001). Having control over the pace of the presentation promoted effective learning through matching the cognitive load of the presentation with the learner's pace of constructing their explanation of the formation of lightning. If simple user interactions lead to deeper understanding this would be indicated by higher scores on transfer tests for students who had control over the pace of presentation than those who did not. The results indicated that the order of control experiences was also important. When students controlled the pace on the first presentation and then passively viewed it on the second presentation, they performed better on the transfer test than students who controlled the pace on the second presentation after already experiencing the passive exposure.

In another experiment using similar learning material (Mayer et al., 1999), the effects of different combinations of narration and animation were tested (e.g., concurrent; narration before animation, animation after narration, narration and animation delivered in small or large bites). Here, an additional issue investigated was how the dual systems of visual and verbal materials are held and processed in limited capacity working memory. The concurrent and small successive bites groups outperformed the successive large bites group, thereby supporting a contiguity effect. These findings demonstrate how specific features of a multimedia environment influence learning (Mayer et al., 2001; Moreno & Mayer, 2002), and have contributed important principles that can be used to design effective multimedia learning environments.

The main contribution of this research has been identification of the specific cognitive processes through which components of the instructional environment impact on students' knowledge and understanding. For example, the cognitive load characteristics of the instructional contents will influence learning. Text and graphics presented together on a screen place more cognitive load on the learner than does text and narration. But the answers for effective instructional design are never simple. Although Mayer's research has demonstrated that contiguity of verbal and visual information in multimedia environments improves learning, it has also shown that individual learner characteristics matter. Students' prior knowledge of content and spatial abilities moderate the effects of the contiguity principle. When the learner has high levels of prior knowledge, contiguity is less important than when prior knowledge is low. Contiguity effects have more impact for learners who have strong spatial abilities than they do for learners who are less reliant on spatial abilities.

Alongside issues of cognitive load, Mayer draws on Wittrock's (1989) generative theory of learning which views the learner as a "knowledge constructor". This introduces into the learning equation differences in the degree that learners are able to select relevant information, and to organize and integrate it into a coherent model of the phenomenon to be explained. While all three sets of processes, selection, organization, and integration, are constrained by the cognitive abilities of the learner, motivational processes are also important.

The level of cognitive load represented by the instructional design can be set to match that of the learner, but, if the learner does not focus their attention on the computer screen, the selection will be less than optimal and the organization and integration processes that follow will be compromised. Factors that determine selectivity are clearly critical. Motivational processes such as learner interest in using computers, self-efficacy, or anxiety about using computers will influence attention and selectivity. In some of Mayer's experiments student interest has been included in the design (Mayer et al., 2000). At the end of the learning task students were asked to report how interesting they found the material. Differences in interest and learning between the experimental groups suggested that the groups reporting higher interest in the material were more likely to try to make sense of the material and to form a more coherent model.

Of special interest in this research has been the consistent finding of different outcomes according to the type of learning measure. Retention indices are not as sensitive as transfer measures. Constructivist theories of learning have been used to provide explanations for this difference in measured learning outcomes. Transfer learning requires deeper processing than retention of factual material. Deeper processing in this context represents making sense of and building a more coherent model that can be used to apply the critical concept or principle to new situations (transfer). The deeper processing that is associated with higher performance on the transfer measures of learning was also significantly related to motivational processes reflecting involvement or engagement with the learning environment (Mayer et al., 2000).

The important insight coming from all of this research is that instructional design of virtual learning environments requires a match between the design parameters and the cognitive capacities of target learners. At the same time this research points to critical role of the motivational processes, such as interest, that direct and sustain learning.

6. FEATURES OF ELECTRONIC LEARNING ENVIRONMENTS THAT OPTIMIZE MOTIVATION

A third approach to the situational factors associated with effective learning in electronic learning environments focuses on the motivational conditions required for effective learning in order to identify features that optimize motivation. A good example of this approach can be found in the research and writings of Lepper and colleagues (Cordova & Lepper, 1996; Lepper, 1985; Lepper & Gurtner, 1989).

In an early paper, Lepper (1985) defined a set of inter-related research issues that link the learner and the instructional possibilities of computer learning environments. He suggested that the design properties related to generating intrinsic motivation, the relationship between intrinsic motivation and instructional effectiveness, and identification of the different philosophies of instruction embodied in educational computer programs were key issues to be addressed. According to Lepper, the increased motivation so often claimed to be typical of students' response to educational software depended on what theorists generally referred to as intrinsic motivation. For some theorists this was described in terms of challenge, effectance, or mastery motivation. Other theories of intrinsic motivation refer to curiosity, complexity, incongruity, and discrepancy, while others refer to perceived control, self-determination, or factors such as fantasy involvement. Lepper argued that these distinct theoretical traditions could profitably work together in the context of understanding the determinants of intrinsic motivation and how this might be reflected in the design of instructional software. This direction was of course predicated on the assumption that the increased intrinsic motivation generated by new educational software would be associated with improved instructional effectiveness. Lepper argued that rather than being a necessary consequence of increased motivation, instructional effectiveness was likely to be bound up in the degree that the motivation-enhancing special effects were interdependent with the problems to be solved or the instructional content. On another occasion Lepper and Gurtner (1989) contrasted the positive expectations of computer enthusiasts with the cautious and suspicious concerns of those educators challenging the computer revolution in education. He predicted that given the variability within computer learning environments, instructional effectiveness will be as varied as the instructional programs themselves both in terms of their formal features and their incidental content. In particular, Lepper argued that the attention students pay to various aspects of the learning environment, how involved they become, and the learning strategies they use all impact on the cognitive outcomes resulting from the experience. Similarly, motivational consequences are likely to be shaped by factors such as students' learning goals, their level of intrinsic motivation, perceived competence, and self-efficacy.

These relationships have been tested in a number of experimental studies reported by Lepper and his colleagues. For example, Cordova and Lepper (1996) experimented with a number of forms of educational software designed for teaching arithmetical order-of-operation rules to fourth and fifth grade students. Specific features designed to enhance intrinsic motivation were incorporated into the separate software conditions that varied the degree to which the learning content was abstract, contextualized, or personally meaningful. The control group engaged in two unembellished computer-based learning games. For the experimental conditions, students received the same learning activities embedded in a fantasy context. The fantasy context was manipulated so that for half the students the fantasies were generic, while for the other half they were personalized on the basis of information elicited from the students at the start of the experiment.

Cordova and Lepper (1996) found significant differences in the motivation of these groups as evidenced by such indicators as their level of task involvement and the extent to which they chose more challenging versions of the game. Significantly higher learning scores were observed when the learning was embedded in the fantasy context, in the personalized context more than the generic context, and in the choice conditions more than the no-choice conditions. In a similar study, Mitchell (1993) identified how using computerized instruction in mathematics classes influenced specific motivational processes. Distinguishing between the initial reactions to the task and the continued interaction required for maximum learning, Mitchell found that the novel, electronic features of the computer presentation were effective in catching student interest. However, the instructional content needed to be involving and meaningful if it was going to maintain and hold students' attention.

Total immersion in an electronically mediated world that defines the reality within which the student can operate is a defining feature of virtual reality environments that separates these environments from other virtual learning environments. Again, issues of instructional design and learner reactivity need to be addressed when assessing the educational potential of these types of learning environments. Findings from the Project Science Space (George Mason University) help to illustrate the complexity of the interactive processes that need to be understood when using this form of virtual learning environment to achieve specific learning objectives (Salzman et al., 1999). The features of these environments that can increase motivation and contribute to greater learning include three-dimensional immersion, frames of reference (FORs) and multisensory cues (Salzman et al., 1999). Combinations of these features of virtual reality environments may also interact and add complexity to the structure of the learning environment. Specific learner characteristics that have been tested for their influence on the experience of virtual reality environments include gender, spatial ability, computer experience, concept domain experience, motion sickness history, and the individual's tolerance of the immersion experience. For example, NewtonWorld (NW) is a physics environment that has been designed to allow students to explore concepts that are often the substance of student misconceptions. One such misconception is that "motion implies force". In NW, the learner is in a corridor where they control the movement of balls of various masses. Additionally the student is able to "beam" between balls and cameras observing how the balls behave in relation to the surfaces of the room. As Salzman et al. explain:

> "In NW, we rely on sensorial immersion to enhance the saliency of important factors and relationships and to provide experiential referents against which learners can compare their intuitions. Learners can be 'inside' moving objects; this three-dimensional, egocentric frame of reference centres attention on velocity as a variable. Multisensory cues are used to further heighten the saliency of crucial factors such as force, energy and velocity.
>
> (Salzman et al., 1999: 298–299)

Observations of students' responses both to the experience in the virtual reality worlds and students' reports after their experiences indicated the importance of motivational factors. Being able to observe what was happening from multiple viewpoints (the FOR factor) as part of the learning experience was motivating for students.

In their analysis of the effects of their virtual reality environments Salzman et al. (1999) distinguish between the interaction experience (simulator sickness and usability) and the learning experience (immersion and motivation). They suggest that a positive interaction experience, a positive experience with the hardware and software interfaces is an important pre-condition for learning. These and similar experimental studies make an important contribution to an understanding of how specific design features of virtual learning environments enhance students' interest and engagement, and how they in turn are associated with stronger learning outcomes.

6.1. Virtual Learning Environments and the Experience of Flow

Another motivational variable that has recently received considerable attention from researchers working with virtual learning environments is Csikszentmihalyi's (1990) concept of "flow". Flow refers to an experience of intense emotional involvement, being completely involved in the activity for its own sake. "The ego falls away. Time flies." (Geirland, 1996). It is the state where the person feels so involved and committed to their current activity that they may not be conscious of their own level of effort and may lose all sense of time. The expanded opportunities for learner choice and control within electronically mediated environments have been interpreted as providing the ideal conditions for flow experiences. When asked about his views on the likelihood of web environments promoting flow experiences, Csikszentmihalyi contrasted a well-structured gourmet meal with cafeteria selection to highlight the need for instructional design in electronic learning environments. He is reported to have said:

> "A web site that promotes flow is like a gourmet meal. You start off with the appetizers, move on to the salads and entrees and build toward dessert. Unfortunately, most sites are built like a cafeteria. You pick whatever you want. That sounds good at first, but soon it doesn't matter what you choose to do . . . web site designers assume that the visitor already knows what to choose. That's not true".
>
> (Geirland, 1996)

In a recent study (Chen et al., 1999) web users were asked about flow experiences. Chen et al. found that the activities most likely to be associated with reports of flow experiences were information retrieval, communication, and interaction. Information retrieval activities were described as provoking challenge and providing feelings of enjoyment. Describing their experiences, students used terms such as "engrossment, exploration, excitement, timelessness" that are very similar to the experiences described in Csikszentmihalyi's (1990) work. From the questionnaire responses, Chen et al. were able to define a number of design factors associated with flow including the web user having clear goals and receiving immediate feedback. Like others using the flow framework, they reported that flow was more likely to be reported when there was a match between web-user skills and the challenges provided by the web environment. From these responses, Chen et al. suggested that design of web learning environments incorporate features that provide immediate feedback; clear rules to follow and goals to pursue; enough complexity which is not easily exhausted; creation of dynamic challenges not static ones (see Chen et al., 1999: 589).

Another study monitoring flow within a web learning environment used the experience sampling method (Csikszentmihaly & Larson, 1987) to collect students' reports of how they felt about a hypermedia learning exercise (Konradt & Sulz, 2001). At designated points in the learning exercise students reported their level of activation, affect, concentration, satisfaction, and motivation by completing experience sampling rating scales. Students were classified into four groups defined by their particular balance of challenge and skill for this task (flow: high challenge, high skills; anxiety: high challenge, low skills; apathy: low challenge, high skills; boredom: low challenge, low skills). Approximately one-third of the students met the flow criteria and this was the largest group. Clearly the hypermedia presentation had engaged a substantial number of the students. One limitation in the complex design of this study was the relatively small numbers of students for each of the hypermedia experience categories. There were only 60 students in total participating in the study. Comparisons between the learning outcomes were reported for the "flow" and the "apathy" groups. All three learning measures (content knowledge, structural knowledge, and transfer) showed higher performance for the "flow" group. Although in the predicted directions, these differences were not statistically significant.

The experience of "flow" and its contribution to learning in virtual learning environments is currently attracting researchers' interest (Pearce et al., 2005). With further refinement of measures and more robust designs this area promises to add substantially to our understanding of the processes whereby participation in virtual environments expands student learning.

6.2. Virtual Learning Environments as Social Environments

In the previous section it was argued that learner responsiveness was critical in any electronic or virtual learning environments. Much of the research we have cited has been seeking those forms of design that will maximize the likelihood that students will engage with, and be an active participant in, the learning environment. The literature on human–computer interaction makes liberal reference to “interactivity” as a major feature of technological environments that support constructivist learning. The response of one person to another person often initiates a chain of action and reaction that we call interaction or interactivity. Human responses in virtual environments can operate in a similar manner, the only difference being that the computer is taking on the role of responding partner. This is turn taking, or acting and reacting in a similar chaining sequence to what happens in human conversation or dialogue. Within the virtual environment there is some form of immediate response to the learner’s action. However, for effective learning to take place the learner must discern or make connections between their own actions and the responding activity in the virtual environment (Pearce & Ainley, 2002).

Recognition of the social character of learners and the influence this can have on the level of interactivity within virtual learning environments has found expression in a range of studies exploiting the potential of electronic learning environments to incorporate social experiences designed to heighten interactivity. Avatars or animated pedagogical agents (APAs) are now part of some significant electronic instructional projects (Lester et al., 2000). When computer users are asked about their reactions to computer-mediated characters their answers clearly indicate that interactions with electronic characters are treated as social interactions (Reeves & Nass, 1996). Some of the work emanating from the Intellimedia research group will be described to indicate how this approach contributes to our knowledge of learner motivation in virtual learning environments.

The designs for the APAs in Intellimedia projects are guided by both motivational and pedagogical considerations. Within the broader set of motivational processes, emotion has been identified as a key social process and so APAs are being constructed to both display and understand emotions (Lester et al., 2000). Student and agent together operate the learning environment. Students’ problem-solving activities drive the system. When the student is inactive for an extended time or when they are using poor problem-solving actions, the pedagogical agent comes in with actions and utterances designed to give direction and control of the problem-solving activities back to the student: “Engaging lifelike pedagogical agents that are visually expressive can clearly communicate problem-solving advice and simultaneously have a strong motivating effect on students” (Lester et al., 2000: 124). Early studies demonstrated that students found the agents with both animation and aural communication to be believable and reported that they found them encouraging and useful (Lester et al., 1997). Other researchers (Craig et al., 2002) have found that learning environments employing APAs with spoken narration result in better performance than where text-only or text with spoken narration are used, confirming the efficacy of realistic APAs for assisting learning. Similarly, Atkinson (2002) found that worked examples coupled with an APA programed to deliver instructions aurally was more effective at promoting learning than text-only examples without agents.

One feature of electronic learning environments that has both positive and negative implications is the wide range of possible paths that can be taken navigating that environment. The positive side has been linked with the motivating effects when students are in control and can make active decisions within the environment. The negative side of this is the possibility that students may be overwhelmed by anxiety as they experience uncertainty associated with both the range of choice available and lack of confidence in their own knowledge and abilities. Based on Vygotsky's social-constructivist approach to learning, contemporary advocates of discovery-based learning environments acknowledge the importance of providing structure or scaffolding for students' choices and decision-making. The APA provides the scaffolding by matching actions and utterances to students' current location in the problem-solving space. Experimental evaluation has shown positive effects on learning in a virtual learning environment with the support of an APA. Using a microworld called "Design-A-Plant" with its APA, Herman, the learning outcomes for students working with an APA version were compared with students having a version of the microworld with no-APA (Moreno et al., 2000). The no-APA group received text information on the screen equivalent to the content of the utterances made by Herman for the APA group. Measures of retention of factual information showed no difference between the two groups. However, both transfer and self-reports of motivation and interest showed significantly more understanding and stronger motivation and interest in the APA group. In the same set of studies it was shown that personalized dialogue was associated with higher transfer scores and stronger motivation ratings than was the same message communicated via a non-personalized monologue.

These research programs suggest that the APA is effective because it taps into motivational systems that the majority of learners bring with them to their learning. The virtual learning environment that includes some form of APA becomes a social situation thereby broadening the appeal to include social as well as cognitive processes. Numbers of students whose interest is not triggered by the cognitive content of the task, or students who are only mildly interested are still likely to respond to the "person" who is communicating directly with them. However, further research is needed to understand these social processes and how they might best be used to maximize student engagement.

Providing conditions that maximize interactivity through the use of social agents or personalization techniques taps into the motivational systems that learners bring with them to their learning. On the indication of these current findings this should be a very fruitful area for further investigation.

6.3. Virtual Learning Environments and Communities of Learners

The importance of the social context supporting learning is also a key feature of instructional programs that are designed to build communities of learners. Classrooms of students working together become communities of inquiry. This means that students are provided with a learning environment that encourages them to construct knowledge and understanding through posing questions, reacting to questions and ideas generated by other students, and reflecting on their ideas, knowledge and understanding. The central character of this process of asking questions, knowledge construction and reflection is to make thinking visible. It is the potential of virtual learning environments to facilitate making thinking visible, and to use collaborative environments to scaffold the development of shared knowledge, that has encouraged a number of researchers to investigate patterns of knowledge construction within communities of learners (Bransford et al., 1999; Koschmann, 1996). One well-known virtual learning environment developed to facilitate communities of learners is the Knowledge Forum formerly known as CSILE (Scardamalia & Bereiter, 1994). The Knowledge Forum environment involves construction of a conferencing system and database by means of networked computer software. Designed to build a reflective thinking approach to knowledge construction this system is based on principles whereby learning is modeled and scaffolded. Individual thinking is cast into the shared language of the community of inquiry and the technology provides a structure for the sharing and development of ideas. Students are encouraged to express their ideas and questions, respond to the ideas and questions of their fellow students, and to develop these experiences into shared understandings. The technology has been designed to mediate the sharing of ideas and so allows this to occur across local environments as well as across time and space. Reports of student learning in such communities describe the gains made by students as they develop skill in knowledge building processes (Goldman et al., 2003). The social character of students' experiences as a member of a community of learners provides an important source of motivation and this is reflected in their attitudes and participation, their willingness to contribute ideas. However, as was the case with our knowledge of the effectiveness of APAs, the motivational processes that are connected with these learning outcomes and attitudes are implicit in the observations made by researchers of collaborative learning communities but are yet to be researched extensively.

> For whatever reasons, the electronic venue seems to call forth more informative comments than students make in the context of face-to-face, whole-class and small-group discussions . . . Perhaps the electronic environment seems less test-like to them. Perhaps it is being part of a community engaged in the same activity. Perhaps it is the ability to see

> their own responses in relation to those of their peers. These are empirical issues that bear further investigation as we continue to explore the value of electronic environments of the KF variety.
>
> (Goldman et al., 2003: 279)

While situational factors such as features of the environment, the opportunity for social interaction and experiences of flow clearly influence reactivity to virtual learning environments, a comprehensive appreciation of the possibilities of virtual learning environments requires consideration of both person and situation. What students bring to their learning in terms of characteristic ways of responding to the mode and contents of learning environments, also needs to be the subject of close investigation so that virtual reality environments can support effective learning.

7. INDIVIDUAL FACTORS INFLUENCING REACTIVITY TO VIRTUAL LEARNING ENVIRONMENTS

Both situational and individual factors impact on learning in virtual environments. However, a significant and not yet well-understood issue concerns the complex ways these individual and situational factors interact. This has been the subject of considerable debate in a number of areas of psychological theory. For example, one of the major challenges to the use of personality theories to predict behavior has been the claim that there is insufficient cross-situational stability to justify their use (Mischel, 1973). More recently Mischel and Shoda (1995) have suggested that it is not a question of either personality or situation (cross-situational consistency or situational variability), but rather how these two perspectives play out in human behavior. They suggest a more productive approach is to view personality "as a stable system that mediates how the individual selects, construes, and processes social information and generates social behaviors" (p. 246). What the person brings to the situation in the form of their relatively enduring patterns of expectancies, goals, and plans makes it more likely that certain aspects of situations are salient. These salient aspects are in turn more likely to be selected for attention and appraised in ways consistent with those relatively enduring patterns of expectancies, goals, and plans. It is also true that situations vary in the degree that specific characteristics have immediate salience. For example, when considered from the perspectives of trait and state (person and situation), Pintrich (2000) argued that achievement goal orientations involve schema or cognitive representations of what individuals would like to achieve. These may show both intra-individual stability and contextual sensitivity. The relative strength of situational cues and the accessibility of specific goal schema will influence actual behavior. "Strong contexts can overwhelm chronically accessible traits, but in the absence of strong cues in the environment, then traits may influence behavior more." (Pintrich, 2000: 102) In this way it becomes possible simultaneously to account for the contribution of qualities of the underlying personality and the predictable variability across situations.

Mischel and Shoda (1995) were addressing issues of person and situation from the perspective of social psychological research. However, the same issues offer important insights into students' responsiveness to a variety of learning environments, including virtual learning environments. Situations may have features that by virtue of their intrinsic character are compelling for most learners. The type of research conducted by Mayer and his colleagues (Mayer, 1997; Mayer & Chandler, 2001), described in detail already, is predicated on the assumption that some characteristics of virtual learning environments will have similar impacts on most learners. Knowledge of these characteristics can then be used to inform instructional design. In addition, learners have personal motive systems and organized networks of schemas and effects that may be salient or require specific situational cues to bring them into prominence.

Some of the investigations into the effects of achievement goals on learning in virtual environments illustrate these patterns of relationships. A group of 11th and 12th grade students used the RiverWeb Water Quality Simulator (Azevedo et al., 2002) to learn about ecological systems and water quality. RiverWeb is a simulation that presents a wide range of scientific data on water systems and water quality. Students engage in a "simulated field trip through a prototypical watershed" and are able to explore the effects of a range of land uses on water quality. The exercise continued over 3 weeks. Students were randomly assigned to two instructional conditions; learner-generated goals or teacher-generated goals. In the learner-generated goals condition the broad goals of the whole learning exercise were presented and within this framework students were free to set their own specific goals. In the teacher-generated goals condition students followed a plan of goals determined by the teacher. Azevedo et al., monitored students' knowledge and understanding across the course of this curriculum exercise, and found that the performance of both groups improved. However, the group which was able to generate their own specific learning goals showed a greater shift in their mental models of how ecological systems operate. Consider what is likely to have happened in these learning environments in terms of the interaction between person and situation. In this experiment the situation has set specific limits on the goal-setting procedure. Students' purposes for their learning in the teacher-generated goal group were tightly controlled by the situation. For the learner-generated goal group the situation defined certain general purposes but within that framework students' own purposes in learning could be expressed. It might be expected that students with similar levels of mastery goals who are assigned to different conditions would be expected to have very different learning experiences and, in consequence, achieve different learning outcomes. What is especially important about the experience and learning for the learner-generated goal group is that it highlights one process whereby the personal and the situational combine. Personal achievement goals were mediated by situational affordances.

In another study (Pearce & Ainley, 2002), first year undergraduate students used a web-based instructional unit designed for exploring the physics of waves. Students' achievement goal orientations as well as some specific reactions to the learning task were recorded on-line. It was reported that after allowing for differences in prior physics knowledge, students with higher mastery goal orientation scores (wanting to understand and improve competence) were likely to report higher levels of interest in this specific topic and were more likely to choose interactive options within the program. When this was related to performance on test questions that involved application of the physics principle to a new situation, the effects of mastery goal orientation were mediated by interest in the topic. Situational cues that triggered interest brought into play students' more general purposes for their learning. The framework illustrated above for achievement goals can also be applied to other motivational constructs. In some recent work investigating dimensions of student interest through responsiveness to text materials accessed through an interactive learning task, the relationship between students' curiosity as a personal variable and interest triggered by specific popular text material was mediated by individual interest (Richardson, 2002).

Key to the connection between the situation and the person is the learner's perception of the learning situation and their perception of themselves as learners (Boekaerts, 1996). For the educator or the instructional designer this requires appreciation of the range of learners' subjective experience, their appraisals of the situation, and the specific self-schema activated or made salient by the appraisal process. The active psychological state draws on both person and context and the question is to identify within particular virtual learning environments the critical form(s) of interdependence between person and situation that occur. The quality of subjective experience is not just an outcome of personality characteristics, it is also a function of the situation as perceived and interpreted by the student.

8. GENDER AND VIRTUAL LEARNING ENVIRONMENTS

Gender is a factor that has been implicated in a wide range of educational outcomes and continues to provide important insights into educational processes (Wigfield & Eccles, 2000). Many of the investigations that have sought to understand why gender is such an important factor have suggested that gender represents critical dimensions of individual's understanding of themselves. This has been documented in terms of teachers' attitudes and perceptions of their students. Students also report differences in attitudes and behavior associated with gender and are aware of specific expectations and pressures associated with these gender differences (Holden, 2002). Patterns of attitudes and actions associated with gender can be understood in terms of the self-understandings or self-schema that have been developed through both the child's biological makeup and their social and cultural experiences (Fivush, 1998). It is not surprising to find similar gender differences when students' attitudes and behavior in virtual learning environments are considered. For example, computer games have always been consumed more avidly by boys than girls (Subrahmanyam et al., 2002).

A recent investigation into the relationship between using a home computer and students' educational use of information technology (Selwyn, 1998) with a sample of 16- to 19-year-olds reported that more positive attitudes were associated with use of a computer at home. In this sample, young men were significantly more likely to have a computer at home than were their female peers. In addition, those young women who did have a computer at home were likely to use it less frequently. Patterns of ownership and use can clearly be shown to be linked to gender. However, there is some evidence that these gender patterns may also be age related. For example, Bergin et al. (1993) reported that this gender bias is "mild or non-existent in pre-school and kindergarten" (p. 438). They argue that gender differences reported with older children represent a personal self-concept of ability focused on computers. This argument is analogous to the self-concept of ability processes that have been shown to account for gender differences in subjects such as maths and science (Dickhauser & Stiensmeier-Pelster, 2002; Wigfield & Eccles, 2000). The psychological process mechanisms here are very similar to what we have described above in terms of person and situation. The personal or self-schema concerned with self-concept of ability incorporated motivational dimensions concerned with success and failure expectations and value dimensions. These self-schema are activated in virtual learning environments and influence the specific learning behavior. A substantial part of what has been studied as computer anxiety, again often observed along gender lines, involves the expectations of failure and threat made salient by the virtual learning environment. A recent study of children from 5 to 12 years of age (Downes, 2002) involved detailed observation of the way children used computers at home and at school. Downes suggested that the development of familiarity with computers was a motivational issue, and drawing on Dewey's writings referred to his concepts of "playful seriousness and serious play". Home use of computers was more likely to show patterns of shifting focus from play to work back to play and so students were able to "complete purposeful tasks through playful means". This blurring of the lines between play and work in home use of computers was in strong contrast to the patterns of use these same children experienced within their school classrooms. Classroom computer use was generally teacher directed and the content of computer experiences predominantly directed to achieving specific criteria in what are referred to as "key learning areas". These experiences while of interest in themselves, also contribute to the development of the self-schema, or self-concept of ability that will be activated in succeeding computer experiences (Downes, 2002).

In this brief, and by no means exhaustive, review of factors influencing students' reactions to virtual learning environments, we have attempted to highlight the importance of considering the impact of both situational and individual factors. Comparisons of the learning outcomes resulting from various forms of virtual learning environments and more traditional methods have generally shown that virtual learning environments can produce higher learning outcomes. But it is also clear that motivational factors also influence learning outcomes. Research findings point to the critical role of motivational processes, such as interest, to direct and sustain learning, and demonstrate how specific design features of virtual learning environments can enhance students' interest and engagement and produce stronger learning outcomes. However, the social character of learners and the influence this can have on the level of interactivity within virtual learning environments also needs to be taken into account.

While the research findings to date allow us to paint a broad picture of the effectiveness of virtual learning environments in comparison to traditional learning situations, there is still much work to be done. Research paradigms that emphasize the real-time reactivity of students to features of the learning environment have the potential to add considerably to our understanding of students' reactions to learning environments. Just as educators have been innovative in their use of the new technologies, so too researchers are beginning to utilize the functionality available in virtual learning environments to provide important insights into learning not easily obtained in more traditional settings. Future work in this area needs to ensure that the critical role of individual and situational factors discussed in this chapter continue to be acknowledged so that the human aspect of virtual learning environments is not lost.

ENDNOTE

1. These questions were an "international option". Twenty of the 32 countries participating in PISA 2000 took this option.

1. INTRODUCTION

In the increasing heterogeneous student population in both the academic and corporate training environments, the need of a customized instructional design is becoming more and more obvious. There are a variety of factors, including the past experience, cognitive abilities, and personal preference, that could influence the knowledge transfer, acquisition, and construction during the learning process.

The ideal learning environment described by Gilbert and Han (1999) consists of many (or more exactly "infinite") instructors, each having their unique teaching styles, available for every learners where the learners could choose the instructor that perfectly matches their own learning styles. Forbus and Feltovich (2001) even added that the instructors or assistants should be at every learner's elbow whenever they are ready to learn, and for however long it takes. Aptitude-Treatment Interaction theory (Cronbach & Snow, 1989) also suggests that the best learning results when the instruction matches the learner's aptitude.

Virtual learning environments (VLEs), which are defined in the context of our research as sets of computer/internet-based tools created to enhance learners' learning experiences, attempt to provide individualized instruction by means of customizing the domain content and appearance of the learning environment, hence matching the instruction to the learner's attributes. In the VLEs, customization could be within users' control (adaptable), or achieved without users' intervention (adaptive). Nonetheless, the generalized term "adaptivity" supersedes both of them and is used to cover the idea in the following discussion. Systems equipped with adaptivity have been proven more effective and efficient than traditional non-adaptive systems (De Bra et al., 1999). Sampson et al. (2002) provide an extensive discussion and examples of VLEs that are built with the idea of adaptivity.

Most of the recent VLEs have been implemented as adaptive hypermedia systems due to the widespread use of internet as a medium of learning. The adaptive techniques used in such systems can be categorized into either adaptive navigational support or adaptive content presentation (Brusilovsky et al.,

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 395–424.

1998). Adaptive navigational support works at the link level and is usually implemented as visual cues attached to links to express suggestions. On the other hand, the adaptive content presentation works at the (learning) content level and tailor the presentation of information according to learners' competence level, preferences, goals, and so on.

One of the most important components in an adaptive VLE is the student model. Attributes of students are collected, analyzed, and stored in student models. Most student models focus on students' competence levels (hence called competence models), and they are implemented either as state models (Staff, 2001) or as process model (El-Sheikh & Sticklen, 1998). However, there is a growing consensus of student (user) modeling community that modeling competence alone could not provide sufficient adaptative ability that a VLE should have in an increasingly heterogeneous demography of the learners (Lovett et al., 2000).

We, therefore, introduce a new and complementary approach to student modeling, called the cognitive trait model (CTM). CTM is concentrated on those student attributes (cognitive traits) that are persistent for a long duration, and consistent for a variety of tasks. The role of CTM is not to replace existing competence models but to supplement in order to provide fine-grained adaptivity. We shall examine the existing adaptation techniques that rely on the student modeling, and then describe how CTM provides a more efficient and reliable way to achieve them.

2. ADAPTATION IN VIRTUAL LEARNING ENVIRONMENTS

The adaptive characteristics improve the usability of the VLEs. Without adaptivity, these environments would present the same material, with the same set of links, to all learners. It could work well if the intended user group has the same/similar learning characteristics, but it is rarely the case in real learning environment. Without adaptivity, such systems will mimic the traditional classroom, with one-to-many interaction.

Adaptive VLEs, with the ability to change the content or structure of the links according to the student's need, provide similar situation as there are many instructors available for each individual student, "the learner's chances of doing well in this classroom would appear to be significantly better than in a classroom with one instructor because each learner would adapt to the instructor(s) that would facilitate his/her learning style" (Gilbert & Han, 1999). Inclusion of adaptivity makes these systems more usable and suitable for a wider range of users. Brusilovsky et al. (1998) further distinguished two categories of features that could be adapted in VLEs: navigational adaptation and content adaptation.

Navigational adaptation focuses on building a sensible navigational path for every individual student. It supports the learning process by providing a customized learning space for each learner. Adaptive navigation plays a supportive role and provides suggestions on how to go through the learning materials in a way that could suit the student's learning style. This is often accomplished by providing guidance on the available paths in a manner that is both pedagogically sound and customized to each individual student.

Content adaptation tailors the learning content, which is to be presented to the learner, according to the learner's current requirements and domain competence. "There is considerable evidence that different people learn best in different ways" (Kay & Kummerfeld, 1994). This means that it is very unlikely that one presentation style could suit to all students. To fully utilize the advantage of adaptive presentation, the systems need to (Pascoe & Sallis, 1998):

- provide supplementary material for background areas to those students whose background knowledge is below what is presumed by the instructor;
- provide different styles of documentation for the definitions/concepts; and
- give answers to the exercises using clearly identifiable supplementary material, so the students can be directed to clarify their misunderstandings.

Most of the research efforts on adaptivity in VLEs have focused on demonstrating the usefulness of technology in providing the adaptivity. However, most of the implementations lack the theoretical background of how the adaptivity should support the learners' cognitive processes during learning. As a result, combinatorial use of these techniques has not provided consistent benefits to the learners. All adaptivity techniques have their strengths and weaknesses, and they do not identify with each other as a mean to support learning process (Kashihara et al., 2000).

Exploration Space Control (ESC) tries to integrate and reorganize existing adaptive techniques and to offer the best result of adaptivity by combining both the adaptive content and the adaptive navigational support (Kashihara et al., 2000). We shall first discuss the theoretical structure of ESC and its formalization and then describe the CTM that uses ESC as its underlying theoretical framework.

3. EXPLORATION SPACE CONTROL

Exploration is a self-directed process and is an effective way of learning (Carroll et al., 1985). Exploratory learning, which involves searching the information, navigation through the learning space, understanding of domain-related conceptual knowledge and acquiring skills, often require high cognitive effort on the part of the learner.

ESC is a theoretical framework to support exploratory learning in multimedia-based educational systems by allowing students to explore/ acquire domain concepts and skills with less cognitive load as possible (Kashihara et al., 2000).

ESC attempts to limit the learning space, called exploration space, to control the students' cognitive load at an adequate level depending on their learning approaches. ESC tries to facilitate adequate learning for a whole spectrum of learning competence by adopting two extreme approaches—active learning support and step-by-step learning support.

Active learning support offers the initial learning space as wide as possible using only those restrictions that are required to protect the students from cognitive overload, and adding or removing restrictions according to students' progresses. This approach fits the students with better competence level and with more familiarity and experiences of the domain; for example, those who come back for further education after working in an area related to the domain.

The step-by-step learning support adopts the opposite approach from active learning support by starting with as restricted information space as possible and then gradually enlarging. This approach provides a sense of comfort and security for those who are completely new to the domain area or do not have active learning styles. By the combination of these two approaches, "ESC can be employed to facilitate proper learning for all types of learners" (Kashihara et al., 2000).

The main concept of ESC is control; to control the available learning space by adaptive navigation and to control the presentation of the learning content by adaptive presentation. The most important reason for the control is to try to give the student the most suitable instructional style to achieve the best results. Several types of control are proposed by ESC at different aspects:

1. *Embedded information:* Information sources (e.g., different text fragments) are selected by according to individual student needs and used by the process of scaffolding to create the information space.
2. *Limiting information resources:* The selection of information resources has great effect on what the student is going to see and interact with. Multimedia resources that suit the student's learning style and integrated with consideration of student's cognitive ability yields the best result.
3. *Limiting exploration paths:* ESC supports the use of navigational adaptation to offer the suitable paths in the learning space. This ensures that the students are not discouraged by the complexity of the entire learning space and do not receive the material that is not appropriate for them at this stage of learning process.
4. *Limiting information to be presented*: When the information includes many media resources and/or is available in large amounts, care has to

be taken on how to present it in order to achieve the best effect. More information does not mean better understanding; sometimes it is a burden on the students. For example, textual explanation that matches the abstractness and granularity currently appropriate for a student may produce better learning result than flashy multimedia presentation. Therefore, all information resources are to be filtered and only the necessary ones to be presented.

The aim for those different controls is to avoid overloading the cognitive capacity of the students as this might greatly discourage them. By carefully adjusting those controls, it allows a student to progress in his/her own pace in a way that the learning satisfaction is obtained and thus the learning efficiency and effectiveness ensue. When the students start to engage in their learning more actively, the levels of the controls are gradually reduced in order to allow the learning to be maximized.

4. EXPLORATION SPACE CONTROL ELEMENTS

Exploration space control elements (ESCEs) are those gauges on both the learning content and the navigational paths that could be modified to create different versions of the same materials to suit different needs. Therefore, the selection of the ESCEs has to cover both the content and the navigation. Table 1 attempts to list some examples of these gauges.

There are two elements for the path: the number of the path and the relevance of the path. Since most of the modern adaptive VLEs are built using hypermedia technology, paths are presented as a series of links. Therefore, the term link and path will be used interchangeably in the discussion.

There are six types of navigational paths identified by Kinshuk et al. (1999) as listed in Table 2.

Links with higher relevancy are links to the concepts that are closely related to the domain (direct successor, fine-grained links), while the links with lower relevancy are to the concepts that are more of supplementary nature (excursion links).

Table 1. Exploration space control elements

Path	Number
	Relevance
Content	Amount (detail)
	Concreteness
	Structureness
Info resource	Number

Table 2. Types of link and their relevance to the domain

Types of Link	Relevance to the Domain
Direct successor link	
Fine-grained link	
Glossary link	
Problem link	
Parallel concept link	
Excursion link	

The category of path (Table 1) covers both the number of paths and their relevance. The number of paths represents the amount of links to be presented to the students and the relevance of paths guides how relevant the linked targets should be and also determines the proportions of link types (Table 2) included.

In Table 1, there are three ESCEs on content; the amount/detail, the concreteness, and the structureness. Amount/detail of content decides how detailed the knowledge presentation is. The detailness affects the volume of the presentation; therefore, both of them are classified as only one ESCE.

The concreteness determines the abstract level of the information. The more concrete a piece of information is the more fundamentals and more examples it should include. Abstraction refers to the opposite of the concreteness.

The structureness of information indicates the ordering, arrangement, and sequencing of the information presented as a series/set of concepts. Concepts may or may not be directly or indirectly related to each other with certain sequence. The elaboration theory (Reigeluth, 1992) suggested a structured approach by stating that the instruction should be organized in increasing order of complexity for optimal learning. The more structured the information is the more orderly fashion it could be presented in. Structured information helps the learner in building up the mental model, but provides less freedom for free navigation.

Another category in Table 1 is information resource (shortened as Info resource). Information could be presented by different media, such as text, audio, visual, and so on. The effect of each media for presenting information is different. "Audio is good to stimulate imagination, video clips for action information, text to convey details whereas diagrams are good to convey ideas" (Kinshuk et al., 1999). Besides, each media type has different impact on each individual's learning. If there is more than one media (e.g., a textual explanation and a chart), it could make the information more impressive and easier for future recall. The greater the number of information resources, the more choices the system has for selection to suit the students' characteristics.

The formalization of ESC provides practical guidelines for producing VLEs that provide the facility of adaptivity, and at the same time adhere to the principle of human cognition base of the framework of ESC. In the next section, we shall discuss the formalization process of ESC.

5. EXPLORATION SPACE CONTROL FORMALIZATION

Exploration Space Control Formalization (ESCF) provides guidelines on how to utilize the ESC framework to assist learning process in VLEs (Lin, 2002). The aim of ESCF is to provide a welding mould where the courseware content can be just cast in and the benefits of adaptivity could be ensured. ESCF matches the levels of control (size of exploration space, difficulty, etc.) with the differences of each student's learning abilities. Various cognitive traits (CTs) have been selected from the literature on human cognition, various characteristics of each of the selected trait are identified, and various control levels of ESC are then adapted to those traits to suit the individual's differences.

6. THE SELECTION OF COGNITIVE TRAITS

Certain human learning abilities are derived from the aggregation of a group of lower-level abilities. Cognitive load is a good example. Cognitive load is an important factor in human learning, and its implication in learning environment has received intense discussion (Kashihara et al., 2000; Kinshuk et al., 1999). But the function and the ability of cognitive load can be broken down into even subtler elements. Students with higher cognitive load learn faster and have better comprehension. The speed of learning is also related to how fast the human brain processes the incoming information (information processing speed), the ability to integrate the new knowledge into existing one (associative learning skill), and the ability to work out the underlying rules of the presented information (inductive reasoning skill). The comprehension is also closely linked with associative learning skills, inductive learning skills, working memory, and also the ability to reflect on what was learnt, and determine whether the previous perceptions were correct or not (reflectivity).

Besides, with higher cognitive load, someone can easily reduce the load on his/her working memory by constructing a learning strategy, which represent higher-order rules and can generate other rules/data from it (Scandura, 1973). For example, some people remember the series of numbers (such as telephone numbers) by remembering the sequence of the positions of the number pad, while someone good in music could remember it as a series of pitches of sound; many others will probably have to look up the phone book and dial the numbers many times just to remember them.

The cognitive load consists of the function of information processing ability (Brown & Hirst, 1983), the inductive and associative learning skills (William, 2001), and determines the load of the working memory and thus its efficiency (Anderson, 1983). Therefore, it could be said that the cognitive load is in the higher level of the ability hierarchy than those of information processing speed, inductive reasoning skill, associative reasoning skill, and working memory capacity. For the purpose of this discussion, we need to consider the learning ability as the most elementary and basic in order to identify clear matches and relationships of the learning abilities to the curriculum designs. Therefore, the definition of CT here is the lowest-level element, in the ability hierarchy, of the current concern which is the study of the relationship and proportion of presentation elements to the learner's basic cognitive ability. The cognitivist view of learning, which posits that knowledge is represented as mental schema and learning is the process of reorganizing the schema, is adopted here and the term "trait" denotes the characteristic of the abilities that is relatively persistent in time and consistent across domains.

Unlike the knowledge or expertise, which is more domain-specific and evolving, CTs are relatively stable and portable over different tasks. Thus, the student model obtained in one domain can provide more reliable prediction of the performance the same student will have in another domain. Differences of CTs cause differences in quality, efficiency, and overall performance on the tasks carried out. Four CTs were selected from the cognitive science literature as the basis of cognitive load, as discussed above: working memory capacity, inductive reasoning ability, information processing speed, and associative learning skill.

7. WORKING MEMORY CAPACITY

Working memory is the cognitive system that allows us to keep active a limited amount of information (roughly 7 ± 2 items) for a brief period of time (Miller, 1956) to temporarily store the outcomes of intermediate computations during solving a problem and to perform further computations on these temporary outcomes (Baddeley, 1986). The research on working memory (Huai, 2000; Kearsley, 2001) shows that the speed of learning, the memorization of learned concepts, effectiveness of skill acquisition, and many other learning abilities are all affected by the capacity of working memory, which is mainly comprised of two components; the limited storage system and the central execution unit carrying out the cognitive operation efforts.

There are already many educational system design guidelines, written by human–computer interaction (HCI) experts, devoted to address the relationship between the storage aspect of the working memory and the good interface designs. The effort to facilitate learning with regard to working memory is mainly focused on the instructional design to assist the synchronized operation with the central execution unit by assisting the formation of higher-order rules, build up of the mental model, and of course not to overload the storage system of the working memory. The working memory is analyzed in the following with respect to learning.

7.1. When the Working Memory Capacity of the Learner is Low

The number of paths and the amount of information should decrease to protect the learners from getting lost in the vast amount the information, from overloading the working memory with complex hyperspace structure (Kashihara et al., 2000), and to allow more time for learner to review essential content if necessary. The relevance of the information should increase so the learners get the important information. The concreteness of the information should increase so the learner can grasp the fundamental rules first and use them to generate higher-order rules as suggested by the structured learning theory (Scandura, 1973). The structure of the information should stay unchanged. The increase of structureness could facilitate the building of mental model and assist future recall of the learned information. But as Huai (2000) indicated, the versatile learners tend to have smaller short-term memory (storage aspect of working memory) than serial learners, and the increase of structureness limits their navigational freedom, which is the primary way they learn. So basically, the net effect cancels out and the structure of the information is recommended to stay unchanged. The number of the information resources should increase, so the learners could choose the media resources that work best along their cognitive styles and allow deeper understanding on the subject domain (Craik & Lockhart, 1972; Cronbach & Snow, 1989).

7.2. When the Working Memory Capacity of the Learner is High

The number of paths and the amount of information should increase and the relevance of the information should decrease to enlarge the exploration and domain space of the learning process so that more knowledge is available to the learners who process more higher-order rules which "account for creative behaviour (unanticipated outcomes) as well as the ability to solve complex problems by making it possible to generate (learn) new rules" (Kearsley, 2001). The concreteness of the information should decrease to avoid boredom for the learners resulting from too many similar examples. The structure of the information and the number of information resources should stay unchanged because there are no direct and apparent benefits associated.

The above discussion can be formalized as shown in Table 3.

Table 3. Working memory formalization

Level	Path		Content		Info Resource	
	Number	**Relevance**	**Amount**	**Concreteness**	**Structure**	**Number**
Low	−	+	−	+	\	+
High	\+	\−	+	−	\	\

Note: +, should increase; −, should decrease; \+, should slightly increase (recommend only) or could increase; \−, should slightly decrease (recommend only) or could decrease.

For example, Table 3 suggested that the number of paths (navigational link) should decrease while the learner's working memory is identified low.

8. INDUCTIVE REASONING SKILL

Induction is to figure out the rules/theories/principles from observed instances of event. William (2001) described it as "inductive reasoning works the other way (from deduction), moving from specific observations to broader generalizations and theories". It is a bottom-up approach and has an open-ended and exploratory nature.

The research on inductive reasoning skill (Heit, 2000; William, 2001) shows that higher the inductive reasoning ability, the easier it is to build up the mental model of the information learned. Mental model, also called cognitive structure, "provides meaning and organization to experiences and allows the individual to go beyond the information given" (Kearsley, 1998). From the constructivist's point of view, the learner's selection and transformation of information, constructs, hypotheses, and the decision process, all rely on the mental model (Bruner, 1973). For students who possess better inductive reasoning skill, it is easier for them to recognize a previously known pattern, generalize higher-order rules and, as a result, the load on working memory is reduced, and learning process is more efficient. For its educational value, there is a need to specify means to support those with lower inductive reasoning skill and to maximize the learning for those who are already good at induction. The following discussion analyzes the effect of poor and good inductive reasoning skill on the learning process.

8.1. When the Learner's Inductive Reasoning Skill is Poor

The number of paths should increase to give the learner more opportunity for observation and thus promote induction. The relevance of paths should decrease and the concreteness of the information should increase so the learner can have more diverse observations to promote induction. The amount of

Table 4. Inductive reasoning skill formalization

Level	Path		Content		Info Resource	
	Number	Relevance	Amount	Concreteness	Structure	Number
Poor	\+	\−	+	+	+	\
Good	\−	\	−	\−	\	\

information should increase to give detailed and step-by-step explanation to the learners, so they can see the rules/theories easier. The structure of the information should increase so that it is easier for the learner to build up the mental model and see the sequential relationship of the topics and relationship of concepts. The number of information resources does not need to change because there are no direct and apparent benefits associated.

8.2. When the Learner's Inductive Reasoning Skill is Good

The number of paths and the amount of the information should decrease to speed up the learning process. The concreteness of the information should decrease to avoid the boredom result from too many similar examples. The structure of the information, the number of information resources, and relevance of paths do not need to change because there are no direct and apparent benefits associated.

The above discussion can be formalized as shown in Table 4.

9. INFORMATION PROCESSING SPEED

Information processing speed determines how fast the learners acquire the information correctly. The learner may process the information in such a low speed that he/she may be unable to hold enough detail in working memory to permit decoding of the overall meaning of the presented domain content (Bell, 2000). Instructional design of VLEs should take into account the consideration of learner's information processing speed. They should be able to provide adequate support in the form of adaptivity by providing hints to the learners with slow processing speed and to facilitate the maximum intake of knowledge for learners with fast processing speed. The effect of differences in information processing speed is analyzed as shown below.

9.1. When the Learner's Information Processing Speed is Slow

The number of the paths and the amount of information should decrease, and the relevance of the paths should increase so that only the fundamental/

Table 5. Information processing speed formalization.

	Path		Content		Info Resource	
Level	**Number**	**Relevance**	**Amount**	**Concreteness**	**Structure**	**Number**
Slow	−	+	−	\	\+	\
Fast	+	−	+	\	\	\

important points are presented to the learner to enable him/her to complete the course on time. The structure of the information should increase to facilitate and speed up the learning process. The concreteness of the information and the number of information resources do not need to change because there are no direct and apparent benefits associated.

9.2. When the Learner's Information Processing Speed is Fast

The number of paths, the amount of information should increase, and the relevance of the paths should decrease to enlarge the information space and hence the available knowledge and gain in-depth insight into the subject matters. The concreteness of the information, the structure of the information, and the number of the information resources do not need to change because there are no direct and apparent benefits associated.

The above discussion can be formalized as shown in Table 5.

10. ASSOCIATIVE LEARNING SKILL

Associative learning skill denotes the skill to link existing knowledge to the new information to make sense of it and thus the information becomes new knowledge. Quinton (2001) pointed out "we do not learn information as discrete, isolated facts, but instead integrate new information with knowledge we already possess. Our best learning occurs when new material is readily connected with what is often 'complex' and multiple link of association".

"Cognitive psychology suggests that a mental model consist of two major components: knowledge structure and the processes of using this knowledge" (Merrill, 2000). Inductive reasoning skill aids to figure out the pattern of the correct operations on how to use the knowledge structure whereas the associative learning skill assists the buildup and storage of the knowledge structure itself.

In order to assist the association processes during the student's learning, the instruction needs to assist the recall (revisit) of learned information, clearly show the relationships of concepts (new to existing), and facilitate new or

Table 6. Associative learning skill formalization.

	Path		Content		Info Resource	
Level	**Number**	**Relevance**	**Amount**	**Concreteness**	**Structure**	**Number**
Poor	+	+	\	\	+	+
Good	\−	−	\	\	\−	\

creative association/insight formation by providing information of related domain area. The associate learning skill is analyzed in the following with respect to learning process.

10.1. When the Learner's Associative Learning Skill is Poor

The number of paths and the structure of the information should increase. More hints and information should help the learner to associate one concept to another. The number of information resources should increase. Different information resources (media) should provide different magnitude of understanding of the same concept. The relevance of the paths should increase to prevent the learner from getting lost in the less-relevant information and create too many useless associations. The amount of information and the concreteness of the information do not need to change because there are no direct and apparent benefits associated.

10.2. When the Learner's Associative Learning Skill is Good

The number of paths and the structure of the information should decrease so learners can navigate more freely and hence enhance the learning speed, and stimulated more associations. The relevance of the paths should decrease to enlarge the information space and hence the available knowledge. The amount of information, the concreteness of information, and the number of information resources do not need to change because there are no direct and apparent benefits associated.

The above discussion can be formalized as shown in Table 6.

11. EXPLORATION SPACE CONTROL AND VIRTUAL LEARNING ENVIRONMENTS

ESC theory inherits the strength of both adaptive navigation and adaptive content presentation. It is designed to be used in VLEs and, therefore, it encompasses the advantages offered by multimedia, hypermedia, and adaptive hypermedia. On the other hand, human's cognitive ability has equal emphasis in the ESC theory, which is the basis for determining different levels of control in exploration process. The overall aim is to make the learning a satisfactory experience for students with varied cognitive abilities.

The formalization of ESC provides a practical way to design VLEs that inherit the benefits of ESC. But to be able to provide adequate adaptation, the VLE should be able to infer the current state of student's attributes and preferences. This creates a need for a student model that is based on the same principles as guided by the ESC. Student model is regarded as an essential component in any adaptive systems and has attracted intensive research focuses in the last few decades (extensive review of student models have been continuously published in the *Journal of Artificial Intelligence in Education*).

But the existing student modeling techniques do not do adequate justice with the inherent exploratory and constructivist nature of the VLEs and rather hinder in the learning process. Constructivism postulates that the knowledge is formed subjectively from the student's previous experience. Knowledge exists only inside human mind (Duffy & Jonassen, 1991) and the existence is unique to every individual. Furthermore, "constructivism says that domain knowledge should not be decomposed and presented to the student in parts; instead, learning should take place in realistic settings with all the ambiguities and extraneous details that entails" (Mayo, 2001). Therefore, the students would be able to better apply their knowledge in real-world context.

Based on the argument that the cognitive structure of every student is unique, it becomes futile to represent the student in any pre-defined structure as current student modeling approaches attempt to do. Does it mean that the efforts on student modeling are pointless? Does or can student modeling or adaptivity fit into the constructivist's paradigm of learning? Mayo (2001) gave an alternative view by pointing out:

1. Novice students often lack the meta-cognitive skill required to explore in a constructivist learning environment. Getting lost in the learning environment is often the cause of disengagement or lost of motivation (Bouillion & Gomez, 2001; Kashihara et al., 2000).
2. New students to a domain require direct guidance, as they have no previous experiences to build on. Advocates of transitory model suggest that the students should initially be taught in objectivist approach before becoming intermediate level for which the constructivist approach could be applied.
3. The adaptivity can be directed to support constructivist principles.

In constructivism, good problems are those, which are able to stimulate the exploration and the reflection necessary for knowledge construction (Brooks & Brooks, 1993). Efficient exploration is one of the key skills required in order to be able to actively engage in a constructivist learning environment. When the inability to demonstrate exploratory skill is detected, the student model ought to advice the VLE to take responsive actions to support the skill.

Modeling of individual differences in cognitive processing is one of the areas where the full potential of student modeling has not yet been achieved (Lovett et al., 2000). This idea may be novel in its wider ambitions, but several HCI researchers have noted its potential (Barnard & May, 1993; Green, 1994; Tweedie & Barnard, 1992). We, therefore, introduce CTM, based on the CTs discussed above.

12. COGNITIVE TRAIT MODEL

It is the increasing need to model student's cognitive abilities/traits that gives rise to a completely new approach of student modeling: the CTM. The ultimate aim of this new approach is to provide system adaptivity to support cognitive processing of students.

CTM enables the learning environment to provide fine-grained adaptivity that takes each individual student's cognitive abilities and resources into account. Traits are relatively stable over a long period of time and persistent across different domains. This new approach to model CTs raises the question: How can a CT be modeled? This issue can be clarified by comparing the CTM approach to the existing student modeling approaches.

Most of the existing student modeling approaches try to represent

- the students' competence state (conceptual and procedural knowledge) by analyzing how much content has been read by tracing the path followed by the student, and how much is learned by analyzing the solutions to questions (state models: Smith, 1998; Staff, 2001; skill tracing: Han et al., 2001);
- the students' understanding of the procedures for solving a task by comparing the problem-solving scenario with the expert's model (constraint-based mode: Martin, 1999; problem-solving state tracing: Stankov, 1996); and
- the students' approach of the procedures for solving a task by analyzing the processes/steps that they have taken (process model: El-Sheikh & Sticklen, 1998).

The existing student models can be generalized as representations of the results of operations by the students (such as reading a page or answering a question) carried out on the presented domain content. Whereas, in order to model CT, students' behaviors have to be recorded at a granularity level, which is descriptive enough that the necessary aspects of the student attributes can be inferred by the VLE.

In order to record and describe students' behaviors, a logging mechanism and a formal language is required. This language must be able to describe which task student had done, and the actions taken to carry out the task. The logging mechanism should also allow those descriptions to be stored and retrieved for future analysis. The granularity of behavior can range from "Chapter one completed" to "Mouse clicked on link A", and the choice depends on the level of behavior useful enough for pedagogical consideration. Goals, Operators, Methods, and Selection Rules (GOMS) (Kieras, 1996), a form of engineering model for user interface design, is a suitable approach for this purpose. NGOMSL, natural GOMS language, provides a structured natural language format for the goal hierarchy and selection rules (Richter, 1997). NGOMSL can explicitly log every method the student had executed. Finer-grained information of the student behaviors, for example steps, can be derived from the logged method. Execution time is recorded as time-stamp for entries in the log. Thus, those properties and ability of NGOMSL make it very suitable for VLEs that require fine-grained student modeling (Kieras, 1996).

The purpose of CTM is not to replace performance-based student models but to complement. Student performance model records dynamic student domain-specific data while CTM stores those students' attributes (could be multidimensional or stochastic) that are relatively persistent over time and across domains.

13. ARCHITECTURE TO INCORPORATE CTM

In order to maintain the logical modularity, a multicomponent architecture of student model is used (Figure 1). The student performance model can be either a state model or a process model depending on the nature of the domain (process model is more suitable for procedural knowledge as it models the process of a problem-solving procedure).

All student actions are recorded in the student behavior history. Actions are recorded according to the desired granularity. In order to provide fine-grained tuning, recording of actions has to be performed at a primitive level. Trait analyzer then takes the logged information in the behavior history and performs analysis. Systems with similar granularity levels include the READY (Jameson et al., 1999) that tries to model users' time limitation and distraction from the system–user dialog, and Meyer et al.'s (1997) that attempts to find out the age group differences in World Wide Web (WWW) navigation, logs all navigational movement between and within pages, and asks participants to think aloud while searching.

The role of the interaction modeler is to represent and interpret the student–system interaction from the inputs of the interface module. The result of the interaction modeler is recorded in the interaction model. The main task of the interaction modeler is to recognize different interaction states and various interaction tasks the student is currently engaged in. Interaction states are the phases of the learning process. Interaction state could include knowledge acquisition state and knowledge application state. Pedagogical criteria are evaluated by the patterns of the state shift (e.g., from knowledge acquisition to

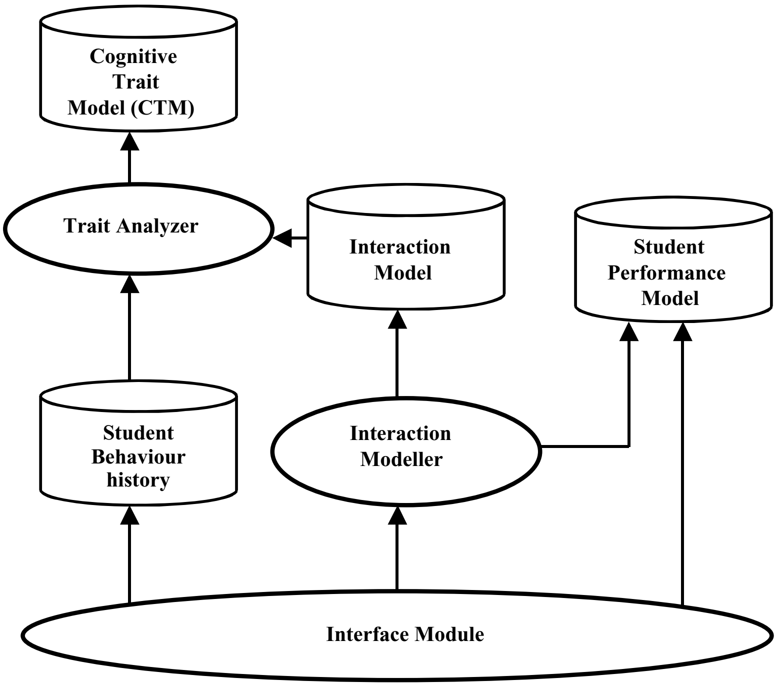

Figure 1. Architecture of cognitive trait model.

application). For example, the criteria could specify that only when a student is able to solve problem A, the knowledge application of concept A can be proved successfully, and then the VLE can assume that the concept A is learned. On the other hand, knowledge acquisition state can be optional due to the background knowledge of the student. The states also serve as the indicator of what the student is suppose to be doing at a particular moment. For example, while the state tells that student A has finished knowledge acquisition state on a concept C, and should now be at the application state of C (could be an exercise related to C), but actually the student A may have returned to an interaction task which has already been carried out in the knowledge acquisition state.

Interaction tasks can be further decomposed into interaction operations and interaction targets. Interaction targets represent the domain content; they could be concepts, examples, exercises, or topics. Interaction operations are those actions that are applied on the interaction target. An example of an interaction task is “Answering question A”, where “Answering” is the interaction operation and “Question A” is the interaction target. Together, the interaction state and the interaction task form an interaction entry, which is a unique identifier in the interaction model.

Every student action recorded in the behavior history has one interaction entry. The interaction entry serves as an indicator of the goal/motivation of why the student performs a particular action. Therefore, the purpose to include an interaction modeler is twofold: to model student performance and to provide indication of the motive for student actions. The nature of the information gathered by the interaction modeler, i.e., the states and the tasks, makes it an essential part of the student performance model that belongs to any one of the state models. On the other hand, every interaction entry serves as the source of explanation for the rationale of corresponding student actions/behaviors.

The trait analyzer is the main component to determine the input into the CTM from analysis of student behaviors. The trait analyzer carries out the task of cognitive analysis of a list of actions. The motivation of those actions can be inferred from the interaction entry, but the cognitive analysis has to be backed up by thorough research in the theories of human cognition. One of the cognitive ability, *working memory*, is accounted as a necessary requirement for a vast number of human activities (Henry, 2001; Calvo, 2001). It is one of the CTs that are part of CTM. We shall now discuss what factors are used to analyze the working memory and the rationale behind selecting those factors.

14. ANALYSIS OF WORKING MEMORY

In earlier times, working memory has also been referred as short-term memory. Richards-Ward (1996) named it the short-term store (STS) to emphasize its role of temporally storage of recently perceived information. STS allows us to keep active a limited amount of information (roughly 7 ± 2 items) for a brief period of time (Miller, 1956). The term working memory refers to the same construct as the STS does, in terms of the capacity of transient storage and, in addition, it also denotes the concept that cognitive processes take place in working memory.

Baddeley (1992) provided decomposition of the working memory into several components. The structure of working memory was described as a control-slave system comprised of the central executive (controlling component), the phonological loop (slave component for verbal information), and a visual–spatial sketch pad (slave component for graphical information). The Central Executive takes the role to control, monitor the output of the two slave systems, and select what is relevant for potential processing (Richards-Ward, 1996).

While Baddeley (1992) defined working memory structurally, others defined it as a process (Salthouse et al., 1989). Salthouse et al. (1989) proposed that working memory consist of (1) a storage capacity sensitive to the number of items presented and (2) an operational capacity sensitive to the number of operations performed on items. They found that young adults have higher operational capacity than older adults especially among the highly capable participants. Little or no difference on the storage capacity was reported across the age differences. Therefore, they concluded, at that time, that it was the operational capacity that causes age-related working memory decline. A further study of the operational efficiency of working memory showed that it was not the operational capacity (number of operations allowed) contributing the most to the efficiency of working memory, but it was actually the speed of execution (e.g., comparison speed) that determined the performance of the overall system of working memory (Salthouse & Babcock, 1991). Even though, these two different points of view do not agree on a common structure of working memory, they both agree that working memory consists of both storage and operational sub-systems (Richards-Ward, 1996).

Several other studies have shown that age-related performance of young children and old adults compared with young adults can be characterized by the inability to retain information in working memory while simultaneously processing other information (Case, 1995). Deficiencies in working memory capacity result in different performances on a variety of tasks. Examples of tasks affected could include natural language use (comprehension, production, etc.), recognition of declarative memory, and skills acquisition (Byrne, 1996).

An empirical study by Huai (2000) showed that students with holistic learning style have a significantly smaller short-term working memory but have remarkably higher learning effect in the long run, whereas the students with serial learning style (highly capable to follow and remember sequentially fixed information) have better short-term working memory capacity but poorer learning result in the long run. This shows that the intricate relationship between humans' in-built abilities and how different learning styles are adopted to circumvent any deficiencies in those abilities. The navigational strategies adopted by serial learners are linear whereas holists sometimes do better by jumping directly to complex concepts (Felder, 1988).

The discussion so far has covered various aspects of working memory from the perspective of its definition and structure. From this discussion, various implications for cognitive analysis can be summarized as follows:

- Working memory temporarily stores material for recall for only a few seconds (Atkinson & Shiffrin, 1968; Byrne, 1996). Constant revisits to the learned materials at very short intervals indicate sign of low working memory capacity.
- As new items enter into working memory, other items become harder to access, and the cognitive system becomes less efficient (Baddeley, 1986; Byrne, 1996). This is called the displacement or interference. Less tolerance of displacement or interference indicates sign of low working memory capacity. Tolerance level can be demonstrated as the ability to learn other "side information", while not get distracted from the main theme. Side information is usually represented by excursions using excursion links (Kinshuk et al., 1999), tips, warning, cases, and so forth.
- Working memory has a limited capacity for storage (Miller, 1956; Salthouse et al., 1989). Constant short-distant reversed navigation indicates sign of low working memory.

- Working memory has a limited capacity for operation (Miller, 1956; Salthouse et al., 1989). Ability to perform tasks simultaneously indicates sign of high working memory capacity.
- Unlike the long-term memory, in which interference is ascribed the main cause of retrieval failure (Reisberg, 1997), simple execution speed (e.g., comparison) greatly determines the overall performance of working memory due to the characteristic of rapid decay (Richards-Ward, 1996). Higher comparison speed implies higher working memory capacity. The amount of time spent on comparison tasks provides indications for working memory capacity.
- Working memory is the intermediate storage to and from long-term memory (Atkinson & Shiffrin, 1968). The ability and speed to retrieve knowledge from the long-term memory provide signs for working memory capacity.
- During a long sequence of calculation or procedure, frequently missing steps or lost components indicate signs of low working memory (Campbell & Charness, 1990).
- Working memory is subjective to vary with age (Kausler, 1991; Salthouse, & Babcock, 1991). Younger age indicates sign for higher working memory.
- Inferential ability is dependent on working memory capacity (Richards-Ward, 1996). Inferential ability to understand high-demand text, or complex concepts for which the inferential ability takes the role of bridging the necessary semantic together and thus called bridging inferential (Calvo, 2001). Greater number of inter-navigation between the current concept and its sub-concepts provides indication of the lack of bridging inferential ability and thus lower working memory capacity.

15. IMPLEMENTATION OF CTM

A prototype web-based tutorial has been developed in the domain of recursion in computer programing to demonstrate the applicability of CTM.

In this prototype, a simple tutorial on the use of recursion in computer programing language is created. The examples and listing in the tutorial is in C language but any other programing language that supports recursion can use this approach. The main focus of this tutorial is on the idea of recursion, principles of writing recursive functions, and good programming practice.

The tutorial is completely web compatible. It consists of 22 nodes (Figure 2) each of which can roughly approximate to single web page except the recursion nodes, which bring the learners to other websites of related topic. This tutorial has 61 relations which are mainly of six types: IsBasisFor, IsBasedOn, HasPart, IsPartOf, ExcursionTo, and IsExcursionOf.

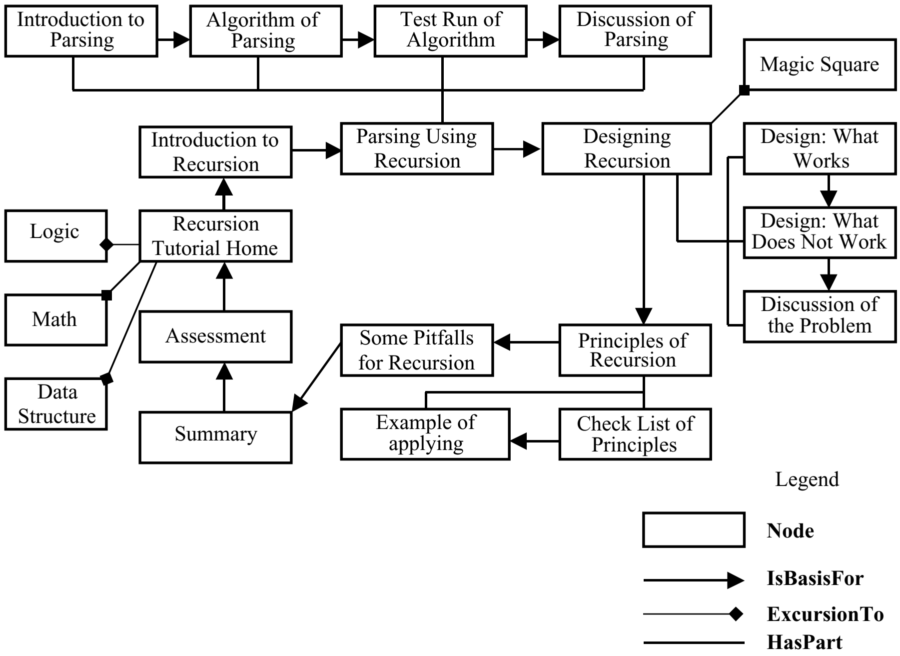

Figure 2. Structure of the domain: tutorial of recursion.

The logical start of the tutorial is Recursion Tutorial Home node, but it is not a strict limit. The learners can go through the tutorial in a linear fashion by following the IsBasisFor and HasPart relations, or they can explore more examples and different perspectives about recursive programming by the ExcursionTo relations. After the assessment page, the learner is automatically brought back to the Tutorial Home. This provides a means in this prototype to experiment with sessions of different length. On the top of every page, there is a navigation bar in which the "next" links to the pre-determined page and in the bottom of every page there is a view report link. There are sometimes excursions available for a particular node, which bring the learners to other websites of related concepts. For example, excursions available in the *Introduction to Recursion* (Figure 3) are recursions to *Data Structure and Algorithm*, *Logic*, and *Mathematics*.

Next, Figure 4 shows the excursion to the *Mathematics*. Recursions take the learner away from the host, called main host, where the tutorial is located, and thus learner's activities in the excursion website are untrackable. However, the activations of the relations ExcursionTo, and IsExcursionOf are still in the control of main host and therefore these activations can be recorded in the student behavior history (Figure 1).

When the learner clicks the Next button in the *Introduction to Recursion*, the tutorial brings the student to the *Introduction to Parsing* (Figure 5). Please

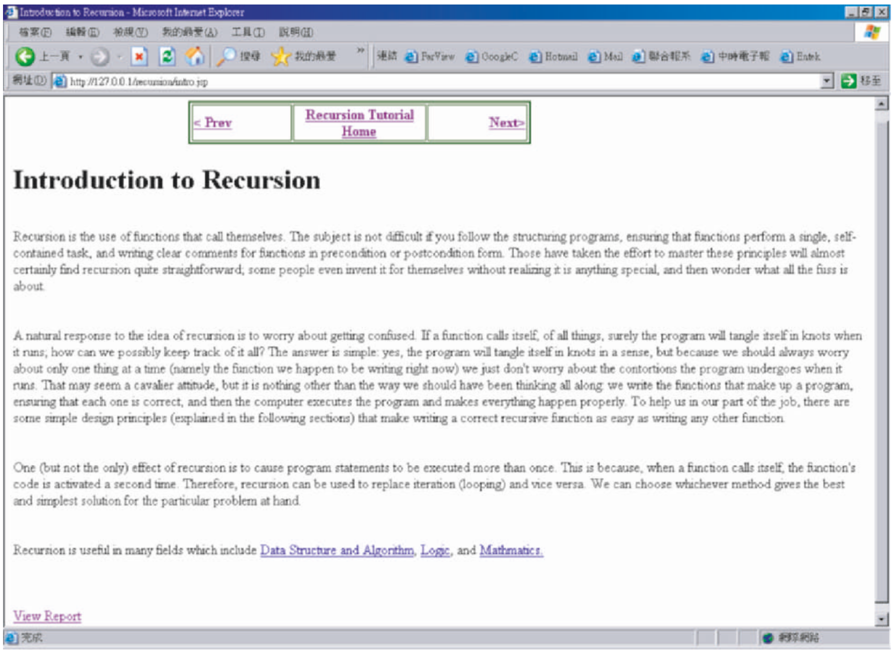

Figure 3. Introduction to recursion.

