> Technology, in and of itself, is not a magic wand. Technology is not going to fix the problems associated with schooling, but, at the same time, the problems that plague our educational system are not going to be remedied without the presence of technology.
>
> (U.S. Department of Education, 1996)

The development of new technology will bring along new and unanticipated problems, such as the violation of intellectual property rights, distribution of inappropriate information, and hacking. A few countries realize the possible undesirable outcomes of ICT use and thus discuss how to deal with these possible problems. The Afghanistan plan points out that ICT networks will multiply the flow of information and the related privacy and security challenges must be addressed, and the principles of privacy protection may need to be enshrined in legislation. India's ICT plan stresses social and ethical issues in ICT use to students at different levels. Ireland's second plan points out the internet safety and security is of "paramount importance" and students' safety is a priority. As an exception, South Korea's ICT plan discusses this issue in great details:

> But the increase of access to cyber space also increases the chances for undesirable outcomes. Vulgar words and insulting language are used in communication by abusing the anonymity of cyber space. The access to pornographic and violent sites is increasing. Criminal activities such as hacking, computer virus circulation, prostitution, and sexual violence are also promoted through interaction in cyber space.
>
> (South Korea Ministry of Education and Human Resources Development, 2001: 73)

To promote a sound cyber culture among the youth, South Korea's ICT plan suggests three strategies: (1) reinforcement of ICT ethics education, (2) expansion of sound cyber culture, and (3) construction of harmful information filtering system; information and communication security for educational information system.

3.7. Summary of Portrayal of Technology

To summarize, we found that the portrayal of technology in the 13 national ICT plans seem to have the following characteristics: reliance on newest technology as the default definition of technology; a utopian view of the potential of ICTs; myopic in relation to the long-term impact of technological innovations; and focus on "hard" aspects of ICT, that is, hardware and structure, rather than the "softer" aspects such as teacher development and school culture.

First, the ICT plans all tend to favor the newest technology. Education reforms are fickle. They always embrace the newest technology innovations with great enthusiasm and try to replace the relative older ones that were newest innovations and also advocated with passion a while ago. Favoring newest technology may have some advantages. However, since it usually takes a long time for any technology innovation to enter schools and even longer to be integrated into teaching and learning, chasing the newest technology may deprive teachers and students the opportunity of exploring, getting familiar with, and making meaningful use of available technologies. Therefore, it is important for schools to settle down with appropriate technologies and to take time to really integrate technologies into their current curriculum. Furthermore, as current technology continues to advance at a tremendous rate, it is increasingly difficult for schools to "catch up with the moving train." (Becker, 1998). This problem is even more serious for countries with limited resources. The most important thing should be to find the most effective and efficient technologies, but not necessarily the newest technologies.

Second, the utopian view of technology is pervasive in the plans. ICT is viewed as a silver bullet that cannot only fundamentally improve or change education, but also solve social problems. All ICT plans express high expectations on technology and great enthusiasm in technology integration in schools. However, we may need a more realistic view on technology. Technology is just another set of tools. "Properly used", it may improve the effectiveness and efficiency of teaching and learning, but it is very unlikely to fundamentally change education. Research has found that technologies are usually used to facilitate existing practice instead of fundamentally change it (Cuban, 1986: 385; Schofield, 1995: 104). A utopian view of technology can easily lead to setting unrealistic educational goals that are actually a burden instead of a blueprint for schools.

Third, the plans seem to ignore possible problems accompanying technology use. Dominated by a utopian view of and ardent enthusiasm on technology, the technology plans rarely question or even raise cautions about the potential negative consequences associated with technology, although we know that "there is no good without evil". Technology or any innovation for this matter certainly brings challenges to current and traditional values and practices. The rapid spread of ICT has already resulted in new social, ethical, and moral dilemmas. Additionally, the introduction of technology in schools is likely to force changes upon teachers, students, and the school as a whole. A thoughtful technology plan should raise awareness of these issues and propose strategies to minimize potential negative outcomes.

Lastly, many ICT plans primarily focus on establishing a technology infrastructure, ignoring the "soft aspects" of technology, including the knowledge and expertise to use it properly, although experiences have taught us that the claimed educational potentials of technology cannot be realized without adequate enabling conditions (Zhao et al., 2002). Only a few of them recognize that "physical access to hardware and internet connectivity is only one dimension of true technology accessibility, access to relevant and appropriate content, to adequate support and training and the ability to make use of technology to both create and consume information and ideas." (U.S. Department of Education, 2003).

Comparing the results of Zhao and Conway's analysis of 15 U.S. state ICT plans with the results of the current analysis found striking similarities between the two despite the different contexts of the individual nations. In the U.S. state ICT plans, technology is portrayed overwhelmingly as a communicative and networking tool, and is touted as an all-purpose, flexible tool that can be used in all educational contexts to support all types of learning. This view is shared by the national technology plans of all 13 nations in that technology is generally viewed as the most current technologies, especially connected the computers and the World Wide Web. Furthermore, all technology plans present technology as a powerful potential fix for current and future educational problems, representing a very strong technological utopian tendency. Moreover, technology is often presented in a rather simplistic, naïvely optimistic fashion. And finally, most ICT plans leave out and devalue the more cautious views of technology.

3.8. Portrayal of Students

Views of the nature of the learner and learning are another defining element of education. Thus an examination of how students are portrayed in national technology plans helps illuminate the political definition of e-learning. Generally a student can be viewed as either a passive learner, a recipient of knowledge, or an active constructor of knowledge, and the latter can be further qualified as solo constructor, the Piagetian little scientist who actively constructs by himself or as knowledge constructor through social interactions. An important finding is that about one-third of the plans do not include a discussion about the nature of the learner, which is surprising in that an educational blueprint does not talk about the learner.

Among the ICT plans that discuss students, none of them portrays students as passive learners. On the contrary, students are believed to be active, quick, competent, and confident learners. For example, The New Zealand plan describes students in the new environment this way: "Students often approach ICT with excitement and curiosity, learning to use them quickly, competently, and with confidence." (New Zealand Ministry of Education, 2002). South Korea's ICT plan makes it clear that technology will transform the passive learner into an active one with the statement that "The student is no longer a passive recipient of knowledge." Accordingly, the school environment should "support activities where students change from passive recipients of knowledge to being active investigators" (South Korea Ministry of Education and Human Resources Development, 2001).

Another obvious tendency is the belief that technology enables students to be both independent and co-operative learners. This is exemplified clearly in Singapore's first Master Plan: "Pupils will develop competencies in accessing, analysing and applying information, and develop habits of independent learning. IT-based learning strategies will also seek to develop pupils' ability to think innovatively, to cooperate with one another and to make sound value judgments." (Singapore Ministry of Education, 1997).

However, views of students vary along the dimension of solo and social constructor of knowledge in different countries. While some ICT plans emphasize more on students' ability of being "co-operative", others focus more on that of being "independent". In some ICT plans, students are expected to actively learn, construct knowledge and to collaborate, co-operate and interact with peers and teachers. For instance, the India ICT plan states: "Students will collaborate, publish and interact with peers, experts and others using communication technology." (India NCERT, 2000). Similarly, the U.S. ICT plan claims that through information technology, students "can communicate their results and conclusions in a variety of media to their teacher, students in the next classroom, or students around the world." The New Zealand ICT plan believes that ICT can "enable students and teachers to communicate and transfer data cheaply and rapidly worldwide." (New Zealand Ministry of Education, 2002). In addition, "the internet can provide a window to the world by allowing users to interact with students from other schools, both nationally and internationally." (New Zealand Ministry of Education, 2002).

On the other hand, some plans seem to emphasize the power of technology to cultivate creative and independent thinking, and prepare lifelong learners for the world of work. For example, although the Singapore Master Plan points out that students shall be both independent and co-operative, it emphasizes more on fostering "independent learning" and helping students become "more independent learners" (Singapore Ministry of Education, 1997). The U.K. ICT plan expects student to: "Be able to confidently take ownership of their learning," (U.K. Department for Education and Skills, 1998), while the South Korea ICT plan advocates that education should "enhance students" ability to carry out self-directed learning." (South Korea Ministry of Education and Human Resources Development, 2001).

3.9. Summary of Portrayal of Students

A look across the portrayals of students across the 13 ICT plans reveals some general patterns of differences and commonalities:

First, the learner is overwhelmingly viewed as an active inquirer in the new environment where technology is supposed to play a major role. This view is used in two ways to justify the investment in technology: (a) because students, as active learners, demand a better learning environment that supports active inquiry as a form of learning and (b) technology can transform passive learners into active inquirers. The omnipresence of this view in technology plans across the world is also indicative of the successful penetration of modern learning theories into the political construction of a new education environment.

Second, nations do seem to differ in their views of how the students construct knowledge. Nations with an Eastern cultural and philosophical tradition, such as China, Singapore, and South Korea, tend to portray students as solo learners, while Western countries such as the U.S. and New Zealand are more likely to portray students as social learners.

Third, many national ICT plans also stress the importance of lifelong learning by promoting the idea that technology can prepare and support individuals as lifelong learners. On the one hand, the ICT plans argue that information technology is changing the world so rapidly that individuals need to be constantly learning in order to participate in this forever changing society. On the other hand, ICT provides the means to make lifelong learning possible.

Finally, the analysis of the state ICT plan in the U.S. (Zhao & Conway, 2001) demonstrated that the state technology plans adopted outcome-oriented views of students. This emphasis is not shared by many of the national plans. In addition, although the technology plans seem to favor modern educational concepts (e.g., co-operative learning, active learning, interdisciplinary learning), few plans directly address any of the important epistemological assumptions about student learning. The technology plans were notably sparse in their description of the learning process or epistemological assumptions whereas technology or teacher professional development issues were outlined in detail in one or more chapters or sections. In this respect, the state ICT plans are similar to the national plans. In other words, the ICT plans, which are supposed to be blueprints to ICT-enabled education, fail to lay out the specific psychological and cognitive mechanism that enable ICT to improve learning.

3.10. Portrayal of the Teacher

Teachers are a key component of any learning environment. All national plans recognize the critical role of the teacher, as the first U.S. educational technology plan puts it: "Indeed, without trained and experienced teachers, we know that computer equipment sits idle in classrooms, unused. ... And we know that without high-quality software and well-trained teachers, computers alone do not help students meet challenging academic standards." (U.S. Department of Education, 1996).

But this critical role in relation to technology can be viewed quite differently, from the ultimate resister—the Luddite to the enthusiastic embracer (Conway & Zhao, 2003a). None of the countries portray teachers as Luddites. Most ICT plans (91.7%) portray teachers as gatekeepers, and only a few countries (33.3%) hope teachers can also be designers.

3.11. Teacher as Gatekeeper

The dominant image of teachers is that of a gatekeeper. Almost all the countries believe teachers are the key to the effective use of IT to enhance teaching and learning. Teachers are assumed to be able to use technology in their curricula and lead students to utilize technology, and professional development is key to effective technology integration and to increased student learning. Thus teaching training has an important place in most ICT plans. Teachers are encouraged and trained to use multimedia educational materials and the internet in classrooms. For example, India requires all teachers be able to handle technology and integrate it into the teaching learning process.

To encourage teachers to open their classroom doors to technology, some countries have developed detailed plans to train teachers. For instance, to motivate teachers to learn and use ICT in their classrooms, South Korea has developed several programs to evaluate and certify teachers, such as the Information Ability Evaluation program, which encourages teachers to develop interest in ICT utilization and increase their use of ICT in carrying out their duties. South Korea ICT plan divides the training of teachers for ICT use into the training of prospective teachers and the training of in-service teachers, and specifies how and where to train pre-service and in-service teachers Singapore's second ICT plan recognizes teachers at different technology proficiency levels, and provides a model that addresses the varied needs of teachers of different competency and job needs, so that teachers can be better trained according to their current technology proficiency levels.

3.12. Teacher as Designer

A few countries hope teachers not only to be able to let ICT into their classrooms, but also to be able to creatively use technology based on their curricula and their students' needs, and to design educational materials in their own fields. South Korea stresses teacher's role as a designer. To encourage teacher's creativity in utilizing technology, South Korea holds software contests. At the beginning (1992), these contests were held just to improve teachers' computer literacy, which was consistent with the early requirement of teachers as a gatekeeper. Now the contests are held to encourage teachers to develop educational software and educational materials relevant to teaching activities in their field and to enhance teachers' interest in ICT use. Singapore's second ICT plan provides a platform for capable teachers to design and develop their own IT-based lessons or resources.

3.13. Teacher as Helper/Facilitator—Teachers' Role in Teaching with ICT

With the rapid development of information and computer technology and its increasing integrating into education system, the role of teachers has been changing to take the opportunities and meet the challenges that ICT has brought about. Some countries also emphasize teacher's role as a helper and facilitator in students learning with technologies. For example, the South Korea plan requires teachers to be prepared to give assistance whenever learners need help. Furthermore, the India plan requires teachers to play a twofold role:

> First, she is an active facilitator of children's learning processes, including those away from the computer. Secondly, she is the student's best guide on when, how and which IT tool may enhance learning.
>
> (India NCERT, 2000)

3.14. Summary of Portrayal of the Teacher

In summary, we found that all ICT plans tend to view teachers mainly as gatekeepers, someone who are critical in allowing the technology into the classroom. The underlying assumption is that technology, once allowed into the classroom can release its own miracles, thus while many of the plans acknowledge that teachers are important in technology adoption but do not go as far as to espouse the "teacher as designer view". In this view, teachers, rather than taking on the role of knowledge dispensers or just adopting existing technologies, design their own teaching environment with a variety of technological tools to facilitate knowledge construction. Accordingly, teachers, like an architect, actively engage themselves in exploring the possibilities and constraints of technologies and other materials to construct the best environment to fulfill their pedagogical expectations. Technology is no longer considered a cure-all tool, but rather a component of the pedagogical ecology. From this perspective, teachers are not only adopters or implementers of technology, but also developers, evaluators, and designers. Unfortunately only a very limited number of plans adopt this view and identify ways in which teachers can be resourceful, knowledgeable, and purposeful designers of educational technology.

The national plans are very similar with the state plans in the U.S., which portray teachers mainly as gatekeepers or adopters. The view of teachers as gatekeepers often leads to a type of professional training that is expected to convince the teachers to open their doors to technology and teach them appropriate ways of technology integration.

CONCLUSION

We set out to understand the political definitions of e-learning by examining how national educational technology plans view educational goals, technology, students, and teachers. We had hoped that different nations, given their own political, economical, and cultural differences, would have significant different views. However, the analysis proved otherwise. In essence, although national ICT plans vary greatly in their length, coverage, and some specific emphasis, generally speaking, they have the same utilitarian educational goals in technology integration in schools, similarly ardent enthusiasm and utopian expectation in technology, and the same images toward students as active learners and teachers as gatekeepers of technology use. Despite some minor differences on some specific goals and approaches, basically we hear one voice on the educational goals, views of technology, students and teachers from thirteen countries with different economic development levels, diverse culture and education traditions, and various political systems.

This monolithic definition of technology-supported education is also very similar with that in the state technology plans in the U.S. analyzed by Zhao and Conway (2001). The technology plans studied by Zhao and Conway (2001) are from 15 states in the United States. Although these states vary to a certain degree on aspects such as size of state, technology related funds, population, percentage of trained teachers, they do not really differ much in that they share the same culture, language, educational tradition, and economic development level and are closely connected with each other. Countries included in this study differ greatly in culture, education, political system, and especially economy. The differences among these countries are much larger than those among the 15 U.S. states. However, the differences among the national ICT plans of the 13 countries are surprisingly not necessarily greater than those of the state ICT plans.

This unusual commonality across the 13 national plans is troubling in four important ways. First, the monolithic definition of e-learning itself is problematic in that its promotion of one view of educational goals, technology, students, and teachers necessarily demote other possible, and perhaps, more viable views.

Second, what is even more problematic is how widespread this view has been. It seems that technology transcends cultural, geographical, and political boundaries (Carr-Chellman, 2005). It wipes out economical and systemic differences. The universality of a single view of technology across technology plans in 13 nations demonstrates that technology has been viewed as the master, while pedagogy the obedient slave. The lack of attention to the differences in economic and educational development in different nations and simply chasing whatever the developed nations pursue may lead to unnecessary waste of already limited resources on hi-tech gadgets that may not even be properly used in less developed nations due to the lack of enabling conditions, such as electricity, class size, teacher readiness, and school building. For example, the type of "co-operative learning" activities that promote active inquiry may not be readily implemented in schools with large class sizes. It is hard to imagine how a teacher conducts an inquiry-based class with over 80 students, which is quite common in many developing nations.

Third, this commonality also indicates the seductive power of the concept of modernization and peer pressure in the international context. It is clear that national technology plans developed earlier, mostly in developed countries, influenced those developed later by developing countries. The simplistic belief that ICT has the equalizing power may have prompted developing nations to adopt what is in the national technology plans of developed nations. While it is not unwise to learn from or engage in policy borrowing from other nations, it surely is not advisable to ignore one's own situations because ultimately ICT has to serve the local goals, contexts, and needs.

Fourth, what is unfortunate is that while the optimistic views of technology in plans of developed nations are shared by the less developed nations, it is not clear that the less developed countries have learned or even tried to learn from the lessons developed countries have had during their implementation of their educational technology plans. Many developed nations had begun investing in educational technology many years before developing countries. They have had many unsuccessful attempts that could become a rich source of things that should not be repeated. If carefully studied, these can become of tremendous value to countries that are contemplating investing in technology. However, such learning does not seem to be taking place, judging from the national technology plans of the 13 nations.

In conclusion, this chapter has situated the proliferation of strategic planning in relation to e-learning within the wider context of globalization. We conclude with two observations that emerge when we consider important in learning from our analysis of ICT planning as case study, what Goodson (2003) refers to as *conjuncture*, that is, a world movement that sweeps around the globe seeping into the policy discourses across nations, that is, convergence in e-learning policies; and second, e-learning strategic plans as a lever for educational change. First, the development of e-learning policies reflects a wider global trend or conjuncture, over the last decade, in which education has become a policy priority among both policy makers and politicians. Many governments' expansion "into ever larger areas of education and training has run parallel to their growing enthusiasm for detailed intervention" (Wolf, 2002: xiii). As such, the development of e-learning policies can be seen within this wider context. Second, the expansion of government planning in the educational sphere across many countries has encompassed the identification and use of ICTs as policy instrument to lever change in educational systems (UNESCO, 2003). The extent to which ICTs can be used as a policy instrument depends in very significant ways on the manner in which teachers, technology, students, and educational goals are conceptualized in policy and practice.

Whether policy makers are considering a small school in sparsely populated rural regions of China or busy urban schools in Delhi, Durban, or Dublin, an increasingly strong argument is being made for ubiquitous computing. As such, the appeal of ICTs as a significant policy instrument in education is not abating, rather it is gaining increasing prominence in the corridors of power at national and international levels. Consequently, it is crucial that the conceptualization of key educational factors (teaching, students, educational goals, images of technology) reflects the complexities of particular cultures and the nuances of educational change across diverse educational systems. Returning to exhortation (noted at the beginning of this chapter) made by

Margaret Thatcher in the early 1980s that *"Information Technology is friendly: it offers a helping hand; it should be embraced. We should think of it more like ET than IT",* we can say with some conviction that ICTs in education are now, 20 years on, being thought of more like ET than IT.

Chapter 27: An Overview of Virtual Learning Environments in the Asia-Pacific: Provisos, Issues, and Tensions

DAVID HUNG*, DER-THANQ CHEN†, AND ANGELA F. L. WONG*

*National Institute of Education, Nanyang Technological University, Singapore, wldhung@nie.edu.sg; †University Centre for Teaching and Learning, University of Canterbury, New Zealand, Victor.chen@canterbury.ac.nz

1. INTRODUCTION

Virtual Learning Environments (VLEs) have increasingly gained momentum in the Asia-Pacific region for the past decade. The aim of this chapter is to provide the reader with a range of issues, examples, and initiatives from this region on perspectives and progress made in VLEs through Information Technology (IT). The countries represented in this chapter on VLEs include Hong Kong, Taiwan, China, Korea, Japan, Singapore, Australia, and New Zealand.

One unique perspective in the Asia-Pacific region is the localized emphasis of flexible learning in Australia and New Zealand. Even though the idea of making learning more flexible goes beyond the employment of IT in education, often, it involves technology-based solutions such as the internet. Some universities have even set up flexible learning centers to promote this philosophy. The development of flexible learning in these two countries has been around since the early 1990s. Many of the experiences that they have gained in this area can be shared with the international community.

Increasingly the countries represented within this region have been witnessing a surge with VLEs with pedagogies inherent from the West. Tensions such as learning epistemologies, cultural and language differences, ease of access and effectiveness toward learning, and other tensions are becoming evident. On the other hand, as VLEs mature, we gradually witness tensions which used to be evident become less of an issue, for example, the gradual diminishing of virtual versus real-life or face-to-face presences.

In our discussions, we attempt to draw issues and implications that are relatively common and generic across the countries represented and hopefully convey significant trends and issues in terms of learning and instruction relevant to VLEs. Although not all countries in the Asia-Pacific are represented, we felt that the current reviews as depicted in the next section would suffice in terms of reflecting the concerns of this region. The descriptions that follow may also not fully represent the initiatives and efforts in the various countries, but we believe they are sufficient to provide the reader with a sense

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 699–721.

of the developments. We recognize that even in the midst of crafting this manuscript, changes and developments in this region are continuing. A corresponding overview of the online learning developments can be found in the special issue edited by Hung and Chen (2003).

2. AN OVERVIEW OF THE VLE DEVELOPMENTS IN THE ASIAN COUNTRIES

2.1. Hong Kong

The attempt to create VLEs in Hong Kong was first started in 1994. The Chinese University of Hong Kong established the Hong Kong Education Information Network (HKEIN) (later renamed Hong Kong School Net), which aimed at promoting internet awareness among teachers by providing local dial-up internet services (e.g., e-mail, ftp) (Hong Kong School Net, http://www.school.net.hk/services/about.shtml).

However, the application of VLEs in education was not (pervasively) started until late 1997. Despite this, its development has been very fast, particularly in terms of infrastructural developments, which were almost completed within 3 years.

> In 1998, the Hong Kong Special Administrative Region (HKSAR) Government announced its five-year strategy plan of integrating IT into teaching and learning in the schools. In this plan, students are expected to participate in staff development resources on the internet. Teachers are expected to participate in staff development programmes to contribute to the paradigm shift from teacher-centred teaching to learner-centred learning.
>
> (Looi, 2001: 1)

In the year 2000, the Hong Kong Cyber Campus became the Hong Kong Education City as a result of the joint effort by the Education Department of Hong Kong, the Hong Kong Cyber Campus, and the Quality Education Fund. In addition to maintaining the established dial-up connection service, the Hong Kong Education City intended to provide all schools with broadband Education Network. It also planned to help promote broadband to home systems.

The Hong Kong Education City also aimed to "become the de facto information center, resources center, and community center for teachers, students, and parents" (Hong Kong Education City, http://www.hkedcity.net) by developing a website that provides (1) packages produced by the Education Department; (2) resources and experiences shared by schools, teachers, and the public; (3) resources collected from the public and the internet through copyright clearing; and (4) resources published by commercial software developers and content publishers.

Schools are now all linked up with fast networks and broadband linkage to the internet. However, students need to change to the constructivist-learning paradigm that includes two principles of learning: active learning and group learning (Lin, 1999a). Active learning refers to the self-directed learning process, which is facilitated by the requirement of developing knowledge from authentic tasks presented in a realistic context (Edelson et al., 1995; Lin, 1999b). The essence of group learning is to enable frequent interaction and collaboration among students toward a common goal (Lin, 1999a). However, such changes are radical in nature and deviate sharply from the usual practices. Previous curriculum reports in Hong Kong show that teachers do not like it (Lam, 1996). On the other hand, students may also not like such changes. For example, Parr (1999), reporting students' view of the change of teacher's role when learning with computers, indicated that 63% of the respondents tended to describe such changes negatively. Students seem to prefer more structured and directed activities rather than independent work (Parr, 1999). They often encounter difficulties when given more ownership and control over the pace of learning and prefer thus to be told what they ought to do (Woodrow et al., 1996). Starting with its goodwill to promote student-centered learning, Hong Kong now seems to be encountering difficulties in putting this new paradigm into practice. Whether the impediments can be overcome in the future or it will be modified to other new paradigms, such as those suggested by recent researches (see Lee, 2002; He, 1998), will have to wait until further research results can be released.

Similarly, VLE developments in Hong Kong in the area of Higher Education are also currently facing a broad challenge in terms of shifts in technology, paradigms, and resources in learning (Vogel & Klassen, 2001). As part of Hong Kong's mandate, the universities and the Special Administrative Region share the goals of assuring that teaching, learning, and assessment take advantage of new technologies. In a practical sense, this means that student-centeredness or directed learning must become a more important component in curricular and programme design. As a result, there are various interactive learning environments being created and evaluated that extend beyond the confines of the traditional classrooms.

Due to an increasing trend toward self-accessed learning supported with multimedia instructional support, students are now challenged with the responsibility and accountability for controlling their own educational discovery process. Skills of metacognition and reflection become increasingly important. Hong Kong is also seeing increasing trends in individualized learning varied according to learning styles and individual demands; cooperative learning where a variety of structures such as cross-age and disciplinary attempts are made; partnering between institutions and communities providing information access to learning; multimedia technologies to enhance interactivity and learning; and assessment portfolios in order to trace formative progress and learning processes.

2.2. Taiwan

In Taiwan, the most popular educational internet program is called TANet (Taiwan Academic Network). The main purpose of TANet is to support an information infrastructure for all schools and research organizations. Thus, TANet not only provides collaborative opportunities for research, but also shares network resources for teaching and learning activities. Taiwan's MOE (Ministry of Education, 2001) and NSC (National Science Council, 2001) are the two major contributors of web-based online learning, while universities and business companies are the two major developers. In Taiwan, several web-based learning programs are popular and have positive effects for learners and instructors. Essentially, many of these learning programs concentrate more on practical usage for schools and classrooms; additionally, some of them apply learning theories onto online learning. Based on this perspective, five different orientations for web-based VLEs and online learning will be discussed. They are courseware oriented, theoretical oriented, instructional oriented, community oriented, and assessment oriented directions.

Courseware oriented VLEs refer to tools that support instructional design, delivery, and management of online courses to improve course and program quality (Huang, 2000). In Taiwan, web courseware is generally developed by business companies such as, TopLearn and WBIPSS (web-based Instructional Performance Support System). Theoretical oriented direction refers to how online learners can learn actively by constructing new knowledge based on their prior knowledge personally, socially, or in combination via the web (Chou et al., 2001; Huang, 1999; 2000; Liaw, 2000).

Instructional oriented VLEs refer to how instructors can deliver content and instruction from a distance. Chou et al. (2001) designed a networked VR system to enhance students' health science learning based on the virtual reality concept. VR can be seen as a tool to provide real-time interactivity between computers and users. Chou (1999) developed web-based instruction according to the macro and micro stages of elaboration theory. The elaboration theory provides recommended techniques for analyzing instructional content in information and knowledge domains.

In the community oriented VLEs, Sun (2000) proposed an integrated concept of online learning called ASIA (Active Learning, Simulative learning, Interactive learning, and Accumulative Learning) to create learning communities. Universities in Taiwan developed web-based online learning environments to achieve learning communities such as the Learning Gas Station (http://content.edu.tw/), E.nctu (http://e.nctu.edu.tw/), IWiLL (http://www.iwillnow.org/left/about/whatis.asp), and EduCities (http://www.educities.edu.tw/). Learning Gas Station focuses on K-12 online instructional designs. It is a meaningful learning and teaching web-based environment where teaching materials are supported. Learning Gas Station also offers enormous network resources of instructional curriculum and provides discussion groups for teachers. As for E.nctu, it is a virtual campus aimed to integrate school resources, establish a virtual community, enrich learning requirements, meet students' individual needs, and accumulate knowledge.

Assessment oriented VLEs include flexible and friendly computer-assisted testing programs to create powerful adaptive assessment environments. These programs include Dear Cat (Distance Evaluation: A Remote Computerized Assisted Testing) (Ho, 2000), concept map testing (Chang et al., 2001; Tsai et al., 2001), and WBLP (Web-based Learning Portfolio) (Chang & Tong, 2000). Web-based concept map testing is crucial in understanding learners' motivation and anxiety of using online testing systems (Tsai et al., 2001). The function of a concept map is based on the principle that meaningful learning occurs when learners construct their knowledge hierarchically and explore the possible linkages between concepts. Concept maps present the hierarchical structure of learners' ideas with an emphasis on the relations between concepts. Based on these explanations, the concept map is not only a learning or metacognitive tool, it can also be used as an evaluation tool.

From Taiwan's perspective, in order to enrich the end users' learning experience, schools must seek more efficient and effective ways to improve learning performance and reduce costs. Essentially, the web predominantly provides information, not instruction or other pedagogical supports for learning. On its own, it is completely incapable of supporting knowledge construction, or providing a context for learning, and the kind of learning communities that schools have always nurtured. Thus, activity, interactivity, and reflection by learners are the hallmarks of any effective web-based learning environment.

From her perspective, Taiwan needs to develop its own learning theory based on its race, ethnic, and linguistic backgrounds in the near future. Traditional Chinese culture has elevated the status of instructors so much that they are often considered to be sages. For instance, Confucius has enormous influence over Chinese education for thousands of years. In traditional Chinese culture, students are accustomed to learning passively, thus they demonstrate less self-confidence in social negotiations. This scenario is refreshingly different in the internet. Online learners learn actively as they construct new knowledge based on peer negotiations. In addition, online learning is based on sharing experiences, identifying practices, and offering reciprocal support for tracking daily problems that may arise in life. Since Taiwan's educational culture is greatly different from that of the western world, it is therefore crucial to develop a learning theory for Taiwan's online and VLE learners.

2.3. China

Although China has yet to resolve many issues relating to VLEs and online learning, its efforts thus far are commendable. VLEs have great potentials in this vast nation. In addition, some ongoing national projects or plans have been introduced. In particular, a concern of the digital divide (between the ones who have and the ones do not have) was raised. Other concerns include how VLE-related pedagogical methods could extend beyond the traditional "information-giving" paradigm to more active and interactive learning environments.

Online education and virtual learning has been evolving in China since the late 1990s, especially in the fields of higher education and basic education. Many higher educational institutions in China are currently encountering a great demand on enrollment due to an increasing population of education pursuers. Online education through VLEs is believed to be a fast and economical approach in meeting this demand. In basic education, the uneven distributions of educational resources and various qualities of educational service providers (e.g., quality of teachers) among different districts in China have triggered the emergence of online virtual schools (Ma, 2001). Meanwhile, some national projects initiated by the Chinese government have stimulated the development of online education in the public school system as well.

In September 1998, the Ministry of Education (MOE) started to grant online education licenses to Tsinghua University, Beijing Post and Telecommunication University, Zhejiang University, and Hunan University as the first batch of higher educational institutions pioneering online education. In the same year, the number of students enrolled in online education affiliated with these four universities reached 9000. In 1999, the Beijing University and the Central Broadcast and Television University were added to the pioneer list. In May 2002, up to 47 universities in China have received online education licenses, and the total number of student enrollment has reached over 400,000 (Mao & Zhai, 2002). Besides public schools, there have been some 200 online virtual schools in China, which are mainly sponsored by enterprises. The total number of enrollment in these online virtual schools has reached over 600,000 (Zhang, 2002). For example, in Beijing alone, there are more than 30 online virtual schools such as the 101 Online School (http://www.chinaedu.com/), the Jingshan Online School (http://www.jsedu.net/), and the Hope Online School (http://www.hoho.edu.cn/).

Basically, two instructional delivery models are popularly adopted in the online higher education in China. One is the distance lecturing model, and the other is the distance self-learning model (Huang & Luo, 2002). In the distance lecturing model, an instructor gives a presentation on campus and the presentation is delivered to remote learning sites through a digital satellite or an interactive video conferencing system. Meanwhile, students at remote learning sites watch and listen to the presentation, ask questions, and get immediate feedback from the local mentors or from the remote instructors through the network. Furthermore, the distance lecturing model is accompanied with asynchronous discussions among students and/or between students and instructors. Learners can also browse learning resources, take online quizzes and submit assignments through the network. The staff in local learning sites is responsible for technical support, practicum supervision, and assessment (e.g., administering final exam). Compared to the distance lecturing model, presentations in the distance self-learning model is not delivered in real-time to remote learning sites. Rather, the presentation is pre-recorded in CD-ROMs and then mailed to the remote learning sites or learners directly. Similarly, learners can have online discussions with their peers or instructors as well.

With the rapid growth of the internet, campus networks in schools are becoming increasingly essential and significant for public schools since they can provide the learners as well as the teachers with more flexibilities in accessing instructional resources and materials. In addition, campus networks have the potential of making the school management more efficient. Currently, more than 10,000 schools in China have established campus networks, and more schools are in the process of being wired up. To promote the development of campus networks in schools, the Chinese government has initiated several projects and invested a great amount of money. Undoubtedly, this investment will help initiate and develop campus networks in the western part of China. Furthermore, the construction and improvement of the China Education and Research Network (CERNET) also accelerate the development of campus networks. As a backbone of educational network in China, the CERNET has fast internet connections. After campus networks in schools have been set up, schools can be easily connected to the internet through the CERNET. So far, the CERNET has connected more than 160 cities, with more than 900 educational institutes and more than 8 million users. More information regarding the CERNET can be found on the web site: http://www.net.edu.cn/.

2.4. Korea

Korea has made tremendous progress in terms of VLEs, particularly in adult education. Although Korea is mentioned generally, the descriptions here refer to South Korea in particular. Three specific applications in VLEs and education training have been predominant: the development of single-mode virtual universities, online education in conventional universities, and web-based corporate training.

In 1998, the Korean government established a 2-year Virtual University Trial Project (VUTP), which was designed to (1) create a cost-effective virtual education system without diminishing quality; (2) develop and implement web-based or other types of distance education courses; (3) identify appropriate policies and standards for running a virtual university; and (4) share experiences during the trial period, which ended in February 2000 (Jung, 2000; Ministry of Education, 1998). Sixty-five universities and five companies have now participated in the VUTP; eight conventional universities participated independently without forming a consortium, and fifty-seven universities and five companies have formed seven consortia. Each of the eight campus-based universities has established a virtual campus within its own university system, and each of the seven consortia has established a virtual institution outside of their member organizations. The government encouraged both partnerships among universities and the private sector and the sharing of existing resources in providing distance education to university students and adults (Jung, 1999).

All the institutions involved in the VUTP have taken on the task to expand distance education throughout the country using interactive technologies. The VUTP has stimulated new experiments with various advanced technologies such as satellite broadcasting, videoconferencing, video-on-demand, the internet and the intranet in delivering distance education. Issues of quality of distance education have been raised and explored. VUTP helped integrate distance education more firmly into the formal higher education system and upgraded the status of distance education.

During its 2-year trial period, the Ministry of Education revised the Lifelong Education Law to accept private virtual universities as part of the formal higher education system. After this period ended in the year 2000 and detailed criteria for establishing a virtual university were specified in the Law, nine "cyber-universities" approved by the Korean government started operating in March 2001. Table 1 shows the list of some virtual universities.

With the expansion of online education programs nation-wide, issues of quality have been seriously discussed and pedagogical models for distance education have been sought. In addition, ways of reducing the cost of distance education using advanced technologies without a decline in quality have been explored. Quality management systems through continuous monitoring and evaluation will help identify problems in training programs and support services and suggest possible solutions. Experience also shows that organized sessions to facilitate self-directed learning are necessary to help learners develop and strengthen competencies in managing the independent learning process at the very beginning of their study. To be an effective online education institution for working adults, open policies toward access, curriculum, methods, and learning processes have to be institutionalized. In addition, providing the appropriate legal foundation is necessary for promoting VLEs and online education in various fields. Even though VLEs are becoming more and more pervasive in the Korean society, this does not mean that all adult learners have equal ease in accessing and using VLEs in their teaching or professional development. The government or institutions should make the policy decisions on access to IT at the outset of a project if it chooses to use IT in education and training. Allowing more flexibility and openness in distance education will be key issues for distance educators and policy-makers. Partnerships with business sectors may help reduce investment costs in hardware systems (such as a computer network), recruitment of students and acquiring

Table 1. List of virtual universities

University	Areas of Specialization
World Cyber University http://www.world.ac.kr	Social welfare, hotel foods, E-business, and theology
Seoul Digital University http://www.sdu.ac.kr	Law and police administration, multimedia, and China and Japan studies
Seoul Cyber University http://www.iscu.ac.kr	Schools of social science and information technology
SeMin Digital College http://www.kcc.ac.kr	Hotel and convention management, English translation, and digital media
Sejong Cyber University http://www.cybersejong.ac.kr	Hotel and tourism management, E-business, and cartoon animation
Open Cyber University http://www.ocu.ac.kr	Internet management and digital contents
Kunghee Cyber University http://www.khcu.ac.kr	Media literature, E-business, and hotel and tourism management
Korea Digital University http://www.koreadu.ac.kr	Digital education, digital information, media design, and practical languages
Cyber Game University http://www.cybergame.ac.kr	Game design, game software, game audio, and game graphics
Hanyang Cyber University http://www.hanyangcyber.ac.kr	E-business, management information, educational contents, and digital design
Korea Cyber University http://www.kcu.or.kr	Venture management, digital multimedia design, and entertainment

of advanced technical skills. Online education institutions also need to find ways of reducing the cost per graduate by improving the graduation/course completion rate.

2.5. Japan

Although Japan has been focusing on VLE implementations in recent years, her educational system and culture remains largely traditional based on her age-old societal values. In 1994, some researchers and teachers realized that the internet has its potential application in the design of learning environments. Thereafter, the national school networking project was started and the internet was introduced nationwide. Following this, a number of projects were initiated, some of these are 100-school project (1995–1997), New 100-school project (1997–1999), and E-square project (1999–2002). These large projects supported and introduced various experimental research projects and collaborative learning projects.

In Japan, a large amount of investment has been made in the research and development for implementation of VLEs in Education. These technologies have yet to make a significant impact on the education sector and schools in Japan. The following are some R&D projects:

- Fujitani and Akahori (2000) inquired about the heuristics for generating the summary of online discussions with higher validity. They developed a web-based mailing list reference application with an e-mail summary browsing function.
- As a support tool for reflective learning, Funaoi et al. (2000) developed a concept-mapping software with a function that enables individuals to reconstruct the learning process using historical data.
- Yanagisawa and Akahori (1999) examined the influence of *information* in VR environments. The results show that the representation of reality is needed for those who lack sufficient practices of special cognition in a VR environment. On the other hand, too much information on real photographed images may cause failure to acquire spatial representation. These results suggest the need for the consideration of the amount of information to be provided to the learner by the creator or the designer of the VR environment for maximizing learning effectiveness.
- Inaba and Okamoto (1995) have developed a computer coordinator on Computer-Supported Collaborative Learning (CSCL) tool with expert systems technology.
- A CALL (Computer-Assisted Language Learning) system based on natural language processing (NLP) tools was developed. The system can provide descriptive feedback to the learner based on his/her input (Yang & Akahori, 1998) using NLP tools for error analysis.
- Using a technologically driven conceptual dictionary, Arai and Akahori (1998) developed a CALL system which allows various correct answers for an input sentence. With the conceptual dictionary, the system can detect synonyms of original correct words to the questions. Using cartoon strips with contextual cues (Akahori et al., 1998), the system enables a more flexible mechanism to be put into practice.

In spite of these seemingly ambitious R&D efforts, large numbers of schools in Japan have not particularly appreciated the use of VLE and online learning. In this country, there exists a deep-rooted idealism about education, which puts a lot of emphasis on acquiring knowledge through memorization and repetition. It has not been realized until now that computers and VLE applications could be used as a partner in learning (i.e., learning *with* technology). Another obstacle to the predominant use of VLEs is that teacher educators are not convinced that such technologies could bring about a real change to the age-old educational practices. A large number of teachers only believe that the internet is useful for accessing information, i.e., knowledge-acquisition. They think about computers and the internet as tools for efficient acquisition of knowledge. But these perceptions are slowly and gradually fading as intense influences and competition from the West arises in their society.

2.6. Singapore

Under the auspices of the Singapore Education Ministry's IT Master Plan, schools in Singapore have been empowered with flexibility in the experimentation of VLEs and online learning. Pioneer schools in the implementation of IT have piloted innovative ideas to the curriculum. For example, some schools have even tried ideas where students do not need to come to school and where learning could take place at home. Such implementations have not been widespread but adopted in terms of short durations. Other schools have adopted IT and online learning for communication and collaboration, particularly in facilitating the understanding of literacy. Project work has also been an emphasis and some schools are capitalizing on the technology to enhance and integrate interdisciplinary or multidisciplinary content—making learning of subject areas more meaningful for the learner. The institutes of higher education have also been pioneering newer technologies such as wireless infrastructure and some of these concepts have transformed "more traditional" set-ups. Schools are also gradually finding ways to use technology to enhance their traditional ways of working in the classrooms and beyond. Students could be actively engaged in their projects at the corridors, canteens (cyber-cafés), and out of classroom settings.

The following are ways in which VLE tools are used in Singapore schools: (a) as an information resource; (b) as a communicative tool; (c) as a visualization tool; (d) as a constructive tool; and (e) as a cognitive tool (Hung, 2001). Increasingly, the concepts of constructivist learning environments are being infused into the school settings and variations of problem-based learning are also being emphasized. Some of the schools in Singapore are also moving away from computer labs to decentralized learning centers and corners where students can engage in their work collaboratively using wireless technologies. In a case example, PDAs are first used as the main tool for reflection of an English language lesson and subsequently as a collaboration device where student compile all notes by transmitting their reflections to one another in a group. In yet another school, students are carrying data-loggers out into the field and capturing data and subsequently comparing it with information on the World Wide Web via the internet. Data captured by the students can also be uploaded onto the Net. Various tools were used for further manipulation, analysis, and visualization. Current forms of technology, for example, web-based tools, have been adopted in relation to curriculum and pedagogy integration.

State-of-the-art video-conferencing equipment is increasingly commonplace in schools, which allows students to participate in interactive lessons through synchronous or asynchronous conferencing. For example, in an international collaboration project, 43 pupils in a Singapore primary school took part in video-conferencing with pupils from Chile (Ministry of Education, 2000a). The project, held in 1998, provided opportunities for students in both countries to discuss issues with their counterparts who are situated in different cultural backgrounds. Lessons can also be recorded and made available through video-on-demand to other users in Singapore, making use of the broadband facility. Schools are also experimenting with a CSCL system, known as *Knowledge Forum*™. This collaborative learning program provides a platform for students to engage in collaborative work and discussion, and at the same time records the development of ideas and tracks student's contribution for assessment purposes.

In another example, 17 primary schools and 17 secondary schools participated in the Konet Plan project, a global environment project initiated by Japan (Ministry of Education, 2000b). In this joint research project, students collected experiment data such as the density of nitrogen oxide in the air and forwarded the findings to the coordinating site. The students subsequently engaged in online conferencing and discussions.

Seemingly, Singapore has been ranked as one of the top nations in international examinations in Science and Mathematics, not due to a constructivist pedagogy *per se*, but rather from the traditional mode through which education has been formed. For this reason, the traditional emphasis on "examination results" as a focus is still predominant in the local schools. As we have seen from the IT projects undertaken by schools, the focus of online learning is not merely on tests and examinations, but also on the quality of thinking processes in activities such as project work. Maintaining this delicate balance between achieving good performances on tests and attending to the metacognitive aspect of learning has become a major challenge for the years to come. We believe that many problems and issues remain in the implementation of online learning and VLEs in Singapore schools. The most important issue probably is how VLE tools and online learning can effectively be integrated into the school curriculum over the coming years, and how IT tools in project work can be an integral part of the school curriculum.

Because of the concern related to maintaining past academic achievements, most online projects have been carefully designed to integrate both the face-to-face and the online distance education approaches. This tight integration is probably partly due to the unique Singaporean characteristics of a city country. There are virtually no suburban areas in Singapore. With the convenience of the mass rapid transport system, schools are physically and readily accessible by all. When learning goes online, there must be an imperative reason! In Singapore, integrating the face-to-face and online learning approaches seems to be taken as a given. Both face-to-face and online learning approaches warrant certain merits and the advantages of each approach should be maximized for the effectiveness of learning. The social interactions involved in face-to-face settings are different from that of online environments, whereas online learning facilitates interactions with certain individuals and experts that may be unavailable locally or in the immediate physical context.

With Singapore's advancement of VLE-integration in the working force and its tight integration of face-to-face and online approaches to learning, there is a unique opportunity for Singapore to experiment with the participatory approach to online learning. Such an experience may only be feasible in small countries, which are flexible enough to make drastic changes at the national level.

2.7. Australia

VLEs can be perceived as one of the ways of making learning more accessible and flexible. However, flexible learning—where the issues of learning are emphasized—should be perceived as one of the ways of making learning more effective. A commonly accepted emphasis in Australia in recent years is flexible learning. The notion of flexible learning goes beyond how technology can facilitate the learning process, the reader will recognize in the discussions below that VLEs and flexible learning are intimately related. The definition of flexible learning within the context of higher education in Australia is that an institution provides students with flexible access to learning experiences in terms of at least one of the following tenets: *time, place, pace, learning style, content, assessment*, and *pathways* (e.g., Browne, 1999; Ling, et al., 2001; Macquarie University, 2001). This definition is based on the view that learning requires the active engagement of students where they should be more independent and responsible for their own learning. Different modes can be tailored according to the styles and learning patterns of individuals. In other words, flexible learning has the inherent assumption of being student-centered, rather than teacher-centered. Other characteristics of flexible learning include students' collaboration with peers and/or practitioners in the field, provision of ample resources, the learning experience being context sensitive, greater emphasis on generic skills (e.g., thinking, metacognitive, problem-solving), and the shift of the teacher's role from being a source of knowledge to a facilitator throughout the students' journey in learning (e.g., George & Luke, 1995; University of Sydney, 1999). In all these instances, different instructional modes are carried out where the responsibilities for learning rest on the individual students.

Flexible learning in Australia has been translated into different levels in implementation. For example, it could mainly focus on flexible delivery, which includes various types of mediated instruction including print, audio-visual, computer assisted or online delivery as well as traditional instructional formats such as lectures and tutorials (University of Wollongong, 2000). It can be considered in terms of course structure, course content, teaching and learning methods, interactions between the teacher and the students, and assessment method (Monash University). Macquarie University (2001), Center for Flexible Learning, has adopted flexible learning as a university-wide initiative. This Center is set up in addition to the Center for Professional Development and the Center for Open Learning (the distance education "arm" of the University). Flexible styles to accommodate different kinds of learners seem to be still relatively unexplored. Some learners could prefer a more instructive approach, whereas other would have preference for constructivist methods.

Ling et al. (2001) surveyed 10 universities in Australia and identified 6 models of flexible provisions in higher education:

1. Removing fixed time and place constraints (e.g., off-campus programs utilizing print or digital tuition materials).
2. Moving time and/or place to suit the learner (e.g., provision in the workplace or regional campuses, study centers, or summer school).
3. Readjusting entry requirements (e.g., no academic entry requirement or recognize and give credit for prior learning).
4. Providing alternative entry and exit points appropriate to the learners.
5. Accommodating learning style, pace, and collaboration preferences (e.g., programs offered in full or in part in more than one mode; programs with flexible time schedules; courses that permit but do not require collaboration).
6. Accommodating content and assessment preferences (e.g., modularized content allowing choice in construction of a program; problem-based learning allowing some selection of content; alternative assessment tasks).

Most of the universities surveyed by Ling et al. (2001) are situated in rural areas and are predominantly distance education institutions or traditional campus-based universities with existing infrastructure to support the provision of education in alternative ways.

2.8. New Zealand

New Zealand shares the same enthusiasm as Australia toward flexible learning but with a more cautious and conservative approach. This is probably due to its lower availability of resources. In New Zealand, it has been a concern that flexibility in many cases seems to become an end, rather than a means to the pursuit of quality learning. Chen (2003) at the University of Canterbury attempted to analyze the provisos underpinning various aspects of flexibility. Chen argued that every form of flexibility comes with provisos. For example, in order to make the time and space flexible for learning, pre-designed activities must be in order. All required reading or directions to collaborative activities must be sent to all participants prior to the commencement of the course. The instruction must be clearly written with as little confusion as possible, in other words, an "inflexible" mode. The flexibility in changing the activity is greatly limited due to the slowness of the decision making process within the VLE environment. In other words, each form of flexibility as afforded by technologies and other provisions bring along certain advantages and constraints. Only when the provisos or pre-conditions are met can one enjoy the benefits of that particular aspect of flexibility.

Despite the scarce resources in New Zealand, VLEs have become a strategic developmental direction in recent years. A report on e-learning conducted by the E-learning Advisory Group (2002) outlined strategic plans to the Ministry. Three major recommendations are

- The establishment of a tertiary e-learning consortium comprising institutions with appropriate expertise in the area. The consortium would be funded by the government to coordinate the development of e-learning within the tertiary sector;
- The creation of a single electronic point of entry, a portal, for people to gain access to a wide range of information, services and resources offered by New Zealand's tertiary education sector. Over time it is envisaged that students would be able to enroll, learn, be assessed and credit transfer between providers and programmes using this portal;
- The establishment of a Collaborative Development Fund (CDF) to provide capital for tertiary providers to access funds to develop their e-learning capability. (p. 5)

Based on the above recommendations, a fund of NZ$ 47 million was set up in 2003 for collaborative projects to develop the nation's e-learning capacity. A national e-learning portal for flexible access to its provision of e-learning portfolio was also introduced in early 2003. The website can be found at: http://www.ted.govt.nz/index.jsp.

Among all the e-learning initiatives, the Open Standard and Open Source movement is the underlying theme. There is a great emphasis on developing learning objects, which conform to the IMS open standard so that they can be shared within the education sectors. The open source movement is to tackle the long-term sustainability issue of any major development project. Open source invites people to use the developed system and grants people access to the source codes free of charge. People are free to develop the system further based on their needs in their respective local contexts. To prevent having too many versions of the same system (with minor differences), a consortium will then be set up to host the "authoritarian" version of the system. Only approved additions will become part of this "authoritarian" version. The long-term sustainability is therefore secured by the many participants from all over the world. The risks and the development cost are also shared by the consortium participants. This strategy is especially suitable for the New Zealand context due to the limited resources. Refer to the

Interact (a home-grown learning management system) open source site for an example of the open source approach adopted by the Christchurch College of Education. Details of the project can be found at the following website. http://sourceforge.net/projects/cce-interact/

Related to e-learning is the notion of reusable learning objects. Massey University in New Zealand has been explored in this direction. Research is underway to create solutions that are practical within the context of the courses delivered by Massey University. Learning resources cannot be just pulled out of a particular context and successfully implemented in another unless the content is designed to be configurable, incrementally extensible and restructurable to allow for change in the context. Three categories of context have been identified: *interaction* contexts within which the interaction between learning resources and learners takes place; *environmental* contexts that surround the design of the learning resource; and *objective* contexts that arise from the educational process concerned with explicit and implicit objectives of the teaching and assessment systems (Patel et al., 1998). A *web-course search engine* has been developed (Gong, 2002), which is a friendly, efficient and accurate helper for finding appropriate learning objects from the vast repository.

3. ANALYSIS AND DISCUSSION

From the overviews of VLE developments in the various Asian countries, we observed the phenomena of diminishing traditional boundaries due to VLE and online developments, and yet emerging tensions arising out of this phenomena. These tensions will be explained below.

First, it seems from the above review that due to the proliferation of the internet and other worldwide globalization efforts, the world has become much more interconnected. Increasingly, there is a blurring of eastern and western cultures as cross-cultural influences pervade. In the same vein, the development of VLEs is also undergoing a similar phenomenon. Underpinning many of the VLE developments, a similar orientation toward implicit notions of active learning and constructivism is evident, although currently VLEs are still "information pumping" methods (Tan & Hung, in press). Constructivism and social constructivism seem most popular as the emerging theoretical underpinnings in the Asia-Pacific regions. Due to such a dominant learning epistemological drive from the West, countries in Asia in particular are experiencing seeming inconsistencies and tensions in learning cultures. For example, Taiwan or Japan may need to develop a different epistemology of learning because their people are largely influenced by eastern ethnic values, which regards the didactic mode as rather appropriate. The Japanese and Singaporean representations also outline the difficulties with technological advancements in the area of education since the system has been deeply influenced by traditional models of learning and instruction. On the other hand, we may be creating yet another legacy of learning that seems to be value-laden in terms of its benefits rather than its limitations. The tension between newer approaches (e.g., constructivism and active learning) and the traditional (e.g., didactic) is increasing because of distinctive learning paradigms. We would like to maintain that there is a place for differing paradigms of learning, including the cognitivist or even behaviorist approaches (Hung & Chen, 2000). Thus while active and constructivist learning is prevailing in VLEs, it should also be recognized that the tensions between pedagogy and andragogy (adult learning) are also fast diminishing. Today, both pedagogy and andragogy advocate active and independent explorations. Andragogy which advocates that adult learners thrive on an accepting, respecting, and helpful social atmosphere for learning is also similarly suggested for pedagogy. Perhaps, the only difference between the two schools of thought is the degree of prior knowledge and experiences children and adults bring to the learning process. In addition, related to the tensions arising from differing learning paradigms, the predominance of VLEs is breaking down traditional physical boundaries, and thus creating a virtual culture that is unique in its own right. While traditional cultures are being co-intermingled, we must necessarily be aware that societies may lose their uniqueness of cultural characteristics due to the pervasiveness of virtual network technologies. As implied in some of the countries as represented, while "walls are being broken down", there remains value in preserving cultural heritages. Societies must have a balance between preserving its age-old cultural heritage and being influenced by other more dominant societies via the mass media and other forms of communication. Thus, on the one hand, cultural divides are gradually diminished due to virtual-communications' technologies; on the other hand, tensions arise within societies when new influences run tangent with age-old traditions. These are issues that have not yet explicitly arisen but will become pertinent as VLEs mature.

Second, the English language dominance on the WWW has created a tension between those who understand the language and those who do not. At the same time, it does provide a standardized platform for communication. However, this tension is gradually fading with state-of-the-art language interpreting technologies. Those who do not speak English can increasingly access resources and VLEs in their native languages. Currently, there are intelligent web pages which are able to detect the preferred language of the user and to present information in that particular language. These systems are still in their infancy (the accuracy of interpretation being still the main developmental bottleneck) and implications of these developments are still largely uncertain. Ideally, these interpreting systems would diminish the language divide. However, how much implicit "faith" can one put into a machine translated document? Besides, the social acceptance is still a major concern even though an ideal translation system can eventually be developed.

Third, with access to resources and instructional materials, there is an increasing demand for content and communication delivered at the individual learners' work-desk. In the past, training has been predominately conducted in out of the workplace context such as training schools and centers—commonly referred to as formal training settings. Increasingly, the WWW and the internet are blurring the distinctions between formal and informal training. Today's emphasis on "on-the-job" training with available resources via the internet is diminishing this virtuality divide between formal and informal training (for example, see Korea's proliferation of virtual universities). The decrease of formal training settings is congruent with the recent emphasis on authentic workplace learning because of the contextual nature of cognition (Brown & Duguid, 2000). Although authenticity of the learning context is crucial to learning, tensions arise because there are other advantages of leaving one's workplace to go to a formal face-to-face setting, for example, taking a break from one's work environment, meeting with other colleagues within a formal class setting, and perhaps other possible reasons. Thus, although companies may believe that VLEs can substantially reduce training costs, employees may miss out on other inherent and implicit benefits of the formal training setting.

Fourth, VLEs over the internet break the barrier of time and space making learning more flexible and accessible. VLEs are changing the landscape of how institutions provide learning and resources. Famous universities such as MIT are invariably and seemingly becoming much more accessible to a worldwide audience. The concern is that those who have access to technology may enjoy more advantages than those who do not. China and perhaps the South East Asian countries are still struggling to provide WWW connections to their people who are so dispersed in many remote areas. VLEs via the internet presume that technical infrastructure such as networks are in place. On the other hand, accessibility does not necessitate that individuals benefit in terms of effectiveness in learning from VLEs. In a sense, technology is presumed to be advantageous or, at least, not inhibiting to learning. It is usually connoted that VLEs are "better" than traditional forms of learning. Such a conception is to our mind too simplistic. Effective learning may not involve VLEs, and learning may also not involve networks and online or virtual means.

Fifth, we consider the issue of the "flexibility" divide which we discussed in relation to Australia and New Zealand. Highlighting one aspect of flexibility will inevitably make other aspects inflexible. Which aspect do we choose? The principle of uncertainty (in physics) seems to apply here. According to this principle, we can never be sure of the position and the velocity of an object at the same time. We either measure the position of the object and forgo the velocity or vice versa. Similarly, in flexible learning, if you want flexible time and space, you will have to compromise on the flexible content, for instance. If you want a flexible pace, you will have to forgo the ease of flexible access to resources and experts (for they are not always available). Hence, different institutions may decide to uphold a certain aspect of flexibility and down play other aspects. This kind of emphasis creates divides.

Sixth, the "standards" divide. With regards to this issue, whose open standard do programmers of VLEs follow? For example, IMS or IEEE for learning objects? HTML or XML for web pages? How do we prevent history from repeating itself? The infamous war between beta and VHS video tapes is a classic example of how "standards" divide. The term "open standard" itself is an oxymoron paradoxical. How can a standard be open since one must follow a particular standard? One is either in or out. Paradoxically, standards are always closed, are they not?

Lastly, there is the issue of open source. For open source programmes, development cost is shared, risk is shared, but maintenance may cost more (due to the programming bugs, etc.), no guaranteed longer-term development once individual institutions run out of money (support). In contrast, the off-the-shelf products have characteristics of lower maintenance, higher upfront capital commitment and is less flexible to amend the applications for local contexts, etc. These issues divide between open-source and non-open source off-the-self product applications.

In the above sections, we have discussed the trends in ICT and educational technology in the Asian countries, and predominately, the reader would recognize the fundamental epistemological stance of learning as influenced by Asian cultures. These Asian beliefs strongly influence the educational systems in the region. One fundamental difference between Asian and Western educational systems is the highly competitive stance toward achieving well in high stakes examinations. Singapore, for example, has students who have topped the international examinations in Science and Mathematics. Asian countries in particular have found efficient strategies for students to cope with traditional models of learning.

The issues of flexibility and the willingness to adopt less rigid structures in course delivery, to our minds, relate to culture and the belief of how learning occurs. Asian countries are heavily influenced by Asian cultures which may be less democratic compared with Western nations. Thus, culture has structured and organized activities around society in ways which impact upon the modes through which perceptions of schooling and learning occur.

In contrast, we commend the kinds of flexible learning efforts found in Australian and New Zealand educational systems which promote innovation. Asian counties need to embrace alternative modes of instruction and learning, allowing flexibility for an increasingly agile workforce. Educational systems, particularly those which support adult learning, must increasingly support the demands of life-long learning and less on efficient strategies for schooling. The systemic structures of less flexible learning mechanisms in countries such as Hong Kong, Taiwan, and Singapore, have resulted in beliefs that learning occurs only in schools and in formal settings. More flexible approaches instead encourage a belief that learning is life-long, and can accommodate different modes in order to fit into the varied patterns of the workforce.

The flexible learning approaches adopted by Australia and New Zealand are commendable and can be modeled by Asian countries. The principles for practicing flexible learning are sound and encourage a diversity of varied approaches to course deliveries. These principles are

1. Flexible time and place constraints to suit the learner;
2. Readjusting entry requirements to accommodate for work experiences;
3. Alternative entry and exit points appropriate to the learners;
4. Different learning style, pace, and collaboration preferences; and
5. Multiple assessment preferences for different learners.

4. CONCLUSION

We have also observed that the trends within VLEs are not applied purely as a distance education mechanism. It is becoming an accepted norm that online learning need not be seen as purely virtual and should instead be used as a means when face-to-face interactions cannot be afforded. It is not the scope of this chapter to discuss the degree of face-to-face and virtual involvements. Increasingly, researchers and educators recognize that face-to-face interactions are critical to social and peer learning, and VLEs can be used to complement the interactions. Thus, the issue of either face-to-face *or* virtual learning is no longer the predominant concern, but rather how both approaches can be used appropriately and as a complement to each other. As VLEs mature in this region, users of these environments adopt them as a seemless process of their learning.

In the context of flexible learning and VLEs, educators are also now more cognizant of the kinds of limitations or provisos which are inherent in any "new" approach. As with any new introduction of technology, it requires some time before the hype "settles down" and a better sense in terms of pedagogical implications becomes evident.

Finally, new and innovative state of the art technologies such as virtual reality, special forms of customization and personalization, video-on-demand systems, and many other expert/AI applications are also making VLEs and flexible learning more readily available. Importantly, we highlighted that technologies *per se* and flexibility do not necessarily imply enhanced learning. There is an urgent need in our opinion for VLEs to be substantiated on the developments made in the learning sciences and not on the hype of e-learning as entertained by commercial enterprises.

1. INTRODUCTION

This international team of online educators will show, true to the title of this chapter, that online education is already a global phenomenon. The World Wide Web, which affords so many educational applications friendly to designers as well as to the users, has lived up to its name by reaching nearly all countries through the internet infrastructure. Online education at first suggests education through the internet, but the "line" in online and offline refers more broadly to networked computers. By necessity in some countries, or by choice, Intranets and other systems of digital devices such as mobile phones, whether connected by ground wires or by satellites, can also serve as media for formal education and informal learning. Issues of access recurring in this chapter imply, however, a goal that all learners at least have the option of studying and communicating with other world citizens through the global internet, that is, online education in the fullest sense. (For more on what online education is, see McCarty, 2001).

Global online education represents not only a technical revolution in access to valuable information for people in developing countries, but also a paradigm shift from education to perpetuate elite classes of hereditary privilege—in all countries—to UNESCO's motto of "education for all"—through the internet. Globalization in this chapter implies a positive diffusion of educational opportunities beyond Western or wealthy countries, so the geographical coverage focuses mostly on non-Western regions. But efforts behind the scenes and sometimes sacrifices of Westerners who collaborate internationally to create a level playing field open to all must not be taken for granted. At the same time, recognizing that globalization for purposes other than education can be harmful, online educators must proceed into this new frontier with intercultural sensitivity. [Cf. the chapter "Global Virtual Organizations for Online Educator Development" in the next chapter of this Handbook. It details how the World Association for Online Education (WAOE) promotes professional ethics in this new discipline along with enjoyable online cultural activities, not

* Chapter Draft for the Case Studies Part III of the *International Handbook of Virtual Learning Environments.*

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 723–787.

centered in any geographical region, serving as a distributed virtual learning environment (VLE) and an open source learning organization.]

"Global" also refers to global issues raised by the advent of online education. As just one provocative example, if equal opportunity for education were realized through the internet, would those who were born to comfort be able to compete with those who are hungry to learn? Conflicts of interest are bound to arise then at the tollgates where gatekeepers represent institutions profiting from the scarcity of access to expert educators and the economic consequences of credentialism. To substantiate this chapter, educators from around the world answer a questionnaire including globalization issues, with questions aimed to be phrased neutrally to elicit responses representative of their country or culture.

"Online education" also refers to learning methods that at least partly utilize the information and communication technologies (ICTs) available through the internet. Given the explosive growth of specialized knowledge and paradigm shifts in educational approaches, lifelong education is needed above all by educators themselves. For online educators not to replicate the classroom but to take advantage of new media, new ways to communicate, and to design educational experiences, renewed professional development for educators in virtually all fields of enquiry is also necessary. Educators are thus utilizing the internet for professional networking regionally and globally to learn from one another about the new media and their applications to education.

While the pendulum of opinion about e-learning may swing from pro to con in economically fortunate countries, the developing world entertains no such luxuries but looks to cyberspace to accomplish the empowerment by global knowledge that would otherwise continue to take too long to trickle down. To leapfrog to 21st century ICTs most effectively, many non-Western countries are developing virtual universities, particularly, through the National Open Universities little known in the West. Non-Western scholars also are among those benefiting from international networks of educators freely sharing expertise in educational technology. In a report adopted by the UN Economic Commission for Africa, Afele (2002) writes that "[d]istance learning has become essential to global development programming". Thus, this chapter will take a geographical approach to case studies, presenting little-known initiatives of both local and international significance where the use of VLEs empowers educators.

The internet has allowed world citizens to bypass their government representatives to a great extent and to organize their own international relations. The world community of scholars with shared academic standards and ethics is particularly well positioned for networking to form global guilds and to reconstitute Academia in cyberspace. Are there any signs, though, that the new media are making a difference in the so-called real world of embodied human existence? With the topic of global online education already so vast, it will be important to focus on far-reaching questions. Moreover, in a world still divided by barriers of hostility, it will be important to find out if there are emerging trends in social evolution whereby education through the internet helps to foster intercultural reconciliation.

The opportunity for education through the internet has reached at least some sectors of nearly all countries. Thus, to address such a broad field as online education worldwide, this chapter takes a multidimensional approach. To frame the issues and provide for cross-cultural comparisons of the likely diversity, results of a Global Online Education Questionnaire are first summarized and discussed. See the Appendix for the "horse's mouth" data from respondents all over the world compiled for each question. Secondly, some key issues in online education particularly for the benefit of developing countries are crystallized from the works of Parker Rossman, a former Dean at Yale, on the future of universities, and Takeshi Utsumi, a telecommunication expert who founded the Global University System (GUS), illustrating the technology, funding, and networking challenges involved in implementing global online education. Thirdly, a geographical approach is taken, with in-depth case studies by the co-authors about their home regions, demonstrating how the quality of education worldwide is improving with widening access to learning opportunities online.

Co-authors drawn from the WAOE aim for wide geographical coverage to address recent developments in online education in the non-Western world and where there is North–South or East–West intercultural collaboration. Reporters from the field for this chapter are Begum Ibrahim for Southeast Asia and an Islamic perspective, Boris Sedunov for Russia and its region, Ramesh Sharma for India and South Asia, and Steve McCarty for the Pacific Rim and overall. All the authors use languages other than English and can therefore bring out information and perspectives from behind language barriers. The authors also have daily cross-cultural experience including on the Net to shed light on the diverse applications of VLEs.

Global issues such as gender, culture, language, economics, and access will be illustrated as to how they work out in local and international contexts. Local case studies such as virtual universities will illustrate how global issues in online education work out in specific cultural contexts. International collaborative projects are also explored for their intercultural significance. Global issues are also examined in different geographical regions to enable comparisons. Whether universality or divergence is found would in each instance help guide future practitioners of global online education.

2. GLOBAL ONLINE EDUCATION QUESTIONNAIRE: SUMMARY AND DISCUSSION

Knowledgeable scholars in various countries were surveyed in the fall of 2002 to compare the state of VLE use, effects of globalization on local cultures, what institutions and associations for online education have emerged, and what obstacles are faced locally such as access to Net infrastructure. In the context of the mission of this Handbook, if the questions are expressed objectively enough, and if the responses are as representative as they seem, then some valuable information and comparisons can be discerned from the results.

Respondents were limited in number but represent some locations not covered elsewhere in this chapter, which aims for the broadest range of voices. The aim here was not to gather public opinions but rather professional opinions representative of various world regions, so the survey was distributed to a few international electronic discussion lists concerned with online education.

Here, the results are summarized and discussed, but the full and unmediated data in the Appendix may prove to be more interesting as well as valuable to investigators. Respondents answered for 16 countries or wider regions, viz. Latin America, Mexico, Argentina, Brazil, Finland, Israel, Turkey, Russia, India and South Asia, Kenya, South Africa, Lesotho and Southern Africa, The Philippines, Indonesia and Southeast Asia, Malaysia, and Japan. Respondents are identified in the Acknowledgments.

With a view to comparing trends in the world, the results will be summarized regionally into *Latin America* (Mexico to South America), *Finland*, *Israel*, *Turkey*, *Russia*, *South Asia* (mainly India), *Africa* (Sub-Saharan), *Southeast Asia*, and *Japan*. The diversity within each region or country as indicated by the respondents will also be described. In subsequent sections, furthermore, the co-authors provide details on online education in the former Soviet region, the Indian subcontinent, all countries in Southeast Asia, most of the Pacific Rim countries, and the Islamic world, thereby representing many more countries and cultures.

The questionnaire enquired first about the state of VLEs used for education in the respondent's region, whether the internet is used mainly by the elite and whether females are involved. Next, do local people feel that globalization effects threaten their culture, or is a broader cultural repertoire welcomed? Have other issues been widely debated such as language, democratization, equalizing of opportunity, or resistance to change by governments? Do leaders or the media see the internet as beneficial for education, international, and intercultural relations? Then, are there virtual universities or other such schools available, and if so, are they accredited, recognized, or considered notorious? Have many people considered studying at institutions in other countries through the internet? Have many local companies entered the e-learning business? Are there academic associations for the professional development of online educators? Finally, is web access an obstacle for many people, and what other issues affect the acceptance of VLEs or online education?

Respondents did not necessarily answer every question thoroughly. What follows here is a concise paraphrasing and quotation of the salient responses that shed light on the questions while being suggestive for regional comparisons. Investigators should refer to the Appendix for the complete and definitive views of the respondents. At the end of each item below, there is a brief statement comparing the responses for global trends and variations. Then in the following subsection, there is further discussion of the results as a whole.

The first substantive question was, *What is the general state of the use of VLEs for education?* For *Latin America*, the four responses seemed to reflect different social strata. A professor formerly with the World Bank saw cultural antecedents in distance education (DE) for e-governance as well as e-learning in higher and continuing education, whereas others found ignorance among all but an educational elite. The latter is probably a more realistic view of the region as a whole, while also acknowledging progress in educational technology and attitudes thereof. In *Finland*, one of the most wired nations and well known for mobile phone technology, the concerns seem to be similar to North America, the United Kingdom, Australia, and New Zealand. That is, how to refine virtual learning possibilities with pedagogical considerations, and reconciling the different interests in education represented by commercial solutions versus open source. For *Israel*, the response was just for its Open University, with half the courses utilizing at least components of e-learning. Compared with open universities in other countries, though, Israel resembles nations advanced in VLE adoption. In *Turkey*, internet penetration was reported as 2% but growing. There is a demand for online education even before facing pedagogical concerns thereof. In *Russia*, VLEs are less developed than in the West because of poor telephone lines, few private educational institutions compared to under-funded public ones, and strong government-centered traditions. In multicultural *South Asia*, VLEs are being adopted rapidly for education in tandem with the infotech sector. In *Africa*, online education is mainly available at the university level. Many schools do not even have telephones and use of the internet does not necessarily extend beyond e-mail to the web. In *Southeast Asia*, for the Philippines, it was reported that virtual learning is popular with few institutions, mostly for the sake of profit. Indonesia is mainly at the public planning stage, whereas in Malaysia "many traditional public and private universities have some or all of their distance learning programmes available online". In *Japan*, virtual environments are popular for socializing, but progress has been slow in realizing their educational potential. University and government bureaucracies are slow to accept change while companies struggle to find a market for e-learning amid so many consumer attractions. Technology tends to race ahead of pedagogy, but individual educators are well equipped to experiment with VLEs. The overall pattern seems to be that VLEs are used worldwide more or less, depending mainly on the level of economic development of the country. For more details see also the next question, the Appendix, and *Cultural and Regional Reports on the State of Online Education* later in this chapter.

Is the internet used for education by a small elite in universities or elsewhere? In *Latin America*, it is elsewhere to an extent, but not all universities are online yet. In *Finland*, internet availability is ubiquitous. In *Israel*, it is used by all students to supplement classroom learning. In *Turkey*, a limited number of English-medium private universities use learning management systems (LMSs) like Blackboard and WebCT, but Turkish-language LMSs are needed for public universities. In *Russia*, the internet is used in almost every university to supplement F2F instruction with skills needed for future jobs. In *South Asia*, most universities are connected to the Net, with libraries in India interconnected. In *Africa*, progress has been slow, with bandwidth and online costs relatively expensive, but there are affluent universities with a high technological level, particularly in South Africa. *In Southeast Asia*, it is used in elite universities and affordable for students. In the Philippines, even the under-privileged can use the internet on a rental basis. In Indonesia, it is the elite among universities. In Malaysia, internet use is progressing in secondary and primary schools. In *Japan*, even elementary schools are well on the way to being wired, but internet use is still mostly supplemental to regular face-to-face education. The responses overall confirm that the internet is used in most but not all universities worldwide. For some regions above it could only be extrapolated how widespread internet use is beyond their universities. More details are available elsewhere in this chapter, particularly on internet use for all Southeast Asian countries.

Are females much less involved? In *Latin America*, centering on Mexico, it seemed to be yes, but the opposite for South America. In *Finland* and *Israel* they are equal. In *Russia*, "[f]emales in former USSR countries, except the Moslems, are much more active and free than males". But rather than technical aspects, "they prefer to utilize completed and reliable software products". In *South Asia*, the difference is rather between urban and rural. Urban females are equally involved. For Africa, the responses were varied: balanced in Kenya; women and girls still caught in traditional roles in South Africa, but females could be in the majority under certain demographic conditions in Lesotho and elsewhere. In *Southeast Asia*, females outnumber males as they do in the whole educational sector. In *Japan*, females are less involved with technology until it becomes very user friendly and fashionable like mobile phones. Having more free time than men, females may be more involved in online education than men in the future when they become comfortable with the Net. Most responses worldwide were contrary to stereotypes and may point to the role of educational cultures in bringing a surprising proportion of females into VLEs globally.

How do people generally feel about globalization effects—do they feel their culture is threatened or do they welcome a broader cultural repertoire? For *Latin America*, the Mexican respondent wrote that "[p]rofessionals feel it is a good thing provided our culture and values are maintained". A broader cultural repertoire is welcomed except in places like Argentina where globalization has had ill effects. In *Finland*, there are no qualms except over whether VLEs are locally developed or not. In *Israel*, most people welcome a broader cultural repertoire. In *Turkey*, "where Europe and Asia meet" there is a strong sense of history and their role as a would-be Muslim nation in the EU. "Globalisation, the result of the impact of technology and power, has its own pluses and minuses [depending upon] pluralist-participatory democracy, market economics, national and international transparency, and interactions". In *Russia*, "Some young and progressive people welcome international relations, but [the] older generation with a former Soviet mentality in a large proportion still do not trust foreigners, especially because Russia after Perestroika was invaded by foreigners who managed to plunder and help some Russians steal huge amounts of capital. So in a way, the old communist accusations of uncontrolled and criminal capitalism have proven to be a reality. It will take a long time to replace that plunder with civilized international co-operation and to restore the lost trust in foreign businessmen and economic consultants." In *South Asia*, "Both. Elders are concerned with the cyber-attack on their culture while young people are excited with the new medium, making global friends, finding communication much easier and at anytime." For *Africa*, a Kenyan wrote "It is welcomed particularly by the elite. The tradition-bound [tribal people] however feel highly threatened." In South Africa, "Civil society seems to be against globalisation, but as we are a country with 11 official languages and many cultures, we are working towards intercultural friendliness." In the Southern African region, "From the cultural point of view, globalization is seen with some degree of resentment. But in the main, the newness of technological development [precludes] its general acceptability and utilization." For *Southeast Asia*, in the Philippines, "People are taking globalization negatively, since . . . locally manufactured products and local companies have suffered from the WTO . . . In terms of culture the people are not actually that bothered." In Indonesia, there are "mixed feelings about both issues, but there are also people who have no idea about the issues yet". In Malaysia, "there is some fear of globalisation". In *Japan,* the culture remains strong and well protected by an insular mentality and the language barrier. Most people would like to expand their options to select from the outside world without being overwhelmed by globalization or losing their cultural identity. Overall there were varied responses, for, against, or ambivalent, depending on how different sectors of each society see globalization affecting them. While everyone seems aware that it is a serious issue, non-Westerners do not seem to dismiss globalization pejoratively, such that they would shun educational opportunities from abroad made available through the internet.

Can you describe any debates within your society about other issues such as language, democratization, equalizing of opportunity, or resistance to change by governments? For *Latin America,* Mexican "people want democratization, justice, and the rule of law". In Argentina, "[p]eople are more worried about ordinary, daily issues, such as social, economic changes badly needed at the moment, and education is one of the crucial issues". In *Finland,* some issues are telecommuting, information overload, and Finnish versus English, but not to the extent of protesting current trends. In *Israel*, debates are on religion versus secularism, the Jewish-Arab conflict, right versus left political orientation, and Eastern-origin versus Western-origin cultures. In *Turkey*, some issues are geopolitics, human resources, cultural wealth, social sub-groups, or regions versus national priorities. In *Russia*, "[t]he government supports new technologies and methods in education, but there is a drastic lack of money. However, a centralized mentality and system of education makes educators wait for governmental funding." In *South Asia*, "[t]he Government of India is promoting infotech growth . . . The State is promoting internet kiosks in rural areas to promote education." In *Africa*, one issue is language, such as in broadcasting . . . English is the main language of communications (among 11 languages in South Africa). Government control versus freedom of speech is also at issue. "Transformation, democratization, accessibility, equity, and gender sensitivity are the concepts now in vogue in societies here and common also in educational institutions." For *Southeast Asia*, "Most Filipinos know that the only way to bridge the gap between rich and poor or to equalize opportunity is through education. Most families strive to send their children to higher education, which is why about 95% of Filipinos are literate. However, even after a proper education they suffer from unemployment because there are no job opportunities in the country, which is why they usually resort to working abroad . . . The government is not resistant to changes; it is just taking all these challenges in a step-by-step manner." In Indonesia, some issues are "democratization, decentralization versus centralization, tolerance, and unity". Malaysia is a multiracial society with an urban–rural digital divide. "There has been a major debate on the government decision to reintroduce English medium instruction for some primary school subjects. The new policy reflected the realization that falling behind in English proficiency could prove to be a serious disadvantage in this ICT era." In *Japan*, there is a perennial tension between the attractions of the outside world and the unspoken prohibition against crossing over by being unlike other Japanese. Overall, language and democratization seem to be vital issues indeed, but rather than blame governments, the obstacles to a better life for citizens seem to be viewed more in economic terms.

Do leaders or the media see using the internet as heading towards positive outcomes for education, international, and intercultural relations, or not? For *Latin America*, no one replied in the negative, but progress is slow even in professional sectors. A Brazilian added that "E-mails are intensively used to spread news and sometimes also to send suggestions to politicians." In *Finland*, the internet itself is well covered, but representative educational issues arousing interest are not VLE pedagogy but rather news about hackers, university costs, and "children's use of computer games (are they good or do they make children passive?)". In *Israel*, *South*, and *Southeast Asia*, it was an unequivocal "Yes." In *Russia* and *Africa*, the public and educators want to use the internet but funding and access are limited. For *Africa*, the answers were positive, yet even in South Africa "a lot of money seems to be allocated to help solve the situation, but I do not notice a vast improvement in South African educational resources output or the improvement in access or training of teachers". In *Japan*, the educational potential of the Net is not widely recognized, and there is some protectionism precisely because Westerners are more advanced in online education. In media and governments worldwide, there do not seem to be significant Luddite or atavistic trends against technological advancement. The perceived problem is rather the expense, yet there may be some unspoken difficulties as the internet to some extent allows users to go beyond the nationalistic ideologies and control mechanisms that empower their leaders.

Are there virtual universities or other virtual schools? For *Latin America*, it was yes with two examples given for Brazil (hereinafter cf. the Appendix for names and Web URLs). But two of the four respondents did not seem to know. In *Finland*, it was yes with an example. For *Israel*, specifics were not cited, just the general embrace of e-learning. Israel's Open University was introduced earlier. In *Turkey*, "There aren't any virtual universities. Only some universities use virtual education for some courses." Then quite a number of ambitious projects were listed. In *Russia*, there are very large-scale DE projects involving the web as well as video-on-demand lectures, but entirely virtual universities were not mentioned. Similar to Turkey and Russia, in *South Asia* several virtual campuses of major universities were cited. For *Africa,* in South Africa, which is not representative of the rest of Sub-Saharan Africa, it was yes, with just one private institution cited. Actually, the Kenyan respondent is associated with the African Virtual University, so it may have gone without saying beyond "Yes." For *Southeast Asia*, in the Philippines they exist but are not popular. For Indonesia, the informant wrote "No". For Malaysia, it was "Yes" and an example was cited. Moreover, "most public universities have incorporated elements of virtual learning to complement the traditional face-to-face classroom". Later in this chapter, there are more details on Southeast Asia. In *Japan*, the established universities can now have virtual programs covering up to half their credits, but there are not yet any wholly virtual universities that are accredited. Overall, it seems much more common for established universities to branch into online programs. If the informants are not cognizant of virtual universities that do exist, then they have not yet made much impact. The following question elicited more details.

If so, are they accredited or recognized, or considered notorious? For *Latin America*, a virtual university based at the Technical University of Monterrey in Mexico was cited, which may render one-sided another response from Mexico pointing to notoriety, *viz*., "they are not recognized; they give their own degrees". For Brazil, it was just written that "[t]hey work together with private high schools". There were no responses for Finland, Israel, or Turkey recorded. For *Russia*, "The problem of recognition is understood and there are well defined quality criteria for distance education." In *South Asia,* "many are accepted and recognised by suitable authorities". Some Indian institutions are formally recognized internationally with branches abroad. For *Africa*, in Kenya they are "[h]ighly recognized". In South Africa, "[t]hey are accredited with our accreditation authority . . . and some of the courses have international accreditation". But elsewhere in the same region there has been a perceived "infiltration of such virtual institutions from America and Australia, [which] have become issues of Cabinet debates in Parliament as to whether or not to recognize them". For *Southeast Asia*, in the Philippines, "[t]hey are not yet accredited. The Commission on Higher Education is planning to come up with an evaluation instrument intended for ODL [Open and Distance Learning] institutions, [not yet encompassing] totally virtual universities." In Malaysia, they are "[a]ccredited by the National Accreditation Board". In *Japan*, since wholly virtual programs are not accredited, for-profit online programs could be considered notorious to hunt for customers in Japan. But if accredited domestic universities provide online programs, they are recognized. Overall, the trend seems to be toward educational reforms recognizing virtual universities, especially as they emanate from established institutions. Rather than stemming from pre-judgments about virtuality or distance from the instructor, notoriety, like recognition, has to be earned.

Have many people considered studying at institutions in other countries through the internet? For *Latin America*, there was just one response: "No, language and costs are a barrier." For *Israel*, "Yes, and quite a few get degrees through distance learning (not necessarily through the internet)." For *Russia*, "Not so many, because Russian salaries are . . . 5–20 times lower than the salary for an equivalent job in developed countries. For many students not only knowledge, but also a formal diploma is of great importance. Free education online cannot provide a solid diploma, but to receive a foreign diploma one must spend a huge sum of money when compared with the average salary. And the language barrier is also a serious obstacle." For *India*, "Yes, for some online certificate courses like those for corporations like Microsoft and Oracle, but not yet for traditional courses." For *Africa*, in Kenya: "Not many, but there is a gradual increase in interest." In South Africa, "Yes, I am currently helping some students with courses from an Australian online institution." In the Southern African region, "not many people even in institutions of higher learning have sufficient provision of computers on their campuses while it may be a mirage for individuals to have personal computers at home with internet connectivity". For *Southeast Asia*, in the Philippines: "Yes, however it is so expensive." For Indonesia, the answer was just "Yes". In Malaysia, "There is still some hesitation in this area, but foreign universities with online distance learning programmes have recorded the participation of Malaysian students." In Japan, there have been advertisements in national publications especially for online MBAs that some working people would consider as an alternative to studying abroad.

Are there many local companies going into the e-learning business? For *Latin America* overall, “Yes”. In Mexico, “There are few, and we are one of them.” In Argentina, “Business companies may be more aware of the advantages of the web. There is a bit of a movement for English language acquisition due to the need for English for job applications, living abroad, and computer literacy.” In Brazil, “Yes, several, including IBM.” In *Finland*, “There are some.” In *Israel*, “Not [many].” In *Turkey*, “Many companies are going into the e-learning business.” A nationwide-scale example was cited. In *Russia*, “There are some, primarily dealers of foreign software companies, that advertise online education technologies.” For *South Asia*, “Yes.” A nationwide example was cited for India. For *Africa*, in Kenya: “Yes”. In South Africa, “Yes, but they are quite expensive and not all that user friendly.” In Lesotho, the informant did not know of any. For Southeast Asia, in the Philippines: “Only a few.” In Indonesia, “Yes”. In Malaysia, “Yes for multi-national corporations mainly, for whom e-Learning businesses span from primary education to university and even professional courses. But the 70% of the workforce in small to medium enterprises lacks the capital and expertise to invest in e-learning training solutions.” In *Japan*, yes, the big electronics companies and some entrepreneurs are trying to precipitate a market for e-learning.

Are there academic associations working on the professional development of online educators? For *Latin America*, “Yes, there are regional and national associations.” Yet in *Mexico*, “Mostly this work is done within each institution.” In *Brazil*, “Yes”, there is a national DE association. In *Finland*, “Yes . . . there is a national ICT Teacher Training Project.” For *South Asia*, “Yes, such as the Indian Association for Online Education.” For *Africa,* two responses from the southern region indicated that there are few online educators and hence few if any associations. For *Southeast Asia*, in Indonesia: “Yes”. Online educators in Malaysia “remain affiliated to academic associations related to their respective disciplines”. In *Japan*, educational organizations concerned with distance learning or computer-assisted language learning have changed their agendas with the advent of the Net.

Is the infrastructure for web access an obstacle for most people or not? For *Latin America*, “Basic literacy, infrastructure, communication costs, and computer literacy are obstacles for the population.” In Mexico, “Yes, because in Mexico only 3.36% of the population have access to the internet, but this number is growing.” In Brazil, “Yes, at our federal university, students have free access to only 8 computers.” For *Finland*, “In a very few cases; usually not.” For *Israel*, “For some, but not for most.” For *Turkey*, “the infrastructure for web access for most people is not enough”. Most users go to cyber cafes. For *Russia*, “In big cities access is affordable, but rather expensive for regular use in distance education.” For *South Asia*, “Yes, outside of institutions, slow telephone lines hinder web access.” For *Africa*, in *Kenya*: “It is an obstacle considering the fee levied which is generally not affordable to many people.” In Southern Africa, “Emphatically yes.” For *Southeast Asia,* in Indonesia:

“Yes, it is an obstacle, but also computer literacy.” In Malaysia: “Sadly, this is true.” In Japan, no, access is hardly an issue anymore. Computers, mobile phones, PDAs, game consoles, and an increasing number of appliances are becoming Net-enabled.

What are the main obstacles to acceptance or use of the internet for education? For *Latin America*, “Access is number one.” In Mexico, “Training, independent learning skills, and cultural perceptions.” In Argentina, “computers have become a luxurious tool at the moment”, yet e-mail use is rapidly increasing. In Brazil, “Access. Many of our students come from humble families.” In *Finland*, “Lack of knowledge about technological possibilities for helping learning.” In *Israel*, “lack of time, partial replacement of [existing] teaching/learning processes, [and] costs.” In *Russia*, “Low quality of telephone communications and high price for internet access when compared with the average salary level.” In *South Asia*, “Ignorance!” For Africa, in *Kenya*: “The cost of equipment, its maintenance and servicing.” In *South Africa*, “Access costs, infrastructure, poverty, and ignorance of what the internet has to offer for education.” In the Southern African region, “Dearth of infrastructure, financial problems, scarcity of telephone lines, and inadequate supply of electricity to many houses, districts, and villages where people live or work.” For *Southeast Asia*, in the Philippines: “The internet is already being used, but expensive infrastructure and all the equipment needed is an obstacle.” In Indonesia, “Computer literacy and computer culture, privacy of information and information rights, and ownership.” In Malaysia, “Cost of access and infrastructure.” In *Japan*, to change the status quo is usually difficult, and there needs to be much more awareness by the general public of the opportunities for education and self-improvement made possible by the internet.