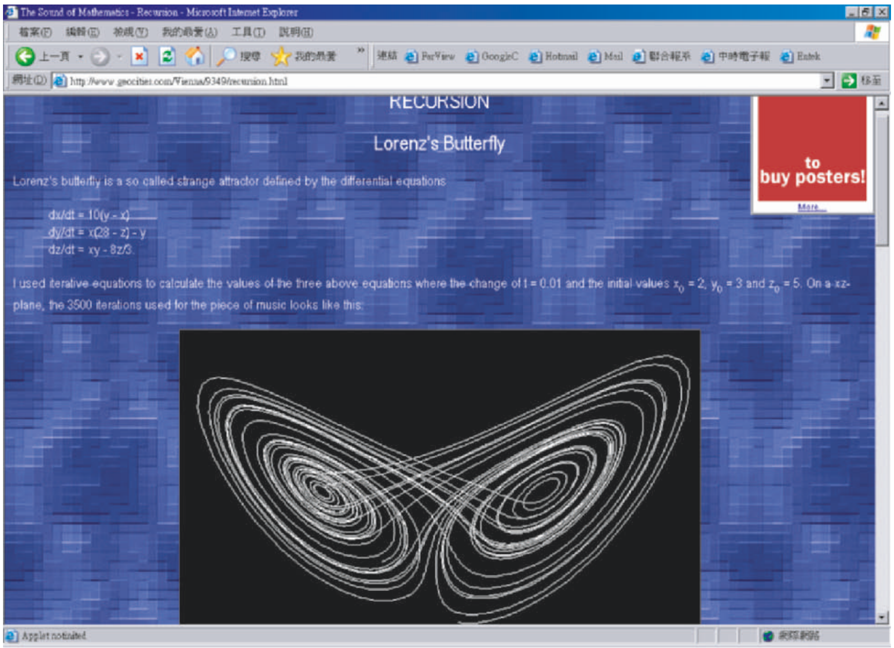

Figure 4. Excursion to the mathematics node.

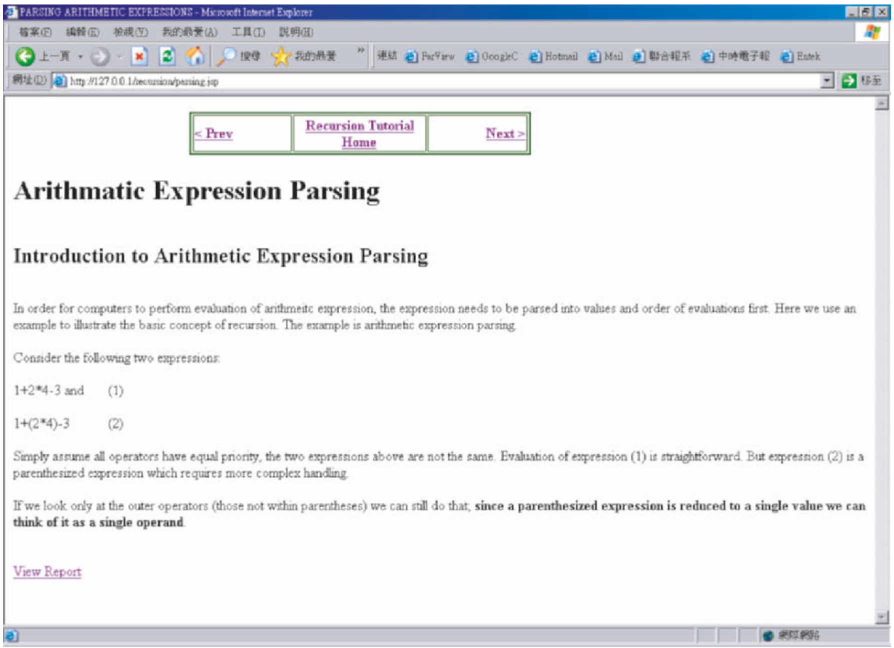

Figure 5. Page for the introduction to the arithmetic expression parsing.

note that in Figure 2, the *Introduction to Recursion* has an IsBasisFor relation to the *Introduction to Parsing*, which is actually a logical learning object only. Logical learning objects are used to relate learning objects semantically, but not necessarily physically (by hyperlinks). A single action of transferring from Introduction to Recursion to Parsing Using Recursion actually activates two relations: an IsBasisFor relation (from *Introduction to Recursion* to *Parsing Using Recursion*) and a HasPart relation (from *Parsing Using Recursion to Introduction to Recursion*).

16. EXAMPLE OF TRAIT ANALYSIS

Learners' actions of navigation are recorded in student behavior history. An exemplary trait analysis is demonstrated below. For example, a learner performed the sequence of navigation shown in Figure 6.

The relations recorded in those navigation are sequentially: ExcursionTo, IsExcursionOf, IsBasisFor, HasPart, IsBasisFor, and IsBasedOn. Those relations can only construct three types of implementations, i.e., navigational linearity, reverse navigation, and excursions. Those implementation patterns are discussed next.

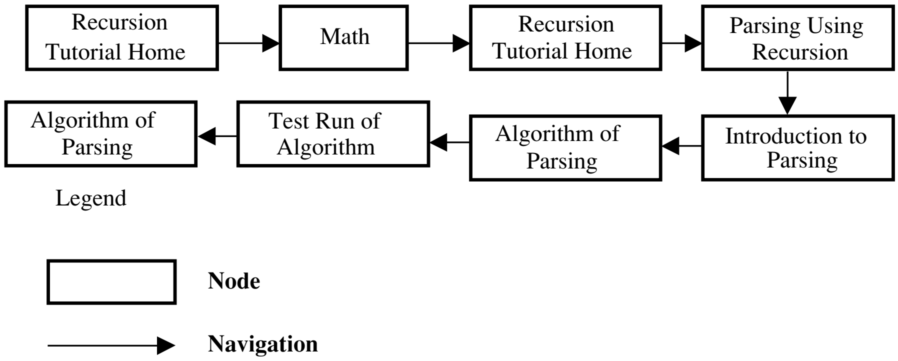

Figure 6. An exemplary session.

16.1. Navigational Linearity

Navigational linearity implies that the learner is traversing the learning space in a way that was originally designed to be the main route. In many learning environments, it is the Next button that guides the learner on the intended route designed by the curriculum designers. In terms of link type, it is the direct successor link, and in terms of relations, it belongs to the IsBasisFor relation, and IsBasedOn indicates the relation with opposite direction to the direct successor link.

For the number of relations, refer to Figure 2. In the navigational sequence in Figure 6, the total number of excursions is three, and the number of excursions visited is one. The number of total IsBasisFor relations is four whereas the number of relations visited is equal to one.

16.2. Reverse Navigation

Reverse navigation includes reverse navigation and revisit already learned materials, because both have some degree of similarity.

Constant reverse navigation (Figure 7A) indicates that a learner goes back to learned material often. In many systems, it may be most obviously represented by the "Back" button. In a general sense, the course of frequent reverse navigation is caused by an insufficient capacity of the working memory to hold on that material that has just been accessed. Frequent revisits to already learned material (Figure 7B) may seem different from the pattern shown in Figure 7A but the pattern "frequent revisits to already learned material" could be a generalization of the pattern "frequent reverse navigation".

In terms of working memory capacity, the causes for these two patterns are qualitatively the same. This is another reason that these two different patterns are treated as a single pattern "reverse navigation".

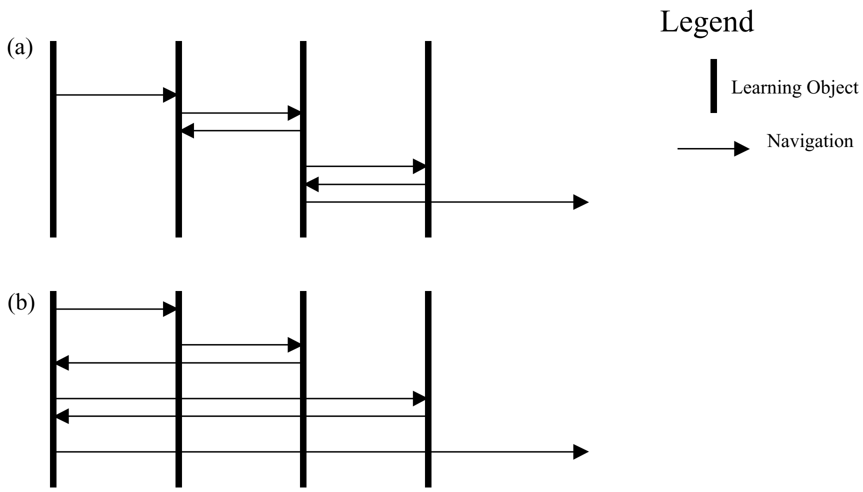

Figure 7. (a) Constant reverse navigation and (b) Frequently revisit learned material.

In the navigation in Figure 6, it is obvious that the learner indeed performed reverse navigation from Test Run of Algorithm to Algorithm of Parsing.

16.3. Excursions

Learners can take excursions to obtain side information during a course of learning. Excursions bring less-relevant information to the student, and therefore broaden the learning experience, and create opportunities for accidental learning. But excursions also bring distractions to the learner. Any distraction would affect the processing and the working of the working memory, which has limited capacity by its nature (Reisberg, 1997).

In the navigation in Figure 6, the learners take excursion to the *Mathematics* website.

16.4. Sample Results

Figure 8 shows the page summarizing the result of an example analysis. The HWMC represents “High Working Memory Capacity” and LWMC indicates “Low Working Memory Capacity”. The “View Report” link is made available on every page of the tutorial in order to facilitate the ease of examining the status of the CTM.

17. DISCUSSION AND FUTURE WORK

To summarize the CTM approach of student modeling, it can be divided into two major phases: modeling the interaction and cognitive trait analysis.

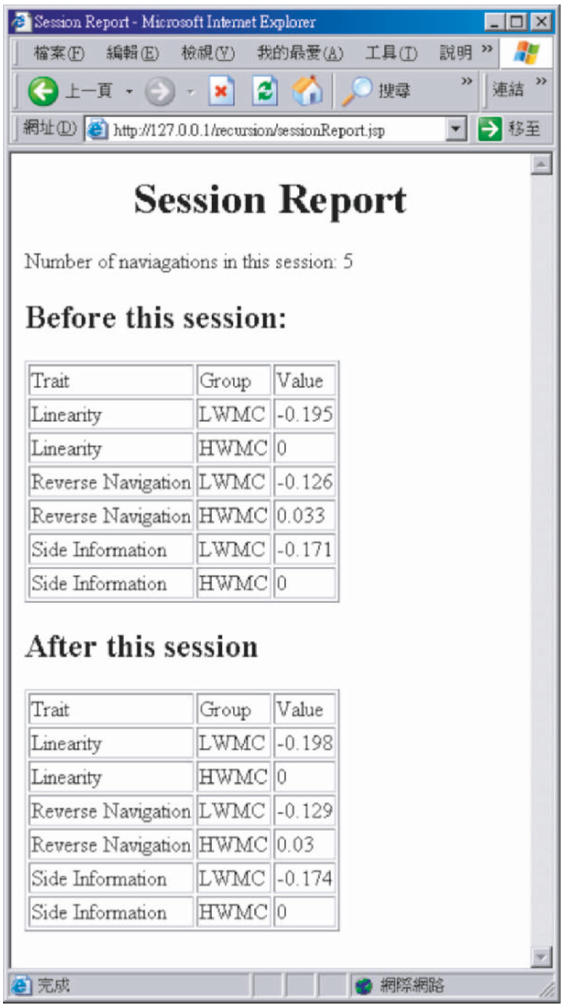

Figure 8. Page for the result of the analysis.

In order to model the students' interactions with the VLE, detailed log has to be maintained. NGOMSL (Richter, 1997), the Natural GOMS Language provides the structural and the formal representation of the student behaviors in the log. In order to cater for the necessary qualitative analysis, the trait analyzer adopts the strategy that incrementally makes use of sparse evidence, integration of unreliable evidence from a diverse set of observations, and explicit reasoning about the ways in which the user's resource limitations change during interaction (as suggested by Jameson et al., 1990). The analyzer can then perform inferences on students' CTs and store the result in the CTM. The CTM can assist instructional decisions the VLE has to make in conjunction with any competence state models.

Quinton (2001) pointed out, in the discussion of meaningful learning, that learning should be "truly holistic, flexible, dynamic, multidirectional, and adaptable", and the role of a learning theory should accommodate those properties in order to provide a guide to comprehensive learning by customizable education in a technologically focused future. The strength of adaptivity in education does not just lie in its novelty; experimental studies have substantially proven its ability to enhance learning speed, memorization and comprehension; its customizable property makes it a preferable choice for the life-long learning.

This chapter provided a very broad outline on the issues of user adaptation in VLEs. The discussion of adaptive navigational support and adaptive content presentation demonstrates the state-of-the-art adaptive techniques used in most of the current adaptive VLEs and the lack of theoretical background. This is perhaps the major reason why most of the existing adaptive techniques do not identify with each other. The ESC approach attempts to address this issue (Kashihara et al., 2000). The ESC formalization serves as a tactical plan on how the strategies suggested by the theories can be carried out.

As most of the current student models are only competence-oriented, the adaptation can only be provided in a performance-based manner. This means that the VLEs adapt themselves in those areas where the student's performance is identified (or predicted) to be sub-optimal.

CTM attempts to tackle this problem and provides a supplementary module to any existing VLEs that wish to support adaptation also at the cognitive level. CTM can be integrated in existing framework of VLEs by the addition of interaction modeling and trait analyzing facilities (Figure 1). The existing competence model can be used for performance-based adaptivity while CTM can supply the adaptivity that addresses the differences of each individual's cognitive abilities.

Another issue for CTM is whether to allow the students to view and modify their own CTM. From the viewpoint of the information processing model of memory (Brown, 2001), information is processed in three "boxes": sensory memory, working memory, and long-term memory among which working memory is the arena where the conscious thought operates. This reveals the point that one's conscious thought is not conscious about his/her own working memory, and therefore allowing the students to modify the values of their working memory is not appropriate. Other CTs may have same or different property as working memory in this regard, and there could also be great educational values for allowing students' conscious modifications on their CTM. This is an interesting future research opportunity.

Chapter 17: Collaborative Text-Based Virtual Learning Environments*

RHONNA J. ROBBINS-SPONAAS† AND JASON NOLAN‡
†*Department of English, The Florida State University*
‡*School of Early Childhood Education, Ryerson University*

MOOs are text-based online environments that allow users to create representations of people, places, and things and share them with others (Nolan, 2001). A MOO is a collaborative space where people come together for communal purposes. They construct the MOO-space according to agreed upon criteria. They can create their own towns, buildings, rooms, objects, and personal avatars and then interact with others in these created spaces. The spaces can be institutional—like a school or a classroom—or they can be literary, like the topology of a novel. Or they can be chaotic, like a frat house. Each MOO has its own personality, characteristics, special features, and purpose that create cohesion and community within its boundaries.

MOOs are collaborative online virtual environments that go worlds beyond the concept of a chat room, online game, or a simulation. A simple way to visualize a MOO is to think of a chat room, then add a room description so the chatters have some idea of a place, perhaps graphics, a character description for each user, objects that the participants can pick up, handle, and manipulate. Allow the participants the ability to create their own objects or object behaviors (e.g., an object designed as a dog may bark at irregular intervals), or to work together to create as many rooms as they would like and link them all together to create a house, office building, or village. Throw in the potential for HTML and multimedia content and tools, and you will begin to have the idea. Unlike online role-playing games (RPGs and MRPGs), there is no inherent restriction or limitation as to what can be created or what object behaviors can be initiated or how they may be modified.

MOOs are generally perceived as being a new and breaking technology, and, perhaps in a biological evolutionary scheme of things, they are. In the fast-paced world of information technology, however, MOOs and their MUD predecessors are rather like the modern-day shark—they are constantly redefining themselves into a more effective species, but they have been around for the data equivalent of eons. Unlike the immediately recognizable silhouette

* An earlier version of this chapter was published as Robbins-Sponaas, R. and Nolan, J. (2005). MOOs: polysynchronous collaborative virtual environments. In: Zemliansky, P. and St. Amant, K. (Eds.) *Internet-Based Workplace Communications: Industry and Academic Perspectives*. Hershey, PA: Idea Group, Inc.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 425–439.

of the shark, however, MOOs have inadvertently maintained such a modest profile that even within the communities which most use them, the technology is still relatively unknown and boasts virtually no recognition value with the general public. While that condition is changing with the advent of more sophisticated MOO technologies and interfaces, blank looks and glazed expressions at the sheer mention of MOO and MOOing are still the general rule rather than the exception.

In fact, MOOs could be said to suffer from dual difficulties. The opportunities they afford for online learning, in a conceptual and practical sense, outstrip anything presently available; they are just too much a part of the cutting edge of both learning and technology. Conversely, much of the code that makes up the bulk of MOOs—even the fancy GUI, web-based MOOs—is moribund and requires significant redesign and coding so that its connection to the contemporary internet is more than jury-rigged patches. Nevertheless, even with these "patches," MOOs currently offer more opportunities than most other tools presently in use. Despite the fact that MOOs offer opportunities currently impossible in any other actively developed online communications environment, they have remained largely the purview of hackers, coders, and academics for a number of reasons, none of which preclude their potential value in mainstream academic and commercial environments. Rather, they offer a potential pathway for collaborative virtual learning environments (CVEs) to reach the promise only hinted at in today's offerings.

MOOs predate the onslaught of interest in the internet brought about by the popularity of the World Wide Web in 1994 by a number of years. Organizations such as Xerox Parc, AT&T Research Labs, and NASA's Jet Propulsion Labs (JPL) have devoted resources to exploring the possibilities that MOOs afford, and many commercial ventures, such as PlaceWare (now known as Microsoft Live Meeting) and Diversity University have developed as offshoots of MOO-based technologies. Organizations and institutions such as the University of Toronto's Knowledge Media Design Institute, MIT's Media Lab, SRI International, and the University of Toledo's Department of Health and Safety have hosted MOO-based projects, with research sponsored by the U.S. Department of Defense, SUN, the NSF, Industry Canada, and NASA, among others.

The first question that comes up when discussing MOOs is, of course, "What the heck is a MOO anyway?" MOOs are collaborative virtual environments that are generally hosted on the internet and are accessible via a variety of programs that range from telnet to web browser. Their ancestors, Multi-User Dungeons (MUDs), were—as the name suggests—originally widely used by the gaming community (Aarseth, 1997; Bartle, 1990; Curtis, 1992; Curtis & Nichols, 1993; Rheingold, 1993). As technology redefined itself and grew increasingly more sophisticated, the environments gained the opportunity to be object-oriented; that is, they could be generated by creating a series of inter-relating but relatively self-contained segments of code that in turn served as rooms, containers, features, interactive objects, player characters, and so on. The development of an integrated object-oriented programming language (the MOO language) within the MOO environment is one of the key differences between MOOs and other virtual environments. There is a certain amount of diversity in the types of MOOs currently in operation, but at the time of this writing, they tend to fall within three different categories: pure text, web-based, and enCore-based. There is an ongoing debate between the two MOO camps—webbed MOOs and text-based MOOs—about which is the better forum. Users of web-based or GUI MOOs often find text-based MOOs cumbersome and awkward, whereas users of text MOOs tend to find webbed MOOs cluttered and distracting. Both styles of MOOs have their particular advantages. For a beginning MOOer, the simple reality is that a GUI'd MOO is easier to learn; MOOing becomes much less intimidating when a user is able to utilize existing skills or find something familiar (surfing the 'net and web pages) on which to base her experience. Text MOOs, on the other hand, are exemplary for pure rhetoric discussion and exploration since the only available input is via the text under examination. The real issue, however, is how well each environment is implemented. For instance, MOOcanada has a very sophisticated text-only interface—MOOzilla—that is more interactive and dynamic than many GUI-based interfaces.

Pure-text MOOs are precisely what one may expect: they are MOOs that operate in a pure text environment. The user (player) must type all communications, commands, and actions, and all object and environment clues are portrayed entirely in text. There are no visuals to speak of; everything—objects, events, and other players—is portrayed and all actions are performed through the written word. From a creative perspective, the success of such environments often depends heavily on the developer's ability to use language in such a way that it is both concise and heavily visual; the more the user is able to form a concrete picture of the space and events, the stronger her experience will naturally be. On a practical level, nothing more than a bare-bones description or contextualization is necessary for the environment to function on the most basic of levels. There are a number of available software clients for both the PC and Macintosh platforms in order to avoid the ugliness of Telnet (e.g., zMUD, gMUD, WinMoose, MacMoose), but the operations and appearances are very much the same: one functions in a flat text environment only through the power of the typed command. In 2004, one of the strongest and most popular educational MOOs—Tari Lin Fanderclai's Connections MOO, operated out of the University of Florida—was laid to rest. While MOOs do have a definite life cycle, the loss of this particular MOO suggests that there is a growing turn away from pure-text MOOs for the general academic environment. Damningly, part of the reason for that turning away from text-based MOOs may be the heavier need for proper orientation, training, and support—and the decreasing availability of time or resources for those very things in academic lives that are growing increasingly more stressed and pressured. As we will discuss shortly, running a MOO can be an exhausting proposition, and the burnout rate for owners and managers with no support system is phenomenally high. The increased simplicity of use GUI'd MOOs offer is most certainly not the only reason for the reduction in text-based MOOs.

As web browsers gained respect—and sophistication and power—an increasing number of MOOs began developing their own web-based graphic user interfaces, most often relying on Javascript and HTML in order to embed a Java Applet right into the web page that emulates the functions of a Telnet client. In these instances, the user accesses the MOO through a browser (typically Netscape/Mozilla or Internet Explorer) the same way she would access any other web page. The screen is traditionally divided into at least two parts: one segment, the Java Applet, contains all the text descriptions, conversations, events, messages, etc., while the other contains icons and images, many of which will be interactive and function as any normal web page. In these environments, a user will still be required to perform most actions by using a typed command, but there is an increased flexibility in how information is presented and accessed. She may, for instance, be able to click on an exit icon and move to another room rather than type the text command for the same action, or click on an icon of a bulletin board to see a welcome message. Because these web-based MOOs tend to be individually designed and built and are heavily dependent upon their owner's programming and coding abilities—and access to outside development resources—they run the gamut in both quality and appearance. Some are clean, coherent, easy to navigate, and are even easier to conceptualize as place rather than just space while others are cluttered, cumbersome environments that make a user feel a bit like she is walking through a construction site before the walls are up. Generally speaking, no two will either look or function alike.

With the release of graphical browsers for the World Wide Web in 1994, MOO developers started to experiment with adding graphical elements to MOOs, and by 1996 MOOkti, TAPPED IN, Diversity University, LinguaMOO and others either had or were actively developing graphical interfaces. The surge of those early years offered up a number of failed efforts and a surprising number of startling successes. Unfortunately, while many of the success stories of that period would be more than competitive with later (perhaps even current) developments, they lacked the funding and promotional resources that would have made them available to the general public—or at least taken them beyond their own small and rather limited niches. Nevertheless, both the successes and failures of that period provided the building blocks and created the opportunity for something that would happen the following year, in 1997.

In 1997, Cynthia Haynes of the University of Texas at Dallas, and Jan Rune Holmevik and Sindre Sorensen of the University of Bergen in Norway released the beta version of a software that was to radically change the face of MOOs—literally—for much of the educational community, and do so in very short order (Haynes & Homevik, 1998; 1999). The release offered MOO designers an alternative to existing resources in a two-part package: the High Wired enCore core (the heart or, in essence, the database skeleton of a MOO), and the graphic user interface, enCoreXpress. While the majority chose to use both the core and the interface, a fair percentage of builders with programming skills and resources opted instead to apply the enCoreXpress interface to their own cores. The interface is what made and continues to make this package most noteworthy; it increased the web applications of the MOO in such a way that an inexperienced user could log onto the MOO and be able to function in a relatively short period of time by taking advantage of her already-present ability to perform basic web browsing activities with Netscape/Mozilla or Internet Explorer. It provided a graphic user interface for those who wished one and lacked the skills, time, or resources to build their own, but it also offered the opportunity for some degree of uniformity and consistency between MOOs. While some functions changed from MOO to MOO depending upon the core or the MOO's programming resources and the owner's ability to fine tune the appearance or function of the existing package, the basic appearance and general operations remained the same, allowing users to go from one MOO to another without having to negotiate a completely new environment and learning curve.

Thanks in part to enCore's funding and publicity resources—advantages most MOO developers do not generally have—enCore has become a by-word within the academic MOOing community. The majority of web-based MOOs are currently using the enCoreXpress interface, and the software's popularity has spread globally, making it the dominant graphic user interface in use at this time, particularly within the educational community for which the program was first developed and introduced. Publication of Haynes and Holmevik's two texts—*High Wired* and *MOOniversity*, texts which are based on enCore's development—has created increased interest in the software and like ripples in a pond, the enCore interface has moved beyond its home court of academia and is becoming a growing presence in the world of social MOOs as well as MOOs associated with industry, science and technology, and the private sector.

Just as the faces of MOOs vary according to software design and coding, so too do their scope. MOOs currently occupy the entire spectrum of online activity, but they are most heavily concentrated in the educational, social, and gaming communities. Even within their niches, however, their range is nothing short of eclectic. One educational MOO in Bergen (cmcMOO) plays host to a display of Shakespeare's "A Midsummer Night's Dream" while others, like the recently defunct Diversity University, replicated campus classroom spaces. ESOL (English for Speakers of Other Languages) and foreign language MOOs include everything from Portuguese to Japanese. One social MOO is heavily "green" and builds clearly defined outdoor spaces while yet another has created a fantasy space of imaginative and impossible proportions. Gaming MOOs cover everything from the original "Dungeons and Dragons" to more modern role-play games. Industry is gaining an increasing interest in the potential of these environments, and MOOs are now being considered for everything from virtual offices and customer support to scientific simulation. Regardless of their purpose, MOOs are very much a technology in a state of flux, and that condition of relative instability brings with it a mixed bag of both positive and negative conditions and results.

In addition to what has been mentioned already, MOOs are polysynchronous environments (Nolan, 1998; Nolan, 2001). The term polysynchronous was coined in order to describe the unique communicative affordances that MOOs offer. Polysynchronous environments are defined as virtual spaces that closely approximate real life environments. People communicating polysynchronously not only talk synchronously (in real time), but also create temporal objects such as mail messages, newsgroup messages, as well as objects that can be experienced by others. This form of virtual reality has potential as a dynamic learning environment.

This concept challenges the prevalent notion that online communication must be separated into synchronous and asynchronous activities. Most technologies only allow one activity; you can chat with your instant messenger or you can send an e-mail message. Though this limitation results from limitations on the part of those who conceptualize and design technologies, it has been taken up by both academics and the general public as a rigid limitation inherent in online communication. MOOs show that this does not have to be the case. MOOs were polysynchronous environments years before most internet users ever took their first online steps.

Almost all the information that passes back and forth across the internet is text, usually in the form of ASCII or Hexadecimal (Nolan, 2004). All our instant messages, emails, web pages, and blogs exist as some form of alphanumeric characters. It does not take much of a stretch of the imagination to realize that what may start as an instant message or a conversation in a MOO (synchronous) can be saved and pasted into a web page, e-mail message, or a blog and become an asynchronous document. This has always been the case in MOOs. What we say (through typed text) can be recorded, archived, consulted, or displayed at a later time. Furthermore, we can asynchronously program or script objects or robots (called bots) that are able to carry on complex conversations with individuals or groups at future points in time, and even the results of those bot/human conversations can be recorded and become material for future conversations (Leonard, 1997; Turkle, 1995). Though it is only slowly being recognized as such, the internet is inherently polysynchronous, and the synchronous/asynchronous dichotomy has been a temporary imposition by software designers.

There are a number of features that make MOOs valuable collaborative environments, and potentially the least of those is the ability to communicate in a real-time environment. While many limit their use of the technology to synchronous communications, MOOs are much more than chat rooms. The ability to converse with students, teachers, and colleagues is indeed important, but MOOs go one step further than most chat technologies in that they allow a fuller mode of expression. MOOs recognize and create the required space for demonstration and performance of identity (Bruckman, 1992). For instance, rather than seeing a dislocated smilie or emoticon beside a user's screen name, the audience sees a sentence that makes that expression both more vivid and more coherent: *Janet smiles*. Or, even better: *Janet smiles at you*. Permanent characters (non-guest avatars) are more than anonymous screen names; rather, they offer an infinite range of options for self-description and self-definition. Depending on the software and interface, users are able to not only provide text descriptions of themselves—including their special interests, e-mail address, or home web page information—but also have the opportunity to add graphics, photos, video, web cams, and sound, all of which help create a sense of the user's individuality and provide depth. Likewise, places—whether designed as outdoor spaces, fantasy realms, historical re-enactment, or traditional rooms—have the opportunity for personalization. Descriptions can be tailored to the creator's personal artistic or professional preferences and needs, graphics can be used (or eliminated) to help develop the setting, room activities and events can be generated in order to strengthen the sense of place and grant it dimension. In short, MOOs offer the advantage of making personal interactions much more "real" and immediate. That immediacy of experience is a large part of what makes MOOs special and helps differentiate them from the usual chat program. The user loses the sense that she is operating in something so mundane as a computer program and feels instead that she is part of a virtual community—often one that has as much reality and life as the "real" one away from her computer (Turkle, 1995; Wellman & Gulia, 1996; Baym, 1988 [1995]).

The ability to describe oneself has opened the path for discussions of gender and identity theory in ways that are not available to the face-to-face class. In a MOO, students can choose to call themselves by non-gender specific names, alter their descriptions, or change the avatar's settings to those of the opposing gender or gender neutral pronouns; they can experiment with genders other than their own. Likewise, they could choose to experiment with different class, race, or cultural identities. While such experimentation does not (indeed cannot and should not) attempt to assume full understanding of the experiences of those who live the lives students are role-playing, the experiment does open the door for dialog that cannot otherwise be generated so freely—or portrayed so vividly. Students are able to redefine themselves, and that process not only raises questions about casting of the "other," but also pokes at the means by which they go about defining themselves in their own daily lives, and the way in which they interpret themselves as well as how they present themselves to be interpreted.

Personality and identity—regardless of whether it is the MOO's or the players'—is, of course, not the only advantage to a MOO. Another very large advantage is the ability to create an object that another user can pick up, look at, manipulate, or use, incorporating a "sensory" and hands-on application to an otherwise purely visual learning experience. Such applications can be invaluable when it comes to recognizing and making the most of different learning styles; they allow students to explore their own learning processes in a manner that works best for them and by which they may gain the most benefit. As part of that approach, not only can the student "handle" the object or lesson, but also she can create her own in response. For instance, if the MOO-lesson guides students through the different aspects of writing dialog for a creative writing class, she may create two objects that "talk" to one another in a demonstration of those concepts, or she may program a bot to perform an interactive dialog with the instructor. Nor is that hands-on experience limited to a single-builder concept. While the MOO is a collection of code, if that code is designed properly and managed well, it becomes an interactive element of its own and performs in response to its users. While not living in the same sense as its players, their use and development of the MOO itself has the potential to turn it into a receptive and expressive environment with a personality of its own.

MOOs are unique for their ability to not only allow but also encourage collaboration. In short, a space may be developed by a group of people all working toward a given goal. For instance, a history class may recreate Civil War Gettysburg using very structured guidelines (each student creates objects and room space given a specific aspect of the assignment), or via the wonderful chaos of a free-for-all approach, allowing the class to brainstorm, create, and implement their ideas in their own unique learning process. The collaborative nature of MOOs is such an inherent feature that it is often overlooked in discussion, and it is frankly a difficult aspect to address, simply because of the sheer enormity of the possibilities. Small groups or entire communities can work together to create a representational space that combines knowledge and personalities of all the participants. A history club may create a series of rooms and objects that represent their understanding of the pre-Civil War American South, or a biology and natural science class may recreate the problems associated with a specific resource depletion. On a more limited level, a single user can create an object or space, then hand it over to another user for further development in a never-ending cycle of creation. By the same token, we must remember that the entire MOO—its programming, representation, geographic structure, and thematic construction—is the result of a collaborative effort of a MOO's community and all its users. MOOs, as with people, do not exist in isolation, but rather are designed, created, and implemented by the society that uses it (Weiss et al., 2005).

An entire chapter could be dedicated to the issue of governance, and there are many resources that discuss the governance of online environments. Nolan and Weiss (2002) go into great detail to describe the major issues surrounding the question of governing MOOs. They describe a curriculum of community that all participants must learn. This process is usually a social act of observation and modeling of acceptable practice. This curriculum is broken down into issues of access—how to connect to a MOO and use the environment; membership—how to interact with others and feel like a participant; and governance—how to keep the environment running both socially and technologically. Very few organizations, online or off, actually take these aspects of interaction into conscious consideration, but rather leave individuals to flounder and make their way on their own. For environments to be successful, however, those who run them have to ensure that not only are they interesting places full of interesting people and interesting things to do, but they also have to govern with a light touch, so that the experience is not a restricting one.

As with any online environment or community, MOOs need an organized system of governance (Collins & Berge, 1997; Fernback & Thompson, 1995; Foucault, 1991, Kollock, 1996; Ostrom, 1990). The environment is indeed a virtual one, but it still requires the same level of administration and support as any successful face-to-face program. That means that responsibilities need to be assigned to staff members, problem resolution avenues need to be prepared, operating expectations and standards established. Because of their online components, MOOs often become very personal very quickly; a sense of community can become so nearly a tangible characteristic that the MOO may well feel more like a family than a professional work environment—a family with all the egos, personality conflicts, and misunderstandings of any face-to-face family. If there is no administrative structure in place, it is far too easy for those critical elements to overwhelm the positive and the MOO to become a place of chaos, confusion, and factions.

It is important to recognize the "living" nature of MOOs. Just as they function and respond as performers—and host the performance of their users—they often have lives of their own. MOOs are born regularly and die equally regularly. The reasons for their passing are many and varied. Perhaps one of the biggest is the simple fact that they can be exhausting to administer and maintain, particularly if the MOO owner does not have administrative resources or funding for programmers and hardware. If the MOO is private and only plays host to the owner's small class of 20 students each semester, the drain is reasonable; it is not much more demanding than maintaining one's existing course materials, assuming the owner has the necessary hardware and internet access. If, however, the MOO is serving a variety of classes or an international community with a varied and active membership, the demand on time, funding, and hardware increases exponentially. Few MOO owners have the resources to hire programmers and administrators out of their own pockets. Simply put, some MOOs die when their owners can no longer support them. Others die because of the complex nature of their memberships. MOOs are living communities, and just as in "real" life, individuals grow away from each other, change jobs or lifestyles, move, and relocate. If a MOO does not have an active promotional program designed to bring in new members, departing members may leave holes the MOO cannot fill, and the place soon becomes a ghost town. Last, some MOOs fall victim to their own members. Churches have long recognized the problem of splits in their congregations—splits that often result in evacuations that ultimately cripple the organization. The situation is no different in the MOO world. Members may fight amongst themselves, feelings get hurt, and people leave in favor of starting their own environment or joining another.

For whatever reason a MOO may die, its demise often creates a hole in the online community and affects real-life friendships and working relationships. Teachers must find other MOOs where they can host their classes, distance colleagues lose their forum for working relationships, and friends lose the opportunity to communicate regularly in a real-time environment. Some MOOers fall away from the MOO community altogether, others search for new homes, and yet others create their own.

Clearly, the overall state of the MOO as a concept is due for a major overhaul. Though it is presently a powerful and exciting tool, with great potential for learning implementations, and there are numerous projects underway using existing cores such as LambdaCore, enCore, and JHcore running on the LamdaMOO server, there are no active projects underway to develop the LambdaMOO server itself. There have been no changes to LambdaMOO since version 1.8.1 in early 2000.

There is no open-source community dedicated to bringing MOOs in line with existing standards of development. And, until there is some concerted effort to collaboratively develop the MOO, it will languish as a powerful and useful oddity, clinging to new changes in internet technologies by virtue of its inherent flexibility and the skills of the programmers working within the environment.

What we need is to reposition MOO as a paradigm for technology development and integration. The MOO paradigm, which is compatible with the hacker ethic and the various open source movements (Raymond, 1999; Raymond, n.d.; Stallman, 1999), is a way of looking at communication, online interactions, and programming. These three features are not seen in the MOO paradigm as separate functions, but rather integrated. Anyone who has an account on a MOO has the potential to become a programmer within the same environment. A user does not need to study programming, but rather learn how the MOO environment functions first through communication, then constructing representations of people, places, and things. Through participation in the MOO community and the sharing of skills, experiences, and stories, the user gains (or constructs) knowledge about the virtual environment. At this point, many users learn to program the aspects of the environment. Programming is one step beyond building "things." It is the point where the user can now delve into the very structures with which the MOO is built. She can now program dynamic interactions, create whole new classes of objects for other people to use, or develop novel tools for communication and social interaction.

There is no other online or virtual environment that allows this breadth of participation from this wide a range of users—from guest, to a participant, to a builder creating virtual spaces, to a data-base programmer—all within a single virtual environment. In fact, very few environments and technologies can even be developed from inside by users. The MOO paradigm, which is loosely based on Seymour Paper's notions of constructionism (Davie & Nolan, 1999; Resnick, 1996), offers the ability to facilitate any kind of communication, social interaction, or experiential learning (Kolb, 1984; Moore, 1981) a teacher or learner can imagine. It is the ability to create an open-ended variety of virtual spaces along with the capacity to develop and program new tools from within a single community that sets MOOing apart from all other kinds of online interactions.

There is a very real potential for MOOs to finally rise to the challenge of being the concept that will truly facilitate the creation of widespread open source user-extensible virtual reality. This is an ambitious statement, but as things stand, there is no available technology that has the potential that MOOs exhibit. The MOO paradigm needs to be stripped down to its basic elements, legacy ghosts need to be exorcized, and MOOs need to return as a lean tool that will allow for the integration of what makes MOOs special with all the other elements of the internet—present and future—that fulfill niche needs.

The MOO paradigm is important for two major reasons. First, it offers constructivist virtuality—the fact that anything that can be described can be created in a MOO. Likewise, there is the internal object-oriented programming language that allows users to co-develop tools and applications from within. These two features allow for the rapid prototyping of new tools, collaborative co-development of virtual spaces, users' construction/control of their own environments, and the ability to glom (stick together or integrate) almost any other technology onto itself with minimal fuss.

The ability of the MOO paradigm to glom other technologies together requires some explanation. Although most internet tools have some rudimentary ability to communicate with each other, and there are multifunction tools—such as web-browsers—which are able to handle browsing, e-mail, chat, web page creation, and usenet news reading, it is difficult to make any changes to the provided suite of tools without waiting for the software vendor to provide a new version of the software.

Even with the existing MOO tools, however, both fledgling MOO programmer or experienced user is able to unilaterally attach any web-based multimedia tool to a MOO object. For example, in early 1996 MOOktiMOO, a precursor to Project Achieve, there was live streaming real-network video through the MOO to viewers who were then able to communicate with each other and post text questions to the live audience using the MOO's chat functions. It took less than a day to work out this prototype. Since that experiment, users have added shared whiteboards, audio-messaging systems, live-cams, and other tools they have found around the 'net and determined to be useful.

Because a user can add a useful tool with just a few lines of code, there is no requirement for a new version of MOO to come out in order to add new functionality. If a user does not like what is available, she can find something better and add it herself. Or, for that matter, she can create her own entirely new tool.

In order to extend the capacity of MOO at present, MOOs have built-in web, e-mail, newsreader, gopher servers, and clients. Keeping these sorts of built-in tools is unnecessary in today's distributed internet. Most users already have tools that perform these functions that are more suitable to individual tastes. What the MOO should, and can, afford is the option of joining the user's selection of tools together in the MOO, along with a plethora of other tools that work best for the user. The MOO would then facilitate the communication between these tools, and those of other users, in a seamless, transparent fashion.

MOOs are bandwidth independent. High-end users can still stream audio and video and use web-based Java tools. But this is not a minimum requirement. Anyone can access a MOO with the most minimal tools, such as a dumb terminal (computer screen and keyboard without a computer) and the oldest of modems to connect to a server with access to the internet. This means that the system requirements for text-MOOing are small enough that MOOs can be used in environments that have poor internet connections or old phone lines, an important issue when considering problems relating to the digital divide. It also means that MOOs can be used via wireless devices. There are no limitations as to what type of tools can be used to access MOOs, and regardless of how MOOs are developed, this capacity is unlikely to disappear.

Taking into consideration these sorts of capacities and flexibilities, it is possible to put together a picture of tomorrow's MOO. Imagine, if you will, a user-configurable core tool, self-sufficient and functioning all by itself. The core would include the following: telnet protocol-based text entry and response to handle communications to and from the MOO; hooks going from the MOO to a web server (probably Apache, since it is ubiquitous on the internet); hooks to PHP, Perl, and other scripting languages that are usually installed as modules in Apache servers; the MOO object-oriented programming language; all the basic MOO objects and classes for creating people, places, and things; all the MOO administration tools, help files, and tutorials; and added utilities for adding and configuring all the various multimedia communication tools that are the staple of the average user of the internet. What we have is the equivalent of an internet sticky tool to which a user can stick anything she or he wants in such a manner that the user can add or change any functioning element (e-mail, chat, streaming media, file and document servers) at will or whim without requiring the intercession of a programmer or system administrator.

At present, MOOs on the internet are charting two distinct paths. Projects such as enCore and TAPPED IN are providing powerful tools and environments for the creation of CVEs. However, TAPPED IN, for example, has minimized the constructionist capacity of MOOs, making building and programming almost impossible. Their MOO hides all its inner workings in a metaphoric black box, not even openly acknowledging its MOOness.

enCore is well on its way to becoming the most popular MOOing platform. Until recently, enCore fell under the control of its developer, Jan Rune Holmevik. Limited resources meant that the program lacked the robustness and development potential of open-source projects where the project coordinators bring together work from a variety of programmers, and it is the highest quality work that makes it into the new releases. As of the fall of 2004, however, enCore's development is being nudged and guided by the enCore Consortium dedicated toward making the software—both core and interface—both more viable and more competitive.

The Consortium's hope is that a competitive array of teaching tools and increased flexibility, user-friendliness, support, and manageability will encourage instructors on all levels to consider the enCore MOO as an alternative to more restrictive and generally expensive courseware and course tools. For instance, an upcoming release of enCore's GUI will include a threaded discussion board and a variety of other tools designed to flesh out the existing package. A number of issues concerning students, teachers, and administrators of all levels are on the table and are being addressed by an eclectic collection of MOOers and programmers, most of whom currently fall within the realm of academia. Security issues associated with the GUI are not the least of these concerns, and a number of the software's former holes have already been closed. The increase in development resources promises a more energetic development program. While still too low profile to meet the need, the organization has been granted non-profit status, and an enCore Symposium planned for August of 2005 increased awareness of and provided publicity for both enCore and the organization itself. If the Consortium is able to draw in the necessary attention, talent, and funding from industry, government, and academia, enCore's future promises to be bright indeed, and its current lead in the world of MOOing will strengthen considerably.

MOO development is not dead, but with the exception of the enCore Consortium, it is somewhat dormant. TAPPED IN and enCore are spreading the popularity of MOO and have well-organized and easy-to-use environments. Clients such as MOOzilla are exploring new ways of interaction that do not suffer from the inherent problems of web-based programming. Both academic and business communities are watching MOOs, however, and no major paper or book on virtual community is complete without reference to MOOs. And with the thousands of young people learning programming skills in these social environments, a high percentage of whom are female, there is a growing body of future professionals who understand what MOOs are and what they can do to extend our experience online. Unfortunately and, again, aside from the enCore Consortium, there are no major projects presently underway that are undertaking the renovation of MOOs or developing a MOO paradigm that facilitates the enhancement of constructionist learning, polysynchronous communication, and internal programming capacities. At present, MOOs are just beyond the event horizon, still waiting to be the next-big-thing.

1. INTRODUCTION

In this chapter, we examine the relationships between pedagogy and the use of information technology (IT) in schools. IT refers not only to computers (hardware and software), but also to the full range of multimedia technological tools that are potentially available to support learning and communication of knowledge (e.g., digital and video cameras, DVD players, etc.). Specifically, we address questions such as: What pedagogical options are available for use of IT in schools? To what extent can IT amplify the impact of different approaches to pedagogy? Is the impact of IT potentially more powerful as a catalyst and support for learning when harnessed to certain forms of pedagogy as compared with others?

These questions reflect the fact that despite the increase in access to IT in schools, it is not clear what educational problems IT is supposed to solve. Policy-makers assume that IT will promote student achievement but, as documented below, there is still no large-scale support for such an assumption. Furthermore, there is no consensus as to *how* computers and other new technologies should be used to support learning. In the United States, for example, schools in affluent middle-class areas increasingly tend to use computers to support higher-order thinking through creative project work while those in low-income inner city areas still use computers predominantly to reinforce students' mastery of basic skills through drill and practice activities (Education Week, 2001).

Drawing from both North American and European research and recent experience, we argue that questions regarding the effectiveness and cost-effectiveness of IT in schools can be coherently addressed only in relation to the potential of IT within particular pedagogical orientations. We distinguish three pedagogical orientations that we envisage nested within each other. In the inner circle, with the narrowest focus, is transmission-oriented pedagogy where the goal is to transmit the information and skills articulated in the curriculum directly to students. The middle circle marks a pedagogical space that we term social constructivist pedagogy (Windschitl, 2002). This orientation

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 441–467.

incorporates the curriculum focus of transmission approaches but broadens it to include the development among students of higher-order thinking abilities based on teachers and students co-constructing knowledge and understanding. Finally, transformative approaches to pedagogy broaden the focus still further by emphasizing the relevance not only of curriculum transmission and knowledge construction, but also of promoting critical literacy among students to enable them to analyze societal discourses and conceptualize forms of action to affect these discourses.

We describe the potential of IT to amplify the impact of each of these forms of instruction drawing primarily on data from a computer-mediated sister-class project between students in Greece (specifically the islands of Rhodes and Kassos) and Toronto, Canada (Kourtis-Kazoullis, 2002; Skourtou, 2002; Skourtou & Kourtis-Kazoullis, 2002). We conclude that among school-age students, the impact of IT, as well as its cost-effectiveness, is likely to be significantly greater when it is harnessed to social constructivist and transformative pedagogies than to transmission pedagogies. However, this impact will be apparent only when appropriate forms of assessment are employed. Most standardized tests and national examinations focus primarily on lower-level skills and information contained in the curriculum and are thus likely to be insensitive to the thinking and literacy skills that social constructivist and transformative pedagogies attempt to promote.

It is important to note that we are not in any way disputing the potential efficiency of IT in transmitting information and skills to adults and school-age students. Transmission of information and skills is certainly a legitimate goal in many educational and corporate contexts. However, the goals of schooling go far beyond these forms of transmission, and to limit our pedagogical vision to a transmission mode represents an anemic orientation to education and a highly inefficient use of IT.

We begin with a brief overview of some of the key constructs that need to be clarified in examining the design of virtual technology-mediated learning environments. These constructs include Literacy, Technology, Curriculum/Pedagogy, Assessment, and Diversity.

2. CLARIFYING KEY CONSTRUCTS

2.1. Literacy

The teaching of literacy in the context of formal schooling has been controversial since its origins in the early 1800s and it remains so in many contexts around the world (see Clark, 2001 for analysis of the volatile "literacy crisis" debates in several countries). Academic debate on the nature of literacy has continued alongside the public debates and has yielded many insightful conceptualizations (e.g., Hornberger, 2003; Kalantzis & Cope, 2000; Willinsky, 1990). Two sets of constructs are worth noting at this point: (a) the distinction between *autonomous and ideological orientations* to literacy and (b) the contrast between traditional linear text-based forms of literacy and the multiple forms of literacies encompassed by the term *multiliteracies* (Kalantzis & Cope, 2000).

With respect to literacy instruction, in most countries curriculum is based on what Street (1999) terms an *autonomous model of literacy* that "assumes decontextualized skills, competencies, basics, a sequence from isolated to more complex units, and it privileges written over oral language" (p. 9). In contrast, many current literacy theorists endorse an *ideological model of literacy* that conceptualizes literacy as a set of social practices that are embedded in societal power relations (e.g., Baynham & Prinsloo, 2001; Gee, 2000; Kalantzis & Cope, 2000; Street, 1995; 1999).

Although autonomous and ideological models of literacy are typically contrasted with each other as opposite orientations, this is not necessarily the most productive conceptualization (Cummins, 2000). We locate our research and theory (elaborated below) broadly within an ideological model of literacy while viewing school-based (autonomous) literacy as one set of crucial social practices in which students must develop expertise if they are to participate productively in social and economic life.

The social practices that constitute typical school-based literacy should not be taken as given and immutable; rather they are subject to critique from the perspectives of both social constructivist and transformative pedagogical orientations. Thus, the relationship we envisage between "autonomous" and "ideological" orientations to literacy is one of constant critical dialog where school-based literacy practices are pushed to locate themselves in relation to societal power relations, and ideological pronouncements and/or prescriptions regarding literacy are pushed to realize themselves in practice in the complex world of schooling.

The term *multiliteracies* was introduced by the New London Group (1996) and includes both new forms of literacy associated with information, communication, and multimedia technologies (e.g., the ability to create web pages) and, equally important, the variety of culturally specific forms of literacy associated with complex pluralistic societies (Kalantzis & Cope, 2000). The construct of multiliteracies reflects the fact that we live in a world where population mobility and technological change are rapidly transforming social, economic, and educational realities. These technological changes, together with the information explosion, have also resulted in demands that schools promote higher levels of conventional literacy (reading and writing skills) together with expertise in new forms of literacy (e.g., computer literacy, media literacy) that are emerging in unpredictable ways.

The normalization of cultural and linguistic diversity in schools, together with the increasing infusion of sophisticated technologies into all aspects of society, has created both challenges and opportunities for education.

Specifically, is it feasible or reasonable to expect a one-size-fits-all homogenized curriculum to meet the needs of an increasingly diverse student body? To what extent should the education system attempt to acknowledge and promote the linguistic and cultural resources that students bring to school? If we see it as educationally desirable to promote students' multilingual and multicultural potential in schools, then what kinds of curricula and pedagogy are likely to achieve this goal? How do we evaluate a differentiated approach to curriculum and pedagogy as opposed to a homogenized centrally imposed model?

2.2. Technology

Computer access has expanded dramatically in North American and European schools. In the United States, the gap between affluent and poor schools in access to computer technology has also been reduced in recent years. The periodical, *Education Week* (2001) reports, for example, that schools in high poverty communities have one computer for every 5.3 students which is just slightly higher than the national average of one computer for every 4.9 students. However, although the "digital divide" between affluent and poor schools has been reduced with respect to quantity indices, the gap persists in the ways computers are utilized:

> With poor children, student-to-computer ratios belie huge gaps when it comes to internet access, according to the U.S. Department of Education. In schools, where fewer than 11 percent of students qualify for federally subsidized lunches, for example, 74 percent of classrooms have internet access. On the other hand, in schools where 71 percent or more students are living in poverty, only 39 percent of classrooms are connected to the internet.
>
> (Manzo, 2001: 12)

The recent massive investment in IT has been undertaken on faith rather than evidence. Critics in the United States have pointed to the absence of any overall impact on national reading achievement levels despite more than a decade of increasing access to IT in U.S. schools (Bennett, 2002). Canadian critics have berated the *disinformation highway* (Barlow & Robertson, 1994) and the diversion of scarce resources from other areas of the curriculum (Armstrong & Casement, 1998).

We argue below that a major reason for the lack of demonstrable impact of IT on academic achievement is that there has been minimal focus on the kinds of *pedagogy* that are required to exploit the potential of new technologies (Cuban, 2001; Cummins & Sayers, 1995) and the forms of *assessment* required to evaluate these potential impacts. Tyner (1998) has forcefully expressed this point: "The scholarship on the uses of electronic and digital communication forms for literacy purposes is abysmally weak" (p. 41). This situation is beginning to change. For example, a recent volume (Feldman et al., 2000) analyzing 10 years of data on the use of computer networking to support the learning of Science (e.g., the National Geographic Kids Network) highlighted the naiveté underlying aspects of the initial pedagogical vision. They articulated the importance of a social constructivist approach to pedagogy if IT projects are to yield academic gains. However, at this point, educators and policy-makers have just begun to address the integration of technology and pedagogy.

2.2.1. Use of IT in Greek Schools

Within the European context, the situation in Greece can be used to illustrate trends that apply across European Union (EU) countries (Kron & Sofos, 2003). EU funding has made possible the expansion of IT within educational contexts even in less affluent countries. IT is regarded as highly significant by EU policy-makers as a means to connect different languages and cultures beyond national borders.

Golemati (2000) has identified different forms of IT use within Greek schools:

(a) the teaching of IT as a subject in schools;
(b) the use of IT as a tool of teaching in other subjects;
(c) the use of IT for administrative purposes (e.g., the use of software for school administration);
(d) the use in IT in experimental student-centered learning environments; and
(e) the training of teachers through Ministry of the Education programs.

She reports that the majority of uses in Greek schools involved situations (a) and (b) above.

Koutsogiannis (1999) separates the use of IT in Greek schools into three periods:

- The first period (1986–1992) includes the first computer laboratories in approximately 500 schools in secondary education and the use of these laboratories for the teaching of computer science;
- The second period (1992–1996) involved the creation of 800 more computer laboratories and the explicit consideration of pedagogical goals;
- The third period (1996–1999) involved (a) small-scale pilot studies involving computer-mediated communication, (b) development of software for the teaching of specific subject areas, and (c) in-school training of educators.

Recent work has highlighted the challenge Greek educators face in trying to integrate the use of IT into a very traditional centrally imposed curriculum. Koutsogiannis (1999) reported that the majority of teachers he studied followed the curriculum of the school and used traditional pedagogy in both the regular classroom and IT contexts. Teachers attempted to transfer the familiar methods they used in the regular classroom to the new electronic environment. This is hardly surprising. Because teachers are required to follow a central curriculum, there is little opportunity or incentive for pedagogical innovation (Raptis & Raptis, 2002). Support materials designed for teachers (e.g., software consisting of practice drills or textbooks on how to use the internet) are also often highly traditional.

2.3. Curriculum/Pedagogy

Clark (2001) points to the polarized debate in many countries between "traditionalists" and "progressivists", the former portrayed as "representing order in the classroom with a defined sense of what was right and wrong whilst 'progressivists' were represented as child-centered, relativist and presiding over chaotic classrooms" (p. 149). The pedagogical framework that we have used to guide our research on computer-mediated sister-class projects avoids these caricatured extremes by highlighting the centrality of knowledge generation in an Information Age economy and the need for rigorous guided student inquiry as a foundation for learning. The framework also emphasizes (a) the centrality of language to all areas of the school curriculum (Cummins, 2001; Early, 2001; Hornberger, 2003; Mohan, 1986), (b) the role of imagination as one of the "most powerful and energetic intellectual tools children bring to school" (Egan, 1986: 18), and (c) the importance of collaborative critical inquiry that builds on and validates students' experience and culture (Cummins, 2001; Greenleaf et al., 2001; Kalantzis & Cope, 2000; Wells, 1999). The framework does not discard the utility of transmitting information and skills but highlights the importance of expanding a transmission or traditional orientation into *social constructivist* and *transformative* orientations. The former focuses on collaborative knowledge building and experiential learning designed to promote literacy and higher-order thinking while the latter similarly highlights the importance of collaborative knowledge building and experiential learning but with the goal of developing a *critical* literacy that focuses on social, rather than just cognitive, realities.

As illustrated in Figure 1, we envisage the three pedagogical orientations nested within each other rather than being distinct and isolated from each other.

Transmission-oriented pedagogy is represented in the inner circle with the narrowest focus; the goal is to transmit information and skills articulated in the curriculum directly to students. Social constructivist pedagogy,

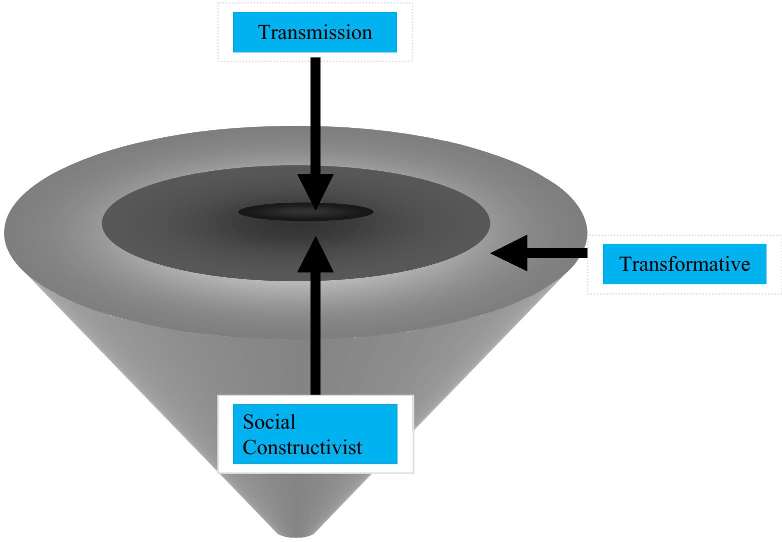

Figure 1. Nested pedagogical orientations.

occupying the middle pedagogical space, incorporates the curriculum focus of transmission approaches but broadens it to include the development among students of higher-order thinking abilities based on teachers and students co-constructing knowledge and understanding. Finally, transformative approaches to pedagogy broaden the focus still further by emphasizing the relevance not only of transmitting the curriculum and constructing knowledge, but also of promoting critical literacy among students to enable them to analyze societal discourses and conceptualize forms of action to affect these discourses.

The rationale for nesting these orientations within each other is to highlight the fact that features of traditional/transmission pedagogy are relevant to all kinds of learning. Both in classrooms that are clearly traditionally orientated and in communities of critical inquiry among students and teachers, structured guidelines and explicit instruction can play an important role in effective teaching/learning. Similarly, as the *DiaLogos* project outlined below illustrates, even in a traditional learning environment, spaces can be opened for social constructivist pedagogy, which, in turn, can sow the seeds for transformative pedagogy.

2.4. Assessment

Standardized assessment has become a major tool in the drive to increase literacy attainments in schools. There is considerable concern, however, that an over-emphasis on tests has narrowed the curriculum and is causing teachers to “teach to the test”, consigning broader educational goals such as the development of imagination, critical literacy, and higher-order thinking to the status of “off-task” activities (e.g., Kohn, 2000). Most centrally mandated large-scale assessment programs in countries around the world focus narrowly on traditional school-based literacy and ignore the multiple literacies (linguistic and technological) that may be equally relevant to students’ future economic advancement and civic participation (Kalantzis & Cope, 2000).

The relevance of re-conceptualizing high-stakes assessment procedures is that the design of innovative virtual learning environments will be severely constricted if students’ accomplishments within these environments are ignored for assessment purposes. If traditional reading, writing, and numeracy skills are the primary (or exclusive) focus of assessment, then students who spend time pursuing multiliteracies endeavors and/or critical literacy activities are likely to be penalized rather than rewarded for their achievements.

From our perspective, assessment should reflect, and reinforce, the range of pedagogical orientations and goals that are being implemented in the classroom. Unfortunately, in many contexts, assessment succeeds in reinforcing only transmission-oriented pedagogy and effectively eliminates other pedagogical orientations from the classroom. Thus, we would advocate different forms of assessment according to the specific learning activities that are being pursued. For example, traditional paper and pencil tests may be appropriate for a vocabulary learning activity, but this form of assessment is incapable of capturing the learning objectives of group-based project work. The latter forms of activity might be better assessed through portfolio assessment that tracks students’ academic accomplishments over time (Tierney, 1991). Thus, just as an applicant for Art College would submit his/her portfolio of work for assessment, students’ accomplishments in multiple spheres of literacy endeavor (e.g., web-page design, writing of bilingual stories for younger students, etc.), both in school and outside school, could be gathered in portfolios, assessed, and given academic credit. Implementation of portfolio assessment was a major factor in the outstanding academic outcomes obtained during the 1990s by recently arrived low-income ESL students attending the International High School in LaGuardia Community College in New York City (Cummins, 2001; DeFazio, 1997).

2.5. Diversity

Cultural and linguistic diversity has become the norm in major urban school systems across both North American and Europe. More than 50% of the school population in Toronto and Vancouver, for example, come from non-English-speaking backgrounds. The same trends are evident in Europe. For example, during much of the 20th century, Greece supplied many immigrants to the United States, Canada, and Australia but during recent decades has become a host country for immigrants from former socialist East European countries. Rhodes, the major site of the project we describe below represents a highly multicultural/multilingual landscape (Gialamas et al., 2000; Skourtou, 1995). The new global economy is similarly characterized by a plethora of languages and cultures, despite the current dominance of English in many cultural, scientific, and economic spheres. Thus, any pedagogical framework that aspires to promote literacy and prepare students for a globalized Information Age economy must assign a central role to linguistic and cultural diversity. Currently, this is not the case in the vast majority of European and North American school systems, despite occasional rhetoric about multicultural and anti-racist education.

The necessity to articulate pedagogical intersections between diversity issues and the design of virtual learning environments can be illustrated by examining one of the central components of a social constructivist orientation, namely the importance of activating students' prior knowledge in the teaching/learning process (e.g., Cummins, 2000; Wells, 1999). In a classroom (or virtual learning environment) characterized by cultural and linguistic diversity among learners, activating prior knowledge will bring a diverse array of culturally specific experiences into the pedagogical space. When the learning environment is designed appropriately, this process will enhance the learning opportunities of all learners. Unfortunately, however, there are currently few pedagogical guidelines or documented procedures for implementing virtual learning environments that respond appropriately to the diversity of student experiences.

In conclusion, although of necessity we have considered these five areas of theoretical and practical concern separately, they are interwoven in virtually all the interactions that educators, individually and collectively, orchestrate with their students. The challenge for educators is to integrate these areas within a coherent pedagogical framework particularly in the context of designing virtual learning environments, which are likely to proliferate in the near future (Tyner, 1998). A major paradox in the current situation is that virtual learning environments potentially provide the means to differentiate learning experiences according to the prior knowledge, learning styles, and goals of a diverse array of learners but they are increasingly being implemented in educational contexts that are retreating rapidly into one-size-fits-all homogeneous pedagogical and assessment orientations.

In the next section, we outline the framework within which we have conceptualized our recent work in designing and implementing virtual learning environments that respond to the considerations outlined above. This framework builds on the nested configuration of pedagogical orientations outlined above. Explicit demystification of how language and literacy operate as semiotic systems is very much incorporated into the framework as is the pursuit of *dialogic inquiry* (Wells, 1999) and the development among students of a critical awareness of how language and power intersect. Both *process* and *product* are seen as important with students encouraged to use language to explore and act on social realities that affect their lives.

3. FRAMEWORK FOR TECHNOLOGY-SUPPORTED ACADEMIC LANGUAGE LEARNING

The central sphere in Figure 2 represents the interpersonal space created in the interactions between teachers and students. Within this interpersonal space, knowledge is constructed and identities are negotiated. In other words, teacher–student interactions can be viewed through two lens: (a) the lens of *the teaching–learning relationship* in a narrow sense, represented by the strategies and techniques that teachers use to promote literacy, numeracy, content knowledge, and cognitive growth and (b) the lens of *identity negotiation* reflected in the messages communicated to students regarding their identities—who they

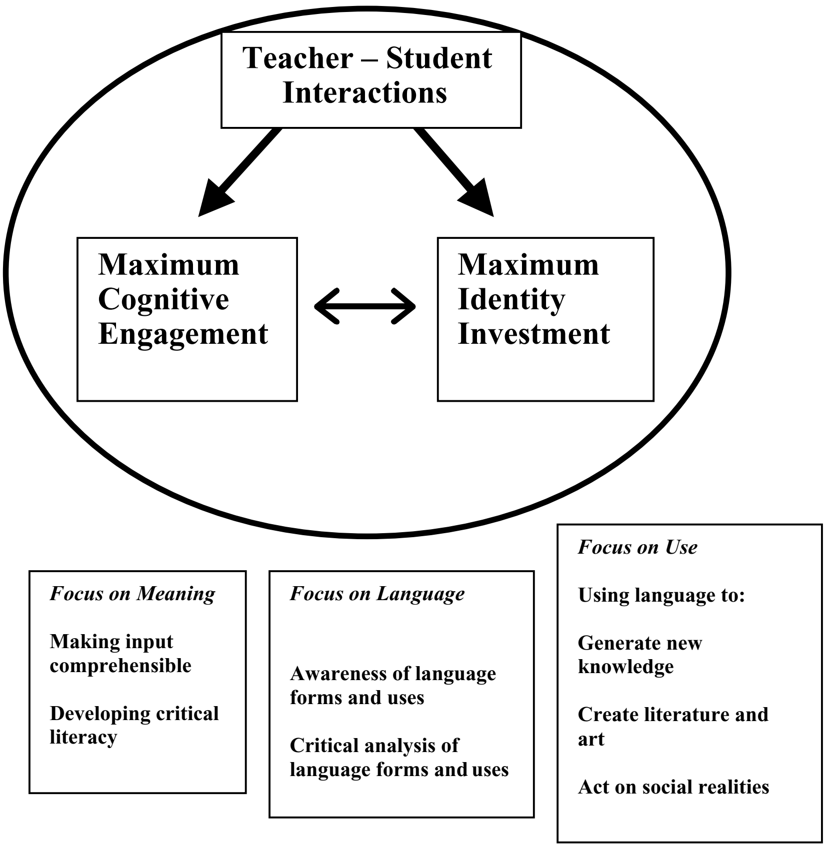

Figure 2. A framework for academic language learning. Source: Adapted from Cummins (2001: 125).

are in the teacher's eyes and who they are capable of becoming. The framework proposes that an optimal learning environment, virtual or "real", requires that both cognitive engagement and identity investment be maximized.

In contexts of cultural, linguistic, or economic diversity, these interactions are never neutral: They either challenge the operation of coercive relations of power in the wider society or they reinforce these power relations. Within the interpersonal space of teacher–student interactions, the more students become engaged cognitively, the more academic progress they are likely to make. Engagement of higher level cognitive processes is likely to produce much more learning for the simple reason that much more of students' brains are involved in the process of learning. If students are involved primarily in rote memorization in the classroom, only a fraction of their cognitive capacity is engaged in learning.

The interpersonal space represented in Figure 2 extends Vygotsky's (1978) notion of the *zone of proximal development* beyond the cognitive sphere into the realms of affective development and power relationships. The dual process of reciprocal negotiation of identity and collaborative generation of knowledge take place within this *construction zone* and are seen as being intimately related to each other. Teacher–student collaboration in the construction of knowledge will operate effectively only in contexts where students' identities are being affirmed. The framework also makes clear that the *construction zone* can also be a *constriction zone* where student identities and learning are constricted rather than extended.

The relevance of identity investment derives from the fact that affect is a major determinant of the extent to which students are likely to engage cognitively and academically. Students will be reluctant to invest their identities in the learning process if they feel their teachers do not like them, respect them, and appreciate their experiences and talents. In the past, students from marginalized social groups have seldom felt this sense of affirmation and respect for language and culture from their teachers, and consequently their intellectual and personal talents rarely found expression in the classroom. This perspective implies that in considering the potential of IT projects or programs to increase academic engagement among students from marginalized communities, two significant factors are likely to be (a) the extent to which students are encouraged to explore and appreciate aspects of their own cultural and linguistic heritage and (b) the extent to which they come to see themselves as intelligent and capable human beings in the process of carrying out these projects.

There is a reciprocal relationship between cognitive engagement and identity investment. The more affirmed and respected students feel in the learning environment, the more they are likely to engage cognitively; cognitive engagement results in learning and the more the students learn, the more their academic self-concept grows, which, in turn, results in more cognitive and academic engagement.

With specific reference to academic language learning, the framework proposes that instruction should focus on *meaning*, *language*, and *use*. Each of these foci is sketched below.

3.1. Focus on Meaning

The framework highlights the fact that effective instruction in a first or second language must focus initially on meaning or messages. Virtually all applied linguists agree that access to sufficient comprehensible input in the target language is a necessary condition for language acquisition. With respect to academic language learning in both L1 and L2, there is a vast amount of research showing a strong positive relationship between extensive reading and the development of reading comprehension (see Cummins, 2001, for a review).

The focus on meaning component argues that the interpretation of the construct of *comprehensible input* must go beyond just literal comprehension. Depth of understanding of concepts and vocabulary as well as critical literacy are intrinsic to the notion of comprehensible input when we are talking about the development of academic language proficiency. This implies a process whereby students relate textual and instructional meanings to their own experience and prior knowledge (i.e., activate their cognitive schemata), critically analyze the information in the text (e.g., evaluate the validity of various arguments or propositions), and use the results of their discussions and analyses in some concrete, intrinsically motivating activity or project (e.g., making a video or writing a poem or essay on a particular topic).

The application of IT tools in this way is consistent with Wells' (1999, 2000) advocacy of communities *of dialogic inquiry* where students, in negotiation with their teachers, plan their topics of inquiry and integrate their prior knowledge into the knowledge generation process within the school. The aim is to offer students multiple opportunities to contextualize learning. In Gee's (2000) work, *context* is a central construct. Learning becomes meaningful to students when they can create a context that integrates what they already know and what they are taught. A major part of this context is the particular discourse community, to which the student must gain access for learning to occur, whose perspectives, values, and "ways with words" (Heath, 1983) structure meaning in specific ways. Kress (2000) similarly argues for the role of context making and transformation in learning. The individual student is seen as a "re-maker" or "transformer" of learning resources (e.g., texts, videos, etc.) rather than as simply a "user" of them. Re-making of learning resources is a necessary process that the student has to go through in order to contextualize the content and make it comprehensible (Wells, 1999). Prior knowledge and contextual support represent the means for this transformation.

Depth of cognitive engagement, as implied by the transformation of learning resources, seldom occurs within a traditional pedagogical orientation because the focus is typically on memorization of content and internalization of particular literacy-related skills. Thus, the comprehensible input that students receive seldom moves beyond superficial literal understanding.

3.2. Focus on Language

The focus on language component in Figure 2 attempts to put controversial issues such as the appropriate time and ways to teach grammar, the role of phonics in reading instruction, etc. under the "umbrella" of *Language Awareness*. The development of language awareness (Toulasiewicz & Adams, 1999) includes not just an explicit focus on formal aspects of the language but also the development of *critical language awareness* that encompasses exploration of the relationships between language and power. Students, for example, might carry out research on the status of different varieties of language (e.g., colloquial language versus formal "standard" language) and explore critically why one form is considered by many educators and the general public to be "better" than the other. They might also research issues such as linguistic code switching and the functions it plays within their own lives and their bilingual communities. Or they might analyze letters to the editor on controversial issues such as immigration and examine how the language used in these letters positions and potentially stereotypes minority group learners such as themselves and their parents.