Are there any other global or local issues that affect the acceptance of online education or the use of VLEs in your region or country? In *Latin America*, “Communication costs are very high[,] technology is more expensive than in the United States, and much of it is obsolete.” In Brazil, “The government intended to connect all public high schools by computer, but the funds were redirected to the electric company to prevent blackouts.” In *Finland*, “Commercial education is not an option, so the fear of having payments for the courses could be one issue. Another is that virtual learning takes time from other traditional learning activities, so there are worries about the quality of the content.” In *Israel*, “the academic culture”. In *Russia*, “There are strict traditions in the educational system and opposition of old teachers to new technologies. Computer classrooms in many schools have obsolete equipment, such as old PCs without internet access. There is also a lack of interest in short online courses or events, which have not yet proven their effectiveness in Russia. An exception is online courses to receive professional certificates from foreign companies, such as Microsoft. [Furthermore], there are difficulties in organizing a complete distance educational system granting professional diplomas.” In *South Asia*, “awareness and access seem to be among the other reasons." For *Africa*, in Kenya: "Cultural tendencies and attitudes." In South Africa, "We currently have a severe food shortage in the region as well as high HIV/AIDS infection rates. Online education becomes a luxury . . . . Basic education itself is in crisis and very many schools do not even have electricity and books." For the Southern African region, "Ignorance, low level of awareness, apathy, and insufficient funds." For *Southeast Asia*, in the Philippines: "Older people are unable to use it and are very resistant to . . . ICT. They argue that nothing can really equal the value of face-to-face instruction, and that a personal human touch better encourages study, whereas the younger generation is embracing the challenges and maximizing the use of ICT." In Indonesia, "National issues: infrastructure is expensive, therefore access is low and difficult, while the users are computer illiterate, and technical expertise is rare." In Malaysia, "The major challenge would be having enough quality online educators who can develop good online courses that offer the kind of support that Asian students look for." In *Japan*, mental attitudes in a traditional culture with elaborate face-to-face rituals raise many barriers. Yet, the internet allows Japanese people to browse world cultures from a safe distance and to consider becoming more involved in the outside world.

3. DISCUSSION OF THE OVERALL RESULTS

Factors such as the state of VLE use for education, internet infrastructure, access, and involvement of companies are closely correlated with the level of economic development of the countries reported. It can be inferred from that correlation that countries will proceed into educational and other uses of the internet insofar as they can afford to do so. On the one hand, fully developed countries like Finland and Israel are at a state-of-the-art level by all indicators surveyed. Whereas, countries like India and Russia are keen to do the same but lack the national budget to spread these opportunities to their large populations. There is no sign of a deliberate elitism to restrict wider access. From Mexico to South America, wide sectors of chronic poverty and limited infrastructure make online education a luxury that many cannot afford to discover. Much more so in Africa, more pressing public problems must be dealt with, lest awareness of what people are missing breeds further discontent.

Next to economic factors, cultural attitudes tend to determine which opportunities are embraced or avoided. Japan is fully advanced economically and in the internet infrastructure to use VLEs, but does not compare with Finland in realizing the possibilities of online education. India has meager resources but reaches out internationally, taking advantage of English-medium education, whereas Japanese people are largely content to insulate themselves in their culture and language. Cultural attitudes also extend to gender roles, yet the results were mixed. Besides a widespread tendency for women to shy away from mechanical and technical things, or to be denied access to such education, they also may either have more free time than men or else be heavily represented in the teaching profession where they encounter opportunities for online educator development. India and Malaysia reported what points to a global issue, a city-country gap or digital divide within countries.

Then there are more nuanced issues like globalization, where individuals in each culture can take up the pros and cons and arrive at different conclusions—or ambivalence. Generally, people would like to expand their horizons but without incurring a threat to their cultural identity or acceptance by their peers. There was no sign in the responses that any sectors of societies would decline the opportunity to use the internet if it were accessible and affordable. Similarly, globalization would probably be embraced in most developing countries if it were not accompanied by a perceived exploitation that widens the gap between rich and poor. In the context of online education, it is vital that DE providers deliver the concrete benefits they promise in terms of valuable information and marketable skills, so that learners' life prospects are improved. Fast-buck operations claiming to provide knowledge, in effect from the high-tech center of world civilization to the benighted low-tech periphery, without intercultural sensitivity and due respect, can rapidly sully the frontier of global education. Whether globalization is good or bad then depends on the fruits of global initiatives, but the uncertain outcomes at this stage may account for much reported ambivalence about globalization.

Furthermore, there are local issues reflecting the circumstances in different regions and cultures that result in unique debates or variations in adopting global phenomena such as the internet. Systems of accreditation affect the development of virtual universities, and whether courses taken over the Net from other countries are recognized or marginalized. Where there tends to be suspicion about the outside world, as reported from Russia, Malaysia, and Japan, the sensitivity is liable to be greater toward bogus educational enterprises, viewing them as representative and confirming doubts rather than as the aberrations that they are. Then, language barriers loom large in many countries where English is a foreign language, compounding other barriers, making it difficult to discern spam and so forth, which reinforces distrust of strangers. While it is not surprising that literacy presents a vast barrier to internet-based education, it may be surprising the extent to which communication costs are inversely related to income, more expensive in the developing countries, which exacerbates the global digital divide.

Thanks to the representatives of countries at various stages of development, fruitful comparisons could be made and patterns discerned. An overall conclusion is that online education can represent a positive form of globalization welcomed in most of the world, provided it is not technologically or economically but rather pedagogically driven. Academic standards and ethics provide the foundation for a new professional discipline of online education.

3.1. Representative Global Issues and International Initiatives

3.1.1. Potential Role of Universities in Global Online Education

Global issues in online education include culture, gender, language, access (-ibility), generation gaps in comfort with computers, differences in wealth or the global digital divide, and so on. The challenge is not so much to find the issues but to envision where to start, how to sort, and prioritize the issues impacting on and resulting from global online education. Some priorities of the co-authors can be seen in the questions and issues raised in this chapter. Parker Rossman takes the approach that universities are the key to mobilizing ideas and resources to work on global issues particularly by helping the developing world. He has thus made freely available a continually revised online book on the future of higher education. Due to the format, chapters are cited rather than page numbers, and it is recommended that readers access the whole online book through the URL provided in the references. The following passages from near the beginning of the online book frame the issues, highlighting priority global issues and approaches worthy of commitment at the interface of higher education, and online learning:

> If some new kind of global lifelong education structure is coming into existence it is propelled not only by the new opportunities provided by communications technology, but also by the desperate needs of underdeveloped areas for better research, political action, and education (Rossman, 2002, Preface). [However,] the shape of the global virtual lifelong university may be determined or strait-jacketed by global non-education forces such as business, technological developments, and pressing government priorities.

The necessity of lifelong education has become axiomatic among Western educators, but here that goal is extended in a challenging way to the whole world. Another range of global issues is alluded to as well, non-pedagogical imperatives that tend to make educational reforms more difficult.

> Quality also requires that higher education should be characterized by its international dimension: exchange of knowledge, interactive networking, mobility of teachers and students, and international research projects, while taking into account the national cultural values and circumstances (*ibid*.). Who but the universities can keep humanity from being swamped and cynically disillusioned with inadequate solutions to social problems such as the population explosion? Soon half of the world's population is going to be under age 20, and already there are a billion young people who ought to have higher education, but who can never reside on a campus or commute to one. (*ibid*., Vol. 1–01)

Here, Rossman provides universities with an inspiring incentive to get involved with education for the less fortunate. The quality and universality of universities will be reflected in how they take up such challenges for social relevance and leadership in and beyond their local communities. Many of those whose volunteer work is presented in this chapter, moreover, have not just waited for grant money but have leveraged institutional resources for immediate results. Provided such individual efforts are organized on a much larger scale, universities do have the residual resources to have a great impact if they make helping international society an explicit part of their mission.

> Tens of millions of people are already participating in distance education, open universities, and other electronic learning networks. As such programs expand globally, sharing of information and courses can be a much more affordable form of aid to the Third World. Indeed, World Bank consultations at the turn of the century have proposed that "education for all"—made possible by the internet—may be humanity's best chance to end poverty. (*ibid.*, Preface)

Besides the great potential of universities, international organizations such as the World Bank and UNESCO could be more effective as their clientele goes online. Besides their own overhead including already-privileged personnel and consultants, their programs to reduce poverty tend to be very expensive, e.g., utilizing videoconferencing by dedicated satellites. The same money could go much further with online education *via* the internet. Educators themselves tend to be willing to share course contents and more if they do not have to travel to various countries each time to do so, but rather by wedding an open source learning approach to online educational technology skills.

> The August 2000 UNESCO COURIER reported on the highly successful Village Internet program in Bangladesh, one of the world's poorest countries. It was bringing the internet into every rural village, creating jobs, providing new product marketing opportunities, giving access to health care, creating a computer literate younger generation in rural areas and providing access to global distance education. Note also the USA Leland Initiative for Africa, and an exploding number of other such projects. It was in 2000 predicted at M.I.T. that within five years a half billion people in the developing world would be using the internet. (*ibid.*, Vol. 1–01)
>
> Skeptics say that most Africans will not have such interactive technology for decades. John Perry Barlow (1998), however, provided evidence that they may leap ahead of developed countries. Women of Africa already show signs that they will move more quickly into wireless space, one of many unexpected surprises ahead for those of us who use wires and cables to connect. (*ibid.*)

Here, Rossman shows that some international initiatives are already working and growing in potential as more and more world citizens go online. In the above instance of African women, though it may upset the current social order based on longtime cultural practices, the empowerment of women is considered a universal value that can enhance human resource development beyond present expectations.

> UNESCO's global higher education vision included: Equity of access with no discrimination on grounds of race, gender, language or religion, or economic, cultural or social distinctions, or physical disabilities in partnership with all levels of education, starting with early childhood and primary education and continuing through life; in active partnership with parents, schools, students, socio-economic groups and communities; should also enhance the participation of women. Higher education, the UNESCO declaration said, should "reinforce its role of service to society, especially its activities aimed at eliminating poverty, intolerance, violence, illiteracy, hunger, environmental degradation and disease, mainly through an interdisciplinary and transdisciplinary approach in the analysis of problems and issues. Ultimately, higher education should aim at the creation of a new society—non-violent and non-exploitative—consisting of highly cultivated, motivated and integrated individuals, inspired by love for humanity and guided by wisdom." (*ibid.*, Preface)

UNESCO's vision comprehensively lists global educational issues, and a further challenge would be to apply online education toward each of the above goals. The last citation from Rossman below points to such a synthesis and presents educators with a challenging horizon:

> The rapid breakthroughs in new information and communication technologies will further change the way knowledge is developed, acquired and delivered. Engaging in networks, technology transfer, capacity-building; developing teaching materials and sharing experience of their application in teaching, training and research, making knowledge accessible to all; UNESCO urges: "creating new learning environments, ranging from distance education facilities to complete virtual higher education institutions and systems, based on regional, continental or global networks, functioning in a way that respects cultural and social identities. The principle of solidarity and true partnership amongst higher education institutions worldwide is crucial for education and training in all fields that encourage an understanding of global issues, the role of democratic governance and skilled human resources in their resolution, and the need for living together with different cultures and values." (*ibid.*)

This chapter treats global and local issues interacting in educational institutions and societies around the world. Online education is by no means fully realized yet globally, but current promising trends point in that direction. Even so, global online education is not an inevitable outcome that everyone can wait passively to enjoy. Knowing the enormity of the task of making it happen or just hastening the trend, this section examines what it is like in practical terms to work toward global online education.

The "trend" aspect points to various forces combining so that most humans at least have the option of connecting to the global internet infrastructure for learning. One huge organization for this purpose may not be as effective in galvanizing individual efforts as specialized teams contributing their resources and co-operating in a division of labor. Many groups like to be the umbrella organization but not to be subsumed under another's umbrella. In the experience of the WAOE (www.waoe.org), an organization can play a unique role if it is neither too new and diminutive to be effective nor too large and established to be unfettered by bureaucracy and the slow pace of paper-based traditions. Yet to bring about global online education, stakeholders from all sectors of society in many countries must agree to align their forces in such areas as technical expertise, funding priorities, and ethical standards.

The GUS illustrates many of these factors and challenges. GUS was founded by one of the first non-Westerners to use ICTs. Takeshi Utsumi, a Japanese engineer with lecturer privileges at Columbia University, early saw the internet as a path toward world peace, and his continual sacrifices to help other non-Westerners in developing countries have earned their trust.

Westerners have also contributed their time and expertise, such that UNESCO has recognized the GUS base at the University of Tampere in Finland among the universities in its UNITWIN program. Perhaps the first NGO to be so recognized, GUS could also be described as a meta-virtual university to incubate online education projects for local community development and global networking.

The most recent formulation of GUS is "Creating the Global University System", a chapter in a book aimed to coincide with the UNESCO Conference on Teaching and Learning for Intercultural Understanding, Human Rights, and a Culture of Peace, Jyväskylä, Finland, 15–18 June 2003. It takes a broader approach than just promoting educational technology:

> The Global University System (GUS) is a worldwide initiative to create a telecommunications infrastructure for access to educational resources across national and cultural boundaries for global peace. The GUS helps higher educational institutions in remote/rural areas of developing countries to deploy broadband internet in order for them to close the digital divide and act as the knowledge center of their community for the

> eradication of poverty and isolation. The GUS has task forces working in various regions of the globe with partnerships of higher education and healthcare institutions. Learners in these regions will be able to take their courses, *via* advanced broadband internet, from member institutions around the world to receive a GUS degree. These learners and their professors from participating institutions will form a global forum for exchange of ideas and information and for conducting collaborative research and development. The aim is to achieve "education and healthcare for all," anywhere, anytime and at any pace (Utsumi et al., 2003).
>
> The mission of GUS has three specific thrusts, to:
>
> - identify, test, and facilitate the deployment of broadband internet and related technologies that are affordable and accessible for underdeveloped areas of the world;
> - coordinate the delivery of content and rich educational experiences leading to a GUS degree;
> - provide a global infrastructure for collaboration among faculty, students, graduates, and policy makers in universities, healthcare institutions, corporations, and governments.
>
> GUS aims to help equip youngsters around the world to be competitive and to strive for excellence. GUS aims to prepare them for a world that seems to be changing from the industrial age where obedience predominated to a knowledge age where creativity and competence predominate. (*ibid.*)

An earlier (unpublished) draft for a mid-east conference had put it this way: "The mission of GUS is not the mere enhancement of job skills with e-learning, but the creation of youngsters aiming for world peace and the eradication of poverty and isolation through the use of advanced ICT in remote/rural areas around the world."

For decades Utsumi has expended substantial time and his own private funds to achieve a

> pioneering role in extending U.S. data communication networks to other countries, particularly to Japan, and deregulating Japanese telecommunication policies for the use of e-mail through ARPANET, Telenet and internet (thanks to help from the Late Commerce Secretary Malcolm Baldrige)—which is now called "closing the digital divide." This triggered the de-monopolization and privatization of Japanese telecommunications industries. This liberalization of the telecommunication industry has been emulated and has now created a more enabling environment for economic and social development in many other countries. (*ibid.*)

After Global Lecture Hall videoconferences around the world from 1986, an International Workshop and Conference on "Emerging Global Electronic Distance Learning" was held in August, 1999 at the University of Tampere, Finland: www.uta.fi/EGEDL.

> About 60 decision-makers and leaders in e-learning and telemedicine from 14 underserved countries brainstormed, and the workshop recommended the formation of the Global University System (GUS)™ with Global Broadband Internet (GBI). The group also formulated specific pilot projects focused on major regions of the world to reduce the growing digital divide between information-rich and information-poor populations, in order to realize education and healthcare for all, anywhere, anytime and at any pace. (*ibid.*)
>
> We can expect GUS to provide the following benefits to students and participating universities:
>
> - Broadband Internet will support sophisticated pedagogy *via* the World Wide Web.
> - Member universities can build a network of facilitators to support e-learners.
> - Learners may take courses from member universities and get their degree from the GUS, thus freeing them from being confined to one academic culture of a single university and country.
> - Learners and faculties can promote the exchange of ideas, information, knowledge, and joint research and development of web-based teaching materials.
> - Learners, faculties, and public policy makers can promote community development and many other advances locally, regionally, and even on a global scale.
> - Researchers in developing countries can partner with colleagues in advanced countries to perform joint collaborative research and development (*ibid.*).

The GUS illustrates the comprehensive vision, co-ordination of stakeholders, and fund-raising efforts necessary to hasten the advent of global online education. Utsumi describes one recent phase in the following electronic distribution list message:

> I then suggested to high echelons of the Japanese parliament and government to direct Japanese Official Development Assistance (ODA) funds for e-learning and e-healthcare to improve the image of Japan, whenever I have visited Japan in the past several years. Subsequently, I helped the Japanese government pledge US$15 billion to close the digital divide in developing countries during the Okinawa Summit in July of 2000. Mr. Koizumi, Prime Minister of Japan, made another pledge of

US$2 billion to aid education and healthcare in developing countries during the G8 Summit in Canada in June of 2002 and at the Environment Summit in Johannesburg, South Africa in September.

Our proposed Amazon project is to combine the Japanese government's ODA funds and electronic equipment (computers, transceivers, dish antennas, etc.) from Japan with the internet technology and content development of North America to help underserved people in rural and remote areas of developing countries. The Global University System (GUS) will follow this approach in other developing countries around the world in the future (Utsumi, 2002).

Progress of GUS projects and daily correspondence can be accessed from the home page: www.friends-partners.org/utsumi/.

3.2. Cultural and Regional Reports on the State of Online Education

3.2.1. An Islamic Perspective on Virtual Education

To seek knowledge is a sacred duty, obligatory for every Muslim, male or female. The first word revealed of the Quran was "*Iqra*" READ! Seek knowledge! Educate yourselves! Be educated! This should say a lot for the importance of education in Islam; and online learning will certainly make education more accessible.

The WWW has made it possible for organizations big and small to spread Islamic education. There are many non-formal educational sites such as Islam Online that provide comprehensive Islamic education in the form of practical guides to living and learning Islam: www.islamonline.net/English/index.shtml. Many institutions in the Western world do offer formal and non-formal online courses on various aspects of Islam. As one such example, Technology-Assisted Lifelong Learning (TALL) of Oxford University's Department for Continuing Education has students who now live in Indonesia, Iran, Pakistan, and other countries where a large majority are Muslims.

In Malaysia, the International Islamic University of Malaysia (IIUM) was one of the early adopters of online learning: www.iiu.edu.my. Some of its distance learning programs have been made available online: www.iiu.edu.my/c-excel/index.htm. The Arab Academy based in Egypt, with partners in the United States, which claims to be the world's first and only professional online site for learning Arabic as a foreign language, has students from Muslim countries including Malaysia, Turkey, Pakistan, Indonesia, Kuwait, Bangladesh, Iran, Qatar, Oman, Palestine, Bahrain, Yemen, Libya, and several others: www.arabacademy.com/about_e.htm. This does show that the Muslim world is embracing online education quite readily.

In Southeast Asia, however, Islam cannot be considered as an engine for virtual education. Education in this part of the world is very tightly controlled by the respective governments, and in Malaysia for instance, any initiative on Islamic education has to adhere to strict government guidelines. Yet while Malaysia and Indonesia have predominantly Muslim populations, these countries have been quite aggressive in getting online to cyberspace to promote education in general. For details see the section on Southeast Asia later in this chapter. There has been no recorded opposition to virtual education in the Islamic world; in fact, the WWW has given a voice to Muslims who wish to express or spread their views to contest the blanket views of the mass media.

4. ONLINE EDUCATION IN THE FORMER USSR

4.1. Leading Distance Learning Developments in Russia

DE programs of typical Russian institutes are a mixture of mailing print and CD educational materials with face-to-face exams at local affiliates of the institutes. So they do not use online methods widely, but in their advertizements the online methods are starting to be mentioned.

Nevertheless, the Russian Ministry of Higher Education has stimulated an experiment in DE development with the participation of about 15 educational institutions. A report about this experiment (in Russian) published in 2001 shows that DE in Russia is quickly developing and the most active institutions are world class.

Among other institutions, two leaders in DE stand out:

– The Moscow State University of Economics, Statistics, and Informatics (MESI) has been prominent for more than 70 years and now is quickly developing its distance educational network all over Russia. MESI http://www.mesi.ru/eng/index.asp has more than 56,000 students learning through distance technologies. Through 150 affiliates in different educational institutions of Russia and the former Soviet Union, this institute spreads its educational technologies, thus promoting DE in governmental institutions in this region.
– The Modern University for the Humanities (MUH) is a non-governmental institution that bases its educational technologies primarily on video and computer technologies, with satellite transmissions of educational programs to 180 affiliates spread all over Russia and the former Soviet Union, appearing even in European countries. MUH has more than 110,000 students involved in DE.

The students of MUH (www.muh.ru) (in Russian) even on its main campus work through the same standardized computer and video technologies as the students in affiliates. Their approach is to work out the best educational technologies for the whole university system and to test them immediately. MUH has a number of scientific institutes working on the psychological issues and methods of DE, working on perfecting their video courses, their computer courses, and their methods of educational quality control. MUH attracts for its courses the leading professors in Moscow and elsewhere in Russia, then records their courses on video and computer memories.

The MUH dispatches its own team of long-distance representatives who facilitate satellite courses in remote regions of our planet. The well-known Russian adventurer Fedor Konioukhov performs his educational experiments while sailing or rowing alone across the seas (Konioukhov, 1999), riding a camel caravan along the old Great Silk Road (Konioukhov, 2002), or with a dog sled team along the Arctic Circle. These experiments help psychologists in selecting the best educational methods. The expeditions attract the attention of local people to the MUH distance educational technologies, thus promoting new affiliates to open in remote regions.

The MUH has its own-patented system of computer testing. They produce more than 500 educational video courses annually. The students also record their coursework on videotapes, and then upper class students evaluate the quality of these works. This institution, concentrating on distance educational technologies, spreads its programs through satellite receiving centers in affiliates and delivers the courses to students with the help of certified tutors in affiliates.

4.2. The International Virtual University Project

Moscow State Institute of Business Administration (MSIBA) is working on a project to create the International Virtual University. The impetus of this innovation includes the following factors:

– expectations of an institute with very competitive admissions;
– limits of existing buildings to expand educational activities;
– the necessity to foster modern economic and business knowledge and skills among Russian students more rapidly through the internet;
– the need for a way to make it possible for very busy entrepreneurs and business persons to improve their economics and business knowledge and skills through a hybrid system of education, joining together face-to-face interaction with computerized self-learning.

Here in a prominent educational institution, online learning may be affordable both for highly motivated students and for successful business persons.

MSIBA presented at an online exhibition representing the region of the former Soviet Union (MSIBA GLD6 Gallery, 2002). This participation was very motivational for the students involved, helping them to improve their computer and internet navigation skills, fluency in English, teamwork, and presentation techniques. Thus the students' involvement in international events though the internet is itself a powerful method of online education. After all, the student is not a vessel to be filled, but a torch to be lit.

4.3. Further Initiatives of the MSIBA

The MSIBA campus in the Moscow suburb of Zelenograd plans to create an affiliate in central Moscow to exchange lessons with high-quality professors, connecting *via* the Moscow fiber optic network. Currently, there is a 24-hour telephone connection to the internet and e-mail. This connection is good for a limited number of users, but for three full classes to work in the internet simultaneously is sometimes stifling. In time to launch the Virtual University in 2003, a broadband connection to the fiber optic net is desired. Currently, there are about 50 Pentium-2 and around 50 486 personal computers (PCs) connected in a local area network with phone modem access to the internet.

The level of business information skills of graduates meets Russian business sphere requirements. Some graduates are involved in e-trade projects; some in the computerization of banks; others in publishing, advertizing, or consultation businesses; and yet others in the computerization of management systems at manufacturing or trading companies.

More than half of the students have home computers that are better than those at the Institute. Many upper class students have part-time jobs at enterprises where they have access to business computer technologies. Orientation of students to features of computer technologies in business offices need not exceed 2 days.

Moscow Mayor Yury Luzhkov commissioned MSIBA to create a DE system for Russian speaking students from the states of the former USSR, hence the internet-based International Virtual University. This writer (Boris Sedunov) as manager of the project sees the Institute as a laboratory to work out the methodology for a virtual university in its educational practice.

The Institute is ready to provide some distance courses with a special certificate for Western students who plan to work with Russia in the future, providing them with lessons on Russian culture, language, and business particulars. The Institute has experience in this respect, having been for some years a training base for United States Peace Corps volunteers.

The Institute has an evening department for adult students, who are very busy with their occupations. Some of them may prefer to study online or to use asynchronous online methods for a part of their courses.

MSIBA also plans to create an International Business School jointly with a respected University abroad to grant MBA diplomas to its graduates. There is a great demand for MBA degrees among prominent business persons in

Russia, who want high-level business knowledge and skills (not an MBA degree from a diploma mill), joining together Western theory and Russian practice. Such co-operative education may benefit from distance educational technologies. Here MSIBA tutors, certified by the Western partner, would provide face-to-face communication with the graduate students while they have e-mail and internet consultations with the Western partner professors. The latter may come to Moscow from time to time for F2F exams, training, and certification of trainers.

A hybrid system is deemed best for a high-level business education at this stage of computer and communication technologies in Russia. Face-to-face interaction aims to provide active business and communication training and business simulations to students. Some business lessons, training, and gaming may be performed in online versions, but not all. For example, to train conversational skills in foreign languages, video and audio tape recorders, and listening to the radio still seem more effective than by computer. By computer-based methods, including online education, a controlled self-study of routine aspects of business education can be provided. For such purposes, having lessons and tests on CD-ROMs along with consultations at a distance by e-mail and so forth seems suitable. For a philosophy of management and business education, predicting its future development (see Sedunov, n.d.).

About 30 former MSIBA students have gone to Japan to finish their studies at Niigata University of Commerce (Sangyo). They wish to receive an MSIBA diploma as well. At such a distance only the use of DE technologies can help them finish their studies. They can take F2F exams once a year in Zelenograd when they visit their families. In October 2002, an MSIBA delegation visited Niigata for a conference presentation and to work out a scheme for this DE system (cf. Kostina et al., 2002).

4.4. Analysis of the Market for Online Education

Considering online education development in different countries and in different social strata, an approach should be based on some methodological principles. Proposed here is the positioning of a student in a “knowledge—diploma” diagram. Another principle is positioning a student in a “motivation—resources” diagram. And a third principle is investigating online education accessibility in terms of a “cost of learning-to-revenue” ratio.

4.5. A “Knowledge—Diploma” Diagram

Here, a distribution of students in a two-dimensional diagram is considered, one axis representing the desire to obtain new knowledge and skills, and another axis indicating the desire to obtain a new diploma or certificate.

"Knowledge–Diploma" Diagram	**Degree of Desire to Obtain a New Diploma or Certificate**	
Degree of desire to obtain new knowledge and skills	Low	High
High	Students possess a solid position in their families or workplaces	Students see that both knowledge and a diploma are needed
Low	Students study under family pressure	Students believe in the magic of a diploma for their future life

In this system of classification, the students of typical primary and middle schools fall mainly in the lower left square. It is difficult to hope that they will be interested in online learning that requires a high degree of self-motivation. For them it does not make much difference to what type a system of education belongs. Only a small amount of children from these schools possess their own desire to obtain new knowledge or a certificate.

Students of professional education in the lower-right corner do not bother about self-education. Their main problem is to spend 4–5 years until they receive their desired diploma. They may be clients of different forms of DE that do not require their own efforts to obtain new knowledge and skills. So, online learning is not for them either.

Students in the upper-right corner may be interested in online learning if these courses provide valuable certificates for the job market and if they can afford the fee level for this type of learning. In general, they are not from prosperous families and do not make such money as would cover expenses for online learning.

Students most interested in online education would be in the category of the upper-left square. These students do not bother about diplomas or certificates; they have great self-motivation to acquire new knowledge and skills. For them, short online courses bring the most satisfaction, if they can provide needed knowledge and skills. In this category fall talented children, wives from prosperous families free from work and school graduates at modern companies whose work has shown them a urgent need for wider knowledge and improved skills.

In the territory of the former USSR, this category is not as populous as in economically developed countries. There are not so many prosperous families, and sophisticated, successful companies are not very many. So, the social base for online learning in this territory is not developed enough.

4.6. A “Motivation—Resources” Diagram

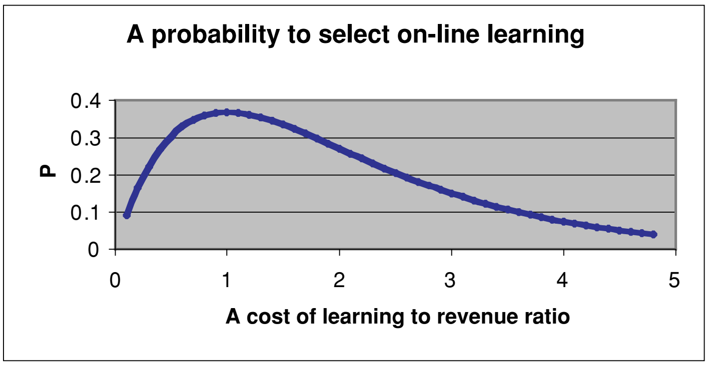
“Motivation—Resources” Diagram	Degree of Financial and Time Resources	
Degree of Motivation for Self-learning	Low	High
High	Students possess a great motivation to overcome poverty	Students can use their family’s resources for their education
Low	Students from poor families study under family pressure	Students expect family support for their future life

In this system of classification, the students from lower squares cannot readily be clients of an online system of education that requires a high degree of self-motivation.

Students in the upper-left corner might wish to take online courses, but do not have the resources to cover such expenses.

Students in upper-right corner would be the most interested in online learning. They are from prosperous families, but such families are not so numerous in the territory under consideration.

4.7. Dependence of Online Education Access on A “Cost of Learning-To-Revenue”: Ratio



If we take the cost of learning-to-revenue ratio in the United States as a unit, then in the former USSR countries, this ratio exceeds five. A simple mathematical model shows that in these conditions the probability to pay for education falls drastically. So, what seems to a citizen of a developed country as a natural process—to buy courses, for citizens of the former Soviet Union becomes impossible.

The main factors influencing this ratio are

– the cost of internet access being almost the same in developed and undeveloped countries; and
– the average salary level in less developed countries being 5–20 times lower than in developed ones.

The situation cannot be redeemed by the fact that the instructors in less developed countries are paid less, because the price for internet access with unlimited time exceeds the anticipated increase in income. Even if the level of income in less developed countries is sufficient for e-mail communication or for internet access limited in time, for online learning a constant access to the internet is needed that is generally not affordable. This analysis following some specifics on online education in the region of the former USSR should help readers see the situation and future prospects realistically.

5. ONLINE EDUCATION IN INDIA AND THE SOUTH ASIAN REGION

5.1. Introduction

Online education has been one of the most significant happenings in Indian IT life. Online delivery of programs through the internet in India and its vicinity is fast emerging, opening new gates for knowledge dissemination to learners placed geographically in remote places. This "anytime anywhere" education has provided both an opportunity and a challenge for South Asian countries, especially to India, in creating a niche for itself in the huge market of offering online courseware. The onslaught of universities from the United States, the United Kingdom, and Europe has flooded these countries by providing accredited and non-accredited courses online. For example, Yale, Massachusetts Institute of Technology, Stanford, University of California, Los Angeles, the University of Wisconsin, Capella University, etc., offer good quality programs in different disciplines. Staying ahead in such a cutthroat environment has become a challenge, particularly with the impact of globalization, WTO initiatives, and the General Agreement on Trade in Services (GATS).

The higher education system in India has grown phenomenally and has witnessed great changes. At the time of Indian independence, there were only 19 universities and 700 colleges. Today, India has 13,150 colleges of different kind and nearly 250 universities. The number of students and teachers has also grown from about 1 million and 15,000 to over 88 millions and 4 millions, respectively. In spite of this massive system of higher education, a large segment of the population is not covered under educational services. A population explosion and financial constraints have put great stress on the traditional educational system. It was in the third Five Year Plan (1961–1966) that the proposal for establishing evening colleges and correspondence courses was proposed, and as a result a School of Correspondence Courses and Continuing Education was established in 1962 at Delhi University. After that, many conventional universities started programs through correspondence, but a thorough-going teaching and learning system was first initiated in 1982 with the establishment of the Andhra Pradesh Open University (now renamed the Dr. B. R. Ambedkar Open University) at Hyderabad (http://www.braou.ac.in/).

The most significant milestone in the history of Indian education was in 1985 when the Indian Parliament passed the Act for establishment of the Indira Gandhi National Open University (IGNOU). IGNOU (www.ignou.ac.in) has national jurisdiction and is at the apex in offering high-quality DE courses. As a result of the success of this system, the individual States followed suit and set up state open universities (OUs). Currently, there are 10 of them and 1 National Open University. In addition, there is a National Institute of Open Schooling (www.nos.org) to cater to secondary education, which offers academic and vocational courses all over the country.

5.2. The Beginning

Toward the end of 1990s, the educational system again observed a paradigm shift and ICT became the hub of services. It was this period when access to the internet increased and private ISPs entered the game.

To meet the challenges and to keep pace with emerging international standards for online course content, leading companies like Aptech and National Institute of Information Technology (NIIT) and educational institutions like IGNOU, Indian Institute of Management, etc., established their presence in the online learning space. The NIIT established its netvarsity.com as early as 1996 to offer completely online infotech-related modules, and adopted a "brick-and-portal learning" model. Very soon, zeelearn.com, classteacher.com, schoolcircle.com, egurucool.com, vidyainfo.com, and entranceguru.com and more followed the trend and became informational and e-learning portals. The NIIT has a 35% stake in classteacher.com and has also taken over egurucool.com. Intel-India has been providing free training to teachers on the use of computers. Such projects indicate that e-learning is being treated a major component of the educational sector.

The Government of India also took initiatives to provide its citizens world-class "on-click" education on demand, and thus a National Task Force on Information Technology (IT) and Software Development was constituted in May 1998 by the Prime Minister of India. The prime mission of this taskforce was to formulate a long-term Indian National IT Policy to develop India into an IT software superpower. According to an estimate by Skoch, an IT Consultancy and Strategy Firm, in revenues the Indian IT industry grew 19% in 2003 at U.S. $2 billion (Times of India, 2004). The firm further reported 21% growth of the IT industry in 2003 to log $16.4 billion in sales, of which

$3.6 billion pertained to hardware and $10.4 billion for software exports. The PC industry also grew 32% with 2.3 million units sold, including 87,499 notebooks, up to 78% largely because of introduction of sub- $1000 products. The recommendations of the Task Force were documented in the form of an "IT Action Plan: Long Term National IT Policy". Among other major recommendations, thought was given to IT-enabled education. The Policy states

viii. All Companies, in IT as well as other sectors, will be encouraged to set aside 6% of their value added revenue (sum of salaries, perquisites and net profit) to support the IT HRD [Human Resource Development] sector in offering IT as well as IT-enabled education through investment in infrastructure establishment/upgrading in educational/training institutes, providing endowments, catering to the recurring expenditures of the institute such as salaries/honoraria to faculty, scholarships to students, providing part-time instructors, etc. These companies will have full freedom to allocate such funds to any institution of their choice and to be utilized specifically in the manner desired by them.

ix. Government in association with IT HRD companies will aim to achieve 100% IT literacy at senior secondary level (10 + 2) in 5 years and at secondary level in 10 years.

ix. All institutes offering engineering education, including Polytechnics and ITIs [Industrial Training Institutes] will ensure that within 3 years all engineering students in the country will acquire IT knowledge to be able to serve in the IT-enabled Services sector besides serving in the IT industry directly (www.nasscom.org).

5.3. E-Learning Initiatives

In India, e-learning is being adopted in most institutions in different forms. Kumar (2004) reported that in the state of Kerala the textbooks where Malayalam or English is the medium of instruction are available online [www.keralaeducation.org or www.education.kerala.gov.in]. Even the Government has taken a decision to provide all textbooks for students of Class 10 on the internet from the academic year (2004–2005). These materials (in pdf) are offered free of cost provided they are used only for educational purposes. Kumar also expresses some concern for the private tuitions by teachers and note taking tendencies by the students, but is optimistic also as if e-learning comes of age in Kerala, then the students need not pay for private tuitions in addition to avoiding traveling long distances for going to classes.

Downloading reports, presentations, and documents for teaching and learning is the most common practice. Trends in IT development globally and within India are expected to be reflected in an expanding e-learning market. According to a market analysis of the American e-learning industry done by Brandon-hall.com, the e-learning market in the United States alone will grow to $212.9 billion in 2011 from the current $10.3 billion, as reported by Center of Education Technology (CET), CMC Ltd. (2002). Although there has been a global slowdown in the IT sector, its impact was much more visible in the United States (up to 44% according to an estimate by the CET, CMC). The Information Technology Association of America (ITAA) reported that 1 out of every 14 workers in the United States is in the IT sector and 1 in every 12 IT sector jobs remains vacant for want of skilled personnel.

India has always been one of the major sources of trained manpower to developed countries. The reasons include cheap labor, good English speaking skills, and hard-working nature of Indians. To cater to the requirements of IT industries abroad, organizations in India have taken some initiatives to establish training centers to produce trained manpower in the field of e-learning. The setting up of cmcvarsity.com by CMC, netvarsity.com by NIIT (www.niit.com), zeelearn.com by Zee Learning, zeeeducation.com/online by Zee TV's online training, learnatsatyam.com, the virtual campus initiative of ignou.ac.in, the Tamil Virtual University, The Birla Institute of Technology and Science (BITS), Pilani virtual university http://vu.bits-pilani.ac.in/, and gurukulonline.co.in by Gururkulonline Learning Solutions are some of the prominent examples indicating preparedness by Indian universities and IT industries to meet the growing demand. They offer degree programs or training courses in e-learning or multimedia, empowering personnel to handle e-learning technologies and methodologies. NASSCOM (2002) has also reported a significant growth in the IT and IT-enabled services sector, with an estimated $10 billion in annual e-commerce sales. But this figure is very low when compared with other Asian countries, e.g., China, the only country that exceeds India's population of a billion.

One of the reasons for the boom in online learning in India is the need for and emergence of anytime, anywhere learning. Owing to modern lifestyles and job requirements, people attempt to gain knowledge within their limited available time duration. There is a preference for specified learning in a specified time period. Learning at one's own pace whenever time is available is the main factor in the growth of online education. Indian soil has been found to be very fertile for the growth of online education. Although the state of online education in developed countries like the United States, Australia, and European countries is far better, certainly India stands out as a leader among Asian countries. In fact, India has become one of the largest producers of CBT and WBT (computer- and web-based training), and this has given rise to occupations in learning technologies, opportunities for instructional designers, web designers, technical writers, and educational subject matter experts. Owing to the high level of scientific and technical skills of Indian professionals, more than 25% of the world's custom software was Indian in 2002. Currently, Indian software professionals are employed by all major firms and most of the global giants have their presence in India. (Giovannetti et al. 2001, p. 99) reported that the Indian software industry is providing its services to nearly 40% of the Fortune 500 corporations.

Higher education institutions in India are also establishing paperless procedures. Universities like Hyderabad University, the University of Rajasthan, the Indian Institute of Science in Bangalore, the Variable Energy Cyclotron Centre in Kolkota, the Indian Institute of Technology in Chennai and Kanpur, the Inter-University Centre for Astronomy and Astrophysics in Pune, and the Orissa Computer Application Centre in Bhubaneshwar are among those selected as Education and Research Network (ERNET) components. This enables these universities to actively collaborate in international research projects, sharing the latest editions of research journals and databases.

In addition to local players, global leaders are also not far behind in their bid to provide e-learning technologies in India. For example, Mentergy Limited (NASDAQ: MNTE), which is a full service global e-learning company, in association with Hindustan Technologies Limited (a subsidiary of Skysat Holdings of Singapore) is providing the TrainNet interactive virtual classroom environment in India for video-based training *via* satellite delivery (www.usdla.org/html/journal/SEP01 _issue/techex05.html). Manipal Academy of Higher Education (MAHE) as their client offers IT training in India. Another instance is of Carnegie Mellon University's project of Virtual Centre for Technology Enhanced Learning (VCTEL) to provide better access to IT education with active support by the Government of India. VCTEL has been established to serve as an "information clearinghouse" for Indian educational institutions (Gerson, 2002).

Toward the end of the year 2000, a Virtual Learning Campus "learnatsatyam.com" was launched by Satyam Education Services Limited, a subsidiary of Satyam Infoway Limited (NASDAQ National Market: SIFY) to provide education and training to corporate employees and students on a par with the international community. Students can get in touch with virtual instructors or web gurus through the "Electronic Instructor-Led Training" system. Other features of this online endeavor include virtual field trips, message boards, real-life application sites, and a round-the-clock online reference facility from Element-K (www.elementk.com) in addition to journals and web resources.

Another emerging trend is the growth of the non-IT educational content market. According to International Data Corporation (IDC), of the worldwide demand, 72% was related to the IT segment, but by 2004 the non-IT content market will overshadow it. Online education has been found to transform learning, with local students undertaking global homework, for one thing. In addition to egurucool.com, NIIT's netvarsity.com, and onlinevarsity.com [www. onlinevarsity . com:81/ovc/ovdbhome.nsf/eIndex.ani?OpenFrameset], other dotcoms that provide online content to learners in ways including digital libraries and discussion forums are classteacher.com, studentsguild.com, brainvisa.com, and more. Online education is seen to have limitations as well. Collaboration among fellow students scattered geographically is provided for by educational technologies, but sometimes effective interaction does not occur between them. Another limitation seen in practice is the lack of tutor-learner contact. The most common method of such contact has been found to be through e-mail in the Indian online educational system, where sometimes a communication gap remains between what is communicated and what is understood. Cultural expectations have been shaped by the face-to-face classroom experience and good practices in online education exceed the interactivity of face-to-face classes, so the development of online pedagogy will be the key to overcoming such perceived limitations of the media.

Another obstacle in the growth of e-learning in India is the high prices of computers and the low penetration of the internet and even telephones. According to International Telecommunications Union (ITU) (2002) figures, the PC and the telephone penetration are very low in India.

Status of ICT in South Asian Countries

Parameter	India	Pakistan	Bangladesh	Sri Lanka	Maldives	Bhutan	Nepal	South Asia
Population (mid-2001) in millions	1033.4	141.5	133.4	19.6	0.28	0.83	23.6	1379.8
Adult Literacy (%)	58.0	44.1	42.0	91.9	96.9	—	42.9	55.5
Telephone main line per 1000 persons (2000)	32	22	4	41	91	20	12	27
Personal computer per 1000 persons	4.5	4.2	1.5	7.1	20.4	5.2	3.0	4.2
Internet Users (2000) in thousands in 2001	7000	133.9	100.0	121.5	6.0	1.5	50.0	5412.9

Sources: ITU and NASSCOM.

According to a Nielson Net report (August 2002), there were 553 million internet users worldwide with the United States topping the list with 166 million (30%), then Europe (24%), and Asia-Pacific (14%). India represented only 1% (5 million) of the global internet users. So India as a whole cannot be called a progressive state. Even after 7 years of internet development, there is only a 0.5% internet penetration rate in India with a population of 1 billion. High internet usage charges and unequal distribution of telephone networks are major factors in this stagnation. By 2002, there were 7 million mobile phone connections and 42 million landline connections in India. Internet usage charges in India are among the highest in the world, in the sense that users have to pay for both ISP charges and dial-up charges. Kumar (2002) reported that 20 hours of monthly Net access in India could be equivalent to 16.8% of the per-capita gross domestic product (GDP), as compared to 0.65% in the United States, 1.30% in Germany, 0.91% in the United Kingdom, 0.77% in Canada, and 0.12% in Sweden.