In short, the framework proposes that a focus on formal features of the target language should be integrated with critical inquiry into issues of language and power. Also, to be effective, a focus on language must be linked to extensive input in the target language (e.g., through reading) and extensive opportunities for written and oral use of the language (e.g., oral or written discussion of controversial issues).

3.3. Focus on Use

The focus on use component is based on the notion that L1 and L2 acquisition will remain abstract and classroom-bound unless students have the opportunity to express themselves—their identities and their intelligence—through language. In order to motivate language use, there should ideally be an authentic audience that encourages two-way communication in both oral and written modes. Clearly, computer-mediated sister-class projects provide such an audience. The three examples of language use presented in Figure 2 (*generate new knowledge, create literature and art, act on social realities*) are intended to illustrate important components of critical literacy. Language must be used to amplify students' intellectual, esthetic, and social identities if it is to contribute to student empowerment, understood as the collaborative creation of power (Cummins, 2001). Unless active and authentic language use for these purposes is promoted in the classroom, students' grasp of academic (and conversational) aspects of their second language is likely to remain shallow and passive.

There is little question that IT can provide many of the essential components required to stimulate active written language use. Collaborative sister-class projects, publication of student work on classroom or school web pages, or simply the use of computers to layout and print newsletters or other forms of publication all facilitate access to wider audiences than would otherwise be possible. IT can dramatically expand the communities of inquiry to which students have access and provide immediate outlets for communicating the results of students' intellectual and artistic work (e.g., through school or class web pages).

The focus on use component in our framework incorporates this transformational aspect of language use, highlighted by Kress (2000), and does not simply involve mechanical application of prior designs. Kress argues that it is insufficient for learners to be positioned only as "users" of an existing stable system without acting on, and transforming, this system.

We illustrate the relevance of this framework as a heuristic device for conceptualizing the relationship between pedagogy and technology with reference to the outcomes of the *DiaLogos* computer-mediated sister-class project (Kourtis-Kazoullis, 2002).

4. THE DIALOGOS PROJECT

DiaLogos was an internet-based sister-class project that was carried out over two school years between elementary school classes (4th, 5th, and 6th grades) in Canada and Greece. The initial objective was to create an environment of *dialogic inquiry* (Wells, 1999) where two different languages (i.e., English and Greek) could be learned. In co-operation with their sister classes, students in Greece were learning English and students in Canada (primarily students of Greek descent) were learning Greek. Students in the Greek primary school attend English lessons 3 hours per week. The *DiaLogos* students attended regular English lessons two times a week using the class textbook. However, once a week the lesson was held in the *DiaLogos* computer room.

The title, *DiaLogos*, implies many things. In the simplest sense, as one word, "dialogos" means conversation or dialog in Greek. However, with the "L" capitalized, *DiaLogos* is separated into two words and implies two different things: (a) "dia logos" or (b) "diadiktuou logos". In reference to (a), dialogos literally means *through words/through discourse/through logos*. The meaning of logos in Greek incorporates notions such as "speech", "discourse", and the system of rules underlying particular discourses. In reference to (b), a diadiktuou logo means *logos on/through the internet*.

On the DiaLogos web page, there was a play on words inviting the students to take part in "dialogos" or communication stating that:

> *A **DiaLogos** needs at least two **people.** It needs at least one **language.** And it needs* at least *one **subject.** We need **many people** to make our DiaLogos interesting. We also need **many languages** in order to be able to carry out the DiaLogos with many people.* And *we need **many interesting subjects** to be able to learn many things from our DiaLogos. In other words, we need **YOU**, the **LANGUAGES** you know and those that you want to learn and the **SUBJECTS** that will help us explore and discover new things.*
>
> (DiaLogos web page)

Although, on the Greek side, DiaLogos was carried out within a traditional textbook-dominated educational setting, the pedagogical orientation of the project itself attempted to be explicitly transformative. However, at different times, the activities that took place in the classroom (with or without IT) ranged across the pedagogical space depicted in Figure 1. At certain times, the activities were partly traditional, partly constructivist. At other times, they were constructivist, moving toward transformative. However, regardless of where the activities were located within the pedagogical space, the "target" was always within the transformative realm.

The activities carried out by students in *DiaLogos* illustrate the major dimensions of the pedagogical framework articulated in Figure 2. As the examples outlined below show, students were cognitively engaged and personally invested to a high degree in the various projects they carried out. They read and discussed a considerable amount of material in the target language (English) originating both from internet sources and their sister-class partners (*focus on meaning*). They became aware of and began to use forms of colloquial English that they would never have heard within the traditional English language classroom (*focus on language*). Finally, they created "products" or "artifacts" (Wells, 1999) that, we would argue, amplified their sense of self. Their use of language (both Greek and English) entailed the creation of literature and art and concrete action on social realities that affected their lives (*focus on use*). These different foci are integrated in the activities described below.

4.1. Critical Awareness of Language Forms and Uses

Within the regular English classroom, a *focus on language* was already apparent with the teacher making the students aware of language forms and uses by explicitly teaching grammar, vocabulary, syntax, etc. in a traditional manner. The English language in their textbook was of a relatively consistent form. In contrast, the English language on the internet was diverse, and the English language used by their sister classes opened up entirely new possibilities for using the language. The Canadian students were using expressions that were completely new to the students in Greece, as the following two examples illustrate [spelling mistakes are original]:

[Student from Canada]

Katerina—I didn't have much of a Christmas this year because I was moviong and we didn't put up a tree and stuff like that but it was fun moving and stuff. On Christmas eve we went to my aunt's house and had a big feast and me and cousin Maria were chilling out. On New Years eve we went to my moms friends house and clebrated it there and we brought in 1999 we [with] a really big bang!!

BYE FOR NOW KATERINA!!!!!!!!!

[Student from Canada]

On my winter break I had a remarkable week. My sister had her 8th birthday party. We had a blast!

Expressions in the letters from Canadian students such as *stuff like that*, *and stuff*, *chilling out*, with *a really big bang*, *we had a blast* and *whaz up*, fueled the students' curiosity and resulted in critical analysis of language forms. *Cool* and *bad* were words that students in Greece were familiar with; however, they were not familiar with the different way in which they were used. The Canadian students were using English but a different type of English. This had a significant effect on the students in Greece who began using the English language in similar ways to the students in Canada as early as the first year of correspondence (Kourtis-Kazoullis, 2002).

4.2. Generating New Knowledge

In Greece, the curriculum is prescribed by the central government and the same textbooks are used in all regions of Greece, despite the local identities and local language varieties of the students. Students in the island of Kassos used DiaLogos to generate new knowledge and share this knowledge with an audience outside their island. Kassos is a small island in the Dodecanese with a strong tradition of local music, both vocal in the form of sung poetry and instrumental in the form of playing the *lyra* (lyre). As in many rural areas of Greece, the teacher plays a central role in incorporating the local culture into classroom practice (despite the national curriculum) in the form of activities, often as a result of play performances or local holidays. The two-room school of Agia Marina, Kassos is a prime example, as the principal had already involved his students in activities such as researching the flora and fauna on the island even before the DiaLogos project. They had a school magazine, the production of which was enhanced by means of the computer equipment made available though DiaLogos.

The English teacher who was not from the island herself was the person who was involved in the implementation of DiaLogos in the school. Initially, she was reluctant to participate and was convinced that the students could not do projects until we suggested that the students write local sung poetry and translate these poems into English for their sister class. The local history, oral stories, etc. became more significant when they were generated for an audience that knew nothing about the culture of the island. Thus, Kassos contributed to DiaLogos local oral stories such as "The Fishman and the Enchantress" and interviews of older members of the community, i.e., grandparents, fishermen, people who had immigrated to other countries and returned, etc. These activities, already carried out with their teacher in Greek, became more meaningful when they were created for students of their own age in a completely different environment, metropolitan Toronto. This student-generated writing was translated into English with the help of their English teacher and shared with others.

Many interviews took place. One example is given below (as written by the students, without corrections):

THE LIFE OF MY GRANDFATHER
AT SEA
INTERVIEW: IOANNI DIM. EROTOKRITOU (GRADE 5)

IOANNIS:	How was your life at sea, grandfather?
GRANDFATHER:	Life at sea was very difficult.
IOANNIS:	What was your job exactly?
GRANDFATHER:	The captain gave us any job there was available, there were not many jobs then and we were in great need.
IOANNIS:	How much money did the captain give you?
GRANDFATHER:	We got paid every 6 months because there was a big economic crisis. I was 25 years old when I went to sea.
IOANNIS:	When the crisis was over how much money did you get?
GRANDFATHER:	We got 5 pounds every month.
IOANNIS:	Was the captain strict? How many years did you stay in sea?
GRANDFATHER:	The captain was very strict. I stayed 30 whole years in sea.
IOANNIS:	How many people were on board?
GRANDFATHER:	We were 60 people.
IOANNIS:	When did you stop travelling and why?
GRANDFATHER:	After 30 years because we shipwrecked and we were in great danger. Many hours later they came and saved us.

IOANNIS:	What else do you remember from your life?
GRANDFATHER:	Once we caught on fire in Venice. Fortunately they towed us out and they saved us.
IOANNIS:	Did you like life at sea?
GRANDFATHER:	It was very tough but I had the opportunity to meet new people and discover new places. We went to England, America, Spain and other countries.

4.3. Creating Literature

Evgenios Trivizas, a well-known Greek writer of children's stories, was asked for permission to use one of his stories for DiaLogos in order to foster sister-class collaboration on a joint project and creative expression through creative writing. Mr. Trivizas graciously went further to give us a handwritten introduction to a story, which he had just begun and had not completed. This introduction was translated into English and was circulated in Greek and English to all the schools via e-mail with directions to the teachers and students on how it could be used. The students were to continue the story in any way they wanted and were to decide on joint endings with students in their sister classes.

The story dealt with a grouchy man, Mr. Stripsidis, who sent away different animals who came to his home for protection. Thus, there was an element of dialog repetition each time a new animal came into the story. This repetition helped students construct their story endings by basing new dialog they wrote on what had already appeared. There was also a problem to be solved. Finding an ending meant finding ways of negotiation between the man and the animals. Students had to also collaborate with members of their sister class on a joint ending. The Greek students were encouraged to use the target language (English) but were free to use their first language when needed—or they could even use both languages in the same text.

Each class in Greece was divided into smaller groups of two or three students who jointly worked on the activity. In the traditional Greek school setting, collaboration of this sort was something new and unfamiliar to the students. In the end of the year interviews, both students and teachers stated that they rarely participated in group work, except for the DiaLogos project. The collaborative group work served as support for the students who were at different levels with respect to knowledge of English. However, it also posed difficulties in the beginning, as students were not familiar with this type of negotiation and collaboration.

In order to assist the students in a new task of this sort, three external experts were available, both in person and electronically: (a) a literature/language advisor, (b) a technical advisor, and (c) a creativity advisor to give students ideas. The literature/language advisor read all the texts the students wrote and answered each student individually, mostly to give the students encouragement.

As part of the communication between the sister classes, some of the students asked for information from their sister classes in order to complete the story. For example, students in Rhodes wrote to their sister class in Toronto and asked for information about the raccoon, as they wanted to use this animal as a character in their story. They knew that raccoons existed in Canada but did not know anything more about them.

Letter from Greece

> Dear friends from Diefenbaker class,
>
> We are team E in Class E3 from Rhodes. Our names are Vivian, Aliki, Eleni and Michaella. We are working on the project with Triviza's story and we need some information about Canadian animals. We want to add a racoon to our story. Vivian has seen a raccoon in Canada because she was born in Toronto. Can you tell us where a raccoon lives? What kind of food do they eat? Are they good or bad animals? Bye.
>
> [from E3 Rhodes]

The students responded with letters such as the letter below and suggestions on web sites to visit.

Reply from Canada

> Racoons live in North America. They live in the forest cornfields and make their homes in a hollow tree called a den. Racoons eat frogs, fresh fish, mice, insects, fruit, birds, corn and their favorite food is crayfish. Racoons are curious, mischievous and annoying. But they don't make good pets.

The information exchanged also dealt with language. In the letter below, one student asks, "How do we say *kakarizo* (the sound of a chicken) [in English]?" and "How do we say *sthrouthokamilos* (ostrich)?" Another student asks (in the student's own words) "What is a sound of a cat? [what sound does a cat make?]".

Letter from Greece

> Letter from E3 (Rhodes) to the Diefenbaker P.S.
>
> Dear children,
>
> We are trying to write the story of Evgenios Trivizas. Do you know things about him.

> We will try to bring information about him. Spiros from D team asks how do say "kakarizo" (the sound of a chicken)?
>
> How do we say "strouthokamilos"?
>
> Maria S. from team F asks what is a sound of a cat.
>
> Bye for now
>
> Write to us soon to see what you are doing.
>
> The E3 class

In the letter above, it is clear that the students were exchanging information about the author. In other letters, information about the author was circulated and students in Greece who were more familiar with the author's work made suggestions about further reading of his books.

The way the students used the bulletin board on the web site was significant. Although the bulletin board was designed only for story endings, the students used it in a way that had not been planned. They used the window to send corrections to the web master. This illustrates how conscious the students were of having their work published and read by others. The text was treated as an *improvable* object. Whereas in traditional classroom settings, corrections on assignments handed to the teacher are not viewed as particularly important by students, corrections on the web page were of vital importance to them. In fact, students became impatient when the web master took too long to make the corrections they requested.

Editing dealt with the content of the story as well as with the correctness of the form. The students often wanted to make changes in their stories, even a long time after they had written the original version. Although the activity was begun in the first year of DiaLogos' implementation, editing of the texts went on throughout the 2 years. The students often went back to the texts, adding information and making changes. The students' sustained interest in one particular text was very unusual.

The story, originally in Greek, became bilingual, as the contributions written by the students were in English and Greek. Eighty different stories were written. Fifty-nine stories were written by the students in Greece (35 stories in Greek and 24 in English) and 21 stories were posted on the bulletin board from students in Canada (9 in Greek and 12 in English). Some texts included both languages, reflecting students' attempt to use the target language. It is evident from the level of Greek of the students in Toronto how hard they tried to write in Greek. They often used English words to express what they could not express in Greek. The students were not confined to only the standard forms of the languages, as is usually the case in school. They used words and expressions that were closely tied to their identity. For example, the Greek–Canadian students in Toronto often used words characteristic of the Greek–Canadian lexicon such as “tzara” (written in Greek) for the word “jar”. The students from Canada also used words that the students in Greece would not normally come across in their English books (which contained only standard English) such as “zapped him”. It is interesting that the students learned the form of the target language that the members of their sister class were using. For example, when one of the students in Canada used the expression, “So, it is cool”, a student in Greece not only figured out the meaning of this expression, but also used it in communication with the sister class.

4.4. Acting on Social Realities: *Ancient Rhodes*

The catalyst for the project on Ancient Rhodes was letters sent from Canada, asking for information about Ancient Rhodes. An (uncorrected) example is given below:

> Hi, my name is Michael. Did you get
> my letter that I wrote to you?
> Do you have any information about
> ancient Greece. If you do can you
> please tell my!

In order to provide information, the students from one school in Rhodes began conducting research (in English class) on their own island and the areas around their homes and school. As the curriculum in Greek schools is specified by the central government and all textbooks are the same across regions, regional history is not taught as a specific subject in school. In some cases, if appropriate, it might be taught as part of the national history. The students began conducting their own research and embarked upon a project that was entitled *Ancient Rhodes*. In order to help students (and teachers) to carry out this research, a learning packet that outlined processes and strategies for carrying out critical research was prepared. The seven phases, summarized below, were articulated and discussed with students (Kourtis-Kazoullis, 2002).

4.4.1. Structuring Critical Research

Phase 1: Setting questions
What do we want to know?

Phase 2: Using what we know and what others know to construct new knowledge
First we begin with what we already know. Once we utilize what we already know, we can gather new information.

Phase 3: Gathering information
a. Finding information (both from our own environment [e.g., local archeological sites, museums] and from other sources such as textbooks, the internet, teachers, experts, etc.).
b. Taking notes.
How do we record the material we find?
c. Documenting our work.
How do we state where we found the material?

Phase 4: Critically viewing our topic
What viewpoints are represented in the material we found?

Phase 5: Production as process not as a static product
When we write our articles we understand that we can change, elaborate, and improve the text at any time either by ourselves or with members of our group

Phase 6: Sharing our ideas with others both orally and in written form
Our articles can be shared between students, classes and schools, sent by e-mail to the sister classes and published on the web page.

Phase 7: Critically viewing our work with others
When we share our work with others, we can critically view our work by asking for other opinions and discussing issues with others.

Although learning rarely takes place outside the classroom in the normal school setting, the students of DiaLogos took part in critical research that went beyond the four walls of the classroom. They went to the archeology department and interviewed archeologists, visited the museum (many of the students for the first time) and a special exhibition commemorating the 2400 year anniversary of the establishment of the city of Rhodes, and they documented archeological sites in their village. They were surprised to find that there were archeological sites very near their school and that there were artifacts in the museum found on a site very near their school. They were given an electronic research sheet that guided them through different internet sites that would be used to collect information. One activity involved taking an electronic quiz dealing with archeology on a U.S.-based archeological web magazine called *Dig Magazine*. A high mark on this quiz would give the students the title of "honorary archeologist", a title that they were eager to get as a result of the visit to the museum and their resulting interest in becoming archeologists. As most of the questions, surprisingly enough for the students, related to Greek culture, they were sure that they would do well. When the students answered the following question in this quiz, they were surprised to find that their answer was labeled incorrect:

> **2. The marble figures and sculptures from the Parthenon in Greece, but have been owned by Britain since 1801, are called**

a. The Parthenon facts
b. The Greek Relics
c. The Elgin Marbles
d. The Olympic Artifacts (Dig Magazine, 2000, quiz 6)

Most of the students answered (a) as they knew that the marbles were from the Parthenon. However, this response evoked the following feedback:

Your answer for question 2, Parthenon, is WRONG!
The answer is c, the Elgin Marbles. The marbles were taken by a British ambassador named Lord Elgin in 1801 when Greece was ruled by Turkey's Ottoman Empire

This had the effect of encouraging the students to take the step from inactive observers to active participants in critical inquiry. What gave them this strong incentive to take action was the mismatch between the information supplied on the electronic quiz and their own image of Greece and their place within Greece. They decided to research the topic, write to the editor, and argue their point. This action may seem like a very small step; however, it was a major step for these 10-year-olds. These *small* students from a *small* island in a *small* country, speaking a *small* language took a big step into the world far beyond their classroom to *battle* with the editor of a *large* educational magazine from a *large* country with a *large* language. They might never have taken this step if they had not felt that someone else was teaching them incorrectly about their *own* identity.

The students, with the help of their teacher, wrote and sent the following letter to the editor:

Correspondence 55: Letter to editor

At 10:02 AM +0300 5/9/00, *DiaLogos* Schools wrote:
—Original Message—
From: *DiaLogos* Schools
To: 'editor@dig.archaelogy.org'
Sent: 9/5/2000 9:55•I
Subject: Letter from Elementary School in Kremasti, Rhodes Greece
Dear Editor,
We visited your site and enjoyed it very much. We learned a lot about archeology around the world and recognized a lot of familiar things from Greece. However, there was one part which we disagree with. One of the questions on the test refer to the marbles from the Parthenon as the Elgin Marbles. This is what we have to say:

≪In Ancient Greece there was a building called the Parthenon. They began building it in 447 B.C. and finished it in 432 B.C. It was made to honor the Godess Athina and was designed by the architects Iktinos and Kallikratis. But in 1820 A.D. a British diplomat who was called Elgin Tomas stole the marbles. Apparently, he did not know their historical value. He took the Parthenon Marbles to Britain and as if that was not enough today they are called the "Elgin Marbles". The marbles were later put in the British Museum.
So, we are writing this letter of complain to you. When you refer to these marbles on you web page, please do not refer to them as the Elgin Marbles. In reality, they are of Greek origin and should be called the Marbles of the Parthenon. Elgin profited by stealing them. He should not profit by having them named after him.≫
We thank you very much. We would appreciate a reply from you with your own viewpoint on this matter.
On behalf of the 6th grade class of the Kremasti Elementary School in Rhodes, Greece,

Two letters were received back from the editor and the "in-house" archeologist of the magazine. These letters noted the complexity of the issue but also acknowledged the legitimacy of the students' concern.

In short, in the context of their critical inquiry, these students discovered that how others depict their own culture might be very different from how they view themselves. But more importantly, they discovered that they could take action and that this action could bring results.

CONCLUSION

We have argued in this chapter that IT *can* play a significant and positive educational role, but only if its pedagogical possibilities are clearly understood. For school-age students, IT is minimally useful as a pedagogical tool when it is assimilated into a rigid top–down teacher-centered textbook-oriented curriculum. It may do little more than the worksheets of old, at considerably greater cost. However, when IT is integrated into a more dynamic and socially transformative pedagogical orientation, it has enormous potential to promote academic language learning, thinking and problem-solving abilities, imagination, and affirmation and expansion of student identities. This orientation will not eschew transmission of information and skills. However, it will go beyond transmission to include collaborative construction of knowledge and the encouragement of social critique as important learning goals. Unfortunately, current trends in many countries with respect to pedagogy in general and IT in particular reflect the former one-size-fits-all pedagogical orientation rather than the more dynamic "knowledge generation" orientation associated with a pedagogy of collaborative critical inquiry. These trends are particularly in evidence in schools serving low-income students.

The DiaLogos project has illustrated how cognitive engagement and identity investment can be increased when the power of IT is harnessed to connect students with sister classes in different cultural, linguistic, and geographical contexts. Students' identities can be expanded when they have to define aspects of their own reality to present to the sister class and when this reality is reflected back to them through discussion and collaboration on concrete activities and projects. Literacy is expanded in the process of carrying out joint projects for the simple reason that students read more, discuss more, and write more than when they are in an isolated, contained, non-communicative classroom situation.

The theoretical framework articulated in this chapter suggests that in evaluating virtual learning environments for school-age students, we should go beyond asking whether the environment is effective and cost-efficient in transmitting information and skills. Although legitimate, these questions derive from and reinforce the normalization of transmission approaches to curriculum and instruction. Instead, we should also ask: To what extent is the virtual learning environment effective in encouraging and facilitating critical literacy? To what extent does it develop among students a greater awareness of language forms and structures, as well as an appreciation of the power of language to influence (for both good and ill) social realities? To what extent do students participating in virtual learning environments generate new knowledge, create literature and art, and act on social realities? When these questions are answered negatively, we would argue that the virtual learning environment is not living up to its potential.

The central questions for the future concern not the adequacy of the technical characteristics of various forms of IT, nor the professional development of teachers in using IT. Rather the major issue is whether as a society we are prepared to implement forms of pedagogy, powerfully amplified by IT, which can promote imagination and critical literacy abilities among students while at the same time potentially illuminating the operation of societal power relations.

Chapter 19: Inclusive E-learning

JUTTA TREVIRANUS AND VERA ROBERTS
Adaptive Technology Resource Centre, University of Toronto

1. INTRODUCTION

It has been very convincingly argued that true innovation and the way ahead can be found at the margins of any field (Rose & Meyer, 2000). In education, accommodating learners who are marginalized by traditional education delivery has and continues to expand the boundaries of the domain and inspire new strategies and practices that benefit all learners.

Disability is a relative and therefore constantly shifting state. A learner using a wheelchair is not disabled in a lecture setting with an accessible lecture hall; a learner who does not have the requisite background knowledge is. In a learning environment disability can be defined as a mismatch between the needs of the learner and the education offered. Given this definition, disability is not a personal trait but an artifact of the relationship between the learner and the learning environment or education delivery. Most educators, given the standard constraints in time and human resources, by necessity, teach to the hypothetical norm. Learners who do not fit that norm are disadvantaged or excluded. Depending upon the teaching approach, learners who are marginalized may include for example, learners who are gifted or shy, or who have a sensory impairment that affects their ability to receive the information presented (Jackl et al., 2004).

While there is little agreement in the research literature regarding the effects of online instruction versus traditional education delivery with respect to cost; instructor time, and learning outcomes for the average student; there is general agreement that computer-mediated learning benefits the student who is marginalized or performing poorly in traditional learning environments. This benifit is attributed to the ability to customize or personalize the delivery and content in computer-mediated online education (Aragon et al., 2002).

Individual customization and optimization is a difficult task in a traditional teaching environment. Diversity of learners and learning approaches is apparent even amongst high school students and post-secondary students who have several years of pressure and socialization to conform to the norm. Successfully accommodating this diversity implies that many students must be given individual programming, that the presentation must be multimodal and the learning activities rich and varied. The most talented and experienced pedagogue has great difficulty creating an optimal learning environment for

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 469–495.

all learners in a traditional classroom. The higher the ratio of students to educators the more difficult this challenge becomes.

Given the reframing of disability above, accessibility can be defined as the ability of the learning environment to adjust to the needs of all learners. Accessibility is dependent on the flexibility of the education environment, curriculum, and delivery, as well as the availability of adequate alternative-but-equivalent content and activities. Accessibility requires individual optimization of the learning process.

Personalization in an online environment has come under criticism recently because of the perceived effects of services such as personalized news channels that deliver only the news the user is interested in, thereby creating an insular attitude and eliminating the opportunity to expand one's views or learn about novel topics (Riecken, 2000). Personalization in the context of this chapter does not imply that the learner is only exposed to topics she is interested in or that she is only presented with learning activities that she is capable of doing and feels comfortable with. Accessible e-learning implies education delivery that optimizes learning: Including activities and materials that are sufficiently challenging to advance the learner's knowledge and skills.

An approach that grows and wanes in popularity is the creation of curriculum, course packs, lesson plans, or modifications for a specific class of learner, such as learners for whom English is a second language, learners with attention deficit disorders, or even science for girls (Alberta Teacher's Association, 2001). The difficulty with this approach is that each learner may have important characteristics that distinguish that learner from fellow learners in a specific classification. These distinguishing characteristics may be more significant in a specific context than the characteristics that qualify the learner for the classification. Classifications also encourage overgeneralization and false assumptions based upon these generalizations. Even for an individual learner, requirements regarding education delivery may change from discipline to discipline or learning goal to learning goal. Given the complexity and fluid nature of each individual's needs, customization must be at a much more granular level. The authors would contend that this customization should be responsive to each individual learner and each learning context.

E-learning or computer-mediated networked learning has the potential to deliver this level of customization. Accessible e-learning is a compelling application that provides a critical purpose for a number of emerging information technologies including the semantic web, intelligent agents, and adaptive web services. Optimizing learning for each individual learner in an e-learning environment is dependent on either or both (a) components that are transformable and/or (b) a sufficiently broad pool of alternative components combined with mechanisms for matching the appropriate components to the learner. Transformable components would include:

– User interfaces that support more than conventional input and display devices (conventional devices being the keyboard, mouse, screen, and speakers);
– content that is amenable to restyling, is sufficiently structured to allow reorganization and has adequately informative labels (i.e., metadata) to allow reuse and re-purposing;
– activities and applications that can be presented and controlled in a number of ways and can be populated with a variety of content; and
– learning or knowledge management systems that implement a variety of ontologies and rules.

If designed and implemented correctly, e-learning may effectively eliminate all barriers learners with disabilities have faced in traditional learning environments. This chapter will outline the principles, processes, and technologies that support accessible networked learning. Existing, emerging, and potential tools and practices will be discussed.

2. THE MANY GOALS SERVED BY ACCESSIBILITY

Accessibility is rarely a priority for e-learning tool and curriculum developers. Traditionally, accessibility has not been regarded as a consideration in the drive for profitability. People with disabilities are not seen as a large enough consumer group to wield a significant market force. Even with legislation requiring accessibility and large institutional purchasers requiring accessibility in purchasing policies (WAI, http://www.w3.org/WAI/Policy/), accessibility is not prominent in the design criteria of most IT products. However, accessibility is consistent with a number of other design goals and agendas that receive a higher profile in corporate strategies. When accessible design principles are followed, other positive outcomes such as interoperability, content portability, device independence (device independence refers to the ability to write content once and display it in many different devices such as cell phones, PDAs, laptops, and desktop systems), internationalization, tool and content longevity, and many other benefits are also achieved (WAI, http://www.w3.org/WAI/EO/Drafts/bcase/). Conversely the technologies developed to achieve these other goals can be harnessed for accessible education delivery.

Information technology tool developers have adjusted to the notion that we do not live in a uniform world. We can make very few assumptions about consumers or even groupings of consumers. Users, their hardware, their software, their networks, and connectivity are very diverse. Technologies and information technology architectures are increasingly constructed to deal with that diversity. This flexibility when properly implemented can be used to provide accessible e-learning environments.

There are significant market arguments for device independence and flexibility in e-learning delivery. Students and other consumers use a large range of devices including stationary workstations, laptops, tablet computers, PDAs, and cell phone based browsers. Each of these have different display specifications and support a different presentation mode with regard to styling and information structure. Additionally, the disparity in available bandwidth is growing as certain nations install broadband infrastructure while the majority of the world continues to be restricted to dial-up access. Balancing the demands for rich content on the one hand and bandwidth efficient material on the other becomes more and more difficult as the gap widens. Globalization creates an added demand that translatable text may be extracted from code that does not require translation. Despite pressure for uniformity from large content producers, browser developers, in an attempt to survive in a highly competitive market, strive to distinguish themselves with unique features and proprietary rendering. Content creators do not wish to create multiple versions of content but would prefer to write once and present in multiple ways. This desire to accommodate multiple devices, bandwidths, languages, and browsers also serves accessibility.

3. THE IMPORTANCE OF INTEROPERABILITY AND ALTERNATIVE ACCESS SYSTEMS

Interoperability specifications and standards are the information technology equivalent of the rules, laws, and conventions that govern social behavior in a civilized society. As in a society, the alternatives to following these guidelines and requirements include living as a hermit, living in isolated and insular cultures, lawlessness, the rule of bullies, anarchy and chaos. It is easy to think of equivalents to all of these in information technology environments. Hermit software applications do not communicate or interact with others. Isolated and insular community applications can only be used in a specific context, content area, or platform. Information technology bullies impose their rule not through consensus or collaboration but through the influence of power and threat. Lawlessness, anarchy, and chaos exist when applications conflict with one another, are redundant and disorganized.

Education is a social activity. Academia cannot thrive without information exchange within the institution, within the community of interest and among intellectually engaged people nationally and internationally. An information technology system or application therefore cannot be an e-learning system unless it is interoperable.

While interoperability is important for e-learning, the importance is heightened for learners who use alternative access systems or specialized devices such as refreshable Braille displays, enlarged keyboards, or voice recognition systems. Many people with disabilities are dependent on alternative access systems to use a computer. From an information technology developer's perspective every person with a disability potentially represents an external system that needs to interoperate. In fact, because of the diversity of alternative access systems, every person with a disability potentially represents a unique external system that needs to interoperate. Thus the equivalent challenge of compatibility between a Mac computer and a Windows computer is played out with each and every learner with a disability using an alternative access system.

E-learning application developers can either provide "direct access", meaning that the learner's alternative access needs are met by the application which provides a range of alternative display and control methods, or the application must interoperate with the personal access systems the learner uses. Applications that interoperate with alternative access systems are said to be "access system friendly". The same interoperability specifications and standards that govern application-to-application and application-to-alternative device interoperability (such as interoperability with cell phones or PDAs) also facilitate access system friendliness (Treviranus & Petty, 2001).

Alternative access systems, also referred to as assistive technologies, can be grouped into alternative display technologies, alternative control technologies, and assistive processing systems (ATRC, http://www.utoronto.ca/atrc/ reference/tech/techgloss.html). Alternative display technologies provide alternatives for anyone who for whatever reason cannot see or hear what is presented through the standard screen and audio system of a computer. Alternatives include screen readers that read or speak out the information presented on the screen, screen enhancement software that enlarges and increases the contrast of visual information on the screen, refreshable Braille displays that provide the visual information in tactile Braille form, and visual cueing utilities to replace audio. Alternative control technologies provide alternatives to the mouse or keyboard for controlling the computer. These include minor modifications to the action of the keyboard (such as providing a way of holding down modifier keys including shift, alt, or control and other keys using a single digit, or slowing down the repeat rate of a key), alternative keyboards (such as keyboards with enlarged keys, miniaturized keys, alternative layout of keys, or alternative key actions), on-screen keyboards with switch input devices that allow input using as little as a single voluntary movement, coded input systems (such as Morse code systems) and voice recognition systems. Assistive processing systems help to organize or translate information into forms that are more suitable for the user or speed up input. These include prediction programs such as word completion programs, symbol input or display systems, and abbreviation-expansion programs. A large number of printed and web-based references exist describing these technologies (ABLEDATA, http://www.abledata.com/).

Because each user with a disability must access a number of frequently changing applications, the alternative access system must communicate effectively with all popular generic applications. Given the unfortunate dearth of "access system friendly" applications, the burden of interoperability frequently falls upon the assistive technology developer. These are usually microcompanies that are addressing the needs of a tiny niche market and are therefore poorly resourced to tackle the complex design task. They are further challenged by uncooperative generic application developers who refuse to give them access to proprietary software design information needed to enable effective communication between the alternative access system and the application. The current conventional assistive technology business model is problematic. People with disabilities or their agents are presently the clients of assistive technology developers and bear the cost of interoperability development. However, e-learning application developers are compelled by law and by institutional purchasing requirements to provide accessible applications. If these e-learning application developers engage assistive technology developers to, in essence, assist them in meeting their accessibility commitments by creating alternative access systems that interoperate with their application, a more sustainable business model would be established. E-learning application developers would be more inclined to cooperate and collaborate with assistive technology developers. This would reduce the cost of interoperability development and lead to more efficient and effective assistive technologies. However widespread transition to this business model will require significant government intervention.

4. TWO APPROACHES TO ACCESSIBILITY

There are essentially two approaches to providing accessible learning resources. The approach most commonly used at the moment can be called the "accessibility compliance approach". Using this approach the education provider attempts to create a single resource that is accessible to everyone. In most cases this resource would meet accessibility guidelines such as the W3C WAI Web Content Accessibility Guidelines (www.w3.org/WAI), described later in the chapter) or the US Rehab 508 Act (WAI, http://www.w3.org/WAI/Policy/). Over the past 5 years educators and students have identified a number of problems with this approach (Jackl et al., 2004). Among the problems noted are: (1) Most educators have little time to prepare curriculum or learning content. It is unrealistic to expect every educator to gain the expertise required to adhere to all of the accessibility guidelines or regulations; (2) Existing resources, created prior to the compliance effort are frequently discarded because they do not adhere to the set of accessibility guidelines, even when they include learning experiences that are highly engaging and interactive for some students; (3) Learning experiences that tightly adhere to accessibility guidelines may be accessible to all students, but at the expense of not being optimal for any student; and (4) When educators feel hampered by the regulations using this approach they frequently create a "media-rich" version as well as an "accessible" version of a learning resource or experience. Students requiring the "accessible" version are effectively segregated from their peers. The maintenance of the "accessible" version is often neglected and it becomes outdated. A more fundamental problem with this solution is that the requirements of people with disabilities vary tremendously. The notion that a single resource configuration or design can optimally meet the needs of all individuals with disabilities is seriously flawed.

The alternative approach is to create a transformable, flexible resource delivery system. This system would match the needs of the learner with the education delivered by transforming the presentation of the resource, adapting the method of navigating or interacting with the resource, supplementing the resource with learner scaffolds or alternative representations of material, re-aggregating the resource or replacing the resource with an equivalent alternative. This approach also supports cumulative authoring of learning material so that many educators can pool approaches to achieving a specific learning outcome for a diverse set of learners.

5. PREREQUISITES FOR CONTENT AND USER INTERFACE TRANSFORMATION

Beyond adherence to open interoperability standards, there are five basic design principles at the core of accessible design in a digital environment. These are:

1) Separate content and structure from presentation.
2) Separate function from method of control.
3) When this is not possible provide equivalent alternatives in other modalities.
4) Structure content.
5) Label resources.

These same principles also support device independence and effective knowledge management.

5.1. Content and Structure Independent of Presentation

By separating content from presentation or style, content may be transformed by replacing one style sheet or display configuration with another. This transformability can be seen when you change the display preference in your browser and view a properly created HTML or XHTML text file. The author may have viewed the file with a blue background with yellow text at a 12 pt size. The reader can choose black on white with 16 pt text size. With more sophisticated browsers the reader can also choose to have three levels of headers extracted and presented as a navigation tool, for instance. This transformation is prevented when the author explicitly asserts details about the presentation in the content markup, or presents text as a graphic.

5.2. Function Independent of Method of Control

Transformability in the user interface is achieved by making the functions independent of the control method. A simple example of this independence is a submit function in a dialogue box, when control independence is enabled more than one method of activating the submit function are available: the user can submit by tabbing to the submit button and hitting enter, alternatively by pointing to and clicking on the submit button using the mouse or by entering a key combination such as control-s. A more complex instance would be a web service with a number of possible user interfaces, for example, a digital repository of e-journals could provide an unconstrained text search or a topic index with browsing to retrieve the desired journal.

5.3. Alternative but Equivalent Content

Some content cannot be transformed. The content is inextricably linked to the medium it is presented in. In these cases, equivalent alternatives of the information should be made available in alternate modalities. Captions or sign language translations would be such equivalents for auditory speech, sounds, and paralinguistic information. Audio descriptions (spoken descriptions of visual information in a video, these are inserted into the pauses in the audio soundtrack of the video), text labels or “alt-text” and long text descriptions are equivalents for video and graphics (CNICE, http://cnice.utoronto.ca). Thus, for example, a learner who is blind would listen to the audio description of a video, as could a learner who is reviewing an instructional video while driving a car. Similarly, a learner using a screen reader would hear text labels for images as would a learner with limited bandwidth or an alternative device that cannot process large or incompatible images.

Creating equivalent alternatives is a relatively straightforward process when the content is purely informational or even conceptual. The same cannot be said for artistic content. Art, whatever form it takes, cannot be a solitary or constrained activity. The perception, thoughts and emotions of the audience are as much the artist’s medium as the paint, the music or the dance. As such it is an unpredictable medium influenced by the myriad of experiences and the cultural contexts of the viewer. If we add interpretation from one sensory modality to another to this complex mix of interactions we can strive to provide an accessible equivalent interpretation but we can never truly achieve this goal. This difference is not a bad thing, nor does it mean that we cannot hope to provide equal access in the arts. The challenge of equivalency spurs us to explore our perceptions, our points of view and the great diversity of the human experience as well as the core elements that we all share. We come to realize that there is no equivalency, no uniform perception, or interpretation among audience members who have no disability. This diversity can be seen as an asset, not a deficit. The question then becomes not how can someone with a disability have the same experience but how can the experience of someone with a disability be as rich and evocative as the experience of the individual without a disability. In the e-learning context, the question becomes: How can the same learning goals be met?

5.4. Structure

When viewing a web page, we do much more than simply read the page word by word from left to right and top to bottom. We approach a new document with a series of questions. These questions are answered using a number of conventions or strategies, many of which are visually based. The first question is: What is this document? We get an overall sense of the document: The topic, the scope, the format, the author's approach, by quickly glancing at the document. We also take a quick inventory of what it contains (e.g., images, image maps, forms, etc.). We get a sense of what the author feels is important by looking at the formatting or other graphical conventions. Concepts or points are communicated or illustrated through pictures, videos, or graphs. We determine what we can do with the document by noting items like forms or links. We assess whether the document contains anything that interests us by scanning the document for key words or graphics. We answer the question "where can we go from here" by noting links. While reading the document, we get a sense of the organization or structure of the document, and the emphasis intended by the author, by noting the format and layout. The visually communicated structure also lets us quickly locate specific sections of the document (Treviranus, 1997).

For many computer users this same information must be gleaned by listening to a synthesized voice that reads only text. In North America, screen readers are the most popular computer access systems for people who are blind. Screen readers present aurally, information that is visually presented on the computer screen. Translating a rich visual environment or document into the audio channel is very difficult. The primary constraint is that, while we can process many pieces of visual information virtually simultaneously, the aural channel is largely serial. When information is spoken using a voice synthesizer, information can only be presented one piece at a time in a linear or serial fashion.

Web pages rely heavily on graphic devices or conventions, spatial layout, icons, pictures, video, and animation to communicate information. Multiple pieces of information are presented simultaneously. There is frequently no logical serial order to the information on the screen. Associations between objects are expressed through visual means (e.g., proximity, color coding, etc.). Interface consistency and predictability are not prevalent (e.g., labels for text input fields could be located above, below or to side of the input field within a single dialogue box or form). Mouse pointer actions have largely replaced keyboard commands.

Due to the evolution of the computer user interface and the digital document, users of screen readers, and other serial devices such as refreshable Braille displays have difficulty receiving the information a sighted person might glean in a quick glance. It is also very difficult to find specific information and to move from one part of the document to another. People who use screen magnifiers encounter similar constraints. The amount of information that can be reviewed at one time is very restricted. When only a small section of the screen can be seen at once, it is easy to miss dialog boxes that pop up elsewhere, it may be hard to determine the relationship between objects, it is also very difficult to locate specific objects on the screen.

A number of these problems can be addressed by properly structuring a document using standard structural markup (e.g., HTML, XML). When a document is structured correctly, a learner with a serial browser can obtain an overview by quickly reviewing just the level one headers for instance. It also becomes much easier to navigate to a specific section of a page. Emphasis and importance can be derived from the placement in the heading structure hierarchy. The document can be virtually compressed to show only high-level elements. The document is also more amenable to logical reorganization and personal annotation.

5.5. Labels

It is very difficult to supply the learner with resources that meet their learning needs if the resources in the resource pool do not have informative labels or metadata. The likelihood of a possible match increases as the pool of resources increases but so does the importance of accurate and informative metadata.

These labels should give information that is relevant to the variety of characteristics a learner may be looking for. Among the questions the labels should address are:

- what is needed to access this resource,
- is this resource amenable to transformation,
- what are the learning goals or objectives this resource addresses?

The more descriptive information available (preferably in machine readable form) about the resource, its usage, and its evaluation, the easier it becomes to deliver accessible content to each learner.

6. WEB ACCESSIBILITY INITIATIVE

The Web Accessibility Initiative (WAI) of the World Wide Web Consortium (W3C) has produced a number of guidelines that govern accessibility on the web (http://www.w3.org/WAI). These guidelines also form the basis of legislation, policy, and regulations in many countries and jurisdictions. There are three sets of guidelines: The web Content Accessibility Guidelines (WCAG) that provide guidance in making web content accessible, the Authoring Tool Accessibility Guidelines (ATAG) that provide guidance in making an authoring tool accessible and in developing an authoring tool that produces accessible content, and the User Agent Accessibility Guidelines (UAAG) that provide guidance in developing browsers, players, and viewers that are accessible. These guidelines provide the groundwork for inclusive design in a web environment.

6.1. Evaluation and Repair Tools

A large number of tools exist to assist in complying with the WCAG (http://www.w3.org/WAI/Resources/#er). A content author can evaluate web content using these tools to determine whether the checkpoints of WCAG have been followed. The tool identifies any known problems, and generates a list of required changes. The tool applies a set of software-based algorithms, however a large number of checks cannot be performed without the aid of human judgment. To complete these checks the tool would guide the user through a set of questions. Some tools also provide step-by-step and semiautomated assistance in repairing any accessibility problems (http://www.w3.org/WAI/ER/existingtools.html#Repair, http://aprompt.snow.utoronto.ca/).

There are several drawbacks with these tools. One drawback is the lack of consistency in interpreting the checkpoints from one tool to another. Also, the tool, by nature of its design, cannot provide a holistic evaluation of whether the content meets the intention of the guidelines. Authors or evaluators frequently rely upon the tools alone rather than also using their better judgment to determine whether the site achieves the goals of the guidelines. Lastly the checking and repair happens once the content has already been created and the mistakes have been made, requiring much more effort than if the mistakes had been prevented.

6.2. The Importance of Authoring Tools

Very few educational resource authors are aware of accessibility guidelines or knowledgeable in accessible authoring practice. Many do not see accessibility as a priority when creating e-learning resources. Most, however, use some form of authoring tool to create online resources (i.e., web editing tools). The prevalence of inaccessible e-learning content will not be effectively addressed through education and advocacy or through compliance evaluation programs. Not all authors need to know the technical minutiae of accessible authoring practices, as all authors do not need to know about HTML to author web content. As discussed above, conformance testing occurs after the fact and is therefore an inefficient method of creating accessible online learning resources. The best and most efficient strategy for insuring that educational curriculum online is accessible is to broadly implement the use of authoring tools that create accessible content. This practice would ensure that even authors who are not knowledgeable about or motivated to create accessible content do so unconsciously. Accessible authoring would also be an integrated part of the process rather than an afterthought, reducing the time required to repair accessibility problems. This integration can be done by mandating or promoting the use of authoring tools that are compliant to the W3C WAI Authoring Tool Accessibility Guidelines (ATAG) (Treviranus et al., 2000).

7. "ACCESSFORALL" SPECIFICATIONS

The "AccessForAll" specifications of the IMS Global Learning Consortium (http://www.imsglobal.org/accessibility) build upon the WAI guidelines and support the second approach to accessibility or an approach that dynamically matches education delivery to the needs of each learner. The "AccessForAll" specifications consist of two specifications: One to describe the needs of the learner and the other to describe resources so that they can be matched to the learner needs. The "AccessForAll" specifications have been proposed and are making their way through the adoption process as ISO/IEC international standards for accessible e-learning (http://jtc1.sc36.org).

7.1. Describing User Needs and Preferences

The first of the "AccessForAll" specifications is the ACCLIP (Norton & Treviranus, 2003), a common structured language for describing the needs and preferences of the learner. The ACCLIP allows learners to declare, in a machine readable form, how they would prefer or need information to be presented, how they need or prefer to control the application and what alternative or supplementary resources they want or need. A single learner can have multiple preferences or ACCLIP records each for a different context. Thus a different preference record can be used in the morning than is used at night when the person is fatigued or at school versus at home where the internet bandwidth is lower. The learner is also able to specify generic settings for a class of alternative access systems (e.g., the speech rate for any available screen reader) in addition to specifying a brand of technology and settings specific to that technology. This allows graceful degradation of functionality if the desired application brand is not available.

The ACCLIP is divided into three main sets of elements: Display, control, and content. Display refers to the appearance of the content and user interface and may, for example, include specifications for text size and color. Control refers to how functions in the interface and application will be activated by the user and enables the user to specify alternative ways to control the device such as keyboard rather than mouse control. Content refers to the kind of information that is displayed. Under the content choice of ACCLIP, users may specify preferences for alternative content such as text instead of graphics or for other equivalent content needs such as captions for any audio. ACCLIP supports the broader conception of disability discussed earlier. The specification is intended for all learners who may have diverse preferences based on learning approach, environment, learning context, device constraints, or disability. Unlike other applications, a learner does not identify a disability, they merely state functional requirements regarding the e-learning delivery system.

Learners or their assistants would create an ACCLIP record using on online questionnaire, also referred to as a “Preference Wizard”. By answering a series of guided questions, or checking off options, a portable record would be created. This record can be read by any “AccessForAll” compliant application such as a Learning Management System, a personal web portal, a digital repository or a multiuser workstation in a library, a computer lab or an internet café, for example. The record can be stored and taken from application to application on a smart card, a USB storage device, a disk drive, or stored on a networked server. The learner would in essence be carrying their preferred and familiar computer, application and learning content configuration with them from one application to the next.

7.2. Requirements for Making the Match

E-learning systems can respond to a learner’s preferences as stated in an ACCLIP record in a number of ways. Possible methods of meeting the learner’s stated needs are:

– configuring the operating system or “system preferences” (e.g., visual signals rather than system sounds, higher speaker volume),
– configuring the application or browser settings (e.g., larger text fonts, larger buttons),
– restyling the content (e.g., using Cascading Style Sheets, CSS, or XSLT),
– launching and configuring alternative access systems (e.g., text to speech systems),

– supplementing the content with additional information (e.g., definitions, caption files), or
– replacing the resource with an equivalent resource that meets the access needs of the learner.

In order to accomplish the last two methods, learning resources must be described or cataloged so that they can be associated with each other and matched to a learner's preferences.

7.3. Describing the Learning Resource Characteristics

The learning resource description mentioned above can be found in an interoperability specification referred to as ACCMD or IMS Accessibility Metadata (Jackl et al., 2004). ACCMD is a common language and information model for describing characteristics of a resource that facilitates matching the resource to a learner's ACCLIP preference statement. The ACCMD divides learning resources into two categories: Primary resources and equivalent alternatives. The majority of learning resources or the default resources created by educators or curriculum producers are primary resources. Recognizing that most developers of digital resources complete metadata records with reluctance and that many of the metadata elements are misinterpreted by authors of metadata, the workload of the creator of the primary resource's metadata is kept as light and simple as possible. The primary resource metadata consists of:

1) A statement about the flexibility of the resource presentation and method of control. In other words, can this resource be restyled, and can it be controlled using devices other than a mouse? This can be described using the output of common accessibility checking tools (encoded in an Evaluation and Repair Language, EARL, Resource Description Framework, RDF, statement). The implication is that this can be created and attached to the resource automatically in a properly constructed authoring tool.
2) A statement about the access modality the resource is presented in. This describes whether vision, hearing, text literacy, or touch is required to use the resource.
3) A pointer to the location of any known equivalent alternatives. For example, if the resource is a video, is there a known caption file or description file somewhere?

The second class of resources is called equivalent alternatives. Equivalent alternatives are replacements or supplements for the primary resource or part of the primary resource. These alternatives address accessibility problems a learner may have with the primary resource. The equivalent alternatives would communicate the same information, teach the same lesson or meet the same learning objective as the primary resource. This information or lesson would simply be communicated in a different way. Equivalent alternatives include caption files for audio information, audio descriptions for the visual elements of video, interactive activities that can be controlled using a single movement to replace an activity that requires a mouse, image intensive communication of a concept to replace dense text, bilingual presentation of a story rather than a purely English rendition of a story, to name a few. The ACCMD records for equivalent alternatives would point to the primary resources they are a replacement or supplement for and they would also describe the resource using the same terms as user preferences are described in the ACCLIP. Equivalent content is usually described in some detail. It is expected that the creators of equivalent alternatives and their metadata will be aware of accessibility needs and motivated to provide the details needed to ensure users can locate the equivalent resources. An equivalent alternative need not have been explicitly created to replace or supplement a primary resource. An educator can create an equivalent alternative resource record after the fact as it were, if they feel that one resource is a good alternative to another. Primary resources may also contain their own equivalent alternative resources in which case they would have both primary and equivalent alternative metadata records.

Most resources on the web consist of multiple objects combined into what are commonly known as pages. Sometimes this is captured in a single static version of the page and sometimes it is dynamically generated each time a page is visited. The AccessForAll approach assumes that the objects that comprise the version of the resource that is sent to the user need not be located in the same place, that is, they may be distributed. In fact, the original composite resource may contain objects that need to be transformed, replaced, or augmented; the equivalent objects used for replacing or augmenting may have been created in the original authoring process, or in response to some other user's difficulties with the original resource.

The "AccessForAll" specifications have been implemented in a variety of systems internationally. These systems include learning management systems, personal portals, public multiuser workstations, digital library portals, and Learning Object Repositories (LORs). One such implementation will be described in detail in a subsequent section.

8. COLLECTIVE RESPONSIBILITY AND POOLING OF RESOURCES

The approach to accessible e-learning delivery supported by "AccessForAll" encourages cumulative or collaborative creation of curriculum. The teacher who creates the original curriculum need not be the one who creates an all-text version or a reduced reading level version for example. To respond to the broad diversity of learners and provide a rich and engaging learning experience for all learners it is only logical to pool resources and to distribute the task of creating equivalent alternatives.

It has become far easier to provide equal access to curriculum for students with disabilities in a digital environment. One compelling example of this is in the area of geography instruction. Prior to digital curriculum, maps were communicated to students who are blind using physical models made of plywood, Styrofoam, string, and other tactile materials. Given the density of information in even a grade 4 atlas for example, the physical models needed to communicate the information in a single atlas would fill an entire classroom from ceiling to floor and wall to wall. The task of shipping and storing these models would be daunting. In a digital environment, these models can be created virtually. Spatial information can be communicated through speech, real world sounds, and through haptics or force feedback devices. "Haptics" is a term which encompasses both the sensing and action involved in touching and manipulating. Haptic devices are computer peripherals that make it possible for users to "touch" objects presented on computer displays as if they were real physical objects. This is done by simulating the forces that one would feel when touching a real object and presenting these forces to the user by using the force and tactile feedback capability of a haptic device. When done properly, this creates the illusion of "feeling" an object. Thus, students are able to feel shapes that represent geographic artifacts such as cities, rivers, mountains, railways, or other objects; the volume and location of real-world sounds helps them judge the proximity to geographic objects. For example, from an associated tone which occurs when they encounter a city on the map, they will be able to determine the approximate size of the city (see Figure 1). For example, a student will hear a real world sound associated with a city as they approach a city. The location of the city will also be marked by a haptic artifact. By pressing on the city they will hear the name. The student can choose to zoom into a specific location and query a large database of associated geographic

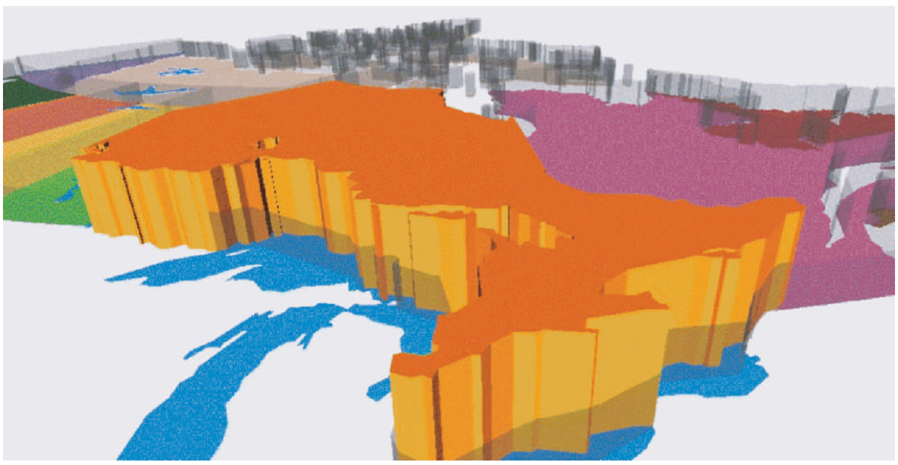

Figure 1. The shape of a province is raised in a computer rendering so that it can be felt using a haptic device.

data. To review the boundaries or shape of a geographic structure, such as a province, the student can choose to raise the structure so it can be examined using the haptic device (See Figure 1). If they want information on scale or relative location they can turn on a haptic grid of latitude and longitude lines which may feel like a number of strings or elastics strung over the map. Once these multimodal virtual maps are created they can be broadly distributed or accessed from a networked server.

Aside from these advanced technologies to support equal access there are other compelling reasons for educators to pool resources and to view the creation of accessible curriculum as a collective responsibility. A common phenomenon in North American education systems over the last decade appears to be the steady erosion in time to prepare curriculum. This is extremely frustrating for educators who recognize the diversity of learner needs and wish to apply learner-centric approaches to education. Despite constraints on time, content is frequently created for one learner or one class at a time. If this effort is pooled among educators, tutors, facilitators, or mentors within a disciplinary domain, contributors can collectively create a source of rich, creative, and diverse content that is responsive to the diversity of learners. If the pooled resources are authored correctly they can be amenable to the adjustments needed to re-purpose or reuse them in different contexts, with different learners.

9. LEARNING OBJECT REPOSITORIES AND "ACCESSFORALL"

One response to this need to pool resources is the development of Learning Object Repositories. LORs are digital repositories that provide support for pooling and sharing learning resources across members or participating communities (Wiley, 2000).

Creating curriculum for a single application or class must differ from creating it for a potential pool of users. The definition of a learning object espoused by each repository defines what can be submitted to the repository and how it should be structured or packaged for more general application. There is little agreement on what constitutes a learning object. In fact a great deal of academic debate has been devoted to defining learning objects (Wiley, 2000). The primary goals of this debate have been to determine what qualities of a learning object will make it most reusable and re-purposeable. Among the characteristics under dispute is the granularity of the object, whether there is an integrated learning design or learning objective (Koper et al., 2003), and whether roles and responsibilities should be described. Is a picture of a tree frog a learning object or must there be an associated learning goal? The approach made possible by "AccessForAll" compliant technologies presents a new perspective on this debate. Given this perspective, size does not matter in determining the most re-usable or re-purposeable learning object as long as:

- the object is sufficiently structured so that content in different media can be separated and supplemented or replaced,
- the presentation or styling is independent of the content and structure so that the presentation can be replaced, and
- the method of controlling interactive components is flexible.

This allows the transformation of learning objects to meet the individual needs of learners in various contexts. What is promoted is not a granular but a layered approach to structuring learning objects in which the presentation layer can be wholly or partially replaced. This requires a considerable paradigm shift for educators and producers creating learning objects who frequently consider the presentation as an integral part of the content or objective. However this layered approach helps to achieve the goal of reusability and re-purposeability because it promotes a learning object that is more amenable to localization, institutional branding, display on a variety of devices, and interface consistency within a diverse set of reused objects. It can be argued that this is a necessary paradigm shift not only to achieve accessibility but also to achieve the primary goals of LORs.

Existing LORs differ greatly in the pedagogical philosophy supported and the functionality with respect to re-purposing. LOR functionality can be divided into three levels. The first level offers sharable learning objects. At this level the LOR has the functionality of a library. The learning objects are retrieved and used as they were checked-in by the original contributor. The structure of the learning object and the LOR architecture do not support their deconstruction and re-purposing other than to accommodate alternative hardware platforms. Most LORs in Canada and elsewhere fit into this category.

However, most educators would like to customize learning content to their learning context. The second level of functionality provides support for learning object re-purposing. The learning content is sufficiently structured or sufficiently granular to allow educators to swap components to adapt the learning object to a specific curriculum requirement, local context, or background knowledge. A number of LORs around the world are just beginning to explore this functionality to positive effect.

The third level of functionality acknowledges the diversity of learners and accommodates collaborative authoring among educators. The design of the LOR is motivated by the premise that each learner brings to the learning situation their own unique set of skills, background knowledge, motivations, learning goals, learning approaches, learning pace, and accessibility needs. This level of functionality supports the construction of learning content that is independent of presentation and control. It provides enough structure and granularity to allow the reassembly of learning content according to the needs and preferences of the learner. This level of functionality is supported by

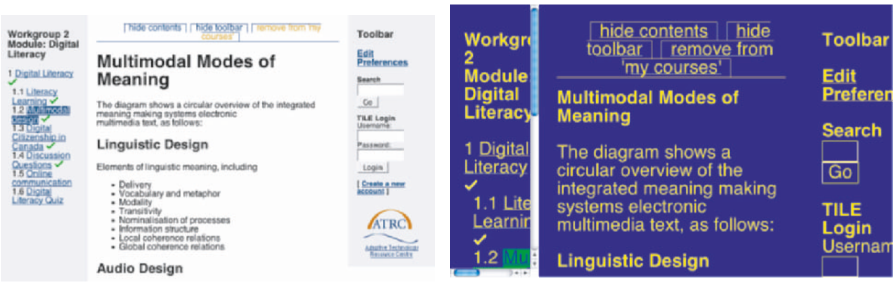

Figure 2. A simple style based transformation of a lesson page for a learner with vision impairment.

"AccessForAll" and implemented in a project called TILE or the Inclusive Learning Exchange (http://inclusivelearning.ca).

The Inclusive Learning Exchange (TILE) is a learning object repository developed by the Adaptive Technology Resource Centre at the University of Toronto. TILE implements both the IMS ACCMD and ACCLIP specifications. When authors (educators) use the TILE authoring tool to publish learning objects or curriculum units, they are supported in creating and appropriately labeling transformable lessons (codified by the TILE system using ACCMD). The authoring interface enables educators to assemble lesson components to form a content package in a personal "staging area" or workspace. Before the content is uploaded to the learning object repository, metadata is collected at the component and package level through a series of dialogues. Accurate and complete metadata is crucial for the successful search, retrieval, and customization of content by the learner. In order to reduce the demands on the author, metadata collection is automated whenever possible. In the same way accurate metadata is crucial for meeting learner needs, it is also vital to a thriving and active learning object repository where content is routinely deconstructed and its activities, media, material, and assessments used in different ways across multiple subject areas. Learners using the system define their user preferences, which are stored as ACCLIP records. TILE then matches the stated preferences of the user with the desired resource configuration by transforming (see Figure 2) or re-assembling the lesson.

The TILE system was implemented in a multisector national partnership in Canada to deliver learning resources to learners from elementary school, high school, university, and learners engaged in life-long learning programs. The TILE repository contains over 2370 learning objects. The project successfully investigated potential structures for accessibility metadata and acted as the test bed for ACCMD. The project also explored new ways of thinking about learning content through a series of community events across Canada referred to as TILE Potlucks. Through these collaborations with educators, and content producers from a variety of domains, the concept of deconstructing, re-purposing, and transforming learning objects was explored. At one potluck, participants demonstrated that activities could be decoupled from content and re-purposed across multiple subject areas. This decoupling represented a shift in the way we normally think about learning objects (Figure 3).

One concern expressed by educators in the TILE project and discussed by Donald Norman is the risk inherent in using modular, re-usable learning objects: By excessive granularity and modularity we threaten the coherency of the learning experience. Through a prior project called the Barrierfree project the ATRC re-purposed and transformed educational film holdings in large film archives into interactive hypermedia learning experiences (http://barrierfree.ca). The caption track of the film was used as a structure to anchor relevant learning materials such as interactive exercises, definitions, illustrations of terms, and links to supplementary material. The captions were also used to navigate through the video content to previous occurrences of a term, for example. Therefore if I was watching a video of an eminent physicist and she mentioned a concept I was not familiar with I could go back to the first mention of the concept, access a definition, illustration or discussion of the concept, or engage in an interactive exercise that illustrated the concept by clicking on the term in the text caption while watching the video. Thus, coherency was achieved by providing a coherent story line as a learning structure. TILE however, re-purposed a full range of media and content types thereby necessitating a more generic learning structure. The backbone of the learning structure provided to educators within TILE was the lesson plan or learning plan. The learning plan acted as the base structure that was populated with a number of modular learning objectives, each of which was populated with any number of content objects. The content objects included exercises, simulations, publications, self-tests, videos, presentations, or other forms of online curriculum. Given the transformability of objects in the repository a consistent style sheet was applied to all transformable content in the lesson plan for each learner, to assist in coherency.

10. "A WEEK IN THE LIFE OF A TRANSFORMABLE LEARNING OBJECT"

The following use case illustrates how a single learning object would be constructed, reused and re-purposed by a series of educators implementing TILE.

> Ryan, a tutor with Frontier College, an adult literacy programme, works with a learner Jim who would like to learn to use on-line banking, since the trek to the bank is difficult during the winter. Jim needs assistance in learning to use the interface, reading and comprehending the information on the screens, paying the bills that he receives regularly and keeping track of his balances. Ryan uses the on-line learning design structure

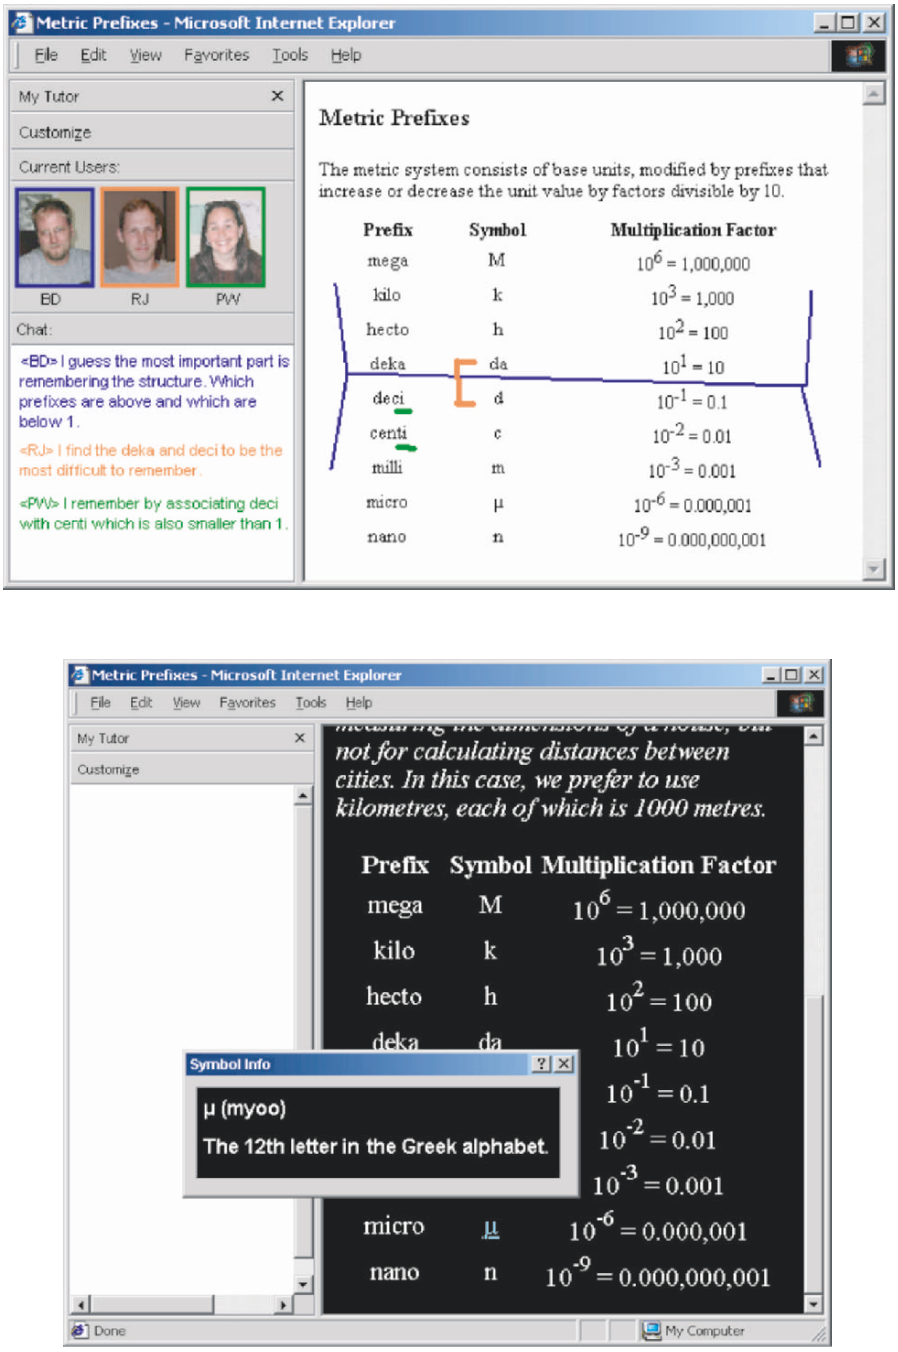

Figure 3. Three methods of teaching metric prefixes according to a learners stated preferences (illustration credit: Jan Richards, ATRC).

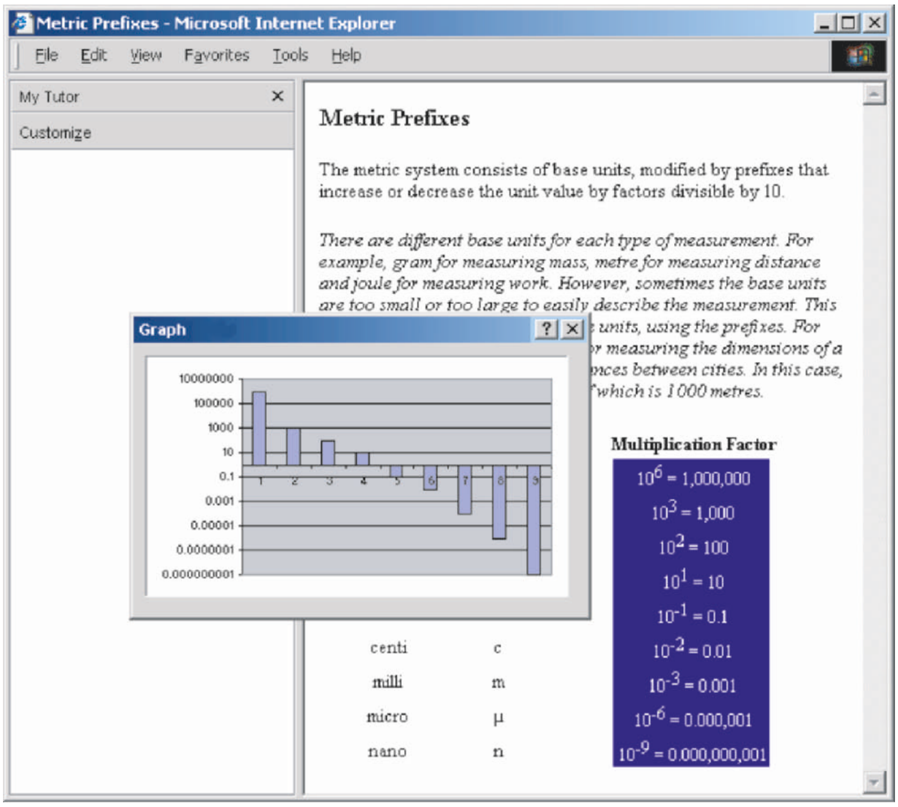

Figure 3. Continued

to specify the overall learning plan and the individual objectives. These he then populates with the actual screens that Jim will encounter at each step, his own clarifications of components of the screen, step by step instructions on how to accomplish each task, ways to recognize and correct errors, and instructions on how to verify that he has been successful. This completed assembly object or lesson is checked into the repository.

When Jim views the lesson the service delivers the assembly object according to Jim's previously expressed learner preferences. His preferences specify where, when and how clarifications, instructions, help, and self-evaluations will be displayed and how feedback will be given. Because Jim has a learning disability all text will be read to him when he points to it using his head pointer. Because he has difficulty pointing accurately all active areas of the screen such as buttons or input fields will be enlarged.

Mary is working with a learner, Fernando, who uses the same bank but has a different set of bills to pay. She checks out the lesson and replaces the learning content pertaining to the unwanted bills with information about bills relevant to Fernando. Because Fernando is learning English and is more conversant in Spanish, Mary adds a Spanish translation of the clarifications and instructions, help and feedback. Mary also remembers a very simple-to-use accessible calculator that she has previously seen in a linked repository. She searches for it and adds a link to it. She then checks this new version of the lesson or assembly object into the repository. When Fernando accesses the lesson he reads and listens to both the English and Spanish text.

Judith is a trainer with the bank referenced in the lesson. She has just created an educational video about on-line banking. She includes verbatim captions of the video and then links the indexed segments of the video to the appropriate points in the learning plan. When Jim next views the lesson he can choose to reinforce what he is learning with the instructional video.

Alfred is a tutor working with a class who need to access the on-line banking service of another bank. He views the lesson and decides that he likes the structure of the learning plan and many of the generic explanations, but he must replace the screen shots and detailed instructions. After making these changes, he checks the new version of the lesson or assembly object into the repository.

Thus a learning object is re-purposed and collaboratively refined by a number of educators, saving educator time and benefiting a larger number of users.

11. PARADIGM SHIFT FOR EDUCATORS AND EDUCATIONAL CONTENT PRODUCERS

As discussed earlier, most educators when creating e-learning content think about the presentation first. This is reinforced by the majority of software applications used to create web content. These applications usually prompt the author to choose a "look" or style for their content first before creating the content itself. The inclusive learning strategies discussed above require a paradigm shift in the way educational content online is created. Educators must first ask: "What do I want to teach, what are the learning objectives I want my learners to meet", and then "what are the many ways or the many learning activities that can be used to meet these learning objectives"? Surprisingly this appears counterintuitive to most producers of online curriculum. These same educators will acknowledge that rich media, in most cases, plays a reduced role in learning (an exception that comes to mind is simulation-based learning). A learner engaged in active learning with little content may have better results than a learner who receives a multimedia slide show. Entertainment does not necessarily create better learning. The authoring tools used to create online curriculum must reflect and support this pedagogical knowledge and prompt educators to consider and express the learning goals and lesson plan first. These software tools must also support the educator in creating learning content that can be restyled without losing the message or pedagogical effectiveness.

12. CONTENT-FREE ACTIVITY TEMPLATES

One of the conclusions reached through consultation with educators during the TILE Potlucks was that the most valuable content for re-purposing and re-use was not, in fact content, but activities or interactive resources. Most educators can easily create static content on a variety of topics but few can control the tools or programming languages needed to create interactive applications on the web or on a computer. One of the other things discovered was that activities could be separated from content and repopulated with alternative content supporting a variety of subjects and learning goals. For example, a debate application on the web can be used to debate global warming or existentialism, a Web Quest application can be used to research math or anthropology. Subsequently, a growing pool of content-free activity templates was added to TILE. These templates were pre-configured so that the activities would adhere to accessibility guidelines no matter what content was used to populate the activities.

13. OPEN ACCESS/OPEN SOURCE

In order to provide access to critical educational resources such as textbooks, learners with print impairments require access to electronic copies that can be rendered in a variety of formats. Frequently, intellectual property protection and associated copyright measures present significant barriers to equal access. In recent surveys it was found that many post-secondary students in Canada do not have access to required readings in an accessible format until well after their mid-term exams. These barriers are eliminated significantly reduced when required readings are provided in electronic format and are open access.

Similarly it is far easier to address interoperability requirements between software or web applications and alternative access systems when the applications are open source. Assistive technology development and distribution does not lend itself well to traditional commercial business models, but is driven by motivations that inspire open source communities. The trend toward a greater adoption of open source software and open access content in the educational domain has a number of significant benefits for equal access to education for learners with disabilities.

14. COLLABORATIVE LEARNING ENVIRONMENTS

Real-time collaborative environments such as audio chats, video-conferencing systems, and electronic whiteboards present an extremely difficult accessibility challenge. There is no time to prepare an equivalent alternative to graphics created on a whiteboard, audio transcripts for live audio discussions or descriptions of visual information transmitted through video-conferencing. In response to this challenge, the Canadian Network for Inclusive Cultural Exchange (CNICE) has created a series of collaborative tools that support peer description and captioning (http://cnice.utoronto.ca). Using these tools, hearing participants in a collaborative forum are assisted in transcribing speech and sounds for fellow participants who are deaf, and sighted participants are assisted in describing images and visual information for fellow participants who are blind. In addition, the whiteboard provides a pallet of objects with associated text labels and the capability to provide a text label for a new grouping of objects. When these labelled objects are used to illustrate a point rather than free-hand drawing, a person who cannot see the images can derive meaning from the text labels.

15. INTELLIGENT AND ADAPTIVE TUTORING

One technology that has the potential to deliver equal access for learners with disabilities is intelligent or adaptive tutoring systems. These systems use artificial intelligence to automatically adapt education delivery (Brusilovsky, 1996). The sequencing of activities, presentation of items and complexity of material among other characteristics are automatically adapted based upon the computers estimation of what is best for the learner. Among the artificial intelligence strategies used is the collection of performance metrics given specific conditions. These are used to create a model of each learner upon which to base design decisions: Does the learner get the answers right faster when the information is presented with diagrams rather than text, does the learner finish with a page faster when there are bold headers or teacher tips?

It would follow that these systems should be ideal for learners with disabilities. However through a series of informal trials, the authors found that learners with significant disabilities did not respond well to these systems. Learners reported that they were frustrated that they could not predict what adaptations were determined to be "good for them", they were concerned that they were not consulted or warned by the system when shifts in the delivery happened. Learners were also frustrated with the constrained sequencing of learning activities; they wanted to give a set of explicit requests at the beginning rather than letting the system determine what is best for them. A number of individuals caused the system to create erroneous user models by exploring lessons and responses. These erroneous models made it impossible to continue with the lesson. One learner made the insightful observation that there is so little he has control over in his life and so many people that try to decide what is good for him that he doesn't need a computer to do this as well.

Although further more formal trials are required, it would appear that in order to apply intelligent tutoring systems to assist individuals with significant disabilities, learners must be consulted in configuration decisions and these decisions should be explicitly stated. Learners should also be able to manually set the default user model including characteristics that should not be adjusted.

16. SEMANTIC WEB AND ACCESSIBLE E-LEARNING

One emerging technology that holds great promise for delivering learning resources that match the needs of individual learners is the Semantic Web. The functionalities foreseen in the Semantic Web would open up the potential pool of reusable learning objects to the entire web without the imprecise searching qualities of search engines such as Google.

Tim Berners-Lee (2001) describes the Semantic Web as "an extension of the current web in which information is given well-defined meaning, better enabling computers and people to work in cooperation". The Semantic Web allows computers to determine the meaning and relationships of content on the web. By creating educational ontologies (files that formally define the relations among terms, most commonly through the use of taxonomies and inference rules) that embed the structure, vocabulary and relationships of "AccessForAll", Semantic Web functionality can be used to accurately retrieve learning resources that meet the specific needs of the learner from the vast pool of resources that is the World Wide Web.

CONCLUSION

By acknowledging and making room for the diversity of learners in the design of e-learning environments, we expand the possibilities and advance the field for all learners. At the same time, modifying our education practices to provide accessible learning experiences frequently prompts us to become cognizant of our teaching goals and the essence of the knowledge to be developed by the learner. It prompts us to re-learn long established "truths" about learning that have been obscured by a focus on new technologies. With dynamic networked learning environments and collective construction of resources, it is possible to optimize learning for each individual learner.

Chapter 20: Displacing Student–Teacher Equilibrium in Virtual Learning Environments

JOANNA BLACK
Faculty of Education, Department of Curriculum, Teaching and Learning, University of Manitoba, Winnipeg, Manitoba, Canada

A great catalyst causing considerable change in our 21st century classrooms is the recent implementation and usage of the now ubiquitous computer; this new technological innovation in the secondary school classroom has had a tremendous over-riding effect on traditional learning environments. With digital technologies supplanting older ones, the computer has had an impact within schools. Not only are computers instrumental in the creation of virtual learning environments, but also within these new environments they also affect student–teacher social dynamics. Consequently, what are being altered are the learning environments themselves as well as the pedagogical and social relationships forged between educators and their pupils.

In the new virtual classrooms, frequently educators rely on their "tech-savvy" students for technical assistance while these "whiz kids" often have developed digital competence far surpassing their teachers (Black, 2002; Negroponte, 1995; Tapscott, 1998). However, it is often assumed (and hoped) that teachers in training have systematically developed a rich and extensive knowledge base in their area of technological expertise before being professionally hired to disseminate their knowledge to future students. Unfortunately, this is not the case. With the rapid change from analog to digital technologies within the last decade, with the embracement of many of these new technologies within educational institutions, and with the swift technological advancements perpetually occurring, many teachers find themselves in complex and tenuous situations. Both new and experienced educators have an extremely difficult time obtaining proper training in order to keep abreast of digital technologies in the schools.

In this chapter I will discuss case study research in which I examined the relationships between teachers and students in virtual learning environments (Black, 2002). For this study, I interviewed both educators and pupils in order to obtain their perceptions of the complex interactions and dynamics they have forged. One of the teachers I interviewed, Mr. Ross observes that good technology teachers obtain much respect because the prevalent student attitude is that mastering technology is not only important but also "cool". The ideal situation is for teachers to have acquired a firm foundation studying computers and technology at university. The condition for this model foundation is superb technological teacher training at a teacher's college; one can then supplement

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 497–424.

this beginning later through teacher support programs and in-service training to keep abreast of ongoing technological changes when student teachers are hired as educators in the classrooms (Jordan & Follman, 1993). Reality, though, is often far from ideal. Schools lose the very people they need: Most educators trained in the computer technology area at university do not enter the teaching profession because there are greater salaries in the computer industry (Black, 2002). Consequently, few new educators have solid backgrounds in computers. Moreover, if more experienced teachers have indeed obtained previous university training, their knowledge would be obsolete as a consequence of rapid technological changes in the last decade. Consequently, it was found that most teachers are self-taught (Pelgrum & Plomp, 1993). Added to this, teacher support is inadequate once educators are working in the field. Jordan & Follman (1993) note that ". . . too many teachers have to play catch-up and learn on the job" (p. 27). Copious methods of staff development have been discussed by researchers, ranging from workshops, online tutorials, mentoring, and modeling to peer coaching and the use of help desks. In an older study by Wiske et al. (1988) it was found that teacher training and follow-up support in schools was inadequate; since then the situation has not improved. Hannafin and Savenye (1993) and Schofield (1995) conducted further studies in schools and found teachers again complained of inadequate training and support. In addition, Greh (2002) who specializes in digital Visual Arts also recently commented that there have been inadequate digital support systems and professional development in place for art teachers. She writes that educators often find there is "no training, no software, no budget. The computers often become dust collectors" (p. 7). Greh advises teachers to pursue computer training: Chances are that it is not provided within the school or board, and hence educators should pursue it within the community. What are the reasons for this less than ideal situation? Laino (1994), Pearlman (1989), and Schofield (1995) point the finger to the bottom line: saving money. Support and training are very expensive and the money is traditionally not earmarked for either; rather it is funneled into buying hardware and software for schools as is evidenced by computer infiltration into many schools throughout North America (AAUW Education Foundation, 2000). For example, an increase of 700,000 computers per year occurred in United States' schools between the years 1992 and 1995 (O'Neil, 1995: 10).

Educators, on the one hand, often find they are ill-trained and unprepared for teaching cutting-edge technologies; yet on the other hand, find themselves having great expectations thrust upon them by administrators and the public regarding the teaching of new technologies, and teaching them well. As a result, they are often confronted with classrooms filled with computers and expectant, excited students, some of whom possess technological knowledge which often exceeds their own. I was particularly curious to explore how this affects the student–teacher relationship in arts education classrooms at the high school level. Those classes which I examined, range from

Communications Technology, Visual Arts, Media English, and Film to Computer courses which have a focus on art or have strong art components built into the curriculum.

In this chapter, I will describe my case study research in detail of two secondary institutions. Both these institutions, one private and the other public, employ cutting-edge technologies in their schools which are vastly different in their implementation of and the way in which the virtual learning environments have been shaped. In addition, I will look at how educators with a range of training have created differing virtual programs and environments. Then I will outline the type of student–teacher relationships which have been established between tech-savvy students and their often tech-unsavvy teachers. Specifically, in this chapter I will examine the displaced student–teacher equilibrium occurring as a result of virtual learning environments.

1. DELINEATION OF TWO SECONDARY INSTITUTIONS

I conducted case study research at two Canadian secondary schools: one public and the other private. Names of schools and students I will discuss in this case study are all pseudonyms.

2. PLEASANT DALE COLLEGIATE

The public school, Pleasant Dale Collegiate, was built in the 1950s and is located in the heart of a major city with a multicultural urban student population of almost 1,200, and a staff of approximately 70 teachers. Forty-four languages are represented in the school and just over half the student population's mother tongue is a language other than English. This school attracts students ranging from the middle to upper middle class and is annexed to Pleasant Dale Middle School. The Collegiate level spans from grade 9 to grade 13 (although by the time of this chapter's publication grade 13 will have been eliminated by provincial governmental reforms). Two specialized programs exist within Pleasant Dale: one a unique program called WiredIMAGE, which has a focus on the integration of Visual Arts and Technology; the other, a program for the gifted. Some of the students I interviewed are part of the gifted program, others are part of WiredIMAGE, and others are part of the so-called "regular" program. Screening occurs in WiredIMAGE and the Gifted Program. For the latter, screening is in the form of pupils taking IQ tests. For the former program they must undergo an elaborate interview process in which they are examined for their aptitude and interest in Visual Arts and Technology. WiredIMAGE students must obtain an average mark of 70%.

During the 1990s Pleasant Dale's reputation as a fine school had become tarnished, resulting in the hiring of a new principal who made radical changes. She developed the mandate to "build students' skills required for the 21st century". One of the ways she accomplished this was to usher in technology: Pleasant Dale thus became a pilot project for its board, with the implementation of a server and the purchase of approximately 300 computers. As a result it was considered a model school. Numerous teachers left who disagreed with the changes at Pleasant Dale, creating a notorious mass exodus which is still talked about within its board of education today. The many vacancies enabled the principal to hire new educators who were far more receptive to working with technology and its integration within the curriculum.

Pleasant Dale has 10 PC computer labs for regular students with a ratio of one computer per three students. These students use such programs as Word, PowerPoint, and Excel. WiredIMAGE, though, is different. The program began in 1995 and was originally housed in the regular school until the new site was built two years later in 1997–1998. It was designed in a post-modern architectural style, housed in a newly built segment of the school. WiredIMAGE is thus set apart from the rest of Pleasant Dale. The ratio of student to computer is one to one and the platform is primarily Macintosh. Students regularly create videos, desktop publishing, animation, web design, and multimedia projects using such software programs as Final Cut Pro, Adobe After Effects, Premiere, Illustrator, Quark Express; Dreamweaver, Flash, and 3D Studio Max. The emphasis in the WiredIMAGE program is to concentrate on four major areas: Visual Arts, Computers, Communications/Literacy, and Media Technologies. Student interest spills over into the regular program in Visual Arts which has a focus on graphic art/desktop publishing courses and Communications Technology which has a specific concentration on video and film.

Support systems for teachers at Pleasant Dale are weak. Educators are not provided with their own computers. In addition teacher training has been inadequate. When computers were first brought into the school *en masse* during 1997–1998, numerous teacher workshops were provided during a two-week period by a private company. Also, during this time Photoshop classes were offered during the school day to teachers and monies were provided to bring in substitute teachers. Since then, with cutbacks of up to 55%, which included reduction in teacher training and development, little has been offered to teachers. No extra time is currently provided for educators to learn the software during the school day. In addition to this, there is only one technical assistant responsible for the smooth operation of all hardware and software and his job is being threatened as a result of continued cutbacks. Overall the area of teacher support and training is inadequate at Pleasant Dale.

In summary, while Pleasant Dale is a cutting-edge school in which students use sophisticated digital technologies, teachers are struggling with lack of monies, cutbacks, and inadequate training and technical support systems.

3. GLEN MANOR COLLEGE

Glen Manor College is the other institution I examined which uses cutting-edge technologies. It is a private school established in the early 1900s and is located in a small affluent city in Ontario, Canada. It has the same number of staff but half the student population of Pleasant Dale. Students span grades 7 to 12 and derive primarily from the upper classes (except for the few on scholarship programs.) Screening is as follows: teenagers must write a successful Secondary School Admission Test (SSAT), and these students' parents must have the ability to pay the $16,000–28,000 tuition fee. I could not find statistics regarding the ethnic breakdown; however, 12% of Glen Manor students are from outside Canada. Originally Glen Manor was modeled after a traditional English boy's school with the mandate to provide students with a well-rounded education combined with rigorous academics with an emphasis on extracurricular activities, athletics, and community service. At Glen Manor, tradition changed in 1992 when the administrators opened their doors to female students; later that decade there was another monumental transformation when a headmaster ushered in the era of digital technology through the implementation of the laptop program.

Glen Manor was one of the first schools in Canada to implement a laptop program in affiliation with IBM Canada—in fact Glen Manor administrators claim it was *the* first secondary school in Canada to fully incorporate technology into its academic curriculum. Every Glen Manor student was required to purchase or lease their laptop and use it in class. Through this arrangement an added financial burden was placed on the parents at Glen Manor. The laptop implementation process occurred in three phases: in 1997, during *Phase 1*, the hardware was installed and the rooms were redesigned; in 1998–1999, during *Phase 2*, grade 9 to 11 students were expected to use laptops in the classroom; and in 1999–2000, during *Phase 3*, the laptop program was implemented throughout the entire school from grades 7 to 12 and 20 labs were set up. As a consequence of this program the ratio of student to computer is one to one.

Most of the classrooms have drops for the laptops as well as overhead computer projectors. As a result of the large investment of monies by parents and the school into new technologies, teachers feel pressure to use the computer when teaching. Administrators expect that laptops be utilized by teachers and students in every lesson. The variety of computer usage varies from teacher to teacher though I found that on the whole, the computer is regularly used as a replacement for the chalkboard. Replacing the traditional wooden desks are more corporate, chic models, bolted to the floor, with numerous ports enabling all students to connect to the internet and the school's Intranet. Hence students are able to do research from the classroom via a connection to the library, download their teacher's notes, use all software programs licensed for the school, e-mail each other easily, even in class much to the chagrin of some of their teachers, and have online conferences. At Glen Manor it is important to note that all hardware and software used is standardized to one platform (as a result of the school's affiliation to IBM) and is similar between students and their peers, between teachers and their colleagues, and between teachers and their students for ease of use and for practical purposes. The "pay-off" for IBM is that it obtains the school's business and that the students, who will in future likely obtain high powered jobs, will use their platform. For the school the pay-off is that using the same platform can alleviate problems and that responsibility for purchasing computers is downloaded to students and their parents.

Out of all the arts classrooms I visited, including English, Media, Music, Film, and Visual Arts, it was only the latter that was not wired (however, there were immediate future plans to build a wired Visual Arts and Science building). In sum, all students have access to technology, providing the classrooms are wired—and most are.

Glen Manor College does not have a similar program to WiredIMAGE. Their Visual Arts remain traditional, with a focus on art history and art production. Any interest in utilizing digital multimedia technologies is regulated to workshop time outside of the classroom in which the Visual Art teachers have hand-picked students to conduct workshops using software programs like Adobe Photoshop and Illustrator. These workshops are not considered to be part of the classroom curriculum nor are marks given for the learning or the works produced.

Glen Manor's history in the multimedia area is quite interesting. Between 1995 and 1998 educators were able to develop a popular media program. For part of this program students studied journalism and for the other part they studied television. Many teachers remember and speak fondly of the successful and popular weekly television show produced by students called "*Glen Manor Live*" which was aired weekly to the entire school population. Macintosh computers were used but when the program was dismantled the equipment was sold. Several reasons were presented for the program's demise, ranging from it being too time consuming to the view that it was not academic enough. In addition, many teachers commented that it was too costly. This last reason appears to be most logical in light of the fact that the multimedia program was dismantled at the exact same time that *Phase 1* of the laptop program, which had great expenses attached, was implemented. The dismantling of this program is still a contentious issue for teachers at Glen Manor. If they had developed it further, the school would have had a unique program in the multimedia area which it does not have at the present time.

To indicate the shift in administrators' focus that occurred during the latter part of the 1990s, I will describe two interviewees, one a graduate and the other still attending Glen Manor. On the one hand, early on in 1995, Lyle was the student who was the catalyst in getting the multimedia program started and running specifically in the area of television. His interest was fostered and developed by teachers at Glen Manor. Currently he is receiving major film awards while also studying film in Los Angeles. On the other hand there is Adam who is still attending Glen Manor. His experience is very different than Lyle's for he has received little support in his pursuit of another area in multimedia, animation. Adam is still at Glen Manor and is experiencing an entirely different environment than Lyle. Much to his distress, Adam was not given the option of being able to take an extra Visual Arts credit: rather, he has been told to take an athletics course in its place (which he intensely dislikes) in order to achieve a "well-balanced" curriculum. Stress is placed on such balance. As a result of a shift in focus at Glen Manor, the two schools I studied remain very distinct: Glen Manor's focus is to use technology to enhance the traditional curriculum; Pleasant Dale's is to use technology throughout the curriculum and also to enhance students' production and knowledge in the area of multimedia.

In 1998, during *Phase 2*, Glen Manor administrators provided all the teachers with laptops. This is a direct contrast to Pleasant Dale where teachers either buy their own computers or compete with other teachers for the scant resources available for educators. At Glen Manor, training and support is far better developed than at Pleasant Dale. Glen Manor has developed an Information Technology (IT) Department with a handful of full-time and part-time help who provide not only technical support if computers break down but also 1 hour bi-weekly teacher training courses; moreover, through this department, teachers also receive six additional hours of workshops every week. Educators who desire further training through professional conferences and workshops outside of the school are often provided with time and financial support to do so.

In summary, Glen Manor is a cutting-edge school in which students use sophisticated digital technologies in their classrooms. Programs, however, are limited to integrating technology within the traditional curriculum. Usage of technology for multimedia development is limited, preventing students from working in such areas as videoconferencing, animation, and desktop publishing production. Furthermore, Glen Manor excels in support and training: Teachers are offered financial backing and strong technical assistance as well as excellent workshops and seminars.

4. RESEARCH DESCRIPTION: CASE STUDY

For this study I used *instrumental case study research* (Stake, 1994: 237) using a *comparative case study analysis* (Hitchcock & Hughes, 1995; Merriam, 1998; Yin 1989). I selected two schools. In one, Pleasant Dale, I worked as a teacher and I also assumed the role of researcher. In the other, Glen Manor I was solely a researcher. Glen Manor was recommended by consultants, teachers, and administrators as an excellent school because it possesses cutting-edge technologies. Recently both schools had much press coverage for their technological innovativeness. For data collection methods I used four main sources: first and foremost, I relied heavily on interviews; secondly, I employed participant observation; thirdly, I took field notes; and lastly, I collected documents concerning the schools, ranging from media coverage (of which both schools had plenty) to brochures, newsletters, pamphlets, and websites written and issued by administrators and teachers in the school. My roles were diverse from (1) researcher as teacher, and (2) researcher as participant observer, to (3) researcher as interviewer.

I collected data over a two and a half year period. Six teachers from each of the two schools (making it 12 in all) were interviewed. They were selected on the basis that they were (1) either knowledgeable or were pressured into becoming knowledgeable about multimedia technologies in an arts area curriculum ranging from Communications Technology, Film Studies, Computer Studies and Media English, to Visual Arts. I was also concerned that educators should (2) come from different backgrounds ranging from engineering to photography and film (many of whom had worked professionally in these fields before entering the teaching profession). Moreover, I wanted to interview teachers with (3) diverse levels of teaching experiences ranging from the neophyte to individuals on the verge of retirement. Furthermore, teachers at both schools recommended students to be interviewed. I had more difficulty narrowing the high school students down as teachers recommended a large number. Eventually I selected 16 (seven from Glen Manor and nine from Pleasant Dale) on the basis that (1) they were tech-savvy; (2) had studied multimedia digital technologies in an arts based curriculum; (3) had assisted their teachers with technology in exceptional ways; and (4) were responsive and articulate during the interviews. These students also varied from the helper (the teacher's Godsend!) and the technical whiz to the computer hacker. For both teachers and students I attempted to have a gender balance between both male and female teachers and students but this was impossible at Glen Manor where all the teachers recommended I interview male students with the exception of one recommended female whom I did not use as she was shy and reluctant to share information during the interview process.

I conducted one to two interviews per person and the first set were *semi-structured* (Merriam, 1998). These interviews lasted anywhere from 50 minutes (the shortest) to numerous hours spanning several days, whenever busy teachers and students were available between classes, on breaks and during lunches. With one student, however, I corresponded over e-mail because he was in Los Angeles. If a second interview was needed, and oftentimes it was, I employed open-ended ones (Yin, 1989: 89) in order to clarify the data I had previously obtained.

All teachers and students were sent the transcripts to check, clarify, and correct. Descriptions of the school programs were sent to key administrators at both schools to further ensure accuracy of information. I employed *data triangulation* and *methodological triangulation* (Hitchcock & Hughes, 1995). Two types of analyses were conducted: firstly, the *within-case*, and secondly, the *cross-case* analysis (Merriam, 1998: 194–196).

5. TEACHING IN VIRTUAL LEARNING ENVIRONMENTS

What happens to the curriculum, to the ways in which teachers teach and the ways in which students learn, when cutting-edge technologies are introduced into schools? How does the introduction of new technologies change the school learning environments? Cuban (1993) has made the observation that research is scarce concerning the manner in which educators teach using technologies in classrooms (p. 284). Based on the current research, there are numerous claims that the role of the teacher naturally alters when technology is introduced to classrooms. (Bagley *et al.,* 1994; Hannafin & Savenye, 1993; Knupfer, 1992; Schofield, 1995).

5.1. Teacher and Learner-Centered Approaches

The teacher-centered approach (in which educators position themselves in the front of the class and lecture through question and answer style teaching) some researchers claim is changing. The position of the teacher as the dispenser of knowledge is being eroded by technology (Doud, 1998; Gregory, 1995; Hannafin & Savenye, 1993; Jeffers, 1992; Knupfer, 1992; Knupfer, 1993; Koehn, 1986; Lai, 1993; Luke, 1996; Schofield, 1995; Silverman, 1995; Willis, 1985). Educators, it is postulated, naturally take the role of facilitator when dealing with media technologies and this is viewed by many in a favorable light (Bagley et al., 1994; Carey, 1993; Hoffman, 1996; Jones et al., 1995; Jordan & Follman, 1993; Knupfer, 1993; O'Neill, 1995; Pearlman, 1989; Tapscott, 1999; Wood & Smellie, 1990). Teachers (1) restructure an environment conducive to untraditional methods of teaching (as opposed to the more teacher-centered one); (2) act as helpers; and (3) make much of the work project-driven (Haycock, 1991; Sheingold & Hadley, 1990).

Many researchers discuss how virtual technologies have affected teachers so that far more teaching is done in *learner-centered classrooms* or what is commonly also called *student-centered learning environments* (Carey, 1993; Hannafin & Savenye, 1993; Lai, 1993; Masterman, 1993; Sheingold & Hadley, 1990; Sivin-Kachala & Bialo, 1994). In this model what is promoted are students learning from one another, and developing problem-solving and independent learning skills. The *constructivist approach* and cognitive–developmental theories are often discussed in relation to this model (Carey, 1993; Cuban 1993).

There are some researchers, however, who have found different results: They postulate that educators' roles have indeed not radically altered since virtual classrooms have been established. Rather than technology altering teaching methods, technology is often merely assimilated into conventional ways of teaching (Collis, 1989; O'Neil, 1995). Willis (1985) and Meinster (1990) maintain that most teaching methods still consist of teachers lecturing and students listening.

Very few researchers have postulated that different approaches can be used in the same school, within the same classroom and indeed by one individual teacher. There are however, a few. Cuban (1993) and Wiske et al. (1988) discuss how many teachers mix their teaching approaches when using technology ranging from using traditional teacher-centered approaches to student-centered ones. Saye's views corroborate with the above. He outlines three types of teachers (1997; 1998). Firstly, there is the *Accidental Tourist* who uses technology to reinforce the teacher-centered approach; secondly, there is the *Voyaguer* who uses technology in a more *learner-centered classroom approach*; lastly, Saye describes how teachers can also adeptly switch roles between the above two. As a result of his recent studies, he concludes that, "contrary to the expectations of many advocates, study data suggested that acceptance of educational technology may not imply a radical shift in educational practices. Although some teachers appeared to have embraced its potential for alternative approaches to schooling, others adapted technology to bolster traditional, teacher-centered instruction" (p. 223). My research corroborates with Saye's (1994; 1997 and 1998) Cuban (1993) and the AUUW's (2000). I found that teachers do not change their teaching methods or the way in which they structure their classes as a result of integrating technology in the classroom. What has the largest effect in virtual learning environments are the following (and I am not listing these in any order of importance as these vary from one teaching situation to another): (1) the philosophical mandate of schools and their administrations; (2) the mandate of programs within a school teachers are working in; (3) a teacher's philosophical approaches to teaching; (4) an educator's propensity towards and comfort level of utilizing certain teaching methodologies; and finally (5) the teacher's past background in technology and present levels of training and support which have direct co-relation to the amount of monies available in schools.

5.2. Models of Incorporating Technology into the Classroom

The two schools I studied differed greatly in the way in which teachers' approach their teaching in their virtual learning environments and the way in which students respond within these environs. Recently the AAUW (2000) conducted a study in which 70 female students participated; they outlined three models in use in virtual learning classrooms. In the (1) *productivity model*, teaching styles and curriculum into which technology is incorporated remain unchanged; (2) in the *career model* the sole reason for using technology is to prepare students for the world of work; and in the (3) *fluency model* the curriculum is restructured so that multimedia technologies are integrated throughout, with an emphasis on the development of problem-solving and critical thinking skills.

I found that at Glen Manor both the *productivity model* and the *career model* are in place. Great emphasis is laid on students at Glen Manor being trained for future leadership careers, and it is touted that Glen Manor will better prepare pupils for the 21st century. Moreover, this school fits well into the *productivity model* in that there are no great changes in curriculum structure, or within the roles of teachers and students. There are some situations, however, which differ. One of the teachers, Mr. Tyke, uses the technology for online classes after traditional school hours. Moreover, Mr. Tyke was also involved in the now defunct multimedia class, described as strongly student-centered. When I observed his classes, however, I found that he only utilized, and was a master of, the Socratic teaching method. Overall, at Glen Manor I found that the teacher-centered mode of instruction greatly predominates. Despite the introduction of the pervasive and expensive laptop program, which meant a restructuring of rooms, large scale building renovations, great amounts of monies spent on hardware, software and personnel, the mandate, nevertheless, within the school has remained unchanged. Traditional private school teaching methods are primarily utilized with teachers lecturing using Socratic methodology. Almost all the teachers at Glen Manor position themselves as authority figures. The computer is the teachers' chalk and their computer projector and whiteboard function as chalkboards. Students quietly listen to their teacher and take notes using their laptops which serve as notebooks and as walkways to their library since all student computers are connected to the internet. Most pupils work on the same material at the same time. It is no surprise that half the teachers interviewed assert that using the technology has not affected their approach to teaching. At the beginning of the 21st century, Glen Manor still follows the British school system's humanistic, well-balanced 19th century educational approach. Educators talk about having control: control in terms of the class, control in terms of students, control in terms of the technology, and control in terms of censorship, particularly regarding pornography and racism found on the internet. In addition, having a computer always available, being able to rely on technical support from the IT Department, having weekly training sessions and ongoing workshops I believe helps teachers maintain their position of authority. On the whole, teachers feel comfortable with this and the students respond well. They believe this approach works effectively.

At Pleasant Dale, teachers vary their teaching styles from class to class and from lesson to lesson. Sometimes educators at this school use a teacher-centered approach and sometimes a student-centered approach: Some educators have a propensity for using one over the other. Sometimes they vary their approaches. Students state that they appreciate all the various teaching methods their teachers use. It is apparent that Pleasant Dale differs from Glen Manor. Overall, the school is best described as fitting into the *fluency model*, particularly where computers and technology are strongly utilized as in the WiredIMAGE program. Here, project-driven, student-centered curriculum is primarily used. Teachers have a less authoritarian approach, veering more to collaborative learning partnerships with students. Multimedia technologies primarily in the WiredIMAGE program are integrated within a number of disciplines, specifically Computers, Communications, Technology, and Visual Arts with a recent, additional component within the last two years of Geography and History. Mr. Kreighoff, the former Program Head of WiredIMAGE, discusses his teaching method:

> Later on, when I brought in other technologies into the programme, then I did have to bring the students as more partners in the set-up as well as even in the skills' teaching—not only to me but to the rest of their peers. You can't help but in that modeling situation to be challenged by the students because you've now opened up the floodgates and you've shared the keys with them. And you can't all of a sudden be the authoritarian or go back to a traditional mode of teaching of the sage on the stage because those students in practice have been partnering with you in a very real way. Once that's stopped they won't allow you because it would be hypocrisy to do so—to go back into a traditional program. It helped that I was naturally comfortable with that environment of partnership and sharing rather than feel intimidated or that I have to be the last authority.
>
> It helped because that was my personality to lend itself to that
>
> (Black, 2002: 173)

Ms. Herbiere (Black, 2002), a teacher in WiredIMAGE and in the regular program, similarly states that her role has changed: "Well, teaching computer based technology has humbled me to a great degree because I'm not the expert anymore. I hate giving that up but that's the reality. I can't do the Socratic thing at the front of the room and give all the answers and be the big guru [for] I am just the voice of many in the classroom as we all try to figure out what the problem is, or what the solution is, or what the potential of the situation is . . . " (p. 174).

From both schools the students I interviewed react favorably to the many roles of the teacher. Teenagers generally agreed that as long as their educators were effectively teaching, whatever role they assumed was fine. Students in WiredIMAGE did note, though, that other WiredIMAGE students who wanted more of an authoritarian teacher-centered educator dropped out of courses in which it was not delivered. The vast majority of students, however, remained and enjoyed the different teaching styles. Joe, a student in WiredIMAGE, describes his perception of the teacher's role:

> The teachers in WiredIMAGE, the staff in WiredIMAGE really are like the head of the class, like the head of the table. They mediate. If you are comparing it to the dinner table: my father sits at the head of the table. He's the head of the family. He doesn't tell us what to eat first. He doesn't tell us how we should eat it. He doesn't tell us if we should put salt on our fish. They just sit there. If I want salt, then I will say, "Dad, can you pass the salt?" If you can compare it, that's the analogy. Teachers are there, and they set a tone. This is probably one of the most important things they do. They set a tone by saying nothing. That's what's amazing about the programme. Similarly to how you're sitting at the dinner table and your Dad's there and you have a certain respect. You watch your language. You make sure that your knife goes in the left hand and the fork goes in your right hand. You eat with your mouth closed. He's there, so you do certain things. You act a certain way, and you make sure to finish your plate—all those things . . . They set a mood. They make sure [things are done well]. Just by them being there you feel energized to work, you feel motivated to work (and you want to). That's what they do
> (Black, 2002: 176)

Why does Pleasant Dale Collegiate differ so much from Glen Manor College in terms of the virtual learning environment it has created? I believe there are many reasons. Firstly, many of the teachers hired who use technology are hired to teach in the WiredIMAGE program and they end up, by virtue of being at Pleasant Dale, also teaching in the regular program. WiredIMAGE has a program mandate which is student-centered and project-driven. Teachers are influenced by this. Secondly, administrators strive and are successful at having an equal representation of male and female pupils in the program. The AAUW (2000) study claims that the *fluency model* particularly attracts females, and WiredIMAGE is noted for its high female population in relation to other technology programs within the city in which it is situated. Thirdly, because of inadequate teacher training and support, a more project-driven, student-centered, less authoritarian model makes sense in this school. The student-centered approach works for the teacher struggling to keep abreast of the technologies. Koehn (1986) writes that a teacher dealing with technologies who strives to be the "all-knowing" educator either has a "very stupid bunch of students or hasn't learned that lesson that . . . [it is a] dangerous role" (p. 30). Hence it is apparent from the two very different case studies that school circumstances, situations, as well as people's backgrounds all have a role to play. It is the (1) philosophical mandates of schools and their programs, as well as (2) teachers' own comfort levels towards and approaches to teaching, in addition to (3) the level of training and supports which all help to shape the way in which virtual learning environments are formed.

6. STRANGERS IN VIRTUAL LEARNING ENVIRONMENTS: RESHAPING TEACHERS AND STUDENTS

Teachers at Glen Manor and Pleasant Dale vary in their attitude towards working with digital technologies. There are teachers who are outrightly critical of and hostile towards the use of digital technology in the classroom, questioning its pedagogical benefits. Conversely, there are also teachers who praise its merits, albeit sometimes unconditionally and sometimes rather uncritically. Whatever their attitudes towards using computers, teachers are expected to use them in classrooms regularly at both schools, but the usage varies greatly. On the one hand some teachers have rarely used computers in their classes, particularly at Glen Manor and particularly with two teachers: one is on the verge of retirement so administrators are leaving him alone; the other uses excuses and she feels vindicated when using these justifications for, she reasons, there are no drops in the classroom to facilitate computer usage and those classrooms that have drops are difficult to book. Then, on the other hand, there are teachers who are extremely innovative in their technology usage. For example, in the case of Pleasant Dale, educators and students took part in an exciting project 3 years ago of implementing videoconferencing with other schools in Ontario (when videoconferencing was not so common). In another case at Glen Manor one teacher implemented a special annual digital conference for his English students in which he had online participation between his pupils and published Canadian authors.

6.1. Educators

Did educators perceive themselves as changing as a result of teaching in virtual learning environments? Teachers at both schools talked about what they have done to learn about the technologies. They refer to experts for help; seek out other teacher's assistance who are more knowledgeable; become more knowledgeable about digital technologies themselves; teach themselves, providing they have the resources and time (which many do not); and use problem-solving skills when faced with technological difficulties. Educators, particularly at Pleasant Dale, also observed that they had become (1) far more flexible; (2) more creative in their design of projects; (3) more focused on teaching theory rather than the technical components of a lesson; and (4) far more apt to establish community ventures. I will elucidate on these last four points further.

Firstly, Pleasant Dale teachers talk about having to be flexible when dealing with the practical problems of computers—and these are truly practical day-to-day problems—because of the temperamental nature of technology. What happens when something as mundane as the last computer projector bulb burns out and when the teacher has prepared her entire lesson based on the use of this equipment? What happens when a student is unable to cross platforms or when software they used at home is incompatible with the software at school? Teachers find practical problems affect their day-to-day teaching and as a result they often plan ahead for technology breaking down, for something not quite working; thus being adaptable and well prepared is important. In addition to this, teachers talk about becoming more flexible in terms of their assignments, particularly at Pleasant Dale. Students are given the freedom to explore and teach themselves. This is very different than how assignments are generally structured at Glen Manor in which students follow prescriptive directions and guidelines, proceeding lockstep through each phase narrowly outlined.

Secondly, educators talk about change in terms of assigning more creative projects, particularly at Pleasant Dale. They design these projects in a variety of ways, based on learners' own individual learning styles, needs, and interests. It is expected that students will research, conduct preliminary work, and document their findings as a part of every multifaceted project. Teachers basically outline the creative project, teach theory relating to it, and then hand over control to their students who design how they will undertake each project within the structure that has been set.

Thirdly, teachers find that in order to teach well at Pleasant Dale they defocus attention on the technology while at the same time they focus more on theory—specifically on the theory in which they are strong. They rely on this transferable knowledge so that, for example, if they are strong in English, they will connect English theory to the teaching of technology. Hence, in an animation project, for instance, in which students are expected to create a pixilation as their final work, a teacher who has a strong animation background will focus on animation theory, animation history, including pre-digital animations, elements of design, and examples of pixilation and the film techniques utilized. Students will use the technology at hand such as video cameras, programs such as Final Cut Pro or iMovie, but teachers will not focus on this software as a primary part of the project. Educators at both schools talk about areas they rely on from journalism and the Classics, to Visual Arts and English. Mr. Ross ruminates:

> I see teachers in the classroom, particularly older teachers, who are not up to steam on the technology, and if they do not have the theoretical background or other backgrounds that apply to the subject it's a nightmare because you can't even design the course so that the kids search for answers to the technology and you deal with other issues that are

> involved like design or whatever the case may be. If you don't at least have one strength to fall back on within that course you are in big trouble. I wouldn't want to be there. If I were put into that situation, if I lasted a year and things did not get better, I would leave
>
> (Black, 2002: 244)

This vastly differs from some other types of teaching approaches in which teachers will specifically focus on the software and hardware and not on the creative and theoretical aspects.

The final change teachers have noticed, again particularly at Pleasant Dale, is their connection to the community. Here projects are created so that students work with professionals in the field. In other words, to be metaphorical, teachers have designed projects so that the walls of the schools are broken down. Students work outside of the school in the community and, vice-versa, people from the community visit the school. Pupils work with people in the industry on joint projects such as was the case when WiredIMAGE students created the website design for the "Toronto Olympic Bid" in conjunction with a major museum. On an ongoing basis, professionals visit the school in order to conduct workshops, give lectures and seminars on topics ranging from website design to how to create professional storyboards. As WiredIMAGE develops, its graduate students (many of whom are now in the workforce) return to talk to, assist, and inspire students. Mr. Kreighoff describes the benefits of this last strategy:

> Currently, we just finished a project—albeit, with a very special group of kids, in the senior WiredIMAGE programme—but this was a project in conjunction with the local graphic arts museum which meant it was going to have ultimately much public profile—a strong public profile . . . The students did wonderful work that is visible on the internet in a creative fashion in an open classroom environment with a very high end quality technology that allowed them to explore their own ideas and learn more than minimal skills in various packages that are used for design that include multimedia development, sound, movies, motion and they did a wonderful job . . . Anybody, forever can see it—there is nothing more motivating than having to show your wares in public. " . . . We pride ourselves here that most things that go on, go on with students around: presentations, meetings. I take students to meetings that are high level—technically and politically high level—and charged not only because they have technical expertise that I don't have but I want them to understand what the world of the corporate suit is like as well. That is also a learning part of school. That would never have happened twenty years ago
>
> (Black, 2002: 219–220)

At Glen Manor, only one teacher was teaching technologies in this manner. At Pleasant Dale all the teachers were working on community ventures.

6.2. Students

How do students perceive they have changed with the advent of technologies in their classrooms? They share some concerns with their teachers, one being the importance of volunteering within the school and greater communities. The other, particularly at Pleasant Dale, is their enjoyment of the flexible, open-ended, creative assignments enabling more control. Students are cognizant of and appreciate the notion of taking control of one's own learning, of acquiring more control over projects, and being more independent learners. As well, students are aware of teachers who connect their theoretical knowledge to technology. From the learner's perspective, they appreciate teachers who do this. Healy (1998) advises teachers not to be intimidated by students' technical "wizardry" but to impart skills and wisdom to the classes (p. 289). I found that students respect their teacher's skill and expertise in those areas that are relatable to computer learning. The one catch is that these areas of expertise must have obvious relevance to technology. If what the students learn has relevance to the learning at hand, students will respect their teachers; the converse is also true, which had been the case with one unfortunate substitute teacher at Pleasant Dale. Educators who have few relatable areas of expertise to the field of technology are particularly vulnerable to students' disdain. It is important to note that power is often granted from below and in the case of the Pleasant Dale substitute teacher it was not given to the teacher by the students.

Learning characteristics students discuss at both schools are similar: They believe they have to be inquisitive, open-minded, unafraid of failure, and risk takers. It makes sense that they would talk about these qualities in relation to the present time for these technologies are new and on the cutting-edge, and hence students are often unable to turn to their teachers for expertise and assistance. In addition, being independent learners is unanimously an important trait. This corroborates with Negroponte's research (1995) who found that our new "digital youngsters" are self-learners. The question of whether technology has shaped these students to develop these qualities or whether these are the types of students who work well with and are thus attracted to computers needs to be addressed in future literature.

7. RESHAPING ROLES OF STUDENT AND TEACHER

Many educators readily admit that some of their students know far more about computers than they do. Teenagers are so keenly interested in digital technologies, many have few responsibilities, and most have ample time to play on computers, leaving their adult counterparts far behind in hands-on digital expertise.

Tech-savvy students themselves generally acknowledge that they have better technical skills and knowledge than most of their teachers. How do teenagers respond to this common situation? Much to my surprise I found that they are very forgiving. That I heard no complaints of teacher incompetence from any of the 16 students I interviewed was even more surprising. Four major reasons explaining lack of teacher knowledge are provided by the teenagers. Some observe that if a teacher developed superb technological knowledge they would not be teaching but in the computer industry where they would be making far more money. In fact one former teacher of a Glen Manor student did just that that: He learned on the job with this student and then promptly left teaching for better pay at a computer company. Some students also acknowledge that teachers have a difficult time keeping up with the swift technological changes occurring in the technology field. Moreover they have little time to learn, being so busy with the day to day running of classes. In addition, the interviewees realize they are the ones growing up in the digital age. Their teachers, however, grew up in a very different world where, for most of them, having a home computer was unheard of, odd as it may seem by today's standards. Today's students are vastly different from any previous generation (Negroponte, 1995; Tapscott, 1998).

The only criticism I heard was from Lyle, a Glen Manor student who points out that it is the teachers' attitude that can be problematic. Lyle believes that even though some teachers may know very little regarding technology, educators must be willing to learn from their students in order to obtain teenagers' respect. Role modeling the learning process is very important. Teachers always expect their pupils to be willing to learn in the classroom environment. Lyle has little patience for educators who will not do the same. He reflects, "How can they expect me to learn from them when they refuse to learn from me?" (Black 2002: 243).

Two-thirds of the teachers interviewed had no previous computer training; they had to learn about digital technology while teaching. Mr. Tyke was one of three key educators to spearhead the laptop program at Glen Manor: he is not only interested in technology but utilizes it well, constantly letting his students know he is cognizant of their computer abilities and he is himself digitally adept. For example, he describes a typical (and problematic) situation at Glen Manor in which students send each other e-mails during class:

> [My message to the person who sent my student an e-mail reads] 'Hi, it's Mr. Tyke and I'm replying to the e-mail you sent to so and so who is in the middle of a class and I know that you are in the middle of someone else's class too. I wonder whose? I wonder if I should tell them? Would you like to tell me what class you're in? I'd appreciate it!' Of course you

> get no response at all. Those things are important as any teacher will tell you . . . It's just enough to let the kids know that not only are you interested, but you are good at it too. You'd be surprised how much they appreciate that and respect it. The last thing you want in the classroom with a bunch of technology, the kind of stuff that this is, is someone who doesn't know anything about it at all
>
> (Black, 2002: 240–241)

Most teachers are not as tech-savvy as Mr. Tyke and therefore are unable to assert their control over students. How does this affect both teachers' and students' roles? How does this affect the student–teacher dynamic?

8. DISPLACED STUDENT–TEACHER EQUILIBRIUM

If one visualizes the relationships between learners and educators in terms of a simile, this relationship would be very much a teeter-totter. In traditional pre-digital times if one placed the teacher and the student on opposite sides of this contraption one would find the weighty educator most often holding the student up in subordinate suspension. However, add the catalyst, technology, as weight and this picture changes radically. Now that teeter-totter is often in flux in an up and down, shared ride between learners and their educators. Why has this picture changed in the last 10 years?

The first reason I believe is that tech-savvy students have been asked to take a far more active role in the schools. From the research I conducted I saw students taking positions of power: they operate equipment, run labs, conduct workshops, teach their peers, collaborate, and in some cases teach their teachers in formal situations. They are taking on a variety of roles ranging from assistant and technician to workshop leader and educator. Some are paid and others volunteer. These students end up taking more leadership roles in their classrooms and in the school community.

Technical jobs are in abundance at both schools. In Pleasant Dale, two students had run the computer server and were privy to confidential information such as teachers' marks. WiredIMAGE constantly has students volunteering as troubleshooters, monitors, and technicians. One student describes how he is regularly approached in the halls by teachers who ask him for technical assistance. In fact, for this particular student, one of the consequences of taking on such an important technical role at Pleasant Dale is that he has been regularly mistaken as a teacher by his peers. At Glen Manor, students help the teacher run the schools' Intranet, volunteer at the Help Desk, and manage the school's website. One student surfs the 565 student websites, making certain that racist or sexist content is obliterated and that the server is not overloaded.

Both schools place students in positions of power. They teach their peers formally and informally. For instance, at Glen Manor, key pupils have been singled out to conduct workshops on Photoshop after school hours of which their two Visual Arts teachers are actually taking part as learners. At Pleasant Dale, students are often asked to conduct formal workshops, particularly on software, to teachers as well as teenagers. Peer learning is also conducted on an informal basis as well. It is a general rule of WiredIMAGE that students must query three other students before they turn to their teachers for assistance. Student mentors are promoted. Ms. Hebiere labels these pupils “lead people” and she elaborates on their importance:

> I’m finding more and more . . . that there is a real sense of camaraderie about sharing ideas and knowledge . . . I find they [students] are very generous with their information . . . You’re all just flying by the seat of your pants. One student knows . . . and so the exponential growth is that if one student knows it in one hour you can bet that in forty minutes another student knows it, and then another student, and then those students teach two more. So, exponentially we can move through the class within a two day period and everybody will know something. I think it is really important to talk about the exponential factor. It’s not one person and then the next person: it goes one, two, four, eight, sixteen, thirty-two. That can happen pretty quickly and I’m just coordinating the show really
> (Black, 2002: 249)

Hence, in technology classrooms at both schools there is great value placed on peer learning. Teachers find this practice invaluable, stating it makes their job easier and it enables students to succeed; indeed, in some cases the solution devised by other students is the only way teachers believe they will be able to accomplish certain tasks.

Student–teacher relationships have been affected in a second area through interesting teacher–student collaborations. I found that at Glen Manor Lyle and Mr. Tyke had collaborated in a rare manner unusual for this school: they worked together to design, implement, and run an entire course. Lyle had been placed in an uncommon situation for he was even given influential responsibilities including curriculum planning and student assessment. Similarly, at Pleasant Dale students work with teachers to help them order the best equipment, to participate in conferences, to collaborate on the launching of new activities such as videoconferencing, and to work on special events ranging from the local to international.

At both schools co-learning has a significant role. This is the process in which teachers and students learn together, tackle problems as a team, gain knowledge of technology, and connect new technologies to school situations. They develop a reciprocal exchange, a reliance on each other, and treat each other as colleagues. (In one case, Mr. Tyke exchanged business cards with an elementary student who helped him out with a conference event.) This is a process in which students and teachers work and troubleshoot together to obtain workable solutions for pedagogical situations. Rarely, in the past, were students given the opportunities they are at present. At Glen Manor, Ms. Smith expresses her perspective on this situation:

> It puts us right on the same level as the students and I think that's fabulous. I think it's going to cause a lot of problems for a lot of teachers, for the traditional teachers and their approach to education but I think it's a humbling experience for educators. A lot of educators get caught up in the fact that they know everything. The technology puts you on the same playing fields and I think it's so good for the students to see the teacher say, 'I don't know how to do this? Does anybody else know how to do it? How am I going to problem solve my way out of it?' We are right there together and we're working together as a team solving the same problems and I think that just increases the respect level. I don't think that the teachers have to know everything all the time. There's the myth that that's how you get respect from your students: that you know it all
> (Black, 2002: 310)

Included in *The Discourse of Language* (1972) Foucault extrapolates upon the interplay of power within institutions. As a result of the displacement of student–teacher equilibrium power is reorganized. One of these ways is what he terms the *principle of exclusion* in which he discusses how people in power such as teachers are given the exclusive right to talk about a topic. This right is now being redefined in virtual learning environments.

Oftentimes the relationship between learners and their teachers is not static but constantly in motion, much like in the teeter-totter analogy. Sometimes the teacher sits in the position of power, sometimes the student; sometimes they are balanced learning equally from one another. Weiss (1992) discusses this co-learning theory in which teacher/learner positions shift. In co-learning, knowledge and learning is shared and there is a co-reliance between teacher and pupil. Tom provides an apt description: "My computer teacher, Mr. Tyler knows the software programmes. He helps out and I'll figure out certain things, different ways of doing it and he'll say, "That's great!" It will go back and forth . . . I think it's more of a reciprocal exchange" (Black, 2002: 260). Co-learning situations such as these vary in terms of duration and intensity from relationship to relationship. Students describe their co-learning experiences in laudatory terms, using such adjectives as "beneficial", "exciting", "wonderful", and "amazing", often observing that co-learning personalizes their relationship with teachers.

Teachers, however, approach co-learning more cautiously because they feel that some students are unable to handle the shift of power between themselves and teachers. They warn that students not only need to be tech-savvy and able to teach but also be adaptable, respectful, sensitive, and mature. Teenagers must have "people skills" and be able to make sagacious decisions beneficial to their school. This is a demanding role for which many are simply too young. At both schools some students take advantage of their new power. They have, for example, actively tried to undermine their teachers through the privilege of their positions. Interviewees at both schools commented on tech-savvy students who developed arrogance, feelings of superiority, and became, to borrow a phrase, "full of themselves". Moreover, another detrimental factor with student empowerment is pupils who overstep the limits and hence further abuse their position. For example, one teenager at Pleasant Dale, Luke, broke into a security system and was banned from computer usage for a year. Another student, Michael, much trusted at the same school, served as a technician and ended up deceiving his peers who were relying on him for important technical information. Yet another pupil who was a technician at Pleasant Dale mishandled highly complex computer equipment (SGIs) which sat for a seemingly interminable length of time in disrepair. Other students at both schools illegally hacked into systems, or granted some of their peers' favors while excluding others. Moreover, handing over power to students can place teachers in vulnerable positions as the power dynamic shifts. To begin with, teachers find that they cannot assert their authority in the traditional manner, notwithstanding the many educators who successfully empower students and do so effectively. Many students, however, do meet the demanding role and meet it well. In summary, teachers and teenagers at both schools often describe their positions as shifting: the teacher becomes the student and the student becomes the teacher in these new forged relationships.

9. DISPLACED STUDENT TEACHER EQUILIBRIUM IN SCHOOLS AND IN THE WORKFORCE

Teachers are taught by teenagers in a variety of ways ranging from informal, spontaneous after class discussions, private tutorials and workshops, to more formal student led class presentations and lessons. The benefit, according to teachers, is that it is an effective way to develop skills and learn needed information. In the case of teachers at Pleasant Dale, students' help and advice are invaluable as teachers have so little opportunity to learn the material through other avenues. One teacher even calls upon tech-savvy students for help during the night when she is grappling with technical problems. Students feel empowered through taking on a more active role in the learning process. Teenagers and their teachers have described these exciting new forged relationships in terms of a paradigm. Joe, a student in WiredIMAGE shares his perceptions:

> "I think what's important is just to understand that we are on a paradigm shift as far as the industrial revolution began [sic] in the 16th Century. Now we're in a new revolution where computers are turning the way we

> do everything and anything around: jobs are completely being turned around. What my point is that education is going to have to take a huge turn . . . Because of technology (everything ties back to technology) the way anything is done is changing including education. I think that's very important to remember: we are watching and I am part of what is going to be shaping the next hundred years of education . . .
>
> (Black, 2002: 264)

Many students reflect that their relationships with teachers are more personal, more caring, and closer. Louise, Dylan Emma, and Zoe comment that the teacher's ultimate role is more than to simply give students marks. They share knowledge and learn together. Respect and trust are key issues. For instance, Lyle comments on his relationship he established with Mr. Tyke:

> Mr. Tyke certainly had no lack of technical knowledge, but was new to some of the things that I was teaching him. Not only was he willing to put the teacher's ego aside and learn from a student, but he was a fast and enthusiastic learner. His ability to learn from me only increased my respect for him as a teacher . . . My relationship with Mr. Tyke was unusual. I think our relationship was different because we had common interest and goals for the school, and worked together to implement them. But more importantly, he always treated me with the utmost respect . . . like an adult.
>
> I always told him that was important to me, and he said that he treats people the way they deserve to be treated. Some students need to be treated like kids, but some really deserve to be on an equal level. I completely agree, and I think that this is one of the most important components of a good student–teacher relationship. I think this was also a key in our collaboration. He trusted me completely, so it was easy for me to design the course the way I wanted to. He obviously had suggestions for formatting it appropriately for the classroom and because I respected him so much, I had no problems taking those suggestions
>
> (Black, 2002: 275–6)

In fact, friendships have been established at both schools between students and their teachers and in most cases this lasts well past those students graduating and leaving the school: It is not uncommon for these students to keep in touch and visit their former teachers with whom they had close collaborations. Students often talk about getting to know their teacher better not only in the teacher/student role but on a more personal basis as a consequence of spending so much time working together. Hence, as a result of working with technology, a close camaraderie often develops between learners and educators which break down traditional hierarchical institutionalized school barriers.

Within this new power dynamic, students are creating a new hierarchy in their school institutions, and with this, reconfiguring their role and status. More power is being handed over to them by educators which place them in positions of power over their peers; in addition it situates them in a more powerful role with their educators; moreover, power provides tech-savvy teenagers more control to shape their virtual learning environments. Through controlling high powered technologies, the tech-savvy students affect numerous people in their pedagogical institutions. Consequently, these new techno-literate teachers and pupils are creating new positions of control and status through the redefinition of their roles and relationships. Sean reflects upon the changing times:

> It's different: it's breaking down walls that were put up and have been instilled for centuries upon centuries, upon centuries, upon centuries. It's all related to the hierarchy: armies, monarchies, and royalty. It's all about, 'I'm the king and you're next in line, then you're next in line, then you're next in line." If buddy at the top tells buddy at the bottom to do something then he'd better do it . . . it's about computers and technology being a new emerging field. It's advancing so rapidly that people are . . . trying to keep up with it because it's growing at such an exponential rate. Because of that and because of the way the technology works, it sort of changes the model of communications between people. It breaks down a lot of the barriers that were once cast in stone. They way business is done now filters down into other types of relationships and the way people have them . . . . It's a different way of looking at things and it is the new world way of looking at things. The long and the short of it is that it's a change in style of communication between people . . . It ends up being more of a perspective where on everybody's front you are breaking new ground; you are going against the social norm. Nowadays at least it's the social norm but in previous generations it wasn't
>
> (Black, 2002: 320–321)

Sean is describing the displacement of student–teacher equilibrium in virtual learning environments. This new model also extends outside of arts education classes; in fact outside of classes in all subjects using new digital technologies, and is even prevalent within our communities. The new dynamic model is visible in relationships forged within our families and within the workforce. For example, Sean talks about conflicts that have arisen with his father who lacks technological knowledge. Sean's father refuses to take any computer advice from his son even though he needs help, owing to his belief that a "father knows best". Sean also relates his experience working with digital technologies at a major public education television station. He has been hired to oversee a man at least 20 years older than himself, which is a situation requiring great diplomacy for, in some areas the man has knowledge far greater than Sean's. Nevertheless, Sean was hired to do a job and do it well, which included his own work as well as overseeing the work of an elder. In fact, articles abound about tech-savvy teenagers starting up and running their own digital companies, creating new software, and sometimes even making fortunes (Coolidge, 1999; Ramirez, 2000).

Some students acknowledge that the new teacher–student dynamic is excellent training for the future because they may find themselves in the position in which they may know more about the technical aspect of the company they end up working for than does the president. Both Tapscott (1998) and Negroponte (1995) write about this new situation. In the media there are numerous articles and fictional portrayals of new relationships being forged between people in positions of power being helped by tech-savvy teenagers and even little children. One student I interviewed talked about an advertisement by Alta Vista in which a small child beats one of the world's best chess players through the help of a computer chess program. Other examples are of administrators and professors seeking technical help from their students (Parrish, 1999; Smith 2000), parents being assisted by their tech-savvy children (Belkin, 2000), the elderly being taught by children their grandchildren's age (Cantarano, 2000; Shenk, 2000; Wallace, 2000), and employees training their bosses (Orlanda Sentinel, 2000; Parrish 1999).

CONCLUSION

In summary, relationships between the "haves" and "have-nots" of authority are being reconfigured, thus breaking traditional hierarchical and institutional barriers. These new power relationships are constantly in flux, being shaped, negotiated, reshaped, and renegotiated by tech-savvy teenagers and the authority figures with whom they form associations. In this paper I have discussed case study research in which I outlined how traditional student–teacher relationships are changing in virtual learning environments within two schools. I specifically examined how these relationships are not only reflective of what is occurring within educational institutions but also of our society as a whole as it radically transforms through the influence of digital technologies. In the last decade, newer upon newer digital technologies have constantly upstaged their predecessors while infiltrating markets at an unnervingly quick pace. As a result, new software and hardware packages have affected marketplaces, businesses, homes, and educational institutions. It remains to be seen whether digital innovators can keep up this frenzied pace. If they cannot, perhaps we will see the new power dynamic slowly shifting back to the traditional one as people holding power learn the technology, tech-whiz kids take positions of responsibility in the workforce, and new educators have obtained in their own educational training superb technological instruction and support from elementary through to high school and university. If, however, the industry can continue their innovative pace in the future we can expect topsy-turvy relationship dynamics to occur in our society for years to come. Consequently, in the future it remains to be seen whether the teacher and student on the teeter-totter will once again revert back to the educator holding the pupil in subordinate suspension or whether they will both remain in flux, sharing the ride.

Chapter 21: Rural South African Teachers "Move Home" in an Online Ecology

ELIZABETH HENNING
University of Johannesburg, Johannesburg, South Africa

1. INTRODUCTION: CROSSING THE DIVIDE FROM A DIFFERENT ANGLE

This chapter presents a narrative of six rural South African teachers' first encounter with e-learning, showing how they learned to act in an ecology that required new epistemological tools. The purpose of the chapter is to address the dominant discourse in educational information and communication technology by giving a glimpse of the lived experience of the research participants who took first steps in crossing the digital divide. These first experiences have shown clearly how the online curriculum needs to be redesigned in order to capture the lifeworld of the students as scaffold for entering the online community. They began to develop both technologies of mind and of *hand*, challenging their existing learning conventions and they discovered, if only emergently, how to be part of a *distributed cognition* system. They also learned how to improvise in *situated cognition* situations (Brown, 2000; Nardi, 1996: 69–98), fashioning emergent ecologies of learning in the process. The main findings of the inquiry pertained to the way the teachers experienced this epistemological and pedagogical shift. They saw the process of *learning to e-learn* as a "move" or a relocation of their cognitive activity, while at the same time also situating their learning in a supportive social setting. They had indeed begun to make the "move", but the process had only started, and they were struggling with many of the same issues that challenged them in advanced degree studies in conventional face-to-face situations; they continued to desire linearly structured curricula with fixed parameters of content and prescribed processes of engagement.

Despite the dominance of a legacy of rote-learning, there were nevertheless encouraging signs of the genesis of an ecology of learning, which may develop and scaffold their learning, both in electronic and face-to-face format. The catalyst for change was not so much the use of computers and of the e-learning environment itself, but the assistance and scaffolding they spontaneously provided for each other. In this chapter, I argue that working to assist each other in small blended learning communities that form spontaneously may be the preferred way forward for adult learners who encounter the technology as mature students who cannot become part of a discourse community on a campus, or directly on the *Infobahn*.

2. ONLINE RESOURCES FOR OPTIMAL SCHOOL AND COMMUNITY DEVELOPMENT

One of the surprising features of rural life in Southern Africa is the rate at which computers and the internet are entering people's lives. Due to numerous efforts by the private sector and Non-Government Organisations (NGO's), as well as governments, this technology is found in small telecentres such as those in the hinterland of Australia (Oliver, 1996) and in many homes and some schools. Often computers that are discarded in the corporate and the public sector find their way to villages and to farms through the system of "pass-on" and "hand-them-down" that is characteristic in a milieu where little is trashed, because someone will know of somebody who can use a tool, a piece of clothing or even food. When traveling on the main roads out of cities over weekends it is not an uncommon sight to see vehicles packed with second hand items on their way to distant villages and even to neighboring countries. In my own work in villages in the north of the country I have come across computers and internet connections in the most unlikely places. With the extension of electricity, some distant schools are now slowly acquiring computers and also internet facilities. There are also a few schools in the country where solar power is used to generate electricity for online connection. Many of these initiatives have been due to the entrepreneurship of local people who have approached funding agents to assist with the technology. There are also continuous professional development programs for teachers in different guises, making use of online learning. Many of these, however, have been launched with the aim of acquainting teaches with curriculum reform more than to scaffold their independent learning. My concern in many of these projects has been that the difficulties with full engagement with the *activity system* (Kaptelinin, 1996) of online learning has not been acknowledged sufficiently. People may learn some computer skills and also how to access information on the internet, but full participation in the medium, beyond, "clicking for survival" (a phrase from one of the interviews conducted in this study) eludes many. Hence my undertaking to explore how teachers who have not been involved in any of these very promising initiatives experience a first encounter with e-learning. I deliberately selected advanced degree students (who are practising teachers) to rule out most problems with literacy and learning. In studying a group of these teachers, I specifically wanted to find out if and how they "moved" their learning and how they changed their processes of communication and scaffolding as learners.

I thus set out to look for clues of how they embraced the activity system of online learning, cognisant of the fact that the jury is still out on e-learning uptake generally (Curtis & Lawson, 2001; Oliver & Omari, 2001). The need for such clues, searched for at grassroots level and in small groups of learners, where the detail of uptake and of learning may be observable, becomes imperative when the spread of the technology is considered and the concern increases that the tools may be utilized within the constraints of information only. I would argue that the people who will have to be the human resources to facilitate the uptake of online learning and who will do so with wide usage of the affordances for distributed cognition, will themselves have to have had some successful e-learning experience. In my exposure to e-learning (and e-teaching) I have become aware that the teachers, also in higher education, who "transfer" their curriculum to the internet without having themselves experienced learning in this mode, are less capable of utilising the affordances of e-learning—especially the opportunities for distributed cognition. Therefore, if access is accelerated, without the acceleration of teachers' understanding and experience of e-learning as way of doing education in distributed mode, the uptake may be slower and may even become replications of print format distance education.

Not only would this impede uptake in schools, but it would also slow down the spread of information to communities where access to information may have an impact on people's lives at a very basic level, such as food security and health. Community education is becoming a focal point of many government agencies and has always been the focus of NGOs in the developing world. If competent teachers and their students can become sources of information and scaffold access to electronic information they may become the true community educators (Daniels, 1999). However, community education is by its nature based in small groups, and mass education of a rural population is not viable. Small emergent communities, or *ecologies* (in the metaphor of Nardi & O'Day, 1999), could slowly influence the learning and development patterns of socially vulnerable rural populations. In focusing on teachers who encounter e-learning, I am not thinking of how they can improve school education only, but how they could affect "keystone species" in emergent ecologies of information and learning (Nardi & O'Day, 1999) beyond the school as well.

3. IDENTIFYING THE UNIT OF ANALYSIS AND DESIGNING THE CASE STUDY

When I first contemplated an inquiry in which I could capture some of the experiences of first time adult e-learners' engagement with online learning activities, I selected a group that would exemplify the unit of analysis: *adult learners' first encounter with e-learning.* In selecting the master's students, who were also teachers, as central component of the unit of analysis, I had delineated the study and the "bounded system" of the case (Henning et al., 2004; Stake, 2002). Stake's definition of the design type, *case study*, has become an accepted description of what this type of research exemplifies, and the term "bounded system" is its most discerning characteristic. In deciding on how to go about this research I selected a group of students of whom, I believe, a case study of first time e-learners' experiences could be conducted.

I have access to research into a number of different groups in e-learning environments, but the set of students that were most eligible for the type of research I had in mind were practising teachers in a part-time M.Ed program at a university in a South African city. The module *Qualitative Research and Writing Composition* was one of six courses in the program and was developed to simultaneously run online and face-to-face in order to accommodate especially those students who live far away from the university. Most of these students had expressed the need for more opportunities to engage with the course presenters and their peers. However, face-to-face engagement was limited to weekend workshops once or twice per month. As the University had already initiated WebCT facilitation of either complete or hybrid/blended ("brick and click", Weigel, 2002) online courses, the partial conversion of the existing course to a parallel, interactive e-learning version could proceed. The course was adapted to provide optimal networking and interaction and to introduce the first time e-learners to the network/information society without expecting them to continue entirely on their own in a virtual learning environment—the scheduled workshops therefore continued.

I selected 6 students from the cohort of 33 students in 2001. The research group or sample consisted of three pairs of students who opted to work together closely and who lived within reasonable proximity to each other. Students in this course were encouraged to work in pairs or small groups and they selected their own partners pragmatically. The three research pairs thus already existed learning dyads when they were selected purposefully (Merriam, 1999) for the inquiry. They were chosen because they were the most uninitiated in computer tool use and suited the criteria for the case narratives—they would show the *realia* of everyday living and of studying. The following criteria were considered:

- The adult learners had returned to university for an advanced professional degree.
- Students lived at least 200 km from the university in semi-rural areas.
- Students speak at least three languages, with English having been their language of formal education since high school at least.

The data that were collected were from the students' engagement with the course over a period of 6 months (the duration of the course). All their discussion postings, some email, their other learning artifacts, such as qualitative research designs and term papers, were also scrutinized for data pertaining to their experiences in engaging with the course. The most revealing data, however, came from their personal reflection journals. These data were narratively-rich (Bell, 2002; Clandinin & Connelly, 2000; Cottel, 2002; Pavlenko, 2002; Riessman, 2002) and had sufficient ethnographic qualities (Hammersley & Atkinson, 1995; Wolcott, 1994) to convince me that I also needed interviews in which they could tell their experiential stories—the "way of life" (Wolcott,

1994) that they had cultivated in the course. With the help of a co-researcher I therefore conducted two sets of individual interviews and also one focus group interview, asking questions related to their "lived experience" and following the same interview protocol with all the interviewees.

We worked with the data in two ways, capturing *content* as well as *discourse* and concomitant stories (Gubrium & Holstein, 2002). We anticipated that the "actual practices of talking and writing" (Woodilla in Phillips & Hardy, 2002: 3) and the "interralated set of texts, the practices of their production, dissemination and reception that brings an object into being" (Phillips & Hardy, 2002: 3) would be reflected by using different ways of analysis. The existing texts (the web-based communication) and the learning artifacts were prepared for analysis by formatting them into analysis texts and the interviews were transcribed. The processes of working/analyzing the data proceeded are set out in Table 1.

The narratives were thus constructed systematically from the different data sources via the various analysis modes ("working the data", according to Holliday, 2002). *Content*, *discourse*, and *narrative* data were crystallized into elements of the eventual stories. In the rest of this section I will present excerpts from these stories of the three dyads. The main themes that were collated towards the end of the analysis process (in the last row of Table 1) were configured into the portraits that follow, with the title of each portrait reflecting aspects of the theme and revealing more about the unit of analysis, which is the students' engagement with the course.

In the rest of the chapter, I will present summarized versions of the stories of the three dyads. As mentioned previously these narrative portraitures were constructed from all the data sources, with emphasis on journal data. Subsequent to the narratives follows a discussion of the significance of these stories, using the framework of Bonnie Nardi and Vicki O'Day's (1999) "information ecologies", integrated with the aspects of activity theory, distributed cognition and with the notion of "cognitive apprenticeship" (Brown et al., 1989; Salomon, 1999). I use this construct to also illustrate an epistemological apprenticeship—learning to see knowledge and knowledge making in a new way and finding a new habitat for doing this. In Figure 1 I present a diagram of how these three theoretical sets were used to integrate my understanding of the research.

4. THE STORIES OF THE TEACHERS

Each of the following three narratives comprises a portraiture-like description of the two members of the dyad and of moments in their learning path over one semester. The information contained in the descriptions comes from all the data sources, although the citations are from the journals only.