According to a survey conducted by eduempire.com in the city of Bangalore, Chennai, and Hyderabad, it was found that only 7% of school students had access to the internet on a regular basis. To reach this un-connected clientele, the entrepreneurs developed different models, e.g., provision of smart cards by eduempire.com to be used for e-commerce and development of e-books by connectschool.com (a venture of Mumbai-based Navneet Publications).

5.4. Social Impact of e-Initiatives

One of the digital revolutions in India from the field of online enterprises can be seen taking place in the lives of farmers in remote Indian villages. In such villages where lack of electricity and telephone lines are common, with very low literacy rates among the farmers, the dream of e-business has come through an initiative called “e-chaupal” undertaken by Indian Tobacco Company (ITC). “Chaupal” means “village gathering place” in Hindi. E-chaupal can be thought of as an Internet Kiosk, established at a place where villagers gather and discuss business and social issues. This experiment was designed by providing desktop computers powered by batteries charged with solar energy panels and through local telephone exchanges with upgraded equipment through ITC’s finances. The e-chaupal services have been found to be very effective, reaching more than a million farmers across 9000 villages in the states of Andhra Pradesh, Madhya Pradesh, Uttar Pradesh, and Karnataka. This initiative helped farmers to earn more at lower transaction costs by eliminating intermediaries and selling their products directly to the ITC. Other advantages of this initiative to the farmers were access to the latest information on crop prices, weather, and scientific farming practices. Although the plans are ambitious, starting modestly with a definite value proposition, there seem to be some bottlenecks to sustaining success such as unreliable networks, costs of telecommunication infrastructure, and limited IT experience of persons handling these e-chaupals.

E-learning has also been found to be an effective mode of bridging the digital divide in rural areas and smaller townships in states like Maharastra.

The Maharastra Industrial and Technical Consultancy Services (MITCON) initiated computer courses through e-learning with 530 centers in the interior locales of Maharastra. Learners can register themselves at any of their e-schools and access the course content either at these e-schools, a cybercafe of their convenience, or at home. Another MITCON experiment in e-learning is launching of e-vidya in the Marathi language in the Maharastra State, targeted to benefit more than 7500 students. They plan to extend this experiment, in the next phase, to Madhya Pradesh, Chattisgarh, and Gurjarat States. Gurukulonline Learning Solutions also offer courses through their e-schools. Srinivasan (2002) reported the launching of online DE in under- and post-graduate courses by the accredited university Sri Chandrasekharendra Saraswati Viswamahavidyalaya. Instructional material is to be provided online and through a cable TV network (2 or 3 days a week) in addition to sending assignments and so forth by post. The students are also to receive audiocassettes, CD-ROMs, and to participate in scheduled classes by videoconferencing.

Another successful implementation of e-learning modules is noted in Haryana state, where Tata Infotech developed modules for school students with a voice-over in local language and dialect. However, the company puts a word of caution to have e-learning facilitated through a physical instructor for success. Creating content that is tailored to the needs of rural learners also seems to be another sound strategy as shown by Mentronix Learning Technologies. Haeems (2002) emphasizes the need for multiple access points with easy pay-off options. Multiple channels like cybercafes, local community centers, and e-learning centers can make this approach effective. He further supports the development of localized content to be used for e-learning, as has been done in Europe, for greater effectiveness. Other factors to consider in taking e-learning to remote areas include the development of relevant courseware, the infrastructure, and the provision of trained manpower for tutorial support. In India, there are already Websites in regional languages, as fonts for Indian languages have been developed.

E-learning may further be promoted in rural areas through the launch of e-post services, where the facility of sending and receiving e-mails are now available at post offices in the cities. The users would have to write down their message on a paper and handover it at any of the designated post offices. The message would be e-mailed to the designated address. The connectivity of the post offices across the country has been made through the general post offices located at the district level. This service has been tested on a pilot basis in the states of Maharastra, Gujarat, Kerala, Punjab, and Andhra Pradesh. The hardware to receive the e-mails has been developed by the National Informatics Center. Efforts are also being made to develop software that could translate the message of the sender into any of the main languages used in India. Currently, the software works in English and Hindi. This will serve those who do not have access either to internet or to a computer.

5.5. Projects Initiated by the Government of India

Some projects initiated by the Government of India (Department of Information Technology, Ministry of Communication and Information Technology) are

- The Virtual Campus Initiative of IGNOU (www.ignou.ac.in).
- Small Industries Service Institute, Government of India, Ministry of Small Scale Industries, Chennai, has also launched some courses that are of 4/6/8 months duration. These courses are offered online through distance learning. Few examples of the courses are Diploma in Export Import Law and Management, Diploma in Company, Tax Law and Management, Diploma in Media Law and Management, Diploma in Trade Mark Law and Management, Diploma in Drugs Law and Management, Diploma in Travels Law and Management, and Diploma in Labour Law and Management (www.sisi-chennai.com).
- Developing a Web-Based Digitized Collection for Distance and Continuing Education in IT—A Demonstration Project on Internet-Based Online Interactive Courseware, by IIT Delhi (www.iitd.ac.in/courses).
- Design and Development of Internet-Enabled Multimedia Courseware for a Virtual University, Pilani (www.bits-pilani.ac.in).
- National Resource Centre for Online Learning NCST, Mumbai (www.ncst.ernet.in/vidyakash).
- Development of Interactive Multimedia Information Services over a Hybrid Internet and Broadcast Digital TV networks, IIT Kanpur (http://www.iitk.ernet.in/).
- Developing Web-Based Intelligent Interactive Tutoring (webIIT), IIT Delhi (www.iitd.ac.in/courses).
- Design and Development of Component-Based Functionality in E-learning tools C-DAC, Hyderabad (http://www.cdacindia.com/html/events/esci/esci.asp #3).
- Multimodel Digital Distance Education for IT and Other Critical Technologies, School of Educational Technology, Jadavput University, Kolkota (www.jadavpur.edu).

The above discussion clearly demonstrates that online education is poised to grow in India. Considerable efforts are being made by the government and non-governmental agencies to establish and promote online education.

6. THE FUTURE OF ONLINE LEARNING IN SOUTHEAST ASIA

Southeast Asia covers an area of about 4,100,000 km^2 containing the following countries: Brunei, Burma (Myanmar), Cambodia, Indonesia, Laos, Malaysia, the Philippines, Singapore, Thailand, and Viet Nam (for general information on these countries, see sunsite.nus.edu.sg/asiasvc.html). Some of these countries could be classified as early adopters of the internet but more than half have been plagued with economic and infrastructure problems and were unable to get on the bandwagon as early as the others. The internet eludes the vast majority of inhabitants in Southeast Asia, as they cannot afford individual internet access—that is, a telephone line, a PC, plus internet access in their home.

A recent UN economic and societal survey of Asia and the Pacific reports that in tandem with the world trade growth slowdown, GDP growth declined sharply in 2001 globally, and in the Asia-Pacific region. This is of relevance because the slowdown was particularly evident in the ICT sector and economies with a preponderance of ICT-related manufacturing activities and with high trade-to-GDP ratios, as in East and Southeast Asia, were most affected by the slowdown. This may have resulted in direct cutbacks in ICT expenditures, a crucial component of virtual learning. The events of 11th September 2001 aggravated the slowdown through a loss of business and consumer confidence.

The slowdown in 2001 needs to be seen against the background of achieving the millennium development goals in the areas of poverty eradication, universal primary education, promotion of gender equality and empowerment of women, reduction of child mortality, and improvement of maternal health. In this regard, there are grounds for optimism that most of the goals, including better ICT and internet penetration can be achieved in the Asian region. As of early March 2002, signs of a global and regional upturn are mixed. However, on balance, evidence of a gentle recovery in both the global and regional economies is becoming more discernible. Most Southeast Asian economies are expected to exceed their 2001 GDP growth rates in 2002. For fuller information on rates of economic growth projected to 2004, see UN (2002a).

Varying factors affect the percentage of online users, the most critical being urban/rural concentration, wealth and affordability, telecom infrastructure, familiarity with computers (as internet access is still broadly PC based until remote devices fully exploit it), and IT sophistication. Other significant factors include culture, government policy, a competitive national telecom business sector, English familiarity (as most internet applications and content are mainly in English), and education. The questionnaire results in the Appendix provide more specifics on these factors in the context of online education.

In online reports to date, some countries like Malaysia, Singapore, Thailand, and the Philippines give accounts of public and private participation in e-learning and virtual learning, but several of the more recent adopters like Viet Nam and Indonesia appear to be dependent on private entities for the development of virtual learning in their countries. This could be due to lack of expertise in ICT and of English language skills. For several of the Southeast Asian countries, for which data are not available on the present status of virtual learning, their future prospects will have to be extrapolated from the extent of internet use.

6.1. Malaysia

The medium of instruction in schools and institutions of higher learning was changed from English to the national language Bahasa Melayu—the Malay Language—in the late 1970s. At that time the policy change was an earnest attempt at nation-building, unity, and to preserve cultural identity through the use of the language. However, in 2002 the government decided to reintroduce English as a medium of instruction in primary schools. The impetus for this came with the realization that the citizens of this country may well be left behind in this age of information where English prevails. The government of Malaysia is committed to ensuring that its citizens will be ICT literate in this knowledge economy and information age.

A path has already been defined by the National IT Agenda (NITC Malaysia, 2001) to accelerate the objective to transform Malaysia into a knowledge-based society by 2020 through seven areas of applications currently being developed in the Multimedia Super Corridor (MSC) by international and domestic companies. These are known as Flagship Applications. The *smart school* is one of Malaysia's Multimedia Development Flagship Applications. The Smart School Flagship Application is driven by the need for Malaysia to make the transformation from an industrial to an information-based economy. The smart school is envisaged to meet the requirements of a technologically literate thinking workforce which is well able to perform in a global environment and to use information age tools and technology to improve productivity. As of 2nd May 2002, technology infrastructure has been completed in 9 urban schools and 81 suburban schools (69 secondary, 21 primary) with Data Center and Help desk fully operational. There are plans for nationwide implementation.

In addition, non-governmental agencies are very much involved in the drive to introduce ICT into schools, with The Chinese Smart Schools project, aiming to set up computer laboratories in more than 100 selected Chinese stream primary schools throughout the country, and Private Smart Schools, incorporating multimedia technology and World Wide Web networking, in addition to using ICT as part of the teaching–learning environment and as a subject in its own right.

There are also several commercial initiatives to provide supplementary online tuition for primary and secondary school children. I-Tutor.net, an e-ASEAN endorsed project my.i-tutor.net/english/ available in Malaysia, Singapore, Indonesia, and Brunei, is one such initiative. There are others offering similar online lessons.

> Malaysia's success story has not gone without recognition. In *The Global Information Technology Report 2001–2002: Readiness for the Networked World* released by the World Economic Forum, a collaboration with the Centre for International Development of Harvard University, Malaysia is ranked 35th among 75 countries included in the survey in terms of "Network Use" readiness. This ranking is way above India (60th), the Philippines (63rd) and China (70th) . . . the ranking was based on an index that measured the extent of ICT proliferation using such variables as internet users and cellular phone subscribers per 100 inhabitants, the percentage of computers connected to the internet, and the availability of public access to the internet (Ooi & Jaya, 2002).

Most public universities have incorporated elements of virtual learning to complement the traditional face-to-face classroom. Most distance learning departments in these institutions have adopted some form of virtual LMSs, whether developed in-house, with technology partners, or proprietary systems. In cases where there are technology partners, content is provided by the university concerned, but the virtual program is managed and delivered by the technology partner. Academics from the respective universities are often expected to be the online learning facilitators. If online learning has not taken off in a big way within institutions, it could be partly due to Luddite academics who see online learning as a threat to their position or those who magnify the limitations of online learning to avoid even participating in trial programs.

MSC Status is the recognition awarded by the Government of Malaysia through the Multimedia Development Corporation for organizations that participate and undertake their ICT activities through the MSC. Organizations with MSC Status are entitled to enjoy a set of financial and non-financial incentives www.msc.com.my/mdc/cs/gc/incentives.asp and benefits from the government www.msc.com.my/mdc/msc/bog.asp. Currently there are 24 higher education institutions with MSC Status.

Students residing in urban areas in Malaysia are able to take advantage of readily available free web resources, in the form of lecture notes, self-access exercises, and internet projects hosted by institutions all over the world.

A leading training institute in the public sector INTAN offers online learning to facilitate learning the English language for officers in the professional and managerial category of the Malaysian public sector: www.intanbk.intan.my/online/main.htm.

The government is very serious about ICT penetration in the country. Statistics show that ICT initiatives in Singapore and Malaysia account for 6% and 50%, respectively, of each economy's GDP. The government is about to set up 100 internet centers in villages by the end of 2003 to bridge the digital divide between rural and urban areas. Sixteen such centers have been set up to date, with about 60 people making use of each center daily to learn about computers and to access the internet. An allocation of 50 million Malaysian ringgits (about U.S. $13 million) was set aside this year to ensure that schools in Sabah and Sarawak on the island of Borneo have internet access, and another RM30 million (RM = ringgits) was provided for infrastructure nationwide. Hence, it is clear that there is strong government investment in communications and IT infrastructure. Internet usage is very high in relation to telephone line provision at 2395 internet users per 10,000 people, with significant levels of local content (Lambe, 2002).

The Government is in the early stages of developing a National Broadband Plan for implementing an infrastructure to support and speed up deployment of broadband services and facilities nationwide. The move to provide high-speed internet access connections *via* the broadband infrastructure is deemed crucial to cater to increasing internet traffic as well as to help spur development of applications and content in the country. This inevitably will be crucial in catalyzing economic growth.

Although the learning demand appears to be quite high, just over 10% of the higher education age range (18–23 years) is in some form of higher education, and this demographic group will grow over the next two decades. However, demand for education is not so sharply defined as it is in the more rapidly developing economies of India and China, for example. Even though there is strong government backing for e-learning and virtual learning, based on the prevailing environment the e-learning market watchers are not very optimistic that virtual learning solutions will take off in a big way in Malaysia in the near future.

6.2. Thailand

IT arrived in Thailand before her neighbors. The first two computers were installed in Thailand in 1964 when only one computer was installed in Singapore and none in Malaysia. The internet was introduced in Thailand in the year 1987. Utilization of computers and the internet is growing steadily every year. As of 2002, about 3 million computers have been installed, and about 3.6 million people in a population of 62 million are using the internet in Thailand. One survey noted that over 70% of the internet users in Thailand are college students who do not own PC's but get access to the internet at cybercafés or university facilities.

In Thailand, the incumbent domestic telephone operator provides free internet access to national Websites and e-mail through a short, four-digit number (1222) to sites located in the country. The government has also announced that by the end of the year 2002, all high schools will be equipped with computers connected to the internet.

Many government and private organizations have introduced e-learning. The first generation of DE in the form of correspondence study was started in the year 1971 and later developed into the 15th generation of Internet DE. For example, Assumption University has established the College of Internet DE, to start by offering 10 degree programs through the internet, and it plans to eventually provide e-learning to 100,000 students per year. One report asserts that IT and e-learning have been fully adopted in Thailand (Charmonman & Chorpothong, 2002).

In 2000, the Thailand Graduate Institute of Science and Technology, a unit of the government's National Science and Technology Development Agency, offered courses, delivered *via* satellite and the internet, from various Thai universities. In conjunction with Mahidol University, the institute also has begun to offer distance learning Master's and Doctoral degrees in areas such as bio-informatics.

In addition, the National Science and Technology Development Agency has requested funds from the World Bank for a new DE program that is designed to develop a competent workforce in Thailand. The proposal envisions using the Thailand Training Network for continuing education for professionals and a system of post-graduate education for engineers, scientists, and other technical personnel through the private sector or colleges outside Thailand.

There is strong government investment in communications and IT infrastructure. Thailand is also improving PC provision in schools, with almost 60% of students accommodated by better than a 15:1 pupil-to-computer ratio (by comparison, in Malaysia and Indonesia such coverage is 6% and in the Philippines, 14%). Since 1998, schools all over the country enjoy free access to the network. The government has also created a large-scale nationwide education infrastructure. Four thousand two hundred and seventy-four schools were online as of early 2002 and this is projected to continue to expand. internet usage of 556 internet users per 10,000 people is relatively high in relation to telephone provision and is the highest of the lower tier in Asia (including India, Indonesia, China, and the Philippines) but has yet to grow to significant proportions. Malaysia with only double the phone access has five times more internet users.

Thailand has experienced a "pre-paid revolution", with over 70% of internet accounts being pre-paid. Launched in 1998, pre-paid cards are very convenient for users, who can purchase them from a variety of retail outlets, recharge them online or at automatic teller machines (ATMs) and purchase them in a variety of denominations.

Seventy percent of the Thai population is rural. Although there are initiatives to connect the rural communities to the internet, there are many disablers that have to be tackled: the problems involved in reaching rural communities, limited infrastructure (electricity and telephone lines), a high illiteracy rate, limited technological know-how, small demand and supply (from rural people), high costs to invest, and culture: tending not to read and write, but loving story-telling (Sopchokchai, 2002). There is a teledensity of 43 telephone lines per 100 inhabitants in Bangkok but only 6 per 100 in rural areas. Put simply, in 2001 it appears difficult to ensure that each rural village has telephone lines, and until that teledensity is increased, it may be almost impossible to deliver lifelong learning by IT means to rural and remote areas.

In addition, language continues to pose a significant barrier, because there are not enough tutors to translate information from English to Thai.

Nevertheless, universities and schools in Thailand are connected to the internet. The UniNet (www.uni.net.th/index_e.html) supports and connects all universities and higher education institutions of Thailand. The SchoolNet (www.school.net.th/index.php3) project provides and manages a network for schools. As of the end of 2002, 4180 secondary schools are expected to be in the SchoolNet with 3 accounts per school and 40 hours per account, each having a storage capacity of 7 megabytes per school (cf. UNESCO, 2002).

6.3. Singapore

In April 1997, the Singapore Ministry of Education launched a "Masterplan" for IT in education to equip every school with hardware and expertise for e-learning over 6 years (Chua, 2001). The Singapore government recognized that school children were future e-citizens and put its efforts into the school sector. It also recognized that adults would stand on "the other side" of the digital divide unless they could be ferried across to the side where the info-society lives. Singapore intends to have one computer for every two children in school, with one-third of curriculum time involved in IT and e-learning. On the adult side, it is the Singapore government's intention to have 70% of adults making use of information and communications technology by 2002 (Chua, 2001). An interesting point is that industry is involved in this process not only on the supply side but also in generating a PC reuse scheme for the private sector and members of the public, bundled with free internet access, and e-learning courses.

IDC www.idc.com forecast in a press release that there would be 270,000 broadband access service subscribers in Singapore by the end of 2002. This compares with 1.8 million dial-up access subscribers in the country. According to IDC, cable modem is the dominant broadband service in Singapore with Asymmetric Digital Subscriber Line (ADSL) a close second. The research company estimates that there will be 140,000 cable modem subscribers by the end of 2002, compared to 130,000 ADSL subscribers. The overall Singapore telecom services market will exceed U.S. $4 billion in 2003.

Singapore also has a high learning demand. Provision of tertiary education covers 18% of the higher education age range (18–23 years), with demand exceeding supply, and this demographic group will grow in size over the next two decades. There is a strong cultural pre-disposition to favor advanced learning primarily in economically pragmatic areas, which have traditionally centered around engineering and IT, but are now increasingly focusing on life sciences and biotechnology.

On the surface, virtual learning appears to be poised to go to great heights in Singapore. A more recent report however paints a bleak picture. At the close of Online Learning 2002, Asia, an e-learning summit in the region, analysts said Singapore companies were reluctant to spend training dollars on e-learning, despite a big push from the Government (Basu, 2002).

6.4. The Philippines

As in Thailand, the introduction of pre-paid internet access cards has led to an increase in the number of people going online in the Philippines. According to a late 2002 report in the Philippine star www.philstar.com, around 70% of internet users in the Philippines are pre-paid card users. The report indicates that the local internet population has reached 4.5 million, of which 3.1 million are pre-paid card users. While the internet has been available since the mid-1990s, the high cost of internet service providers and monthly fees meant that Filipinos have been slow to get online. However, the introduction of pre-paid cards that allow users to go online in internet kiosks, schools and at home has led to a dramatic increase in the numbers of internet users in the region.

Around 40% of online Filipinos are aged between 20 and 29 years, while 12% of internet users are aged 40 or above. The report also indicates that 40% of internet users are based in the capital, Manila.

The Philippines has embarked on the Infotech project for remote areas. Infotech was piloted in six schools and two division offices in the two contiguous provinces of Antique and Guimaras in the West Visayas. Two central schools with access to the internet serve as the downloading stations that access teachers' lessons from the UNICEF Websites, www.unicef.org/teachers and www.unicef.org/voy as well as other Websites focused on student learning. Downloaded materials are shared with the other schools and the division office. The aim of the Infotech project is to provide teachers and students from far-flung areas of the country with the knowledge, the skills, the facilities, and the materials to use IT and with access to information from the internet.

6.5. Brunei

There appears to be a strong government commitment to promote ICT within the country. The government spent 11.3 million Brunei Dollars (about U.S. $7 million) to provide computers to government schools nationwide. Brunei, the smallest yet richest APEC economy, has relatively low internet uptake compared with other developed economies. One government project aimed to increase computer literacy among the younger generation, in the hope that it could stimulate their interest to learn more about the functions and uses of IT and thus produce IT-skilled Bruneians. From this it can be inferred that Brunei still lacks IT-skilled professionals.

Brunei has a high telecommunication penetration, both for households and mobile phones—95% for households and 30% for mobile phones. And yet PC penetration stands only at 10% and internet penetration is only 7%.

The government introduced the first ISP in Brunei on October 10, 1995. As of November 2001, there were 15,000 BruNet users, of which 14,000 users have subscribed for the dial-up connection and another 1000 are ADSL e-speed subscribers. Introduction of pre-paid internet access cards has also gained popularity among Brunei Internet subscribers. The actual number of internet users in the country is not available, as there are also pre-paid internet services in the form of cards. Pre-paid cards were introduced to cater to the demand of the less heavy user and low-end users as well as to enable users, especially students, to browse the internet within their budget.

A random survey showed that the majority of the users in the low-end category comprised young adults and students, meanwhile the high end users are made up of professionals, especially those involved in the business, multimedia, and academic fields (Garip, 2001).

Unlike in countries like Viet Nam where internet charges are seen to be coming down, in Brunei charges went up early in 2002 by about 20% for dial-up access and 100% for pre-paid cards. Furthermore, there have been recent press attacks on Brunei's ISP for its inefficient administration. In fact, worries have been expressed about the country's march toward the e-future coming to a grinding halt, which would bear on the advent of virtual learning in Brunei.

6.6. Myanmar

Reuters reports that internet usage in Myanmar is expected to increase 10-fold from 2002 to 2004, from 20,000 to as many as 200,000 people. According to an official from a state-run agency, restrictions have been lifted, which will allow more people in the region to go online. However, blocks on certain political and pornographic Websites will remain in place. The military junta first allowed people to go online in January 2002. However, high costs have meant that the majority of people cannot afford to access the Net.

The military junta in Myanmar has recently approved the setting up of a second ISP, in which private enterprises will be allowed to invest. At present, only domestic e-commerce is possible in Myanmar as the junta has forbidden cross-border online purchases. These kinds of restrictions do pose questions as to whether virtual education originating outside the country will be allowed into Myanmar.

6.7. Indonesia

Indonesia was one of the lowest ranking countries in IDC's study, which tracked 55 countries that account for 98% of IT adoption in the world. IDC based this study on 23 indicators, including the number of PCs per capita, percentage of networked PCs, and the extent of e-commerce.

IDC attributed inconsistent IT progress of lower ranking countries, including Indonesia, to limited financial resources in relation to the vast population. Indonesia's IT market was said to have "expanded vigorously" to achieve 42% growth in 2000 but this figure nose-dived to 1% in 2001. However, this performance is seen to be far better than some countries in the region (Loo, 2002).

Both fixed telephone lines provision in Indonesia at 3.7 per 100 people and internet usage at 186 internet users per 10,000 people are considered low. In addition there are language challenges with literacy in English being low, but fortunately with no script/character set problems as in the case of Thai. The written Indonesian language is based on Romanized Greek.

6.8. Viet Nam

Viet Nam hooked up to the internet in late 1997, but high fees for slow connections and download times have kept the majority of Vietnamese from using it (Borton, 2002). According to NUA Internet surveys, the number of registered internet users in Viet Nam rose by 30% from June 2001 to June 2002. That is, around 175,000 registered internet users were recorded in Viet Nam, equivalent to just 0.4% of the total Vietnamese population. However, it is estimated that as many as 1 million people access the Net through the country's 4000-plus internet cafes (NUA, 2002b). At present Viet Nam remains the lowest in overall per-subscriber and per-capita bandwidth in all of Southeast Asia, and thus suffers both the slowest connection speed and far above median cost for that privilege. There are foreign private corporations who are distributors of e-learning solutions in Viet Nam.

6.9. Cambodia

The first ISP which began operation in 1997 in Cambodia provides various internet packages: dial-up e-mail only, full access, leased line, and wireless access connection with lease of the necessary wireless equipment. In the current offer, after 40 months the equipment will belong to the customer. This means internet connectivity is not restricted to phone line availability (cf. www.camnet.com.kh). The Cambodia National ICT Policy (www.nida.gov.kh) has recently been proposed within the framework of the eASEAN Agreement. The four main areas of the proposed policy are enhancing information infrastructure, developing human resources, developing local content, and creating the necessary legal and regulatory environment. Goals include creating mass awareness among selected groups by sensitizing decision-makers and government workers to ICT, and introducing the use of computers at schools. The source does not elaborate on the details of how computers will be introduced.

In Cambodia, the status of females is very low and they are faced with considerable oppression. It is difficult for women to enter the public sphere and there are only a few female journalists. The Women's Media Centre (WMC) recognizes the power of media to facilitate social and behavioral change—by giving a voice to women. WMC aims to reduce these inequalities.

6.10. Summation on Southeast Asia

Some conventional indicators discussed when comparing ICT penetration are fixed and mobile telephone subscribers in the population, internet users as a percentage of the population, and PC ownership. For full and up-to-date information on these indicators in ASEAN countries and elsewhere, see UN (2002b). The ITU reports that in 2000, internet users as a percentage of population in SE Asian countries were as follows: Singapore 24.9%, Malaysia 15.8%, Thailand 3.8%, Philippines 2.0%, Indonesia 0.9%, Viet Nam 0.3%, Cambodia 0.1%, and Lao P.D.R. 0.1% (Minges, 2001). No statistics were given for Brunei. More recent statistics (NUA, 2002a) show growth in internet penetration; for example, Singapore has risen to 51.84 as of April 2002; Malaysia has charted 21.15% as of December 2001; Brunei 9.97; the Philippines 7.77% as of September 2002, Thailand 5.76% in 2001, Indonesia 1.93% as of January 2002, and Viet Nam 0.49% as of December 2001. There has been substantial growth in several countries. Even in countries like Thailand and Vietnam, where language is seen as a disabler, the number of internet users has risen more than 30% recently.

As seen from the above, the vast majority of inhabitants in Southeast Asia do not enjoy internet access, and this is probably because they cannot afford ownership of individual internet access—that is, a telephone line, a PC, and internet access in their home. If internet access is to be boosted, it will have to be through public locations such as schools, universities, and internet cafés. Indonesia has been a trendsetter in this respect.

The growth of virtual learning can be said to be broadly pegged on internet usage. The data above can give a rough indication as to which countries are potential growth centers for virtual education. However, another driver would be the demand for higher and lifelong education. Malaysia, one of the Southeast Asian countries with good growth in internet penetration, does not have that great a demand for formal education sufficient to spur virtual education. Anecdotal evidence shows that when the virtual arm of a distance learning program was introduced in 1999 in a local institution in Malaysia, there was good response in enrollment, but which sadly dwindled the following semesters. Perhaps, the learning culture is still very much dominated by F2F instructor-led programs. In countries like Indonesia, Thailand, Malaysia, and even Singapore, where a major proportion of the workforce works in small or medium enterprises, which tend to lack access to capital and talent, it is less likely for large slices of the corporate sector to invest in e-learning training solutions.

It is inarguably also a fact that language continues to play an important role in internet usage, and correspondingly in virtual education. Since the internet is led by English language content, some countries, where English is widely spoken (such as Singapore, Malaysia, and the Philippines), have a strategic advantage *vis-à-vis* their neighbors. Thailand and the Indochinese countries especially face extra barriers because their alphabets are Sanskrit-based, making them difficult to adapt to computers. Most policy makers seem to agree that while content development in the local language is very important, the promotion of second languages, especially English, is an effective way of increasing internet usage.

Apart from Singapore, the less wealthy countries of Southeast Asia—Thailand, Indonesia, and the Philippines—have a much lower proportion of the population online, though Malaysia is clearly leading this group due to relative wealth, English speaking capabilities and a higher urban population. However, Malaysian growth, especially for the poorer population segments, is hampered by per-minute phone charges for dial-up access and relatively higher internet access fees. Southeast Asia can expect some strong growth in virtual education if demand for education increases as a whole, if telecom facilities become more sophisticated, and if monopolies in the sector are reduced.

7. PACIFIC RIM OPEN AND DE HEADING ONLINE

Asia holds about half of humanity, and it quickly becomes apparent that various assumptions based on Western culture cannot be taken for granted as universally human. The use of educational technology for distance learning is viewed through culture-colored lenses before manifesting in diverse ways.

The Open University of Hong Kong has surveyed Open and Distance Education (ODE) in much of the Asia-Pacific region (Jegede & Shive, 2001), including Northeast Asia from Mongolia to Taiwan, Southeast Asia, South Asia from Pakistan to Sri Lanka, and the Pacific Rim: Australia, New Zealand, the South Pacific, Canada, and the United States. Most countries in Asia have large OUs, having drawn inspiration from the United Kingdom Open University. But they are little-known abroad, and not many have moved far beyond correspondence by post. OUs in the developing countries are often dependent on outside financial aid to make progress.

It is apparent that the economic level of the country correlates with its use of educational technology and access to online education. Canada and Australia were among the first to adopt DE to challenge the tyranny of distance separating their citizens, and to provide equitable access to educational opportunities. While Canadians are most inclined to form domestic consortia, universities in most countries in Asia are competing among themselves and wary of foreign entrants taking their potential customers with web-based approaches. Meanwhile the United States, seemingly content with its huge domestic market, as in other areas of trade, has put relatively little thought into going international with DE.

Other themes running through the book are the emphasis on quality assurance and the need for teamwork among content specialists, curriculum designers, and computer support staff. When correspondence education goes online, in order to go beyond the so-called shovelware, the application of instructional design principles, much time, experimentation, and expenditures are required. Online media have bared the teacher-dependent learning styles in East Asia, the lack of facilitating skills among veteran teachers, and therefore the need for hands-on in-service teacher training as well as technical support staff. Recognition is also increasing for many other new needs: modularization or standardization for transferability, market surveys, multilingual courses, cultural sensitivity, the need for continuous lifelong education, interactive web-based approaches, and above all, learner support utilizing every available means of communication.

In Japan, the personnel system in public universities has not yet allowed for new occupational categories such as media or learner support staff or instructional designer. Media literacy is recognized as a problem for faculty, not students, contrary to the traditional masterly image of "sensei" that makes faculty development a sensitive issue. Quality assurance also presents an obstacle when fastidious administrators examine a new approach. While progress is deliberate, there is considerable demand for DE programs among teachers, who recognize that computer literacy will be expected of them in the future.

South Korea has made remarkable progress, for example, providing even non-degree programs for teacher training, and aiming for Net-based, government-supported teacher education programs with their own software platform. But they have found teachers not facilitating learning, with students passive, using the PC just for information processing, not as a communication tool.

Similarly in Taiwan, 70% of adult students were found to be teacher-dependent. This finding by the Taiwanese themselves is important, especially for those ready to teach Asians with Western assumptions about student-centered learning. What was found for Taiwanese adults in continuing education is liable to hold more so for traditional students through university age and across the originally Confucian cultures of China, Korea, and Japan, plus Vietnam, and other parts of Southeast Asia to some extent.

Moving to Southeast Asia, countries may know what to do but lack the resources or funding. The elite minorities, however, who do get a university education, stamp ODE as second class. This was brought out in the Indonesian context but will be a global issue until there is a paradigm shift realizing that "education for all" can only be achieved by ODE.

Malaysia is trying to retool its workforce for the information age, but too few local institutions are preparing ODE materials. Yet, there is a wariness in their questioning if international DE programs can cater to the needs for learning support and regular interaction with instructors. A similar undercurrent is seen in New Zealand. Their government has encouraged open competition, but local universities fear competition from foreign low-cost web-based educational providers. Educators lament that other countries protect their local educational industry.

In Papua New Guinea, where most do not have Net access, officials want those who do have access to take advantage of it with multimedia delivered over the web, but there are also voices criticizing how it serves a privileged minority.

Across the Pacific Rim, North America presents quite a contrast, for example, with Canada's CANARIE aiming to bring fiber cable connections to the whole country. In the United States the big issue identified is commercialization of higher education, in the "volatile technology sector of the 'new economy"' (Shive & Dirr, in Jegede & Shive, 2001: 435) where the bubble ended up bursting as commentators in Pacific Asia had long warned. "[F]or-profit educational service companies (*ibid.*) can staff up with many adjunct instructors, [which] trend haunts teaching staff of mainstream universities and fuels their skepticism and anxiety . . . which they tend to associate directly with DL" (distance learning).

The poorer countries show that the above considerations are a luxury, as they have little choice but to admit their need for assistance in getting onto the playing field before asking that it be level. The Jegede and Shive book goes some distance in showing nonetheless that East–West learning should be two-way and interactive like the educational technologies that can facilitate such exchanges.

CONCLUSION

This chapter has demonstrated that online education is already a global phenomenon. The rapidity of its growth is partly due to the lifelong updating of knowledge and other shared ethics of the global community of scholars, which makes the educational sector ready-made for networking. Indeed this Handbook itself exemplifies the collaboration of co-authors, editors, and the publisher all in different regions of the world. This chapter and "Virtual Organizations for Online Educator Empowerment" in this chapter and the next one were organized through the WAOE, readily bringing together writers in Japan, Malaysia, Russia, India, the United Kingdom, and Canada. Besides the citations from existing scholarly literature, news sources, and other online resources, the informants thanked in the Acknowledgments below could be rapidly mobilized to present the most up-to-date picture of the emerging discipline of online education.

The world is too large a place to be covered by any chapter, however. Further research, besides gathering more details in more regions on the professional and public issues treated in this chapter, could seek wider perspectives such as those of students and the general public worldwide who could choose to access online educational opportunities in the future. Technologies *per se*, often requiring hand-on experience or training, are accessories or utilities of the global social phenomenon of online education described here. So while any amount of attention could be given to the plethora of software and connectivity alternatives available, more research is needed on how educational objectives are to go through an instructional design process, translated into technologies suitable to the purposes of educators in a given scene of instruction or cultural context. New chapters will be written more rapidly in practice than can be chronicled, so rather than a static field to be surveyed, the ongoing process of scholarly networking itself needs to be recognized as an essential part of the discipline of online education.

ACKNOWLEDGMENTS

The authors wish to thank Parker Rossman and Takeshi Utsumi who permitted extensive citation of their work, and those aside from the co-authors whose replies to the Global Online Education Questionnaire are quoted in this chapter: Yolanda Gayol for Latin America, Jesus Granados for Mexico, Rita Zeinstejer for Argentina, Roberto Mueller for Brazil, Miia Suoranta for Finland, Sarah Guri-Rosenblit for Israel, Bunyamin Atici for Turkey, Cecilia Junio-Sabio for the Philippines, Paulina Pannen for Indonesia, Maggie Verster for South Africa, and Dele Braimoh for Lesotho, Nigeria and the Southern African region. The informant for Kenya preferred to remain anonymous.

APPENDIX: GLOBAL ONLINE EDUCATION QUESTIONNAIRE DATA

Questionnaire responses were streamlined and discussed above, but here is all the data considered valid in the respondents' own words. Respondents are mainly non-native users of English, so some responses are edited for clarity or paraphrased without quotation marks, with additions in brackets, also for clarity. Responses that seemed subjective or unrepresentative of a geographical region have been eliminated. The questionnaire was distributed in September 2002 and most responses were received shortly thereafter.

The questionnaire first asked: *1a. What is your name, organization, country of origin and residence? 1b. What country, region or culture are you answering for?* As for question 1a, respondents cited besides the co-authors have all been identified in the Acknowledgments. As for 1b, the responses below are identified according to the country or region indicated by the respondents.

2a. What is the general state of the use of virtual learning environments for education?

Latin America: "Regionally well developed, with multiple actors, a tradition, a culture in distance education and the use of e-learning for higher education, continuing education, and e-governance." *Mexico*: "Some universities are trying to develop courses in this methodology, but very few are taking serious steps to get there." There is not much knowledge about it among public education officials nor the formal politics to authorize online studies. *Argentina* ("educated middle class"): "Virtual learning environments are still being ignored by most teachers. Educators seem to ignore/reject/fear the inclusion of computers for learning, in general." *Brazil* (Vicosa, Minas Gerais region): "Its popularity is increasing slowly for a large group and rapidly for a small group." *Finland*: "There are plenty of development projects around the country and ambition exists to build up communication and coordination for providing more virtual learning possibilities. However, there is a lot of work to do, for example best practises with pedagogy with networking and having enough competence in making good use of technological possibilities in teaching and learning. Also heterogeneity of learning environments and philosophies (open source vs. commercial solutions) is sometimes making cooperation harder." *Israel* (and Israeli culture): "Our Open University of Israel has a special center for integrating information technologies into our courses. More than half of our courses (about 250) have some components of e-learning." *Turkey*: "The Internet usage penetration rate is approximately 2% in Turkey. Primary demand must increase. There is an increasing demand for online education but less pedagogical concerns." *Russia*: "Virtual learning environments in former USSR are not so widely used as in Western countries. There are some causes: bad telephone lines, small amount of private educational institutions as compared to public, lack of money in public institutions to develop distance learning technologies, methods and departments, strong traditions in old governmental schools and institutes." *India* ("the South Asian region, a multicultural society"): "India in specific and South Asia in general is fast adopting VLEs for education. Already universities and private organisations are going online. Even some universities like Tamil Virtual University provide culture-specific orientation education to the younger generations of learners to tell them about their cultural heritage. Indira Gandhi National Open University (IGNOU) also launched the Virtual Campus Initiative to meet the demand–supply equation for the infotech industry way back in 1999." *Kenya*: "It is picking up steadily." *South Africa*: "Very poor. Online education is basically restricted to the university level. Our organisation was formed by teachers wishing to improve the use of the Internet as a tool for sharing maths resources in order to try to improve the poor maths performance in our country. Computer usage in some disadvantaged areas is limited indeed as quite a few schools do not even have telephones, let alone pc's! Even with 'advantaged' teachers and students, use of the Internet is largely restricted to e-mail." *Lesotho and Southern African region*: "At an embryonic level, with some countries in the lead, but not widespread." *The Philippines,* "Southeast Asian Region and Filipino culture": "In the Philippines, virtual learning is not yet that popular and only a few institutions, mostly profit-oriented groups, venture into such business." *Indonesia* ("and Southeast Asia"): "There are some efforts taken by various institutions—public as well as private institutions, and government. However, they are still at the initial stage of planning and preparation of the infrastructure, structures, etc." *Malaysia*: "Promising. A National IT Agenda aims to transform Malaysia into a knowledge-based society by 2020 [see details in the section on Southeast Asia]. Many traditional public and private universities have some or all of their distance learning programmes available online." *Japan*: Virtual environments have become popular for socializing, but progress has been slow in realizing their educational potential. University and government bureaucracies maintain control and want to know a new territory before allowing it to be popularized. Therefore, a deliberate pace has started with top universities experimenting with virtual university projects and electronics companies doing R &D to supply a perceived future market in e-learning. Technology tends to race ahead of the reasons for its use, with products such as learning management systems appearing before people know what to do with them in terms of pedagogy. While individual educators are experimenting with virtual learning environments, there is not yet a systematic acceptance of online education by the authorities or the general public.

2b. Is the Internet used for education by a small elite in universities or elsewhere?

Latin America: "Elsewhere." *Mexico*: "Some of them." *Argentina*: "Very few schools have Computer Labs, and out of these, few make good use of them." *Brazil*: "Internet is used a little by many universities." *Finland*: "Internet is definitely not used only by a small elite, but it's widely used nationally regardless of where the user is working, studying or living." *Israel*: "No, it is used by all students in the relevant courses, but for small and specific portions of the teaching/learning process." *Turkey*: "A limited number of universities have used virtual learning environments for education. Most private universities are based on the English language. But most public universities cannot use software like Blackboard and WebCT because their teaching language is Turkish." *Russia*: "Internet is used in almost every university, but not in place of face-to-face teaching. It is only to give students the skills needed for their future jobs, because many workplaces require Internet skills, and the proportion of such jobs will grow very quickly. Graduates of universities, colleges, and professional schools need the knowledge and skills of Internet utilization to improve their competitiveness in the job market." *India*: "Most of the universities are connected to the Net. There are also many ISPs. In some regions even cable modems have started functioning. Libraries are also connected through DelNet." *Kenya*: "The population of users is still negligible." *South Africa*: "Indeed. The government has started putting measures in place to make Internet access available to all students and teachers, but progress has been slow. Bandwidth and online costs are enormous." *Southern African region*: "Yes, in some of the affluent universities with a high technological level." *The Philippines*: "Only a few institutions are using it. At [Polytech] PUP, I encourage students to use the Internet for research. A recent study by our [Open University] PUP OU revealed that 80% of our subject facilitators and students are using the Internet in their teaching-learning process. It is very affordable for students. Not just the elite or those well off but also the underprivileged or marginalized sector of the Philippine society can use the Internet. Computer rentals with Internet cost only 10 pesos or around US 20 cents." *Indonesia*: "There are some universities that have required all students to use the Internet, but in most places it is used only by some faculty members and students." *Malaysia*: "Not only universities. Smart Schools with IT infrastructure have reached 69 secondary and 21 primary schools, and the plan is to go nationwide. 100 Internet Centres are to be set up in villages by the end of 2003." *Japan*: The government has aimed to connect all schools, so even some elementary schools have started web investigations or exchanges with other schools. It is almost all supplemental to regular face-to-face education at this stage.

2c. Are females much less involved?

Latin America: "Yes." *Mexico*: "About 60%–40% (men–women)." *Argentina*: "Females are more involved in education than males all across the country." *Brazil*: "Females are more involved." *Finland*: "Females use computers as much as males. There's no difference in the school world." *Israel*: "Not at all." *Russia*: "Females in former USSR countries, except the Moslems, are much more active and free than males. There are no cultural or official limitations on women's activities in business. They can use modern technologies equally with men. But they do not like to get involved in programming. Instead, they prefer to utilize completed and reliable software products. And in this utilization they can be more active than men." *India*: "If at all, the difference may be of urban vs. rural rather than males vs. females. We have found that females in urban areas are involved to an equal extent." *Kenya*: "The status is balanced." *South Africa*: "We are trying to encourage equal access between sexes, but women and girls are still caught in traditional roles." *Southern African region*: "Females are sometimes in the majority because of the population ratio between males and females." *The Philippines*: "Research has revealed that females outnumber males in terms of access and familiarity with the Internet. Females know a lot more about computer technology than males. And most of the students in the open learning system in the Philippines are female." *Indonesia*: "Yes." *Malaysia*: "Female students outnumber males students in tertiary education. The same can be said about the academicians." *Japan*: There is still a tendency for females to be less involved with technology until it becomes very user friendly and fashionable like mobile phones. Although they are Net-enabled, the phones have not been used for much more than e-mail messaging yet. Sex roles will be slow to change, but housewives have the most free time for accessing the Net, so they could be more involved in online education than men in the future when they become comfortable with the Net.

3a. How do people generally feel about globalization effects—do they feel their culture is threatened or do they welcome a broader cultural repertoire?

Latin America: "Academics are aware of the differences in cosmovisions between developed and developing worlds, speak them out, and are able to negotiate international networks and participation in global projects." *Mexico*: "Professionals feel it is a good thing provided our culture and values are maintained." *Argentina*: "Due to the critical times the country is going through, globalization is rather regarded with distrust. Yet, many welcome a broader cultural repertoire." *Brazil*: "They welcome a broader cultural repertoire." *Finland*: "There seem to be both opinions; in universities there is little resistance toward a broader cultural repertoire, although there are some disagreements among developers that we should use virtual learning environments developed here in Finland, as they are more flexible." *Israel*: "Most Israelis do welcome a broader cultural repertoire." *Turkey*: "The Turks are among the most important nations who have played a role over thousands of years of history. Turkey is situated at an important geographical location, where Europe and Asia meet. The secular state of Turkey has the largest Muslim population in Europe. Globalisation, the result of the impact of technology and power, has its own pluses and minuses like all social and economic facts. The effective operation of the global system with a minimum of errors depends upon the functioning of pluralist-participatory democracy, market economics, national and international transparency and interactions." *Russia*: "Some young and progressive people welcome international relations, but those who do not know foreign languages or are affected by the former communist propaganda are wary of foreigners. The older generation with a former Soviet mentality in a large proportion still do not trust foreigners, especially because Russia after Perestroika was invaded by foreigners who managed to plunder and help some Russians steal huge amounts of capital. So in a way the old communist accusations of uncontrolled and criminal capitalism have proven to be a reality. It will take a long time to replace that plunder with civilized international cooperation and to restore the lost trust in foreign businessmen and economic consultants." *India*: "Both. Elders are concerned with the cyber-attack on their culture, while young people are excited with the new medium, making global friends, finding communication much easier and at anytime."

Kenya: "It is welcomed particularly by the elite. The tradition-bound [tribal people] however feel highly threatened." *South Africa*: "Civil society seems to be against globalisation, but as we are a country with 11 official languages and many cultures, we are working towards intercultural friendliness." *Southern African region*: "From the cultural point of view, globalization is seen with some degree of resentment. But in the main, the newness of technological development [precludes] its general acceptability and utilization." *The Philippines*: "People are taking globalization negatively, since they are seeing the effects of it especially in trade and industry and in business. In terms of culture the people are not actually that bothered. But in terms of business (as in import–export) they are actually threatened because currently they are seeing how locally manufactured products and local companies have suffered from the WTO, which is a form of globalization." *Indonesia*: "Mixed feelings about both issues, but there are also people who have no idea about the issues yet." *Malaysia*: "There seems to be some demonstration of this fear [of globalisation]." *Japan*: Japanese culture remains strong and well protected by an insular mentality and the language barrier. Most people would like to expand their options to select from the outside world without being overwhelmed by globalization or losing their cultural identity.

3b. Can you describe any debates within your society about other issues such as language, democratization, equalizing of opportunity, or resistance to change by governments?

Latin America: "There is a permanent debate at the citizens' level led by municipal organizations on all the above-mentioned issues." *Mexico*: "With President Fox a lot of things have changed; people want democratization, justice and the rule of law." *Argentina*: "People are more worried about ordinary, daily issues, such as social, economic changes badly needed at the moment, and education is one of the crucial issues as well. Teachers are concerned with making ends meet, unfortunately." *Brazil*: "The public online university at URL www.unirede.br maintains a list of discussions involving distance education subjects." *Finland*: "Telecommuting is one of the things people are trying to solve, both technically and psychologically. Knowledge-intensive work has been very much debated because of the burnout phenomenon that is usual in IT work. Information overflow also has been a very popular debate, how to cope with ever-increasing amounts of information. Of course there has been a debate about our language vs. English, because more and more new words are born that don't have good Finnish translations. But no concrete changes have been demanded to abate this trend so far." *Israel*: "There are many debates as to religion–secularism, Jewish–Arab conflict, right–left political orientation, Eastern-origin vs. Western-origin cultures, etc." *Turkey*: "Turkey could be among those societies shaping the future of the world if it efficiently utilises its geopolitical location, physical and social capital, human resources and cultural wealth. It is also important that people believe and share the goal of Turkey becoming one of the most effective countries of the world in the coming 10–20 years and their participation in the efforts to this end have to be ensured. In this respect, the general outlook of the country should be presented to the public to enable them to harmonise the requirements and priorities of their own social sub-groups or regions with national priorities. They will then be able to influence the decision-making and implementation processes in this direction." *Russia*: "The government supports new technologies and methods in education, but there is a drastic lack of money. However, a centralized mentality and system of education makes educators wait for governmental funding for a transition to distance education." *India*: "The Government of India is promoting infotech growth. Very recently Internet telephony has been opened to the public. The State is promoting Internet kiosks in rural areas to promote education. Just a few days ago the Indian Army gave training to girls and adults on computer fundamentals in terrorist affected areas of Jammu. So the government is fully backing this for the advancement of society." *South Africa*: "A current debate is one of language in broadcasting as our new broadcasting bill is coming under the spotlight. English is the main language of communications (67% of broadcasting) and we do have 11 languages. Also, the government is seeking to gain more control over broadcasting issues, with the fear being that freedom of speech may be impaired. Our 'Internet Act' has just come into effect recently, and the same fears surfaced with regard to government control. As we fought hard for our democracy, we fear that our current government will repeat the ills of the past." *Southern African region*: "Transformation, democratization, accessibility, equity and gender sensitivity are the concepts now in vogue in societies here and common also in educational institutions." *The Philippines*: "Most Filipinos know that the only way to bridge the gap between rich and poor or to equalize opportunity is through education. Most families strive to send their children to higher education, which is why about 95% of Filipinos are literate. However, even after a proper education they suffer from unemployment because there are no job opportunities in the country, which is why they usually resort to working abroad. Efforts are being made by the government in embracing the challenges of Information and Communication Technologies. Laws have been made about e-commerce and ICT, and several offices and commissions has been set up to work on government modernization, particularly e-government in the whole bureaucratic system. Filipinos can get a passport, birth certificate and many other services through the Net. The government is not resistant to changes; it is just taking all these challenges in a step-by-step manner." *Indonesia*: "Issues of democratization, decentralization versus centralization, tolerance and unity." *Malaysia*: "The importance of ICT is generally well acknowledged by all levels of the society. But the digital divide between the rural and urban population remains a problem. Since Malaysia is a multiracial society, there has been a major debate on the government decision to reintroduce English medium instruction for some primary school subjects. The new policy reflected the realization that falling behind in English proficiency could prove to be a serious disadvantage in this ICT era." *Japan*: There is often a tension between the attractions of the outside world and the unspoken prohibition against crossing over by being too unlike other Japanese. Being poor at English and other languages is quite acceptable as a badge of cultural allegiance, but it makes international relations difficult. There is always resistance to change by vested interests, and change can imply that something was lacking in the lifestyle arranged by the paternalistic authorities.

3c. Do leaders or the media see using the Internet as heading toward positive outcomes for education, international and intercultural relations, or not?

Latin America: "Yes." *Mexico*: "Yes, they see it, but the change is going too slowly and will take time." *Argentina*: "Very few professionals appreciate the benefits of Internet." *Brazil*: "Yes, especially those with an open mind. E-mails are intensively used to spread news and sometimes also to send suggestions to politicians." *Finland*: "Leading public media are not very much interested yet in virtual learning environments. They cover more about the Internet itself, news about hackers and costs for universities around the world, children's use of computer games (are they good or do they make children passive?) . . . So I think it has been quite neutral in the media." *Israel*: "Yes." *Russia*: "Russian education still is one of the best in the world, in spite of extremely low salaries of teachers equivalent to $100–200 per month. Private schools and institutes pay much more and can develop new technologies, but there are relatively few private institutions." *India*: "Yes, with more and more schools and universities going in for online education, it is certainly poised for positive outcomes." *Kenya*: "Definitely yes." *South Africa*: "Yes, definitely, and a lot of money seems to be allocated to help solve the situation, but I do not notice a vast improvement in South African educational resources output or the improvement in access or training of teachers." *Southern African region*: "Especially the elites may be open to using it, but the problem remains that the Internet is inaccessible to the majority who may be inclined to use it." *The Philippines*: "Yes." *Indonesia*: "Yes." *Malaysia*: "Absolutely. The Malaysian Prime Minister has been strongly behind efforts to make the use of the Internet a success in the country. Malaysia has also embarked on an online Continuing Medical Education programme." *Japan*: The first reaction tends to be protectionism from outsiders, knowing that Westerners are more advanced in online education, so foreign institutions are denied accreditation or recognition in a credentialistic society. What Japanese can accomplish among themselves profitably is fine. Authorities and purists do not want intercultural relations to get out of control, but for now the language barrier provides enough protection.

4a. Are there virtual universities or other virtual schools?

Latin America: "Yes." *Brazil*: "Yes, for example Escola do Futuro, Universidade de Sao Paolo at URL www.futuro.usp.br/mapa/mapadosite.htm or the Post-graduate program in Information and Education at Universidade Federal do Rio Grande do Sul: www.pgie.ufrgs.br." *Finland*: "Yes, a Finnish Virtual University is starting as a framework for providing on-line courses and support services: www.virtuaaliyliopisto.fi." *Israel*: "Altogether e-learning and computer-enhanced learning is viewed positively." *Turkey*: "There aren't any virtual universities. Only some universities use virtual education for some courses. For example, there is a virtual education centre at in Bogazici University at www.tekmer.boun.edu.tr/sem.htm, an education project in virtual environments at Istanbul Technical University at http://www.saneg.itu.edu.tr/sanalegitim/turk/proje/amac/amac _ana.htm, an Internet-based education program at Middle East Technical University at http://idea.metu.edu.tr/, and a virtual campus of Anadolu university at http://bde.anadolu.edu.tr/sanalkampus/webct.html. I implement my courses from the Firat University Virtual Learning Environment which I developed, at http://fuvle.firat.edu.tr and http://fuvle.firat.edu.tr. Also, there is an Internet committee in Turkey at http://kurul.ubak.gov.tr/." *Russia*: "Among governmental institutes there are some that have some support for experimental development of distance education technologies. Private universities are working actively and have noticeable results. The largest and the most prominent Russian university working in distance education is the Modern University for Humanity (MUH). It has 100,000 students all over Russia and even abroad. Educational programs are delivered via satellite transmission. They produce more than 500 educational videos a year, have an electronic library, excellent computer classes, hundreds of affiliates, and their own original system of electronic testing. They get the best educators involved and record their lectures. Their sites www.muh.ru and www.video.muh.ru have English versions." *India*: "Yes, like IGNOU's Virtual Campus Initiative, Tamil Virtual University, NIIT's virtual university, Punjab Technical University online, and many more." *Kenya*: "Yes." *South Africa*: "Yes, quite a few universities locally are taking their courses online. Also a few private institutions are setting up online courses, e.g., www.elearn.co.za. Distance education, which has always been popular in our country, is definitely moving online fast." *Southern African region*: "This is a new phenomenon just gaining ground, but not commonly known even among educational institutions." *The Philippines*: " Yes, but I do not know them and they are not actually popular here." *Indonesia*: "No." *Malaysia*: "Yes, UNITAR: www.unitar.edu.my. And most public universities have incorporated elements of virtual learning to complement the traditional face-to-face classroom." *Japan*: The established universities can have virtual programs covering up to half their credits, but there are not yet any wholly virtual universities that are accredited.

4b. If so, are they accredited or recognized, or considered notorious?

Latin America: "Yes, ITESM is the most visible example" [a virtual university based at the Technical University of Monterrey]. *Mexico*: "No, they are not recognized; they give their own degrees." *Brazil*: "They work together with private high schools." *Russia*: "The problem of recognition is understood and there are well defined quality criteria for distance education." *India*: "IGNOU has a Memo of Understanding with Edexcel foundation of UK, NIIT has a strong reputation in the global industry with many branches abroad also. So many are accepted and recognised by suitable authorities." *Kenya*: "Highly recognised." *South Africa*: "They are accredited with our accreditation authority SAQA www.saqa.org.za and some of the courses have international accreditation." *Southern African region*: "In some countries of the Southern region there has been an infiltration of such virtual institutions from America and Australia, and have become issues of Cabinet debates in Parliament as to whether or not to recognize them." *The Philippines*: "They are not yet accredited. The Commission on Higher Education is planning to come up with an evaluation instrument intended for ODL [Open and Distance Learning] institutions, [not yet encompassing] totally virtual universities." *Malaysia*: "Accredited by the National Accreditation Board." *Japan*: Since wholly virtual programs are not recognized, for-profit online programs could be considered notorious to look for customers in Japan. But if accredited domestic universities provide online programs, they are recognized.

4c. Have many people considered studying at institutions in other countries through the Internet?

Latin America: "No, language and costs are a barrier." *Israel*: "Yes, and quite a few get degrees through distance learning (not necessarily through the Internet)." *Russia*: "Not so many, because Russian salaries are so low that only a small proportion of the population could pay for that kind of education. There is no currency problem, as the country is saturated with currency exchange kiosks. The main problem is that a Russian salary converted into hard currency is 5–20 times lower than the salary for an equivalent job in developed countries. For many students not only knowledge, but also a formal diploma is of great importance. Free education online cannot provide a solid diploma, but to receive a foreign diploma one must spend a huge sum of money as compared with the average salary. And the language barrier is also a serious obstacle." *India*: "Yes, for some online certificate courses like those for corporations like Microsoft and Oracle, but not yet for traditional courses." *Kenya*: "Not many, but there is a gradual increase in interest." *South Africa*: "Yes, I am currently helping some students with courses from an Australian online institution." *Southern African region*: "People may have such dreams, but the reality is that not many people even in institutions of higher learning have sufficient provision of computers on their campuses, while it may be a mirage for individuals to have personal computers at home with Internet connectivity. This has implications for the awareness level and socio-economic development." *The Philippines*: "Yes, however it is so expensive." *Indonesia*: "Yes." *Malaysia*: "There is still some hesitation in this area, but foreign universities with online distance learning programmes have recorded the participation of Malaysian students." *Japan*: There have been advertizements in national publications especially for online MBAs that some working people would consider as an alternative to studying abroad.

4d. Are there many local companies going into the e-learning business?

Latin America: "Yes." *Mexico*: "There are few, and we are one of them." *Argentina*: "Business companies may be more aware of the advantages of the web. There is a bit of a movement for English language acquisition due to the need for English for job applications, living abroad, and computer literacy." *Brazil*: "Yes, several, including IBM in Brazil." *Finland*: "There are some." *Israel*: "Not [many]." *Turkey*: "Many companies are going into the e-learning business. Some of them are going into institutional e-learning solutions such as Humanitas at www.humanitas.com.tr/sem.htm." *Russia*: "There are some, primarily dealers of foreign software companies, that advertise online education technologies. Many successful young businesspersons are selling the best foreign products, including computer hardware and software. Most of them do not work for affiliates of foreign companies, but have trade contracts with foreign suppliers." *India*: "Yes, one example is NIIT (National Institute of Information Technology)." *Kenya*: "Yes." *South Africa*: "Yes, but they are quite expensive and not all that user friendly, in my view as a teacher." *Southern African region*: "Not that I know of around here [Lesotho]." *The Philippines*: "Only a few." *Indonesia*: "Yes." *Malaysia*: "Yes for multi-national corporations mainly, for whom e-Learning businesses span from primary education to university and even professional courses. But the 70% of the workforce in small to medium enterprises lacks the capital and expertise to invest in e-learning training solutions." *Japan*: Yes, the big electronics companies and some entrepreneurs, although the dotcom boom has fizzled for the time being.

4e. Are there academic associations working on the professional development of online educators?

Latin America: "Yes, there are regional and national associations promoting it." *Mexico*: "Mostly this work is done within each institution." *Brazil*: "Yes, see the Associacao Brasileira de Educacao a Distancia: www.abed.org.br." *Finland*: "Yes. For example there is a national ICT Teacher Training Project OPE.FI: www.edu.fi/koulutus/opefi/english.htm." *India*: "Yes, such as the Indian Association for Online Education, whose chief architect is Dr. Sanjaya Mishra." *South Africa*: "What online educators? I am currently struggling to get teachers to use the Internet as an educational resource; teaching them to 'educate online' would present major difficulties." *Southern African region*: "Few if any at all." *Indonesia*: "Yes." *Malaysia*: "Not clearly defined. Online educators still very much remain affiliated to academic associations related to their respective disciplines." *Japan*: Educational organizations concerned with distance learning or computer-assisted language learning have changed their agendas with the advent of the Net, while the government maintains a window to the academic and business aspects of e-learning with the Advanced Learning Infrastructure Consortium: www.alic.gr.jp/eng/index.htm.

5a. Is the infrastructure for web access an obstacle for most people or not?

Latin America: "Basic literacy, infrastructure, communication costs and computer literacy are obstacles for the population." *Mexico*: "Yes, because in Mexico only 3.36% of the population have access to the Internet, but this number is growing." *Brazil*: "Yes, at our federal university, students have free access to only 8 computers." *Finland*: "In a very few cases; usually not." *Israel*: "For some, but not for most." *Turkey*: "the infrastructure for web access for most people is not enough. There are a lot of cyber cafes in Turkey. Most people access the Internet from there." *Russia*: "In big cities access is affordable, but rather expensive for regular use in distance education." *India*: "Yes, outside of institutions, slow telephone lines hinder web access. In some areas availability of an ISP or telephone infrastructure may be a barrier." *Kenya*: "It is an obstacle considering the fee levied which is generally not affordable to many people." *South Africa*: "Emphatically yes. The highest speed our national phone line provider allows us is ±28bps, and if you want faster access, ISDN is quite costly to set up. Leased lines are very expensive and out of reach for even advantaged teachers and students. Only larger businesses (25 or more pc's) can afford leased lines." *Southern African region*: "Certainly yes." *Indonesia*: "Yes, it is an obstacle, but also computer literacy and computer culture." *Malaysia*: "Sadly, this is true." Japan: No, access is hardly an issue anymore. Computers, mobile phones, PDAs, game consoles and an increasing number of appliances are becoming Net-enabled.

5b. What are the main obstacles to acceptance or use of the Internet for education?

Latin America: "Access is number one." *Mexico*: "Training, independent learning skills, and cultural perceptions." *Argentina*: "With the rise of the dollar (4 times our "peso" in a few months), computers have become a luxurious tool at the moment. Yet, only three years ago very few people had an e-mail address, while now almost everybody does, which is a step forward." *Brazil*: "Access. Many of our students come from humble families." *Finland*: "Lack of knowledge about technological possibilities for helping learning, learner-centered pedagogy, and lack of good software." *Israel*: "Many difficulties, dilemmas and paradoxes—lack of time, partial replacement of teaching/learning processes, costs, etc." *Russia*: "Low quality of telephone communications and high price for Internet access as compared with the average salary level." *India:* "Ignorance!" *Kenya*: "The cost of equipment, its maintenance and servicing." *South Africa*: "Access costs, infrastructure, poverty, and ignorance of what the Internet has to offer for education." *Southern African region*: "Dearth of infrastructure, financial problems, scarcity of telephone lines, and inadequate supply of electricity to many houses, districts, and villages where people live or work." *The Philippines*: "The Internet is already being used, but expensive infrastructure and all the equipment needed is an obstacle." *Indonesia*: "Computer literacy and computer culture, privacy of information and information rights, and ownership." *Malaysia*: "Cost of access and infrastructure." *Japan*: To change the status quo is usually difficult, and there needs to be much more awareness by the general public of the opportunities for education and self-improvement made possible by the Internet. Beyond educational activities among Japanese people exclusively, there is still great cultural insularity and the language barrier when it comes to the outside world.

5c. Are there any other global or local issues that affect the acceptance of online education or the use of virtual learning environments in your region or country?

Latin America: "Communication costs are very high in Latin American countries; technology is more expensive than in the U.S., and much of it is obsolete." *Brazil*: "In big cities with high demographic density there are non-governmental organizations interacting with young people in the "favelas" and spreading basic computer use. The government intended to connect all public high schools by computer, but the funds were redirected to the electric company to prevent blackouts." *Finland*: "Commercial education is not an option for Finland, so the fear of having payments for the courses could be one issue. Another is that virtual learning takes time from other traditional learning activities, so there are worries about the quality of the content." *Israel*: "Yes, the academic culture in each national setting." *Russia*: "There are strict traditions in the educational system and opposition of old teachers to new technologies. Computer classrooms in many schools have obsolete equipment, such as old PCs without Internet access. There is also a lack of interest in short online courses or events, which have not yet proven their effectiveness in Russia. An exception is online courses to receive professional certificates from foreign companies, such as Microsoft. These courses provide a quick return on investment: they are very short and the gain in salary after taking them is very high. Maybe it will be the main direction of online education development in Russia, while the salary gap between a certified professional and an ordinary worker remains at a level of 5:1. How much gain in salary and how quickly may be the main criterion for Russian users to select a particular course. Finally, there are difficulties in organizing a complete distance educational system granting professional diplomas." *India*: "Yes, awareness and access seem to be among the other reasons." *Kenya*: "Cultural tendencies and attitudes." *South Africa*: "We currently have a severe food shortage in the region as well as high HIV/AIDS infection rates. Online education becomes a luxury when seen in the light of the suffering and food shortages experienced by a vast number in the Southern African region. Basic education itself is in crisis and very many schools do not even have electricity and books." *Southern African region*: "Ignorance, low level of awareness, apathy, and insufficient funds." *The Philippines*: "Older people are unable to use it and are very resistant to [acquiring] knowledge of the use of ICT. They argue that nothing can really equal the value of face-to-face instruction, and that a personal human touch better encourages study, whereas the younger generation is embracing the challenges and maximizing the use of ICT." *Indonesia*: "National issues: infrastructure is expensive, therefore access is low and difficult, while the users are computer illiterate, and technical expertise is rare." *Malaysia*: "The major challenge would be having enough quality online educators who can develop good online courses that offer the kind of support that Asian students look for." *Japan*: On the one hand, mental attitudes in a traditional culture with elaborate face-to-face rituals raise many barriers. Living in a social world where relationships are all important, new commitments are problematical because they incur heavy obligations. On the other hand, the dynamics of the Internet itself will attract Japanese people and allow them to browse world cultures from a safe distance. The Net-connected screen may thus provide a 21st century version of the traditional hand-held fan or folding screen, buying the time necessary, uncommitted and free, to consider becoming more involved in the outside world.

Chapter 29: Global Virtual Organizations for Online Educator Empowerment

NICK BOWSKILL*, ROBERT LUKE†, AND STEVE McCARTY‡
**University of Sheffield, England;* †*University of Toronto, Canada;* ‡*Kagawa JC, Japan*

1. INTRODUCTION

The authors of this text have never met. We live in different continents and different time zones. We do however share the same space and the same organization for at least some of our professional development. We are all members of the World Association for Online Education (WAOE), which is a virtual and voluntary organization for those interested in online education. Entirely virtual organizations represent a significant new form of social organization. The world community of scholars with shared academic standards and ethics is well poised to utilize the online medium for mutual empowerment and relevant social action in the so-called real world that originates, organizes and builds strength in cyberspace. So as a virtual organization and professional development vehicle for educators, WAOE itself can also be understood as a virtual learning environment (VLE).

In this text, we conceptualize the WAOE as a VLE not in the sense of another WebCT or Blackboard (or similar software system), but rather as a perceptual home for learning in virtual spaces. The organization is an online venue for global all-comers who share similar values and interests in professional development and online education. As such the software used is not the central issue. By providing activities, events and resources within the online community we become a VLE in the manner of a floating venue for globally accessible interaction, offering learning opportunities for all. We thereby extend and re-conceptualize the more traditional understanding of VLE as based on a set of tools into a conceptual and cognitive apparatus. This re-visioning fits more tightly with the ideas of empowerment that we explore in more detail below.

Two leitmotifs run through this discussion. One is about the concept of transfer into self and the other is about informal learning as a vehicle for professional development. Taken together, we believe there are interesting messages for the empowerment of individuals and groups within communities of practice. We will discuss this goal of transfer into self as a holistic and constructivist goal and as an idea that marks a contrast to the more popular goal of transfer into practice. Our discussion of transfer to self *vis-à-vis* transfer to practice is intended to elucidate how online communities of practice can function in a distributed environment such as WAOE to empower participants.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 789–819.

This chapter also stresses the importance of informal learning in contrast to, yet in conjunction with formal learning processes. After highlighting the significance of informal learning, we will move on to talk about how this kind of method can be supported, and discuss some of the mechanisms for both individual educator and group development. The method used to develop the case study was the development of a rich description of our collaborative activity accompanied by autobiographical accounts of those involved. These accounts help toward any wish to assess the validity of the particular case study and also function as a reflective and developmental apparatus. We use our own collaborative experience within a voluntary online community as a case study of these ideas being put into practice. The aim is to convey this framework as an architecture for empowerment and as a form of distributed learning. Defined as that learning which is distributed in time and space and enabled by new technologies (such as VLEs), distributed learning is a particular catchphrase for learning within the networked relations of the digital world. Distributed learning may be formal or informal; it is marked by the "any time, any place" ubiquity afforded by the internet and the World Wide Web, and the manner in which people engage and interact in learning activities both locally and globally. The WAOE functions as a distributed learning environment—a VLE in support of learning about learning and learning about learning online.

We begin with a brief discussion of the transfer of experiences into learning whereby experience is made personally meaningful. This has much to do with the identity of the learner. We use the term "Transfer into Self" in opposition to the more current and popular learning goal of transfer into practice. We advocate a focus on transfer into the self for a number of reasons. The first of these has to do with the changes in the world that many of us experience first hand. These changes are external changes over which we often have little control. Economic changes and altered career prospects have an enormous impact upon individual lives. Likewise, political and technological environments are equally volatile, and in such circumstances our sense of identity is vulnerable to disruption. To invest in a focus upon practice is fine and has value, but it should not be the primary focus of learning. If you no longer have a job or a practice in a month or a year's time, the focus of development needs to be intrinsic to the self.

Another reason for looking beyond transfer into practice is the implicit behaviorist or instrumentalist view this takes of learning and knowledge. How we practice is a manifestation of what we think and know, but the rationale for that practice may be hidden from view. In addition, our practice is different according to context, so to view only the practice is too situated a position from which to make generalizations. A focus on the transfer into the self is much more portable and humanistic in the context of concepts such as lifelong learning and holistic development. We will make the case for transfer into self and show how this might be achieved through writing processes and autonomous approaches to professional development within online communities. This will be considered in our own context of collaboration *within* a community of practice. We offer this as a model for empowerment.

We are concerned with the development of individual and collective autonomy/autonomies and therefore attach importance to mutual support and informal learning development. The value of informal learning beyond or together with formal learning will be more evident in this context. We believe that each strategy offers unique resources and learning opportunities. We describe our own informal learning activities that are supported and sustained within a voluntary virtual learning community that provides global access to professional development activities. This particular community, the WAOE, is a collaborative initiative offering a range of events, activities and resources for members to access independently at any time or to utilize together at scheduled events.

The WAOE encourages, and thereby hopefully empowers people across the world to participate and to shape the activities and development of the community. We will describe the range of such activities to give a flavor of this infrastructure for collective empowerment and also go on to talk about one particular shared event. This event will serve to illustrate the use of the community to identify common interests and to co-construct a learning project to address those interests in an equitable relationship with benefits for all. This example illustrates how autonomy and power relationships can be addressed and developed outside formal educational systems. We believe that although there are clearly times when formal learning plays a vital role in learning and development, formal systems can also be an inhibitor to learning. A simple example would be when a casual conversation with a colleague or friend results in some valuable but unplanned learning. One of the conversational participants observes that such conversations are too few and therefore proposes another meeting on a set date at a set time. When that appointment comes around, it is quite possible that one or other of the participants is not ready for an in-depth discussion or has forgotten the origins of the initial idea. The formalizing of the casual conversation has killed the learning in this instance. When shared concerns are housed within systems that need to follow schedules and external criteria as well as also needing to work within course structures and designs, they can be barriers to learning. Such an environment can add psychological noise to learning projects. Informal learning, at its most effective, can offer a low noise environment conducive to exploration, discussion, and creative learning. We will illustrate this with our own case study drawn from our shared experiences.

Learning communities like WAOE can be part of a vital and valuable informal learning support framework. They can support top down and bottom up ideas and projects and they can support a move along the axis of development from dependency to autonomy. For some participants, it is enough to be a vicarious learner acting as a learning audience in discussions and events. For others, they may participate in some events more actively, and for yet others it offers an opportunity to identify needs and interests, to collaborate with others to design and deliver events for others in the community. We will give an example of this from within the WAOE. This community-based environment is one way of supporting informal learning.

Another method for the support of informal learning is to intermittently crystallize understandings into a communicable form. This means to be able to externalize tacit knowledge and it also means to crystallize and share understandings amongst a wider audience. We will show how this is done within the WAOE community through shared autobiographical reflections upon learning events constructed amongst members. This is elaborated in published writing that explores and refines initial understandings into conceptual frameworks that support further research and development in the community. We have already published some initial work reporting on our learning activity elsewhere (see Bowskill et al., 2000) and here we reflect on that in greater depth and begin to theorize around that initial work together. These different approaches to the use of writing are a by-product and further evidence of informal learning. It is also a very empowering approach, both individually and collectively, in the way it feeds into other areas of professional activities.

We begin with a very brief overview of the WAOE as the heart of our own informal learning environment before moving on to explore more general issues in informal learning. We will give a wider historical view of the organization later as a means of conceptualizing our case study of empowerment. Following the section on informal learning, we look at issues of support. We consider support and development beyond formal education systems. The community model is used to show the empowerment opportunities for global participants who may have no access, money or qualifications to participate in formalized arenas.

1.1. Overview of the WAOE

The WAOE is a non-profit public benefit corporation registered in the state of California, but its membership spans five continents without being dominated by any geographical region. The WAOE is chiefly a virtual association serving the needs of academics and educators concerned with turning online education into a professional discipline. The WAOE focuses on combining dedication to online learning with social and cultural exchange. The objectives and purposes of the WAOE explicitly promote humanistic ethics and global collaboration in online education, specifically:

(i) to maintain a global perspective as a world organization, supporting multilingualism and multiculturalism in online education, preserving human rights to diversity and mutual respect despite differences, and encouraging intercultural sensitivity and world reconciliation through intercultural communication among global citizens;

(ii) to be as inclusive as possible in scope, serving the aspirations of all members and working for equitable access to online education and to membership.

For more information see: http://www.waoe.org/npo/bylaw.htm.

WAOE is an informal learning environment, a space where its members can collaborate, learn from each other, and engage in meaningful dialogue across cultures on the nature of learning, learning online, and of online culture in general. Educators have a special responsibility to acknowledge and analyze how "cultural practices relate to future vision[s] of community life" (Giroux, 1992: 239). Undertaking this analysis in practice means cultivating critical communities of practice that have common goals and respect for difference. WAOE represents a critical step toward acknowledging how active participation in the networked society can create meaningful conditions for cultural difference and diversity to be celebrated and incorporated within the logic of the digital era. This active participation includes the exploration of how the self relates to broader practices within online education, and the further refraction of this within broader communities of practice.

The WAOE originated appropriately at an entirely online conference (McCarty, 1997; Shimabukuro, 2000). At the First Annual Teaching in the Community Colleges Online Conference in April 1996, McCarty contributed a "paper" to the conference Website, exchanged asynchronous e-mail discussion list messages automatically posted to web archives *via* hypernews, and joined other presenters not only in synchronous MOO (Multiuser chat rooms utilizing Object-Oriented programming) sessions to discuss papers, but also in "digging" one's own Webbed MOO room accessible either by chat programs or *via* a web interface. In such text chat, descriptions of the environment and a repertoire of communication gambits rely mostly on the imagination of literate participants to share a virtual reality in the VLE. To the extent that participants took advantage of opportunities to interact with one another at a distance through such communication tools, evaluations showed that little was left to be desired compared to face-to-face conferences. Such online conferences were open to all kinds of educators, especially those outside of North America, with the access, content, and educational technologies all empowering to participants.

So then, with such tools available, why not try to network with educators globally all year round? The keynote address of the Third Annual Teaching in the Community Colleges Online Conference (McCarty, 1998) proposed the need for an organization to turn the new frontier of online education into a professional discipline. Online conference discussions continued for months until an independent, almost completely online organization was born, the WAOE. Through an Estonian organization the www.waoe.org domain was registered, and a professor in California's capital registered the WAOE as an NPO. However, the location of web servers makes little difference, and NPO status turned out to involve no tax savings but to represent the WAOE's idealism. An e-democracy from the start, the founding principles, then Bylaws and Directors were voted upon entirely online with impartial procedures supervised by a Cyber-Parliamentarian.

WAOE was announced in November 1998 and quickly approached 1000 participants from 50 countries, showing that a need had indeed been met". [O]fficers hail from nine countries thus far, so WAOE is not dominated by any geographical region. WAOE is open to all those who are committed to pedagogical principles and interested in networking with other online educators worldwide (McCarty, 1999). Wandering from list to list, Website to Website, like so many nomadic masterless samurai, what online educators have been missing is a real organization".

That WAOE has shown sustainability belies the notion in business circles that a virtual organization is *ad hoc* and temporary. Communities of practice such as WAOE are organic wellsprings of like-minded people engaged in learning together. Though people do not meet face-to-face, a virtual organization like WAOE using all sorts of electronic means of communication to bring people together for information exchange, mutual support, and collaboration in a new field demonstrably serves real needs.

It is human nature to shy away from trying something new, and educators are no less susceptible to technophobia. So WAOE has made conscious efforts to use the widest range of VLEs. WAOE officers have also expected to field questions about the options available or comparisons thereof. Even the legitimacy or motives of VLE vendors and purveyors of experiences therein have been at issue. So WAOE officers have had to be particularly bold and take every opportunity such as executive meetings to try mastering yet another VLE.

e-mail discussion lists have provided a sort of environment for WAOE communications and, archived on the WWW, have left a trail of WAOE's proceedings. During and after the TCC Online Conference, from April to October 1998, 320 messages still available at the University of Hawaii at URL http://leahi.kcc.hawaii.edu/org/tcon98/discuss/keyone-l/ show how WAOE was incubated by the conference registrants. Within weeks of the conference *per se* a moderated news list for the nascent organization was secured at the University of Idaho, with 71 messages from April 1998 to June 1999, recording milestones still available at URL: http://www.uidaho.edu/list-archives/waoe-news/. In July 1998, the unmoderated discussion list WAOE Views, open to anyone interested, was established and continues to this day with over 2500 messages as of September 2002 available at URL: http://groups.yahoo.com/group/waoe-views/.

While the Views discussion list has been archived through Yahoo Groups, the listserv has actually been based at WAOE's ISPs. In terms of environments, the new organization needed a (virtual) home, especially with no particular office in so-called real life. About a month after the online conference, in early

May 1998, Mihkel Pilv in Estonia registered the domain name www.waoe.org and found an economical ISP in the U.S. Among the Charter Members and a Steering Committee that gathered, some of the latter started developing the Website to give the group a permanent central residence in cyberspace.

Other VLEs were nevertheless utilized as the ISP could not serve all the kinds of communication called for by WAOE activities. An unconventional Constitutional Convention was convened at a bulletin board system in Connecticut. There was also a cgi form with which to respond to messages from one's browser. Already a pattern was emerging of leveraging the skills and institutional resources of active members' institutions rather than waiting for grants or other types of funding. Also in May 1998, the WAOE-affiliated Journal of Online Education was established at New York University, available at URL http://www.nyu.edu/classes/keefer/waoe/waoej.html.

In June 1998, Prof. Jenna Seehafer of California State University started incorporating WAOE in Sacramento as an NPO, after intense discussions on what kind of organization WAOE should be. In August 1998, Charter Members voted to approve WAOE Founding Propositions and the first slate of elected Directors, with a view to establishing formal Bylaws. A cyberspace equivalent of non-partisan face-to-face parliamentary procedures was developed to hold all voting and elections online, through web forms feeding into confirming e-mail messages, conducted by disinterested scholars. The State of California Attorney General's office readily accepted the WAOE Bylaws despite all the Directors being in different countries, never meeting in person as is customary for NPO proceedings. Rather the State was watching WAOE with a view to future online elections.

American facilities were conspicuous at the beginning, with Westerners providing most of the VLEs, but always sensitive to the international membership. A wholly positive form of globalization has been evidenced in the way Westerners have often stayed behind the scenes, amplifying non-Western voices and encouraging their ownership of the organization, which has manifested in a balanced geographical and cultural composition of the officers. WAOE-commissioned Websites in an increasing number of countries lent a palpable sense of a deliberately distributed organization actively avoiding centralization in any geographical region or cultural norm. The intent of the W in WAOE was to start from that goal.

In 1999, the Multilingual WAOE project was launched, strengthening the commitment to multiculturalism. A number of cultural events were also planned from that year so that members worldwide could learn from one another and exhibit cultural diversity while enjoying their shared interest in online education. The WAOE World Culture Festival in February 1999 utilized an array of VLEs, with synchronous chats and WebBoard events along with asynchronous e-mail discussions. Web-based presentations with photos captured festivals taking place at that time of the year from Balkans to Brazil. In July 1999, WAOE collaborated with the Child Research Net on Summer

Festivals in Japan, discussions accompanying a web presentation. At the end of 1999, New Year's greetings for the year 2000 were compiled in 20 languages with photos of Brazil and an interactive game by Prof. Roberto Mueller.

WAOE's affiliations have followed a similar pattern, promoting online educational efforts in Latin America and Malaysia as well as the U.S. and Japan. While some founding members had donated funds to start WAOE's online presence, dues were deemed necessary from mid-1999. But paying the U.S. $10 yearly figure online was problematical especially for those using other currencies, so there was a significant loss of participation. Within a year WAOE found modest sponsorship through officers' services to a Tokyo educational NPO, so in mid-2000 WAOE abolished dues and returned to its desired ideal of access for all concerned with the improvement of online learning. All along WAOE maintained a dual mission of serving international society as well as serving members, so there was always free access to WAOE's information and the public discussion list Views.

Prof. Jenna Seehafer conceived of the mid-1999 Annual Members' Meeting in the form of a web tutorial, where members could follow a certain sequence of steps, and visitors could learn about the organization in that way from then on. Remaining valid so long as WAOE needed membership dues, the tutorial format intuitively appealed to the human need for an orientating structure to navigate the complex labyrinth of cyberspace with a sense of situatedness.

1.2. Informal & Formal Learning

> "The existence, significance and necessity of informal learning needs to be more widely acknowledged by policy makers, practitioners, employers and researchers."
>
> (Coffield, 2000: 8)

Common conceptions of the WWW as an educational setting are largely predicated on the formal, directed use of technology. However, informal aspects of learning often go unacknowledged within formal educational settings (Apple, 1990; Cherryholmes, 1988; Giroux, 1983, 1988, 1996, 2000). Informal learning is important in itself; important in the way it is connected to formal provision; it is important within a course and institutional context and also within a wider community context. This section will explain these positions in more detail and consider issues about recognizing the significance of informal development through the provision of appropriate support. It will lead into a discussion of WAOE as an open learning environment.

We begin by looking at informal learning in contrast to stereotypical models of formal learning provided by Eraut. A brief overview of the literature shows the difficulty in trying to define informal learning. For some, it is defined in contrast to formal learning. The list below is a re-phrasing of one view of

Table 1. Overview of the relationship between formal and informal learning

	Formal	**Informal**
Percentage of all learning (Masie, 2002 cited on Managers Forum)		50–70%
In an average week (Livingstone, 1999 in Long, 2001: 18)		15 hours per week
In first 3 months of starting employment in a company (Bishop, 1991 in Long, 2001: 18)	8%	92%

formal learning (Eraut, 2000: 12) available as a basis for considering all that sits outside or in contrast to such a model:

- Set learning environment.
- Organized events or packages.
- Presence of teacher or trainer.
- Accredited.
- Someone else's outcomes.

If we use this model to construct an initial definition of informal learning this may help us understand the relationship between and use of the two modes. There are some interesting statistics in the literature that indicate the relationship between the two ends of the range. The table (Table 1: Derived from Long, 2001) below gives an overview of the use of formal and informal learning from different studies in the literature.

The key point that emerges here is that although formal learning may be very important in providing opportunities and space to develop learning and to seek accreditation for instance, it plays a comparatively small part in the totality of our learning. Whether we look at this based on an average week, the initial stages of new employment or across a lifetime, the message is the same. Informal learning is the major part of our learning activities and yet receives much less recognition and much less support. Part of this lack of support has to do with the obvious difficulty in pinpointing how to offer support and what kinds of support might be most useful. There is a need to make a rich enough provision to address different levels of need and different areas of interest.

Learning may begin with a discussion at the informal end of the range and move through to registering for a course. Informal learning may sit alone or as part of a progression toward participation in more formal provision. People may also be at certain points in this range and have no need to move from those positions. Informal learners may feel they can address all their needs this way, and likewise a formal course may be all that is required to resolve a problem. Our argument here is that one of the best ways that a learning community can support informal learning amongst its members is by facilitating discussion amongst its members. Beyond this, learning communities can more usefully facilitate focused discussions on the particular needs and interests of collaborating members.

The uses of casual conversational opportunities are important within this range, hence the highlighting of discussions in the table. Rowland (1993) talks about the potential of such discussions as learning conversations. These are both timely and sense-making opportunities when they are available. This issue about availability is key for thinking about the provision of support for informal learning. Smith (1999: 12) mentions a need to offer "a range of accessible and useable opportunities for self-education" as a guide for such support. In what follows, we begin with a possible scenario in which institutional support is provided for informal learning. This is partly drawn from practice, but the main reason for offering this is to relate a vision of how support for informal learning might be developed and implemented. Support for informal learning needs to look beyond accessibility issues toward issues of self-management and support for greater control. Learners might define their own needs and address them in different ways using different resources.

In his discussion of self-managed learning, Cunningham (1994) relates different scenarios wherein a learner calls upon a community to support personal learning goals and uses a course to provide a framework in which to learn within a course community. This description indicates ways in which support for personal concerns can be drawn from fellow learners and community members as well as from tutors, etc. Smith and Cunningham share a view of the significance of discussions and community support as vital to the development of informal learning. Indeed, we hold the facilitation of focused discussions and the value and role of a learning community to be vital issues in the support of informal learning. We therefore hold these issues in the foreground of this text as we seek to explain and explore the value of informal learning in our own context.

Smith talks about accessibility to learning opportunities. Boud (1981) on the other hand highlights the role of a learning community as available support. Boud (1981) goes on to discuss the goal of supporting and developing autonomy. He defines autonomy as learners becoming their "own person in context with others" and Cunningham's self-managed learning is referring to self-directedness within a mutually supportive wider group context. The missing link is the development of a recognition in the learner of the potential implicitly available within an online community and the factors that contribute toward the development of awareness in the learner. It is not enough to suggest this potential to the learner. Much of it comes from experience but it the kinds of experiences and the support provided can also be influential.

Boud and Cunningham discuss their theories in the context of a course-based model. It is our contention that this is entirely reasonable but that perhaps the real test of self-management and autonomy is within a more open setting. This is important in a lifelong learning context. In a networked world, learners are afforded and demand a wider view of the possibilities for development. The boundaries for interaction are not imposed at the edge of the campus for example. It is possible to associate and collaborate with highly distributed people with shared interests. The form of collaboration is also flexible in terms of time and purpose. Local provision may also be inadequate for addressing the needs of particular people and expertise may be more limited in its availability. Jobs and careers may also be more prone to fracture and professional development needs may span different contexts. A new perception of learning communities as sustainable meeting places for professional development activities is required. This may already be partly in place but we suggest a need for such communities to look beyond being context providers and toward becoming informal project centers is more useful.

So far, we have looked at a sampling of the literature that makes extensive reference to course-based informal learning and we have outlined an institutional scenario of informal learning and support. In a networked world, the sources of informal learning may be internal and external and with those possibilities in mind we turn now to look at online voluntary communities as another extension of that informal support. These communities are a valuable source of resources, knowledge, and most importantly, dialogue opportunities. When local informal opportunities are exhausted or unavailable or inappropriate the value of such communities is high. Such communities are part of the bridge between informal development and formal development and they also extend the resources and accessibility of them for informal learners. The role of these communities as part of the informal support system becomes much clearer in this model and its accessibility provides an alternative and/or complementary learning arena.