Table 1. Working the data towards narrative portraits

	Data Source		
Working Procedure	**Discussion Postings and Email Communication**	**Learning Artifacts**	**Interviews and Journals**
Content analysis: coding and categorizing	The content of what they wrote—coded in units of meaning, categorized and clustered in grounded theory analysis mode	The content of their production of artifacts adjudicated and then coded according to the performance criteria of the course and clustered	What they said—coded strictly in terms of content and then categorized and clustered in grounded theory mode
Discourse analysis: identifying discourse markers related to how they were constructing meaning of course content and mediation, support, and social context	Locating the system of meaning from which they were expressing their own sense-making. "Marking" stretches of language with an inductive code/marker of discourse	Locating the artifact in the discourse of a theory of learning and also of activity theory levels of action (both as systems of epistemological meaning)	Locating their talk/text in a discourse and identifying references to discourses. Capturing how they were making sense of their experience by invoking these discourses
Narrative analysis: identifying stories of experience—locating sequential markers, characters, settings, actions, tool use	Elements of stories, episodes, and examples with a story element. Grouping story markers and chronology	Identifying whether the artifacts aligned with learning products, the stories of learning that have been told	Capturing the elements of their experience in narrative
Cross method collation of content, discourse and narrative themes	The main themes and categories at the level of content	The main discursive indicators reflecting the dominant discourses. Identifying the main metaphors and meaning-making structures	The stories and how they articulated in other stories. The essence of individual stories as reflected *across the data sources*

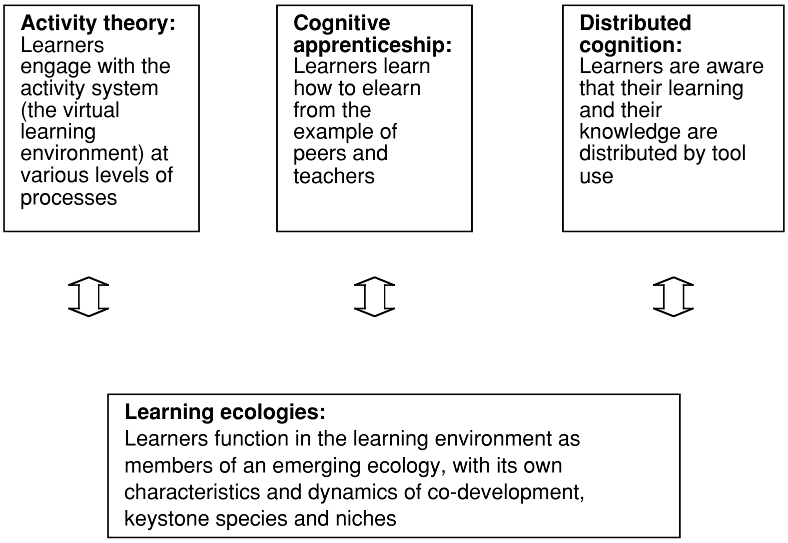

Figure 1. Connecting four theories for interpreting adult learners' e-learning narratives.

4.1. Dhimpo and Penny: Are We in this Machine or Is it in Our Heads?

The first story tells of how Dimpho and Penny engaged with the online course and what they communicated to each other. Dimpho is a 45 year-old woman who teaches at a high school in a village that is 40 km from the nearest town. Recently electricity and running water were introduced to the village, but the infrastructure for this connection and reticulation is still poor. The school accommodates 730 students and Dimpho is one of 19 teachers, but the only one who is licensed to teach Biology at 12th grade level. She was introduced to computers in the previous semester in the skills development program in the Faculty of Education at the institution where she is studying. She travels 344 to the university to participate in workshops and to use the library twice per month. Dimpho speaks Sepedi, one of the eleven official African languages of South Africa. She also speaks Tsonga and Setswana and Sotho. She learned English in school and uses it only outside the village and for pedagogical purposes in the school. She completed her previous degree at the major distance education university in South Africa.

Penny lives in a town, where she teaches in a *township*[1] school. She is an English teacher and also encountered computers interactively for the first time during the semester prior to the one reported in this chapter. She speaks all the languages that Dimpho speaks, but is also conversant in Afrikaans, which is a language of Dutch descent. Penny studied at the same institution and also at a university that was created for black South Africans during the apartheid era, when these institutions were established in the segregated "homelands" for different African ethnic groups.

The first entry into Dhimpo's journal already set the scene for her engagement wit the course. She was wondering,

> Are we in this machine or is it in our heads? I am wondering because I feel when I click and start that it is sweeping me off my feet. I feel I am watching a cinema film (movie) but that I am also in it. When I wrote my first discussion posting I was so afraid. Would this get to the others? Will they laugh? What will Prof say? I am still very much mixed up. I feel I have not the same control as before. I type and I read and I am scared to click, because when I do that I feel I am falling down—like I slip and I slide on the wet ground. I will read more. That is also not so nice. Hey—when I click and there is this magic page I feel I want to quickly print it. Before I lose it. I want to read it on paper. Maybe I don't trust the computer. Maybe I don't trust myself. And even when I read and then there is a blue part (hyperlink) I feel I must first go there, because this man he put it there because he wants me to go there too. But hey—I do that and then I'm lost because I get mixed up—I go on a different path and get lost in the bush. Where is my head—is it in the machine? Then I go back and I first read the whole one. It is hard to ignore the blues. And I can say that I am not very much confident that I will learn this way. I can't wait for the next workshop to talk and to see if there is something on the reserve in the library. And I will phone Penny. I know I must email her, but first I am going to hear her voice.

Penny was also grappling with the conflict of who was in charge in the learning environment—who was "in her head". She, however, decided to speak to Dimpho before she wrote in her journal. In an interview they referred to this telephone conversation. Penny dialled and when Dimpho picked up the phone she was curious to know how Penny was feeling. Penny said that she was too scared to even write, because she did not "trust her mind". She did not know whether what she was experiencing was "real", or whether she was "dreaming up ideas just to get something on paper". They concurred that the first online learning unit had been "terrifying, because (we) felt so hopeless and so homeless". Penny said she felt "like I had moved my house. This machine was there in my room, but it was not mine. It was not me. My fingers walked, but I was not sure if my mind was there, walking too". In this telephone conversation they decided to "be brave and to write up how (they) were doing in terms of the coursework in their journals", but that they would consult each other if they were concerned or did not know what to do.

Penny eventually did make an entry in her journal. She was especially concerned with the exhibition of her work and the public scrutiny.

> So at last I am writing. I still don't know how to say it, but it keeps on eating at me.... How will I be able to write my work when I know

> that the whole class (and maybe even some others)—their friends and whoever they may want to call and say—come and look at Penny's work. Ha-ha, she does not get it!! She is mixing things up. She is copying and she will get fined for her plagiarising. I can't stand the thought of people reading my work. I think it (her work) is not too bad—I am not a bad student, but I want my things to be safe. So, Prof, when you one day read this—and then it will be too late because the course will be finished—please remember that I don't think this is a good idea and that I will take feedback from you or my teachers but I really don't trust my fellow students. Maybe they are even *skelms* (rogues) who will steal my ideas and copy them. Maybe I will even see my ideas on someone else's distinction. So that is what I write for today. I haven't said yet that I am slow on the computer and that the internet work is maybe fascinating and I like to travel so quickly to another place and meet with someone who I don't know, perhaps I don't like this person at all, and I don't even know where the country is but I learn a bit from their page. Still, I want to do this alone rather. My head is my head—like Dimpho said—she was worried because she thinks her head is mixing with the wires, well I don't care about that. I just don't want others to come and sit in my head or on my head! This learning feels a bit like a jail. I miss real old classes and lectures and even the distance education by post where the lecturer wrote to you and the work was in a guide.

These two women were very careful at the outset. They both did not have a computer, and were wary to invest in one before they were sure that it would be worthwhile. Buying a computer, a printer, and keyboard and monitor amounts to 2 months of netto salary of the average state employed teacher, she assured me.

So, as a start, Dimpho used the *telecentre* next to her school. This is a privately owned enterprise, where the community can use cell phones, telephone landlines, fax machines, computers, and printing and copying facilities and also the internet. I went to the centre on two occasions to observe some of the activity and found an efficient enterprise, owned by an ex-teacher. The centre is situated next to the school and also adjacent to the local community health clinic. The newly installed telephone lines contrast strongly with the building, which was previously a two-roomed house. Inside the building the electricity connections, with wires taped to wall, ceiling, and even floor surfaces, continue to illustrate this contrast. Two youngsters dressed in uniforms with logo tee shirts advertising the enterprise work in the waiting room (translated as the "Talk-talk Shop"). There are two computers, one fax machine, a (really vintage) copy machine, two telephones, and three cell phones. It costs the equivalent of a cup of coffee in town for 10 minutes on the internet or on the phone. The cell phone is double the price.

The centre from which Penny worked looks more like an internet café and also operates along those lines. It is much more sophisticated and there are 10 computers—all internet connected. The price for services is slightly lower.

As time went by both the women decided to invest in their own computers and internet connection. They were fortunate because they could purchase the technology through a wholesale agent. They convinced each other—comparing the cost to that of cable television and video recorders and also to instalments on car payments.

Halfway through the course Penny noted in her journal:

> I am now not yet used to working from my house. When I connect and "speak" to the others I am still so thrilled. I am actually quite happy. We are all in the same boat, but I think mine is a bit rockier. I forget to close the modem and I have had to pay so much. But I'm not sorry I paid all this money, because I can sit here after supper and talk to my friends in the course and I can SURF THE WEB! I don't do general things—we were warned in the course that it is better to start from the sites that have been suggested, but I am learning to find my own ones too. And I am still worried about giving my ideas in the discussions and to put up my own work so that they can all read it and give me tips. I don't trust it yet. But I am learning a lot. I see that most of the people in my class have the same problems.

At this time Dimpho was experiencing different problems.

> I am finished—FINISHED!!. Too much trouble with the connection and sometimes the university's lines are gone! And when I post something it disappears, I feel I want to see my work in pen or printed, but like this it scares me. I am losing the control I had. I feel my mind is gone when the typing is gone.

Both Penny and Dhimpo were surprised at what they had done—both in learning to work in this mode and in purchasing the hardware and registering with an internet server. For them these were two giant steps. However, they never really engaged fully with the discussions and remained unsure of their work on display. In this there were ample signs of "cutting and pasting" and of a need for more explanatory assistance. They had begun the apprenticeship of being in a virtual learning environment, but the course itself was still not part of the change. They continued to look for content and to try to "learn" this content. Even though they were learning to navigate a personal learning path in the virtual environment they still believed that the ultimate aim was to find and then to "know content". Penny said at one stage, and it was affirmed by Dimpho, that the "knowledge" they encountered was strange and mixed—like "our feelings". These two teachers were fast learning the "hand technology", but had yet to make the shift to the technologies of the mind, in which the navigation itself would become the learning and in which, as Betty Collis and her research associates (2003) so aptly describe it, "the process constitutes the curriculum" and I would add, the "knowledge-making".

4.2. Thanyani and Tshepang: At Whose House are We Anyway?

These two male students in the narrative sample were close friends and started the course as "brothers who do many things together since we were young kids". They are both school principals and share a passion for teaching, because unlike many in their position, they continue to teach classes. They live in a large town, but both their schools are in villages. They speak Setswana as a first language and like Penny and Dhimpo, they encountered English in the 5th grade and mostly only in school context. These two men are also keen sportsmen and coach the schools' football teams. Thanyani originally lived in a distant village but moved to the town when his own children had to start school. He wanted them to have access to libraries "and other things". He therefore moved to the town, where his wife secured a position at the local government offices. Tshepang sees himself as "township man—even a city man now that I drive to Joburg so often for classes [sic!]". They both completed their previous degrees at the "homelands university" (also known in South African educational parlance as a "Historically Disadvantaged Institution or HDI"). They are in their late thirties and wish to secure high positions in the province's education department so that they "can have a say in how things must develop". The drive from their hometown to Johannesburg takes three and a half hours and they usually travel together—often conversing about course topics as they commute. They jokingly refer to the "new language of curriculum reform" as a "policy patois" or a "new educational dialect".

Thanyani did not start his journal at the outset of the course. In an interview he explained that he "was not ready yet to think and to report to himself what he was doing" because he was "too busy just trying to DO it". He said that he could not get himself to write about his experiences and feelings when the course started because he was "too bewildered" and he wanted to feel more secure "before he bound himself to paper". When I asked him if he could recall more of his initial experience he said, "Yah, I can—I felt I needed to press on and to click all the clicks and to learn to see where they took me—to find out in whose house I am". Here he referred to, Scott Kerlin's website (http://kerlins.net/scott/edResearch.html) which is designed like a house, and also to the work by Jim Burke, which is one of the suggested readings in the course (Burke, 2001). For him it was important to try to get an idea of the size of the network that was suggested in the course and also to get a feel of the magnitude of the internet itself (!). At one point he reflected, "You know, I was so surprised. I thought I would be able to lay my hands on it like a library, but I just could not, because as the screen switched and I clicked the mouse I felt like I was in a catty (catapult) that shot me somewhere far away. Then I tried to find the map in my head to see the place and it would be far away from where I thought it would be. I felt it was gone". In this interview and in a subsequent interview as well as in the journal that Thanyani eventually started this theme would surface continually. He used the image of the *location of learning* consistently. He was looking for signs of the "house" that he had entered. He wanted to make a personal connection, "It seems there was nobody there in this one site—just words and pictures and in that other one there was a person—a nice person—a somebody that said to me, 'Come in, sit and talk'. And that one with the rooms—man I felt I was visiting my friend. I was in a TV movie—I was in *Generations*".[2] He also did not really create much in the line of interpretive or critical work and continued to gather information, which he summarized and only rarely commented on.

He emphasized that it was very difficult to start working like this without any real training in online learning. He wanted to have a trial course in which his work would not be evaluated. At the end of the course he noted in his journal:

> I have learned something, but not a lot. I have to summarise everything and write it down and my class mates mostly say . . . things that I don't even want to read because they are wasting my time. I expected more of them. What I think they should do is to teach us how to behave in this sort of set-up before we do a course. I mean not just computers, but the real e-learning thing. By the time I got used to it, it was too late and I think I will fail this one. I still dream of a book and a neat study guide and I am not happy with professor . . . She thinks we are Americans who breathe through the lungs of the web.

Tshepang wrote in his journal on the first day that he accessed the course online and also often spoke about his experiences in the VLE during the workshop sessions. His third entry explains his involvement:

> I phoned Thanyani, my friend and brother in oppression, when I opened the classroom door the first time. I said, "Brother, you must see this. It I like I'm going to a pub, but I don't know how to get there and I want to meet my friend. Please Man, come into the discussions, I need you there to talk to because I can't just talk to the wall, These other students will not know what I am saying. I need you there. Or come to my house so we can do it together. My wife has supplied me with the machine and the connection and the children will respect us for peace and quiet. I like this thing. I just move up and down and this way and that. I stop if I see something that I like, but I skip most of it because it looks like

> a mixed up study guide and there is too much. So, now I have looked at all 14 destinations and I still don't know what to do or where to go. All the things that Prof says we must look at—I won't do it. To put your head into the discussion is far from my mind. I just listen to the others and they talk such . . . . I can't stand it. Maybe they will think that am also stupid—a *mampara*—so I am not going to. Even if we are getting a mark. But I will look at the sites and maybe if I can hook up something that is the same as the themes in the workshop I will print it out and into the file it will go. But the problem is the printer and the expensive ink. The course is now costing much more.

When Tshepang reached midway in the course and had still not submitted any of his work on the classroom board and had not posted a discussion contribution I approached him. He seemed to be well informed about the content of the course, some of which he could have accessed only via the online links. He admitted to printing articles and other texts, but being unable to become an interactive member of the VLE group. He offered the following explanation:

> You see, I feel I am out of control—if I am not in my house anymore but lost on the streets. Even when Thanyani started to write in the virtual classroom I was still lost. It's not that I don't know what to say—it is just that I feel I want to first practise it—maybe I can do it in the workshop. I did not grow up like this—it is a big change and I'm stuck in my ways. My hand does the pen, not the keyboard—even if I can type a bit now. But I don't mind looking up information on the internet. Even if I don't like the links. I wish they can rather give a list of contents like a book, because it's the same in a way. So you can have an overview. Now you have to go in blind and feel around which page you want to turn to.

Towards the end of the course Tshepang communicated in the discussions and made this one pertinent contribution on the choice of data analysis methods in qualitative research—the topic of the week.

> That was not right Patricia. You can't just say you are going to do content analysis like this or that because so-and-so or so-and-so said so. You must know why you want to work with the information like that. Like me—I am going to use field notes from observing a staff meeting at my school. I can't just say so-and-so suggests you must look for themes—so now I look for themes. I must first read the notes over and over and then think—h-mmm—what now? Then I can maybe see that there is a certain order to the turns people take to speak and the way they begin their speaking.

> So now I may think, h-mm, this is good data for conversation analysis and I can ask myself why are people always beginning like this or why are they always looking at the principal before they speak and why does this one speak all the time and that one just shakes her head and that one frowns and smiles?

In the end he used the discussion facility very meaningfully—giving his own thoughts. He said upon being asked about his, "I was very happy at that time because I understood that she was learning like a parrot and in research if you are a parrot you are not delivering. So I could speak, but if I have to say something just to say something I can't."

4.3. Thembi and Sipiwe: Chewing the Bones of the Mind

This dyad was originally formed because the two students shared a first language, Zulu. The workshops invite discussion and debate in the primary languages of the students and these were the only Zulu speaking students in the group. It turned out that they had much more in common than a primary language. Thembi, a female first grade teacher, had not studied formally for more than 20 years. She had decided to register for the course because she wanted to "refresh (her) knowledge and make (her) mind alive". She has no car and traveled to the university by public transport, often being in transit for more than 6 hours. The village school where she teaches is in a mountainous area and many of the children walk up to 10 km to school each day. She stayed with relatives in Johannesburg during the weekend workshops. Sipiwe lives about 30 km away from her and they discovered that they could travel together. He has a car and Thembi would contribute to the cost of the drive. There is no *telecentre* in the area and they would have to travel 60 km to the nearest town to make use of internet facilities. There is also no electricity in Thembi's village. Sipiwe, who lives on a farm, has access to privately maintained electricity supply and also telephone lines. He lives on the land of his father's employer and teaches at the local farm school, which now also boasts electricity supply.

When the course started Thembi was surprised to hear that she would use a computer and later also the internet. She had never interacted with a computer and did not really know about the existence of the internet. Sipiwe had some knowledge of the affordances of the internet, but had not worked with a computer either. He just knew "that you can connect with people all over the world". When he found out what websites were he said, "I tell you I never thought of this. I can only think it is like a big, big *indaba* (meeting of elders), with people speaking from all over and leaving their tracks, like papers strewn all over".

Thembi lived out her anxiety during the first part of the interactive learning. She refused to try and threatened to take the matter to the university administration, because she had not been warned that she would have to become an e-learner. Gradually she changed her position on the matter when she started working with Sipiwe. She relied on him to mediate the process of becoming e-learning literate. Towards the end of the course she noted in her journal:

> I never thought I could do this. That is why I was so angry at the beginning. Did they not know that I had no electricity? Did they not know that I had no telephone line? Did they not know that I could hardly type? Did they not know how strange this would be? But I was in luck. I met Sipiwe—he held my hand in his and he walked with me all the way—together with his daughter. First we stayed over in Joburg for an extra day when we could because that was the only way we could get to computers. We lived there in the lab for two days—with a tutor trying to help us and later his daughter came with us and just sat through it all with us. I don't know where this girl learned so much. She is only in high school. I was slow at the beginning. But every time I wanted to cry I looked at Sipiwe. He was so much younger than me and here was this man who is so intelligent and he was helping me and saying "Gogo—you can do it. Come again". Even through my tears I could see the difference. When Prof asked me if I knew the expression of, "chewing of the bones of the mind", I did not recognize it, but he said he knows it—it means to think about something hard. Well I have done that. I have thought hard and even though I still have no computer at home, I can say that I have learned to get information from all over. And I still don't like it, because I prefer to work form a book or from talking with people or to look at something. But at least I can do it now. And when I am in town and I have a few minutes and also some few cents I go to the post net and check my course and I also quickly post something on the discussion board. I only learned the meaning of the word virtual now. It is real, but I wish it was not.

Thembi concentrated on getting to the information that had already been listed in the course and did not venture too far away from the suggested pathway. She confirmed in the interviews that she did not want to get "confused with too many little roads to the destination"—referring her to hyperlinks. She, like so many other students, printed out as much of the material as possible and converted the electronic text to print. However, she indicated that there was still a difference—"you have to go out and get the knowledge—it does not come to you". She also valued the learning relationship that she had developed with Sipiwe, saying "sometimes in life you just end with the right person to open the doors and even to carry you through". Her work in the course remained at the level of information condensation, with some application and integration, but little interpretation and argumentation. She was one of the students who used her primary language in the discussions, providing a summary in English for non-Zulu speakers. When the course ended she noted, "I am very much a stronger woman"

Sipiwe had a different experience and also demonstrated different capabilities. He commented that he learned by mediating. In his capacity as Thembi's co-learner and mediator he explored and explained many things for himself. He also accessed the hyperlinks with courage—making notes (in a computer file) on how far "back" he should go to retrace his steps and to keep the "thread of the day". His discussion postings were more sophisticated than the other students and he read the texts critically. He enjoyed the Burke (2001) text especially, noting that it taught him how to be en "internet student". He also applied for private funding for two computers for his school and started literacy programs for the staff, aiming to expand this to the wider community. He is also working on a way to get more computers and to bring e-info to the classrooms. His daughter had learned to use computers in school. She was in the 11th grade at a state school that was part of an NGO computer literacy project. She assisted her father in the weekend workshops for teachers (only four). Sipiwe did not yet have sufficient funds to buy a computer, but was saving for it.

In these brief summaries of highlights in the narratives of students the events and actions are not untypical of adult students who enter the university at master's degree level. In other classes, with many more students, the trend is the same. In the case of teachers who had to share their income with their families and extended families there is often not sufficient funds for the student to register for a degree. The students who enter the university are therefore the ones who can afford to do so.

5. DISCUSSION: ECOLOGIES OF LEARNING EMERGING IN THE ONLINE ACTIVITY SYSTEM

In the summaries of students' narratives I highlighted issues that were relevant to the unit of analysis of this inquiry, namely the adult students in their interaction and engagement with the VLE, which is identified as the *activity system* in this inquiry (Kaptelinin, 1996; Kuuti, 1996; Nardi, 1996). The descriptions were therefore by no means intended to capture full stories, although the following discussion should render them as "thick descriptions"—presenting and interpreting the data to present the *emic* as well as the *etic*[3] perspective of the participants' experiences.

In order to be able to see the full picture I had to capture essential aspects of the "way of life" of this "identifiable group of people" (Wolcott, 1994; defining ethnographic research) to further my understanding through the ethnographic lens as well—thus foregrounding *the activity*—which is also *the* highest level in the hierarchy of processes in activity theory. "Activities are oriented to motives, that is, the objects (the environment with which the human mind interacts) that are impelling by themselves" (Kaptelinin, 1996: 108). I needed to find out what happened at the interface of students and the VLE that would demonstrate the "compelling" force that drives rural teachers to become engaged and to appropriate the VLE—beyond short term goals (of *actions* in the activity theory hierarchy of processes) and immediate skills (described as *operations* in the processes described in activity theory). In other words—towards the notion of *activity*, where mind and environment (object) meet in mediated action. Kuuti (1996: 30) explains:

> Activities are longer-term formations; their objects are transformed into outcomes not at once but through a process that typically consists of several steps or phases. There is also a need for shorter-term processes: activities consist of actions or chains of actions, which in turn consist of operations.

In Figure 2 examples from this case study data are presented in the activity theory hierarchy of processes.

According to Luria (Kuuti, 1996: 30) "cognitive processes occur in practical activity", and the type of practical, observable activity indicate some of the cognitive activity. "Activity theory does not accept a dualistic conception of

Activity level: Engaging with and completing an online course such as "Qualitative Research Methodology"

↕ Learning and reflection; negotiation of new rules; formation of new community; reorganisation of division of labour (Finding a 'home')

Action level: Completing a learning task, such as writing an interview guide.

↕ Tools and procedures visible; sense-making actions in the activity externalised; set of rules visible; communications and networks visible (Completing a task)

Operation level: Using computer and Internet skills to download information needed to perform a learning task.

Automating routines; required data indicated; rules embedded; embedding certain division of 'labour' (Performing a search operation)

Figure 2. Activity, action, and operation in the online course. Source: (Kuuti, 1996: 33, 36).

an isolated, independent 'mind'. It means that a person's mental processes acquire a structure necessarily linked to sociohistorically formed means and modes, which are transmitted to him by other people through teamwork and through social intercourse".

I thus realized that as an educational anthropologist I would have to search for understanding of the small community, where the meeting of mind and object could be witnessed and harnessed in *primary* encounters, more than of the larger system (Nardi, 1996), where evidence would be secondary and also more general.

I also sought my own space as higher education teacher in this landscape where I was trying to capture the activity; therefore elements of autoethnographic (Coffey, 1999; Reed-Danahay, 1997) writing would be evident. As designer and teacher I continually think of the design of future courses and how I will need to take cognisance of the "human and computer" *in* the world—the world of rural and semi-rural South Africa—more than of the "human" *and* the "computer in the world" (Kaptelenin, 1996).

My point is that the need for contextual research in online learning has not been addressed in such a way that design could benefit the marginalized learners of the developing world sufficiently. I reasoned that the varied data sources would give a glimpse of some of what has been missing in design by giving a picture of what happens to newcomers to the internet in their first encounter and how this happens in an everyday context.

In this regard Kuutti (1996: 37) argues that conventional Human-Computer Interaction (HCI) research, especially up to the mid-1990s, has been narrow, covering most adequately "the area of error-free execution of pre-determined sequences of actions". She then says that humans are adaptable and learned these procedures quickly and that more research is needed in "supporting work and sense-making in work". I would like to emphasize the notion of "sense-making"—not just in terms of the content of a course, but in the whole *activity*, as theorized in activity theory. One suggestion forwarded by Kuuti with regard to research to find the way sense is constructed is that HCI in social (everyday) context should be a focus. Kaptelinin (1996: 45–68) also takes this approach, pointing out that it is becoming a preferred view instead of the purely "cognitive" approach. I agree that the space where meaning is generated and where communities/ecologies of learning can be established is not at the interface of the face and the screen, but in the interaction of this interface with a broader system on the one hand, but also, on the other hand, with a more contained ecology. I argue that in the case of first time e-learners this is vital as it may form a bridge to a discourse community of learning in a virtual environment, which in turn could change their lives (Henning et al., 2000). If the social self, in addition to the psychological self, can be invoked in learning programs in VLEs, the distribution of cognition will go both ways—through the electronic network and through the "landlines" where faces meet (Henning & Brown, 2002; Henning & Van Rensburg, 2002).

I decided to use Bonnie Nardi and Vicky O'Day's (1999) metaphor of "information ecologies" as heuristic frame through which to explore the data, because in working with the data initially I realized that what I was encountering could not be placed in the broad category of HCI theory only, but had to be seen in a more specific theoretical perspective, and along with activity theory as theoretical position, the metaphor of ecologies would assist me in understanding the teachers' engagement with the course. I was looking for a contextual explanation and position from which to work with the data and also for one that would foreground the landscape where the apprenticeship (or other form of learning) was being fostered. The sociocultural context, ultimately, would offer more "affordances" than the technical opportunities of the electronic system, I argued. I could not see how most of the students could continue without some mediation, because the concept of virtuality, more than the skills for the keyboard and the screen, was the most troubling to students that I had introduced to the VLEs previously. Creating ways to learn and using the social structures and the "way of life" of a social group affords learners the opportunity to explore and to learn because they have a sense of continuous and close support. I reasoned that without social affordances the affordances offered by the machine would be less "affording".

Nardi,[4] an anthropologist who focuses on sociocultural and activity theory as theories that capture context as roleplayer in learning constructed a theory that captures activity in small learning communities. It is from this theoretical foundation that she extracts the metaphor of "ecologies", relating it to original sociocultural theory and cultural psychology (Kozulin, 1990; Vygotsky, 1978, 1992). Later like-minded scholars (Bruner, 1990, 1996; Engeström, 1991; Rogoff, 1990; Wertsch, 1991) expanded it, always emphasising mediated action, tool utilization, culture, and language and mediation for learning in a "zone of proximal development". An offspring of these theories has been activity theory, with Leont'ev (1976) as the scholar who gave format to this theory. Activity theory posits more than the hierarchical levels of processes that I have already referred to (operations, actions, and activity); it also holds that the mind will interact with the environment and its tools and create will new mindtools to do this. The premise of this study is that this epistemological shift (inherent in the creation of new mindtools) is not recognized in online courses for adult first time users whose mindtools originated through printed text and oral literacy. Different theories, related to the corpus of knowledge known as sociocultural and activity theory, will give different interpretations of this epistemological non-readiness, invoking related theories to explicate the integration of tool and cognition.

The difference between these related theories, such as situated cognition/action (Brown et al., 1989; Lave, 1988; Lave & Wenger, 1991), distributed cognition (Brown, 2000; Salomon, 1993) and also activity theory itself is explored by Nardi (1996: 78–88). She comes to the conclusion that:

> All three approaches to the study of context have merit. The situated action perspective has provided a much-needed corrective to the rationalistic accounts of human behavior from traditional cognitive science. It exhorts us not to depend on rigidly conceived notions of inflexible plans and goals and invites us to take careful notice of what people are actually doing in the flux of real activity. Distributed cognition has shown how detailed analyses that combine the formal and cognitive properties of artefacts with observations on how artefacts are used to understanding useful for design.
>
> Activity theory and distributed cognition are very close in spirit, as we have seen. And it is my belief that the two approaches will mutually inform and even merge over time.

Nardi critiques *situated action* as theoretical perspective, as it purports to be goalless, but, according to her, cannot really be a view that sees action as objectified only in retrospect. I do not agree with her entirely, because I think that situated action, with its understanding of a sense of immediacy and improvization can be used to understand what people do when they are challenged with a sudden "unknown" or a breakdown, when the broader goal or objective recedes to the background and the immediacy of the moment requires a "practical intelligence" in the situation. Situated action is, for me, the action of contingency and immediacy and only someone who is well aligned with the way the context works will be fruitful in a situation of immediately needed action. My own view is thus that these three approaches together can be used to frame learning for novice e-learners. And having said that, I see Nardi's metaphor of "information (learning) ecologies" as a blending of the three traditions, with activity theory perhaps as the more dominant one.

From this view the context of a learning event is seen as steeped in a sociocultural context (Chaiklin & Lave, 1993; Wertsch, 1991) and also in an activity system (Engestöm, 1991). The computer as medium, mediation and as thinking tool, digital information, and the *hyperworld* in the broadest sense are part of a cultural environment created by humans as both mental and material tools to use—to be prostheses of both the hand and the mind (Bruner, 1990). But that is not the only world; in order to explore the very concept of VLE the "real" environment, including the historical context of this space, needs to be explored as well. Adult South African students, who mostly have a history of educational deprivation and segregation, and who have studied at institutions where they could get by on rote learned information, will approach a VLE in the context of their experience and their sociocultural "situatedness", Yet they will also have to learn how to enter the e-world of distributed cognition by

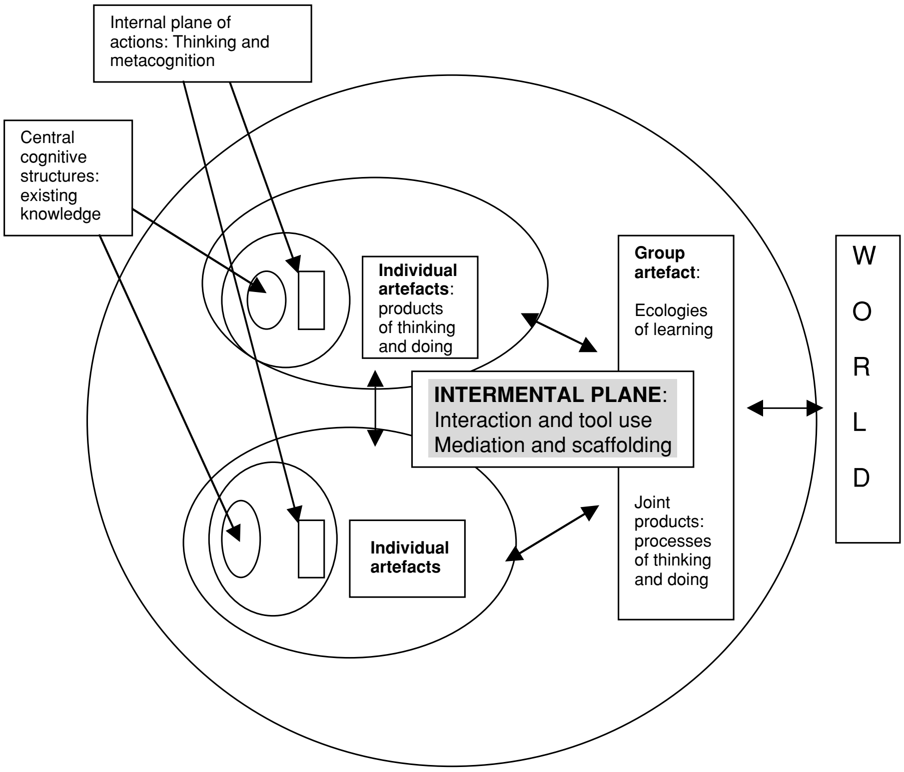

Figure 3. Computer-mediated group activity (after Kaptelinin, 1996:59).

learning to "work" at various levels in the activity theory typology of action, working both as teams and as individuals.

Kaptelinin (1996: 59) presents a visual representation of "computer mediated group activity", or this "working" in a distributed space in "the world" (plus the *hyperwold*). In his rendering of a group activity he captures the three approaches to understanding learning (as analyzed by Nardi) in a VLE succinctly. For me the diagram that I adapted from Kaptelinin (1996: 59), and which is presented as Figure 3, shows how a learning ecology "works": The "group artifact" is the ecology itself and not a separate "project" and "the world" interfaces with the "individual artifact and cognitive processes" on the "intermental plane". The metaphor of the ecology is thus simultaneously, in my rendering, also a symbol for intermental processes.

The individuals in the ecology interact with each other and with the environment (but via the keyboard and the spoken and other face-to-face contact and representations of contact, such as the written word and the semiotic systems in which actions are embedded). The "intermental plane", a Vygotskyan term that refers to the mediation from mind to mind, or from the environment to the individual is multidirectional and reciprocal. This means that individuals change the environment as the environment changes them. In this regard Kaptelinin (1996) talks about "the world" (also "the group") as a complex system that can contain, in Nardi's (1999) words, "keystone species"—those that exert a strong force on the environment and who can play a key role in changing it. In this study the keystone species have set actions in motion that have compelled me, the course designer, to reconsider the introduction to the course.

The counter argument can be that this species may advance to the learners' mental lane directly "via the screen", and by being invited through the keyboard and the mouse—in other words, the computer as tool can be both mediated and mediation. However, where novices that I have studied are concerned, the existing familiar "species"/faces have shown to be the main proponent of mediated action—and these are facilitating and mediating *people* who act at the interface and who co-create the ecology.

Nardi & O'Day describe an "information (learning) ecology", as "a system of people, practices, technologies and values in a local environment" and "(l)ike their biological counterparts . . . are diverse, continually evolving and complex" (1999: 49). Like these authors I have found that it is vital not only to describe *how* and *what* people encounter (in) technologies, but *why* they do so in specific contexts and learn new literacies within the social context (DiSessa, 2000; Warschauer, 1999) thereby expanding their tool use and concomitant mindtools. Because ecology is a system of balance and of change to ensure an "equilibrative" survival, one needs to find the meaning of actions—the reasons for the way people engage with an object (in activity theory parlance) in different situations and what the implications of this engagement are. In this system students need to seek the a balance between so-called "course content" and ways of doing—thus of learning to e-learn. That is also the reason why I use the concept "learning" ecology instead of "information" ecology. I thus expand on the Nardi & O'Day metaphor and explore how the teachers became apprentices and how they started to develop a way of living with e-learning in their daily lives.

In contemporary views on learning, from a constructivist perspective (Bransford & Brown, 1999; Phillips, 2000) it could easily be said that the process of a first engagement with a VLE is a matter of prior learning and exposure and that novice e-learners need an induction program and so forth. However, the complexity of the context, the "why" questions will not have been answered and future planning will therefore be based on the description of the "how/what" question only. I argue that it is not reasonable to expect novice e-learners to encounter a new course and a new medium, in effect thus a totally new way of "doing" learning, without a truly inviting and context-rich design. This inquiry and, I hope many others like it, aims to search for these "extras" that are needed in design in order to harness the resources of the new learners and not to only recognize their deficits in terms of technological literacy.

At present we use a tool for e-leaning that was designed with the technologically advanced communities of the world in mind. *WebCT* is Amero-centric. Its language and its icons address the worlds of the middleclass American student and all who have been "Americanized" in this way. Unless we explore HCI at grassroots level in a different context, we may lose the learners who need the system most. That is why both observations and interviewing, as well as document analysis, at grassroots level need to be conducted and comparative data need to be assembled across nations and borders to find out how different Indigenous Knowledge Systems (IKSs) can be blended with the Western discourse and way of doing of the electronic world. My point is not that a completely "different" discourse should arise, but that there should be more of the local in the global.

To this end the ethnographic component of this inquiry aims to capture the type of information needed to explain what the local reasoning is and what local tool utilization and ecological adaptations look like. The assumption that "one glove fits all" has been dangerously erroneous in my experience of lives of e-learners (Fortuin, 2002; Henning & Van Rensburg, 2002). "Borderless courses", I argue, are for those learners who have been initiated and inducted into the "ways of the web" over time. In the instance of the students in this inquiry, who I describe as "bordered", they need to make the border-crossings from their side of the digital divide—also for pedagogical and empowerment reasons.

The VLE as a space for this type of inquiry is abundant in its ability to yield data of various types and sources. It is free giving, because the ecology is forever changing and this dynamics, coupled with the social change that accompanies it, can be captured optimally in some form of ethnographic research.

5.1. Making a Home and Greeting Each Other "Across the Valley"

In the discussion I will now firstly indicate what the significances of the study were and then reason how the "learning ecology" metaphor could be used to argue that a specific type of apprenticeship learning and entry into the VLE is needed for specific contexts where there has been little if any initiation before. I also show how the data reflected the main finding, namely, how the notion of *making a home in a VLE* was the dominant theme that explained some of the problems the students encountered, while also mirroring *activity* more than *action* or *operations*.

The six teachers accentuated in interviews and in the journals, as well as in the discussion postings, that the implications of effective e-learning in this part of the world are far reaching. They say that no one needs to be convinced of the urgency of the need for viable information networks and virtual learning opportunities anywhere in Southern Africa. If this were to be a successful intervention on a large scale, if the internet can truly come to villages and huts in distant areas, the sub-continent may be afforded a better chance to develop its human resources.

Thus I focus on the stories as illustrations of how the notion of information ecologies, or "learning ecologies" for the purposes of this inquiry, can become a powerful heuristic in thinking about sustainable VLEs, not only in the higher education landscape, but also at community level. What I learned form these stories is not how to teach and to set up an environment, but how to listen to the voices (and the tone of the voices) on the ground as guidelines for development. In one of the interviews a teacher said that learning to work in online format reminds her of a television advertisement of a telephone company in South Africa.

> In the advertisement an old man shouts a greeting from the doorway of his hut on a hilltop to his friend across the valley, who then returns the greeting, "Hello, one of my own!" This is a daily ritual. Then telephone landlines are installed and both the old friends are equipped with a telephone. They learn to dial and to use the receiver for the first time. At last the first real phone call is made. The old man lifts the receiver and dials. He listens to the ringing and hears someone pick upon the other side. He then goes to his doorway, points to his receiver and shouts the greeting in his customary way, with echoes over the valley: "Hello, one of my own!"

This was his first effort at telephone communication. He used the information technology, but also wished to make sure that the sound traveled in the way that was customary to them. With the necessary technical support and sufficient funds, this little communication ecology will be able to sustain itself and the teacher expressed the opinion that very soon the valley will be "chatting away".

In the same way I believe that the VLEs that we have initiated have the potential to be sustainable—not because of the technology itself, but because the people who have engaged with it found ways to get support and to reciprocate in supportive ways. The main characteristic of this developing ecosystem is that it has a good chance of sustaining itself and my argument is that a VLE intervention should have at least the potential of *sustainability*. In the three stories there is evidence of potential for sustainable development. The adult learners had all found ways to acquire knowledge and skills (and ultimately also a disposition) to learn and to get access to computers first and then also to the internet. The stories are perhaps no more than research vignettes at this stage, but they also have the potential to become powerful narratives of how, given the opportunity to bring together a societal, educational trend and a number of people, (a "fortuitous coupling" event) change can come to people and to their social environment. However, the sustainability will be threatened if the ecology does not evolve, and with some skills and knowledge alone, I argue, the chances are that it will not prosper. It needs what Bonnie Nardi (1999) has termed, a "heart"—it needs people who can use it with discretion, but also with some intuition.

In addition to intuition the nurturing of a critical capacity is also essential, because for an ecology to develop without a critical capacity, I would argue, is to render it vulnerable to power and control (Warschauer, 1991: 74–175) and to new technological hegemonies—the fear expressed by Postman (1993) and Ellul (1964).

5.1.1. The Internet in Huts and Villages—Where are the Keystones in the Ecology?

The first component of a learning ecology that I noticed in the data is the role of keystone *species*. According to Nardi & O'Day (1999: 53) "keystone species, whose presence is crucial to the survival of the ecology itself" is a main characteristic of ecology and "(o)ften such species are skilled people whose presence is necessary to support the effective use of technology". These people can be facilitators, translators or teachers. I particularly like the reference to these species also being *mediators.* Nardi and O'Day (1999: 54) relate an anecdote about the unusual hiring practices of a big corporation that shows who these species could be. This corporation looked for people with a caring disposition for certain positions, despite their possible lack of background and experience in the areas of the job description. As mediators they needed certain personal qualities and interpersonal skills. As I understand the notion of keystone species, they need not be the experts, but they just need to be the "right" people for the "job".

The keystone species in this inquiry made their presence known by acting according to the need of the situation, without having had a prior goal. Therefore the emergence of the species is typical of learning in *situated action* mode. In all of the cases the major "teacher, mediator, facilitator or translator" was a person who came to the fore organically and provided the support and the scaffolding that was needed. In each of the narrative portraits of the dyads the partner is a keystone. In the practical and epistemological struggle to get their knowledge built the presence of the reliable other learner was the ecological component that kept the system together. The learning ecology itself comprised more than the two persons, because their virtual and workshop communication webbed into the rest of the group, but the dyadic partnership was crucial. The students in these narratives may not have appropriated the course optimally as some other students with more experience and skill did in this course, but they stood out as examples of strength in unity. I also found it significant that they hardly addressed the rest of the group of 33 students in their discussions, but spoke to each other, with only a number of references to the other students. They preferred to engage in the smaller ecology where they clearly felt more secure. They addressed the course presenter quite often, though mostly in plaintive tone. In the instance of Thembi and Sipiwe it is significant that his daughter became a keystone as well and that she remained with her father when he extended the *emergent distributed cognition* system to other teachers in his school.

My argument is that the teachers all found extra support in a keystone species and thus created the genesis for an apprenticeship in learning, VLE style. The members of the dyad found what they regarded as a "more experienced craftsperson", who, in some way, mediated the process. The *cognitive apprenticeship* was both situated and slowly evolved and will probably become, ultimately, an example of learning in distributive mode, with a strong social component. The teachers cannot be expected to study online in global "borderless" courses as yet, before they had not completed the cultural ritual of learning in apprenticeship mode (from each other and with a body of people) how to enter this discourse community and to become empowered. For the moment they are not "borderless" in their thinking or their skills. As "bordered" learners they first had to engage in the immediate struggle together to form a viable learning ecology. At one stage the words "I click, therefore I am (not)", and the problems involved in finding an epistemological identity and a space came to mind when I observed teachers working away. The expressions of fear and loss, the "hopelessness and the homelessness" that Dimpho referred to were often observed in workshops. The sense of being lost and not knowing how to get to a safe destination became a dominant theme in the data and I also reflected on this in my own journal:

> This loss of identity was buffered by the folk that made the experience more "human". I feel lost myself when I think of the clumsiness of this course. How did I manage to design a learning environment that has no identity—no character, no safe space? I did not see the students' lives and how these should feature in the hyperlinks (I could have made these myself if I had given it any thought). Now I have thrown them to the global wolves and they feel strange and unsure. Maybe I should have asked colleagues at other institutions if we could perhaps share courses, so that we can be each others' hyperworld to start with—just at the beginning. But then—our students read international textbooks and they cope. So why is this so extra hard? Why does Thanyani talk about me wanting them to "breathe like Americans through the lungs of the web"? This is painful. But how can I not introduce online learning? How can I be happy and deprive people of the opportunity to help build access routes to knowledge and to knowledge-making and, ultimately also to really valuable information ecologies? What is it really that makes them so insecure. I am not sure that it is simple fear of the unknown.

Despite these misgivings and that it took the six students nearly the whole semester to enter the environment, the fact remains that they did so successfully, even if not entirely at the process level of *activity* in the activity theory hierarchy. It does show, however, how important it is to introduce students to the environment in induction mode and to keep the pace slow at the beginning. Therefore, the fact that most of them did not advance to higher levels of engagement does not trouble me too much at this stage—the first in a longer journey. What excites me is that the role of the keystones became evident and that they would probably become a keystone in their own teaching of computers and helping more people to become active members of VLE's.

5.1.2. Diversity: Each to Their own Niche

The six e-learners in the research sample have all begun to find a place in the virtual learning environment where they are comfortable and where they have started to function as e-learners. In these cases the functioning can be seen as a blending of learning from the view of *situated action*, *distributed learning*, and learning within an *activity system*. The most prevalent learning has, however, been in the category of *situatedness*.

And this makes sense, because in the close containment of the individual situations learners sculpted a niche in which they can operate "in" the moment. Dimpho and Penny, like the others, saw the dyad itself as a niche. Working together was essential for them. They also complemented each other. Dimpho found her way of doing by writing extensively in her journal and Penny was asked to share this and to comment as well. So, together these two women reflected and strategized. It is significant that it did not take them long to acquire their own computers and internet connection—bringing the technology "home" in more than one way. My sense of their experience is that they wanted to make the learning more personal and in this way they found an operating niche. At the outset, therefore, their *activity* was to not only to "meet with the computer", but to do so on their own home turf. The course itself became secondary.

Nardi & O'Day (1999) say,

> (i)n a biological ecology, different species take advantage of different ecological niches, which provide natural opportunities to grow and succeed. The complexities of biological ecologies ensure that there are niches for many different kinds of roles and functions. In an information ecology there are different kinds of people and different kinds of tools.

They continue to say that the tools and the people are complementary in a healthy system and that a monocultural system is brittle and therefore vulnerable. The members of the learning ecologies in this inquiry present a landscape that is, indeed, as these authors argue, “teeming with different kinds of people and ideas”, with the potential of cognitive fertilization and hybridization.

In both the other dyads it did not take the students very long to establish their niche and their path where they could optimize their growth. Sipiwe’s daughter joined her father and became the third member of a learning triad; they both found fulfilment in teaching as they were learning—a specific niche for accelerated growth.

The differences in niche areas are not just at the cognitive/psychological level, but also at the level of sociocultural action. It is noteworthy that the University campus with its sophisticated computer laboratories and much faster internet connection did not become a place where people “found” their niche. The niche was found in the immediate social environment, where they felt comfortable and where there was personal support. What was more important was the linking of their everyday life and their process of entering into the VLE.

5.1.3. System: the Course, its Students and “Others”

The most cogent comment on the notion of the system in the authors’ metaphor of ecology is, to my mind, that “(w)hen one element is changed, effects can be felt throughout the system” (Nardi & O’Day, 1999: 51). Whether one views the dyads and their immediate surroundings as “the system” or whether one takes a broader view and includes all the students in the course, the program and the designers and teachers, does not really matter. Small changes, if they are sustainable, change the broader phenomenon. And in this system many people have changed their way of doing. The way they appropriated the VLE as individuals has significance for how the course will grow.

Thsepang and Thanyani worked at a faster pace from the outset. They also started working beyond skills learning (at the operational process level) very soon after they had made their first posting in the discussion forum. Tshepang was one of the first students in the larger group to critique a fellow student’s discussion posting. After this, more students followed this example. Also, some of the more privileged students in the larger group, who were continuously complaining about the lack of access to computers, the expense and the need to be constantly engaged, slowly stopped their complaints when they started realising that the students in this inquiry, their peers with few of their communication and access privileges, had actually put them to shame.

Tshepang also delivered a good research design, with an outstanding design logic and with references to eight hyperlinks that he had made to set up his research proposal with its innovative design (a hybrid of ethnomethodological and ethnographic research in a school). At the process level of action he had delivered an admirable piece of work and is probably the only student in the research sample of whom it can be said that he engaged with the *activity* system (along with six in the larger group) of the course.

The system's most significant impact has been, however, on the design. Having encountered so much data about the students' first encounter showed me how weak the design logic of the course is and how it negated the students' sociocultural context. The change in the system will impact the design of many courses at the institution.

Also, their own immediate environment has changed irrevocably. Once electronic learning happens it will not stop—if technological support is sustained. The "apprentices" have all said that they will never *disconnect* and forego the networked world. In the ecology, which gives signs of its sustainability already—the chances are that much will change in perhaps a shorter time period than is usually anticipated when forecasts about the *African network* are made.

5.1.4. Coevolution: The Electronic Village in the Global Community

Every household or other entity that appropriates electronic communication and sustains access will be in change format as the innovations are introduced. Already the participants in this inquiry have commented on new mental tools/mindtools accompanying the use of new material tools. Though this is coupled with perturbation and often also with epistemological angst (Henning & Van Rensburg, 2002), the equilibrium that comes with the competent use of both types of tools sets a *renewed zone of proximal development* in motion. This predisposes the learners to continual evolution in learning. Even in the space of a few months there is evidence of evolution, and more specifically co-evolution. All six members of this inquiry group developed with and according to the eco-existence of at least one member of the ecology, but also because of the sociocultural context. There were not only people who influenced each other, but a telecentre, an internet café, a postal centre with internet, and a wife who bought her husband a computer. Thembi wrote in her journal towards the end of the course, "I was slow at the beginning. But every time I wanted to cry I looked at Sipiwe. He was so much younger than me and here was this man who was so intelligent and he was helping me and he was saying, 'Gogo you can do it. Come again'. Even through my tears I could see the difference". And in his capacity as mediator and teacher Sipiwe thrived on assisting Thembi. In their various niches they were coevolving in the learning ecology.

5.1.5. Locality: Are the Computers in our Heads?

In this inquiry two notions of locality became evident. Firstly the *mental locality* of the newly developed learning skills, and secondly, the place of *habitat of the computers*. The most important finding from the inquiry has, in fact, been the notion of habitat or location. In the data examples that have been included in the narrative portraits it is evident that the notion of "home" or a place to be is very strong. Dhimpho starts her journal with the words, "Are we in this machine or is it in our heads?" Penny said in one of her entries, "I felt like I had moved house" and that she felt "homeless". Thanyani said that he felt "catapulted" and that he wished he could "lay my hands on it like a library" and that he tried to "find a map in (his) head". He expressed the wish to enter a house and to find someone he knew there. Tshepang goes further and invites Thanyani to his physical house, because he "can't just talk to the wall". Later on he says that he feels lost, as if he is "not in my house anymore but lost in the streets".

In the citation from Shakespeare's *A Midsummer Night's Dream*, Nardi & O'Day (1999: 54) highlight the notion of location or habitat in ecology and the role of imagination to create the location. They say,

> We believe that a key to becoming an active participant in technological change lies in joining ranks with the poets, whose creativity is grounded in local settings. The notion of "local habitation and a name" captures for us the essence of information ecology. The *name* of ecology identifies what it means to the people who use it. In a sense it positions the technology more under the control of its users. We do not just refer to what the technology is called, but to how people understand the place it fills.

5.2. What the Portraits have to Say for Course Design and Implementation

In these narrative portraits there is sufficient evidence that the present format and content of the course do not invite the students to engage with the object—the whole envisaged learning experience. It is significant that before the teachers started to locate the VLE *in their lives* they had to locate *themselves in the VLE*. They were finding ways to name, at a personal and almost metaphysical level, the new epistemological home they were entering. So, before they even thought of locating the technology, they had to redefine their own mental habitat with regard to the technology. And why this is significant is because it indicates that the appropriation of the technology happens first at a highly personal level—much like things happen in one's home.

It is this theme that has led me to argue that the new epistemological tools that adult learners in this type of context need can only be made if there is a sufficiently accepting and supporting ecology. That is also why I argue for a gradual process of initiation into the ways of "doing VLE" for such learners. They cannot "breathe through American lungs" as Thanyani said. They need the opportunity to appropriate the discourse, its genres and all its tools and symbols in apprenticeship format, in which the *activity* (in the language of activity theory) is "*getting to know you*" and also "*getting to myself in this new landscape*"—finding their homes in a new "living area".

And to this end I forward a number of suggestions for the design of first time e-learning courses for adult learners in this type of context. They are very simple and they are geared for the cultivation of learning ecologies in which the culture of learning involves a stronger blend of the familiar social environment and the virtual environment. In future, when I hope open source learning will be the way forward and will replace learning and content management systems, the students can co-design curricula and make the product the process, as Collis (Collis et al., 2003) so often argues.

Firstly, the life world of the students needs to be linked to the tools, signs and symbols of the e-world. For example, the discourse of the hyperworld can be linked to a local, social, or even educational discourse that can cross-articulate. Instead of having "discussion postings" (one of the least successful components of online courses I have introduced) these communications can be named in a local language. The format can be adapted as well. Visual material, icons, sounds, even a simple term like "click" could, to start with, is replaced by a local word too. The interface can be so much more "environmentally friendly".

Secondly, initial tutoring, when the ecology is still in its genesis phase, needs to be focused on the students' lives, rather than course content. In other words, the initial "course content" needs to also be a "getting to know you" and "getting to know myself in this space" (the new "home"), before the links to the *Infobahn* are introduced. I suggest that much more is made of the opportunity to hyperlink to each other and to establish *emergent personal Webpages* instead of using class email facilities and discussions. A personal webpage has an "address" and this signifies that the learner has indeed "moved house"—has relocated to a place on the internet, where millions of other people also "live"—but where the individual has a personal space.

After having learned the basic skills of working the hyperworld, and after having acquired a personal "page" (home), or *homepage*, design logic for the rest of the course can be established. My fear has always been, and has been substantiated in the courses that I have started and witnessed on the web, that the secure designer-teacher prefers to have a complete course—and that most students believe they want it too, packaged neatly with envisaged outcomes and clear standards of (so-called?) performance. At this stage I would rather see students establishing the "move" first—settling in at the new address—and then exploring the neighborhood, which does not yet include major hyperlinking. I propose a first "less is more" learning unit with secure pathways and specific signs and criteria for achievement and for self- assessment. The new learners first have to make sure that they are comfortable in their "new home", and this is something, which only they will know. They will communicate about themselves and their "move" experience and will set up their house/homepage with the help of instructors/tutors and visit each other before they explore. This means that the ubiquitous (and in my experience mostly unsuccessful) discussion postings become less important. I have found that organic networking and the development of a more "e-natural" ecology suits the learners in this context far better. They will communicate and share their ideas and their struggles in learning spontaneously. The formal area of threaded discussions is, for many, a daunting forum. I would argue that students who are engaged and motivated will come to share their learning when they are ready. Forcing learners to "thread" a discussion is only one way of facilitating shared processes and may, for some, exclude them in what is intended to be an inclusive project of distribution.

Does this mean that very little "course content" is introduced and that the focus is initially on getting the process going as organically as possible? My answer would be a tentative "yes". After the first learning unit progress can be made according to the learners' growing awareness and competence. The curriculum design would therefore never be more than "emergent" and the "packaged course" would not be made available at the outset, because it is bound to change. The design logic would be evident, however. The indicator of success of implementation would be the type of ecology that is cultivated, the way the distributed cognition system/network evolves and how learners act contingently in situated cognition mode. More than anything, the logic would display a design awareness that invites a sense of the *activity* more than a collection of disparate *actions* and *operations* in isolation. And in the case of this type of group, the activity would be to "move to the hyperworld", with some of the belongings needed to traverse its spaces.

CONCLUSION: TOWARDS A SUSTAINABLE ECOLOGY OF ONLINE LEARNING

The first conclusion that can be drawn from the discussion is that ecology has been a viable metaphor for exploring online learning in its *real* context and that the understanding that has arisen from this has contextual validity. In this inquiry I was led to the notion of "moving house" because my focus was on the interaction between the mind ("consciousness" in activity theory terminology) and how it interacted with the environment. The mental tools that I was applying in looking for meaning in the data were themselves mediating and my own mind, my own thinking, was framed and mediated by the notion of *ecology* and of *activity*, and to a lesser degree by *apprenticeship*. In thinking about "activity", I inadvertently was drawn to the realization that the teachers were at first frustrated at the operational level of processes in the *activity* of "moving house" and of finding an identity in "clicking" (I click therefore I am?). In this process the motivation, or compelling force, for becoming an e-learner was dominant—and it was also the biggest stumbling block. At other levels of processes they could learn at their own pace and would have, eventually (and some did) become adept in the activity, some actions, and many operations. Moving house was, however, not possible because in the constraints of the course and its facilitation via WebCT the students could not "move". They performed actions and operations that were related to the activity of moving to the online space, but they did so, except maybe for one of them, as transients who had not established an identity and a location for themselves.

Kaptelinin (1996: 108) says actions are, "the processes functionally subordinated to activities (and) they are directed at specific conscious goals". He furthermore argues that the "objects" of the activity (moving house and feeling secure and localized on the internet in the case in this chapter) may be dissociated with the "lower" level of processes in actions, with goals (teachers writing a discussion posting to participate for grading and thus assessment, or delivering other artifacts of learning) and that such dissociation is significant. The teachers in the inquiry did not really engage with the course, because their basic motive (towards processes at the *activity* level) was not recognized by the design, which expected full course engagement. Although designed from a constructivist epistemological approach, the curriculum invited little thinking and inquiry and perpetuated rote learning and copying. Without being "at home" and appropriating the VLE, the students mostly could not identify the latent opportunities for inquiry and also did not have the courage to venture into more than default learning mode, and thus reverted to rote learning.

They did not find it difficult to perform processes at the operational level. Kaptelinin (113) says, "(w)hen *operations* are frustrated . . . people often do not even notice and automatically *adapt* themselves to a new situation". He continues to say that at the level of *actions*, when goals are frustrated, actors have to *set new goals* and start again. The point I am trying to make is that a basic and overarching frustration was dominant in the teachers' engagement with the online course—they had not really *engaged in the activity, because the activity was not identified as object for their learning*. The course designers did not address the *motive*, the compelling force, that the teachers spoke and wrote about in detail in the journals and the interviews—namely that they "felt homeless". Thus the other processes were less significant than they would have been if their need at *activity* level had been addressed.

Finally, I would argue that all the best intentions might yield less fruitful outcomes if the identity of the learners who are not comfortable with the virtual world is not considered. In the very first extract from a journal entry reported in this chapter, Dimpho had said that she was not sure whether the computer had come "into their heads" or whether they had moved "to the computer". At an ontological level she was essentially saying that she was not sure of what the *activity* was, but she was left struggling at the level of operations to find an answer to such a fundamental (activity) question. The tool can never become the mind, but the mind *and* the tool (the environment, the object that motivates and energizes processes) are the activity. So, indeed, she had "lost some of her mind", but not, as Postman (1993) and Ellul (1964) and others (Nardi & O'Day, 1999) argue, "to the technology". She has engaged in meaningful, conscious tool use and in the process she has developed new mindtools—expanding her mind through tool-mediated action. Thus, she is "stretching her consciousness" as she would if she were to study, for example, Mozart music. Here too, she would enter another world where she would also have to find a home, and then an ecology, and then a niche for herself, before she would become meaningfully operational and active.

The overall conclusion of this inquiry is thus that, viewed from the perspective of an ecology of learning and using activity theory as analytical tool, adult learners such as the teachers in this context need a home and an identity as e-learners before they can engage in a course. They need to be ontologically and epistemologically secure. Additionally, they need to be introduced to online learning in a gradual apprenticeship mode that will afford them the opportunity to establish their own *location* and to *name* their experiences and their position in the ecology of learning. They need to have the opportunity to enter this discourse community from a position of strength and not of deficiency. One way of securing this position is to design courses for novice adult e-learners that invite them to establish a home, and with it an identity, on the web. In this home they can then learn many of the operations and actions needed to learn online, but, more importantly, they will have the opportunity to perform the activity—to engage with and to appropriate the environment, and not just to learn some skills and acquire some knowledge via the web. They said that they were lost and "homeless". A personalized homepage may be the answer as foundation for further interaction with the VLE.

ENDNOTES

1. Racially segregated urban living areas in South Africa, designated for black people in the apartheid era.
2. This is a very popular, primetime television series drama.
3. See the edited work by Headland, Pike, and Harris (1990) for analyzes and discussions on these terms of the "insider's view" (the emic view) as opposed to the view from social science categories (the etic view).
4. I will not include O'Day every time I refer to the authors' metaphor.
5. In a recent paper I propose (Henning, 2003) that the borderless courses aimed at a global learning community need to take account of the "bordered" people of the world who have to follow different learning paths before their learning and the e-programs they engage with can be termed "borderless".

Chapter 22: Virtual Communities of Practice

KATHRYN HIBBERT AND SHARON RICH
Faculty of Education, University of Western Ontario, 1137 Western Rd., London, Ontario, Canada N6G 1G7

1. INTRODUCTION

There is an increased interest in the use of virtual technology and distance courses in professional education. Teacher education is no exception, particularly with pressures to maintain professional standards. The problem of course is that the conception of what it is to be a professional teacher influences the development of such courses and programs. If teacher is characterized as *discerner*, with the ability to "transform understanding, performance skills, or desired attitudes or values into pedagogical representations and actions" (Shulman, 1987: 4) then teacher knowledge (of content, students, and pedagogy) is of paramount importance. If however, teacher is characterized as *disseminator,* charged simply with carrying out the dictates of others, then complex forms of knowledge are not essential. The former implies a need for professional development that informs, enriches and extends teacher knowledge. The latter suggests that training in new materials is sufficient.

Current curricular conditions and a plethora of supplemental *teacher-proof* materials would seem to support a non-professional characterization of teacher as disseminator. Such a reductionist view of the teacher has led to a model of 'professional development' commonly referred to as *train-the-trainer*. The model provides systematic training in recently released documents, programs or materials to a target group of people. In pyramid formation, the newly 'trained' would then re-inscribe large groups in exactly the same fashion.

The characterization of teacher as disseminator inhibits meaningful professional growth and perpetuates curricular conditions that limit the potential of the teaching learning process. Reflecting upon the adage: *Treat people as if they were what they ought to be, and you help them become what they are capable of being*, we wondered whether characterization of teachers as discerners would lead to changes in curricular conditions and in the ways in which online courses could be constructed.

Smylie and Conyers (1991) have argued that it is necessary to shift from "deficit-based to competency-based approaches in which teachers' knowledge, skills, and experiences are considered assets" (p. 2). The conceptualization of the online learning environment as a way to value teacher

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 563–579.

knowledge enables the development of a critical complex epistemology (Kincheloe, 2004). This epistemology

> . . . involves teachers as knowledge producers, knowledge workers who pursue their own intellectual development. At the same time such teachers work together in their communities of practice to sophisticate both the profession's and the public's appreciation of what it means to be an educated person. (p. 51)

As other researchers have observed, an online learning community can be designed to "support the actual practices and daily tasks of the participants" (Shultz & Cuthbert, 2002) at whatever point they may be in their learning. At the same time, it can bring professionals together to discuss new research and ways in which their learning informs their professional practice. In this chapter we draw from the work we have done with in-service teachers at the Faculty of Education, University of Western Ontario to consider the ways in which online courses can become communities of professional practice that support and extend the notion of the professional teacher as a discerner who develops a critical complex epistemology.

We begin by discussing communities of practice in both the face-to-face and virtual community, indicate the ways in which Shulman's model of pedagogic reasoning and action can be applied to the online environment, and finally use the example of our carefully designed online courses to highlight the ways in which virtual communities of practice can assist teachers to be come professionals who are discerners rather than disseminators.

2. WHAT IS A COMMUNITY OF PROFESSIONAL PRACTICE?

Social learning theorist Etienne Wenger (1998) notes that communities of practice are celebrated by businesses within the knowledge economy while for years educators have recognized the notion of community as creating a supportive learning environment in which learners are expected to be active and involved in creating knowledge. Dewey (1963, 1966) talked about such communities and Rich (1991) referenced the concept in a study of informal teacher support groups noting that in these groups the members became excited about new knowledge as they integrated information about best teaching practice with their experiences. They shared with others and advocated for new ways of teaching language and literacy.

Wenger's model of a community of practice (Wenger, 1998) places learning in the context of social practices. For him, a community of practice has coherence created by three factors: indigenous enterprise, regime of mutual accountability, and shared repertoire. He suggests that meaning in communities is derived through the negotiation of two main components, *participation* and *reification* and examines the potential for a community of practice to negotiate meaning as it respects the informed contributions of all members.

For Wenger, indigenous enterprise develops within larger historical, social, cultural, and institutional contexts with both fiscal constraints and supports. The conditions may be explicit, or implicit, but both are binding:

> . . . even when the practice of a community is profoundly shaped by conditions outside the control of its members . . . its day-to-day reality is nevertheless produced by participation within the resources and constraints of their situation, and is therefore their enterprise.
>
> (Wenger, 1998: 76)

Members of a community of practice may face common problems, but each may define and approach them differently. For example, in a learning context involving teachers, participants may tell stories about struggles encountered in meeting the expectations of curriculum documents, administrators, parents and the needs of the students. The storytelling and the responses from others, who have resolved similar issues, assist them to come to new understandings and move forward. Indigenous enterprise is always negotiated by the professional community.

The regime of mutual accountability refers to members' concerns about their professional practice and the context within which they act:

> While some aspects of accountability may be reified—rules, policies, standards, and goals—those that are not are no less significant. Becoming good at something involves developing specialized sensitivities, an aesthetic sense, and refined perceptions that are brought to bear on making judgments about the qualities of a product or action. That these become shared in a community of practice is what allows the participants to negotiate the appropriateness of what they do.
>
> (Wenger, 1998: 81–82)

Teachers in a professional course may eventually tell a story of a student(s) with whom they have had little success. Sometimes, this lack of success is blamed on external factors (poor preparation by the home, English as a Second Language, learning differences, lack of resources). While any and all of these conditions may contribute to struggles in the school setting, responses from a supportive, professional community (including the instructor) encourage the teacher to develop a sensitivity and awareness of the student's predicament, and a recognition of what can be done.

Shared repertoire is the shared pursuit of an enterprise (i.e., teaching reading well). Routines, words, tools, ways of doing things, stories and so forth all belong in this third characteristic, although the elements themselves can be very different:

> They gain their coherence not in and of themselves as specific activities, symbols, or artifacts, but from the fact that they belong to the practice of a community pursuing an enterprise. . . . It includes the discourse by which members create meaningful statements about the world, as well as the styles by which they express their forms of membership and their identities as members.
>
> (*Ibid*.: 83)

In the online environment, teachers come together to learn ways to improve their practices in teaching. Discussions and language assume a basic level of familiarity with acronyms (i.e., Individual Education Plan—IEP) and reading practices. Through mutual engagement, participation and reification weave together. As individuals engaged in joint enterprise, they create relations of mutual, professional accountability. Through engaging in dialogue, the community becomes a resource for negotiating meaning.

The following five questions determine whether an environment has evolved into a community of practice:

1. Do group members take responsibility for their own learning?
2. Do members share their learning and the learning of the group?
3. Do group members believe that they can improve their practice?
4. Do group discussions show development of ideas?
5. Do group members see themselves as constructivist knowers?

If the answers to these questions are yes, then a community of practice has been created and members share knowledge and support one another in knowledge construction. As the group matures, the members develop a group expertise distinct from that held individually and are committed to collective goals.

Communities of practice exist inside and across institutional boundaries. The community of practice offers possibilities for transforming learning and linking individuals who share a set of problems and issues. What we consider in the next section of the paper is how the elements of a community of practice might be reflected in the virtual context. We assume that in a virtual community, those who access the web can begin to realize its potential to build knowledge and we draw on our experiences as researchers and teachers in the online environment to explicate what can and does happen in such communities.

3. WHAT MAKES AN EFFECTIVE VIRTUAL COMMUNITY OF PRACTICE?

Virtual communities of practice are similar to those outlined by Wenger. They share the characteristics of indigenous enterprise, regime of mutual accountability and shared repertoire, but also provide an 'enunciative space' in which participants can make meaning. Enunciative space is defined as:

> the opportunity to articulate what it meant to be a [professional in a particular practice]; to tangle with social issues beyond the technicalities of [the profession]; and having some agency within which to question and challenge the wider structures surrounding [the practice]; and in the process gaining some ownership of the determination of ones' own [professional] work.
>
> (Smyth, 2001: 159)

Many have described online learning as a "powerful tool for the development of critical thinking and deliberative skills. The dependence of current conferencing technologies on writing enables students to reflect more deeply (than the immediacy of face-to-face responses) on their ideas as they try to articulate them effectively" (Eastmond, 1998: 73). Bliss and Mazur (1996) examined ways in which technology could support the creation of a shared culture, concluding with a call to create cases to be used to support and encourage those working through constant change.

Research into online education, in general, supports successful learning attributes of adult learners (Bereiter, 2003). An online environment can offer a degree of flexibility, independence and choice that appeals to adults, many of whom are studying in addition to raising families and working outside of the home. In addition, opportunities exist for collaboration with others around a shared interest, interaction with issues that they deem to be important, application of their learning and the development of a sense of community (Eastmond, 1998). A virtual community of professional practice respects learners through its design, by capturing participants practice in a way that makes visible not only methods and techniques, but also making visible the beliefs, values, policies and institutional structures that may have informed that practice. A virtual community of professional practice:

1. Establishes and build on commonalties
2. Fosters dialogue between participants
3. Encourages links between and application of learning to practice
4. Recognizes the expertise of learners. (Rich, 2002)

Palmer (1998) argues that professional communities assist members to grow while at the same time he points out the irony that while individuals often can serve as the best resources for each other, the organizational structure of the institution often inhibits access. Online communities can help counter isolation in part through sustained and purposeful interaction outside of the structures of the individual institutions in which people work. Asynchronous online communities of professional practice provide participants with the

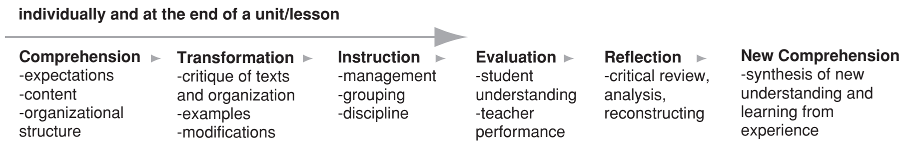

Figure 1. Linear model of pedagogic reasoning and action: individual. Source: Adapted from Shulman (1987).

ability to compose and post messages after they have had an opportunity to "digest and reflect on information" (Eastmond, 1998: 35).

In the professional practice world of the teacher, a virtual community of practice can provide an enunciative space that is not often found within schools. Shulman's model of pedagogical reasoning and action (Figure 1) aims to assist teachers in developing a wisdom of practice that presumably leads to 'good teaching'.

Yet this model is limited when the teacher is alone in the classroom because the individual has access to only his/her current understandings and experience. Moreover, if teachers are trying to *perform* their job in ways that have been narrowly conceptualized and presented as *best practice*, there is potential for a static understanding of teaching. In this scenario, teachers' descriptions of practice are generally considered interpretive, highly personal and insular.

To consider our virtual communities of practice in teaching we adapted Shulman's model to the virtual environment (see Figure 2). In the virtual context rather than reviewing practice in a systematic and hierarchical fashion alone, individuals were challenged to deliberate about their practice as they participated in it. While deliberations about practice provided a broader base of experience and circumstances, the skilful integration of theoretical and academic discourses provided an overarching framework and the tools needed to critique practice addressing larger socio-political and social justice issues.

Although Shulman (2004) did not investigate virtual communities specifically, the principles developed in studies of communities (i.e., generative content, active learning, reflective practice, collaboration, passion) apply.

4. DEVELOPING A VIRTUAL COMMUNITY

Six years ago, the Faculty of Education, University of Western Ontario made a commitment to providing online in-service course for practicing teachers. As faculty members, we knew that many of the teachers we encountered in our in-service work across the province were eager to increase their level of expertise and knowledge. We also knew from a survey that we had conducted that many teachers were hesitant to embrace new technology but would do so if it were easy to access and enabled them to participate in professional

Figure 2. Online model of pedagogic reasoning and action: community. Source: Adapted from Shulman (1987).

development at their convenience. Thus one of the first issues we had to address in our move to online in-service was the technology itself. That is, what could the technology 'do' and did its ability to 'do' something overwhelm or support the interaction of the participants? We knew from our experiences with teachers that people had to matter more than the technology and we suspected that the principles discovered in face-to-face communities would be just as significant in an online context, that is, people like to talk; they rarely like to be told what to do; and, they want to learn in order to improve practice. Technical developments need to evolve in a way that supports and facilitates interaction in order to nurture the development of community.

Technological development should reflect the needs and desires of the members. In considering how technology will facilitate the development of a virtual community, we thought about how community members would access the web. The answer to this question informed decisions about the types of supportive web-based material that could be used. For example, if members access the web from rural areas without high-speed connections, streaming video and live chat could be problematic. The geographic location of users also influenced decisions about the value of particular technologies. If users are all in one time zone then synchronous chat might be a viable option.

Issues of web security also need to be considered. Our research has indicated that closed virtual communities may provide a greater sense of security for members because they know who has access to their discussion. They can be more open and discuss a range of topics when an enunciative space is created for them to interact with each other. A private community needs a secure, password-protected site with controlled entry. On the other hand a public site can garner diverse opinions (freedom in anonymity) but may inhibit the creation of a knowledge building community.

5. THE VIRTUAL COMMUNITY OF PRACTICE TRIANGLE: USING THE WEB AND ITS POTENTIAL

After experimenting with a number of commercial platforms, all of which purported to be able to deliver the type of course we wanted, the Faculty invested in the development of its own platform, eCampus. Able to work closely with information technology personnel, we developed a platform that married technology and pedagogy in ways that allowed us to be more responsive to instructors and teacher-learners. Through our work we discovered that conceptualizing our courses as triangles help to determine what has to be in place for successful evolution. We noted that to be effective virtual communities of practice use the web, online conferencing and independent reading and thinking to facilitate changes in individual community member's and groups of members' practices. In short, knowledge construction in the virtual community of practice requires:

1. A website with content specific to the target community.
2. Resources for community members' individual and shared professional development. Many of these include online readings and resources.
3. A discussion tool that can simulate the face-to-face interaction in an online context.

We learned too that in the courses that were most successful in establishing community, the group leader or facilitator plays a critical role in establishing the tone of the group and helps to move its work forward. As part of a dynamic ensemble, the instructor functions as co-learner (Rich, 2004). The entire community interacts in the learning process to negotiate meaning through discussion around readings, course content and with each other. The three points of the triangle touch on the three main components of a dynamic environment.

The content created to support a virtual community conforms to principles of good web design and provides links to areas of potential interest to the

Figure 3. Model of online learner. Source: Rich and Hibbert (2004).

group. For example, in an online community dedicated to learning more about literacy practices, specific areas might be devoted to early, middle or late years' literacy development. Controversial issues such as high stakes testing may also be featured. Embedded within the web content will be key questions that help community participants think about the issues. In other places on the website, a mouse click may spawn a daughter window that takes the community member to an online article for further reading. Still other areas of the website provide a series of resources that the community member can order or access through a local library. Each time the community member logs into the site there is possibility for conversation since a user friendly conference is linked to it. When the community member goes to the conference, he or she can see the topics that have been posted. A click on a topic provides a glance at what others have said about an issue raised on the website. A click on another topic provides an opportunity for the community members to raise questions about a reading that has just been completed. Learning occurs as a result of reading the discussion, the web content and the additional websites or local articles and actively participating in writing responses to questions and comments posed by other members of the online community. As group members write their responses they present emerging concepts and relate those to previously held ideas. As others respond to their postings ideas are clarified and refined. Over time the group members each take control and push the thinking and interaction of the group as a whole to a new level as knowledge is constructed through discussion.

6. THE GROUP FACILITATOR'S ROLE IN BUILDING AND MAINTAINING COMMUNITY

As noted previously, if the online environment is to move from simply knowledge dissemination towards a supportive community of practice, the facilitator plays a key role. First, a supportive learning environment must be established. Creating that environment demands a substantial time commitment that permits reflection and thoughtful responses. The facilitator establishes a series of topics in the conference area, some of which may be related to web content and some of which may arise from particular readings that members share. Each of these topics may have a defined start and end date to focus discussion. Interaction is fostered initially by the facilitator who starts the process to enable each member to share ideas, be supported and to learn. Since in an online community, discussion takes place across time and space, participants bring experiences from widely spaced communities to bear on the talk. Rich and Woolfe (2001) point out that in order to generate a socially integrated learning community, the facilitator has to help community members recognize that they are interacting with real human beings at the other end of the computer. By encouraging comments on each other's posts and occasionally summarizing the discussion, the facilitator makes the discussion more interactive and real.

The facilitator also has to recognize that electronic discourse in the virtual community has embedded within it a set of possibilities and limitations. For some, fear of writing ideas and exposing them in a semi-public forum can be an inhibiting factor that may cause them to lurk rather than get involved in the community. Expecting regular interaction and modelling the types of discourse expected, the facilitator can alleviate any initial fears. Ideally for a community of practice to develop, online expectations need to be established. For example, if a face-to-face community meets once a week, members of the virtual community should be expected to participate in virtual discussion once a week. Once those expectations are in place the group has a greater likelihood of being successful in becoming a community of practice.

As virtual community members write their responses to each other, they select words to represent their emerging understand of the issue at hand and relate those emerging concepts to ones already held. When others respond to their postings, emerging thoughts and ideas may be reconstructed to take in new information. Meaning is negotiated, a sustained history of practice is created and members can let each other know about opportunities for ongoing development. New members to the community infuse it with alternative practices and knowledge and at the same time learn from the established members about the practices of the past. The tension between new and established forms of knowledge creates a dynamic learning community. Wenger (1998) has suggested that any creative work requires personal investment and social energy. We have suggested that the online community of practice, if facilitated appropriately, can provide a space for personal investment and social energy that can enrich lives of participants and become a site for knowledge construction.

7. WHAT CHARACTERIZES EFFECTIVE VIRTUAL COMMUNITY-BUILDING INTERACTION?

In order to sense real people in the virtual world, group members need to have opportunities to see themselves reflected in the others online. Establishing commonalities creates the sense of ‘others like me’ and sets the groundwork for later discussion of difficult concepts or complex ideas. One way of establishing commonalities is the creation of a topic that is devoted to learning about community members. In many of the contexts we have researched this common area is called a bistro. The facilitator’s modelling establishes the tone and the type of language used. For example the first post by the facilitator might look something like this:

> Hi, and welcome to our online community. Grab a cup of coffee and get to know the other members of our community.

The facilitator then goes on to say:

> Welcome. I have been involved with early childhood education for more years than I would like to tell you. My interest is both professional and personal since as a mom I raised three children and hope to someday be a grandmother—to something other than a puppy. I have been involved in CAYC and presently teach courses in early childhood in the public school through my work at a faculty of education.

The first post is a key one because it opens the possibility for non-threatening discussion and we know that as human beings we are interested in the personal lives, work and worlds of others. Once the introductions have been made the conversation needs to be sustained through the use of immediacy statements. Such statements comment on what is currently happening in the online discussion. For example, in one of the communities we studied a post read, “Wow! People with lives. . . babies, puppies, gardens and all of us interested in teaching.” The community member who made that post went on to comment on the previous nineteen posts prompting another community member to write,

> I am really looking forward to getting to know everyone. Has anyone here read Vivian Paley? I heard that she has a new book and can’t remember the title.

The immediacy of her statement cued other members to ask for assistance and interact around their own social and professional needs.

To build an effective community of practice, the facilitator uses probes to further the discussion and get more information into the community context. Bringing additional information, challenges or different perspectives into the group forum helps the members build knowledge. For example,

> Paley worked out of the University of Chicago preschool. It seems to me that some of her observations of children's language have much to tell us about the ways in which good teachers interact with children. I wonder how her observational research into children's language complements some of the more structured data that some researchers are interested in.

This probe builds on a question raised before, adds some additional information and encourages community members to think about different approaches to research with young children. Rather than imposing information on the group, the question encourages group members to take ownership and think about the questions for themselves. The probes could also be accompanied by a link to Paley's website and another link to a site in which a different type of language research is conducted. Essentially, the facilitator is modelling effective interaction for knowledge construction.

There are times too when group members and the facilitator must challenge perspectives presented in the discussion. Challenges take various forms and may include several different viewpoints that drive the discussion from a surface level to one where insight and new learning can occur. They are an important part of the repertoire of discursive practices in an online environment. The facilitator or another community member may suggest something like:

> The website suggests that early years' teachers should respect ESL students' first language and culture. Some of you have provided examples of first languages and cultures clashing in the classroom. You have noted that when these biases are there you often wonder whether there should not be a place for a Canadian language and culture. How might we be sensitive and reconcile these issues as we work with the children in our care?

Participants have the opportunity (and time in an asynchronous environment) to first reflect upon the discussion, and then extend their ideas, thinking about the issues that inform their practice. By referencing the website, the facilitator encourages members to read further and draw on information from the site for further reflection and dialogue. Community members eventually construct their own knowledge within the learning environment. Their knowledge is not borrowed from the website but through thoughtful interaction is constructed through personal and social experience, informed by external sources.

8. IN WHAT WAYS CAN VIRTUAL COMMUNICATION ENHANCE PARTICIPANTS' GROWTH?

As participants enter 'enunciative space', they are more likely to shed institutional 'cover stories' (Connelly & Clandinin, 1999) and have in-depth conversations that deal with their concerns, their fears and their feelings of vulnerability and inadequacy. For example, teaching all children to read adequately can be a monumental task, and some children (and their particular ways of learning) can challenge even the most successful, seasoned and dedicated teachers. Recognizing and facing these challenges and concerns in a supportive group of peers allows fears to be voiced and enables movement beyond them to develop strategies to cope with feelings around a lack of competency. In turn, participating in professional dialogue with others works to develop a culture of professional respect.

Developing knowledge, in the 'wisdom of practice' sense that Shulman describes is achieved through a dynamic process of negotiation: "of continuous interaction, of gradual achievement, and of give-and-take" (Wenger, 1998: 53). A significant level of intimacy and knowledge about the professional practices of the participants is achieved when the virtual community develops.

Perhaps because participants depended solely upon written language to communicate, they are obliged to lay their practice out (and in many cases this includes their struggles) in ways that allows it to be viewed, understood and critiqued by others. In some virtual communities, many report that this to be the first time they had looked closely at their own practice or had acknowledged what was not going well. The resulting scrutiny goes beyond the pedagogic model of reasoning Shulman (1987, 2004) proposed and Schön's (1983) reflection-in-action. When reflection is made public in the virtual environment, the participants' reasoning and reflection evolves into a more complex fluid process that generates a deeper understanding that is capable of leading to transformative change. A virtual community of practice can create a culture of professional respect.

Wenger's social theory of learning functions in the virtual community of practice in a way that encourages shifts in practitioners' attitudes, knowledge and identity. The components in the virtual learning community are:

1. *Making Meaning*: enables members to individually and collectively experience their lives and the world as meaningful.
2. *Discussing Practice*: provides members a way to talk about their shared historical and social resources, frameworks, and perspectives that sustain mutual engagement in action.

3. *Growing into a Community*: members become a community as the social configurations of their practice and their group is seen as worth pursuing and helping us gain competence as professional persons.
4. *Reformulating Identity*: participation in the virtual community provides a space for talking about how learning changes who we are and reshapes our personal histories within the context of our communities (adapted from Wenger, 1998: 5).

Participation in a virtual community of practice causes a shift from a singular identity, to a more complex and dynamic one. Viewing practice in critical complex ways, through the eyes of their colleagues' and facilitators' contributes to that shift in identity from a technical worker, to a more expansive identity of a professional. As 'Roz' reflects,

> I find my own strengths as a teacher lie in my ability to accumulate and connect resources and ideas and integrate them across the spectrum of my teaching, however needs assessment and evaluation are areas I need work on. I think my greatest challenge ahead will be figuring out what does and doesn't work and finding a tangible means to measure it. Whereas I would have included myself among those teachers uncomfortable with the word 'teacher researcher', I see that to ask these questions and seek the answers are on the path to becoming what it means to be professional. It's an exciting journey.

This shift is important, as community members become more aware of their professional responsibilities to act, rather than simply to accept knowledge uncritically. Virtual communities of practice also encourage participants to find their 'voices', respect the voices of others and begin to take risks in their thinking and in their professional lives. Finding voice, and having opportunities to talk (write) through thinking has long been recognized as a pedagogically significant practice for learners. The mutual respect that evolves as members enter the enunciative space of the community allows them to step back and rethink their own practice as viewed through the eyes of colleagues. When online courses are designed to evolve into a virtual community of practice they provide opportunities for members to engage in transformative learning.

9. CONCLUSION

Just as the conception of what it is to be a professional teacher has profound implications for courses and programs, the way in which the virtual learning environment is conceptualized has similar repercussions to the courses and programs developed.

If the virtual learning environment is conceptualized merely as a vehicle for a teacher as disseminator of information then the technology and supports developed will ensure just that. Course content will be pasted into technical environments that students can access. Virtual contact with the instructor will be minimal. Assessment will depend largely on the technological tools available (i.e., electronic quizzes), rather than what may be pedagogically sound practice. The role of the instructor in this scenario is likened to that of a tutor, with participation reduced to posting announcements, clarifying instructions and responding to e-mail.

Alternatively, if the virtual learning environment is conceptualized as a site for knowledge construction, then the ways in which it is supported and designed are significantly different. The focus remains fixed on pedagogy and building learning communities. The technology responds and evolves to address those needs. Instructors/Faculty are not in place to simply manage and assess, but are invested in developing a meaningful learning environment in which they also engage intellectually in the learning and knowledge construction.

Decisions around the implementation and use of virtual learning environments are influenced and informed by political and economic factors, and often to a lesser extent, pedagogical considerations. We believe that in order to sustain the momentum experienced by many early adopters, attention to pedagogy must move to the forefront. Unless the virtual learning environment becomes an effective community of professional practice where enunciative space is created for participants to learn and grow and re-energize, technological saturation and fatigue will set in. The convenience of distance education that may have initially attracted participants to a virtual learning environment may be abandoned for something more intellectually, socially and creatively satisfying.

Further research is needed to understand this more fully. It is difficult to imagine how we can expect participants in virtual learning environments to apply their knowledge and understanding in new and innovative ways in the workplace, if we do not create such environments for them to grow professionally. We hearken back to Senge's challenge to learning organizations, to build

> . . . organizations where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together.
>
> (Senge, 1990: 1)

It is a notion worth revisiting. In virtual learning environments, students are already separated by time and distance. When institutions (under pressure to 'get online') design and develop courses without the necessary thought, infrastructure and planning required to create appropriate conditions for learning in a virtual environment, they are in essence creating electronic tools and appliances that *virtually sabotage* transformational learning. Those of us working in the field where virtual learning environments are being considered, have a responsibility to our institutions, and more importantly to our students, to ensure that the appropriate conditions for meaningful and engaging learning are met.

Chapter 23: Increasing the Democratic Value of Research through Professional Virtual Learning Environments (VLEs)

LISA KORTEWEG* AND JANE MITCHELL†
*Lakehead University, Ontario, Canada
†Monash University, Melbourne, Australia

> "... if it (the internet) remains acephalous, then the abundance of information will be such that you will desperately need a filter ... some professional filter. So you will ask somebody ... an information consultant ... to be your gatekeeper!"
>
> (Eco, 1995)

One of the many promises ascribed to the internet is its potential contribution to the intellectual and the democratic life of the wired nation and the educational community (Burbules & Casllister, 2000; Barrell, 2001; Pea, 1998, 1999). We examine this potential as it is focused on the development of an education portal or a Virtual Learning Environment (VLE) that would serve teachers and researchers in the field of education. John Willinsky (2000, 2002) contends that an education portal needs "to consider how turning educational research into a more accessible public resource can further the connection between democracy and education." An education portal that seeks to serve a larger public must pursue the goal of making more research accessible by "publishing open-access scholarly resources in an easily managed and well-indexed form" (2002). Another expression of this approach to increased e-democracy is Phil Agre's (2001) contention that the purpose of web tools is to support the intellectual life of society:

> Although the cultural language of intellectual community among non-intellectuals is not yet well-developed, internet discussion forums have obviously provided a generation of experiments in that direction. Ideally this should lead to a new kind of social (democratic) mobility: the continual building and rebuilding of intellectual community that aligns with individuals' unfolding intellectual lives. (p. 294)

If we understand the intellectual life as one where a person has questions, thinks about them and pursues them, then it is supporting and extending these democratic functions of teachers' professional lives that concerns this project.

One dramatic, quickly escalating use of the internet for democratic participation is the access of health research and information by patients and their families. A recent figure quoted by the University of Toronto's Continuing

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 581–608.

Medicine's Knowledge Transfer Project is that 58% of GPs have been approached by at least one patient with internet healthcare information and 65% of this information was new to the GPs (Wilson, 1999). The internet is a democratic means for patients to alter their knowledge relationship with their doctors.

Part of this democratic potential of the internet is its ability to post and broadcast on a global basis. The knowledge technologies developed for medical research, such as PubMed, have enabled people to come, locate, and read articles, and use them in their encounters with their doctors. The central question for our research as part of the Public Knowledge Project (PKP) at the University of British Columbia is how can we build and achieve this type of portal tool or VLE for educational research? How could we make educational research knowledge move in the same way as medical research on the internet to democratize educational encounters (parent to school district, student to teacher, teacher to researcher)?

We know that there are many real or manufactured problems in education publicized by the media. There are kids who cannot read, kids who drop out of high school and there are computers sitting in closets rarely used in the classroom (Cuban, 2001). There is also a significant amount of important substantial educational research produced every year that addresses and informs these educational crises. Yet, there are no signs that the public is taking up the cause for reading and discussing educational research, as it is with medical research. In our study, we believed we could increase public engagement with educational research if we built the right tool, the right VLE, to support the reading, discussing, and use of research by teachers and others education stakeholders.

We pursued this idea based on a conception of education where individuals explore resources freely in large multimedia databases, matching their perceived needs and interests to easily accessible research. The public users transform and synthesize this information for particular democratic purposes. The results of their intellectual work would then evaluated by themselves and others when negotiating terms of agreement in their educational encounters. We pursued an admittedly utopian vision in which teachers and interested groups, such as parents, would pursue answers to their educational questions and problems by turning to educational portals or VLEs on the internet. The design assumption was that after reading, they would want to discuss what they have found and what they have experienced. If teachers and the public do not read and discuss, then they are just caught in the world of popular prejudices. Read and discuss is the democratic antidote. Reading and discussing research is the intellectual means by which citizens can participate online in a greater democratic education system (see Herman & Mandell, 2000; Noveck, 2005; Dahlberg, 2001).

Our two PKP projects, which we will detail below, attempted to achieve this democratic participation for two groups of teachers. We set out to test what would happen if we gave teachers easy access to research on the topic of the social impact of educational technologies. To move academic research more thoroughly into the public domain is to create a substantial alternative source of public information. In each situation, we put most of our energies into a tool for delivering this public information, into making and constituting a database of filtered educational research that addresses questions, problems, and crises of educational technology. We, as part of the PKP research consortium, decided to create experiments that would attempt to increase public participation in educational research access, if not necessarily to the degree that is occurring in health research portals. However, our discovery is that ideas and knowledge, once made available, do not tend to circulate without additional support, even in well-managed, freely accessible technological environments, such as our two examples of VLEs. Our important discovery is that people, those with special skills called intermediaries, are needed to move these ideas and knowledge. Machines alone cannot do it.

Educational researchers know a lot about education but their research just does not travel that well out of a research archive or database. We need teacher-intermediaries who have exemplar local stories and who know how to engage fellow practitioners in intellectual conversation in order to pass on advice that is research-informed. From a teacher's point of view, such translators of knowledge or intermediaries are extremely useful. Much more than most professors or academics, they offer shared concrete experience and application into a classroom context for the teacher participants in VLEs.

We need to examine two strands of publication through the internet: the way in which web-based technology can broaden and broadcast the professional and the public value of educational research texts as well as what intellectually occurs when an educational researcher or teacher-educator enters into electronic discussion with teachers. The possibility exists that researchers can publicize their intellectual practices and influence more of the public in what is still a very public and malleable forum, the internet.

The policy entrepreneur adopts conventions of the media to make knowledge move, in order to get covered on the front page. At the same time that we want research knowledge to move into the teacher world of practice, we are going to have to figure out the conventions of teacher understanding and teacher reception of ideas. Teacher-educator intermediaries are beginning to find themselves in a position to figure this out. They are beginning to adapt academic knowledge so that it can travel into the teacher realm to make it work. As good public intellectuals, located in the university but speaking to the public on critical issues, they also know how to make knowledge move. They work as a kind of translator who makes insights and perspectives of intellectual and professional work accessible, meaningful, and relevant to as broad an audience as possible.

According to the political philosophers, Gutmann and Thompson (1996, as cited in Willinsky, 2002), the public needs to learn more about how to participate in deliberative democracy in the following ways: "to justify one's own actions, to criticize the actions of one's fellow citizens, and to respond to their justifications and criticisms" (p. 65). Willinsky argues that scholarly publishing through the internet (in portals or VLEs) could do more to help people turn to research and discuss documents in this critical democratic fashion. But he adds that if we are to cultivate these critical abilities, it "will fall to the schools to teach new lessons on locating and drawing on intellectual resources that best serve these processes of justification and criticism." (Willinsky, 2002).

Our central question in this paper is who is teaching teachers to locate and draw on intellectual resources to clarify the implications and consequences of their teaching? Who is modeling for or working with teachers on these new methods of intellectual participation through the internet? In our two case studies, we determined that it is teacher-educator intermediaries who are teaching teachers this type of intellectual engagement and social competency.

The current organization of schools does not provide teachers with the opportunities necessary to foster intellectual engagement in questions and issues arising from their practice. There are few, if any, available structures or time for sustained intellectual investigations, networks, or collaborations. The need and recognition of teachers as researchers (Cochran-Smith & Lytle, 1993; Grumet, 1990) and intellectuals (Giroux, 1988; Giroux & Shannon, 1997) have been offered in the literature but a palpable schism remains between the two institutions of schools and universities. There has been established in the research literature a clear disjunction between the educational research and the professional learning and experiences of teachers (Gore, 2001; Tom, 1997). In our study, we endeavored to examine whether an online environment and integrated digital resources could assist teachers and researchers to make connections between research and practice in ways that might extend their understanding of, in these cases, educational technology in schools. In our analysis, we sought to test and improve the accessibility and the utility of scholarly research using electronic infrastructure and knowledge management strategies (see Willinsky, 1999; 2000). After developing and implementing tools for accessing scholarship by teacher audiences, we believe it is an opportune moment to return to reflect on the primary question of what exactly is the purpose of a teacher professional portal or VLE, or, for that matter, what is the purpose of any educational portal?

The chapter describes and presents the findings from a qualitative comparison of two case studies of teachers and researchers in electronic discussion. Both groups were consulting a large digital library of electronically accessible research texts in order to participate in a threaded discussion. In both discussions, located in two different VLE platforms, academic-researchers participated in the role of guest moderator or expert leader to the discussion forum. The results of this study are based on data gathered between November 1999 and March 2000 for the first case study discussion and between August 2000 and February 2003 for the second case study.

In our analysis, we focus on ways in which teachers grapple with new technology, how teachers reflect on the educational implications of these new tools through access to research inside VLEs, and the degree to which the technology enables them to extend their professional learning and make connections between research and practice.

1. VLE #1: PKP—PRE-SERVICE TEACHER EDUCATION*

The first PKP prototype was used in a pre-service teacher education context. This PKP prototype was a repository for resources concerned with educational technology. When first launched, the prototype linked to a series of feature articles about technology and education in the *Vancouver Sun* newspaper. In this educational situation, we worked with one instructor and the 39 student teachers in a cohort to establish an online discussion that was an assigned, credit task in an Education Studies (social foundations) course. We took an active role in this curricular situation, working with the instructor to design the task, introduce students to available electronic resources, and coordinate and participate in the online discussion.

The purpose of the "Ed. Studies Online" task was to provide a forum for students to consider the ways in which access to and uses of computer technology in schools intersected with social background and types of educational opportunity. The task set for students was to identify what they saw as crucial equity issues pertaining to technology and education and to determine action that schools and teachers can take in relation to these issues. The task asked students to bring a critical perspective, as well as some ideas for action, to an educational problem that is often based on polarized conceptions of the benefits and the drawbacks of technology. The task required students to consider the issues in a structured, electronic bulletin board discussion. Participants could draw on the PKP database to inform their ideas.

Six people external to the cohort also participated in the discussions. These people had different backgrounds and included one schoolteacher working in a local school district, a district technology consultant, but mostly, academics and graduate students working within universities. The external participants all had expertise in educational technology and/or teacher education. It was hoped that the external participants would broaden the professional scope of the discussion, and provide students with an opportunity to communicate directly with researchers, practitioners, and policy makers.

Seven discussion forums were created on an electronic bulletin board. Each forum had six students and one external participant. The forums were "public" to those with access to the bulletin board site and students were encouraged

* Some date from this case study was originally published in Mitchell, J. (2003) Online writing: a link to learning in a teacher education program. *Teaching and Teacher Education*. 19(1), 127–143.

to read and contribute to other forums. Students were required to make a minimum of four contributions over a 7-week period. This 7 weeks comprised of 3 weeks of campus-based classes, 1 week of class-free, and 3 weeks of practicum. The guidelines for contributions were that students be succinct and address the topic; draw on web-based resources to support and provide evidence for ideas; and build on and respond to the ideas raised by other participants.

Each group chose a topic for discussion. Across the discussion forums the following topics/themes were considered: gender equity and technology; social class and technology inequities; funding for computers in schools, especially the ethics of private funding; teacher education and technology and the way that this affects educational opportunities for students; and the moral dimension of children's access to the internet. For all of these issues, there was substantial number of resources available in the PKP website.

The participants in the forum discussed in this chapter, examined issues related to technology, gender, and equity in schools. We focus our analysis on this one discussion forum because it provided clear examples of ways in which the participants used the technology to connect the research literature with their personal experience, campus-based coursework, and professional practice. It is of note that the connections that students were able to make between experience and research in this forum were more consistent and uniform than the connections made in the other forums, a point we discuss later in the paper.

The following was the first student contribution to the gender, technology, and equity discussion.

```
In the GenTech Research Findings Final Report by Bryson and
de Castell (1998), they stated "evidence from research
on gender and access to, and uses of, new information
technologies (NIT's) indicates that in public schools,
female staff and students (in comparison to male students)
are: (a) disenfranchised with respect to access and kind of
usage, (b) less likely to acquire technological competence,
and (c) likely to be discouraged from assuming a leadership
role in this domain." It is obvious from the references
cited in this article that there is a lot of research
out there regarding this statement. I think it would be
interesting if we discussed any one of the three areas
mentioned. A question that comes to mind is are female
and male users of technology using technology for the same
purposes?
  If you would like to read the final report before
responding, here it is:
  http://www.educ.sfu.ca/gentech/research.html.
```

In this contribution the student made three intellectual moves: she quoted a research summary and identified issues worthy of discussion; she posed a question to other participants by way of starting discussion; and she provided her peers with a reference to the report that she had read, if they wanted further information. Her suggestions and questions assumed that there was more to know about this topic and that research may shed light on these issues.

Responses to this opening comment noted that typical patterns of technology use often exclude girls. These students' comments stemmed from articles and reports that they had found on the web. One student drew on a PKP resource to illustrate strategies to encourage girls to use the computer, such as Barbie Doll software.

> Barbie is trying to change this situation. They have come out with Barbie software to market to the 6 to 16 girls market. What do you feel about this type of software for girls? Here is one quote from the article I read: "Anything that develops computer skills is good," says Julie Sheridan-Eng. "Even if it's just point and clicking; they don't feel intimidated by it." PKP site: http://www.pkp.ubc.ca/sun/gender/issues/index. html.
>
> *Source:* http://www.electronic-school.com/0697f1.html.

The above comment drew three responses including one by Caroline, the external participant. Caroline was a technology and resource teacher in an elementary school. In her response she presented her point of view on the Barbie Doll software:

> Why Barbie for heaven's sake? The woman whose body proportions are so out of whack to be laughable, who has never in her fifty year lifespan had a career and who devotes herself completely to fashion.... Unlike the teacher quoted in the article, this software is not something that I could ever -- in good conscience -- present to a girl in my classroom. I think the Barbie-as-airhead message undoes any of the perceived good gained by just "pointing and clicking".

Caroline rejects the argument that any use of technology is acceptable and she ties it to her own perspective in the classroom. This connection serves to contextualize the discussion and adds a critical democratic dimension.

Another part of Caroline's contribution outlined her experiences with technology and her interests in technology and gender issues. Caroline was familiar with the research conducted by Bryson and de Castell and had participated in some of their research projects conducted in schools. Thus, Caroline used this experience to make a connection to the opening comment in the discussion.

```
My understanding of the ideas developed by Bryson and de
Castell helped me to acknowledge the power imbalance that
exists around girls and technology, and I tried to ensure
that this imbalance did not prevail in my classroom.
```

Caroline's comment provides a demonstration of ways in which a teacher can draw on research to inform classroom practice. In acknowledging Bryson and de Castell's influence on her thinking, Caroline identified power issues as being central to technology use and gender. This brought an obvious political dimension to the discussion that linked neatly with the social justice themes embedded in the Education Studies course.

The excerpt from the discussion below illustrates how one student extended the comments made by Caroline. In this case, the student worked to build ideas and connect research with experience. In the first instance, she made a link to a web-resource by way of agreeing with Caroline on Barbie Doll software and supporting her own opinion.

```
I agree with your opinion on the Barbie software. I
feel the girls may be interested in it because the
majority of them have been exposed to her since they can
remember. I believe if girls are introduced to software
that is engaging and thought provoking, presented in
an interesting package, they would be excited about
technology. After all, on the following website,
http://www.pkp.ubc.ca/sun/gender/issues/index.html, in
the article called Gender, Computing and Kids, it is
stated that "girls often use computers to accomplish a
goal", not just for the sake of interacting with Barbie for
example.
Source: http://www-cse.stanford.edu/classes/cs201/Projects/
gender-gap-in-education/page5.htm.
```

The student also extended the discussion by asking questions about the experiences of other participants.

```
Have any of you observed situations in your classrooms
where you felt the software was appealing to both genders?
Did you observe one gender playing more than focussing on
the task at hand?
```

The questions provided participants with an opportunity to corroborate their experiences with one another, and with the research literature they had been reading.

The student also asked Caroline some questions about power and the classroom strategies she employed in acknowledging power.

```
Caroline, I am also interested in hearing about the
specific changes you made to your teaching style and the
selection of models and mentors you made in your classroom.
Also who did you allow access to in the computer lab at
lunch and recess? Did you permit those students who showed
initiative and productive working habits, or did you allow
access to those who did not have computers at home? What
were your strategies because as a pre-service teacher,
I am not all that confident I would recognise the power
imbalance you are talking about.
```

In responding Caroline talked about her position as a technology teacher and the strategies she employs to disperse and develop expertise.

```
During class time I intentionally pulled together small
groups of girls and taught them one new skill, then asked
a question like, "I wonder how you could use this in your
report?" and walked away. Similarly I selected groups of
students (boys and girls both) and made them experts in
the use of specialised hardware like the digital camera,
projection unit and the scanner. When other children
needed to use one of these extras for their work, the class
experts were the designated mentors.
```

In outlining her theories of practice, Caroline acted as a mediator for some of the research ideas presented by Bryson and de Castell. On the basis of this discussion, one student predicted how these ideas would link to her upcoming practicum experience.

```
I am going to be teaching computers in my practicum next
week, so I will be conscious of the power struggles that
may be going on, and how I can help facilitate a more
equitable environment.
```

When we interviewed students involved in this discussion, they noted the value of the PKP site, and the factors that enabled them to make connections between the electronic resources/discussion and the school experience. With respect to PKP they made the following observations: "It just kind of backed things up and I think it helped me formulate my argument too. Like I was not exactly sure how I would feel on some things and then when I did the research I found things that I could connect with and then that added to my argument".[1]

With respect to factors that enabled connections students noted two key points: the topic and Caroline's contribution. Regarding gender they noted "it is in every classroom—you can see it everyday". Regarding the external participant they said, "Caroline talked about Bryson and de Castell's work . . . and then that kind of linked to what we found on some of the websites". Further, "Our person was Caroline and she knew so much about the topic we chose. So it was incredible, she had such practical information and feedback that was immediate". These connections highlight ways in which a useful teaching and learning dynamic developed in this medium. Student teachers had an opportunity to talk to a practitioner about some research. In this case, the teacher linked key concepts from the research to her classroom practice. This assisted student teachers to connect the ideas raised in the discussion to their own experiences, develop a point of view on an important educational issue, and construct a set of classroom strategies that respond to their concerns.

2. VLE #2: EdX—INSERVICE TEACHER EDUCATION

The second VLE prototype developed by the PKP, known as EdX or the Educators' Exchange, was a knowledge management system tailored specifically for a professional diploma program for inservice, experienced teachers. The 2-year, 30-credit university administered program was designed for teachers to learn how to enhance teaching through the integration of educational information technologies. The program is conducted in schools and credits are gained by teachers conducting self-study, action research projects investigating their own learning and teaching with new technologies. The program combines two face-to-face summer institutes with self-study during the rest of the year. The teachers' learning and progress are monitored and supported by a mentor, a teacher-leader in technology, jointly hired by the district and the university instructor. Every teacher is a member of a mentor's group that is composed of seven to eight teachers. In this particular study group, the program cohort numbered 100 teachers and 14 mentors in a suburban school district of a large metropolitan city.

Unlike most university teacher professional diploma or certificate programs, this program is structured around teachers' designing their own challenges and field studies that they implement and conduct in their classrooms. Each assignment revolves around a technological tool or application and its educational value to the teacher and the students in its classroom or curriculum use. Each assignment can be an odyssey into making a tool or application technically function in the classroom or school lab but the university instructor also consciously emphasized that the educational value must be considered. The program culminates in a demonstration festival in the third summer institute where teachers display their competencies learned through the various projects or they can expound upon one particular meaningful and valuable project in detail.

The teachers in this specialization program needed to decide what they would take and learn of the technology in order to compliment, emphasize, or challenge what they were practicing or questioning in the classroom. The means in which they were to determine their projects, the technical steps and the reflections on the educational purpose of the technologies, were in consultation with a teacher-leader or their mentor of technology. The means for the mentor to respond supportively and resourcefully to their teacher-mentees was (ideally) to consult the field, to consult the literature and resources that would speak to, inform and guide the individual teacher questioning technology and its meaningful integration in schools. The resource base for this program and mentor support was a VLE called the Educators' Exchange (or EdX).

EdX, the knowledge management tool modified specifically for the technology diploma program and its challenges of distributed delivery, was tailored to give the teachers and the mentors as much intellectual or knowledge support as possible. EdX provided many tools for sharing knowledge and resources, for posting user profiles to build recognition and a sense of community, for participating in online discussions, and for searching and locating useful resources recommended and uploaded by other users in the system. It was the most sophisticated and expensive knowledge management system that the PKP had yet produced.

3. USING EdX

The participation by the mentors and the teacher-mentees on EdX was completely voluntary with no reward of credits or program recognition as a technological application for project work. Every discussion that occurred in EdX or resources that were contributed by the users were intended for lifelong learning and the users' own intellectual curiosity. The institutional setting did not support the users spending time on EdX in the manner that corporate settings might recognize and reward employees for contributing to or participating in designated knowledge management systems. This incentive issue became one of the greatest obstacles for EdX as well as one of its greatest virtues. EdX was an instrument for intellectual pursuits as part of one's lifelong learning or democratic participation in education.

Perhaps needless to say, without explicit incentives or rewards, very few mentors in the diploma program made the effort to encourage their mentees to participate in discussions, or, made the effort themselves to contribute resources to the shared digital library inside EdX. The mentors did not use the tool as a means to overcome the distributed nature and the distance between themselves and their mentees. Many mentors complained over the course of the 2 years that they rarely saw or communicated with the teacher-mentees except at demonstration time when assessing credits. However, there was one mentor who contributed resources, initiated EdX discussions and, through her modeling and enthusiasm, convinced a core group of her mentees to participate in several EdX discussions. This mentor, Deborah, invited Lisa (author 1) to work-in-progress sessions of her teacher group at different points in the diploma program, as well as to final demonstrations of her mentees' competencies earned through their projects, and to participate in some of the online discussions.

Deborah was different and distinct from the other 13 mentors in the program due to a variety of factors. Deborah was one of only three female mentors. She did not identify as closely with the technology as the other mentors; she was committed to teaching primary grades; she believed in the increased expression of children's ideas, creativity, and imagination through artistic and multimedia representations; and she was the only mentor who had sought and completed a Masters degree at a large education graduate school. Deborah was certainly intellectually engaged in her teaching.

There were two other mentors out of the group of 14 who did contribute resources to the shared content repository of EdX, but who did not attempt to create any online discussions with their mentee groups. Deborah and her group became the case study of this VLE as they were participatory in their very use of the tool. We do not wish to emphasize this case study as an individual anomaly, a rare heroic act of individualism that leaves our question of the purpose of education portals or VLEs at an individual level of analysis. The case of Deborah's group (being the only one out of a cohort of the 14 mentor groups to actively participate in EdX) demonstrates how the institutional apparatus of the course, the credits, the incentives, and the rewards, can make a significant difference in the implementation and use of the tool. The importance of these institutional motivators (such as marks) is dramatic when we compare the rate of participation of EdX with our first case study of Ed. Studies Online.

The organizational support of the EdX implementation was one that the majority of mentors recognized and quickly ascertained as unsustainable. They understood that new IT applications would quickly disappear if not bought, endorsed, and supported at the school district level. They recognized the rippling effects that a tool of this sophistication would cause and the requirement of hours to themselves, and, in support of their mentees, to learn to navigate it effortlessly and effectively. They intuitively understood that their individual costs of time and effort would not be matched by any organizational commitment by the district. They knew there would be no rewards. And they became reluctant indeed! And their reluctance matched the reluctance of the university instructor to institutionally locate and support the tool through diploma credits. And this reluctance was matched by the school district administration who were reluctant to endorse or even mention a prototype that was not their product of choice or purchase.

Despite these conditions of reluctance surrounding her, Deborah still saw significant intellectual value in the use of EdX for her teacher-mentees' learning, expansion of ideas, and support for the articulation of their questions and project formulation. The EdX-VLE matched Deborah's definition of what intellectual support she needed as a mentor and the need for a knowledge network in her work as a teacher-educator.

The three discussions that Deborah initiated on EdX and moderated were all similar in form. Deborah would initiate the discussion and set it up in the EdX system. She would select the topic and open the conversation with a statement or questions. She would also reference electronic documents to support and footnote the conversation.

In one discussion, echoing an objective and competency of the diploma program, Deborah wanted the teacher-mentees to engage in ongoing reflection on the educational purpose of technology. She wanted to counterbalance the tendency and tone in this and many educational technology programs of a concentrated focus on technical skills. In this first discussion, Deborah lists 11 prompter questions that she believes will be useful as a template for the teacher-mentees to engage in a depth of reflection on the learning rather than skill acquisition.

Discussion: *Creating an overall reflection of your learning this first Term.*

Deborah, October 19, 2000

SUMMARY: Here are some questions to ask yourself when you are beginning to plan how to submit a synthesis of your learning this first term.

Deborah: Questions to think about.
What competencies have you addressed?

What proof do you have of these competencies?
Summarize what you have learned, i.e., How has the learning gone beyond technology?
How did I learn? The processes.
Why is this learning important to me? This is an educational purpose.
What am I planning to focus on next?
Am I ready to begin a draft of my new Learning Plan?
Is there an educational purpose to my next learning Plan?
How would you evaluate the quality of your learning?
What criteria have you set to assess your quality of learning?
What did you learn as a technology user?
Lots to think of. Now is the time to begin drawing your first term's work to a close. Don't Panic, though!!!
We will talk about all this next Thursday from 4--6. We could go later and go out for dinner or have pizza in.
I'm looking forward to learning so much myself from all your Journeys. I know we could all benefit from group presentations.

REPLY: Jay

The first part of this journey has gone so quickly. As I ponder the questions posed, my mind is full of ideas and comments. I think it would be helpful as a group, if we discussed some of these questions at our next meeting. (That is probably your plan.) It is helpful to know that our thoughts are shared or supported within our group. I'm looking forward to sharing these ideas and learn more from our group. Jay

REPLY: Deborah

I have always found ending a project is more like a gateway to a new one! I hope that everyone has enjoyed their first term journey. The Horizon's conference is great! Meeting, talking and sharing with people is always such a wonderful learning experience. See you
Thursday!
Deborah

Deborah helped the teacher-mentees realize that reflection is an ongoing process and that it can be optimized in a social collaborative setting. Deborah and her teacher-mentees believed in the give-and-take of ideas in their collaborative face-to-face settings. This teacher-mentee states the appreciation of this process and locates her own examination on how she best reflects.

```
TOPIC: Reflection

Bettee
As always after conferencing with you Deborah, I leave
filled with many more possibilities. I'm realizing that
reflection time is just as important as engaging in the
"task". Tonight I've been sitting with my thoughts and
thinking of ways to deliver my group presentation). I
forget that the creative process does take time and
like art, it usually comes together when I am relaxed
and 'playing' with my ideas and having fun. As far as
discussion topics? I would still love to look at your
kidpix (cdrom) presentation given the server did not
cooperate that day. I just love a presentation to get the
juices flowin for others. Group discussion from viewing
your work would be beneficial...
```

In another discussion, other documents were referred to that existed in the EdX content repository. Users had the ability to insert the hyperlink into the discussion messages. Readers could then click on the link for a view of the document while they were participating in the discussion board. There was no technical need to exit the system or open a new browser window.

```
Since you are a group interested in multimedia, I
thought you might enjoy looking at this article in EdX
Multimedia and Multiple Intelligences Just click on the
underlined title (a hyperlink) and it will take you to
the article. when you are finished reading it, just close
the EdX document window and you will be back in this
discussion.
Good luck to everyone. Lisa

REPLY: Deborah, August 22, 2001 08:22 PM

Lisa, Howard Gardner's work on the Multiple Intelligence
is important research to consider when designing and
implementing new content. Learners learn differently.
Options are important. Much like in this diploma program!

REPLY: Jay, August 23, 2001 02:46 PM

Lisa, Thank you for the time and energy you spent with our
group (Deborah's) in order for us to reach the level of
understanding that we have reached. What a fantastic
program. There is so much that it offers! What a treat
to be in this program and have the opportunity to access
its information. Thanks again! Jay
```

Deborah also used the EdX discussion boards as a means to give a mini-course or just-in-time learning sessions for her teacher-mentees. In this case, the topic was sharing ideas for upcoming field studies, the longer term, in-depth studies of the educational purpose of technology and the social issues arising from the application of tools in classrooms. Deborah began by inviting the mentees to read and visit Ricki Goldman's MERLin site for technical tips and skills for capturing images of students and classrooms immersed in the use of educational technology as well as what a digital ethnographer can do with these images. Deborah was trying to introduce her inservice mentees to the idea of ethnographic research as a means of conducting and framing a field study.

The purpose of sharing collaboratively

SUMMARY

This is a conference where we can discuss our upcoming field studies. We can share and extend ideas. Check out the MERLin site for ideas of how to use digital picts and movies in studies of classrooms.
For details, click here

Projects @Educators' Exchange

The purpose of sharing collaboratively

TOPIC: 2nd year

Deborah, November 27, 2001 08:03 PM

Here are the university instructor's words about field studies for second year. Please refer to the program resources to check how to write up your field study proposal. Lisa said she would look for some sites that may have some ethnographic examples. Download your form. Remember that it must answer an educational question.

```
We are all on the right track, but we need to refine the
wording of field study proposals.

REPLY: Guiding Questions

Lisa Korteweg, December 06, 2001 02:03 PM

Guiding questions to help develop an interest into a
field study may be helpful at this time. Remember, the
distinction of a field study is that it must have an
educational focus and purpose. Deborah and I thought a
field study could be a type of ethnographic research. The
basic point of ethnography is to study and gain insight
into the educational worldview of a group of people or
students through thick descriptions. Common formats for
guiding questions might be:
▪ How do a particular group of students perceive of or
  understand a certain social or cultural phenomenon?
  (This is often seen through behavior of some kind.)
▪ Example: How do active primary students in inner-city
  "Stanton" (fictional name) conceive of and negotiate the
  idea of a computer professional?
▪ How is a certain social or cultural practice socially
  constructed among members of a certain group?
▪ Example: How do students in a computer club control
  access to computers for students at lunch hour? And what
  happens when a new protocol is introduced such as 50% of
  the computers must be occupied by girls?
  I would be happy to help any of you try and answer these
  questions inside your own particular interests.

REPLY: Guiding Questions

Deborah, December 06, 2001 08:10 PM

Lisa, Thank-you for modelling some questions for an
ethnographic field study. I know they will be helpful.

REPLY: Guiding Questions

Janice, December 06, 2001 11:40 PM

Thanks for the sample questions Lisa. I think this will
help me in the wording of my field study question.
```

4. CONNECTING WITH A RESEARCHER AND RESEARCH METHODOLOGY

While these discussions with Deborah's groups were interesting and informative, they did not attain the seminar quality of the Ed. Studies Online case. While Deborah's mentees did some reading, they did not refer directly to articles or resources in their postings. They also did not discuss the readings in any detail, rather, they used the discussion forums to reinforce ideas of supportive and collaborative community.

When Lisa attended the diploma program's final demonstrations festival, she was surprised by the quality and depth of thought given to the educational significance of the technologies in use by the majority of teachers in Deborah's group (as compared to the other mentor group demonstrations). Each demonstration of Deborah's group focused on a situation of children expressing greater cognitive depth than the teacher had encountered in non-technological curriculum situations. Each demonstration concerned projects that integrated art forms with multimedia (KidPix slides by Grade 2 students for a critical thinking exercise to music compositions on the web by Grade 7 students). The group had coalesced around the theme of how to capture young children's thinking and experiences through multimedia images and then, as a teacher-researcher, how to capture images of young children engaged in that exploration/thinking/learning.

One presentation by a teacher-mentee, Janice, from Deborah's group presented us with the realization that online resources and discussions can plant connections between teachers and research texts that are used and implemented in classroom practice. Janice's presentation was a detailed in-depth account of how she attempted to teach her students following the video ethnography framework developed by Ricki Goldman (1998) in her book (and website), *Points of Viewing*.

In interviews with Janice and Deborah subsequent to Janice's final presentation, we discussed how Janice became interested in the ways in which Ricki Goldman's work could be used in her classroom. Janice's classroom is 80% ESL with many new immigrant children in a suburban school. As Janice states: "I'm living with this (*diverse, conflicting cultural representations and images presented by children*) all day long in my teaching." Janice was perplexed and driven by a desire to know "what do these children understand of their lives—some very traditional cultural lives—and at the same time being located in a suburban Canadian school where many different types of cultures and cultural values mix and interact." Through considerable deliberation, Janice worked out with Deborah that what she really wanted to achieve in her field study was to look through her students' eyes, to see the world in their way and from their points of view(ing). Deborah believed Ricki Goldman's work would make an important connection with Janice and could best inform Janice's thinking about these issues for her field study proposal. Deborah brought Goldman's book to the second Summer Institute for Janice to borrow and she referred Janice to Goldman's website, cataloged and accessible through EdX and referenced in one of the online discussions.

Janice's first self-directed assignment after the second summer institute was to present images that children took during a field trip. In Janice's words, the purpose of this field study was "honouring and assessing what children capture as images." Janice wanted to involve her students in meaning-making by imitating the pedagogical promise of Goldman's Constellations model, without access to these sophisticated tools. Janice wanted her students to achieve the following:

- create images;
- speak about their images;
- speak to their own and others' images in textual form;
- give opinions about the other images and how this collective bank of images/representations makes them review the topic or question.

What made the work of Ricki Goldman-Segall (1998) more meaningful for Janice was that she experienced a type of "Theatre de preuve" (a term from the French sociologist/philosopher, Bruno Latour (1987), that refers to a demonstration of proof). Janice experienced Goldman's theories as workable and cognitively successful in a classroom like her own. When Janice attempted to film her students, cloistered away in a quiet hallway, to achieve better sound quality for an i-movie presentation. But the context for the filming resulted in her students not elaborating their ideas, not divulging much detail but rather becoming silent, timid, out of context. However, back in the middle of the classroom activity, the students freely articulated their ideas and comments using the digital tools. For Janice, it was a replica of the situation that Goldman had observed and described in her research with her own students. The intense activity atmosphere created a situation for greater expression by the students as their presentations were recorded. Janice was impressed that Goldman's findings had been replicated in her suburban, multicultural school, and she became convinced of the framework's validity.

What also impressed Janice was the personal–professional connection Deborah had made with Ricki Goldman. Deborah had invited Ricki to her classroom and to accompany her and her students on field trip excursions to sensitive ecological areas. Ricki Goldman did indeed come and it was apparent to Deborah that they shared a similar vision of primary education, multimedia, and artistic representations in the curriculum, and the use of digital tools.

Janice also stated that she appreciated how clear and articulate Deborah was in her interest and focus as a mentor, right from the first day of the first Summer Institute. In an interview, Janice described how the mentor group and Deborah worked well together because they formed a community of practice and interest around the pedagogical purpose of capturing children's representations (whether visual drawing, music composition, or video clips). Deborah's group seemed different from the others because of this expressed interest and intentional purpose in a topic that extended beyond the technical realm. Deborah was also very committed to a vision of teaching that used representations, electronic and artistic, as a means of permitting children's ways of seeing the world. She was a strong advocate of this kind of pedagogical exploration and teaching.

When a community of practice (Wenger, 1998), such as the Deborah mentor group, is centered on a pursuit of practice clearly defined, knowledge/information is received more readily. Members are open to engaging with research on the topic and they attempt to practice it in their classrooms through situated learning (Lave & Wenger, 1991). They take great support from their fellow mentees as they teach in isolation from one another in different schools with different staff cultures. Even though each member's project, topic, grade level, or medium could have been quite different and the subsequent adhering technical problems complicated, the members knew each other's projects intimately and were willing to support each other in the quest to make it a successful experience. Knowledge traveled and knowledge stuck in this community of practice. Members helped each other with analog/digital conversion problems and they encouraged each other to pursue the goal of letting children create their own digital representations of their work, regardless of any technical obstacles. Deborah and Janice brought the ideas of Ricki Goldman to discuss with the group and each member felt reassured that they were going somewhere educationally significant and valuable with their course work with children, rather than simply in their acquisition of technological skills.

5. SIMILARITIES BETWEEN THE CASES: FINDINGS FROM THE COMPARISON OF TWO VLEs

The two cases described above, Ed. Studies Online with Caroline and EdX with Deborah's mentee group, stood out from all the other discussions in each VLE. While each VLE addressed a different community of teachers, pre-service and in-service, they had similarities of purpose and intent. Each VLE was attempting to provide intellectual support to an exploration of issues concerning technology and education. Moreover, both VLEs shared many of the same documents and resources in their resource databases. Each VLE also supported a program of study. In the first case, Ed. Studies Online, it was a social foundations course for the 12-month teacher preparation program. In the second case study, EdX, a 2-year program of action research projects for teachers to increase their technology skills in the classroom and to gain a specialized certificate.

In the first case study, the pre-service participants seemed intent on understanding what could constitute important professional routines in the classroom or the lab. They were curious about the code of practice that teaching could entail. The pre-service teachers were asking Caroline to elaborate on the routines that she was implementing in the school computer lab in order to shuffle and rearrange the gender practices. They wanted to examine alternative routines to what they had experienced as students or had observed as pre-service teachers. In the PKP-VanSun VLE, pre-service teachers were attempting to understand how their previous 5 years of university study would translate into routines of practice in a living classroom. How would their identity and roles emerge in this new situation of practice and professionalization? How would they be prepared to take on their roles and socialization given the knowledge they were being offered in their teacher education program?

In the professional diploma example, in-service teachers were attempting to understand how new technologies could be integrated into their own classroom and curriculum. How would their identity and role as teacher adjust or shift in the face of integrating these new tools into their established practices? These teachers were in-service teachers, already routinized and socialized into the professional practice of teaching. But they were entering a risky stage of learning where they knew they would be exposed to problems or new "puzzles of practice" (Munby & Russell, 1990) as they engaged with technological tools in the classroom. Depending on the mentor, these in-service teachers were offered a program designed to engage them in a process of reflection, on what technology would imply for their teaching practices and their self-directed study of themselves as practitioners teaching with technology.

The in-service teachers in Deborah's group were merging two critical concerns or grievances related to their ongoing practice. They wanted to give the arts a greater prominence in the expression of the curriculum through their teaching and by their students and they wanted to understand how technology could help them achieve this kind of work. These were not puzzles but rather grievances as these teachers felt often misunderstood, unrecognized, and unsupported in their schools for their efforts to nurture artistic expression by their students as a legitimate way of stating their ideas. Feeling isolated in their schools for the kind of artistic integration in the curriculum that they wanted to achieve, Janice did not want to take on any more "controversial" study such as gender and technology. She felt judged enough by her colleagues in her school. She was searching for a question and a focus of study that was meaningful to her goals of culturally sensitive approaches to teaching that would not give her a controversial identity amongst the staff in her new school.

The Deborah mentees were also marginalized (and, consequently, stronger in their convictions about their technological work) as some mentors and teacher-leaders in this school district believed computers and educational technology did not belong in primary grades. Thus, these in-service teachers had two simultaneous struggles that they were engaged in pursuing through their diploma work: technology in the primary grades (for greater conceptual expression by their students) and the recognition of the arts as an important medium of expression.

All these factors contributed to the emergence of these two discussion groups as important, revelatory cases to investigate and consider in the use of teacher professional VLEs. What we determined was that there was something different about the level of connection and knowledge probing in the cases of these two teacher-educators and their discussion participants. What we wanted to understand was how these levels of intellectual engagement could be the regular intended consequences of using knowledge VLEs rather than the exception, rather than the case study. The prevalent theme in both networks became the discussion moderator as the critical intermediary between the teachers' questions and needs and the research literature available through the VLE database of resources.

We began to recognize Deborah and Caroline as intermediaries in each VLE. We follow the definition of intermediaries as described in the literature of the sociology of science. "An intermediary is an actor (of any type [i.e. human or non-human]) that stands at a place in the network between two other actors and serves to translate between the actors in such a way that their interaction can be more effectively coordinated, controlled, or otherwise articulated" (Kaghan & Bowker, 2001: p. 258). Because networks are never completely stabilized, translation is continual. This is the work of intermediaries. The actor-network theorist, Michel Callon states that "an intermediary is anything passing between actors which defines the relationship between them" (1991, p. 134). Deborah and Caroline were in a constant state of translating the resources of the knowledge network and the requirements of the program curriculum to their students. These intermediaries defined not only their own relationships with the students/mentees but they were also in a process of defining the relationships between the electronic documents and the classroom practice.

In the cases of Deborah and Caroline, we realized that they acted on the network in an unforeseen and unintended manner but that the network or machine system also acted on them and their forms of teacher education. This is the excitement and revolving door of promise of work with early VLE and knowledge technologies. We do not yet understand what form the conventions and genres of technological tool use will ultimately take but we are hopeful that they will leverage a democratic difference. We outline here below how the human–machine interaction of Deborah/Caroline with the two VLE tools created "leverages" that added value to the various technical and social functions of the VLEs.

1. Deborah and Caroline used the tools in ways that the other mentor/moderators did not. The network, the technical entity, acted on them and allowed them to perform functions that they would not have been able to do outside the boundaries of this network.
   - Created and contributed to archive-able, hyperlinked discussions.
   - Cited electronic documents.

- Invited secondary guests or knowledgeable contributors to inform the discussion.

2. Deborah and Caroline engaged in intermediary functions as information brokers and knowledge translators. They added value to the system, to the machine that was not automated in the design's configurations. They were able to connect needs of the end-users with resources of the system in a manner that the technical system could not perform on its own. Deborah and Caroline added trust and witness to the VLE, in ways that could not be automated. Yet this labor represents a powerful form of "invisible" labor or articulation work (Star & Strauss, 1999) for teacher education and the intellectual engagement of educators.
3. Deborah and Caroline became teacher-educators in ways permitted by the PKP tools that they had not engaged in before.
   - They performed intellectual connections that were material and accessible on the screen.
   - They became public in their support of teachers, in their own teaching, and in the articulation of their reflections.
   - They connected the inside/outside of the classroom (and their teaching).
   - They posed, explored, and articulated half-formed questions/observations with their discussion participants.
   - They solicited peer review or community feedback in the process.
   - They referred to and reflected on their own observations and practices.

The VLE permitted and leveraged a type of teacher-educator interaction or way of engagement that the other moderator/mentors had not realized or imagined as they did not have their own experiences of direct researcher contact.

This study yields several important themes, exemplified by the experience of Caroline and Deborah as they negotiated their moves from classroom practitioner to translator or connector in an electronic teacher education setting. Taken together, these central themes are organized to highlight key problematics of public intellectual engagement that beginning VLE moderators or participants may experience as they attempt to connect between the texts (knowledge), the participants (people), and the technology (new tools). These themes or problematics of intellectual connection and engagement in VLEs are also instructive for designers of future VLEs who will need to consider these findings to define an intellectual space for teachers and researchers in education.

- Research becomes accessible and meaningful when a skilled intermediary helps the practitioner make connections to the research and readings.
- Skilled intermediaries in these VLEs were teacher-educators, not classroom teachers or researchers outside of classrooms.

- These intermediaries had interacted/engaged with academics in conversations about common interests (common interests, problems, campaigns) outside of course requirements or university instruction. These academic-researchers, Bryson, de Castell, and Goldman, had engaged in conversation with these teachers in their sites of practice while the researchers had been involved in field work.
- Face-to-face interactions with researchers made these research texts meaningful to the intermediaries. As teacher-educators (in VLEs), the intermediaries had a technical means of connecting texts to users (uploading the work, direct link to the full-text document—a commodity view of knowledge as comprised of discrete units). Through the VLE (and virtual library), the intermediaries could connect the teachers with the unit of knowledge, the article, and state "here it is, now read it". It is step one in the access to knowledge. But if the interaction would stop here, it would be a zero-sum transaction. Instead, these skilled intermediaries understood how to encourage emotional investment, practical connections—intellectual engagement—with these texts.
- By presenting, explaining, and describing how the texts worked for them personally inside their practices as a teacher, the intermediaries gave "I" witness to the authority/validity of the document and its concepts. It was their vouch, their witness for this research informing their own learning, and practices that made the VLE participants want to read the documents/books, engage in discussion, and use the ideas in their practice.
- The intermediaries made visible and explicit the importance of these texts to their own understandings of themselves as teachers and the work of teaching. They gave testimonials, they gave explicit witnessing of the value of these texts or frameworks to their curriculum design, student observations and the reconsideration/reorganization of their practical work as teachers.

The present situation we have observed in our two attempts at creating knowledge networks between teachers and researchers has shown that we have new technology with old social relationships. In our two case studies, we observed a lot of labor by the two intermediaries (Ehrlich & Cash, 1999) that had to occur to establish the value of the research knowledge. Trust had to be established by the intermediaries telling stories of being there (Geertz, 1973): being in conversation with researchers, being in the classroom, being a teacher, being a technology integration specialist, being through the same observations and experiences as the teacher-participants. This authenticity convinced the in-service/pre-service teachers to trust the accounts of Deborah and Caroline and to trust their interpretations. Deborah and Caroline became the reverse of the anthropological idea of "native informants", as they proved to be guides for the natives' appreciation of the research community. They are between and betwixt two communities: the research/university community of teacher educator and the practice world of teacher in classroom. Their accounts are valid and authoritative because they are still practitioners with classroom descriptions and observations.

CONCLUSION

Our experiments with these two VLEs were attempts to augment and enrich the university–school (academic-teacher) relationship by expanding direct access to each community's knowledge, and, in the process, observe whether a new community of practice would develop or indicate signs of developing. We follow Nancy Van House's idea that communities of practice arise spontaneously whenever people have common concerns and have a way to share knowledge (Van House, 2003). (We are substituting here the term VLE for Van House's use of Digital Library.)

> . . . it (*the VLE*) cautions us to be sensitive to the variety of communities' existing practices of knowledge creation and work and indicators of credibility. A successful (*VLE*) has to fit with these practices. In particular, the (*VLE*) has to articulate with participants' hierarchies of credibility and processes of establishing trustability for people to be willing to use and contribute to the (*VLE*). And these vary across communities of practice.
>
> The world and the work that the (*VLE*) serves are continually changing; so too must the (*VLE*). Its design needs to be deliberately fluid and dynamic, to accommodate emergent work practices, and on-going enrollment and co-constitution.
>
> (p. 272)

Many teachers are unfamiliar with these attempts at an intellectual life through VLEs. They are unaccustomed to stating and articulating half-formed questions and ideas aloud and publicly in front of their peers. Many university researchers are unfamiliar with publicly engaging in conversations with teachers from a distance and in a semi-public manner. They do not know how to make connections between content, tools, and services in a VLE in order to create an engaging electronic seminar. They are also unaccustomed with other definitions and conventions (other than a university seminar) of intellectual participation with teacher practitioners. In their work, they are generally accustomed to the conventions and genres of intellectual work that they observe in their own workplace institutions, the university.

For the most part, academic knowledge is disembodied. Caroline and Deborah represent the most local embodied form of knowledge. They can translate the disembodied knowledge and give it authority from their own local examples. The focus in this paper became the teacher-intermediary as we observed the incredible labor and the intense service needed to move these ideas from documents, move knowledge from articles in the system's database to discussion in electronic forums, and finally (in the most successful instance) to classroom use and application. To build a set of social conventions to accompany a technological tool, like an education portal, or a teacher VLE, takes a lot of social labor. What we have attempted to do in this chapter is recover the non-constitutive events of the technology. Technological competence (in this instance, the effective and democratic use of a VLE) is a social competence. A democratic VLE is the product of the effective distribution of knowledge. But, what we have discovered from the cases of Deborah and Caroline is that technology does not cause the knowledge to move: it is the non-technological events and social circumstances that cause the technological and democratic success. In this ethnographic study, we attempted to recover the non-technological that would redress the asymmetry of the technical and the social that is occurring in many educational technology experiments.

In this chapter, we have examined the question of what the intellectual participation of teachers and teacher-educators in discussion through web tools could look like and how it could democratically effect the processes and reforms of teacher education. At this stage, no one can really determine what shape these VLE tools will ultimately take inside universities and schools. In our analysis of these two case studies of VLE participation, we attempted to be attuned to the processes of intellectual engagement by the pivotal intellectual intermediaries inside these environments. Further empirical research is needed to challenge, build upon, and modify the findings of this research. For the purposes of this study though, the analysis of Caroline's and Deborah's experiences as research intermediaries or translators in the field yields the rough start to a theoretical map that could guide further research and programmatic efforts in teacher education through VLEs. We believe it will take the sustained and participatory effort of teachers *and* researchers attempting to speak to each other as public intellectuals in VLEs that will help determine and constitute new cultural or institutional relationships between practitioners and researchers and new definitions of the intellectual life of teachers, teacher educators, and researchers.

ACKNOWLEDGMENT

The authors wish to thank John Willinsky for making important comments and suggestions to the paper. We would also like to thank all the teachers who gave of their time to participate in this study.

ENDNOTE

1. It does need to be noted that the comments have been made by students in this one forum, students in other forums had differing points of view on the value of the exercise and the resources.

Chapter 24: Virtual Learning Environments in Higher Education "Down Under"

BRIAN PAULING
New Zealand Broadcasting School, Christchurch Polytechnic Institute of Technology, New Zealand

1. INTRODUCTION

The use of VLEs, while not as extensive as in Europe and the U.S.A., is increasing in this part of the world. There is a rapid uptake of communications technologies in the tertiary sector of education but it is uneven and not without criticism (Brabazon, 2003). Watching developments elsewhere from this perspective on the edge of the world's stage it is difficult not to conclude that technological developments in education are driven by a complex set of forces that include not only the enabling factor of the convergence of the technologies but also the economics of globalization and the politics of techno-capitalism. There is a case to be made that the arrival of the virtual classroom whilst creating a paradigm shift in the ways teaching and learning are delivered also presents a range of opportunities and threats for both the teacher and the learner and offers significant and particular challenges for small local tertiary institutions in small countries.

New Zealand is a small country at the bottom of the world. Colonized by the British in the 19th century it remained for over 100 years a colony in reality if not in name. Until the 1970s when the U.K. became involved with the European Common Market, New Zealand was the "market garden" for the "Mother Country". Great Britain each year took over 80% of its exports, which were almost exclusively primary products (Sutch, 1966).

Now no country takes more that 18% of its exports (Statistics NZ, 2004). New Zealand was the first Western country to completely deregulate its markets. It is possible for overseas interests to own land, businesses, and banks. There are no restrictions placed on external commercial dealings. The Government has a "hands off" approach to economic activity limiting itself to intervention in the fiscal arena to minimize taxes and control inflation by interest rates and money supply (Kelsey, 1997a).

Despite this the cultural heritage is strong. New Zealand has been, and to a greater extent still is, Eurocentric even although it has spent the last 20 years fending for itself in a competitively uneven world marketplace. Its tertiary education structures, like that of Australia our nearest neighbour, are based on the Anglo-Saxon model and the culture of England is pervasive.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 609–652.

However, the New Zealand culture has been strongly influenced from another direction in this period. There has been a renaissance, both cultural and nationalistic within the indigenous New Zealand race, the Maori. A belated recognition of responsibilities under the partnership Treaty of Waitangi[1] has led to the establishment of a bi-cultural nation with increased sharing of the political and economic processes with Maori.

Geographically New Zealand is as far removed from its historical centre of influence as it is possible to be, sited alone at the bottom of the South Pacific Ocean. The two major Islands each have over 4000 km of coastline. It is long and narrow, the widest point in the North Island being less than 300 km. Mountains, forests, rivers, lakes, glaciers, hot springs, deserts, fjords, volcanoes all make it an attractive destination for tourists.

The population is just 4 million with Maori making up 13%, Pacific Islands' communities another 8%, people of Asian origin 8% the remaining population is of European origin. Over 1 million live in the major city of Auckland at the top of the more heavily populated North Island. Around 800,000 people live in the South Island. The HE system consists of eight universities, twenty-four polytechnics, six teachers training colleges, and a large number of private providers operating under a national educational standards authority the New Zealand Qualifications Authority (NZQA).

2. THE ORIGINS OF THE NEW ZEALAND UNIVERSITY

According to the Oxford English Dictionary the meaning of the word "university" has been generally understood for nearly a 1000 years as being "the gathering of teachers and students in pursuit of higher learning".

The heritage of New Zealand's universities can be traced back to early 19th-century German and English philosophers. It began in the rational ideas of Kant and was applied, in the United Kingdom using the ideas of Cardinal Newman and Matthew Arnold and in Germany those of Humboldt and Schiller. Reflecting the influences of the leading personalities, in the U.K. the concentration was on literature in Germany it was philosophy. Both changed from the religious influences of the previous medieval universities based on the constraints of theology and tradition. The enlightenment broke the boundaries of these constraints with appeals to reason, inquiry, and scientific methods of discovery and experiment. The arrival of industrialization and the resulting modernism also impacted on the ideas of the 19th century. However, unlike their medieval counterparts the modern university stood aside from direct activities within the culture, maintaining a critical distance thus preserving the high culture from the excesses of the drive to industrial modernity.

The university system had remained stable for well over 100 years. There was little challenge to the accepted role of the university from without. Within, the internal structures, the behaviors of staff, faculty, administration, and students were constant. The key change within universities during this period was the continuous trend towards subject specialization as society demanded greater expertise to meet the challenges of industrialism (Smith & Webster, 1997). Whilst universities continued to expand, both in size and diversity of disciplines and multiply in terms of the number of universities in total, the process was steady, controlled and, in organizational terms, predictable. The core business of the Anglo-Saxon university was to maintain a culture that provided for the nurturing of a meritocratic elite intellectual minority that would provide the stable leadership nations required for survival.

And so it was in New Zealand. The early settlers from the U.K. established four university colleges in the main centres of colonization. They became constituent colleges of the University of New Zealand. The term (trimester) patterns were the reverse of the northern hemisphere with summer occurring over December and January. However ties to the U.K. were so strong that even although exams were sat in October, graduation was held in May of the following year to allow time for papers for final year undergraduates to be sent to the U.K. for marking and/or moderation and returned.

Since the early 1960s the role of the modern university in New Zealand and Western societies has been changing and there has been increasing uncertainty as to the function of the modern university. During the 1980s the pace of change increased. At the millennium it was no longer clear what role the university played in society and this uncertainty was being increasingly reflected in the literature (Readings, 1996, Scott, 1997, Melody, 1997, Filmer, 1997, Kumar, 1997).