To connect the social setting of the online community with the individual interacting within the community we are interested in the role of autobiographical accounts. Such accounts contribute toward the individual and collective knowledge management task. In the following section, we look at the issue of capturing knowledge and supporting reflection on experience. We will show how this can be done at an individual and a group level through the use of autobiographical writing and research.

1.3. Autobiographical Research

The use and validity of autobiographical research methods are becoming more widely valued and accepted (Dhunpath, 2000; Merrill, 2002) but what are these methods? Perhaps, we should begin by saying that autobiographical methods, used for research purposes, are quite distinct from the use of autobiographical writing as a general contribution to literature (Griffiths, 1994). In the research community they have a specific purpose and, broadly speaking, that is to understand the meaning of experience(s).

There are similar but distinct variations within this area of research methods that include life histories, biographical research, narrative inquiry, and more. There are differences between these methods and implications resulting from the selection of any one. It is not our purpose to explore the different flavors and distinctions between them, but for those interested we would point to a useful overview provided by Dhunpath (2000). Here our purpose is to explain and argue for our use of autobiography as both a personal and collective professional development and research method.

The use of narrative forms of inquiry offers the author and reader "the inside story". This means we have a view of the experience as it is understood by those involved. This approach may be more respectful of the individual's views and culture. It may also be a more accurate way of investigating the experience in contrast with a template of questions given to each participant. This is in contrast to the more interpretative view of a given researcher as an outsider to the actions and thinking processes involved. This method is distinct in its narrative form having an explanatory role for the self and others. Oral history is a related methodology, and interviews are sometimes involved in the capturing of the story, but such methods have other implications for control, publication, and development. The written form is particularly significant in this kind of approach. It is therefore quite distinct from oral traditions, for example, although it has much in common with other forms of self-explanation in general as a communicative act. Autobiographical approaches bestow some control upon the subject and may thereby help to overcome the feeling of being perceived as a data mine for other people's research.

These strategies can be positioned within an action research framework to form part of an overall development process that may include other strategies in the study. We believe that the use of autobiographical methods within an action research approach offers the best chance for the development of a voice for all concerned (Winter, 1998). In the following section, we position such strategies alongside other possibilities in order to further explain our reasoning for valuing this method.

Above all we should hold in mind that any approach to research cannot be considered neutral. The researcher in any study comes with an agenda and accordingly frames the data and the research project in a particular way. The researcher is always involved in a selective process, and subjective responses and individual perceptions are as much a part of quantitative strategies as they are in qualitative methods. It is quite likely that two researchers replicating the same experiment will act differently, select differently, perceive significance to be located differently, and will understand or frame the context differently. We would argue that any research strategy has a subjective element, and it is valuable to understand more about the subjective nature of any research. This should go part way to justifying the use of autobiographical methods, but rather than simply defend the use of this strategy, we should perhaps explain some of its benefits and its appeal to us. Moreover, all reports from any study are constructions framed in particular ways for particular needs and with a particular audience in mind. We must not be blinded by the apparent authority of any given research method.

One of the roles of autobiographical approaches is to explain the meaning of phenomena. This approach can show how people subjectively experience institutions, organizations and other phenomena (Gitlin et al., 1992: 32). Equally important in our decision to adopt narrative methods is the unique way that it affords a view of both the individual and the collective in context. More importantly, this kind of approach has particular value in considering the tensions and relationships between the private and the public domains.

> "...the life history approach is probably the only authentic means of understanding how motives and practices reflect the intimate intersection of institutional and individual experience in the postmodern world."
>
> (Dhunpath, 2000)

An authored text is constructed in personal, social, and historical time. Any story created will involve and represent influences from outside—and is therefore colored and influenced by the social context. This situated text is valuable for all concerned in the way that it provides a learning resource for the individual, the group and those beyond.

1.4. Autobiography and Groups

Autobiographies are important and relevant to research on groups and organizations. There are several reasons for this.

They are an expression of a group experience. The author is situated in a group and the discourse of the group. What is written often contains parts of that discourse and is situated within the culture of the group. The narrative becomes what Goodson (1988: 201) refers to as a grounded phenomenon of the totality.

They contribute toward a group identity. Through an awareness of these artifacts the group comes to know its members and a profile of the group emerges. The group is also changed over time by the self-development of the authors along with the addition of new authors and new voices.

They constitute a resource for the group. The collection of autobiographies produces a resource not only for members of the current generation of a given group but also for future generations. The same might be true among groups of an existing generation, for example, across groups in a course.

They construct a memory for the group. The collection of narratives when shared constitutes not only a shared memory of time spent together but they also contribute to the defining of that group at that time. In this respect, the narratives and the significance assigned to them construct a group identity. Giddens (1987) refers to this as the narrative as a cultural resource. Such a resource for researchers represents "a sophisticated stock of interpretive procedures for relating the personal and the social" (Wengraf et al., 2002).

The group acts as an audience for the autobiography. The text is shaped according to a sense of the audience in the author's mind. In this way the group is a significant influence on the author and the narrative. As Merrill (2002) points out, "biography is, therefore, never fully individual." They are a sampling of phenomena at a moment in time that is made public either to the self or to a wider audience.

In addition, the relationship between the personal and social in autobiographical approaches offers a unique window on the dialectical relationship between the two positions. As suggested by Dhunpath (2000), this is a unique opportunity afforded to the researcher as well as to those involved in the study.

1.5. Autobiography and Personal Empowerment

There are different ways in which autobiography can be viewed as empowering and therefore justifying support for further learner development. The list below is not exhaustive and there are more developed lists like this in the literature (see for example Rainwater in Giddens, 1997: 74)

1.5.1. Narratives as Explanation

Autobiographies construct a narrative that does more than simply communicating the past. The author makes a selection from the available pool of personal experience and creates a new story with that sampling process. As part of the process the author is selecting events that have personal significance and gives the selected content new meaning. It is an act involving externalization of those events, communication of them into a narrative form and an explanation. Self-explanation or explanation to others is recognized as a valuable learning experience and method (Chi et al., 1994). Amongst the reasons for this is the requirement to tailor the explanation and the author's current knowledge to the perceived audience. This involves several shifts in perspective and therefore increases the cognitive effort and processing (Dillenbourg & Schneider, 1998). This is an act that gives form to thoughts and experience and shapes them into a communicable form. It therefore involves considerable cognitive effort to conceptualize the thoughts into a sensible form that gives rise to new understandings.

1.5.2. Narratives and Constructivism

In learning, constructivism involves recall of the current understanding that is changed through an encounter with new knowledge that appears not to fit into the person's current schema. This gives rise to cognitive dissonance and through a learning activity the new is assimilated into the old view to extend the original understanding or develop new concepts. The authoring of autobiographical narratives is a similar project. The past is re-visited, de-constructed, and re-assembled to create a new construction with new meaning.

1.5.3. Narrative and Continuous/Lifelong Learning

Through the construction of several narratives authors become aware of themes and interests that emerge from the texts. These interests and themes are available as projects that begin to inform the identity of the author. The self, understood as a reflexive project (Giddens, 1997), is a process over time that uncovers, shapes, and develops identity in a dynamic process. This process is within the author's control despite the numerous influences and demands made upon an individual.

1.5.4. Narrative and the Development of a Voice

Autobiographical writing and research is a means of developing personal views and interests. Through the writing of journals and autobiographical pieces authors develop a voice. Even where the narrative is communicated only to the self, it is a process of establishing one's own interests and emphases. Authors begin to generate a voice for personal change and this will impact upon the groups in which the individual interacts. Especially for those from non-Western countries or less privileged communities, this is an empowering process.

1.5.5. Narratives as Political Acts

The writer can frame a different view attaching his or her own meaning to the phenomenon. This is important if people are to feel that they have a valued role in society and that they have a voice that is heard. The alternative is that people risk becoming dejected or alienated. The system must "connect teachers to the system and society in an activist way, where they can see themselves not just as effects of the context, but as part of the context, contributors to it, and as agents who can and must influence how others perceive, shape, and support their work." (Bascia & Hargreaves, 2000 in Tait, 2002)

By writing in this way, authors take control in a political act that thereby resists dominant discourses and views. Writing privileges personal time over actual time (Rainwater in Giddens, 1997: 77). By taking control in this way, authors create a space for their own voice to be heard.

2. THE WAOE AS A CASE STUDY

In this part of the chapter, we present our own educational involvements as a case study to illustrate one implementation of the theoretical perspectives articulated above. We begin with a view of the organization as a learning community and an Open Source Learning (OSL) environment. We then describe the range of our professional development provision before going from there to present one co-constructed event in some detail. Section 3 will offer a summary and a refinement of theory based on our practice.

2.1. Open Source Learning: The WAOE as a Virtual Learning Environment

WAOE is itself a VLE. Constructed as a network, existing within networked relations, the WAOE is a virtual organization for learning about online education in general. The network, and the networked relations that comprise WAOE's membership, constitute an environment, an information ecology that organically serves the needs of its constituents. Just as distributed computing marshals a vast array of resources to create greater computational power than the sum of its parts, so too does a community of practice like WAOE create educational value by bringing together people from various cultures and institutions. Whereas distributed learning is generally defined as the use of a range of media and technologies to distribute teaching and learning over time and space, WAOE exemplifies learning as distributed within the network itself. WAOE is an environment, an information, or a knowledge ecology wherein the constituents are an amorphous yet coherent whole that is greater than the sum of its parts.

The WAOE is a distributed virtual organization that uses VLEs as a means of communication and interaction. These include WWW courseware technologies (WebBoard, Blackboard), and also basic web pages and e-mail as a means of further communication. WAOE is an open environment, an "OSL" environment distributed globally and connected *via* network relations and a shared concern for online education: "Open Source Learning (OSL), the theory of knowledge sharing and production in both formal and informal settings, typifies how the free availability of information and the sharing of knowledge can benefit communities" (Luke, 2002). OSL is congruent with how Lave and

Wenger construe "learning in terms of participation [that] focuses attention on ways in which it is an evolving, continuously renewed set of relations" (Lave & Wenger, 1991: 50). This participation is marked by a supplementarity that is always situated within a given context, be this personal, community, civic, or otherwise. This "pedagogy of the supplement" (Trifonas, 2000) is contextual, continual, and situated within communities of practice. The iterative, autobiographical approach expounded above is one way for the individual members of WAOE to relate their own personal experience to the broader concerns of the online educational community.

As an OSL environment, WAOE resembles the open source communities that have in common the free sharing of knowledge and information for the public good. Open Source programming is defined by its iterative process. It produces products (programs, software) that are open documents, works-in-progress, that are continually updated and augmented. This additive and iterative process exemplifies the manner in which WAOE's members work and learn together within the virtual space of the Internet and WWW. The open source movement, supported by the philosophy of open access to information and the sharing of information and knowledge, forms communities of practice that share and work together for the public good (Castells, 2002). Open Source is an apt metaphor for the iterative *process* of collective intelligence and shared knowledge production that is congruent with current conceptions of lifelong learning. OSL is one way to describe how open environments of knowledge sharing for the public good create opportunities for people to learn about ICTs and learn how to use ICTs. For WAOE this includes learning how to use ICTs in education, and includes learning about other cultures while acknowledging social difference as an important feature of global culture.

In a business context, Goleman (1998: 183) discusses leveraging diversity, but there is still a top-down sense of center to periphery for the benefit of the former. One of WAOE's defining characteristics is its not being centered in any geographical region. WAOE operates as a distributed learning environment in and of itself; in Derridean terms WAOE is "not a fixed locus but a function" (Derrida, 1978: 280) of global knowledge on education. Nor is WAOE even pre-occupied with non-Western concerns like a development NGO or, for that matter, any unidirectional agendas. Rather WAOE's orientation or basic stance is intercultural, in the knowledge that intercultural communication among the widest diversity of participants is of the greatest educational benefit for mutual learning, whether east-west or north-south, but going both ways in mutual respect. The immediate subject matter of online education cannot command balanced global participation, nor can WAOE wait for that, but fortunately pioneers have gathered from every continent who are living examples of intercultural online education.

Interpreting information means bringing it into context and producing meaning and relevance. Knowledge constructed within the new digital environment can be part of an ongoing interactive and iterative process within the social contexts particular to time and place. Contextual understanding of new technologies and their role in mediating knowledge is particularly important for understanding media effects and the informal structures of learning that characterize everyday life. This context is very much predicated on the various disciplines and cultures that comprise the globally networked culture(s) online. And it is within this context that WAOE fills an important need by offering a space for the sharing of knowledge and information across disciplines and cultures, collaboratively contributing to the creation of diverse—and geographically dispersed—networks of educators. As a VLE in itself, WAOE exemplifies how learning within a community of practice, though globally distributed, can be localized and relevant to individual needs and practices congruent with the larger learning community. The global sharing of information and knowledge with WAOE (as in other organizations) is sensitive to its context within the framework of each individual member. WAOE as VLE is thus situated within each iteration of its constituent members. It is this global context that gives WAOE its strength.

WAOE is a VLE—and not just an organization—that fosters collegiality and shared respect for diversity in the digital world. A fundamental premise operating here is the recognition that active participation in the networked world is *socio-technical* in nature (Agre, 1994; Lave & Wenger, 1991; Wise, 1997). Recognition of the socio-technical nature of ICT development and use, and the ways in which the social construction of knowledge is part of an ongoing process of living within technologically mediated interactions can aid in the formation of digital pedagogies and literacies that are relevant to communities, both locally and globally. The social contexts of learning (about/with ICTs and cultures) are important aspects of socialization within communities of practice, particularly as regards open learning environments. For knowledge constructed within open environments and communities of practice is part of an ongoing interactive and iterative process within the social contexts particular to time and place (Luke, 2002). Communities of practice, whether online or off, are constructed, mediated, and conducted within a complex system of community exchange that is a combination of social and technological forces (Lave & Wenger, 1991). More to the point, communities of practice legitimize knowledge, providing context to information and the basis for community relevance. WAOE as a VLE constructs legitimacy for participating individuals, offering an organizational context for the personal experience with online learning to be connected to broader concerns around the world.

2.2. Diversity of Informal Learning Support with the WAOE

In this section, we present a view of the range of different ways the WAOE has utilized the online environment to support informal learning in a professional development context. We present a historical view of the organization to show this diversity in a clearer context. This case study will highlight our conception of WAOE as an OSL VLE—how WAOE operates as a locus for learning utilizing various VLE tools.

In 1999, Nick Bowskill proposed the idea of a notional WAOE Online Educators Course as a shared experiment to explore the issues and concerns to be contained within such a course. It was also a problem-solving professional development exercise for sharing ideas and to try and make a pilot implementation to apply some of the learning in a meaningful context. This was done with the BlackBoard learning management system (LMS) free version, and a number of officers were eager to evaluate its functionality and possibilities. The guiding concept of a library of experience meshed well with the sense of responsibility among officers to know the terrain of a new discipline and to provide signposts for others who follow. An organizational library of experience could be found in web-based records of the collaboration of individuals through WAOE. This library would function as an OSL document, continually updated as a living archive. Officers have shared access to different LMSs among each other and then freely to members during the Annual Members' Meetings mandated of an NPO but held online.

Officers have learned from each other in a continuous process of professional development. The WAOE Coordinating Ring had its own listserv for organizational communications first based at California State University, then with WAOE's ISP. But there was a constant effort to reach out to other VLEs to explore how WAOE's mission could be better fulfilled. In this process it was discovered, for example, that an issue was the cobbling of free or nearly free VLEs, which was a very economical form of empowerment but with a lingering sense of frustration. The fragmentary inability of various tools to add up to a coherent experience led to unrealistic expectations that some LMS would provide a satisfying answer. That is, human nature in cyberspace yearned for a seamless and consistent VLE that would fulfill all the knowledge-building, interactive and communicative needs one would envision or expect. But the reality was that prices soared as the imperfections of such systems were reduced but not eliminated. Discussions in the free Blackboard environment and later with an inexpensive version of the MetaCollege LMS leased by WAOE have been pre-occupied with what the systems cannot do in terms of functionality and so forth. But these realizations about human nature were necessarily the fruits of collective experience, which each individual can then pass on. The nature of this collective intelligence reinforces the contextual and situated nature of learning online within a community of practice. WAOE thus functions to legitimize knowledge production within this context, particularly as it relates to the personal professional development of each participant.

If there were now wholly virtual organizations, there should be virtual organization software for all of an online organization's needs in a networked infrastructure. But there, too, it was found that only fragments of such functions were available. WAOE officers therefore investigated what groupware or teamware was available for free. There was already a WAOE WebBoard at Embry-Riddle Aeronautical University available for formal events in addition to the Ring discussion list, but WAOE explored the possibilities of virtual organization environments by selecting QuickTeam as the venue for the February–March 2000 Board of Directors' Meeting. Limitations in functionality again resulted in a gain mostly of experience, while QuickTeam was eventually absorbed into another company, as its business model of advertisements in the free VLE proved unsustainable.

In a somewhat similar instance, WAOE officers investigated what LMS could be used so that WAOE could operate on the model of a virtual university. Vendors such as WebCT were found to be too expensive for WAOE in their minimum services, so officers selected the free version of MetaCollege for an Online Educator Development Practicum that was opened to members at the Annual Members' Meeting in mid-2000 (AMM2000). Later MetaCollege also apparently found advertising revenue insufficient, and WAOE decided to start paying for the minimum service. A danger of VLE freeware was discovered, in that the companies are vulnerable to going out of business or starting to charge for formerly free services, so educators may lose the work invested in good faith in a certain VLE. This marks a clear need for open source courseware systems that can be sustained by non-profits such as WAOE.

For the following Annual Members' Meeting in mid-2001 (AMM2001), members were challenged to utilize various online venues, voting through web forms, discussing by mailing list and by logging into WAOE's WebBoard, plus members were e-mailed access codes to enter the MetaCollege Advanced Site. While most individuals would not lease their own LMS, the organization could leverage a tiny budget to provide such experiences to members.

Synchronous events of AMM2001 were held in the combination chat room and whiteboard of WAOE's online seminar course in MetaCollege, hosted by four Asian colleagues and Steve McCarty in Japan. Again the discussion quickly turned to the lack of functionality, such as being disconnected from chat after using the whiteboard for illustrations. With current technology, officers have found that it is still better to separate those communication tools.

Also at AMM2001, Prof. Mike Holmwood offered open house to visit the WebCT VLE at his college in Vancouver, for WAOE members who had only heard of WebCT and wished to experience it. Such individual contributions can increase the services to members, expanding collective expertise and a growing library of experience. And a continuously learning organization is an increasingly empowered educational organization. The iterative process of a learning organization such as WAOE reveals the fact that, to a large extent, any particular VLE is almost incidental to the working of an online community of practice. For it is the aggregate knowledge produced as part of the OSL process that marks WAOE as a learning environment in and of itself.

WAOE was cited as a model for collaboration at a conference in China by K. Narayanan of the Commonwealth Educational Media Center for Asia in New Delhi: “Various patterns of collaboration can be envisaged. They range from individuals voluntarily sharing resources to institutionalized collaboration in course and credit sharing” (Narayanan, 2001). He quotes extensively from Bowskill et al. (2000), including two of WAOE’s 22 stated Objectives and Purposes (see URL: http://www.waoe.org/npo/bylaw.htm#a2). “The reference to WAOE has been made to highlight voluntary collaboration for offering professional development courses online, with a concern for multilingualism and multiculturalism in online education. The success of the WAOE as a voluntary organisation would suggest that similar organisations with like objectives be multiplied for deeper collaboration amongst educationists for offering online courses of study, training or professional development” (Narayanan, 2001).

As part of WAOE’s dual mission to serve international society as well as members’ professional needs, a global digital divide policy was passed at the 2001 Annual Members’ Meeting. The idea was to leverage the services offered for the same fee by WAOE’s ISP to offer many more free services to members and even to non-members in developing countries. WAOE officers just needed to master the web-based functions offered, and to volunteer the time. WAOE paid for four mailing lists, so four different types were set up. e-mail accounts, aliases thereof and web directories were virtually unlimited, so officers were encouraged to make the most of them or to help others.

Those who were using free e-mail accounts or web services with limits and intrusive advertisements were thus invited to have addresses at waoe.org. e-mail aliases further serve to form sub-groups of the Coordinating Ring: For example, e-mails sent to membership@waoe.org are forwarded to everyone in that Committee for better service. Aliases are also better than individuals’ e-mails for mailto: Links on WAOE’s web pages.

In 2002, the WAOE Websites and e-mail accounts of officers have become quite numerous and have been extended to general members. The Indian Association for Online Education (IAOE) inspired by WAOE is led by WAOE member Dr. Sanjaya Mishra who has changed to WAOE’s web-based e-mail and is one of those who receives e-mail to the alias journal@waoe.org. In a similar vein, at the Annual Members’ Meeting in mid-2002 (AMM2002) officers resolved to step up WAOE publications to institute more visibility for WAOE as a VLE. An e-mail newsletter WAOE Electronic Bulletin (WEB) will be hard pressed to keep up with new developments, while an e-journal is under discussion, with volunteers already for languages in addition to English, and a suggested title of Intercultural Cyberspace Journal.

Another virtual environment WAOE would like to expand into is a relational database whereby members could manage their own membership status through a web interface and network with other members having similar research interests through the database of members’ information.

On the agenda of AMM2002, business included elections, with candidates from Singapore, the U.S., an Indian in Germany and a Mexican in Hawaii, which showed that non-Westerners are identifying with WAOE and making the organization their own. Aside from business, WAOE annual meetings also feature discussions on the Views mailing list and other venues. At AMM2002, the discussion of online education turned deeply philosophical with balanced participation from all over the world. Prof. Asif Daya specifically led a discussion on accessibility and e-health technology. As a result, it was decided at the following Board of Directors' Meeting in July–August to hand over the designer role of WAOE's MetaCollege LMS license to Prof. Daya for courses in of Kenya.

Another topic of discussion was the Future of Universities, with Dr. Parker Rossman, formerly a dean at Yale, to discuss his online book. WAOE collaborated with the TappedIn Summer Carnival 2002, holding a synchronous discussion in their MOO. The transcript is available at: http://waoe.org/president/future.html. This in turn led to Dr. Rossman deciding to accept the offer of the WAOE WebBoard for continuing asynchronous discussions of his online book and specifically how to attain education for all in developing countries through the internet. As with TappedIn, which is predominantly at the K-12 level, this discussion starting in August 2002 is also not particularly for WAOE members but has WAOE's cooperation. WAOE provides the venue for the invited participants with international development experience, and offers orientation for those new to the technology.

When Dr. John Afele, on the Executive Board of the Global Knowledge Partnership and a prolific author of original scholarship, lost his International Program for Africa at a Canadian university, it was WAOE's privilege to revive its web presence in August 2002, available at: http://www.waoe.org/africanknowledge/index.html.

These are some of the milestones of WAOE's brief history as a virtual organization delivering palpable results, seen through WAOE's use of VLEs. In sum, this history reveals WAOE itself as an expansive VLE serving those concerned with online education. The open knowledge structure of WAOE exemplifies how OSL environments are those that foster collegiality, cooperation, and learning within shared interests of communities of practice.

2.3. An Informal Learning Event in More Detail

In this section, we provide details of a collaborative learning event in which a group of volunteers within the WAOE used the construction and testing of a notional online course as a developmental apparatus. This apparatus scaffolded our discussions and explorations around key issues in any implementation rather like a problem-solving exercise. The details of the course we co-constructed are discussed in more detail elsewhere (Bowskill et al., 2000). Here, we offer an overview of the course and discuss the issue of assessment as important in a voluntary informal context, and from the point of view of empowerment for non-Westerners and Westerners alike. It should be noted that our model of empowerment is one that considers non-Westerners both in isolation and together with Westerners.

2.4. The Course Design Details

The ability to work collaboratively is a key skill for networked teaching and learning (see for example, Sherry, 1996; Tompkins, 1997). In recognition of this need, the course design offers a collaborative, experiential approach to understanding and working in a dispersed teaching team. It is also an online apprenticeship, as learners experience the course to understand the content and structure before perhaps having an opportunity to apply their learning from the course in tutoring roles as they support another generation of learners.

As learners, the participants proceed through the course and discuss concerns about online team teaching as well as completing related activities in each unit. Having completed the course, participants are invited to become part of the teaching team (subject to their having satisfied the assessment conditions) in order to teach what they have experienced to the next generation.

2.5. The Course Structure

The course contains a set of five online units that model different online teaching and learning strategies along with a discussion space. During the 16-week course, real-time chat sessions are also held whenever required.

Unit 1: Acclimatization and Introductions.
Unit 2: Collaborative Tutoring.
Unit 3: Reflecting Upon Real-Time Sessions.
Unit 4: Online Guest Expert/Case Study.
Unit 5: From Learning to Teaching.

2.6. Assessment

Participants are required to complete a written report discussing their experiences during the course and setting this experience in the context of their own working lives. This contribution is then made publicly available for all future generations of course participants in the Library of Experience. Participants must complete the activities and the reflective report before being eligible for consideration to join the tutoring team next time round.

2.7. The Design and Development Process

The course design has gone through a number of cycles of development and changes of online environment/location. An invitation was extended to members of the WAOE's Ring discussion list (board and committee members' list) along with a request for volunteers to role-play a sample unit.

A core group of five members from California, Arizona, Canada, New Zealand, and Japan role-played a chosen unit over a 4-week period. All participants successfully completed the unit activities and a resource base was collaboratively developed as an outcome. Two real-time sessions were held: One between participants in Canada, England, and Japan; and another between participants in California and England.

2.8. Pilot Implementation/Environment

The course was constructed on Blackboard (www.blackboard.com), which is an integrated courseware environment for hosting online courses. Blackboard was chosen for the WAOE Online Educators Course because "Blackboard.com is a FREE service that enables instructors to add an online component to their classes, or even host an entire course on the web. Without knowing any HTML, you can quickly create your own CourseSite—a Website that brings your learning materials, class discussions, and even tests online" (http://company.blackboard.com/Bb/index.html). Since the WAOE is a virtual organization with limited resources, Blackboard was the most attractive alternative that would enable us to get the Online Educators Course up and running while at the same time eliminating the need to administer our own environment.

An overview of the implementation for the Online Educators Course that covers some basic features of the courseware is shown in Figure 1.

2.9. Discussion of the Course Design as an Exercise

There are a number of issues arising from this collaborative exercise and the design process. Not least of these is that the course design and construction provided an informal learning opportunity for a group of members within the community. It arose from a series of casual online discussions about the need and interest in such a course and that led on to discussions about what such a course might look like.

Those involved in the design and construction process worked together because we had found a common interest and each person brought different skills, experiences and ideas to the activity. The activity was a slight formalization of the casual learning conversation that we had as a group, as indeed

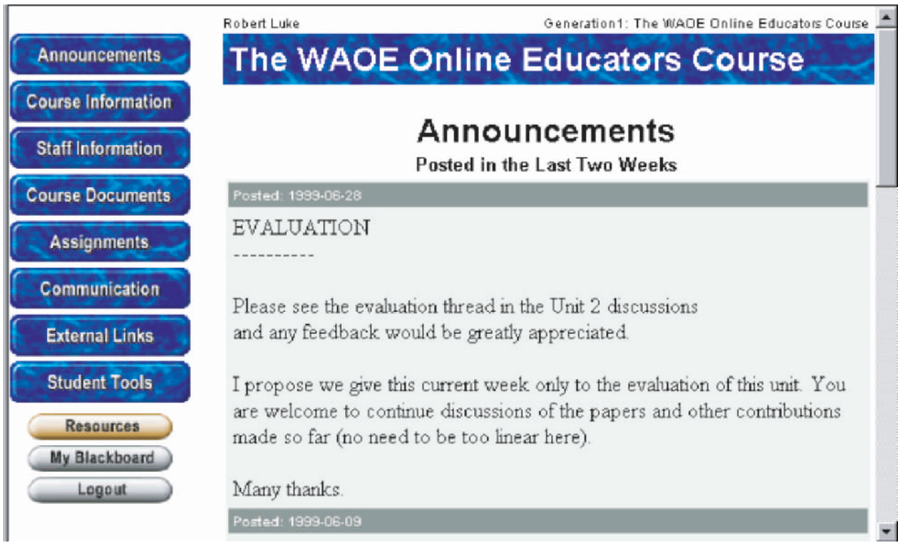

Figure 1. The WAOE online educators course home page.

was the idea to publish our activities and findings in a journal. Writing has become an important part of our activities together and this is reflected at other levels most notably within the course.

We were concerned to keep in mind that people were volunteers and that although we might offer advice and ideas to each other, we should in no way be judgmental. The idea of inviting participants in this notional course to construct an autobiographical piece aims to help them reflect and re-conceptualize their experiences. In providing such a document this activity simultaneously also offers the voluntary learning community a resource. This resource facilitates evaluation of the course design and the course experience and also provides a deeper insight into the membership of the community written by the members themselves. In the following section, we also think about the role of writing in a community as well as in informal learning and empowerment.

3. DISCUSSION

> "Self-identity . . . . is not something that is just given, as a result of the continuities of the individual's action-system, but something that has to be routinely created and sustained in the reflexive activities of the individual".
>
> (Giddens, 1991 in McConnell, 2000: 250)

We have highlighted the role of informal learning as a possible aid to personal empowerment. We have also considered informal learning in isolation and alongside formal provision within an institutional context and beyond. We have described a means of supporting the development of informal learning and extended a traditional view of that support to encompass online learning communities in order to accommodate global involvement.

There is an important issue in the power relationship between participants in any learning event. Others involved perceive the tutor in a formal course differently. There is much talk in the literature about the role of online learning communities as an alternative model for development. However, many of these are conceptualized and delivered within a course or institutional context. Pedlar (1981) for example, talks about the problematic nature of the tutor in such a model of community. Although the tutor may move from a central position to one of facilitating, that role does nonetheless come pre-loaded with assumptions and expectations. There is a difference in power relationships in such cases that may militate against equal participation and discussion. Where events are constructed within a voluntary virtual community, relationships are more equitable. Everyone is participating in a spirit of willingness and shared interest, and there is certainly little coercion that can be applied in a voluntary context. As such, a model such as we have described above offers greater empowerment both of the group and of the individuals. Pedlar (1981) also talks about the goal of promoting autonomy through a supportive structure that allows for different learning goals and outcomes. We have shown through the earlier description of the diversity of events and resources how this is facilitated across the WAOE as well as in the particular example described in detail. The WAOE, as a voluntary virtual organization, functions as a supportive environment for informal learning and autonomy in a variety of ways, empowering all concerned by accommodating different learning projects (Tough, 1971).

A key part in our work together is writing. This is a means of personalizing understandings and sharing them with others both within and outside a community event. We believe that writing and sharing documents supports the transfer of experience and learning into the self. Reflective writing is a sense-making process in the language of the individual authors and a process under their own control. The act of externalizing tacit knowledge reflectively is constructivist and contributes toward the formation of identity in a way less vulnerable to external change (accepting that such change remains a factor). The author has the control of the document, what is included and what is left out. The same is true collaboratively in the way that a shared collection of autobiographies and of articles acts as a learning method and a learning resource.

It is therefore culturally more sensitive and thereby empowering. Examples were given within one event of this principle being applied. We find that this is a process that supports people transferring an external event into the self through reflective writing. The sharing of these documents provides a learning resource for all involved and informs the identity of participants and organization alike. This is central to the organizational aim of facilitating learner development at an individual and collective level in a culturally respectful manner and very much a part of the empowering process. Marsick and Watkins (1990: 221) discuss the importance in informal learning of raising automatic actions to the surface for examination, and they rightly see this as part of learning how to learn. They also note that such approaches are "indeed empowering and potentially transformative". We believe that working in online communities in informal learning activities is not enough. It does need to be reflected upon, and the use of autobiographies in the way we describe above accommodates the transfer of learning into the self.

This principle of transfer into the self manifests in different ways and through different documents. It includes writing articles and other texts together, online text-based discussions, and support for others to contribute autobiographies as part of a shared learning process. All of these documents empower both the individuals involved and the community at large to become a learning organization. Those documents that are published also share knowledge and experiences with a wider audience, and the sum of our writing goes some way to the development of our identity as educators. The collection helps the organization to better understand the people that make up the membership and to recognize the knowledge located within.

SUMMARY

In this chapter, we have presented a life history of a virtual voluntary organization, and as a VLE in its own right. We have shown activities at an organizational level and taken them to the individual level. Life history methods use different research methods and may contain autobiographical accounts as a grounded phenomenon of the totality (Giddens, 1997). This chapter crystallizes our understanding of the organization at a moment in time taking an ethnographic approach to the production of a "thick" case study. This approach seeks to develop and share an understanding of a culture from the inside and in some detail. It is therefore important to reflect and think about what might be generalizable from our experience and our attempts to facilitate empowerment.

Our model then has six key parts that support autonomy within a global learning community context. These elements (in no order of priority) constitute our emergent architecture for empowerment in networked professional development:

Informal learning has unique advantages and features in relation to formal methods. These features should be considered in comparison with and in connection with formal methods. These features offer a viable framework for those unable to access formal provision in a supported self-help model.

The need to facilitate transfer into the self, not just transfer into practice. This is to overcome the often temporary nature of employment, economics, and political uncertainty. It is also to move toward an intrinsically motivated model of professional development through professional activities and writing.

The need for online communities to be a vehicle for supporting diversity of culture and interest that accommodates a dynamic global learning community. This can be done through self-reflection and self-assessment of participation.

The need for online communities to allow for different opportunities and access for all. This means working toward accommodating autonomy at different stages of development wherein people can move from being a vicarious learner (McKendree et al., 1998) to an active co-constructor of events and experiences within the virtual organization.

The idea that informal professional development should not and could not be limited to local provision or formal provision in a networked world. This is particularly true of those interested to understand the nature of online education and its impact on both local and global contexts. It is also particularly important in the context of the non-Western world where access and needs may vary enormously.

The idea of supporting individual diversity that also supportsand feeds into research at the distributed center. This means that writing is shared so that it can function as a resource for both further learner development and research at different levels within the virtual organization.

We have demonstrated how the WAOE has empowered members in a number of ways through its unique, OSL approach. This is centered upon an informal learning framework that allows for shaping and direction in an equitable, mutually respectful, and supportive framework. At its heart is support for the transfer of learning and experience into the self through shared reflective writing. Shared reflective writing supports further research in a voluntary virtual organizational context. As such, this text is our latest contribution to our library of experience and learning.

Chapter 30: An Online Journal as a Virtual Learning Environment: The Case of the *Teachers College Record*

GARY NATRIELLO AND MICHAEL RENNICK
Teachers College, Columbia University

The *Teachers College Record* is an academic journal that has been published by Teachers College at Columbia University since 1900. For most of its first 95 years the journal appeared in print on at least a quarterly basis. During that time it has featured the work of most of the leading names in the field of education and educational research, including early papers by Thorndike (1901), Dewey (1914), Kilpatrick (1918) and more recently articles by Berliner (1997), Apple (1993), and Greene (1994), among many others.

Over the years the journal has taken seriously its mission as a vehicle for education. In its earliest volumes, the journal published original syllabi drawn from courses in such areas as the principles of education (Butler, 1900), the history of education (Monroe, 1900) and school administration (Dutton, 1900) offered as part of the curriculum of Teachers College. The journal has also co-ordinated its publishing program with various workshops and colloquia in conjunction with degree and non-degree programs at the College. It has published sets of papers and special issues derived from conferences and special educational events. Throughout its existence, the journal has sought to maximize its educational impact.

In this article, we report on recent efforts to extend the educational impact of the journal through online publishing activities. We begin by reviewing our early attempts at establishing an online presence for the journal. We then consider the impact of developments in academic publishing, the changing online experiences of readers, and our educational goals on the design of our current online journal site. We discuss the current publishing site in detail and examine data on user patterns over the past several years. Finally, we outline the major features of a next generation publishing site designed to enhance and expand the educational program of the journal.

1. EARLY EFFORTS AT PUBLISHING ONLINE

The 1990s marked the beginning of efforts to produce fully online academic journals. As the decade progressed, there was a remarkable growth in the number of journals publishing online. In the early 1990s, most online efforts made use of electronic networks to distribute papers to defined lists of readers.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 821–848.

Following the advent of accessible browsers and the explosive growth of internet use, this gave way to publishing papers on the web. The Association of Research Libraries began tracking online journals in 1991 with the publication of the *Directory of Electronic Journals, Newsletters, and Academic Discussion Lists.* The 1991 edition included 110 electronic journals and newsletters. The number of entries grew to 240 in 1993, 675 in 1995, and 3400 in 1997 (Mogge, 1999).

In the field of educational research, perhaps the best example of an early electronic journal is the *Educational Policy Analysis Archives* (*EPAA*), an online journal started in 1993 as a listserve and later moved to gopher and then to the web. The *EPAA* had 800 subscribers within 3 weeks of its founding, and by 1994 it was being accessed by over 600 readers each weekday (Glass, 1994), a number that continued to grow throughout the 1990s (Glass, 1999). Although *EPAA* was publishing online early in the 1990s and attracting readers, established print journals in education were not yet moving online.

In the mid-1990s with the emergence of opportunities for online publishing made possible by the internet and the World Wide Web, we decided to take advantage of new online publishing and communications tools to pursue the original educational mission of the *Teachers College Record* in new ways. We viewed the online environment as offering new means to reach those scholars, researchers, and graduate students who had been the traditional audience for the journal. We also anticipated that publishing online might allow the journal to expand somewhat beyond its audience of scholars to reach educators and even the general public.

Although the history of the journal as a deliberately educational vehicle provided both some orientation and a rationale for our efforts to move online at a time when educational offerings were moving in the same direction (Lewis et al., 1999), along with that same history came a sense of tradition that made it difficult to depart from what had become a rather standard pattern for an academic journal. As we considered our initial move online we confronted resistance from our editorial board of established scholars in the field and from our readers, who as of 1995 did not have much experience with online journals. Indeed, if we had polled our board and our readers in 1995 about whether we should move the journal online, we would have received either blank stares or outright warnings of the dangers of devaluing the entire journal enterprise. Perhaps most importantly, we had concerns that our authors would be reluctant to submit manuscripts to an online journal, both because they considered online publication less legitimate and because they feared that promotion and tenure committees at their institutions would think likewise in evaluating their work (Kling & Covi, 1995; Sweeney, 2000).

We began publishing online in the most limited way. Our first online site for the journal consisted of the name and contact information for the journal along with some basic information on how to order a subscription by calling the journal office. At the time this seemed like quite an accomplishment, but, of course, we quickly grew discontented with our single page and decided to try to do more.

Our second online site had multiple pages and included tables of contents from recent print issues together with abstracts of at least some of the articles. It also included detailed directions for authors interested in submitting materials to the journal. The design of the entire site reflected the design and organization of the paper journal. We did implement one feature at this point that reached out to authors by allowing them to consult a page listing all papers under review by an identification number along with the status of the number of external reviews completed. This allowed authors to interact with the journal through the online site and reduced the number of phone calls or e-mail messages coming into the editorial office.

For a time, we built on this basic site by adding new tables of contents and abstracts whenever a new issue of the print journal was released. Perhaps more significantly, we added a new feature that listed basic information on the major journals in education as a resource to authors who wished to find the right outlet for their work. This marked a departure for the journal because we became a conduit for authors to reach other journals and for the first time we offered something other than our exclusive content.

At this same time, we made a decision to begin putting the full text of the lead article from each print issue online at the time the print issue was released. This generated greater interest in our online site, and the immediate response of readers was to ask for more full text content online. We investigated offering both more current content online and the possibilities for bringing articles from past issues online as well. In retrospect, both moves seem like straightforward decisions to give readers what they want and need, but in 1996 things were not so clear. Members of our editorial board and others at the College questioned the wisdom of offering full text articles online without charging while we were trying to increase revenue from our print product.

In the spring of 1997, all of our efforts to add content to our online site resulted in another re-design that became our third online site in as many years. This version looked and felt more like the print journal than anything we had done online in the past. Readers were able to page through tables of contents of each issue and read the full-text of lead articles, editor's columns, and all book reviews. Although the model for organizing the online site was the print journal, about this same time, we began to re-design the print journal based on what we were learning from our experience with the online journal. The best example of this impact of publishing online was the re-design of the table of contents for our print journal to include short descriptions for each article in the issue. These same short descriptions were first added to our online content pages to give readers an easier way to learn about our content before clicking on the link to move to the abstract or the entire article.

In the summer of 1997, we embarked upon a major project of producing a cumulative index for the journal since its inception in 1900. We had always had an appreciation of the history of the journal and its unique role in publishing the major voices in the field in the 20th century. However, prior to the advent of the web and the opportunities for online publishing, we had never had a real opportunity to capitalize on the extraordinary collection of materials published over the years. Once we began publishing online, we quickly realized both that the online environment can require vast quantities of content in order to generate sufficiently broad and valuable resources for readers and that we had such content in the historical archives of the journal. This all came together in the cumulative index project in 1997. Once the index was completed, we quickly configured it so that readers could search it online from our web site. Of course, putting the index online only served to highlight just how far we had to go to get even a fraction of the journal's past content online in full text. The growth of our online content also placed a new set of problems before us. Up to this time, we had been relying on the organization of the print journal to orient our online publishing efforts. By 1997, our online site looked as much like our print journal as we could make it. But, it was clear that our plans to publish more new content online as well as to make more content available from the archives would require a totally different approach to organizing our efforts on the online site.

In the summer and fall of 1998 and the winter and spring of 1999, we worked on creating an entirely new approach to publishing online. This time our site reflected not the organization of the print journal, but the orientation of the growing number of online sites in all areas. We designed the site to meet the needs of readers to move through large number of articles; and in so doing, we jettisoned the use of issues of the print journal as an organizing device. Instead, we created a home page that displayed content drawn from different sources, including, new online only articles, book reviews, articles from the current print issue, and related articles from prior print issues. We also added a set of new online only features including, calls for papers, an opportunity for readers to join our e-mail list to receive e-mail updates, an online advice column for graduate students, a feature that highlighted an educational research site of the week, a feature noting new journals added to our journals database, and announcements of recently accepted papers that would be forthcoming in the print journal. This new online site, our fourth major design, was deliberately livelier, more engaging, and more oriented to the online environment. Most importantly from an editorial office standpoint, we promised to publish online weekly, a dramatic change from our quarterly print schedule, and our infrequent updating of our earlier online sites. We launched this site after many months of work in the fall of 1999. It generated great interest among our readers and generally positive responses. Almost immediately, we began to see new ways to improve this latest version of our online site.

Our early efforts at online publishing were experimental in all senses. We clung tightly to our print journal for its format through most of the early web site designs. We also clung tightly to the print journal both for the legitimacy it offered our authors and for the revenue stream it provided to support our editorial activities. Even through most of 2000, we never made a commitment to continuing our online publishing activities. By the time we did make such a commitment with the launch of our fifth online site in November 2000, we acted because we understood not only that online publishing met the needs of our readers (Vrasidas, 2000), but also because it had become clear that our online presence was largely responsible for raising the profile of our entire publishing effort and for increasing the number of high-quality manuscripts submitted for our print journal. The online site had become an integral and essential part of our publishing program. By the fall of 2000, we had ceased to become a journal with a web site; from then on, we were a publisher with both online and print products.

2. INFLUENCES ON THE DEVELOPMENT OF TCR ONLINE-2000

As it became clear that the *Teachers College Record* would become a permanent online publishing operation, we focused even more intently on ways to make our online efforts truly educational. Our goal was to create an online site where readers would have an opportunity to learn something at each visit. By this time, our planning for the next generation of the online publishing site was influenced not only by our growing appreciation of the educational opportunities available to an online journal, but also by changes in academic publishing and changes in the experiences our readers and the general population were having online.

2.1. Emerging Forms in Academic Publishing

Our commitment to permanent online publishing was made in the context of major forces affecting academic publishing in general at the turn of the century. These forces included the growing costs and growing number of academic journals, the declining individual subscription base for many journals in education, the growing resistance of institutional subscribers such as academic libraries in the face of stable or shrinking budgets, the development of online journals in a range of fields, and the realization that scholars were taking advantage of other means of communicating the results of their work to colleagues. Each of these shaped our understanding of the challenge of developing a successful online journal.

The growing cost of academic journals is a widely recognized problem confronting higher education (e.g., Association of Research Libraries, the Association of American Universities, the Pew Higher Education Roundtable, 1998; Born & Van Orsdel, 2001). This problem is felt acutely by libraries forced to deal with a 207% increase in the price of journals between 1986 and 1999. The problem of the rising costs of existing core journals is exacerbated by the growth of new journals in virtually all areas of scholarship, as each specialized group seeks a means to communicate its work to those both in the specialized area and outside the area. Between 1986 and 1999, the number of journals increased by 55% (Smith, 2001). Library budgets are failing to keep pace with both the increase in journal costs and the growth in the number of available journals.

In the face of growing costs and the growing number of journals, some librarians and campus leaders have called for various new approaches to cost-control (Association of Research Libraries, the Association of American Universities, the Pew Higher Education Roundtable, 1998). Suggestions include pressuring commercial publishers to contain costs (Kiernan, 1999), weighing in on decisions regarding the issue of mergers among the already small group of academic publishers (McNabe, 1998), the creation of new alternative journals based in universities and libraries that have lower subscription rates (Kiernan, 1999), and the use of online publishing technologies to reduce at least the cost of producing a print product (Association of Research Libraries, the Association of American Universities, the Pew Higher Education Roundtable, 1998).

Although online publishing has been viewed as means to contain or reduce the costs of academic journals, a number of analysts have argued that publishing online or in print does not affect the cost of producing a journal. These analysts point out that a large part of the cost of any journal lies in the editorial work to prepare manuscripts for publication, and these costs are typically not affected in a substantial way by the shift to publishing online. However, these analysts have typically not devoted sufficient attention to the costs that institutions such as libraries must bear in making print journals available to patrons, costs not associated with online journals (Odlyzko, 1997). These include staff costs for processing print products into a catalog and checking to make sure that all physical print issues are delivered as well as costs for binding annual volumes and placing and replacing them (after use) on library shelves. In addition, online subscriptions do not require library shelf space, shelf space that is becoming more expensive and less readily available as library collections grow. Thus, publishing academic journals online offers a number of efficiencies for libraries that are hard to resist. Many libraries are now moving as quickly as possible to subscribe to online journals as a way to reduce processing and storage costs even if publishers are maintaining basic subscription fees.

The movement of academic journals online, driven by library needs, has resulted in a fairly direct translation of the standard journal format to the online environment. The vast majority of print journals moving online are offering their regular content in the regular format, often through pdf files that present the exact images of the articles that might appear in the print version of a journal. These files are collected in large repositories by companies that publish large numbers of journals. The databases of journal content are offered to subscribers for fees that track the regular subscription fees, sometimes a bit more for combined print and online versions, sometimes a bit less for the online version only. The organization of these databases allows readers to access an entire collection of journals for articles on a subject, but at the individual journal level, the articles are organized through traditional volumes and issues with tables of contents that mimic the print versions. Despite the online availability of journals that published exclusively in print in the past, there has been a notable lack of innovation in the use of online tools as these journals simply seek to replace print issues with online issues to meet the needs of libraries.

While print journals have moved online in a rather traditional format, new online only journals have been a bit more innovative at times in exploiting the advantages of the online publishing environment (Vrasidas, 2000). These journals often invite authors to make use of new online technologies to make more extensive use of graphics and simulations. They also often depart from the rigid publishing schedule, formerly dictated by shipping needs, to release or publish articles individually when they are ready. Despite efforts to utilize online opportunities, most online only academic journals still mimic the form and functions of a traditional academic journal. Our own experience leads us to suspect that one reason they maintain journal conventions is because radically divergent approaches raise questions of legitimacy that create problems for academic authors seeking favorable tenure and promotion reviews.

2.2. Changing Online Experiences

While we were influenced by developments in academic journal publishing as we designed the fifth generation of the TCR online site, we were also influenced by the changing online experiences that our readers were encountering as general users of the internet. By 2000 when readers of TCR went online, they encountered sites that promised broad and deep collections of materials, whether those materials were consumer goods, news stories, or more specialized properties for niche audiences. They also were increasingly likely to find opportunities to interact with other readers or with the purveyors of the online fare. This interaction included opportunities to voice opinions about products as in the readers' reviews of books on Amazon.com or the critiques of electronic products on CNET.com. In fact, entire sites such as Epinions.com were devoted to the opinions of users.

In addition to broad content, choice, and opportunities to voice opinions, our readers were also increasingly likely to encounter content personalized for them individually. Sometimes, the personalized views were created automatically as in the pages of related materials offered by Amazon.com. At other times, the personalized views were deliberately selected by users as in the case of hometown weather reports offered by MSNBC.com. Online sites also began coupling content with a range of services as in the case of the greeting card site Hallmark.com that offered to maintain a list of important dates and remind users when they needed to send cards.

The evolving online sector was evidencing what Hage and Powers (1992: 60) had noted as the characteristics of post-industrial society, namely, a focus on "customization, quality, and innovation" in the services delivered to increasingly well educated and discerning consumers. This focus on the consumer of online products introduced a new challenge to our publishing program if we wanted to find a broader audience for educational scholarship. We had always catered to authors and sold primarily to other scholars, but the web made it possible to reach an entirely new kind of audience. That audience, however, was becoming accustomed to entirely new levels of service every time they went online.

2.3. Educational Perspectives to Guide Online Publishing

Our interest in reaching beyond our traditional audience of scholars was driven only in part by the possibilities afforded us by online publishing. Perhaps more important was our historic goal of educating the broader public about the promise and possibilities of education. In considering our educational mission, we sought to embody a certain set of educational principles long associated both with the journal and with Teachers College, contributed by scholars from Dewey (1938) to Cremin (1976).

First, we viewed ourselves, along with our authors, as teachers with something to teach or convey to the broad audience of students of education. Thus, we sought to maintain a strong voice for authors and for the editorial team. Moreover, we sought to ensure that the teaching functions of the journal would drive its technical development and not the reverse. This meant that we would evaluate each new technical opportunity from a teaching framework. If a newly possible practice contributed to effective teaching and learning, we would consider adopting it. If a new technical possibility contributed little to the creation of a better teaching environment, we would shun the investment of scarce resources. So, for example, we would be more inclined to invest in better editorial development of content than in flashy display technologies that communicated less well than simple text presentations.

This emphasis on quality teaching and investing in authors was a particularly important issue at a time when the role of the author was being diminished in some online venues and when the role of the teacher was being decomposed and parceled out as numerous online educational operations sought to divide the labor of teaching and assign it to actors in diverse roles, including content developer, instructional designer, platform presenter, etc. (Burbules &

Callister, 2000; Noble, 1998). As part of our effort to reinforce the primacy of the teacher or the author of material on the journal site, we re-doubled our efforts to make the journal experience congenial to authors and their interests and to provide opportunities for authors to engage with readers. We remained on the watch for opportunities to highlight the role of authors.

Interacting with readers or learners was the second major aspect of our approach to education through the online journal. Editing a print journal for which the print production and shipping processes meant that months would elapse between the time, an article was edited and the time it arrived at the offices of readers left little or no immediate opportunity for serious interaction with readers. Despite an occasional letter to the editor or more formal response to an article, the level of interaction with readers was minimal. Moving the journal online opened up the possibility for more immediate and more regular contact between authors and readers and between the editorial team and everyone else involved with the journal.

Increasing opportunities for interaction was consistent with long-held perspectives on the importance of interaction and engagement to create the conditions necessary for effective teaching and learning, perspectives that had been reflected in early articles in the journal itself (Dewey, 1914). Moreover, the importance of interaction and engagement for learning has found increasing support in contemporary work on cognition (Bransford et al., 1999; Pea, 1994; Resnick & Klopfer, 1989). Accordingly, we sought to engage in lively interaction with the readers of the journal and hoped that the readers would become co-creators of the online publishing effort.

Third, in pursuit of the first two principles, we were prepared to share control of the online journal not only with our authors but also with our readers. Ideally, our readers would join with us to construct the online journal in a more immediate and interactive way than had ever been possible with the print journal. We hoped to create an online community (Hafner, 2001; Rheingold, 2000) of those interested in education and educational scholarship. We anticipated that such a community of practice (Wenger, 1998) focused on evolving scholarship in education would lead to powerful learning experiences for all concerned, including the journal staff.

3. THE DESIGN OF TCR ONLINE

To pursue our educational goals for our online publishing effort, we designed an entirely new online site. This site drew on recent developments in online academic journal publishing, on emerging conventions in online sites in general, and perhaps most importantly, on our educational goals. Because it was our educational agenda that had the most influence, we discuss the design of the publishing site in terms of central aspects of the educational enterprise. Bernstein (1975) identifies three such aspects—curriculum, pedagogy, and assessment. We begin by considering curriculum and pedagogy in the design of the site and then move to a discussion of how the operations of the editorial office allowed us to assess reader responses.

3.1. An Expanded Curriculum

As a long established academic journal we had a clear conception of the content or the curriculum of our educational enterprise. For nearly 100 years, we had published the very best scholarship in all areas of the field of education, and we would continue to do so as we moved online. But publishing online allowed us to do something that we could never do in print; it allowed us to make available simultaneously all of the content that had ever been published in the journal. Over the century that the journal had been published, over 10,000 articles had appeared in its pages, and any of this could now be available to the editorial team and to our readers.

Having the entire corpus of TCR materials online opened up several exciting new educational possibilities and posed a few problems as well. First, the accessibility of the material from earlier issues allowed any piece of content to be shown in a related content area of a page on which a new article appeared. This convention had arisen in general online sites, but it seemed particularly suited to our purpose of showing readers how new articles built upon or departed from earlier work. We anticipated that this would allow readers to learn not only from individual articles, but also from the relationships the editorial team discovered between new material and older papers. For the first time in the history of the journal, we were able to demonstrate the intellectual heritage of a paper or set of ideas by reminding readers of earlier work and then taking them directly to the full text of that work. This allowed us to emphasize the connected nature of knowledge.

Second, the availability of potentially every paper ever published in the journal allowed us to think very differently about grouping papers across issues and even volumes to create thematic special issues of papers published years or even decades apart. In creating special issues in the print journal, we often struggled to get just the right set of papers in a limited amount of time to produce an issue. By drawing on both our archival materials and the latest papers online, we were able to exercise much greater editorial discretion in assembling sets of papers. This allowed us to reveal different aspects of papers by embedding them in different knowledge contexts.

Along with the new possibilities came at least two new challenges associated with the large collection of published articles. First, since digital files were not available for most of the papers published in the print journal, such files would have to be created each time we decided to use an older article online. We approached this challenge by securing funds to digitize articles from the most recent 20 years since these articles were the most in demand.

For articles published even earlier, we developed an on-the-fly system for digitizing an article whenever we had an editorial need to use it. This allowed the editorial team to use the entire online catalog to find related materials and then request digital copies to be placed on line.

A second challenge of working with the large number of articles from the history of the journal was to develop a way to make this content archive accessible to readers. By linking from current articles to older materials, we could direct readers to selected pieces from the past and by assembling online special issues we could attempt to teach the intellectual heritage of an idea. However, in keeping with our educational goal of sharing control over the content and its presentation, we needed strategies to allow readers to access the content in response to their individual needs.

By the time we designed our site, there had been plenty of examples of sites using search engines to allow readers to seek content by topic or theme, and so we quickly decided that our new journal site would have both a quick search and a more complex advanced search function readily accessible on the home page. This strategy addressed at least part of our goal of giving readers control over content.

With special online issues and links from new papers to older ones, we had succeeded in giving the editorial team control over the presentation of materials on the new site. With the quick and advanced search functions, we had succeeded in giving readers control over materials as well. But we felt that we needed something in between these two options that would allow for sharing of control.

We arrived at a design solution that we eventually labeled as a set of edited "content collections" on the journal home page. These collections brought together different types of materials all related to a certain topic or theme. The set of content collections grew to over 70 during the first 2 years of the online site; examples include collections in alternative assessment, adult literacy, educational psychology, urban education, and technology in the classroom. Each collection includes TCR articles and book reviews, related journals that publish on the topic, related research centers, articles available on the web on the same topic, new books on the topic, and a discussion board to hold the comments of readers on the theme of the collection and the materials that appear in the collection. To organize the set of collections we devised a small set of 18 major headings that cover most aspects of scholarship in education.

Creating the set of content collections required us to survey the field and make some editorial decisions about which topics were major ones and could serve as organizing areas for the collections. It also required us to designate the collections themselves. This forced us to make many editorial decisions regarding what was important for readers to focus on in examining the archives of TCR. These are not final decisions, and it is clear in discussions with our editorial board that different scholars might devise different sets of collections.

By featuring the content collections on the journal home page we provided readers with another point of entry into the large archive of material from the journal as well as related materials from other sources identified by the editorial team. Readers were able to begin with a collection close to an area of interest and then delve into the various resources as they saw fit. In effect, each content collection page becomes a new home page of the journal organized around a new theme.

3.2. A New Pedagogy

As we found ourselves in the midst of designing the new online home for the journal, we also found ourselves developing a new pedagogy suited to the online world. This pedagogy began with the look and feel of the site and extended to the arrangement of content on pages and the scheduling of the home page. The online site gave us the opportunity to orchestrate the entire environment to achieve our educational goals.

We began inevitably with the look and feel elements of the online site, those design features that would characterize the journal in the online environment and immediately let web surfers know that they had found us. Having only recently re-designed the print journal, we were reasonably well versed in the issues of design, but the online world presented some new challenges. We had to balance the need to position ourselves among the new and somewhat experimental online publications and general sites while retaining some connection to our heritage as an academic journal. We had witnessed other publications with long histories struggle with the same tension. For example, the *New York Times* had begun publishing online by providing readers with an exact replica of its traditional front page in a downloadable graphic file, but soon moved to a quite different but more web appropriate design that was consonant with the feel of the print product while making good use of the online venue.

The design we arrived at organized the home page in three columns with new features at the top of the center column, new book reviews at the top of the left column, and utilities for interacting with the journal on the top right. Further down the center column readers could find our list of content collections, and a community bulletin board occupied the lower portion of the left column.

The design was deliberately fashioned to avoid looking like our traditional print journal table of contents since we would not be using volumes and issues to organize material online. The design was also deliberately text-heavy compared to other online sites since we wanted to maintain the primacy of text to reinforce the authoritative and somewhat traditional approach to academic work represented by the journal. As one of our students noted, we looked “more like the *Wall Street Journal* than *People Magazine*”. The home page had only one graphic in the masthead to identify the journal site clearly and consistently.

The design was deliberately simple with none of the bells and whistles that were appearing on other online sites at the time. This strategy was designed both to keep technical wizardry from overwhelming the content and to make our site accessible to the broadest possible audience, particularly those with slow connections and without multimedia computers. The design of the look and feel of the online site was a deliberate attempt to convey our first lesson that the journal was a place to come for ready access to the best content in education and educational research.

The focus on the content or the substance of the journal was conveyed also through the way each content page on the site was designed. Each article appeared in the large center column of a three-column page. This signaled again the central role of articles. The title of the article appeared at the top of the center column, followed immediately by the name of the author and his or her institutional affiliation. Beneath the author and affiliation line were two links, one to a short biography of the author and the other that popped up a window with a form to send an e-mail message to the author. We hoped to encourage dialog among readers and authors by making the e-mail process an integral part of the page on which the article appeared.

In the left column, immediately adjacent to the main body of the article were various kinds of related materials: related articles from TCR, related content collections, and related books. These related materials provided the intellectual context for considering the focal article, and each entry for related materials was a link to take readers directly to the related pieces.

On the right column on each article page were a set of tools for working with the content. These included a utility to send a link to the article to a colleague. This kind of utility had started to appear on other online sites, and we believed that sharing our articles among colleagues was a key part of enhancing scholarly communication. We also believed that it would help expand the base of readers for the journal. Also included in the right column was a utility to allow readers to create a printer ready version of the article. This version created a page with only the article without the TCR masthead and the related content and tools columns. We hoped that readers would use this utility to create printed copies of TCR articles for use in class or for their own files. Finally, the right column also offered readers a link to a discussion board for the article. The discussion board held comments from any and all readers who wished to react to the piece in question. Since encouraging interaction among readers was one of our educational goals, we hoped that offering readers online space to comment would generate online discussion.

We believed that the online journal would allow for much greater interaction among the editorial team, the authors, and the readers of the journal.

A key aspect of our approach to encouraging such interaction was a fundamental re-thinking of the timing and parceling of our content. For our print journal, we had been limited to publishing six to eight articles in issues sent by mail four times each year. When we approached online publishing, we had an opportunity to re-think both the way we packaged our content and the frequency with which we made it available to readers.

The tremendous flexibility afforded in the online venue was both liberating and confusing. We had no guidelines to help us think about how often to publish new content or how to organize it. Certainly, it made little sense to replicate our print schedule and issue structure. We approached the question with our educational goals in mind. We wanted to engage readers with each article we published. We began to think in terms of lessons and finally decided that each article was in some sense a single lesson. With this in mind, we decided to publish one new feature article at a time and later decided to include several book reviews as well. This seemed like enough to attract readers but not so much that they would find themselves unable to make their way through the material in a reasonable amount of time.

We also had to decide on a publishing schedule. We had published our print journal four times each year, but online publishing allowed us to publish as often as we wished. We could publish quarterly, monthly, weekly, or even daily if we chose. To arrive at a schedule we tried to imagine a typical reader and asked ourselves how much time a reader interested in education and educational scholarship might devote to any single publication. Our best guess, and it was literally a guess since we had no hard data to guide us, was that a faithful reader could not be expected to peruse our journal more than once or twice a week at the most. We also believed that publishing less than once a week online would allow the journal to fade from the readers' minds or easily drop from their set of habits.

With these considerations we decided to publish new content online once each week. This allowed us to feature a single article and a few book reviews. By featuring a single article, each of the articles we published became the "lead article" for a week. This allowed us to focus reader attention on the lessons to be gained from that article. We released a new edition with a new feature article every Monday.

We also decided to create a second weekly edition that would highlight sets of articles from our archives. This edition, which we designated as the "weekend" edition, was released every Friday. This second edition gave us another opportunity to focus reader attention on the rich collection of previously published material.

With our strategy of publishing new content every week in place, we decided to add one more element to allow us to reach out to our readers in an active way. We launched a weekly e-mail newsletter designed to remind readers of the journal and to introduce them to the new articles appearing that week. This newsletter gave us another opportunity to teach readers by focusing their attention on certain aspects of the new papers being released. The newsletter became an additional set of "mini-lessons" designed to compete for reader attention in a very short amount of time. Although we always thought of the newsletter as an important element of our online publishing effort, we did not fully appreciate just how important it was until we learned from the comments of at least some readers that they valued the newsletter alone and seldom or never visited the journal site to get more detail on the topics covered in the newsletter.

In addition to the regular weekly publishing schedule and all of the related content, content collections, and resources, the online journal has given us unanticipated opportunities to engage readers in special educational events. Three such events illustrate just some of the possibilities for enhancing the educational impact of the journal.

When we launched the re-designed journal site in the fall of 2000, we were also offering a course in educational policy at Teachers College in both campus-based and distance-learning modes. The lectures for this course were delivered by a diverse group of faculty at the College, and the course served as a general introduction to the field of policy. The lectures were transcribed and digitized to make them available to the students in the distance-learning section of the course and as a reference tool for students in the campus-based section. We also offered the set of lectures as new content on the online site for the *Teachers College Record*. We treated the lectures as articles with multimedia components and encouraged readers to respond to the lectures using the integrated discussion boards on TCR in the same way we encouraged students registered for the distance-learning section of the course to discuss the material on the online course site. This experiment in online learning as part of the online journal proved popular for readers and suggests the possibilities for additional educational experiments with a hybrid journal-course format.

A second educational experiment was launched for the holiday season between the fall 2000 and spring 2001 semesters and has been repeated annually. Each holiday season we have devoted several weeks to featuring materials related to a major figure in the field of education and educational research. One year we focused on John Dewey and published papers by and about John Dewey from the TCR archives. In subsequent years, we have done the same thing focusing on Edward Thorndike and Maxine Greene. Each of these experiments has generated reader interest and attention during a normally quite time for academic publications.

A third experiment illustrates the power of seizing the teachable moment through rapid online publishing. In the immediate aftermath of the attacks on the World Trade Center and the Pentagon, we understood the great need of educators to make sense of the tragedy and help their students deal with it as well. We quickly posted a call for papers on the responses of educators and the educational system to this national emergency. As part of this call, we included a call for educators to submit examples of the artwork and writing of students in response to the attacks. While we waited for our readers and authors to respond to the call, we also put online a series of articles from our archives dealing with the responses of educators to World War II in the aftermath of the attack on Pearl Harbor, the last major surprise attack on the United States. These articles dealt with the full range of issues that were strikingly parallel to those arising after 9/11. One of the lessons we took from this experiment is that the value of our archival materials can rise rapidly, as new events occur for which they carry special relevance. There was probably no other time in the last few decades when the papers on educators' responses to World War II would have gained such careful attention, and we happened to have the materials and the means to republish them online.

The design and operation of our online publishing platform has allowed us to advance our educational goals. We have done much more to allow the editorial team to reach out to readers. We have seized new opportunities to use all of the assets of the journal to enrich the conversation about educational scholarship and practice. We have found new means to share control of the journal with its readers and to engage them in the publishing effort.

3.3. Integrating Submissions and the Automated Editorial Office

We have already discussed doing many things online that we were not able to do with our print journal. Indeed, since we began regular online publishing at *Teachers College Record*, we have done much more than ever before. We have published more content more frequently and provided more related resources in more diverse formats. We have done this by working harder to some extent, but we have also used our online publishing platform to achieve productivity gains in the operation of the editorial office.

When we launched the online publishing platform in the fall of 2000, we also moved our entire editorial operation online. We began requiring authors to submit all papers online, and we started handling all correspondence with reviewers online as well. From the time a paper is submitted, throughout the review process, and up to and including publication, all processing is handled on the computer desktop. This system also provides a complete record that allows us to track each manuscript at every stage in the process. The result has been a large gain in our capacity to receive, review, prepare, and publish papers with a smaller staff than we had before we began publishing online.

The integration of all journal operations through our online publishing platform has also allowed us to address problems that plague many academic journals. First, we have used our online publishing program to solicit manuscripts more widely than ever before. We provide complete and easy online directions for any author interested in submitting a manuscript to the journal. We also use the online site to issue special calls for papers. The fully online process reduces submission costs for authors who no longer need to make multiple copies and pay for postage to submit manuscripts. This has led to a dramatic increase in the number of papers submitted annually. In particular, we have received many more papers from authors outside of the United States than we did before we began publishing online.

A good illustration of the effectiveness of using the online platform to solicit content for the journal comes from our efforts to expand the number of book reviews we publish. To develop a list of potential book reviewers, we put out a call for book reviewers on the online site and asked those who might be interested to complete a brief survey describing their interests and their expertise. We also gave them the option of providing a link to their online vita, so we could understand their background more fully. Over 1200 individuals volunteered to become book reviewers in response to this call, and we have been able to invite many of these scholars to become book reviewers. This has allowed us to involve individuals who might not have been involved in the past.

A second problem addressed by the online publishing system is the need to find and invite experts to serve as reviewers for the manuscripts submitted. Because our entire readership is registered in our member database, we are able to identify a large pool of qualified reviewers. We can query the database on any topic and find scholars with appropriate credentials to invite to become reviewers. The invitations are sent from the online platform, and reviewers can accept or decline our invitation and then, if they have accepted, download the paper at their convenience. After they have read a paper, they can submit the review again using the online system. By using an automated system for finding and inviting reviewers, we have been able to expand dramatically the pool of individuals involved in the review process.

The system tracks all manuscripts and all reviews and presents them to editors upon request. Editors can use the system to communicate decisions to authors, and authors can follow-up by submitting revised versions for publication. The system incorporates the copy-editing process, and the copy editors retrieve manuscripts and submit copyedited versions online. Finally, copyedited manuscripts can be moved to the online publishing site quickly and with little staff effort. Versions of papers scheduled for the print journal can also be sent to the printer.

The dramatic efficiency gains we achieved from using the online system together with the far greater reach of the journal has allowed us to do something we did not contemplate prior to moving online. With more manuscripts being submitted and more capacity to process them, we have expanded our schedule of print issues from four per year to 12 per year. At the outset, one of our concerns was that we might have to choose between publishing in print and publishing online. Thus far in our experience, moving online has allowed us to do both at a higher level.

4. PATTERNS OF USER EXPERIENCE

We have discussed our approach to the curriculum and the pedagogy of online publishing. In this section, we consider the third of Bernstein's (1975) elements of education, assessment. We do this by examining the behavior of users or members of the *Teachers College Record* online site over the 30-month period from its launch in November of 2000 through April of 2003. We address three questions that we have interested us since the outset of our online activities: how we might build an audience, how we can learn more about our readers, and how we can gain a greater understanding of what our readers want in an academic journal?

4.1. Building an Audience

One of our goals in moving the journal online was to expand and diversify the readership. We wanted to reach more scholars than we had been able to do with our print journal, and we hoped that providing our content online would make it more accessible to educators and the general public. Of course, we also understood that there was no guarantee that we could achieve either of these goals.

With our print journal received by several thousand libraries and other institutional subscribers and with fewer than a thousand individual subscribers, we believed that the opportunity to increase readership was substantial.

When we launched the new online publishing site for TCR in the fall of 2000, we began requiring users of the site to register by providing a name and an e-mail address. This allowed us to track not only overall use of the site in terms of page views, but also the number of unique individuals accessing the content of the online journal. In October 2000, we began with about 8000 individual members largely gathered from users of our earlier online sites, subscribers to the print journal, and individuals who had submitted papers. By the spring of 2001, the membership totaled about 17,000. By the spring of 2002, the number of members of the online site reached 34,000, and by the spring of 2003, the number of members exceeded 65,000.

In addition to keeping track of the total number of individuals who had registered as users of the online journal site, we also monitored unique visitors to the site. Figure 1 shows the number of unique visitors for each month from June 2002 through May 2003. The site received nearly 6000 unique visitors in June 2002, and this number rose to well over 9000 unique visitors in May 2003. The increase in monthly unique visitors rose throughout the year with notable declines during the summer month of August and the holiday dominated month of December.

With the reading audience growing rapidly, we were interesting in knowing whether the audience was becoming more diversified and whether we

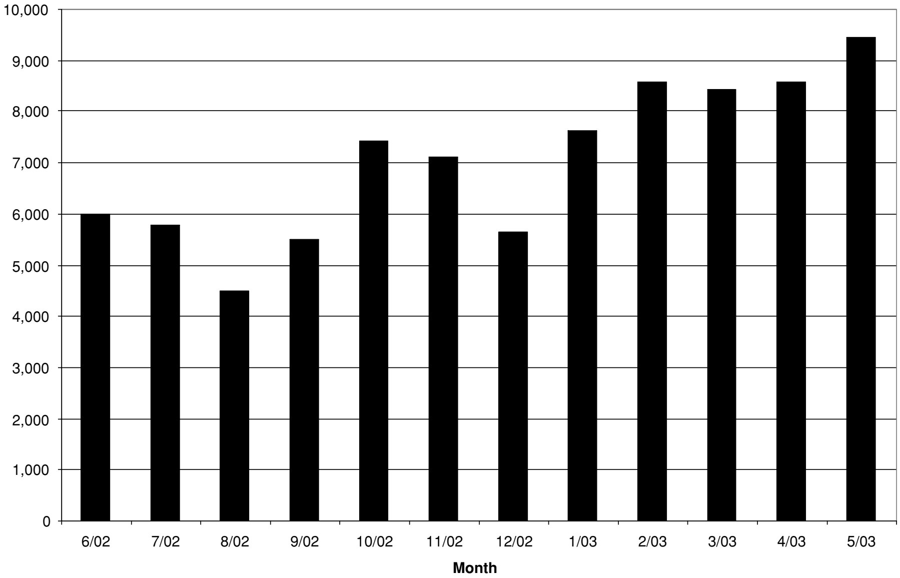

Figure 1. Unique visitors to the Teachers College Record online site—June 2002 through May 2003.

were reaching readers outside our traditional audience of scholars in institutions of higher education. To gain some understanding of the distribution of readers, we drew a random sample of 1000 members and examined their e-mail addresses and institutional affiliations for those who provided such information. Because individuals often provide a personal e-mail address instead of a business e-mail address and because many members decline to provide affiliation information, this analysis is less than ideal. Nevertheless, it does provide some indication of the diversity of the reader audience for TCR. About 27% of readers can be identified as associated with institutions of higher education. These are the readers traditionally reached by the journal. About 21% of the readers can be identified as being employed by k-12 school districts, and 10% identify themselves as students in higher education institutions. Smaller proportions of members were employees of research and development organizations or foundations (7%), independent professionals in education, and other sectors such as publishing or nursing (6.4%), and employees of a government agency (3.1%). For nearly one-fourth of the sample, we were unable to classify members according to sector.

Our monitoring of web site traffic also allowed us to understand the impact of the weekly newsletter that we typically send to those members who request it once each week on either Tuesday or Wednesday. As Figure 2 indicates, on those days when the newsletter announcing new content is sent to readers, the traffic is about three times as great as on the day prior to the newsletter.

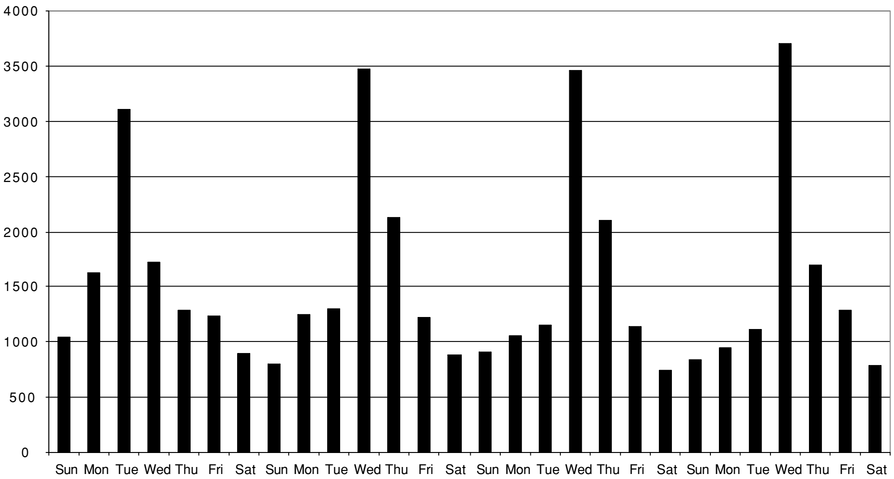

Figure 2. Unique visitors to the Teachers College Record online site by day—Sunday, May 4, 2003 through Saturday, May 31, 2003.

The traffic typically peaks on the day the newsletter is released, but it remains higher than normal for a second day.

An unanticipated byproduct of the dramatically larger audience for the journal has been an equally dramatic increase in the quantity and quality of manuscripts submitted for review. In the year prior to the introduction of the new online system, we received about 200 manuscripts. During 2001, the first full year of operations under the new system, we received over 300 manuscripts. This number increased to nearly 450 manuscripts in 2002, and nearly 300 manuscripts have been received during the first 6 months of 2003.

Our analysis of the level of use of the online site indicates that readership is growing over time, that the readership is extending beyond those scholars at institutions of higher education who have formed the traditional audience for the journal, and that the weekly newsletter serves to increase use of the materials available at the online site. Thus, moving the journal online is serving to build a larger and more diverse audience.

4.2. Understanding Online Behavior

In addition to following the growth in the readership of the journal, we used the online publishing site to gain a greater understanding of reader interests by tracking reader behavior online. During the 12-month period from June 1, 2002 through May 31, 2003, there were 36,229 unique readers of the online journal, and these readers generated 1,955,452 page views on the journal site. (We have used page views as the unit for measuring use of the site since a

Content posts made	285

view of an entire page is more meaningful than the often cited hit statistic what counts every graphic element on a page as an additional hit.)

Table 1 indicates the resources on the journal site that were used by readers during this 1-year period. Users viewed individual articles 409,067 times during the 12-month period. These include any of the over 1000 full-text articles from the past 20 years that are available online as well as older articles for which only a title or an abstract might be available. Readers viewed the journal's home page 224,826 times during this same time.

The next two most frequent uses relate to the two major ways of finding materials on the journal site, collections and searching. Readers accessed a content collection 148,256 times, and they used the general search utility 87,348 times. If we consider the content collections as the result of searches conducted by the editorial team, then the editorial voice represented in the collections appears to offer some value to readers, and they appeal to those collections in searching to meet their own needs more frequently than they use the general search.

The next two most frequently used resources, downloadable portable document files and the print article utility, allow readers to make print copies of journal articles. The portable document files are available for many articles and offer the same format as the print journal; the print article utility provides a full-page printer ready version of articles in html.

The next most frequently used resource on the site, collection posts, refers to readers accessing the comments of other readers posted on the discussion boards in the content collections. Readers accessed the 475 comments of other readers in the content collections 39,016 times. Looking further down the table, we see that readers accessed the 285 comments of other readers attached to individual articles 8547 times.

The online catalog of journals in education was used 26,047 times, and the search utility attached to the journals catalog was used 19,496 times. Other resources not directly connected to the content of the *Teachers College Record* were also accessed by online readers. Links to external articles from the content collections were followed 24,745 times, links from content collections or book reviews to book information on Amazon.com were followed 16,371 times, and links to research and development centers from the content collections were followed 5319 times. Together, these other resources constitute a substantial portion of user activity on the journal site.

The utility that allows readers to send a link to an article to a friend or colleague was used 10,417 times during the year. This utility engages readers in promoting the content of the journal. The annual index that provides a view of journal content by volume was accessed 7906 times, and the page that allows users to manage the options on the online account, such as whether they wish to receive the weekly newsletter and whether they wish to serve as a peer reviewer, was used 5132 times.

Following reader behavior online also allowed us to gain some understanding of the topics within the fields of education and educational research that were of most interest to readers of the journal. We did this by tallying the reader visits to the various content collections displayed on the home page. Table 2 shows the number of reader accesses of the content collections organized by

Table 2. Reader accesses of the Teachers College Record content collections—2001 through 2002

the 16 broad categories we created to organize articles and other resources. As Table 2 indicates, collections in two broad categories, policy (19,924 visits) and curriculum (15,635 visits), received more than 15,000 visits. Collections in five categories, social context (13,724 visits), student diversity (13,449 visits), assessment and evaluation (12,079 visits), technology (10,956 visits), and research methods (10,177 visits), received between 10,000 and 15,000 visits. Collections in administration (9896 visits), teacher education (8905 visits), learning (7956 visits), teaching (7674 visits), early childhood (6424 visits), and adult education (5892 visits) received between 5000 and 10,000 visits. Finally, collections in higher education (4444 visits), international education (3629 visits), and counseling (2226 visits) received fewer than 5000 visits during 2001 and 2002.

4.3. Lessons Learned

Several things are clear as a result of our analysis of patterns of use of the online journal site. First, the online site for the journal is a powerful tool for increasing readership and generating both more and higher quality submissions. The growth in readers appears to involve both drawing more readers from our traditional base among faculty members and students from institutions of higher education and engaging new readers from k-12 school districts, and from foundations, government agencies, and other sectors such as publishing. Second, our weekly newsletter appears to work very effectively to bring registered users of the site back to the site to view new content.

Third, once readers are using the online site, as might be expected, they are most interested in the content provided in the form of articles. Fourth, again as might be expected, the home page is the most popular single page on the site. Fifth, the content collections of articles and resources organized by topic or theme are the next most frequently used resource and appear to be substantially more likely to be used by readers than the general search function.

The pattern of use of topics related to the discussion boards led us to several additional conclusions. Sixth, the rate of user comments differs by venue of discussion board with discussion boards attached to content collections generating more user comments than those attached to individual articles. This could be the result of our practice of featuring reader comments from the content collections prominently on the home page or it could be the result of readers being more inclined to comment on the more general topics represented by the content collections than the specific issues raised by individual articles. Seventh, there is substantial reader interest in the comments of other readers with each comment on individual articles being read an average of 30 times by other readers and each comment within a content collection being read an average of 82 times by other readers. Again in explaining the seemingly greater popularity of the comments attached to the content collections, it is not possible at this point to disentangle the impact of the venue of the discussion board from our efforts to promote such discussions on the home page.

Eighth, readers at the online site did make use of other resources provided, including those not directly produced by the editorial team such as links to other online resources, although the use of such resources was less frequent than the use of *Teachers College Record* resources.

Ninth, reader interests as reflected in visits to the content collections are broad-based but concentrate on some collections such as policy and curriculum substantially more than others such as international education and counseling. The editorial implications of this pattern are at least twofold. On the one hand, substantial reader interest might suggest that greater investments should be made in editorial content in high use areas. On the other hand, if our goal is to create a broad-based journal in the field of education we might decide to invest greater effort in areas that receive less reader attention in the hope of increasing the utility of the journal to readers in these areas. The data available from the online site at this point do not allow us to understand the impact of enhanced content in an area on reader use.

5. NEW HORIZONS AND NEXT STEPS

Our experience thus far in creating an online venue for the *Teachers College Record* leads us to be very optimistic regarding the future of the online journal as an educational environment. We have used online tools to empower a small editorial team to build a large and still-growing audience with diverse interests in high-quality content and a willingness to participate in the continuing creation of the online site as an educational resource. The broad use of the online resources and the growing number of submissions attest to the self-reinforcing and self-sustaining nature of the enterprise. We anticipate significant further development of the online site in terms of its content or curriculum, its publishing or pedagogical approach, and in terms of its business and technology infrastructure.

Our success in operating the online journal has allowed us to address two enduring issues. First, despite initial reservations on the part of a substantial portion of our editorial board, the success of the online journal in reaching a larger and more diverse audience of educators, policy makers, and scholars has led the board to become more supportive of additional online efforts. Meetings of the editorial board are now dominated by discussion of our online initiatives, and board members regularly offer a range of suggestions for new online activities. Second, the popularity of the online journal has allowed us to improve the overall financial position of the *Teachers College*

Record. For many years, the *Record* operated with a subsidy from Teachers College. The online journal led to increases in both readership and the number of submissions received each year and allowed us to increase the number of print issues from 4 per year to 12 per year while enhancing the selectivity and the quality of the journal. The increase in subscription rates associated with more frequent publication has allowed the journal to cover all of the operating costs for the editorial office. Thus, although the online journal is available to readers without charge, the greater prominence of the journal overall has strengthened its financial position and made its future more secure.

Building on the expanded print journal, there is a very substantial opportunity to expand the content provided through the online journal site. With the growth in high-quality submissions, the journal will be able to provide more material of a higher quality. Moreover, the weekly publishing schedule allows us to do more to highlight every paper published. As the content grows, we will consider segmenting and targeting the weekly e-mail newsletter to subgroups among the readers so that those interested in a particular topic will receive information most relevant to their interests. Based on our analysis of reader online behavior, we will be re-doubling efforts to publish in areas where we offer relatively little and where our online audience has the potential to grow. This will necessarily involve some experimentation as we move forward. For example, we will be issuing calls for papers in areas such as counseling where we currently offer relatively little to determine if more content in an area will draw more readers to that area.

We also anticipate investing effort to create more powerful tools for readers to move through the sizable collections of content on the journal site. In addition to our current organization of content collections and search functions, we anticipate allowing readers to move through the different segments of articles, once those articles are online in full text html as opposed to the portable document files that now provide page images that cannot be searched. For example, we plan to allow readers to search for all articles referencing particular items.

In terms of our pedagogical approach at the online journal site, we are sufficiently encouraged by the results of our early efforts to stimulate reader engagement and participation to expand those efforts. In addition to our current discussion boards attached to each individual article and to the content collections, we plan to introduce a site-wide discussion board to attempt to create a critical mass of reader/discussants across all areas covered in the journal. The discussions attached to individual articles are scattered across the more than 10,000 individual pieces, and the discussion boards attached to the content collections are spread throughout over 70 collections. We want to experiment with a discussion or commentary area of the online site that will bring together provocative peer reviewed commentaries with reader comments. We hope to use this area of the journal to share even more control with users.

As part of our instructional mission, we also plan to introduce a new section devoted to authors that would contain a range of resources to assist them in preparing articles for publication through *Teachers College Record* or through other journal outlets. This new section will bring together current resources such as the journals catalog with short instructional pieces on how to prepare journal articles. We are also engaged in the early stages of exploring the development of an automated system of providing feedback to authors before their paper enters the review stream. Such a tool could link diagnostic feedback on a paper to available online resources for authors. We view this new set of resources as both a service to authors and as a way to enhance the quality of papers submitted even further.

Encouraged by our experience in mixing *Teachers College Record* resources with those from other sources, we plan to seek new opportunities to collaborate with others engaged in teaching either through classes or workshops or through conferences on important topics in the field. These joint ventures will inevitably blur the lines between teaching and publishing in ways that have the potential to enrich the educational program of the journal. Other online journals are also obvious candidates for collaborative ventures that would draw on resources from multiple journal sources. Publishers handling multiple journals may also be in a good position to present resources from groups of journals. For example, Taylor and Francis has organized collections of journals that it publishes in web arenas that offer access to articles for all journals in a content area such as education (http://www.tandf.co.uk/journals/arenas.asp).

One of the unanticipated byproducts of our work to create the online journal has been a continuing interest in the creation of online environments and the development of tools to reduce the costs and enhance the functionality of such environments. When we created the 2000 version of the *Teachers College Record* online publishing platform, we built a hand-crafted system to publish a single journal. This platform has served us well, but we no sooner completed the technical development of the platform than we discovered many reasons to change and enhance it. Rather than continue to invest in improving a single dedicated platform, we embarked upon a course to create a general publishing and education platform creation tool. This tool allows us to create any number of journals or other educational environments quickly and inexpensively. (For more information on this platform, see www.frameworkers.com, named, incidentally, to honor those cottage weavers whose work was transformed by the industrial revolution and moved into factories where they labored attached to frames of one sort or another.)

The flexible, re-configurable publishing platform that will form the basis for the next generation of the *Teachers College Record* online site will allow us to engage in more experimentation as we position and re-position content and utilities to engage readers and then assess their response. It will also allow us to create new online journals or parts of journals at low cost. This will make it possible to do things such as creating instant journals to chronicle the work of particular projects or events. It will also allow us to experiment with journals devoted to new topics to determine if there is a sufficient audience to justify further development. In the case of the *Teachers College Record*, it will allow us to mount new projects with ease. For example, we might create new content collections tailored for individual courses or we might allow each registered member of the online site to create collections for any course they might be teaching. This is but one of a host of strategies that might be pursued to make the resources of the journal more relevant to the needs of its readers.

We began this chapter by highlighting the educational mission and history of the journal. We end it after having demonstrated our record of early activities and after speculating on the next stages in the educational development of our online publishing venue. However, our presentation would be incomplete if we did not also note the importance of our own learning experience along the way. What began in the mid-1990s as a traditional academic journal has been transformed by the effort devoted to creating and sustaining an online-publishing operation. We have learned more than we ever imagined we might when we began, and it is clear that there is much more to learn about the educational role of our journal and the educational needs of our readers in the years ahead.

Chapter 31: Professional Development & Knowledge Management via Virtual Spaces*

NORIKO HARA AND ROB KLING
Center for Social Informatics, School of Library & Information Science, Indiana University, Bloomington, IN 47405.

1. INTRODUCTION

In the U.S., the mid and late 1990s was a boom period in many ways that included an expanding economy, a growing emphasis upon the value of people's working knowledge, and a range of new Information Technology (IT) applications and information services that depended upon computer networking—often the internet. These themes were represented in professional discourse by a special emphasis upon "knowledge work", "knowledge workers", and new practices, such as "knowledge management". While genuine referents for the "knowledge categories" are often elusive, at best they refer to serious efforts of managers to improve their staff's abilities to become more knowledgeable by sharing information and insights within organizations and to leverage their enhanced knowledge for organizational value.