The expanded and interventionist roles of governments within society immediately following World War II, typified by the welfare state in the U.K., post-war reconstruction in Europe and immigration in the old colonies (New Zealand and Australia), saw increased funding for HE. It also led to an increase in student numbers as social policies pushed for increased access to education on the grounds of equity and arguments, both economic and political, for a well-educated society. The "new" universities were the products of this period. In the United Kingdom the number of universities doubled in the period to the end of the 1960s. In New Zealand the constituent colleges of the single entity of the University of New Zealand were reformed as four independent universities and two new universities were created.

The first signs of the stress created by these changes occurred with the student riots in France in 1968.

The election, first in the U.K. of Margaret Thatcher and then in the U.S. of Ronald Regan pioneered a radical shift to severe right wing politics driven by the strong ideological belief that the social democratic policies of the post-war period were deeply flawed. The emphasis on social cohesion, collective responsibility, and state involvement in a wide range of social, economic, and cultural activities was dramatically weakened by political beliefs that emphasized less government, individual responsibility, consumer sovereignty and the dominant role of business and the market as the sole economic determiners.

Furthermore, rising government debt and declining incomes for most of the population in developed countries encouraged a close review of the performance of virtually all agencies of the welfare state. Universities did not escape this scrutiny. Similar shifts in political thinking and consequent changes of governments followed in Canada, Australia and, in 1984, New Zealand.

Universities sustained heavy criticism, especially from the newly dominant business sector. Previously universities had been criticized, from time to time, by other dominant institutions, historically first the church and then the state. Now it was the turn of business. They challenged the "relevance" of many university courses to the needs of the marketplace of commerce and industry. Many courses that were developed in the 1960s and 1970s as part of the expansion of university departments and growth in student numbers were considered irrelevant and often seen as threatening to the new conservatism e.g., feminism, Marxism, colonial studies, race, and cultural studies. The individual academic was criticized as being "soft" because they had a job for life (tenure) and did not have to perform to survive as most workers in the marketplace did. They saw academics as gaining large salaries (courtesy of the taxpayer), long holidays and, most critically, no accountability for their work and for their productivity. Universities were considered to be "out of touch" with the needs of the nation, slow to respond to the learning needs of the community and irrelevant to the needs of students requiring skills to make a living in the post-industrial, information technology-centred late 20th-century workplace.

Under a deregulated economy institutions of HE in New Zealand developed corporate behaviors which included heavy advertising and branding, establishing trading entities, putting in place principles and practices more in common with business operations than traditional academic activities and, most significantly, they began competing with each other for students, funding, and recognition. Such activities were previously unknown in the traditional Anglo-Saxon university.

While such behaviors have been generally maintained there have been moves in the last 5 years, particularly in New Zealand, to mitigate the excesses of commercial behavior and competition and return to a "light" regulatory environment that puts some emphasis on universities performing in the interests of national goals and strategies.[2]

3. HE'S NON-ENGAGEMENT WITH ANALOGUE TECHNOLOGY

One of the criticisms of education in general and HE in particular was that it had failed to change with the times and this was no better illustrated than in the university's use, or to be precise, non-use of technology. Someone once said that if a person from the 19th century were to return today the only thing they would recognize would be the classroom. For over 500 years text formed the basis of every learning experience in the West.

The 100 year history of non-print based mass communications technology (radio, film, television, telecommunications, and computers) appears, until recently, to have had little impact, in New Zealand or anywhere in the world for that matter, on the ways in which teaching and learning have been delivered in formal education systems. To use an analogy, education's engagement with mass communications covers a gamut of experiences that epitomize an "on-again-off-again" relationship—attraction, excitement, fear, and loathing. But on the whole it has been an unconsummated relationship (Rushkoff, 1994).

Whilst all the aforementioned forms of mass communications have increased their influence over virtually every other aspect of human activity, there is considerable evidence to suggest that their impact on the tasks of teaching and learning in formal education have been limited. Teachers and teaching institutions either resisted these new forms or, as Australian writer Carmen Luke puts it, they were "passed over" as the non-print based communications revolution gathered pace (Luke, 1996).

Radio, cinema and film, telecommunications, television, computers, videotext, and multimedia, are all technologies located, on the whole, "outside" of mainstream pedagogy and curriculum. The notions of "technoculture" and "cyberspace" recognizable in the discourses of cultural studies, sociology, and anthropology, have not been identified in discourses on formal education (Luke, 1996).

In Luke's construction the "single-order" development of print technology over 400 years ago created an educational environment dominated by the printed text and universities stuck with the single order well past the time when just about every other aspect of society had been saturated with "second-order" media.

4. THE INITIAL IMPACT OF DIGITAL

The concepts of "single order" and "dual order" in this context are used to describe the methods of distribution of stored information. In Western society, following the invention of movable type, print technology gradually replaced aural and hand-written traditions and, eventually, became the principal method used for information storage and dissemination in literate societies. Except for illustration and the development in the 19th century of photography, it was text based.

The "second-order" distributions that became possible just over 100 years ago with the invention of electronic media such as radio and television and mechanical moving pictures created a "dual-order" media and information environment, The electronic and mechanical analogue based, non-text media on the one hand, the existing print based traditions on the other. The second-order media developed rapidly reaching the “maturity” of social saturation in very quick time (Bittner, 1985).

With the development of digital transmission the method of dissemination returns to a single order, bits and bytes being used for everything—text, sound, moving image, graphics, and illustration.

However whilst society, outside of the world of teaching and learning, increasingly operated in a dual-order mode, teachers, on the whole, eschewed the dual order and maintained the exclusivity of teacher-mediated single-order printed text. Only rarely were radio, film and television used in the teacher-mediated classroom for the storage and/or dissemination of information. This remained so despite attempts to integrate the second-order media with teaching and learning. Such attempts occasionally led to excessive claims.

Radio was going to “liberate” learning for the masses and reduce the “tyranny of distance” with educational broadcasts. Radio “. . . is a modern and . . . most efficient tool which could be used for the furtherance of the very plans (education, welfare, development) which now have priority over it” claimed a UNESCO report in 1972 (Waniewicz, 1972: 58). Further: “the role that radio can play in fundamental education is thus a matter of vital importance to the present day world” (Williams, 1950: 7).

Film and television were going to revolutionize instruction by adding pictures to voice and replace text as the dominant means of distance learning. “Educational Television is the most powerful tool of all and it won’t be so long before it is universally available. We should be planning and experimenting in anticipation of that day”. (Potts, 1979: 16). Maclean (1968) believed that television was the “most effective” channel for “straight teaching” (p. 8). Again, educationalists and broadcasters talked about “the great educational potentialities of classical open circuit broadcasting” to deliver learning to all (Robinson, 1964: 9). Schramm (1960: vi) wrote that “educational television has shown a remarkable capacity to reach, to interest, to teach, to enlighten”.

In New Zealand it was stated in the 1972 report of the Commission of Inquiry into the uses of Television in Education (Williams, 1972: 72) that “television has a valuable contribution to make to education in New Zealand”. The Commission recommended the immediate establishment of a national television channel devoted solely to education, formal and informal. It didn’t happen.

Computers were going to make teachers redundant with computer-aided learning (Stonier & Conlin, 1985). The initial development of the computer after the Second World War coincided with the strong influences of behavioral psychology on teaching and learning (Watson, 1925) and the application of “scientific” principles to the study of management. B. F Skinner applied behaviorist principles to learning and developed the concept of programmed learning

(Skinner, 1954). He pushed for the development of a "teaching machine" that would "free" the teacher. "We are on the threshold of an exciting and revolutionary period in which the scientific study of man will be put to work in man's best interest" (p. 97).

By the mid-1960s the research and writing on the role of computers and teaching machines reached such a level that Schramm (1964) concluded that "no method of instruction has ever come into use surrounded by so much research activity". Research peaked in 1967 (Spencer, 1988). The arrival of the personal computer saw a revival of interest in computer based learning but writers (e.g., Kulik et al., 1983) investigating computer-based learning commented that there was not "a great advantage for the computer in this role" (Spencer, 1988: 38). The expectations of over 30 years of experiments and evaluations suggest that the hopes and visions of the protagonists were not fulfilled.

To continue with the preceding analogy therefore, whilst education has "flirted" with each medium as it developed, there was never a commitment to any substantial long-term relationship.

However, since the late 80s there has been more engagement with non-print media by a myriad of educational agencies than was evident in the preceding 90 years (Watts, 1999). With the development of digital transmission and the consequent convergence of the three previously independent technologies of broadcasting, computers and telecommunications the dual-order environment has been replaced by a new single order which has broken the exclusivity of text on paper bringing together all modes, text and non-text, in a single data stream. Within this stream new hybrid textualities have been created and a new generation of young people are engaging with new forms of literacy and alternative discourses. The challenge is succinctly summed up by Luke:

> Multimodality (forms of expression), multiliteracies (modes of reading/writing/representation) and multivocality (multiple author-voices and social identities)" are increasingly challenging the relevance of the traditional discourses of teaching and learning. The classroom is being forced to acknowledge the montage of difference, (the) pastiche of multiple author-voices, (the) endless criss-cross of quotation to other cultural texts, media forms and symbolic languages.
>
> (Luke, 1996: 190)

Some theorists even argue that society is about to see the "death" of the book as we know it (Birkerts, 1996).

Furthermore, interactivity, the strength of text-based teacher mediated learning, previously denied the analogue electronic media in the old dual order, has been achieved, at least partially by the arrival of single-order delivery.

For the first time technology has demonstrated the capability of replicating the three key elements of the classroom which are:

Student–teacher interaction
Student–student interaction
A repository of knowledge that can be accessed

The key to this change is the move from analogue to digital. Digitalization has removed the barriers and returned media to a single stream of zeros and ones.

5. HE'S ENGAGEMENT WITH DIGITAL

A cynic could argue the case that universities eschewed second-order technologies because any perceived use for them was solely in the teaching role, the least valued role within the university. When computers were first developed their value in research became immediately apparent. The ability to sort and analyze large volumes of data had particular appeal to the quantitative research model that dominated academic research at the time. Universities were quick to install mainframe computers. As size and costs reduced the computer was embraced by academe as an essential research tool, first by the scientists and mathematicians and then, as more sophisticated software packages were developed, by the wider university community.

In 1987, Abraham Peled (1987: 57) wrote: "The way computing has permeated the fabric of purposeful intellectual and economic activity has no parallel". This was just 4 years after the invention of the personal computer. Since then the convergence of the technologies and the creation of the internet have seen an unparalleled transformation of the worlds of business, science, entertainment, the military, government, law, banking, travel, medicine, agriculture, and education.

So, in contrast to the previous dual-order technologies universities have been to the forefront in proclaiming the information revolution and have pioneered the use of computers in a range of areas from administration, data storage and distribution, library technologies, electronic mail and as alternative tools for teaching and research. Many universities have seen the adoption of technology as a way to spread the role of teaching beyond the confines of the traditional campus and have invested heavily in the technology to provide computer enhanced or computer-based distance learning. The large number of courses available on the web is testimony to this. However, the development of the "virtual university" where time, distance, and space become irrelevant as the student interactively accesses the best university minds irrespective of location while a distinct possibility is not yet a reality.

It has been no different in this part of the world. One commentator has noted that:

> The proliferation of VLEs running on desktop, networked computers, has allowed a number of institutions to offer subjects online to some extent. But, on the whole there is not a well articulated, homogenous, online learning strategy rather, "the majority . . . are patchy initiatives using piecemeal methods to deliver uncoordinated services via the web".
>
> (McKey, 2003)

This criticism has some currency. Currently there is little coordination so that different institutions and even different faculties within the same institution are using different software systems based on a range of *ad hoc* decisions which include cost and using what staff skills are available. Often it's a question of taking existing course material and "digitising" them making no changes to meet the unique opportunities offered by the new medium. Often the support and administration services offered these programmes are based on the 9am–6pm mindset of the campus institution and do not accommodate the 24/7 needs of the online student.

And while students in Australia and New Zealand are taught using an increasing variety of teaching methods, print is still by far the most common mode. For distance students it usually includes a subject outline, study guide, readings or laboratory manuals and student purchased textbooks. In some subjects, audiocassette tapes or videotapes are used as supplements to text. Increasingly faculty are using the e-mail to communicate with students and provide one-on-one feedback.

However, within these critical constraints the development of e-learning and VLEs in this part of the world can be broadly categorized into three areas:

- Traditional campus-based institutions adopting various modes of VLEs;
- Traditional distance learning institutions adding technology to their already well developed distributed learning; and
- New ventures specifically designed to take advantage, especially in the global marketplace, of VLEs.

Traditional campus-based institutions are building facilities to enhance traditional classroom-based learning using the web. It is estimated that over 60% of all courses in New Zealand now offer some web-based component (Tyler-Smith, Personal Communication, 2004). Many institutions use proprietary enterprise software such as Blackboard, First Class and WebCT to enhance both classroom learning and the distance learning offerings many are experimenting with. Most have their library information on line and provide access to electronic databases through their web portals. Some provide for online enrolment and post results online. The majority of students at universities and full time polytechnic courses have e-mail addresses. Courses use a range of applications from simple e-mail communication to fully online programmes that provide all resources electronically and require all communication electronically. The very small number in the latter category use purpose built websites, electronic newsgroups, online interactive discussion, blogs, electronic submission of work and in some rare cases web delivered audio and video. However, many of these developments are fragmentary and lack cohesion. Some programmes have been offered only to be withdrawn and some have been criticized for unacceptable standards.

Changing student needs are seen as one of the major drivers of the traditional campus-based institutional move towards VLEs. The student profile is aging. As regular career change becomes more common the need for flexible learning increases. Because of the increased costs of education and the perceived heavy burden of student loans more students are trying to work while studying.[3] Also many people already in jobs see the need for regular, if not continuous up-skilling. All of this challenges the traditional campus-based institution to engage with the technologies that offer the promise of widely distributable flexible learning.

In the Anglo-Saxon world the strongest development of VLEs is occurring within institutions that are already distance education providers and they are combining VLEs with traditional distance learning methods to expand their programmes both nationally and internationally. Not surprisingly an organization like the U.K. Open University which, unlike most other universities was a very early adopter of both radio and television as media to supplement print and post, found it easier to adapt to the web. Their radio and television experiences meant that they were already skilled in screen and graphic design and understood the role of sound singularly and as a complement to vision. Videotapes and audiotapes, even slides and photographs were already widely used. They could more easily adapt to the VLE technologies than most. Furthermore, being totally committed to distance learning they had no classroom commitments to confuse the situation thus they were not adding a new dimension to their teaching methodologies. They used new technologies as a supplement to already existing delivery platforms not as a replacement. Students were eased into using e-mail and the web.

New Zealand's equivalent The Open Polytechnic of New Zealand (TOPNZ) also has been a distance education supplier for many years. The institution has 30,000 enrolled students studying in New Zealand and 40 overseas countries. Like the U.K. OU, it is an exclusive distance institution with no campus activity. TOPANZ has taken a cautious approach to engaging with digital technology. They have surveyed students and have found that an overwhelming number of them still prefer paper-based delivery. Surveys suggest that only a minority (19%) would prefer their course delivered fully online. So TOPANZ is applying VLEs at two levels. The first is to slowly introduce e-learning as an add-on to their traditional paper-based courses. The second is to develop a suite of new courses for discrete online delivery. These are mostly in business and applied sciences. At the end of 2003, 60 courses were using VLEs for most activity. It is the stated intention of TOPNZ to expand online courses so as to eventually be able to offer most programmes in dual form (TOPNZ, 2002).

Some newer institutions are emerging as major users of VLEs as they compete against older and more traditional players in the HE marketplace. The University of Southern Queensland (USQ) is a dynamic, young university created from an institute of technology in 1990 that offers programmes at undergraduate and postgraduate level in three modes, on-campus, off-campus, and online. USQ has a number of campuses in southern Queensland offering face-to-face learning, the off-campus mode is traditional paper-based delivery enhanced with some video, audio, and digital media content and the online service is delivered exclusively via the internet requiring students to have facilities that can handle e-mail, access websites, download text, audio and video files and enable interactive engagement with faculty and other students Many students choose different modes of delivery for different periods of their study. The University promotes flexible delivery and markets itself as a regional, national and international university (USQ, 2004).

At a third level a number of regional institutions are participating in global developments of VLEs. A strong regional influence in this regard is NextEd, a Hong Kong-based company that works with a range of public and private education institutions throughout Asia, the Pacific, the U.K., and the U.S.A. It offers in partnership a proprietary system, which uses a digital education delivery platform designed to "allow students in multiple locations throughout Asia, to access post-secondary education and training, often from course providers located in another city or country". NextEd is the private technology partner in the Global University Alliance, a consortium of ten universities which aims to provide university-level education to people from anywhere in the world—taught entirely online. The Universities, all public (state) institutions, are from New Zealand, Australia, Europe and North America.

The purpose of the Alliance is to provide "students from around the world with accessible, rewarding educational experiences by leveraging the latest interactive web technologies". GUA claims that it "provides students and teachers with access to course material and support services 24 hours a day, seven days a week". A number of Australian and New Zealand institutions are partners of NextEd including TOPNZ, the Auckland University of Technology, the Royal Melbourne Institute of Technology, and the University of South Australia. All of these institutions operate extension programmes in Asia and the Pacific (NextEd, 2004).

The University of Auckland, three large Australian universities, and four universities in the U.K. are members of the international consortium called

Universitas 21. Universitas 21 is an international network of universities with the purpose of facilitating "collaboration and cooperation between the member universities and to create entrepreneurial opportunities for them on a scale that none of them would be able to achieve operating independently or through traditional bilateral alliances". In a major alliance with global media giant Thomson Corporation it has created an online university called Universitas Global. Its first venture was to launch an MBA programme in 2003. In a unique move the degree certificate awarded by Universitas 21 Global will bear the crests of all the Universitas 21 partners (Universitas 21, 2004).

A VLE created in Australia in a specific response to the fact that other commercial LMSs were U.S.-centric is Moodle. It's an open source software package for producing internet-based courses and web sites and is an ongoing development project designed to promote a particular "social contructionist" educational framework.

One of the greatest attractions of Moodle is that under its public license arrangements, although copyright protected, it is available for use for free if you agree to its conditions. "Moodle" stands for Modular Object-Oriented Dynamic Learning Environment and, according to it's website, it's also a verb that "describes the process of lazily meandering through something, doing things as it occurs to you to do them, an enjoyable tinkering that often leads to insight and creativity". Apparently anyone who uses Moodle is considered a "Moodler" and there are a considerable number of them. Seventy-nine sites are listed as using Moodle in Australia and a further eleven in New Zealand. Internationally over 1100 sites are listed as Moodle providers. While they do not seem to have a large presence in the university market (only a few Australian universities and one New Zealand Polytechnic are listed) it appears to be very popular in schools and private learning establishments (Moodle, 2004).

As mentioned previously, there has been a return to a more regulated education sector in New Zealand and this has seen the creation of a number of central government initiatives to assist in the growth of e-learning and coordinate the development of technology and the expansion of programmes. The current government sees the need for New Zealand to adopt a cohesive, national approach to developing e-learning. It fears that global developments are impacting on the provision of tertiary education services, and that new uses of ICT to create e-learning opportunities and VLEs are creating fundamental changes in the ways learning is conceived and practised.

Accordingly, these changes are seen as having both risks and opportunities for New Zealand, in terms of its competitiveness in an increasingly globalized education market and its ability to provide relevant, high quality educational opportunities for its citizens. The government believes that the development of e-learning capability will assist in the achievement of national educational goals. While it acknowledges the many promising developments that occurred in individual institutions under deregulation it holds that there are benefits to be gained from improved co-ordination between tertiary education organizations.

Since 2002 New Zealand's Ministry of Education has been developing IT-related strategies for the tertiary education sector. These include a "tertiary information strategy" (Tertiary Information Strategy, 2003), an "interim tertiary e-learning framework" (Interim Tertiary e-learning Framework, 2004) and the creation of web portals for the tertiary sector and for tertiary e-learning (elearn, 2004; Ted, 2004). According to government statements the tertiary information strategy is based on a number of principles common to the expression of educational policies that are inclusive and favour education as a public good. They include the belief that "everyone can learn and everyone must learn". It requires "secure, seamless access to education" and seeks to remove any barriers that inhibit learning through VLEs. The government's published material states, inter alia, that its goals are to have all communications and dealings with external parties that relate to business transactions (including educational business) occurring electronically, that all authoritative sources of information will be accessible electronically from which legal copying can be generated on demand, that work (including much teaching) will become location-independent, that there will be access to all personalized educational information via a tertiary portal and that there will be an open interoperability of rules and standards across the sector. It is clear from documentation that the Ministry of Education sees itself as responsible for driving the strategy forward and wants to develop a coordinated approach across the sector to overcome the ad hoc developments some of which are listed above.

To this end a Tertiary Education Commission (TEC) has been established to implement this Tertiary Education Strategy. The creation of the TEC is a big step way from the previously diverse market driven education sector and returns the sector to a significant level of bureaucratic control. The TEC is responsible for allocating over $2 billion annually to tertiary education organizations and it uses this money to assist the sector to built capability and capacity to contribute to national economic and social goals. All forms of post-school education and training come under the TECs umbrella. These range from full-time academic study, on-job and work-related training right through to tertiary research and development, foundation education, distance education and part-time study (TEC, 2004).

However, it should be noted that these policies are not those of the national oposition parties. They favour the previous less regulated regime and espouse principles that promote education as more of a private good and view teaching institutions as a form of trading entity.

7. IMMEDIATE ISSUES FACING HE IN NEW ZEALAND

Despite the initiatives of the current government the conditions that will foster the development of VLEs in countries like New Zealand are heavily affected by a number of issues that can hinder or help institutions to embrace technology and grow VLEs, and they are significant. Indeed it is hard not to observe that currently HE is challenged in every sense—epistemologically, sociologically, economically, politically, and technologically, so much so that the future of the traditional university is not assured.

The engagement with online learning that has been so noticeable over the last decade is driven by a number of forces and although it would not be possible without the technology, technology itself has never been the sole condition for any change. Technologies can languish for a number of reasons. An example could be the lack of a market. Broadcast technologies have been faced with this problem over the establishment of digital television and radio. If there is no demand, no "business model", then the technology remains sidelined. Or a technology can be developed that people just don't see as useful. The fax machine prototype was developed in the 1930s but it was not until the mid-1980s that they became prominent. For over 40 years it was a technology in search of a use. Also technologies have been developed that have swept into cultural maturity in very short time but the classroom has eschewed them. Analogue radio and television and cinema are examples.

Raymond Williams discussed this in relation to television when he suggested that the rise of television as a medium was not exclusively technologically driven. Strong elements of cultural history and political economy also informed the medium's development.

> It is commonly believed that inventions such as the printing press, radio and television set the stage for a more democratic society. Quite the opposite actually occurred in all instances—not because of the technology itself, but because of the interests of those who made decisions about how the technology was used.
>
> (Williams, 1974)

So, it is argued that it is not just the technology that has driven the development of e-learning. There are other factors that have propelled the momentum towards VLEs and those factors have a lot to do with the interests of those who make the decisions about how the technology will be used in e-learning. Those decision makers are, in turn, influenced by the social, cultural, economic, and political pressures currently in the ascendancy.

8. THE VISION

Administrators and governors of HE have seen in the technology the chance for the first time to fully replicate the classroom. Previous technologies have fallen far short of meeting the three essential elements of classroom processes. But computer-based interactive communication comes close. Those three elements—teacher/student interaction, student/student interaction and an accessible source of stored information and knowledge have enabled the teacher controlled classroom to dominate educational practice for centuries. The Aristotelian model of a small number of students engaging (in the truest sense of the word) with a mature, knowledgeable teacher in seclusion and for long periods of time has been the time-honoured system of the elite Anglo/Saxon universities. The poor relation at the lower end of the same system is the 500-seat lecture theatre and the 2-hour lecture.

Interactive digital technologies of the VLE provide institutions with the ability to further increase the effectiveness and efficiency (in economic and time terms at least) of this model. The vision is of much larger numbers of students engaging with their tutors via the internet thus increasing the number of students able to be accessed by one tutor and without the costs of building and maintaining more lecture theatres. More EFTS (equivalent full time students) leads to more fees and greater revenue all supposedly at less cost. Students would be off-campus thereby reducing the stress on such services as libraries, facilities, and computer suites.

Governments have also perceived value in using the technology, the contrary goals of modern states wanting to reduce the costs of education whilst at the same time wanting to achieve a better informed, educated and trained workforce could perhaps be reconciled by using technology. The increasing competition between nation states to create economically viable "product" for a marketable return in the so-called "knowledge economy" propels governments to support the development of VLEs.

Something that appeals to both governments and administrators is the increased "flexibility" of organizations delivering learning on the new platforms. More tutors would be needed for shorter periods and for easily defined tasks. The university workforce could become increasingly casualized permitting a more business oriented method of managing staff with easier hiring and firing and greater control over a more passive workforce thereby reducing the "difficulties" that tenure can bring including the "stroppy" academic and the barriers of working with people that have long term institutional memories (Brabazon, 2003).

There is no doubt that a technological solution to the rapidly increasing costs of HE has strong appeal to bureaucrats and politicians regardless of educational efficacy and any demonstrated need for teachers and learners to have personal contact and real-time interaction. So this vision argues a "business case" could be made to adapt the technology and spend the money on developing VLEs because the return would be worthwhile.

However, "success has yet to come" (Williams, 2003). While convergence of the technologies can enable the vision, other events are impacting at the same time and they may be as significant as the technology. The reality is that students are not engaging with on-line learning in the numbers expected, institutions are finding the costs of creating and delivering online learning greater than expected and other forces economic, political and social are putting pressures on educational institutions at unexpected levels.

Barriers to the successful implementation of VLEs include economic issues, issues of the political economy that HE is engaged with, the nature of teaching and learning and the very essence of the university itself as it struggles to maintain relevance in an increasingly "hostile" world.

9. ECONOMIC ISSUES

Traditional universities had comparatively few economic worries. Budgets, often generous, were set by the state and the perceived role of the university as the provider of the culture that nurtured the meritocratic elite that would continue the supply of stable leadership required for the nation's survival almost guaranteed security. Over the last 40 years changes both to the role of the university and the costs to the state of maintaining them have led to a raft of economic "worries" for HE administrators.

The first is the cost of IT infrastructure. The major costs of installing, maintaining, and keeping up with the rapid changes in information technology have been a strain on institutions and an inhibiting factor in growth of VLEs. Certainly HE expenditure on information technology has increased dramatically over the last 30 years but it still remains low in the overall comparison with commercial institutions. Institutions in New Zealand have struggled to remain viable facing the extra costs of IT infrastructure and this has been reported as a world-wide phenomenon. While salaries continue to be the largest expenditure item in university financial reports IT cost have steadily risen from below 1% in the late 1970s to an average of 4.6% in 2002. (University of Canterbury, 1979, 2003) Comparisons with commercial organizations show education institutions are lagging. Some international surveys suggest that telecommunications, banks and other heavy technology users spend almost three times what education does. On an even more significant ratio, that of IT spend per employee, education fares even worse. Education overall spends less than $1000 per employee. This compares unfavourably with, for example, media companies that spend over $5000 per employee and top spending telecommunications and banking organizations that spend in excess of $10,000. Whilst this maybe considered an unfair comparison given the nature of education it actually signals a significant concern (Leach, 2003). As is discussed in more detail later, HE institutions internationally are facing significant challenges from newly emerging "corporate universities" whose lineage is commercial not educational. These bodies are likely to invest heavily in technology because they appear committed to delivering the online experience. Many of them are located in large transnational corporations that have branches in small countries like New Zealand and they are investing in the technologies to provide VLEs to their staff. Most, if not all, of these corporate universities are located in organizations that spend considerably more on IT development and support than universities, especially local ones, and have the budgets to support it. Thus an alternative to the university is created. This could impact on NZ universities because a feature of the university ecology is that many organizations, governmental, industrial, and commercial, send key staff to university either part-time or full time for intensive periods to gain relevant knowledge and skills. If these institutions take their learning in-house local universities will lose custom.

There is the possibility that the cost and maintenance of delivery technologies and their infrastructures will be too great for many small and scattered learning institutions to sustain.

Secondly the fear of failure or of economic loss has become a strong factor in HE thinking. New Zealand, like other countries has had its share of IT projects that have gone horribly wrong. Following deregulation there were a number of high profile public sector IT failures and less publicized corporate IT investment debacles that have created considerable caution and anxiety in making investment in large, costly and heavily IT focused projects. Moreover, local HE institutions cannot fail to observe that a number of high profile forays by major universities in larger countries into developing online programmes have been reported as failures. According to Brabazon Columbia University and New York University both spent large sums of money ($25 million each) on ventures that either folded or where greatly reduced. The University of Maryland, Virtual Temple (the online offering from Temple University), and the University of California closed their first attempts at online services and the London School of Economics stopped charging for its online courses and put them up for free using them as a taster for conventionally delivered programmes. The same author claiming that “e-learning has failed through the desire to make money—and quickly” cites the spending by companies supplying online material for the education market in the U.S. dropped to U.S.$17 million from U.S.$483 million just 2 years earlier (Brabazon, 2003). More recently, and with considerable impact in New Zealand, it was reported that the highly promoted and state of the art e-university in the U.K. (U.K.eU) had folded. With U.K.£32 million of a budgeted £62 million spent it was said to have less than 1000 students enrolled world-wide for its courses. The e-university’s activities are to be “scaled down” and most of its activities transferred to other established universities. The U.K.s Open University lost U.S.$9 million in an attempt to enter the U.S. HE market (MacLeod, 2004).

Criticisms of the e-university failure highlighted that the underestimations of the costs of developing and delivering e-learning were substantial:

> E-learning was seen as an opportunity to cut costs by automating a recognised process (learning), cutting out the middlemen (teachers and admin staff), reducing inventory (books) and minimising real estate (classrooms).
>
> (Williams, 2003)

John Beaumont, chief executive of U.K.eU argued that the cost-cutting aspects of online learning were so attractive that the e-university failed to invest in the technology and content design that would have made the VLE of the university a rewarding one in which to learn.

> Courses should have been entirely rethought, if not rewritten to take account of the strengths and weaknesses of the new medium. This pedagogical failure was compounded by technical problems. The process was orientated towards the supply side rather than the students, and some of the early platforms were designed around the needs of academics rather than the people who would actually be trying to learn online.
>
> (Beaumont, cited in Williams, 2003)

It is important when reviewing how a small country should move forward to try and understand what went wrong to ensure that costly mistakes are not repeated. Critics have suggested a number of things. There was some resistance from faculty both in terms of technophobia and perceived increased workload. Lack of training and at times poor technical support meant that much of the online menu was far from appetising. Course notes and lecture notes were thrown up on the web, there was little genuine interactivity either between students and lecturers or between students, and standards of design both of the content and the screen varied. The internet promised much but delivered less especially when it came to bandwidth and was often frustratingly slow. And, most importantly, it turned out to be far more expensive to establish and maintain than the early adopters believed.

These high profile first generation online mistakes have made smaller nations more cautious. Such overseas experiences have created if not scepticism certainly a strong sense of caution within local HE institutions when faced with making heavy financial commitments to online delivery.

Thirdly is the experience and threat of competition. The Anglo-Saxon university has felt the impact of market forces on the sector as institutions compete against themselves in what was once a collegial non-competitive environment. The language of the marketplace has infiltrated HE. Students are now seen as "customers" and learning has become a "product". Major changes to the administrative structure of universities have occurred as an outcome of the market approach to HE and this has been maintained despite some return to centralized control in some countries like New Zealand. The business model of fiscal responsibility and accountability has quite quickly replaced the public service model of funding based on need. Accountability procedures such as audits, performance, and compliance reporting give primacy to the manager or administrator rather than the academic in HE leadership roles. Universities now promote and market themselves. Advertising, an activity previously unheard of in many universities, takes increasingly large slices of institutional budgets. Universities are competing for students and, as the technology allows, seeking custom from outside of their traditional geographic boundaries.

New technologies have also created new channels of knowledge creation and dissemination, some of which are a direct challenge to the hegemony of the university. Scott (1997) identifies new forms of "knowledge" institutions not based on the same structural ideas as the university which he sees as direct rivals to the university. The university as the local repository of knowledge no longer has a monopoly when other repositories can be accessed online from around the globe (Kumar, 1997). Moreover, as Kumar points out, there are two key roles that appear to be changing as technology intervenes. The roles of the teacher and the library seem to be most under challenge. It appears that the personal quality of teaching is losing value and is slipping in status in this age of mass education and large classes.

> It is not at all clear that the instruction provided through the new media technologies, especially those involving interactivity, is markedly inferior to that provided by teachers. As for libraries, for anyone who has a personal computer the best libraries in the world will soon be available to be screen-read at home. Universities need libraries but libraries do not necessarily need universities.
>
> (Kumar, 1997: 30)

Nor does it have dominance in the distribution of knowledge. New institutions, often lacking both the traditions and value of the university are evolving that play an increasingly important role in distributing ideas and information.

Not only is the corporate university, developed for the advanced training needs of knowledge-based companies and large R&D units in both industry and government departments, a direct challenge to university exclusivity, there are new, alternative and open sources of knowledge that also claim some authority. Learning Channels owned by media companies, commercially owned and operated web portals and the web itself are current examples of a rapidly increasing field.

Recognized brands such as BBC Television, Thomson Publishing, a host of private research bodies (e.g., Gartner) and many internet sites are claiming authenticity and authority equal to such institutions as the university and openly challenge the university's position as the sole and "rightful" place for the discovery and dissemination of knowledge. Some argue that fragmentation is inevitable when difference is such a strong factor (Smith & Webster, 1997).

In the future HE institutions may form only a part, and maybe a small part of the knowledge-producing centre. Few, if any, universities have the resources to match the large transnational media conglomerates that are staking a claim to knowledge creation and certainly none in New Zealand.

> Teachers may be forgiven if they cling to old models of teaching that have served them well in the past. All of their formal instruction and role models were driven by traditional teaching practices. Breaking away from traditional approaches to instruction means taking risks and venturing into the unknown. But this is precisely what is needed at the present time.
>
> (NCATE, 1999)

Then there are the pedagogical issues. Universities are facing challenges to the tradition mode of educational delivery. Some educators still argue that the classroom model in which the authority and power of the teacher is paramount produces the discipline, the control and the ruthless concentration necessary to inculcate good learning. There is also considered to be a loss in the quality of the teaching and learning experience when it moves into VLEs. Computers are at their best when handling concrete ideas, ideas and content that can be neatly bundled into a series of discrete 1s and 0s. Some educators argue that they are less competent when involved with abstract and complex qualitative or philosophical ideas. Further there are elements of the classroom that still cannot be translated to VLEs, among them the senses of smell and touch and the observance of body language. Good teachers will argue that a significant part of their success is in performance. The classroom is like a stage and the lecture most engaging when the performance has elements of embedded drama—surprise, bathos, pathos that catch the listener unawares, that shock, amuse and engage with the pace and direction of the narrative. All this is harder to do *via* a computer, although not impossible. But both the unwillingness to change and the slow speed of change are significant barriers to the development of VLEs.

The traditional pedagogies which originated in the medieval university where the knowledge was passed down through generations to uncritical reception were replaced in the enlightenment with a more critical and sceptical pedagogy. However, it still was not the student's role to challenge but rather that of the researcher/teacher. Good marks were still achieved by repeating back to the teacher what the teacher wanted to hear. It was not until the student moved out of the classroom and into the higher research-based degrees that the roles of critic, innovator, and challenger were permitted.

At lower levels of learning the role of the student to listen, absorb, understand, and then do was dominant. The industrial societies of the 19th and early 20th centuries wanted workers who were skilled in replicating knowledge and actions and not thinkers who challenged them.

Over the last 30 years the litany has changed. Students are required not only to understand and do but also to think, to challenge and debate. Creativity is the buzz word. The "knowledge economy" needs original thinkers (Florida, 2002). The new product is not material or stable in nature. The new product is intangible, unstable and forever in need of reversioning or, to use the language of the media, repurposing. The users of such product need to be original, sui generis in thought and able to compete by developing original and compelling product able to sustain a return in the post-modern marketplace of ideas.

In contrast to the classroom the development of VLEs shifts the control, and to a growing extent the power, of the student teacher relationship to the student.

A number of theories and methods are being developed to provide sound pedagogical grounds for the new learning environments. These theories include the U.K. Royal Society of Arts' "learning for capability", immersion learning, cooperative education, and contract-based learning (Stephenson & Yorke, 1998) They challenge the traditional classroom pedagogy and provide foundations for new methods of delivering learning and suggest changes to the political and social thinking around the role of HE. Faculty have been slow to investigate them and even slower to accept them and much online delivery is heavily constrained from reaching its potential because of this theoretical hiatus. But universities are being warned that:

> as the nation's homes acquire greater information technology power by the day and provide [students] with the chance to explore global networks and utilise increasingly sophisticated multimedia technology, so the pressure will grow for [teaching institutions] to redesign their operations.
>
> (Lee, 1995)

11. THE CHANGING "NATURE" OF THE UNIVERSITY

The relationship of HE to the economy has always been ambivalent. Scott (1998) calls it "latently dominant". But prior to the massification (see below) of HE there appears to be little evidence of the sector having much economic power. Today it would appear that the economic role of the university is the key determinant to its future. It appears that HE is playing a more significant role in the political economy than previously. Just what that role is, and how it will eventuate is less clear. Issues to do with the future of HE and its role in the broader political economy are holding back developments including the development of the "virtual" university.

Right wing theories surrounding the "private good" nature of education, the emphasis of learning as a tool for employment and career options, user pays and the shift of the capitalist business values of competition and profit into the social sector are part of the changes, as are current theories surrounding the knowledge revolution and the rise of the post-industrial information-based society.

> In addition to their educational role, universities had served a range of public service functions: the creation and expansion of knowledge, research and publication; advisory and servicing function for the state and professional repositories and transmitters of historical, cultural and social knowledge; and (rather too rarely) as social critics. The neo-liberal model sought to reduce that role to the production of education and training—commodities that would be bought and sold in an artificially constructed education market and driven by forces of supply and demand. Education could then be defined as a private good, with the burden of funding increasingly shifted from the state to the student.
>
> (Kelsey, 1997: 30)

Jane Kelsey, a New Zealand academic and critic of globalization argues that the status of both HE institutions and staff are changing. She argues that a country the size of New Zealand could end up with only one or at the most two research-based universities charging elite fees to attract elite staff and students, the remainder being relegated to a form of educational industry.

> Most students and staff will end up at the bottom tier. Constant cost-cutting; courses overflowing with fee-paying students; high birth and death rates as courses and qualifications pander to market demand; frequent mergers and take-overs; and minimal research.
>
> (Kelsey, 1998)

In this regard it is salutary to remember that New Zealand has eight universities, twenty-five polytechnics, 2300 primary schools and 330 secondary schools all for a population of 4 million people, a population not much greater than Birmingham in the U.K. which has three universities and four other tertiary institutions. Among the matters challenging HE and the status of the university are issues surrounding massification, globalization, corporatization, intellectual property rights, the urge to privatise and/or make HE institutions into businesses, the reduced influence of governments and the rise of the knowledge industry and they deserve a brief discussion.

11.1. Massification

There has been a dramatic increase in the tertiary student population of the Anglo-Saxon university which until recently was elitist and cloistered. The term "massification" has been coined to describe this. It was once thought exceptional to win a place at university. The later part of the last century saw Anglo-Saxon HE institutions changing to the more accessible American model of the university. The scale of the recent expansion has been unprecedented. According to Trow (1973) a system can be called elitist when it enrols less than 15% of the eligible population, when enrolments exceed 40% it has the potential to become a universal system. In the U.K. as late as 1987 only 17% participated in HE. This had reached 40% by 1998. The U.K. university system moved from elitist to popular more than doubling its student population in the short space of 10 years and was transformed from a relatively small and rather elitist institution into a large, diversified, multi-disciplinary organization similar to those in the United States where access to HE had for much longer been more open.

In the 1960s less than 10% of New Zealand"s school leaving population went on to tertiary studies. The majority of first time job seekers left full time education in the fifth form (Year 11). A substantial number obtained their first time job at the end of the fourth form (Year 10). In New Zealand, to gain University Entrance was considered a major achievement. For those who chose it was the key to a university place, for others, the key to entry into first time appointments in highly sought after public sector institutions. By the late 1990s the majority of school leavers went on to full-time tertiary study. Most first time jobs are now accessed from varying levels of HE.

It is claimed that one of the significant effects of massification has been the increase in economic efficiency of universities. With increased staff to student ratios, more efficient use of classrooms and facilities, the automation of systems such as libraries and record keeping there have been significant productivity gains and a sharp reduction in unit costs (costs per student). One assessment in the U.K. suggests significant productivity gains with real costs per student falling about 40% in the 21 year period to 1997 (King, 2004: 16). This confirms that mass systems of education have a different economic structure than elite systems and it is demonstrated by the downstream effects on human resources, equipment, and cultural structures within the university. For example there is a "significant intensification of the academic labour process" (Scott, 1997: 39) which is not only reflected in sharp increases in staff student ratios but also in greater staff involvement in revenue generating research, students taking more responsibility for their own learning via self-directed learning, self assessment and the automation of assessment techniques. Scott argues that one of the less tangible effects can be seen in the area of personal relationships. The increased use of electronic mail, the increased time consumed by bureaucratic compliance procedures, and the dramatically increased numbers of students, particularly in the first and second year classes all contribute to an attenuation of personal relationships.

A further reason for university expansion is that it provides, in part at least, a solution to the problem of youth unemployment in western post-industrial societies. Modern, automated and information technology rich societies require less and less human labour, particularly physical labour. Delayed entry into the labour market helps reduce the unemployment figures in the same way as early retirement does at the other end.

Another reason for university expansion is the market for mature adults and continuing professional and personal education. The university is increasingly playing host to a group of mature students, often forced to return to university because of the loss of a job, the break up of a relationship or markedly changed personal economic circumstances. Brown and Scase (1994) see such students using access to HE to provide for the "reconstitution of personal networks, cultural interests and socio-political activities" (p. 98) that provide for "identity reconstruction". They suggest that this may be as important an outcome for HE attendance as formal learning is. It may also suggest one reason why the "virtual" university will not replace, at least entirely, the traditional campus-based institution.

Scott (1997) suggests that massification moves the whole field of HE onto a plane where its very visibility creates challenges not previously faced by smaller universities. The vision of technology enabling efficient and effective access to these vast constituencies becomes not only a social but also a political and economic goal. The roles of HE in the political and economic spheres have never before been as substantial.

11.2. Globalization

Globalization practices are increasingly impacting on small countries like New Zealand. State owned and operated HE is facing increased competition from private institutions set up to make a profit from the provision of learning services. Such institutions are governed by people comfortable operating in the corporate environment; they carry no "baggage" of tradition and are not limited by charters that give prominence to public non-profit activities. Such institutions embrace the opportunities that global trade in education provides. Bodies such as The World Trade Organisation (WTO) and conventions such as the General Agreement on Trade and Services (GATS) see many elements of education, particularly HE as tradable professional services. Education may be used by national trade negotiators as leverage or "trade-offs" to gain favourable access for other parts of the exporting economy to a foreign market. Universities will find it hard if not impossible to resist the trends towards the globalization and commodification of learning perhaps to the detriment of the traditional public service roles of HE. On the one hand this may mean that larger and better-resourced universities will capture a part of the international market while on the other hand smaller, less well resourced, regional or local universities may become the victims of the international market. Why would one take a business degree from the local university when a Harvard degree with all of its associated prestige can be obtained online?

There are also trends towards setting global standards in HE. Organizations such as UNESCO are strong supporters of qualifications that have an international imprimatur and a global organization called the Global Alliance for

Transnational Education (GATE) has goals of establishing a global network of learning and an international certification regime.[4]

Melody (1997) sees universities being forced to grapple with the global marketplace of information expanding nationally and internationally and in doing so they will tend to compete against themselves. Already education is exported from many western economies. Melody sees a weakening of the traditional relationship of universities with the ministries of education and a strengthening of ties with ministries of trade and commerce.

The nature of the student body is also influenced by this process. There has always been some sense of student internationalism on most university campuses usually determined by state foreign policy objectives but on the whole universities were local institutions serving local cohorts of students. However, as Scott (1998: 117) points out these "students flows" are no longer based on such relationships. Now Students are no longer tied to the local university and market forces determine the nature of student flows. There have been two principal outcome of the embracing of market conditions. The first is that overseas students have now become an essential contributor to the revenue stream of many universities and colleges. Some now rely on overseas full fee paying students to balance their budget. The second is that subject choice has changed. As Scott points out under the government driven model science, engineering and public administration were the topics of choice for foreign students. Under the market model business, management and accountancy now dominate.

The global flow of students moving internationally for HE is increasing exponentially. In the U.K. the number of overseas students rose from just 70,000 in 1990 to just under 200,000 by 1996 (Bruch & Barty, 1998). In New Zealand the number of overseas students enrolled in New Zealand educational institutions in 2001 was 60,000. Their economic impact is significant. Although foreign students were just 8% of enrolled students at the University of Auckland they provided 24% of the university's fee income (Ninness, 2002).

Where previously people had relatively little choice about where to study unless they were privileged by selection to an overseas university, opportunities to enrol across borders, to take courses adjusted for part-time and short-term study, and participate in academic discourse without leaving "home" are rapidly increasing. There are now several thousand accredited courses available on the internet (Spender, 1995). Prestigious universities offer online programmes globally. The new single-order technology generates more demand for internationalized education. And while the increasingly competitive Western economies are hungry for choice and quality in education there are also growing demands for access to education from developing countries (Tiffen & Rajashingham, 1995). The number of students entering tertiary education who are also users of multimedia and the internet is increasing rapidly. This is to be expected given the strong share that computer games have in the teens and pre-teens consumer market (Laurilland, 1996). Parker Rossman (1992) suggests that a worldwide electronic university is emerging. He gathers together a range of research reports on experiments and demonstrations that suggest technology is being used to create a global HE industry, which is gradually developing its own set of goals, priorities, values and philosophies. Partnerships in cooperative education ventures are crossing national boundaries.

Whilst the global virtual university has not yet developed perhaps there is a precursor in the phenomenon of the Open University, an example of this being the U.K. Open University. Daniels (1997) coined the phrase "mega-university" to describe such an institution. There are nearly 50 universities identified with the title "Open". Only one The United Kingdom Open University teaches exclusively in English. These universities share a number of characteristics. They do not have teaching campuses, rather they have an administrative centre and a whole series of geographically situated "call-in" centres. They have, by current standards, huge enrolments. The UKOU has 220,000 students. The Chinese and Turkish open universities each have over half a million students and those in India and Thailand have reached a quarter of a million. They seek students over a wide geographical range (the UKOU has 80,000 students offshore). They are becoming aggressive in their local marketplace and in the case of the UKOU the global marketplace. They have embraced technology for the purposes of educational delivery (the UKOU has over 150,000 students working online). They spend large amounts of money in "front loading" their courses, that is they invest heavily in course preparation and course presentation. Costs of producing multimedia products are not cheap but the principle is that costly high production values will pay dividends by attracting students. In turn, high enrolments spread the capital development costs and reduce the need for high margins as courses reach critical mass consumption. As an example the combined budgets of the largest 11 open universities is around $900 million. Per capita that's just $390. This compared with the per capita average of U.S. universities of $12,500 and in the U.K. $10,000. Even allowing for internal comparison, say within the U.K., the UKOU per capita cost is just less than half the average for campus universities. Open universities are all state supported and respond to state educational policies (Daniels, 1997).

11.3. Corporatization

Corporatization is also a threat. Krishan Kumar (1997) suggests it is an even further barrier to the continued viability of the traditional university. The response of many universities in their attempts to remain relevant has been to promote themselves as corporations and mimic the behaviors of commercial organizations. He sees immanent failure for this strategy for universities lack the resources and skills, organizational and human to compete with experienced private commercial organizations. “They become absurd and increasingly despised as they compete among themselves like manufacturers of washing powders, employing increasingly grotesque marketing strategies” (1997: 27).

The impact of this behavior is being seen at many levels. First there is the lessening of the status of the academic as leader of the university. Academics are increasingly being replaced by bureaucrats and corporate business people as leaders in the university system. The skills of a modern vice-chancellor lie in managing human resources, efficiently overseeing a business plan and, increasingly important, fundraising skills. As the role of the administrator increases the academic life is seen as less attractive with lower salaries, increasing redundancies, penny-pinching budgets and the increase in contract appointments as opposed to tenure. Secondly, there is heavy investment in lobbying, public relations, advertising, and the development of “mission statements” and other documentation that demonstrates accountability and claims the ability to “quantify” the activities of the institution. Thirdly, there is increasing pressure to generate income and other resources by behaving in a “business-like” manner. They seek moneymaking consultancies, profitable conferences, the setting up of companies and other business entities and the search for research projects than produce income rather than enhance knowledge. Finally they demonstrate the typical market behavior of the firm, offering themselves up to partnerships, mergers, take-overs, and cross-border activities. They confirm by their actions that they are part of the globalized economy operating in the marketplace.

Kumar suggests that they may fail as corporate entities but if they succeed they will act more and more like firms, competing with others in the knowledge industry in terms of how quickly they create knowledge, how ingeniously they configure knowledge and how well they distribute and store knowledge. In such areas will lie, if at all, their comparative advantage. Indeed, as competition increases and the pressure to behave like a firm increases, the extraction of economic benefit from university activities will become a prime objective. This may be seen less in terms of new knowledge than in terms of the commercial realization of already existing knowledge configured in varied ways. In doing so universities are becoming enmeshed in the corporate world and behaving in such a corporate manner that they are “viewed as part of a single pattern of interactions with corporations which [will] need to be fostered and maintained over the long term” (Gibbons, M. et al., 1994: 88).

11.4. Intellectual Property Rights

Intellectual property rights and the changes in the status of knowledge have a pervasive effect on the institutions that supply information. In this regard universities must now rank with the rest—newspapers, publishers, radio, television, film, telecommunications, computers, libraries, banks. These institutions are now grappling with the tasks of assigning "property rights" to information, separating public from private information and establishing information "markets". This change to an "information economy" has generated an extraordinary rapid growth in the global industries within the information sector. As of 1998 the communications and information sector of the world's economies provided nearly 20% of the world's trade (Broadcasting and Cable Yearbook, 1998). Many states are staking their economic futures on the stimulus that the communications and information industries will provide.

The concept of the private ownership of property has been central to the capitalist economic system. Coupled with a system of law that protects ownership and provides contractual responsibilities these concepts have enabled the development of capitalist economies, given them the "strength" to compete against and overcome other models (e.g., communism) and created the current phenomenon of globalization. For centuries the focus of property rights was on land and materially created products. As more abstract and symbolic elements of society emerged so did new forms of protection such as the notion of copyright (books) and patents (ideas and concepts). As capitalist society moves from an industrial-based to a knowledge-based economy universities, the traditional source and repository of much knowledge, will become more closely involved in the trade and consumption of knowledge product. The impact will be felt in a number of ways. There will be pressure on universities to use their knowledge creation and storage for revenue generation. They will be less willing to share knowledge through the traditional channels, rather they will seek protection to maximize the economic value. Knowledge which traditionally would be released quickly to the peer community for purposes of review and critique will be held back, patented and released only in a marketable form. The value of the university "product" will cease to be a public good and become a tradable property in the marketplace of ideas and knowledge.

11.5. Deregulation

Deregulation was welcomed as a precursor to privatization by many economists, businesspeople and politicians, especially those of the Right. Over the last 20 years the New Zealand government has divested itself of many functions (telecommunications, banking, insurance, and broadcasting) by selling them to private purchasers, usually wealthy overseas corporations. If this trend continues through into education it is possible that education may be bound, by policy or budget, to accept just a few sources, the diversity of the many classrooms and teachers becoming the conformity of just one or two. The rush towards the privatizsation of education may see a multitude of players but if other examples are any indication it is more likely to be a cabal of a few international giants. Education may, like broadcasting, aggregate around a group of internationally respected "names". Educational multi media may become the battle ground of a few big corporations with vast resources to invest.[5] Furthermore, in the push to gain market share the organizations themselves may be driven not just by educational outcomes but by other gauges of public satisfaction such as entertainment value or user friendliness. The traditional information industries (radio, television, and newspapers) have been heavily influenced by "infotainment" and many have changed formats to accommodate audience expectations. The concept of "edutainment" may develop as the education industry vies for market share.

Large multi-million dollar corporations have been created to develop "edutainment". Disneyworld in Orlando, Florida in 2002 launched what is being referred to as an "edutainment" pavilion. Companies like Education Technology Inc. and International Multimedia Learning Corporation have been established with the view that "entertainment, technology, telecommunications and education will continue to come together to create a new dynamic for education" (Nocera, 1996).

11.6. Privatization

Bernard Woods points out that the new systems will be "driven by their potential profitability, by the new markets they create and by the new solutions they offer". (Woods, 1993: 133). We live at present in a "dual reality" between what is possible now and what we know will be possible in the near future as the technology comes on line.

Karel Tavernier, one of the founders of the International Conference of HE, a European-based agency argues that, worldwide, university funding systems need overhauling. His research suggests that

> Vastly expanding opportunities, greater internationalisation, decline in the dominant position of the traditional university, sharper competition, increasing privatisation, and higher resource intensity are just a few of the recent trends which have affected modern universities.
>
> (Tavernier, 1993: 89)

These trends separately and in combination will force major changes on the "traditional bureaucratic ways" of university operation.

Whilst organizations like the New Zealand Business Roundtable (1994) are understandably pushing for more private involvement in education, a number of academics are also lending their voice and backing it with research. D. Bruce Johnstone argues that private institutions at tertiary level can "provide HE benefits at lower costs than state-owned and state-run institutions through their greater managerial flexibility and their independence from state civil control" (Johnstone, 1993: 19).

While there are currently constraints in place that mitigate excessive privatization agendas in New Zealand there are constant pressures to permit greater participation in HE by the private sector.

11.7. Reduced State Involvement

One of those pressures is the growing reluctance of governments to meet the spiralling cost of HE. Social services like health and education are claiming more and more of the government's limited financial "cake". In health the relevant features are increased technology costs and an aging population that uses more health services, in education they are greater participation rates, the need for a higher standard of education within the general population and the life-long learning needs of the aforementioned aging population. Educational economists like George Psacharopoulos at the World Bank argue that "the demand for HE and enrolments have grown by such proportions that government can no longer foot the university bill, admit to the university all those who want to enrol, or provide education of the same quality as they did before . . . The way of the future is some form of recovery or privatisation in HE" (Psacharopoulos, 1993: 61).

In support of massive restructuring of tertiary education Michael Clarke and Alan Williams quotes from The Economist:

> Universities must adapt to a world in which governments are reluctant to fund HE; in which students are as likely to be middle-aged managers, trying to update their skills or change their careers, as impressionable school leavers; and in which knowledge-intensive industries, happily innocent of life-time tenures and union-negotiated pay scales are busy competing to buy talent.

They also draw attention to the immense growth in revenue that tertiary education is providing in some areas:

> Conservative estimates for the earnings created by management education alone run at some $US50 billion per annum. Australian estimates of export income for services for the year 1993–4 stand at some $A14 billion, of which $A1.2 billion was earned from educational exports.
>
> (Clarke, 1995: 87)

The growth of private providers in education within New Zealand has been strong. Encouraged by access to some government funding, the ability to charge high fees because of student loan availability, private providers now exist across the education spectrum, challenging even universities. They are particularly prevalent in that part of the tertiary sector previously the exclusive domain of Polytechnics (NZQA, 1995). One of the effects of the economic, market-driven, post-Fordist, and plurist philosophies that seem to drive the thought processes of bureaucrats and politicians may have on the HE structure is that a system of plural provision is developed. More than one writer (Filmer etc.) argue for a stratification in which the HE system may be broken into categories. Category one being a small number of "high end" universities involved exclusively in pure and applied research and post-graduate teaching. A middle category of small and more numerous institutions involved in smaller scale research and post graduate teaching (i.e., specialist schools) and the remainder involved primarily in undergraduate teaching, professional and vocational in-work training, and continuing education.

11.8. Rise of the "Knowledge" Industry

A further feature is the rise of knowledge industries in response to the growth of the so called "knowledge economy". One of the anomalies of the massification of HE is that universities are producing too many highly skilled graduates for the system to itself absorb. The result is that many more people familiar with scientific and social disciplines and skilled in research, unable to find jobs in the universities are moving into commerce and industry. The number of people leaving HE with the ability to become knowledge producers themselves is increasing and will continue to do so. Many of these people will continue to engage in activities that have a research dimension.

The more of these people the university produces the more they undermine their own exclusive role as knowledge makers.

> The core of the thesis is that the parallel expansion in the number of potential knowledge producers on the supply side and the expansion of the requirement of specialist knowledge on the demand side are creating the condition for the emergence of a new mode of knowledge production.
>
> (Gibbons et al., 1994: 13)

Capitalists and capitalist enterprises have discovered that there is money to be made in the "knowledge industry".

The requirements placed upon HE institutions by society are undergoing a massive transformation. John Stephenson (European University of Industry) talks about an economy in which the industries that survive will be those that are "knowledge capable" (Raven & Stephenson, 2001). The emerging global economy requires a workforce capable of handling an exploding knowledge base. Whilst technology has been the enabling force behind this change the discovery by the business structures of techno-capitalism that knowledge and information have commercial value has been the driving force.

There are unique elements to this "new" commodity. On the one hand information, unlike many commodities, is not destroyed when it is consumed. It remains to be passed on from consumer to consumer. A multiplier effect means that once a critical level of consumers of the same information has been achieved (the information learned) the spread of information is rapid. Thus the cost of generating knowledge is higher than the cost of replicating it. On the other hand both the volume of knowledge and the temporary and local nature of much of it mean that the costs of generation and storage are very high. Universities have traditionally been a major source of knowledge generation. It is therefore unsurprising that they have come under intense scrutiny.

However other market forces come into play. As the cost of information generation is high there is value, in business terms, for that information to remain scarce and therefore attract premium prices. As information has become more and more important for the success of a business strong efforts to privatize the gathering of information are being made. Enormous amounts of information are now in private hands and businesses pay a high price to access it. Even universities are caught up in this process. Much funded research at universities is now carried out on behalf of private organizations and restrictions on ownership of the results of the research are severe. There have been criminal charges brought against university staff in the U.S. for violating privacy clauses in contracts (Melody, 1997).

Economic theory suggests that when there is a market in which the product is expensive to manufacture but cheap to distribute, both to existing markets and to grow new ones, the tendency is towards global conglomerations with centralized and monopolized structures (note oil as an example).

The university is mandatorially caught up in this process because of its very nature as an information provider and the process has just begun. The changes occurring now and about to occur will see an "order-of-magnitude increase in the automation of the 'labour-intensive' educational services sector, including the university" (Melody, 1997: 81).

With all of these threats and challenges to the university "condition" it is easy to see why the goal of a truly "virtual university" has been hard to achieve and it also explains to some degree the limited impact of VLEs on the local educational ecology.

12. LOCAL RESPONSES

All of these issues are creating challenges and choices for the HE sector in New Zealand that are outside of its control and it is unclear how the sector will respond. There would appear to be three broad scenarios, one pessimistic, one less so and one which emphasizes separation between the institution as such and its academic staff.[6]

The pessimistic scenario predicts increasing competition within New Zealand both between local and national institutions and from overseas and these changes will be intensified with changes to the way state funding is applied. Institutions will concentrate on student numbers and offer courses to suit. Under this scenario, institutions compete for market share by seeking to be all things to all people, significantly reducing both the quality of the educational services they offer and their own financial and academic viability. Students, for their part, turn away from local institutions as they recognize the declining quality on offer and look instead to overseas institutions delivering services across the internet. During a period of heavy deregulation (1984–1998) this appeared to be the scenario most likely to eventuate in New Zealand.

(There is some historical significance to this scenario. During deregulation of the financial sector in the late 1980s institutions, relatively unused to competition, sought to expand rapidly and internationally without putting in place the necessary quality control and risk management measures and without understanding the implications of the limited New Zealand market and geographical isolation. Not only did significant business failures occur but many of these institutions ended up being substantially owned and controlled by trans-national corporations.)

In the second scenario competition is more disciplined. The state takes a strong interest in the governance and management of tertiary institutions looking to avoid excessive duplication or waste. There is a growing trend towards specialization driven by factors such as: more discriminating students, changes in research funding, responsiveness to employer concerns, recognition of the importance of developing niche rather than mass market approaches and co-operation/collaboration is valued above “no holds barred” competition. Local institutions gain some “protection” from international institutions. Since 1999 a change of government and the ascendancy of a centre-left coalition suggest that this now appears to be the current approach with the recent legislation to establish the previously mentioned Tertiary Education Commission with its wide powers to regulate and monitor all state HE institutions.

However, under both of these first two scenarios rationalization and economic efficiencies will still be sought and there will be a continuation of merger/acquisition activity in the belief that bigger must mean better, and further reduction in funding. Business modelling will continue to be applied to HE and students will increasingly be seen as consumers. There is a continuing process of development of niche oriented and specialist institutions.

The third scenario suggests that increasing technology efficiencies along with continued pressure both nationally (the main opposition parties are still free market oriented in matters of education and health) and internationally (pressure from world trade bodies such as the WTO and trading partners) to push for scenario one, creates a growing distinction between institutions and academic staff. Under this scenario academic staff recognize that the changes in the way student funding is applied provide an opportunity for them to establish their own enterprises. For some the motive may be the opportunity of earning an increased income (breaking free from rigid salary scales which do not reflect market valuations of different areas of expertise). For others, the opportunity to take control of their own teaching environment is the main motivator—it may include a commitment to "public education" values enshrined in the use of dedicated not for profit structures. It may include the emergence of institutions intended to serve the interests of particular groups. (This would be particularly the case for Maori and Pacific Islanders in New Zealand.) This leads to the breakdown of traditional HE institutions and the emergence of new models of teaching and learning that provide the flexibility and resources to follow the demands of a fragmented and demanding student population. Partnerships and alliances may come and go in response to specific and discrete learning needs.

Understandably the university struggles to find its "rightful" place in all of this. It seems as if the post-industrial society, in particular the postmodern (post-Fordist) period, coupled with the primacy of market theory has undermined the formally privileged position of the university by creating new centres of knowledge generation, training and research. These are challenges to universities on their own territories as they come to grips with the fact that a range of new specialist organizations can offer at least as good a service to government, business and the community as they can.

If, as Readings (1996) claims the university is "in ruins" is it possible to rebuild it? Will something arise from the rubble to continue the academic traditions?

13. THE FUTURE

> Anyone who tries to make a distinction between education and entertainment doesn't know the first thing about either.
>
> Seen on a T-shirt and attributed to Marshall McLuhan

If the processes of globalization and techno-capitalism continue then it appears that national economies will become even more inter-dependent as technology enables information flows to increase. In other information systems, especially broadcasting but also telecommunications and the internet the market structure gravitates towards a small number of businesses with immense global power and connections. In the media environment this has ended up with a tight cartel of transnational corporations whose search for consumers is driven by profit. These large organizations are searching for new product and are taking an interest in "learning" as a product. Some are fast developing their own versions of VLEs. The range of providers capitalising on the “learning market” include The Learning Channel, Thomson Learning, and BBC Online. These can already be observed in a variety of expressions. Examples include the BBCs interactive website for children and their interactive nature series, *Talk with the Animals.*

There are other examples of media-based competition for traditional educational institutions. Michael Milken, more readily known as a Wall Street junk bond dealer, is currently promoting a virtual education and training organization called the “Knowledge Universe” (www.knowledgeu.com). Karl Jones, a prominent U.S. television cable company owner, is promoting the International University. The strong interest in education demonstrated by entertainment and communications organizations such as Microsoft (Encarta); MCI (Caliber Learning Network in association with Sylvan Learning Systems, Inc); and McGraw-Hill (McGraw-Hill World University) all indicate the high level of media influence and media production values that may push HE towards elements of “infotainment”.

Ironically, universities appear to be behaving more like broadcasters. Noam (1995) developed a theory about the three stages of television and the third stage, which he identified at the currently developing stage he called cyber-television. The characteristics of cyber-television as outlined by Noam and the characteristics of the virtual university as outlined by various commentators look very similar (see box).

Inherent in these developments are a number of threats to universities. Among them is the fact that media organizations are more financially resilient and can bounce back more readily from mistakes and failures. Witness the failures of Warner’s 500-channel experiment in Orlando in the early 1990s and the Cambridge Interactive TV Trial of the mid-1990s. Financial disasters that would sink even the most well endowed university. They just do not have the infrastructure to sustain such costly failures and recover from them. Again, media organizations have the resources and knowledge to develop compelling content in the VLE. Years of working with video and audio, graphics and text provide a solid basis for creating attractive content. Universities do not have this heritage and cannot easily compete. Moreover as media companies “discover” the knowledge economy they are moving into the territory that was previously the sole right of the educator. The aforementioned online Jones International University had its origins in cable television. Such entrepreneurs may “cherry-pick” the universities seeking out the information “commodities”, the top information creators (academic staff), the best laboratories and libraries. Such “asset stripping” may become a feature of university life and universities might be forced to play the same game.

According to a recent Merrill Lynch study quoted in a Universitas newsletter (Universitas 21, 2000) it was stated that in 1990 there were 48 million people enrolled in HE courses globally. This was predicted to grow to 97 million by 2010, and to 160 million by 2025. The principle reason for this

Cyber-Television	*The Virtual University*
According to this model the developing generation of television is not, as today's trends might suggest, a move from multi-channel environment to mega-channel television. This is an incorrect extrapolation. Just the opposite will happen. Distributed, decentralized cyber-television will create a one-channel world. Noam called it the "Me Channel".	Like Cyber-television, this is not just a prediction but a possible outcome of the direction of today's techno-capitalistic educational environment. This model has no campus and firmly seeks its identity in cyberspace.
Some of the features include:	Some of its characteristics are:
1. A Barrierless Market: There will be no dominant entry points or dominant gatekeepers. Many companies, organizations, and individuals, as many as the market will support, will operate thousands of servers, making an income from a mix of usage fees, subscription charges, transaction fees, advertising charges, and sales commissions.	1. An Open Educational Market: Many institutions, as many as the market will support, will operate locally, nationally, and internationally. Students will enrol at their institution of choice after considering a range of criteria that will include not just the traditional ones of subject, institutional status, faculty quality but also ease of access, speed of delivery, levels of technology such as asynchronicity, the quality of the "bots" and perceived "value" of the "product" in the marketplace.
2. Infinite Diversity: Video servers, acting as large storage devices and holding thousands of films, documentaries, dramas, comedies and other kinds of programming, will be linked by high capacity telecommunications infrastructures and accessed by	2. Infinite Diversity: Subjects and courses will be of a diversity limited only by human creativity. Courses will be flexible and designed or tailored for the individual student. The technologies of cyberspace will enable large storage devices to

broadband switchers and routers providing an immensely flexible access to many networks.	hold thousands of courses that will be delivered over high capacity telecommunications infrastructures seamlessly organized to individualized menus.
3. The Media Supermarket: Television programmes will become totally commodified competing against each other for purchase, positioning themselves on the "shelves" of the servers to attract attention and to become the "preference of choice".	3. The Educational Supermarket: Much learning will become commodified. Courses will compete against each other for purchase by the student. Much energy will go into "positioning" the courses to ensure attention and long "shelf life".
4. Navigators: The viewer becomes the controller of their own televisual environment employing intelligent navigational agents to search out, access and download programming that interests them. Channels will disappear or become a "virtual" individualized and seamless channel based on the viewers expressed interest, past viewing habits, influences such as friends, critics, and other media sources with a bit of randomness on the side. Viewers will interact with programes entering into quite complex relationships which are enabled by "return path" technologies. Interactivity will be the key which engages the viewer in a range of social, cultural, commercial, and perhaps political associations.	4. Navigators: Students become the controllers of their own learning environment. They will employ intelligent navigational agents to search out, access, enrol, and deliver the courses that best suit the student's needs at the time. A student may enrol at multiple institutions; seek approval for an award that is unique to their own situation. They will be much influenced by the "front window" of the possible competing institutions' shows.

5. Asynchronicity: Viewers will see what they want to see when they want to see it. Except for those few programes when synchronous viewing is preferable—live sport for example, the "me channel" will give access to all programming where and when the viewer wishes it.	5. Asynchronicity: Students will learn what they want to learn when they want to learn it and where they want to learn it. The university of the future will be on-line all of the time. Face-to-face tuition will be an expensive add-on option. It will be offered probably only to an elite and for specialist courses where real-time participation is essential—music, dance, drama etc.
6. Customcasting: Broadcasting doesn't become Narrowcasting, the prediction of the cable companies in the 1980s. The simultaneous mass media experience will be replaced by individualized experience. Interactivity will dominate as the media seeks to engage with the individual at unprecedented depth and provide customized content to individual wishes.	6. Customized Learning: Students will design their own learning environment and interact with it. The economic costs of learning will be balanced against such concepts as "just-in-time" learning, "life-long" learning and the needs of the workplace. Many students will just want to "get in, get out, and get a job" (Ruch, 2001: 122). They will use the technology to interact with the courses, faculty and institutions and in the process take over control of their learning experiences.

growth was online learning and globalization of programming. In 2000 in was estimated that this market was worth U.S. $15 billion to U.S. educational institutions. Such growth rates coupled with such returns will be a prime driver of the virtual university. David Kirp, professor of public policy at the University of California at Berkeley, warned that "in this high-stakes world money, not quality, talks the loudest" (Kirp, cited in McLeod, 2004).

Perhaps an embryonic transnational university already exists. Universitas 21 is a company incorporated in the United Kingdom with a network of 18 universities in 10 countries. Collectively, it enrols about 500,000 students each year, employs some 44,000 academics and researchers, and has a combined operating budget of almost U.S.$9 billion.

According to their own publicity this network provides a framework for member universities to pursue agendas that would be beyond their individual capabilities, capitalising on the established reputation and operational reach of each member. The Company sees its core business as the provision of a "pre-eminent brand for educational services supported by a strong quality assurance framework". It states that Universitas 21 has been established for the purposes of:

- Developing international curricula for graduates educated and trained to operate in a global professional workforce, with credentials that are internationally portable and accredited across a range of professional jurisdictions;
- Providing a quality assurance structure that operates globally to offer internationally valid processes for the enrolment, instruction, assessment, and certification of students, and an internationally recognized brand identifiable with a global network of high quality universities;
- Providing partnership opportunities for major new providers, including corporate universities, wishing to access a fast-growing international market for HE and advanced training;
- Bringing to such partnerships international recognition and legitimacy, premium HE branding, a demonstrable quality assurance capability, and a proven capacity for producing and delivering quality HE and training programmes. (Universitas 21, 2004)

Certainly their publicity suggests that they are in a position to leverage the reputation, resources and experience of the member universities to work for the establishment of a "global brand" and, on paper at least, they have the elementary requirements to develop the "boundary-less" virtual university. Yet they are far from being a demonstrated success. They seem to be like many others mentioned in this chapter, they have lots of potential but little actuality.