For example, in *Microsoft Secrets*, Cusumano and Selby (1995: 330–339) report the ways in which Microsoft's managers and software developers reviewed major software development projects through extensive and relatively open "project post-mortems" with the aim of improving future software developments. In *Working Knowledge*, Davenport and Prusak (1998: 6) mention the efforts of managers at Chrysler to develop "Engineering Books of Knowledge" for each new car platform to help to better inform designers of future platforms about more effective design strategies. While Microsoft's post-mortems were based primarily upon written reports and intensive face-to-face meetings, Chrysler's "Engineering Books of Knowledge" represent a 1990s move to use electronic environments as integral elements for helping professionals to share their information and knowledge with others in their organizations.

They also illustrate important forms of professional development. The elastic term "professional development" can refer to almost any way that working professionals are supported in efforts to increase their capabilities and competencies including courses, mentoring, workshops with experts, discussions with peers, and (in some cases) onsite observation, etc. In this chapter, we

* To appear in: Joel Weiss, Jason Nolan, and Peter Trifonas (Eds.) *International Handbook of Virtual Learning Environments.* Kluwer Academic Publishers.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 849–870.

will focus on forms of professional development that overlap with knowledge management strategies—especially discussions with peers.

This chapter is divided into five sections. In the first section, new terms, such as knowledge management, professional development, and virtual spaces are introduced. The second section addresses discourses about professional development and knowledge management including e-learning—primarily because e-learning is a means to support professional development with IT and currently receiving intensive attention. For the third section, four case examples are described in order to depict possibilities and problems with professional development in virtual spaces. The fourth section discusses these cases and the implications they have for professional development in virtual spaces. Finally, we conclude the chapter by pointing out the hype surrounding knowledge management and noting that knowledge management is not just an IT system.

In the 1990s, the development of varied IT applications that enabled professionals to share ideas and information at work flourished. These ranged from new forms of groupware (Kirkpatrick, 1993), such as Lotus Notes, which consist of online documentary repositories that enabled web-conferencing systems. In educational communities, these were often called Virtual Learning Environments, while in corporate settings these knowledge management systems were often referred to as groupware. In this chapter, we use the term Virtual Spaces to refer to this diverse collection of artifacts. We view learning and sharing professional knowledge as accomplishments that can (sometimes) be facilitated by Virtual Spaces. For example, there were a number of projects that supported professional development via peer conferencing for K-12 teachers, such as LabNet (Ruopp et al., 1993; Spitzer & Wedding, 1995), "Tapped In" (Schlager et al., 1998), and the Internet Learning Forum (Barab et al., 2000).

Many of these projects were IT-driven; they tended to focus the majority of their resources on developing the supporting information technologies. However, as we shall show below, the research has found that learning and knowledge sharing are not automatic consequences of the development and deployment of Virtual Spaces. The more successful projects are based on an integrated socio-technical intervention in which supporting social processes are given as much attention as the technological design of the Virtual Space.

2. DISCOURSES ABOUT PROFESSIONAL DEVELOPMENT AND KNOWLEDGE MANAGEMENT IN VIRTUAL SPACES

There are several discourses about innovative organizational practices. One set of discourses is very public and appears in mainstream business and professional publications. In the 1990s, much of the professional and popular writing about internet support activities, including e-commerce, e-learning, and knowledge management was promotional and tinged with technological utopianism (Kling, 1994). In a study of management fashions, Abrahamson (1996) observed:

> fashionable management techniques must appear both rational (efficient means to important ends) and progressive (new as well improved relative to older management techniques). Many management fashion setters—consulting firms, management gurus, business mass-media publications, and business schools—compete in a race to define which management techniques lead rational management progress (p. 254).

The term, "knowledge management" appears to be one of today's fashionable management techniques. Lambe (2002) justifies this perception by listing several indicators: new topical magazines have sprung up; institutes and societies have appeared out of nowhere; new job titles, such as Chief Knowledge Officer, are being invented; etc. He concludes his essay by saying that some knowledge management practices that were adopted as a part of a fashion move may disappear, but that many leading companies have taken knowledge management rather seriously.

We searched the practitioner literature for articles that mentioned the term "knowledge management" in the information service Factiva that includes articles from approximately 8000 sources such as major international newspapers and business magazines. On October 27, 2002, a search for "knowledge management" on Factiva retrieved 40,203 articles. We further plotted the numbers of articles that mentioned knowledge management between 1988 and 2001 (see Figure 1). The number started small, i.e., 3 references in 1988,

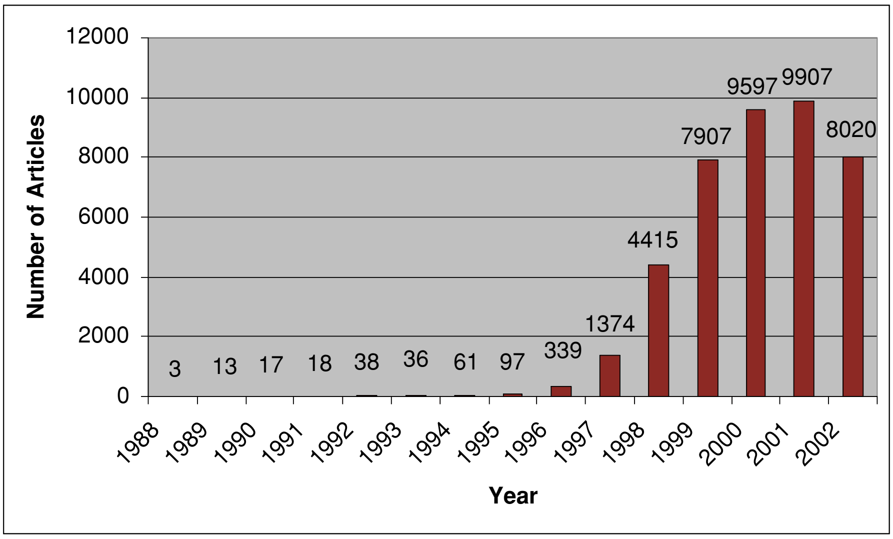

Figure 1. Number of articles in Factiva that mentioned knowledge management.

13 references in 1989, and 17 references in 1990. In this early stage, most of the articles that referred to knowledge management discussed Knowledge Management Systems, databases, and expert systems. The number of articles in 1996 was more than triple the amount of knowledge management articles written in 1995. During this stage, articles related to consulting practices and strategic management began to appear. The tremendous increase of knowledge management articles did not stop until 2000, when it dropped to a 3% annual increase compared to a 21% increase between 1999 and 2000. In 2002, the number declined approximately 20% from 9907 in the previous year to 8020.

E-learning is another trend that seems to attract many companies. The term e-learning is subject to many slightly varied definitions, but they all emphasize the centrality of some kinds of electronic information technologies to support learning, from CDs to computer networks. E-learning is also used to support professional development with distance education. It has been discussed rather enthusiastically, but without much empirical evidence to support important claims. For example, Davis and Botkin (1994) preached about the vast possibilities of education with technology. However, their focus was more on promoting the technology use in education and less on pedagogies and practical implications. Empirical research conducted by Anderson and Kanuka (1997) found that students who used online forums for professional development reported that they had a difficult time socializing with others and getting their ideas across compared to the use of face-to-face forums. Research (Howell & Stinson, 2001) suggests that a hybrid type of e-learning (i.e., use both face-to-face and online learning) would be more effective than either online or face-to-face alone. In addition, we need to consider specific pedagogies applicable to online environments. Bonk and Cummings (1998) introduced a dozen recommendations for making web-based instruction student-centered.

Although both the field of e-learning and that of knowledge management deal with techno-enthusiasts, the issue of professional development via e-learning and that of knowledge management are slightly different. In distance education, knowledge is “available” in teaching materials, whereas knowledge management projects often require participants to share, not just to “receive” (c.f., Kling & Hara, 2004).

Unfortunately, the literature on professional development is scarce and tends to be clustered around different professions. It is a rather application-driven field. Due to rapidly changing technology and increasing knowledge in recent years, professional development has become crucial to various professions (including teachers, physicians, lawyers, and engineers) even though technologies have supported professional development efforts throughout years. For example, Feenberg (1993) described his efforts to support a course offered to corporate executives in the 1980s with computer conferencing. This kind of effort, along with Hiltz and Turoff’s (Turoff, 1991), stimulated the use of computer conferencing for professional development, and these ventures did not begin with the public access of the internet.

A good deal of the professional literature concerning professional development via web conferencing and IT support for knowledge management is written with a high level of normative enthusiasm and relatively little attention to the socio-technical complexities of achieving the desired outcomes. In many cases, IT was characterized as a "magic bullet" (Markus & Benjamin, 1997) that could readily enable important kinds of organizational change without much pain. For example, Davenport and Prusak (1998) used the efforts of managers in five different locations at Chrysler to develop "Engineering Books of Knowledge" for each new car platform to illustrate their approach to knowledge management. But they never discussed the ease or difficulty that the managers faced in persuading busy engineers to effectively contribute to these "Engineering Books of Knowledge", nor did they ever discuss the actual quality and value of any of these "Engineering Books of Knowledge" whose contents were based on "altruism", i.e., the engineers could not bill their writing time to their own projects. Rather, Davenport and Prusak's readers are encouraged to believe in the quality and value of Chrysler's Engineering Books by implication. Some of Chrysler's managers took these "Engineering Books of Knowledge" very seriously, and Davenport and Prusak saw them as useful examples of knowledge management. However, Davenport and Prusak do not provide evidence on how useful the "Engineering Books of Knowledge" had been to the engineers at Chrysler. They are treating this example of knowledge management strategy as a "black box". In other words, they do not tell us what is happening with the strategy and the tool. They merely present the black box and mention the outcomes of the black box, but not the internal mechanics.

On the other hand, this example also works as a romantic lure that implies that electronically shared Engineering Books in a Lotus Notes database can be used as a technological fix for effectively improving the design expertise of an automobile manufacturer whose products usually had notably more manufacturing defects than their competitors in the late 1990s. In a similar way, much of the professional writing about web conferencing for professional development has amplified the lure of possibilities rather than examined complex socio-technical realities.

One might expect the scholarly research literature to provide a richer and more nuanced understanding of professional development and knowledge management with electronic support. Unfortunately, the research literature concerning knowledge management via Virtual Spaces is very mixed at best. Schultze and Leidner (2002) systematically examined the character of research that was published in six international information systems journals that focused on knowledge management between 1990 and 2000. Over 70% of the 75 studies that they examined were primarily normative, involved consensus-based findings, and were written from the perspective of organizational elites.

Studies of this sort would echo Davenport and Prusak and supported knowledge sharing projects such as the "Engineering Books of Knowledge". Only 28% of the studies (21 out of 75) examined knowledge management from the perspective of multiple participating groups and knowledge management practices as seen by these groups. On the other hand, knowledge management projects, such as Chrysler's "Engineering Books of Knowledge", place critical emphasis upon the participation of non-management groups, such as the engineers whose expertise is being sought. It is unfortunate that so little of the knowledge management literature helps us to understand how knowledge management projects look from the vantage point of the participants who have to be mobilized to share their knowledge.

In this chapter, we will briefly describe four empirical case studies of professional development that were supported by Virtual Spaces, such as Lotus Notes, web-based conferencing systems, or LISTSERVs. These include

(a) the efforts to use Lotus Notes to support knowledge sharing by the consultants of major consulting firms;
(b) the creation of a web-based conferencing system to support online classroom visits and discussions of teaching practices by secondary school science and math teachers;
(c) the efforts of public defenders in a metropolitan county court to improve their skills via discussions with other public defenders; and
(d) the experiences of in-service teachers who took an online graduate course as part of their professional development.

3. CASE EXAMPLES

3.1. Lotus Notes in Consulting Firms

One way to illustrate a contextual inquiry of IT and social behavior is to examine case studies of organizations. Examples can be found in studies of how some consulting firms have adopted and used computerized documentary systems. The following two cases illustrate the importance of incentive systems. In one case, reported by Orlikowski (1993), the consulting firm did not provide effective rewarding for consultants to share their knowledge. By contrast, a case reported by Ernst & Young (E&Y) revealed that incentive systems promoted knowledge sharing.

One major consulting firm, identified by the alias Alpha Consulting, bought specialized equipment and 10,000 copies of Lotus Notes for their staff in 1989 (Orlikowski, 1993). Lotus Notes, a documentary support system, is superficially similar to an internet system, with bulletin boards, posting mechanisms, discussion groups, and electronic mail for organizations. Depending upon how Notes is used, it can act as an e-mail system, a discussion system, an electronic publishing system, and/or a set of digital libraries.

Alpha Consulting is an international consulting firm with tens of thousands of employees worldwide (about 10,000 of those employees are located in the United States). Their director of information and technology believed that Lotus Notes was such a powerful technology that its usefulness would be patently evident, and that the main thing to do was to rapidly make it available to the consulting staff and let them use it to find creative ways to share information. The director of information and technology felt that Lotus Notes was so revolutionarily valuable that people did not even have to be shown illustrative business examples of its use, and that providing examples would, in fact, be counterproductive as it might stunt employees' imaginations. The consultants, by being given an opportunity to use it, would learn how to use it in creative ways.

The line consultants were intended to be Lotus Notes' primary users. Organizational informatics researchers found that the senior line consultants, who were partners in the firm, tended to be modest users, while the more numerous junior line consultants, called associates, were low users. These junior consultants often seemed uninterested in learning how to use Lotus Notes, readily gave up if they faced early frustrations with Notes, and as a group, did not spend much time with the software. What can explain the differences in practices of use of Lotus Notes between two different groups in the same organization?

One explanation focuses upon the incentive systems in the firm, and starts with an analysis of the different ways that the associate consultants and partners were rewarded. Alpha Consulting, like many other large consulting firms in North America, reviews its consultants via a demanding promotion system. The associates receive an "up or out" performance review every 2 years. In the first few career reviews at major consulting firms, about half of the associates are fired. Associate consultants, afraid of these major layoffs and wanting to be made partners, will not spend the time to learn Lotus Notes due to the lack of company incentive. Once consultants are promoted to the status of partners, they can expect annual incomes of over $300,000 at these major firms. Partnerships are the golden ring that these firms use to motivate their associate consultants, and partnerships are earned by performance.

The way many consultants in E&Y, another major consulting firm, organized Lotus Notes as a more integrated socio-technical intervention is equally instructive (Davenport, 1997; Gierkink & Ruggles, 2002). In brief, E&Y created an organization (Center for Business Knowledge) whose charter was to organize E&Y's consultants' know-how in specific high-profile areas. The new organization was staffed with consultants from other E&Y offices who were given 6-month assignments to play a special role as "knowledge networkers". By 1997, E&Y had developed 22 distinct cross-office networks of consultants with expertise in certain industries, organizational reforms, or technologies that were a focus of E&Y's business. Each consultant network was assigned a half-time person (the knowledge networker) to codify the insights from specific consulting projects in Lotus Notes databases, to prompt line consultants to add their own insights, and to edit and prune a project's discussion and document databases. In some cases, they developed topical "Power Packs" in Lotus Notes. These are structured and filtered sets of online materials, including sales presentations and proposal templates. Davenport (1997) observed that these knowledge networkers understood their consultant network's topics, and that since these were short-term assignments for the consultants, they expected to utilize any newly gained expertise to advance their own careers when they returned to their consulting positions.

In this case, E&Y designed a human organizational "intelligence system" for sharing insights, ideas, and materials in specific topical areas. Lotus Notes served as an information support system—a medium for storing, organizing, and communicating these materials, rather than as a magnet to mobilize consultants to capture their knowledge so it could be shared with others.

3.2. E-Forums for Professional Development Among Teachers

This case describes the difficulty of community building in an online environment. The Inquiry Learning Forum (ILF) was created in 1999 by researchers at Indiana University's School of Education as an online forum to support inquiry-based teaching and learning practices among Indiana science and math teachers at the secondary school level (see http://ilf.crlt.indiana.edu). The underlying conception was to provide a set of interesting teaching materials, including videos of a class, lesson plans for that class and the teacher's reflections about the class. Each specific class (such as teaching the Pythagorean theorem) was organized in a separate unmoderated forum with its own threaded discussion list. Teachers could register at any time. While the registrants were screened to insure that they were appropriate teachers (or student teachers), the e-ILF was "open" in the sense that its membership could continually expand. New teachers could join and participate in any of the online forums, long after their discussions had started.

The ILF's organizers expected teachers to discuss the teaching materials, reflect on their own teaching practices, and function as a "community of practice" (Barab et al., 2000). "Communities of practice are informal networks that support professional practitioners to develop a shared meaning and engage in knowledge building among the members" (Hara, 2000: 11).[1] By mid-2001, the ILF's support staff worked with 17 teachers to develop videotaped "classrooms" on the ILF's web site (which we call the e-ILF). Over 200 in-service teachers out of approximately 26,000 secondary math and science teachers in Indiana had registered for the e-ILF, along with nearly 200 student teachers at Indiana University. However, participation in the e-ILF has not reflected the breadth of this membership: statistics collected in March 2001 show that only 29 teachers had logged in five or more times, and 19 had logged in ten or more times. Most discussion in the online forum has been limited to a relatively small group: 31 of the registered in-service teachers had posted five or more messages, and 14 posted ten or more messages. The number of posted messages connected to each "classroom" vary widely, but a typical set of 15 posts is threaded into 6–7 topics with anywhere from 0 to 3 responses each. The "lounge" section of the web site contains general topics for discussion, with a typical topic taking up 15–30 posts over a 1-year period.

Unfortunately, the difficulties of supporting reflective dialog and community building in online forums seem to be under-appreciated within the educational technology communities. Sherry (2000) is all too typical in unreflectively reporting claims that:

> One advantage of text-based communication is that written communication tends to be more reflective than spoken interaction. 'The very act of assembling one's thoughts and articulating them in writing for a conference audience appears to involve deeper cognitive processing'.
>
> (Berge, 1997: 10)

Arguments framed in this way make it appear that the use of text-based electronic communication will almost certainly lead to reflective dialogs where assumptions are evaluated, alternatives discussed, contexts carefully explored, etc. However, according to research on typical teaching practices in the U.S., teachers rarely engage in this kind of discussion when they are meeting face-to-face (Little, 1982; 1985; 1990). Perhaps we should not be surprised to find that such reflective discussion does not spontaneously arise in the e-ILF.

Our observations of the e-ILF discussions are consistent with mid-1990s research findings from the LabNet project, an e-forum designed to support the professional development of science teachers. DiMauro and Gal (1994) examined the online discussions of a group of science teacher leaders who were acting as liasons with the staff of an online professional development project. A network infrastructure was designed to enable these teachers to "exchange messages to reflect upon their peer support". The messages were characterized as informative, responsive (to a query), or reflective (one in which a participant "thinks out loud" about some teaching practice and different ways of approaching it). DiMauro and Gal note that reflective postings were very infrequent. With shrewd insight, they observe that:

> "Reflective responses are difficult to formulate and risky to post because of the personal nature of the content . . . "

They speculate about the conditions that support reflective postings, and suggest that they include "protected workspace for reflection, retrieved text base, collaborative research, access and response to messages, structure dialogue, linking action with reflection, forming reflective practice inquiry, and participatory motivation". Some of these conditions are found on the e-ILF (i.e., retrieved text base). However, only the Bounded Groups have a protected workspace for reflection. In contrast, postings in the virtual classrooms may be read by any teacher who joins the e-ILF in the future.

By mid-2000, the ILFs designers expanded the range of forums to include some for "bounded groups" where reading and posting were restricted to a specific membership (Kling & Coutright, 2004). The bounded groups included teachers who were engaged in a specific curricular reform, as well as classes of student teachers. The bounded groups proved to be much more viable than the open-ended classrooms. The participants of each bounded group usually knew each other and had some reason to believe that their postings would not be read by people who did not belong to the group (other than ILF researchers). Most importantly, members of the bounded groups met face-to-face periodically, and developed some workable trusting relationships in various face-to-face encounters. The e-ILF and its support staff did not face the challenge of developing trust and a sense of community within an exclusively electronic environment. As was the case of E&Y's organization of professional knowledge sharing through Lotus Notes, the technology was seen as supporting complex human relationships that were developed offline.

Developing high levels of collegiality and critical engagement among K-12 teachers has long been perceived as a major challenge. In fact, the nature of the e-ILF interactions described above is consistent with empirical research on teachers' interactions in general, which are characterized by a lack of direct advice or criticism (Ellis, 1993; Little, 1985; 1990). Overcoming this "etiquette" (Little, 1985) and promoting greater critical engagement and sense of group identity might require mechanisms—both online and offline—conducive to forging greater trust among e-ILF's members for open, frank discussions, and engagement.[2] In order for the ILF to build strong mutual ties among members so that it represents a vibrant community instead of a dispassionately used online discussion site, certain structural changes might be necessary to stimulate such engagement, trust, and group identity. Community development is likely to be an accomplishment that is difficult to initiate without purposive interventions from some kind of leader or steward. This will rarely happen spontaneously in online forums.

3.3. Listserv for Sharing Knowledge Among Public Defenders

Hara (2000) examined how two public defenders' offices shared and constructed their knowledge and how they used collaborative IT to learn from each other. It was estimated that 20% of the attorneys in a large metropolitan public defender's office used the listserv provided by the state public defender council for defense attorneys in this state. A listserv is an e-mail list which can be subscribed by multiple people and allow them to engage in online discussions. The study used the pseudonym "pubdef-L" for this listserv. About 250 attorneys subscribe to this listserv in order to share information. It is not open to the public. In order to be a part of pubdef-L, a user must be a member of the state public defender council and send in a request to join pubdef-L. The traffic in pubdef-L is relatively heavy. For instance, there were 214 messages within 2 weeks, between October 1, 1999 and October 16, 1999. Linda Ellis,[3] a misdemeanor attorney who subscribed to pubdef-L, summarized its characteristics: "There are a lot of experienced lawyers on there, so you get different information. A lot of wisdom comes through pubdef-L to help solve problems and give suggestions, and cite and find cases. It's a good asset". Roy Stewart, a major felony attorney, also had high regard for pubdef-L:

> [The listserv is] great because attorneys all over the state are on that, and it's not uncommon for an attorney in a small county to ask a question, "how do I deal with the situation"? and he'll get responses. Other defense attorneys are willing to help. The attorneys all over the state give him some ideas. So, that's really helpful. That's like being able to brainstorm with your whole community of defense attorneys. It all came together within about the last three or four years. Before that, I don't know how people kept in touch (interview with Roy Stewart).

Roy was an experienced attorney, yet he valued the information coming through pubdef-L because he considered it a brainstorming tool within the community of defense attorneys. Further, we infer that pubdef-L helps connect the defense attorneys throughout the state and creates a sense of a community among them.

Pickering and King (1995) examined the motivation for e-mail use in interorganizational communication. They note that "most of the messages posted to Usenet newsgroups are requests for particular information and assistance with problem-solving" (p. 481); the discussions in pubdef-L have similar characteristics. Pickering and King further argue that Interorganizational computer-mediated communication supports dispersed occupational communities. Pubdef-L appears to uphold this function.

In addition to information sharing and problem solving, Cathy, a less experienced attorney, sees pubdef-L as a great learning resource: "Since I'm new, I just learn a lot, I'm not at a point where [I'm responding much] . . . But I just learn a lot from hearing about different issues". Hence, pubdef-L provides a learning space for less experienced attorneys as well as the more experienced ones.

Angela, an experienced attorney, cautioned that pubdef-L can reduce the opportunities for less experienced attorneys to conduct research by themselves, because the listserv is only for question-and-answer sessions, not for research. There might also be a danger of relying on the information from pubdef-L too much without critically judging its quality. Alex Gordon, supervisor of the major felony attorneys, warned that attorneys needed to be selective about the information that can be obtained through pubdef-L by saying there is "lots of junk in it". Therefore, these attorneys who are on pubdef-L have to evaluate the quality of the information obtained through it. Both Alex and Angela mentioned that their criteria for judging the information was based on the message senders, e.g., whether they are good courtroom attorneys. They both emphasized the importance of knowing court performance. They have been practicing in this field long enough to know most of the other attorneys and their reputations. On the other hand, less experienced attorneys did not mention this type of evaluation process while reading messages on pubdef-L.

In summary, the attorneys appear to use pubdef-L for many purposes: to ask questions, share updated information, brainstorm strategies in trials, discuss current legal issues, and learn from the discussions. The study found that the characteristics of pubdef-L resemble the attributes of the communities of practice.[4] Significantly, this online community of practice appears to have been developed to share legal expertise, partially because it is a closed listserv and most of the attorneys knew each other in courts. However, there are some components that do not exist in this online community of practice. For example, it is difficult to confirm that these defense attorneys develop a shared vision because all members of the community were not necessarily public defenders. Some of the members are contract (part-time) public defenders who are private attorneys.

3.4. Coordination Issues in Distance Education

The following case describes coordination issues in a web-based distance education course, B3002 (Hara & Kling, 2000). It is an ethnographic case study of students' experiences in this course undertaken in 1997. One major aim of the study was to understand the experience of taking an asynchronous text-based, internet-enabled course from the point of view of its student participants. At the time, very few such studies had been completed. While students' perspectives are sometimes represented in the research literature, they are generally gleaned through course evaluation forms (Rossman, 1999) and concise characterizations based on students' comments or experiences.

In this case, the students and instructor relied upon e-mail as a primary means of communication. In fact, the instructor required that students post e-mail to the class discussion forum "at least five times during the course". Her syllabus also noted: "Participants are expected to check the list daily". The students and the instructor in B3002 generated intensive online discussions through e-mail, and all of the students posted far more than 5 one-to-two page-long messages. During the week of October 19th, they posted 35 messages; this volume was common throughout the semester. On the surface, this volume of discussion indicates a lively class. However, we found that there were some underlying problems with the reliance on e-mail.

First, it was evident that some students did not read other people's postings before writing their own e-mail messages. Second, some students were unable to make time to read and post e-mail during short intensive discussion periods. For example, one student did not post any comments when the other students intensively discussed a particular topic for 2 days in the middle of the semester. After another student summarized the overall discussion in his e-mail, she sent an e-mail that had a subject line saying, "Ah . . . I cannot catch up with all of you : (."She was one of the students who posted the fewest number of e-mail messages to the online class discussion. Some other students also reported that they were overwhelmed by the volume of e-mail, and that they fell behind in reading and responding online. The research literature indicates this complication of asynchronous computer-mediated communication. Wegerif (1998) also reports a student's comment of the "daunting prospect" of being behind reading messages. In this course, the instructor and students did not discuss the question: how much posting is sufficient to satisfy the course requirements?

As noted in the above example, the discrepancies between students' behaviors and the instructor's expectations were a major issue. Another example is of a student who was working at night alone in a computer lab and had not received specifications for the assignments from the instructor; he was confused about the instructor's expectations. In this course, the students and instructor did not have discussions about each other's expectations, e.g., how long it takes for the instructor to get back to students' questions in general. The students did not know whether they should expect to receive replies within 24 hours, 72 hours, or a week.

A major advantage of asynchronous computer-mediated communication is that it reduces the constraints of time and location (Ahern & Repman, 1994; Burge, 1994; Harasim, 1990; McIsaac & Gunawardena, 1996). However, it can be very demanding for students and instructors to read all their messages and to respond thoughtfully (Hara et al., 2000; Hiltz, 1998; Kang, 1988; Wiesenberg & Hutton, 1995). The instructor also commented that at the beginning of the semester she was spending all day doing nothing but reading and responding to e-mail messages. Later in the semester, she was able to reduce her workload, because she became familiar with how to handle e-mail messages for the course (i.e., not spending too much time on individual messages), but still spent a large amount of time on this course.

4. DISCUSSION

4.1. Social Processes in Virtual Space

One of the key issues that has not gained attention in the research, and particularly in practice, is that workers' incentive structures influence the level of knowledge sharing within Virtual Spaces. This issue is not specific to the activities within Virtual Spaces. In general, people in certain organizations are hesitant to share their knowledge because they might loose their competitive edge. An article in *The Wall Street Journal* reports a view from the shop floor on knowledge management (Aeppel, 2002). It reports that many workers resist sharing their knowledge in workplaces, because they are afraid of losing their jobs once the companies have the knowledge. In order to encourage knowledge sharing, incentive systems need to be changed, so that workers will be rewarded, instead of punished, when they share expertise. This incentive issue was illustrated by the first two cases: the Alpha Consulting firm (Orlikowski, 1993) and E&Y (Davenport, 1997). The former case did not succeed in supporting the sharing mechanism because the management did not take the incentive structures into consideration. Conversely, E&Y altered their original incentive structure in order to reward the knowledge sharing process.

As Markus and Benjamin (1997) note, many IT practitioners perceive IT as an enabler "magic bullet". However, IT applications are not sufficient by themselves; one needs an associated social process to encourage participation. As illustrated in the case of E&Y, social processes, such as incentive structure and organizational structure, need to be architectured so that people participate in intended activities—in this case, knowledge sharing. In the ILF case, the tool was developed without consulting with the actual users, i.e., teachers. ILF did not have the materials that the teachers needed for their immediate use, did not consider the time constraints of teachers, and did not engage in community building to offer a safe environment for teachers to give each other critical feedback. As a result, ILF suffered from low participation. These two cases vividly illustrate the importance of installing social processes as well as technical applications.

Trust issues also have to be worked out between participants to enable sharing potentially embarrassing "knowledge" and practices. This issue was described in the ILF case, in which teachers were afraid to criticize other teachers' teaching or postings. Once they posted their messages in the classroom e-forums, they could be viewed by any teacher who registered for the e-ILF. However, they were not given opportunities to get to know each other very well, and hence, were unable to develop the trust necessary for meaningful rapport. Consequently, their postings ended up becoming self-reflection, rather than more useful mutual feedback. It is very difficult to establish trust in virtual environments (see Jarvenpaa & Liedner, 1999). One way to facilitate the development of trust is through face-to-face meetings.

On the other hand, the pubdef-L listserv provided an online space in which participants who worked in many different city and county courts were willing to share certain legal knowledge. Some of the participating lawyers knew each other personally; and they participated in a relatively small, relatively stable professional world of public defenders in their medium-sized state. Violations of trust could be readily known and "come back to haunt" the violators.

Coordination issues can be complicated in distance education courses. Hara and Kling (2000) emphasize that students' ongoing desire for "prompt unambiguous feedback" is much more difficult to achieve in text-based asynchronous courses than in face-to-face conditions. For instance, students working on the course during late evenings and weekends had to wait longer for the instructor's feedback. This issue could be even more amplified in larger classes. What is needed is for students and instructors to learn how to negotiate their expectations about when they should be able to have reliable, fast communicative responses.

Part of the communicative complexity of constructing adequately unambiguous conversations via text-based media comes from trying to anticipate the level of detail and phrasing that will be sufficiently helpful to others. But, as Hara and Kling noted, their informants were also unsure what meta-communicative conventions would be appropriate in their online conversations. e-mail that represents the nodded heads of a face-to-face group could be valuable to an instructor to confirm others' understanding. Or it could result in yet more e-mail glut. These kinds of practices need to be negotiated within each group. In B3002 and many other courses, both face-to-face and online, participants do not explicitly question and negotiate meta-communicative conventions—even when they are confused and frustrated. These discussions and negotiations require a higher level of social skills from all participants, and their enactment (for instance, the creation of a strong social presence in a written medium) also requires time and expressive capabilities. This is not well explained in the literatures of e-learning or distance education.

Both authors taught online Ph.D. seminars for short-terms. The seminars were 2-week long. One author was contacted by a person at the university about teaching a 2-week online seminar during the fall semester. Since she had other teaching obligations during the regular semesters, she specifically asked to teach it over the summer, but was told that it was not possible. She was then contacted by a coordinator of the Ph.D. program to post some instructions for the students in their online space. Shortly after that, she was asked to contact a technical support person. While waiting to receive log-in information from technical support, she was frequently asked to log-in to the system by the coordinator. This instance indicated that the technical support person and the coordinator had not interacted with each other. When she was finally able to log-in to the system, more than 10 messages from the students were posted. One of the messages said that the students had been given an article in July and had been waiting for the seminar to start since that time. Apparently there was miscoordination, miscommunication, and misunderstanding among the instructor, the students, the technical support person, the person who originally contacted the instructor, and the coordinator. The other author taught the same online seminar during the previous summer. He experienced other coordination issues with his students since they did not know what the expectations were with regard to a time frame for responding to messages. Therefore, it is important to note that distance education courses require substantial forethought about communications and coordination that are usually not problematic in face-to-face classes.

4.2. Differing Social Organization of E-Forums Across Types and Within Types

E-forums can be a component of Virtual Spaces. One way to facilitate e-forums is to consider five socio-technical issues.

1. E-forums organizers and participants need to determine who can participate and who is excluded. For example, the listserv among public defenders was restricted to defense attorneys. Thus, the attorneys felt comfortable brainstorming strategies for trials and asking questions about judges and prosecutors. If they were uncertain about who was reading the messages, they would not have freely discussed the above matters. Similarly, the bounded groups of the e-ILF facilitated discussion by restricting their membership.
2. The genres of acceptable communication need to be established in e-forums. Some Virtual Spaces make it more explicit than others. For example, a mailing list among educational researchers facilitated by American Educational Research Association periodically sent out messages that listed the rules for the mailing list, such as what and what not to send to the list. E-forums need to articulate what topics are appropriate for their e-forums.
3. Participants' activities (e.g., speak/post, read, role-play, buy, sell, etc.) need to be identified. For instance, eBay clarifies the roles of participants with their accounts. The users need to create separate accounts for sellers and buyers. Sellers' information is available in public for buyers to make decisions whether they want to buy items from particular sellers. Some e-forums have restricted speakers, yet other people are allowed to view their activities without participating in the discussions.
4. Acceptable communication conventions should be determined. This category concerns norms for online behaviors. Do you politely correct others or flame them? These questions need to be discussed. On the other hand, if participants are not certain about the expectations of the e-forums, the participation rate might be reduced. In the case of the ILF, the teachers did not have a clear understanding of what comprised acceptable communications within the e-forum. They were

not sure whether the video clips were supposed to be bad examples or good examples of teaching practice, or how much criticism would be acceptable in that type of e-forum. There were no discussions about this point among the participants, and it was not explicitly explained to them at the beginning.

5. Social control agents and practices need to be clarified. Some e-forums are established and enforced by e-forum organizers and some are by participants.

More often than not, designers of Virtual Spaces tend to overlook the fact that these socio-technical factors need to be in place. These five issues must be effectively addressed if an e-forum is to be successfully implemented. For example, e-ILF did not consider these issues. As such, there was little participation in the forum.

Hara's (2000) study of the listserv among public defenders identifies different types of working knowledge including book knowledge, practical knowledge, and cultural knowledge. Cultural knowledge is very difficult to share online. Consequently, we need to identify what kinds of knowledge to share and what types of tools to support such knowledge sharing.

Hara coined the term "cultural knowledge" in reference to the social nuances of the role public defenders play; it includes their professional identities as defenders of indigent people who often have been mistreated. Most of the tacit knowledge that is necessary to become a full member of the community of public defenders is embedded in the culture of the public defender's offices. Therefore, younger attorneys learn how to be public defenders by observing more experienced attorneys and by talking with them. As Huseman and Goodman state, "culture is one of the most powerful stores of knowledge" (Huseman & Goodman, 1999: 121).

In a community of practice, knowledge is constructed socially rather than individually. There are three types of knowledge that the members have to learn: cultural knowledge and two kinds of subject-matter knowledge.

Hara further classified subject-matter knowledge as either book knowledge or practical knowledge (see Hara, 2000). Book knowledge refers to mere facts, such as case laws and statutes. In contrast, practical knowledge refers to using the book knowledge in practice; for example, how to use the latest case that an attorney found in Lexis-Nexis[5] in a bench trial. The attorneys have learned most of their fundamental book knowledge in law school, but they also have to keep learning new book knowledge because criminal laws are rapidly changing. In addition, they have to learn how to use their book knowledge, which will eventually become practical knowledge. In some communities of practice, the subject-matter changes rapidly (e.g., communities of practice among lawyers) and sometimes cultures change rapidly, perhaps because of the high rate of turnovers.[6] Therefore, it is imperative to address the learning of subject-matter knowledge in communities of practice.

Different types of knowledge require different learning formulas. Cultural knowledge and partial practical knowledge are tacit. Apparently, the mechanism of learning cultural knowledge and some practical knowledge relies on observing experts doing their work. On the other hand, parts of practical knowledge and book knowledge are explicit. Therefore, explicit practical knowledge and book knowledge can be shared through documents and electronic formats, such as messages exchanged through a listserv. As mentioned, not all kinds of knowledge are easy to share in online environments. The designers of Virtual Spaces ought to be aware of these limitations when providing learning opportunities in Virtual Spaces.

In our view, Virtual Spaces needs to be designed socio-technically (Kling, 2000). Designers may try technical means (such as IP-address checking or personally-reviewed registration) to limit participation to some kinds of people or groups. An e-forum's charter may describe the kinds of acceptable communications, but, without human review, it may be difficult to enforce. The e-forum may enable some specific kinds of activities while providing no explicit support for others. Also, the e-forum may be designed so that any group of participants may easily form their own (private) group, or they may require the assistance of an e-forum administrator, or it may be effectively impossible. It is easy to set up an online conferencing system on the internet for people to participate. However, the technology itself does not facilitate the process by which people share thoughts and ideas and build a community. There needs to be social support mechanisms embedded in the e-forum.

5. CONCLUSIONS

As noted earlier, knowledge management and professional development in virtual environments is much more difficult than in face-to-face settings. We suggest that the notion of knowledge management is too narrow to support knowledge creation and sharing activities in workplaces, and that incorporating the socio-technical perspective would enrich the online community and thus create a supportive learning environment. Knowledge management literature as well as e-learning and other technical focused fields are likely to focus too much on the technological issues. We strongly support the socio-technical perspective that considers social processes that would support the intended activities in addition to the technology itself. It is easy to develop a piece of software and name it Virtual Spaces, but it requires more effort and consideration to develop Virtual Spaces that *facilitate learning*. When IT fails to facilitate social processes, its effect on knowledge management is limited.

In the literature of knowledge management, knowledge management itself is often "black boxed". A large portion of the literature does not address the workplace issues as experienced by potential participants, such as incentives for participating, trust that their communications will not hurt their status in their workplaces, the commitments of others to participate, and time to participate. As represented by the case of "Engineering Books of Knowledge" at Chrysler, knowledge management strategies or technologies are described, but these cases do not address the issues of the people who are involved in, and influenced by, the knowledge management initiatives. We certainly need to understand how the people on the floor use the technologies, what are the problems are that they face, what works, and what does not work. In the framework of Schultze and Leidner's study (2002), we need more studies with local perspectives.

By understanding local perspectives, we can fully incorporate socio-technical considerations into design and implement virtual spaces that support professional development and knowledge sharing. The socio-technical aspects that we need to pay attention to include: identifying needs of users/learners; developing trust among users; installing incentive structures for knowledge sharing; and determining users, their communication topics, norms, and behaviors. It is important to recognize that virtual spaces are more than an IT system allowing communication and data exchange.

As a field that is focused on technologies, it is easy to jump on the bandwagon of newly fashionable technology-based techniques, such as e-learning or knowledge management. Professionals who organize professional development through virtual spaces need to remember that the technology does not make learning better, but rather it is that the pedagogy and social processes that facilitate better learning. If this is not the case, many IT applications for virtual learning environments will end up going through a cycle of high expectations followed by relatively uneven and low participation rates; and these in turn will be followed by disillusion and disappointment.

ACKNOWLEDGMENTS

We thank the editors, Joel Weiss, Jason Nolan, and Peter Trifonas, for their careful reviews and insightful feedback. In addition, Zilia Estrada and Phil Eskew provided helpful comments.

ENDNOTES

1. This definition is based on the Wenger's elements of communities of practice (CoPs): negotiating meaning between participants; preserving and creating knowledge; and supporting the development of identities (Wenger, 1998).

2. The best research that we have found about trust building for on-line groups has been conducted by Information Systems faculty who study teamwork online (c.f., Jarvenpaa & Leidner, 1998).
3. All of the names in this case description are aliases.
4. Hara (2000) studied four different communities of practice: one in a small office, one among experienced attorneys in a larger office, one among less experienced attorneys in the larger office, and one in online.
5. Lexis-Nexis is a database that provides full-text access to a variety of topics. In this case, attorneys use it to search information about state law.
6. The original definition of a community of practice by Lave and Wenger (1991) appeared to be concerned about only static cultural knowledge and subject-matter knowledge. However, many jobs require the learning of subject matter that frequently changes.

1. INTRODUCTION

The internet, in its proliferating forms, continues to attract an increasingly diverse set of users. Since the explosion of the World Wide Web and the broadening of internet access in the mid-1990s, the internet is no longer dominated by Euro-American software developers, academics, and government agencies. It is currently estimated that 10% of the world's population is online—an astonishing figure that includes a large proportion of youth in many countries, as well as many seniors like those in our study (Cyberatlas, 2003). Over half of the Internet's users are from non-English-speaking countries (*Global internet statistics by language,* 2003). And of course, most of today's users of the internet are not professionals or students in computer science and related fields, as was the case in the early years of networked computing.

Diversification of populations with internet access will continue, as will the influx of internet newcomers spanning a wide social and cultural range. When newcomers make their first online forays, they are confronted with a strange and often incomprehensible "networked world", a social, technical, and cultural system built up through an idiosyncratic history and shaped by the unique perspectives and backgrounds of early participants. While the technical and social features of the internet are in perpetual flux, many of the deeply embedded technical and cultural assumptions that have been part of the internet since its inception continue to shape user experience. For example, the ASCII encoding of text makes it easy to exchange e-mail or documents in European languages, but it is a real ordeal to do the same thing in Japanese, since ASCII is not large enough to encompass the Japanese character set (Nolan, 2005). Similarly, Lessig (1999) points out that the early design decision to make networking protocols decentralized (so the network itself would be more resistant to total failure) also makes it difficult for corporate interests to police network traffic, as we have seen in recent music industry cases. In numerous instances, the technological choices and assumptions of the early internet are associated with cultural biases of one kind or another. Manuel Castells (2001) argues

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 873–893.

that the internet continues to be characterized by a youth-identified techno-utopianism, even after the addition of corporate interests, entrepreneurs, and communitarians to the ranks of internet architects.

We are interested in how newcomers meet the internet under these conditions. In particular, what do newcomers need to learn about the social and technical features of the networked world if they want to become fluent participants? How do their experiences with other communication and information technologies (such as telephones and postal mail) help or hinder them as they learn how to navigate their way through online activities and services? In this paper, we explore these issues, drawing on data from an ethnographic study of SeniorNet, an organization that supports senior citizens in gaining access to computing.

Our analytical approach is centered on a close examination of the questions seniors asked in computing courses as they learned about the networked world. The seniors in these courses were situated largely outside the frame of reference of "locals" of the networked world—those people (such as their teachers) who had acquired enough online experience to feel comfortable and knowledgeable about the way things work on the internet. When the seniors asked questions from their outsider's perspective, they shed light on what an insider's perspective looks like. Because newcomers do not take things for granted, they are in a privileged position to make visible the implicit assumptions that organize a culture or community, which are no longer apparent to long-time participants. We argue that looking closely at newcomers' questions can help developers of internet software and services to reflect on their own assumptions, which may help them to design networked applications that are more readily understandable to new users.

This study was conducted in 1998, before the years of inflated internet hype that accompanied the dotcom bubble and the mainstreaming of the internet user base in the United States. Yet we believe that our findings regarding the experiences of new internet users still apply. The goal of this chapter is to unpack some of the underlying cultural assumptions that organize the networked world. These assumptions are keyed to the context of 1998, but they continue to be relevant as the internet extends its reach.

Several prior studies have investigated what newcomers to the networked world do when they first gain online access (e.g., Bier et al., 1996; Kraut et al., 1996; 1998). In each of these studies, researchers provided families with home computers and network access to investigate the use and the impact of