Meanwhile, the technology keeps surging ahead creating its own challenges to the shape and directions of future learning. A New Zealand academic, John Tiffin (Tiffen & Terashima, 2001) and colleagues in Japan are carrying out significant experiments on what they term "hyper-reality". Their work suggests that the current concepts of "reality" and "virtual reality" may blend into a seamless hyper-reality where the human experience will find it difficult to know what is "real" and what is not. Learners will move between reality and virtual reality adapting to whatever suits their needs at any one time. Tiffin talks about a "world of the virtual, a place where you could be hard pressed to know if the person standing next to you is physically real or virtual or whether they have human or artificial intelligence". Bridging the gap between the natural and the artificial creates this seamless world creating new opportunities for education, medicine, and communication. Tiffin talks about hyper-translation—the ability to speak in one language and be heard in another and virtual reality popping out of books to create "media to co-exist with us".

In that regard the Human Interface Technology Laboratory in New Zealand (HitLabNZ, 2004), has produced a "book" that interfaces reality and virtual reality. The lab has developed the concept of the "Magic Book". This adds value to a "real" book by permitting the reader, through the use of glasses, to have virtual content superimposed over the real pages. Aimed especially at children, when they see a page with a scene they like they can "fly into the scene and experience it as an immersive virtual environment". The book permits more than one reader to interact and this enables one reader to view the other as a virtual character in the scene.

These two examples show that while New Zealand searches for a clear role for VLEs in the HE environment and demonstrates both caution and uncertainty about their roles, the country is sharing in the excitement of building the technoloy and experimenting with the models that may yet provide the universal application to both learning and a hosts of other human acitivities that will be enhanced as a result.

CONCLUSION

In seeking to understand what the emerging organizational models in 21st-century HE may be and to reflect on what digitalization, competition, and globalization may do to current institutions of HE in New Zealand this chapter concludes by suggesting that the tendencies demonstrated by media organizations to converge, expand and seek global markets may also be reflected in the behavior of universities. As learning becomes one of the fastest growing "new media" products and media organizations like BBC Online Education, The Learning Channel, The Discovery Channel, Thomson Learning, The Disney Channel, and PBS all seek to promote this new product then it may be possible that either universities will behave more like media organizations or media organizations will take over some of the roles of the university. Or, perhaps these two previously separate activities will "converge" into a yet to be conceived structure that will combine the capital wealth, technology, distribution networks and content creation skills of broadcasters with the knowledge, research skills and teaching and learning resources of HE. Such structures will overcome the barriers to the development of true online universities, create portals through the television screen to a plethora of learning opportunities all tailored, via the Noam concept of the "me channel", to provide for the immediate learning needs of each individual.

Along the way, small countries like New Zealand will be "swallowed up". Thirty years ago in New Zealand broadcasting and telecommunications were privileged, local, state owned and operated. Each broadcaster was independent and reflected the culture and the community in which it resided. The telephone network was state operated and controlled. Today 80% of New Zealand's communications infrastructure is foreign owned. Conglomerates, either in the form of networks, or large multinational companies operate virtually every outlet. Many of them have alliances and other contractual arrangements with overseas operators. The amount of locally created content on television screens is extremely small compared with imported programming. The implications of this model suggest that what has happened and is happening in electronic communications is happening and will happen in HE. This suggests that the independence and localism of HE in New Zealand will eventually be lost.

ENDNOTES

1. The Treaty of Waitangi is New Zealand's founding document, an agreement signed in 1840 between the colonizing power Great Britain and the indigenous Maori tribes. It was an exchange of promises many of which where broken or had lapsed as immigrant populations dominated. In recent years there has been increased awareness of the pivotal nature of the Treaty and its role in protecting Maori interests and creating a partnership of equals in the nation (see http://www.treatyofwaitangi.govt.nz).
2. New Zealand has a short electoral cycle (3 years) and a unicameral legislature. It is rare for a government to have three successive terms. Thus the political economy is subject to quite substantial swings as oppositional parties move in and out of government. Currently (2004) a Centre-Left government is in its second term and is modifying many of the policies of the previous Centre-Right incumbents.
3. Student loans are a recent phenomenon in New Zealand. Until the early 1990s many students were paid an allowance to attend university. Also, course fees were low. Student debt is now at a record level of NZ$7 billion and course fees are approaching, and in some cases surpassing, US levels.
4. http://www.edugate.org/.
5. Tendencies to consolidate are exemplified by media organizations. The last 30 years have seen the media industries collapse into eight major media conglomerates responsible for the production and distribution of over 80% of all news, information and entertainment. In New Zealand following deregulation there were more than 100 separate companies operating in the radio industry. By 2003 two large companies, both overseas owned, dominate.
6. These scenarios are built from material extrapolated from conversations with the author and from data gathered from presentations at local professional conferences, newspaper reports, and internal institutional policy documents.

Chapter 25: Technology and Culture in Online Education: Critical Reflections on a Decade of Distance Learning

TIM W. LUKE
Department of Political Science, Virginia Polytechnic Institute and State University, Blacksburg, VA, U.S.A.

This chapter is a set of critical reflections on a decade of digitally driven distance learning on the web with e-texts, online courses, and virtual faculties. It reconsiders the project of building a virtual campus for existing brick-and-mortar universities around online communities—with their many perils and prospects—amidst broader shifts in the global economy. This "brick-and-click" option has been up and running at one particular North American university: Virginia Polytechnic Institute and State University, or Virginia Tech, for a decade. And, this analysis recounts the pluses and minuses of this experience. It, first, indicates why many existing offline university practices prevent change, and, second, it suggests how some online functionalities easily accelerate change. Yet, in considering how all universities might be transformed with digitalization, it also worries about what kind of changes, change defined by whom, and change for whose benefit in the larger society?

Most importantly, however, it sees e-learning on virtual campuses as an on-going reinvention of existing university institutions. Such organizational innovation can enable universities to create new learning communities and learned discourses, while keeping many of their traditions alive. Rather than permitting corporate entities to switch societies into shoddy substitutes for present-day universities with very misguided efforts to commodify the forms of higher learning that universities historically have produced, virtual campuses can use online classes to reach both existing and new clients.

1. THE FOUNDATIONS

Virginia Tech began constructing its virtual campus in 1993 with the launch of the Faculty Development Initiative (FDI). This experiment depended upon the implementation of distributed computing, which was launched by the Provost's Office and the Vice President for Information Systems. By closing down the university's old centralized mainframe systems, the FDI gave a new

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 653–671.

Apple desktop computer, a suite of software applications, and nearly a week's worth of hands-on training to a cadre of Arts and Sciences faculty with the hope that they, first, would quit using the old, expensive mainframe system and, second, might start playing around with these new personal computers in their teaching, research, and service. Without this first piece of almost accidental history, far less would be occurring at Virginia Tech because this one decision got computers out of the control of those who everyone once believed *should* have them—engineers, computer scientists, physicists—and into the possession of those who many thought did not need them—philosophers, political scientists, poets. Once those who supposedly did not need or allegedly could not use personal computers got a hold of them, several new virtual communities—both online and offline—were more easily "imagined" (Anderson, 1991) at Virginia Tech. And, everything began to change rapidly, fundamentally, and unpredictably.

At the same time, a small group of faculty in the College of Arts and Sciences was charged by Dr. Robert C. Bates, who had just been appointed the Dean, to think about using computers to break the credit-for-contact paradigm in response to fiscal pressures: Rising enrollments, falling numbers of faculty, and decreasing state appropriations. Led by Associate Dean Lucinda Roy, this committee advanced a proposal to construct a virtual college in November 1994 (Luke, 1994) around a series of online courses, which came to be called the Virginia Tech Cyberschool. Because of a parallel development in town, or a new off-campus online community, the Blacksburg Electronic Village, many students, and faculty had the internet access and technical skills to put this initial vision of a virtual campus into practice during summer 1995 with the first Virginia Tech Cyberschool courses. At that juncture, a major Sloan Foundation grant also allowed another team develop new computer-enhanced introductory biology courses in the ACCESS project, and a larger mix of totally online courses was offered at a distance over the Net in summer 1996 in the humanities, sciences, and social sciences.

Running parallel to these successes, the university self-study of 1996–1998 aimed at re-imagining Virginia Tech around its high technology strengths, including the enhancement of the university's online teaching capabilities. Totally online M.A. programs in physical education and political science went up on the web in 1996–1997 and 1997–1998, and Virginia Tech Online (VTO)—a full service virtual campus site—was activated in the College of Arts and Sciences to support its online courses during 1997–1998. Finally, all graduate theses and dissertations were required by the Graduate School to be archived as digital documents in 1997, and all entering students were required to have a computer during the Fall 1998 semester. And, the entire e-learning environment was anchored in Spring 1999 to a new dedicated organization—the Institute for Distance and Distributed Learning (IDDL)—that reported to the Provost's Office.

1.1. The Cyberschool Idea

The key issue for Cyberschool, which the founding faculty anticipated in 1994, has been how to value instruction in virtual teaching environments. Does online teaching enhance and enrich the education that university has always provided? For the most part, Virginia Tech students tend to agree that it does, both as an on-campus complement for face-to-face instruction and an off-campus virtual source of on-campus educational activities, because online technologies do create a new kind of learning community. Students consistently indicate that Cyberschool classes have increased their interactions with each other and faculty, have given them more convenient access to learning opportunities, and have enhanced their opportunities to work with course materials in a newer, more informative ways that emulate many corporate, governmental, and not-for-profit work environments.

By 1996, then, the exponents of Cyberschool-style classes could say this experiment had fulfilled most of its original design agendas. As the 1994 Cyberschool plan proposed,

> The cyberschool must be designed as an experiment to change (but not increase) faculty workloads, enhance (but not decrease) student interactions, equalize (and not shortchange) the resources, prestige, and value of all disciplines, balance (and not over emphasize) the transmittal of certain vital skills, concentrate (and not scatter) the investment of institutional resources, and strengthen (and not reduce) the value of all academic services. Technologies do not have one or two good and bad promises locked within them, awaiting their right use or wrong misuse. They have multiple potentials that are structured by the existing social relations guiding their control and application. We can construct the cyberschool's virtual spaces and classrooms so that they help actualize a truly valuable (and innovative) new type of higher education.
>
> (Luke, 1994)

There have been many rewards in creating Cyberschool-style classes. Students were enthusiastic about these innovations, and many measures of their learning showed considerable gains. Nonetheless, it also did prove to be a more punishing way to work for faculty. Instruction modules take time to develop, and most online course interactions with students are much more intense, time-consuming, and demanding than regular face-to-face teaching. Keeping machines, software packages, network links as well as course websites, listserves or chat rooms up and running was an exhausting ordeal on top of simply "teaching" the class once all of the IT components do, in fact, work online. IDDL mitigates this load considerably, but online teaching still requires different skills.

These demanding new work obligations caused friction inside of many units, because so few departments materially supported, financially rewarded, or professionally endorsed these new initiatives in e-learning. Of course, such success also brought additional expectations for publicity events as faculty colleagues and administrators made demands upon the pioneers to do demonstrations, speak their mind about the pluses and minuses of Cyberschooling work, or consult with the next wave of innovators as they launched Cyberschool-style classes. This agitprop work typically turned into "defend what you are doing" episodes as often as they served as "show me how to do it" events.

Many of the changes in workload brought to faculty by Cyberschool were, at bottom, net individual add-ons as well as basic departmental increases. Cyberschool faculty did new kinds of work, but they also did more of it. Resources were provided temporarily through infusions of one-time grants and other funds, but the university did not make changes in the basic structures of faculty rewards. And, even today in 2004, there is insufficient stable base funding for this activity. While Cyberschool used technology, its participants also have not altered an academic culture that still underappreciates, for instance, the prestige and resource needs of arts, social sciences, and humanities programs against those of the natural sciences, business, or engineering. While the College of Arts and Sciences responded positively to e-learning, the university moved very slowly to rethink the rewards (in tenure and promotion, salary raises, or departmental prestige) for this new kind of teaching-centered, research-and-development work at the heart of many Cyberschool innovations.

The combined faculty challenges—measured in terms of workloads and rewards—have led to cases of "burnout". Most of those who first helped initiate the Cyberschool project at Virginia Tech have moved on to other interests. They feel that they cannot afford the costs that their participation incurs against professional research projects or their tenure and promotion reviews. Early Cyberschool pioneers often expressed a sense of exhaustion as they struggled to achieve excellence on both a new, and the traditional, scales used to measure teaching, research, and service success. Cyberschool was an initiative rooted in the college of Arts and Sciences with faculty from English, Philosophy, Communications, Music, Theater Arts, Art History, Psychology, Biology, Political Science, and History. Most of Cyberschool's initial efforts focused on the classroom, but no school is merely a collection of classrooms for faculty teaching. Such e-learning activities also need an extensive administrative infrastructure to support its activities. Until given new support with online community infrastructure at the university-level through IDDL in 1999, Cyberschool did not move forward too far.

From 1994 to 1999, then, Cyberschool essentially ran on a "demonstration project" basis in one college. In times of very tight budgets, Dean Bates in Arts and Sciences supported Cyberschool with some college funds and the time of his staff. A university center, or the Center for Excellence in Undergraduate

Teaching, provided seed money for developing online courses, the FDI support staff helped immensely, and the Departments of English, Communications, Biology, Art and Art History, Music, and Political Science also contributed to the Cyberschool initiative. Yet, it was time by 1999 to move beyond the "demonstration project" stage with IDDL so that online education at Virginia Tech would not lose momentum entirely.

1.2. Pushing Cyberschool up to the University Level

In 1994, the Cyberschool faculty also proposed that Virginia Tech construct a set of virtual environments for online education that could provide:

a) A set of basic orientation, enrollment, credit acquisition, syllabus, and fee payment information about all Cyberschool instructional sessions;
b) a system of secure access and use rules to insure that students are who they represent themselves to be, are fee-paying legitimate users of the system, and are guaranteed confidentiality in their interactions with the Cyberschool, which also would guard this fair use of copyright restrictions of online materials;
c) a series of multi-user domains, structured as online chat sessions or time-delayed bulletin board structures, that can be assigned to an instructor, a student or groups of instructors and students in order to work through pre-arranged course of instruction;
d) a linkage to second-source educational packages switched from VPI&SU libraries, other VPI&SU college Cyberschool systems, or off-campus sources of video/audio/textual educational information; and,
e) a means of collaborating with off-campus corporate, university, and government offices to test new networking, software, hardware, multimedia technologies, and services that might improve the VPI&SU Cyberschool campus (Luke, 1994).

Cyberschool faculty made these proposals, because their biggest needs were *logistical* or *administrative*.

The Cyberschool faculty and the College of Arts and Sciences provided the real push needed during 1994–1998 to get the university focused on online learning and its new institutional requirements. By 1996–1997, Cyberschool coordinated about fifteen online classes, and collaborated with the Vice President of Information Systems to construct VTO as Virginia Tech's portal to distance and distributed education courses. The College of Arts and Sciences covered VTO's administrative costs as well as paid buy-outs for faculty to teach online in 1997–1998. That year was spent as a focused pilot project to demonstrate the demand for more online instruction, which brought the Provost's Office, Educational Technologies, and the College of Arts and

Sciences together to build the IDDL unit. A matrix organization, the IDDL was organized by the Provost's Office, but much of its personnel and resources come from the Vice President for Information Systems, Extension and Outreach, and the College of Arts and Sciences. With a teaching and research faculty executive director as well as an administrative and professional faculty director, the IDDL was assigned the task of bringing more Virginia Tech classes and programs to the web in addition to the Commonwealth's large ATM network, or Network.Virginia.

Virginia Tech by 1998–1999 had many distance and learning courses, but lacked a friction-free means of publishing distance learning course details through an online catalogue, updating an online timetable, registering students on demand for online classes with an e-commerce utility, managing the mechanics of online class enrollments, administering the demands of online student grading or major/minor/core requirements fulfillment, or paying for class credits and other student fees online. Initially, VTO in the College of Arts and Sciences provided some of these services, but it was not until 2000 under IDDL that VTO finally could manage online education as e-commerce transactions. Still, something more comprehensive was plainly needed, even 5 years into the Cyberschool project. Most of Virginia Tech's online classes were undergraduate classes, no single program of study was put entirely online until 1997, most of the courses were core curricular offerings, and no course was designed outside of the normal time/credit/work rules of conventional contact teaching. For the most part, this outcome was cost conflict and a turf question. Cyberschool was regarded as a College of Arts and Sciences project, which had very limited funding and its Liberal Arts approach was unpopular in the professional schools and more applied fields.

With scores of courses in Virginia Tech's eight colleges using Cyberschool-like methods of instruction by 1999, the university did put its e-campus on a more solid administrative footing by creating the IDDL in 1999. Its task was to develop reliable means for: (a) rewarding faculty materially for their efforts; (b) supporting departments for their engagement with these innovations; (c) consolidating new administrative software, procedures, or rules for coping with expanded online teaching; (d) preparing students for online learning by insuring "one student–one PC" access levels with adequate network and computer support for all students; (e) publishing information about distance and distributed learning course availability more widely to increase enrollment; and (f) organizing all of their activities through a central site to avoid duplication of efforts, standardize curricular planning, and reduce lead times in scaling up Cyberschool-like classes for access by anyone anywhere anytime. This involved new expenditures of time, energy, and money in the Provost's Office, but that investment was well-worth the effort.

Like many other groups elsewhere, the Cyberschool faculty at Virginia Tech operated as an advocacy organization, issue group, or social movement to criticize and popularize the use of computer-mediated communication in university instruction. This point is important, because despite what all of the digital futurists claim, technology does nothing on its own. Technically driven change is neither automatic nor easy; and, every apparent technological innovation either is hobbled by significant anti-technological resistance or advanced by supportive pro-technical allies. Unfortunately, however, myths people share about technological inexorability make it difficult to think "outside of the box" when it comes to using most new technology (Luke, 1989).

In many ways, the virtual campus at Virginia Tech is an uneasy amalgam of post-Fordist flexible work organizations and digital network technologies (Jameson, 1991). When combined together by academics, they can provide a new model for flatter, leaner, more responsive academic work organizations. Despite such alluring prospects, however, none of the changes happened on their own. They became possible only by determined groups of people that worked to re-order how the university actually operated in 1994. In 2004, e-learning is now a routine service provided by special administrative units like Virginia Tech's IDDL.

Given its experience from Cyberschool with online undergraduate instruction, for example, the Department of Political Science also launched the development of its fully online Masters degree program in Political Science (http://www.olma.vt.edu) during 1997, and individual courses were being taught through it as early as Summer 1998. The College of Arts and Sciences was asked at that time to expand its teaching presence in the state's urban areas across Northern Virginia, and this approach seemed like a relatively cost-effective strategy for providing the M.A. in political science to non-traditional students residing in the DC area. Of course, the site is available to anyone anywhere anytime in the world, so nearly sixty students are now taking courses in the program from all over the U.S.A. as well as Europe and Asia. Most of the online M.A. students are individuals serving with the U.S. military, working for international agencies and state governments, or teaching in secondary school and community colleges. Its first full-class was admitted in 1999, and all of them graduated by 2003.

The deployment of digital technology in this program has had two aims. First, it helped to overcome the university's place-bound qualities by making the M.A. degree offered by the Department of Political Science fully available online. And, second, it addressed the needs of place-bound students whose career and family demands made it impossible to pull up stakes to move to Blacksburg for their studies. The decisions taken by the university at-large to put much more emphasis on digitized library resources, to provide an excellent support structure for registration, enrollment, and records-management with VTOnline, and to push for a campus-wide electronic thesis and dissertation requirement made it possible to produce an excellent graduate educational experience online. The first OLMA/PSCI student finished writing his M.A. thesis during Fall 2001, and he orally defended it before his committee members in Blacksburg, Virginia, and Washington, DC from his place of work near Frankfurt, Germany during an extended videoconference in December 2001.

A majority of the faculty at all ranks in the Department of political science has participated in the online M.A. program. The common caricature of university faculty members as neo-luddite opponents to technological innovation simply is not true. Once faculty were shown the utility of new digital teaching tools, which enable them to communicate more effectively as well as allow students to learn more flexibly, they adopted such innovations. While some faculty will remain quite wary of administrative dictates from above, they enthusiastically join challenging new projects, like Cyberschool or OLMA/PSCI, that afford them fresh opportunities to try out new approaches, to learn different educational techniques, and to use better communications.

2. BUILDING AN ONLINE COMMUNITY FOR EDUCATION

The semester that the IDDL was launched, there were 17 distance and learning courses with under 1000 enrollments. Most of these courses originated in the College of Arts and Sciences from Cyberschool, but the IDDL gradually promoted more diversity and depth in the course offerings. In Summer 1999, there were 35 distance learning classes with 1155 enrollments; in Fall 1999, 73 distance learning classes were given with 2218 enrollments, and, Spring 2000 saw 88 distance learning courses with 3001 enrollments. The total online inventory of courses was over 100 by 2001. While it is not a huge number, 6374 enrollments in distance learning classes in 1999–2000 represented a 24% increase over 1998–1999. At the same time, the number of courses offered rose from 135 to 214, which is a 60% increase. By 2002, over 300 courses were available online, and its was possible to fulfill most of the core curricular requirements entirely online.

Much of this increase came from IDDL efforts to support distance learning in all of the colleges and departments of the university. Of the university's nearly 1500 faculty, 136 were involved in 1999–2000 as instructors in distance and distributed learning. The IDDL gave fifteen faculty summer stipends for courses in Summer 1999, and fourteen more course development fellowships were given out in 2000. An online IDDL newsletter was started to publicize distance learning achievements and developments, and the IDDL touted the merits of online teaching for faculty to their deans, directors, and department heads. New personnel were hired to manage marketing, assessment, and new course development, which also demonstrated the university's resolve to take new teaching techniques seriously.

While financial challenges are difficult, they often are easier to tackle than overcoming the entrenched routines of face-to-face interaction embedded by everyday administrative practice. Virginia Tech was teaching courses over the web in 1995, but it still has not cycled all of its administrative and information systems (AIS) to work on internet time. The contradictions made obvious by doing coursework online, like registering for classes with paper forms, paying with a paper check, getting paper documentation of registration, and checking on records with paper archives all brought the university to a major upgrade of its AIS services in the mid-1990s. Existing AIS systems from the 1970s tended to pull data into peculiar pockets of power and privilege from which it neither circulated widely nor linked easily with other information sets.

The infiltration of net-centered thinking in the classroom as well as the desire for an enterprise level integration system moved Virginia Tech to contract with SCT. This partnership adapted Banner™ to Virginia Tech's workings in ways that it made logical to support network-based teaching and administration. Nonetheless, the IDDL still had to lobby hard to convince the Bursar's, Registrar's, and Treasurer's Offices to accept credit cards from distance learners for tuition and fee payment, dedicate specific index numbers for online classes, break apart 3-hour/3-credit courses for distance learning students, and allow flexible scheduling for online classes. All of these provisions are necessary to succeed at distance learning, but each one of them transgressed existing practices that favor on campus enrollments. The architecture of Banner™ has been modified to deal with these needs, but it would have been much more difficult to make such policy innovations without this on-going enterprise reintegration project growing alongside, albeit separate and apart, the IDDL.

Instead of starting with a clean sheet of paper to build a corporate-oriented thin, for-profit, skill competency based virtual university, like the University of Phoenix, Virginia Tech has renovated the public-supported, thick, not-for-profit, and degree granting structures of the traditional university, injecting bits of market response into its virtual campus while remaining committed to traditional education ideals. After offering their first classes in 1995, and even once IDDL was started in 1994, Cyberschool faculty have continuously worked as change agents, pushing the university to adopt many new reforms, ranging from mandatory individual computer ownership for students, new technology support fees, student peer learning and teaching, and mandatory electronic thesis and dissertation submissions to online student registration, electronic records access, digital university press publications at a digital discourse center, alumni-centered lifelong learning initiatives, and redefined faculty reward systems. At the end of the day, these reforms have effectively restructured some of the university's research, teaching, and extension services to be more responsive to changing demands off campus and new needs on campus. Virtual campuses at traditional universities, then, can advance radical changes that are far greater and much more diverse than simply deploying computer multimedia to teach workplace skills, because they build new online communities. Many visions of the virtual university do little to move past a limited changes in content delivery, while a few, including the Virginia Tech, push to make these technology-driven changes much more creative.

First, a virtual university can be in many ways an entirely new form of learning community. Anyone who has paid attention to everyday practices since 1994 in the U.S.A. should see this change. Today most colleges operate extensively through computer-mediated communications every working day. e-mail interactions are displacing telephone conversations, F2F meetings, and personal exchanges in ways that once were carried exclusively by written texts. While this traffic often is also fleeting, underdeveloped, and exhausting, it has textual, hypertextual, or multimedia qualities unknown outside of computer networks. Written words carry more and more instructional activity, while most basic information resources once printed in catalogues, mailed out as brochures, accumulated in libraries, or posted on bulletin boards now must be pulled down from websites. They can be changed more frequently, and hard copy costs are shifted to users. Physical location, synchronously shared times, and group meetings are becoming less vital to learning than network connectivity. So access to education has been quickened and broadened. In addition to everyone who would be traditionally on campus, one finds non-traditional students, clients abroad, not-for-credit students, and residential students temporarily located elsewhere all commingling together in e-learning classes at virtual campus sites in new kinds of communal interactions.

Second, new discursive possibilities are developing within, and as integral parts of, the virtual campus at this university as online technologies begin to do much more than simply electrify print documents. The WWW, CD-ROMs, hard drive software, and floppy disks all represent new communicative media whose functionalities sustain fresh modes of discourse with their own conventions, formations, and practices as well as unconventionalities, misformations, and malpractices. The electronic thesis and dissertation, online catalogues, student access to registration sites, and online advising are all good cases in point. In-house administrative discussions and external research communications on the WWW in PDF, Eudora, or Word software packages are carrying hypertextual, multimedia, or technoscientific discourses, which lead to a profusion of new logics, pragmatics, and rhetorics in their arguments that print cannot capture. Research is being conducted, written-up, peer reviewed, published professionally, and then permanently archived all in entirely online modes—often cheaper, more accessible, and much faster. This experience at Virginia Tech indicates that research, reflection, and reasoning about knowledge in almost every discipline must confront this new communicative dimension of virtualization in tertiary education.

Third, the virtual campus at a traditional university leads to new disciplinary coalitions and social networks. The pervasiveness of changes brought on by computer-mediated communication has remade, if only in part and for a while, the disciplinary divisions and canonical conceptualizations embedded in the structures of the university's essentially industrial, nationalist, and scientific organization. Globalization and marketization are reshaping economies and societies, and legitimate forms of knowledge about them also are evolving in ways that no longer mesh as fully with the existing organizational outlines of established academic disciplines. Newer networks of knowledge production, consumption, circulation, and accumulation nest now in processional consultancies, for-profit enterprises, and state agencies. Off campus, there is a market-based sense of knowledge consumption, a quick-and-dirty approach to knowledge production, and a task-oriented sense of knowledge definition that all are reshaping what some disciplines do research on, when they do it, why they do it, and how it gets done. The virtual campus of traditional universities can import insights or experts from these parallel networks of scientific investigation off-campus as well as begin to rebuild traditional on-campus faculties to emulate these new modes of research.

A fully virtual university is technologically feasible at this juncture. Yet, there are many obdurate material practices and cultural values impeding its development. On one level, new tremendous infrastructure requirements—whose costs and complexities have not been fully grasped by most supporters of the virtual university—loom over the growth of every e-campus. In 1999–2000, barely 50% of all households in the U.S. had a personal computer with internet connectivity, and most connections moved up and down their link at baud rates of 28,800–56,600. By April 2004, things here have improved in the U.S.A. with 50% of all homes having a computer, and over 55% having a high-bandwidth connection <http://www.pewtrusts.com/ideas/ideas_item.cfm?>. More political jurisdictions in the world, following trails blazed by Commonwealth of Virginia and the city-state of Singapore in 1995–1996, are building widely available high-bandwidth networks, internet 2 level networks are spreading, and wireless technologies can address some of these problems. Nonetheless, like most traditional media, the internet creates its own inequality (Schiller, 1996). Connectivity still is geographically patchy, unequally enjoyed, and technically immature. Even then, these telecom systems can fail, charge high basic rates, and limit equipment choices in a manner that obstructs communicative ease, ready connection, and cheap websurfing.

On a second level, there is real gap between the predicted level of network use puffed up, on the one hand, by hardware producers, telco operators, and software firms and the actual numbers of users, on the other hand, that show up at the virtual campus' digital doorsteps. Most people use their PCs for doing e-mail, visiting sex sites, hitting online casinos, or visiting shopping outlets. After 3 years of intense public relations on campus, Cyberschool enrollments in Summer 1997 barely hit 350, or an average class size of about 10 students. Off-campus interest is quite intense, but total IDDL enrollments for its courses during Spring 2000 only just barely reached 3000. So F2F connections at our university's home and extended campus outreach sites still anchor Virginia Tech's enrollments. Much of this is due undoubtedly to access costs, bandwidth limitations, and hardware shortages, but institutional barriers, cultural inertia, and professional prejudices also cannot be discounted as sources of serious resistance to virtualized instruction. Ultimately, online education with the virtual campus is a niche market for most universities and many students.

For academics, the most basic issue raised by the virtual campus is "job control". The model of flexibilized efficiencies promised by the University of Phoenix masks a knotted tangle of serious job control questions by bundling them up with fancy technological innovations. Going online with university instruction conducted through multimedia packages does abridge many prerogatives now exercised by professors in F2F classroom teaching. These online alternatives mostly presume that professors simply are dispensing information in their traditional lectures and seminars, and therefore their information-dispensing efforts should be enhanced, extended, or even extinguished by technological surrogates.

This type of technological intervention can rob professors of their authority, and cheapen the educational experience. Nonetheless, as scale increases, many course syllabi can be designed and constructed by technical designers, panels of experts, or outside consultants, and then sold as mass media products online or in boxes by publishers. Lectures, in turn, can be automated with such multimedia replacements. Testing might be contracted out to assessment businesses, and student advising, tutorial discussions, or independent studies could be conducted by paraprofessional workers without Ph.D.s.

This image of the future is not favored by academics; instead, it is a dream of corporate players, like Microsoft or Intel, or lobbying groups, like EduCause. Behind these simplistic narratives, it is claimed that technological imperatives, economic necessity, or unserved markets "make change inevitable" for professors as researchers, teachers, and service-providers. Yet, such allegedly inexorable forces of change essentially are, in fact, lobbying campaigns by hardware manufacturers, software publishers, telecommunications vendors, and educational consultants.

At this time, online education as e-learning at Virginia Tech still works in the opposite register: small-scale, handicraft production for local use, not global exchange. Often one instructor is mapping his or her existing courses over to a self-produced or common utility website, generating computer-animated overheads, or organizing multimedia demonstrations to enliven traditional contact-style teaching and/or to experiment with asynchronous learning interactions. The material still mostly is a "home-made" production for "on-campus" circulation through "in-house" means of student consumption or at "on-site" centers of knowledge accumulation. The IDDL's biggest project since 1999 has been a joint master's degree in Information Technology jointly created by Computer Science, Electrical Engineering, and the School of Business. While the enterprise is larger, it too largely follows these handicraft models. Therefore, existing pedagogical practices in the university, academic department, and professional discipline still capture and contain e-learning by providing virtual flexibility and multimedia enhancements in established programs of study.

Despite the rhetoric of accessibility, democracy, flexibility, participation, or utility associated with cybernetic technologies, most networks today are, in fact, formations whose characteristic qualities in actual practice are inaccessibility, non-democracy, inflexibility, non-participation, or disutility. Many web domains are not readily accessible, and those that often are nearly worthless. Some schools like MIT have their whole suite of course curricula on the web, but quality and quantity vary widely. There are at least 2 billion pages on the WWW, but the best search engines only capture about 300 or so million of them. No one voted to empower Microsoft, Intel, IBM, or Netscape to act as our virtual world-projectors, online terrain-generators, or telematic community-organizers, but they behave as if we did by glibly re-imagining our essentially choice less purchases in monopolistic markets as freely cast votes. Inequality and powerlessness are not disappearing in the digital domain; they simply have shifted their shapes and substances as human beings virtualize their cultures, economies, and societies in networked environments.

After a decade of experience with designing, launching, and using online education applications at Virginia Tech, it is clear that many of the initial naysaying claims made by opponents of online learning have proven dead wrong. There is no significant difference between online and offline classes in terms of the quality of instruction, level of student satisfaction, effectiveness of faculty work or overall student success that can be attributed to the use of digital technologies and networks. In fact, the nature of the entire project, if anything, often shows that VT Cyberschool courses were, and still are, such that overall student success is slightly higher, faculty are more effective in communicating with students more often and directly, many students are satisfied with the flexible course environments time-wise, and the quality of instruction due to greater emphasis on clear, cogent, and continuous writing is seen as better.

Of course, the VT experience is unusual in that this institution consciously focused upon its core curricular and large enrollment courses at the undergraduate level, which was meant to keep the time-to-degree durations down and lower class sizes in F2F on-campus courses. This policy also essentially "saved" summer school as an institution, because many of its courses had the same orientation historically. From 1990 to 1994, summer enrollments were falling due to state budget cuts and economic recession: these two forces reduced both the supply of and demand for summer classes in Blacksburg. In 1995, around 25 students took courses online, or far less than 0.025% of the student body. By 2004, about 12,000 students took a course online, or nearly 45%. The Cyberschool experiment widely is acknowledged as keeping summer school alive at VT as well as making it possible for undergraduates who return home in the summer to remain enrolled on the University's "virtual campus". Beyond the summer school and core curricular foci, however, few undergraduate classes are taught online at VT.

At the graduate level, VT's location in a comparatively remote and underpopulated area of the Commonwealth with no large urban sites nearby forced it online to serve niche markets at the graduate level in masters' degree and graduate certificate programs. With five major off-campus graduate centers scattered around the state, the use of online courses also broadened and deepened the number of course choices available for such course of instruction. During the 1980s, the University did offer a handful of classes over K-band satellite uplinks as well as with "freeway flyer" instructors doing long road trips. In 1994, several scores of students took such courses, but there were few full degrees offered by VT through such means. By 2004, over 5100 graduate students were enrolled in online graduate classes, seventeen degree and certificate programs were available fully online, 85% of all departments had an online class, and the diversity of classes available for students at the five off-campus centers was enriched greatly.

Nonetheless, these 2004 enrollments constitute a 90% increase in online graduate student enrollments since 1999, and a 325% increase of graduate courses available internationally, so these innovations are starting to change a fairly traditional campus with residential requirements into one of an entirely virtual campus. There is much more resistance to starting new graduate programs now among the faculty and administration due to changes in the top academic leadership, willingness to fund such educational experiments, demand for additional degree options, and the culture of risk taking caused by draconian state budget reductions. While there is a real interest in online doctoral work, university policies and national accreditation practices make this move quite unlikely in the near future. Most master degrees entail discrete bundles of 30–48 hours of work, and only one program requires a demanding research project like a full M.A. thesis. The thesis requirement has been successfully adapted to online environments with committee structures and writing requirements equal to those of on-campus programs as well as oral defense sometimes held as videoconferences intercontintently. Still, the faculty and administration are unwilling to push forward with online doctoral degrees at this time, even for those disciplines in the humanities, social sciences, policy studies, or arts that could easily tailor their degrees to operate in online environments.

It would be disingenuous to deny that much of the momentum behind online education at VT in the 1990s came from the excessive exuberance of the decades' dot com mania. Too many believed the spiel spun up by the time's enthusiasts about everything changing rapidly overnight; and, since not all that much did change; and, since most firms behind these changes went bust, there now is little interest in maintaining what already has been achieved, much less making any bold new moves. University administrators make their reputations by launching bold new initiatives or dismantling allegedly broken old institutions for the greater good of all. Even though existing strategic plans and mission statements are on the books at VT with online distributed and distance learning at their core, it is obvious that the money, the commitment, and the will to push forward for Cyberschool-style instruction has fallen considerably from 1994 to 2004.

A great deal of this doubt has come after 2000–2001 with the dot com implosions, but some of it simply derives from changes in administrative focus, leadership, and will. Funding for online instruction was championed most fervently by a dean now long gone to be a provost elsewhere. A former VT provost with some commitment to online learning has been replaced by an outsider with less interest in, support for, and understanding of what VT attained form the early 1990s to 2001. And, the discretionary funds once allocated to online learning have had to be diverted elsewhere simply to keep the University running after several reductions in state monies coming to VT from Richmond. Consequently, energy and time from faculty and support personnel that once went into expansion and invention is being diverted to holding onto what already has been achieved against rising resistance to doing more.

CONCLUSIONS

On one level, the project of distance learning in the knowledge business is the latest promised land in many corporate market-building strategies. There are 3600 colleges and universities, for example, in the United States alone, and over 14 million FTE students are enrolled in their courses of instruction. Marketing departments share a dream: What if every department, all libraries, each dormitory, every student center, all classrooms, each faculty office, not to mention administrative and support personnel, got a personal computer and/or web appliance installed at a level of concentration approaching one per student and faculty user, then millions of new product units could be sold, installed, and serviced. Being rational entrepreneurs, then all of the world's computer builders, software packagers, and network installers are exerting tremendous pressure on colleges and universities to open their campuses to computerization so that these markets can be made, serviced, or conquered.

On a second level, however, the project of e-learning meets stiff resistance on campus. Few faculties see the merits of computerized teaching, not all students are computer literate, and most administrators are unable to find funds to pay for all of the computers and network connectivity that the private sector wants to sell them. Most people use their machines for e-mail, word processing or game playing. There are few on-campus agents of change who will ally themselves with new economic modernizers off-campus to transform education through computerization and networking as the corporations imagine it. They are aided, in part, by digital capitalists, who want to build new markets on campus for their hardware, software, and netware; in part, by the digital mass media, which want to popularize wired cultures and informational communities; and, in part, by digitizing content providers in the entertainment and publishing industries who want to reconfigure or repackage their products for computer-mediated on-and-off-line delivery systems. Still, their effect is limited; and, after a decade of real change at Virginia Tech, only five or six packages have been created in this style.

The sale of computer-mediated communication and online multimedia to teachers, however, is not where the virtual campus starts and stops. Increasingly, as the Virginia Tech Cyberschool has illustrated, when these technologies are introduced into the practices of university administration, they create new online communities whose members can force very closed, hierarchical, and bureaucratic institutional structures to become slightly more open, egalitarian, and consensual sites of collective decision-making. Online information sources, self-paced online application forms, and user-oriented online records management can take access to bureaucratic information out of the hands of special administrative personnel and hand it over to the faculty and students who actually are using it to coproduce educational services. Universities can retain their older, closed bureaucratic structure, but online enterprise reintegration applications usually start to restructure them as looser, flatter, and more responsive entities just by deploying computer-mediated communication technology to new users as a labor-saving strategy. A virtual campus, then, does not necessarily represent business as usual plus some computer multimedia. Instead, it often marks the onset of far more fundamental organizational changes, which give many faculty and administrators on campus the opportunity to rethink and rebuild what they are doing.

The scope and depth of these moves toward e-learning on a virtual campus shows that the ideas advanced by the original pioneers at Virginia Tech in 1993–1994 do "work". Indeed, the concept of a "virtual university" complements, questions, or even challenges the ways of the "material university" works at Virginia Tech in many fundamental ways. This collision of values and practices obviously fuels the on-going reinvention of institutions for Virginia Tech's virtual campus. Like Lucinda Roy, many believe Virginia Tech successfully made it through the first phase, but deeper cultural contradictions still require us "to assess what we've learned and start anew with some new approaches" (Young, 1998: A24).

To sense the significance of using computers to teach college and university courses, and begin making a new start, as our experience at Virginia Tech shows, one ought not to fixate upon the machines themselves. Plainly, the acts and artifacts used to reproduce collective understandings among specific social groups are changing profoundly: Print discourses, face-to-face classes, paper documents are being displaced by digital discourses, online classes, electronic documents. Because they are so flexible, the former will not entirely disappear, but so too can they not be counted upon to continue uncontested.

The latter will never fully be perfected; but, so too can they not be expected to remain oddities.

Many choose to misread this shift as a classic confrontation of humans with machines (Noble,), but it is, in fact, a conflict between two different technocultures—one older and tied to mechanism, print, and corporal embodiment, another newer and wired into electronics, codes, and hyper-real telepresences (Diebert, 1997). Building the facilities of a virtual campus is only one piece of this new technoculture, just as the first founding of medieval universities articulated the technics of yet another technoculture tied to the scriptorium, lecture hall, and auditor. While the two technics can throw much light upon each other, the workings of new university technocultures do not exhaust the full range of structural change occurring with informationalization in the global economy and society.

Without being as dismally dismayed about this shift as Birkerts is, the process of digitalization itself does bring a fundamental transformation in many fixed forms of being, especially those tied to communication, discourse, memory. With the proliferation of computer-mediated networks, "the primary human relations—to space, time, nature, and to other people—have been subjected to a warping pressure that is something new under the sun . . . We have created the technology that now only enables us to change our basic nature, but that is making such change all but inevitable" (1994: 15). Of course, the same was said about steam locomotives, telegraphy, airplanes, radio, and telephones but much still remains the same. This change does bring about a move from printed matter to digital bits as a technics to accumulate, circulate, and manipulate stores of knowledge. There are, as Turkle (1996: 17) claims, different "interface values" embedded in each particular medium, and those embodied in print inculcate a special measured, linear, introspective type of consciousness that has anchored our understandings of higher education for several decades. Yet, it took print decades to move universities in the 18th and 19th centuries out of their oral modes of operation.

Inasmuch as digital discourses with their own digital debates, documents, and disciplines supplant libraries of print, a remarkable erasure of experience can indeed occur. Again, Birkerts asserts:

> our entire collective subjective history—the soul of our societal body—is encoded in print . . . if a person turns from print—finding it too slow, too hard, irrelevant to the excitements of the present–then what happens to that person's sense of culture and continuity?
>
> (1994: 20)

Shrewdly enough, Birkerts recognizes his worries and warnings essentially are overdetermined questions, leaving no one with an effective means for pulling single strands of this question out for easy analysis. Instead too many are left with both a sense of profound loss and immeasurable gain as the popularity of digital modes of communication spread.

Without succumbing to Birkert's fears that everything will change forever, and mainly for the worse, when it runs through electronic circuitries, we should realize in the same moment that everything will not remain the same in online communities, only now in silicon instead of on paper. Instead of "the death of distance" (Cairncross, 1997), the internet often creates "the creation of community". Along the fractures of these faultlines, what is new and different in digital communities must be mapped to address the impact they have upon the culture of universities.

No educational technology exists simply as such with its own immanent dynamics separate and apart from the declared and implied uses for it (Bowles and Gintis, 1976). Technics remediate the pragmatics, logics, and economics in the politics of artifacts (Lyotard, 1984). Some outcomes are unintended and unanticipated, but they emerge from human use. Online learning, then, represents a cluster of much more performative technical applications that are being invested with special importance and power. So, ironically, the WWW is, and is not, just another way for delivering substantive content to content-users by content-providers. Technology is not, as many believe, "just technology". It also is culture, economics, and politics; and, when such technology is combined with education, it becomes even more culturally unstable, economically demanding, and politically threatening. On one side, many exponents of technologically enhanced teaching envision it as leading to new discursive formations, intellectual conventions, and scientific practices. On the other side, many opponents regard any efforts taken toward making such change as malformations, unconventionalities, and malpractices. Strangely enough, a decade of experience with e-learning at Virginia Tech suggests there is merit in both positions that deserves a broad hearing.

Chapter 26: A Global Perspective on Political Definitions of E-learning: Commonalities and Differences in National Educational Technology Strategy Discourses

YONG ZHAO*, JING LEI,† AND PAUL F. CONWAY‡[1]
*Michigan State University; †Syracuse University; ‡National University of Ireland, Cork

1. INTRODUCTION

> *"Information Technology is friendly: it offers a helping hand; it should be embraced. We should think of it more like ET than IT".*
> (Margaret Thatcher, former U.K. Prime Minister, in an opening address at an information technology conference in the early 1980s, cited in Robins and Webster, 1989: 29)

The apparent immense educational potential of the new Information and Communication Technologies (ICTs) has captivated politicians, policy makers, educational leaders, teachers, communities, and business over the last decade around the world. For example, *Education in and for the Information Society*, a UNESCO publication, launched in conjunction with the United Nations and International Telecommunications Union-led World Summit on the Information Society (WSIS), held in Geneva in December 2003, reminded readers that educational ICTs are seen as having the capacity

> . . . to offer unlimited access to information and invite a profound rethinking of the purpose of education and its relevance to national development. They have the potential to widen access to education at all levels, to overcome geographical distances, to multiply training opportunities, and to empower teachers and learners through access to information and innovative learning approaches—both in the classroom, from a distance, and in non-formal settings.
>
> (UNESCO, 2003: 9)

Given the intense global interest in educational ICTs over the last decade, developed countries are now embarking on their third wave of strategic planning for ICTs in education (Conway et al., 2005). While the first wave of educational ICT planning focused on getting technology hardware into schools and up-skilling teachers, the second wave concentrated on the integration of ICTs in

[1] Paul Conway's work on this chapter was supported by a grant from the Faculty of Arts, National University of Ireland, Cork.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 673–697.

the daily of fabric of teaching and learning, the third wave, typically, emphasizes a more contextual understanding of ICT integration within the confines and supports of particular school cultures (Conway & Zhao, 2003b). Regardless of which wave of planning is the focus of analysis, a powerful and seductive rhetoric at national and global levels seeks to signal the importance of investing money and minds in driving the integration of ICTs in education.

The seductive power of the infinite educational benefits promised by adopting ICTs, and the unchecked fear of missing the fast ICT train to global prominence have resulted in this global chase after e-learning, a concept that has been labeled with a multitude of names, including e-education, virtual learning, or educational uses of technology. This chase would otherwise be non-consequential and discarded as typical political exercises for educators had there not been so much political roar and generous investment of both precious financial and human resources, which have significant implications for education and educators. The serious financial, political, and social commitment can substantially affect the lives of teachers, students, and others who are involved in education through policies, regulations, allocation of funding, curriculum reform, and institutional reorganization. Thus it is wise to understand what is in store for education by understanding what is being chased after politically. In other words, since e-learning or educational uses of ICT is such a vague and new concept that it can conjure up quite different images for different people, it is useful to learn what e-learning is and is not in the minds of those who promote it on behalf of a nation and whether and to what degree the promoted version is reasonable and realizable.

In an analysis of state educational technology plans of the United States, Zhao and Conway (2001) demonstrated that governmental plans for educational uses of technology is a rich source of images of e-learning that represent the minds of the government. Zhao and Conway focused on how state educational technology plans portray the four defining elements of e-learning—technology, teachers, students, and educational goals—in their analysis. After an analysis of 15 state technology plans, they found tremendous similarities across these plans and even more remarkably, these plans conspicuously reflect a techno-centric, utopian, and economic-driven mindset toward e-learning. As a result, they were able to show how the promotion of certain images shadows other viable, perhaps more reasonable, images of e-learning.

To understand how e-learning is defined in the international context, we applied the framework developed by Zhao and Conway to the analysis of national educational technology plans of 13 nations. Through comparing and contrasting national educational ICT strategic plans of these countries that differ in terms of economical development, cultural and educational traditions, and political systems, we hope to find out how e-learning is viewed in terms of the promoted images of technology, teacher, student, and educational goals so as to understand what version of e-learning is valued politically in different nations. In this chapter, we discuss our analysis of the national educational technology plans in the wider contexts of the massive global investment in educational technologies. A prefatory comment is necessary in relation to terminology. In the U.S.A., where we undertook our initial study of educational technology strategic planning, the term of choice is educational technology. In many other countries, ICT is the preferred term. We use the term e-learning to distinguish our focus from wider discourses and strategic planning in countries in relation to cross-sectoral ICT policy for society as a whole. We focus on strategic discourses generated by governments and inevitably our discussion is partial in that various corporations (e.g., Microsoft and Intel) and transitional organizations (e.g., OECD, World Bank, APEC, etc.) have both developed and influenced strategic discourses on educational ICTs. For example, Microsoft's laptop-focused *Anywhere, Anytime Learning* initiative has garnered considerable attention in terms of the potential of more mobile and personal ICTs such as laptops and PDAs. With a somewhat different focus, Intel's *Teach to the Future* program, aimed at improving pre-service teachers' competence in the use of ICTs, has been adopted by numerous teacher education programs worldwide.

An additional impetus for this analysis is that while ICT technologies across the world are similar in the technical essence, different countries may view them differently according to their own economic development levels, culture and education traditions, and political systems, and thus may portray different images of technology, education, teachers and students, set different goals, and propose different approaches in achieving their goals. Therefore, a comparison of these national educational technology plans can not only identify the general trends in educational technology planning in a global context, but also discover the differences in strategic discourse between different countries. Furthermore, through comparing the findings from this study and Zhao and Conway's study, we can find out whether the problems existing in U.S.A. state technology strategic plans are unique to the U.S.A. because of its cultural and economic development and if other countries can avoid similar problems. Finally, an analysis of ICT in education strategic discourses provides a powerful case study of how globalization is impacting the development of educational policy.

This chapter is divided into two parts. The first part discusses emerging trends in e-learning strategies (readers are referred elsewhere for details of the 13-country study, Conway et al., 2005). The second drawing comparisons between the discourses in our 13-country study and the Zhao and Conway (2001) of educational technology planning discourse as represented in 15 state educational plans in the U.S.A. Each section ends with a summary of the key insights gained on each theme drawing comparisons where appropriate with the U.S. study. The last section discusses the implications of the findings in the context of policy discourse in guiding educators, politicians, and the public in an increasingly global world.

Our study involved an analysis of national education ICT plans of 13 countries from three economic development levels: Developed countries (Ireland, New Zealand, Singapore, U.K., U.S.A.), emerging economies (Chile, China, India, South Africa, South Korea), and developing countries (Afghanistan and Bangladesh). The selection of these ICT plans was based on their representativeness in terms of geographical dispersion (America, Africa, Asia, Europe, Pacific), population size (from 3745 thousands to 1,266,838 thousands), technology development (phones per 100 persons ranges from 0.1 to 67.3), education development level (illiterate percentage ranges from 0 to 58.7[1]), and time of creation (1996–2002[2]). The second ICT plans, if available, were also included in this study. We used the same analytical framework developed by Zhao and Conway (2001), which identified technology, teachers, students, and educational goals as the four defining elements of e-learning. According to Zhao and Conway, how these four elements are portrayed to a large extent represents how e-learning is viewed and could be implemented. For example, when technology is viewed as networked computers only, it is reasonable to expect that wiring schools and putting multimedia computers in schools would dominate the agenda of hardware deployment. Similarly if teachers are viewed as "gate-keepers", it is likely that the government will focus on educating the teachers to open their classroom doors to computers. The essence of this analytical framework is the idea that each of these elements can have different interpretations and by comparing the interpretation promoted in technology plans with all possible interpretations will help us identify what is promoted and what is demoted politically, hence obtain an understanding of how e-learning is defined in each nation.

The analytical framework was first developed and used by Zhao and Conway in their study of the U.S. state level educational technology plans. Using a typical grounded theory (Lincoln & Guba, 1985) approach, they generated categories from the educational literature on educational technology and the plans within four focal themes: educational goals, conceptions of technology, and images of students and teachers. For example, in relation to images of teachers as Luddites, gatekeepers, and designers, which we used to categorize images of teachers in the national plans, Zhao and Conway generated these from their review literature on how teachers had been portrayed in various waves of technological innovation in education over the last 100 years (for a detailed discussion see Conway & Zhao, 2003a; Zhao & Conway, 2001). As such, the three chosen categories in relation to images of teachers (Luddites, gatekeepers, and designers) provided a lucid and defensible set of categories with which to both analyze and discuss changes, patterns and implications of particular images of teachers across technology plans. In a similar fashion, Zhao and Conway drew up on the literature in cognitive science and educational psychology and generated three images of student learning: passive responder; active solo inquirer; and active social inquirer. Table 1 summarizes the analytic rubric we utilized in our analysis of the 13 national ICT plans. In both studies, the authors adopted conventional qualitative analysis methods, that is, individual analysis of data followed by cross-referencing of findings

Table 1. Rubric for analyzing images of educational goals, technology, students, and teachers

Educational Goals	Technology	Student	Teacher
Economic competitiveness	As "stand-alone" information machine	Passive respondent to stimuli	Luddite
Democratic equity	As "network"	Active solo inquirer	Gatekeeper or filter
		Active social inquirer	Designer

to ensure validity of the claims being made about how to categorize the focal images in each national ICT plan.

As shown in Table 1, Zhao and Conway (2001) suggest that there can be two major educational goals for ICT integration in schools: to improve economic competitiveness and/or democratic equity. Similarly technology can be viewed either as "stand-alone" information machine and/or as networked computers. The student can be viewed as passive respondent, active solo inquirer, or active social inquirer, while the teacher can be viewed as Luddites, gatekeepers, or designers.

2. TRENDS IN E-LEARNING STRATEGIC DISCOURSES

In this section, we first discuss the general trends and descriptions in these national e-learning/ICT strategic plans, and then discuss the findings according to the four elements identified in our theoretical framework: educational goals, technology, students, and teachers. We will also discuss how digital divide is treated in national educational technology strategic plans. The emerging general trends in our study revolve around the following themes: economic development level and date of first ICT in education strategic plan; significant variation across strategic plans; and funding.

2.1. Economic Development Level and Date of First ICT in Education Strategic Plan

As noted earlier, the first and second waves of ICT planning have different emphases, with the first wave focusing investment in hardware and upskilling teachers, and the second wave while continuing to address hardware and teacher skills devote more attention to the integration of learning technologies into the daily fabric of the curriculum. It is immediately clear that a country's economic development level has a strong influence on its stage of educational ICT planning, and thereby the content of national e-learning discourse at any given point in time. Taking Gross National Income (GNI) per capita as an index of economic development level, Table 2 shows an obvious trend that more economically developed countries developed a national educational ICT plan at an earlier time. The countries that have a GNI per capita higher than

Table 2. Economic development level and time of ICT plan

Country	Gross National Income per Head—2000[4] ($)	Year	
		1st plan	2nd plan
U.S.A.	34,637	1996	2000
Ireland	25,066	1997	2001
U.K.	24,058	1998	2002
Singapore	22,959	1997	2002
New Zealand	13,441	1998	2002
South Korea	9782	1996	2001
Chile	4669	1999	2001
South Africa	2954	1997	2001
China	866	1998	
India	476	2000	
Bangladesh	362	2002	
Afghanistan	100	2002	

U.S. $9000 all had the first national education ICT plans before or in the year 1998, while countries with less than U.S. $500 GNI per head had their first national ICT plans in or after the year 2000, 2–6 years later than more developed countries.

To statistically examine this observation, a correlation analysis of economic development level and date of the first educational ICT plan publicized was conducted. The Pearson correlation coefficient is -0.65 and it is significant at $p < 0.05$ level. This result suggests that there is a strong negative correlation between the economic development level and the date the first educational ICT plan was published, which means that the more economic developed countries published their national education ICT strategic plans at significantly earlier times, while the less economic developed countries had their first national education ICT plans much later.

Table 2 also shows that developed countries also tend to have more than one national education ICT plan. As current ICT develops at a tremendous rate, the first ICT plan may be out of date in only a few years. Almost all the countries that had their first ICT plan before the year 2000 now have a second ICT plan. The United States had the first ICT plan in 1996, the second plan in 2000, and now is planning the third National Education Technology Plan (Culp, Honey, & Mandinach, 2003).

2.2. Significant Variation Across Strategic Plans

From our analysis given the variation in detail in national plans, the specificity of e-learning discourse varies between countries. This variation has implications for the degree of elaboration in relation to the four focal categories in our theoretical framework. As such, ICT plans vary greatly among different countries in terms of the length, coverage, and emphasis. In terms of length, a few plans are short, with only a few pages; but some others are very long, such as the South Korea ICT plan and the USA's ICT plan. In terms of coverage, some plans are general guidelines, such as Afghanistan and New Zealand, whereas some plans have very detailed strategies, such as South Korea and India. For instance, India's ICT plan not only gives detailed technology literacy standards for students at different education levels, but also provides specific curriculum guidelines and syllabus for information technology in schools. The Bangladesh plan even further specifies that "5694 and 15,748 number of junior and secondary level institutions as well as 922 colleges, 347 professional institutes and 1462 mid level technical and vocational institutes will be brought under IT education by 2010" (Bangladesh Ministry of Science and ICT, 2002).

Furthermore, some national plans include very specific strategies for addressing local situations. For example, the Bangladesh's ICT plan contains specific strategies to improve IT in the whole country based on its current economic level. For instance, it stipulates that "[E]xpatriate Bangladeshis may arrange to buy second hand computers at either free or small cost and to distribute them to schools at their home. Bangladeshi missions at abroad may collect computers from expatriates and then send them to Bangladesh by national fleet at free of cost." (Bangladesh Ministry of Science and ICT, 2002). In addition, "[H]ighly educated and skilled teachers and trainers will be brought from abroad on contract basis to meet the present shortage of IT teachers and trainers in the initial stage." (Bangladesh Ministry of Science and ICT, 2002). Considering Bangladesh's current economic development level (GDP $39,139 million, GNI per capita $362, and 0.3 phones per 100 persons in 2000) and education development level (overall illiterate rate 58.7%[3]), these strategies are very practical and pragmatic.

The China ICT plan also contains some specific strategies that address regional differences:

> The network will provide a variety of channels for learning and training programs to the general public. High-quality courses will be available at low cost on islands, grasslands and in mountainous areas. More practical technology will be provided for the farmers. Distance education facilities will also be used to transmit quality courses to the economically less developed western regions in China so as to promote educational development there.
>
> (People's Republic of China, 1998)

An interesting comment in the Afghanistan plan, which was founded by UNDP reflects an influence from Western countries. On page 6, it states "The national ICT policy should be made in Afghanistan, by Afghans, for Afghans.

It should be consistent with Afghanistan's history, economic realities, the international context, and the country's unique cultural and social requirements." (Asia-Pacific Development Information Programme, United Nations Development Programme (UNDP-APDIP), 2002). One must wonder why a national plan would make such obvious statement if it had not been written or promoted by an outside force. Overall, the main implication of the variation in the length, elaboration and coverage in strategic plans, for us as researchers endeavoring to understand policy through close reading of key policy texts, was that it drew our attention to the important issue of policies' *strategic force*. In terms of discourse, one might characterize this in similar fashion to the socio-linguistic term *illocutionary force*, that is, the impact or potential impact of utterances on target audiences.

2.3. Funding

To achieve the goals proposed in these ICT plans, funding is a key issue. However, only a few plans discuss the issue of cost of putting ICT into schools. Less than half of the national plans specify sources and amount of funds needed, among which are the U.S.A., the U.K., Bangladesh, South Korea, and Ireland. Ireland's second plan not only promises an investment of €107.92 million, but also specifies how much will be spent on what, whom, and at what school level. On the other hand, South Africa and China point out possible sources of funding but do not specify the amount. The funding issue is completely omitted in other countries' ICT plans (Singapore, New Zealand, South Korea, India, and Afghanistan).

3. DEFINITIONS E-LEARNING: PORTRAYAL OF GOALS, TECHNOLOGY, STUDENTS, AND TEACHERS IN NATIONAL EDUCATIONAL TECHNOLOGY PLANS

3.1. Portrayal of Educational Goals

As previously discussed, we examined the goals the 13 national educational ICT plans purported to achieve through ICT in schools. That is, how national educational ICT plans justify the importance of ICT.

3.2. Economic Competitiveness

Using technology to improve a nation's economic competitiveness in a globalizing marketplace is the most salient rationale across the national educational ICT plans. Without exception, the plans all argue that the rapid development of information technology is changing the world into a global village where the competition of economy among countries is more and more a competition of knowledge and technology is viewed as a powerful tool in improving the country's competency in a global economy. Thus improving education with technology is not only essential to each citizen, but also critical to the nation's global competitiveness. The strong belief that the integration of ICT into education system is crucial to their economy and their country is ubiquitous. For instance, the first national ICT plan of the United States claims:

> Our economy is characterized by rapidly changing technologies and increasing international economic competition. And, our society is complex, diverse, and mobile. Success as a nation will depend substantially on our students' ability to acquire the skills and knowledge necessary for high-technology work and informed citizenship.
>
> (U.S. Department of Education, 1996)

Similarly, Singapore claims that technology integration in education aims at "anticipating the needs of the 21st century and producing a workforce of excellence." (Singapore Ministry of Education, 1997). In a similar vein, the South Korea plan further points out:

> The future image of Korea in the new vision is that Korea plays a leading role in the world as a knowledge-based strong country. For the realization of this vision, the promotion of ICT use in education plays an essential role.
>
> (South Korea Ministry of Education and Human Resources Development, 2001: 79)

Socio-economic development has a paramount priority for every country, but may be even more crucial to developing countries, who view the use of technology as one potential turning point in improving their global economic competitiveness. For example, Bangladesh is determined to use ICT as the key-driving element for socio-economic development. As a country with the largest population in the world, China is committed to "a new round of educational innovations which aims to change the tremendous population pressure into highly productive human resources," (People's Republic of China, 1998), and ICT is said to play a critically important role in this process.

ICT is also promoted with the fear of possible risks of not being able to catch up with other countries in using ICT. These risks are emphasized and specified in some plans. For instance, the first ICT plan of the United States asks this question: "Can schools afford the investment? The real question is, can they afford not to make the investment?" (U.S. Department of Education, 1996). In a similar fashion, South Korea also points out the potential risks of not being able to make full use of current ICT in education:

> If an individual, company, or state does not keep up with the changing paradigm, it may fall behind with the times, miss the mainstream of the age, and lose global competitiveness.

3.3. Democratic and Human Development Goals

> *"The potential of the Information Age seems overshadowed at every turn by the ancient forces that separate the rich from the poor".*
>
> (Dertouzos commenting on the role of ICTs in the developing world, 2002, p. 204)

Another possible goal of education is the preparation of democratic citizenship and the full development of individuals who can competently participate in democratic societies and live a happy life. Although many ICT plans do include some discussions about the potential of technology in equalizing educational opportunities, few justify the investment with arguments that ICT may better prepare and promote self-development, as exemplified by the following statement of the U.S. ICT plan:

> Properly used, technology increases students' learning opportunities, motivation, and achievement; it helps students to acquire skills that are rapidly becoming essential in the workplace; and it breaks the barriers of time and place, enabling students in any community, no matter how remote or impoverished, to have access to high-quality instruction.
>
> (U.S. Department of Education, 1996)

Ironically, technology itself has become a major source of inequity, as Sayers (1996), among others (e.g., Sutton, 1991) pointed out, "equity in access to educational resources faces new challenges in our age of rapid technological change, threatening to produce a society of information "haves" and "have-nots" through schools where disparity in access to educational technology is already glaring" (Sayers, 1996). Instead of equalizing educational opportunities, technology may actually exacerbate the inequities it is supposed to remove because schools in affluent communities have the resources and expertise to provide efficient access to ICT while their counterparts in impoverished communities have neither. This is now known as the "digital divide".

Most national technology plans recognize this "digital divide" and maintains that equal access to information and computer technology should be provided to all citizens, whoever they are and wherever they are (Fitzpatrick & Conway, 2005). Thus, providing equal access has become a goal of itself. Afghanistan stands out among these countries because of its extraordinary stress on democratic goals. While the plan claims that "ICT will become the medium that will provide Afghans in all parts of the country the opportunity to acquire knowledge and skills", the plan states, "[T]he government has declared that it is a fundamental right of all citizens to have access to diverse means of communication" (p. 7) A few plans specifically address the gender inequalities. For instance, the Afghan ICT plan loudly argues that "special attention must be paid to gender to ensure that specific programmes are directed to enhancing the capabilities of girls and women" (p. 8). The ICT plan of India addresses this issue with specific instructional strategies that may be adopted by teachers to make IT-based activities in the school "free from gender bias".

3.4. Summary of Portrayal of Educational Goals

The examination of the educational goals promoted by national technology plans of 13 countries reveals a number of interesting patterns. First, current economic development level has certain influence on setting educational goals in ICT plans. Countries at different economic development levels have the same goals—to improve economic competitiveness through integrating ICT in education. For more developed countries, the goal is to maintain their current advantages in global economy. For example, the ICT plans of the United States stress "the importance of technology innovation to maintaining the economic and political dominance of the United States" (Culp et al., 2003), and the New Zealand ICT plan aims to "continue to interact at a global level". While developing countries focus more on improving their national status in global economy competition. For instance, one of the economic goals of Bangladesh is to "emerge as a major software exporting country". However, an important caveat in formulating a conception of links between education generally, and ICTs in particular, and economic development is, as Fägerlind and Saha (1989) have argued, that ". . . it clearly cannot be assumed that the link between education and economic growth is a direct and linear one, or that it operates in the same manner for every kind of society" (p. 80).

Second, less developed countries are under pressure to catch up with more developed countries. In the global context, countries, especially less developed countries, seem to have a "peer pressure" in integrating ICT to improve education and economical competitiveness. Therefore, one major force for integrating technologies in schools and having a national ICT plans is the pressure to catch up with countries that already have ICT plans. For example, China cited the ICT and economy development in India and United States. Citing India is because China and India are at similar levels of economic development level and thus are comparable and convincing, while citing the example of United States is somewhat setting a goal for economical development. Bangladesh clearly expresses the influence from other countries: "The developed countries have achieved a high standard of living by effectively using IT as a tool for the growth of their national economy. Upon observing the success history of some neighbour countries, Bangladesh Government has declared IT as a thrust sector." (Bangladesh Ministry of Science and ICT, 2002). This pressure can be a double-edged sword for developing countries. On the one hand, the acknowledged difference motivates developing countries to make great efforts to catch up with more developed countries. On the other hand, the pressure may also lead developing countries to set ICT goals that are too optimistic to realize based on their current economic development.

Third, a utilitarian attitude toward using ICT is pervasive in all plans. By emphasizing the economic benefits of using ICT, all plans take a utilitarian attitude toward technology integrations in schools. The main goal for integrating technology in schools is to improve the performance of school children and thus enhance the country's competency in a global economy. This view ignores the development of human beings and how the use of technology influences the overall development of students.

Lastly, these findings are similar to those of the analysis of the state technology plans in the U.S.A., which shows that the U.S. state plans clearly favor the economic aspects of education. All plans are very concerned about the prospect that new technologies are changing the job market, placing new demands on future employers in the preparation of a productive and adaptive employee pool or technological workforce (Tyack & Cuban, 1997). Although many plans mention providing equal access along with preparing students for the 21st century, the goal of democratic equality is seldom elaborated as concretely as the goal of economic competitiveness. Nor is it anchored in as many implementation activities as economic competitiveness.

3.5. Portrayal of Technology

Technology is a very ill-defined term. Just in terms of hardware, it can mean anything from pencils to microscopes, from television to DVD players, from hand-held devices to networked multimedia computers. A technology plan needs to specify or at least project an image of what technolog(ies) is under discussion.

3.6. What is Technology?

3.6.1. Technology as Network

The dominant image of technology in the ICT plans is computers, especially networked computers. The internet is probably the most visible ICT innovation of the past 10 years and has attracted the most attention. Pelgrum (2001) points out that many governments have formulated explicit plans to equip schools with access to the internet before or shortly after the year 2000. This observation is well evidenced by the prominence assigned to the internet in all the ICT plans examined in this study.

For example, the Afghanistan ICT plan calls for an "interconnected and interoperable network of networks". The U.S.A.'s Telecommunications Act of 1996 "will help ensure that every child in every classroom in the U.S.A. will be connected to the information superhighway—opening up worlds of knowledge and opportunities". Singapore's first Master Plan envisages the internet is "becoming a key content and learning resource in schools with its increasingly vast amount of information relevant to education". And the second plan is to "connect all schools, colleges, universities, public libraries and as many community centres as possible to the Grid [via the internet]." Ireland's second plan envisions that "[A] digital network for schools will be developed to provide broadband access to all schools and access to research networks."

To achieve these goals, providing internet access is one of the main objectives of most ICT plans. The New Zealand government has initiated a project to deliver high-speed internet access (aka broadband) to all schools and to most provincial communities. South Korea revised its comprehensive plan for ICT in education to increase the budget input for LAN installation, PC distribution to teachers and classrooms, and financial aid for internet access in the schools. Similar suggestions are also made in other ICT plans.

3.6.2. Stand-Alone Technologies

However, technology, even ICT, is not only the networked computer. Many other technologies also hold great educational potentials. Unfortunately only a few countries' ICT plans reflect this trend by including some other types of technologies such as video, television, telephone, tape recorders, cellular phone, etc. For instance, South Africa ICT plan gives a detailed and comprehensive definition to technology-ICT:

> ICT encompasses all forms of electronic communication in both digital and analogue form. Digital electronic devices include computers, CD players, cellular telephony and satellite broadcasting. Analogue devices are largely confined to conventional radio broadcast technology and audio, such as tape recorders. Bandwidth, the volume of data that can flow through a communication channel, is constantly increasing. In addition, there are more and more ways of accessing this data. Due to this increased bandwidth and the different forms of connectivity, the various technologies are converging into the broad filed of information and communications technology (ICT).
>
> (South Africa Department of Education and Department of Communications, 2001)

Similarly, South Korea also includes technologies other than computers, such as TV, VCR, visual presenter, overhead projector and screen, printer, encoder, decoder, and so on. New Zealand's ICT plan differentiates IT and CT. It defines IT as the kind of technologies that "allow us to access, retrieve, store, organize, manipulate, and present information by electronic means" and it includes personal computers, scanners, digital camera, and software; and CT as the kind of technologies that can seek and access information, such as phones, faxes, modems, and computers. Calculation tools such as calculators and graphics calculators are also cited as learning tools.

In analyzing these plans, we also noticed a utopian tone, an unqualified extremely optimistic view of technology. Without exception, all technology plans operates as if technology will cure all educational ills. Technology is believed to be able to greatly facilitate education reforms, improve student achievement, and thus solve social problems and achieve democracy and economic competency. In the ICT plans we have reviewed, technology is often associated with such phrases as "key-driven element", "essential", "crucial", and thus is given a "high priority" or "the highest priority". The U.K. ICT plan believes that technology can "enrich and enhance all aspects of schooling—teaching, learning, management, and administration". The U.S.A.'s ICT plan expresses a strong faith in technology's power in solving education problem: "Properly used, technology can enhance the achievement of all students, increase families' involvement in their children's schooling, improve teachers' skills and knowledge, and improve school administration and management." In one U.S.A. school superintendent's eyes, technology is "the paper, pencils, encyclopaedia, dictionary, thesaurus, textbook, and library all rolled into one." (U.S. Department of Education, 1996).

In a similar way, the New Zealand ICT plan also portrays technology as an improvement of existing practice, or a solution to all problems in education system: teaching, learning, and school administration. It believes that ICT can provide opportunities for authentic, independent, and collaborative learning, provide access to a wide range of changing and developing information sources, enable active participation and the application of knowledge in authentic contexts, enable learners to be more focused on inquiry, problem solving, synthesis, and other higher order thinking skills, and provide opportunities to focus on the acquisition and use of information skills.

All countries embrace ICT with high expectations and great enthusiasm. Few of them mention the possible limitations of technology. One exception is the American's first ICT plan, which, in a few occasions, points out that technology needs to be "properly used" to enhance the achievement of all students. It also goes a step further to point out:
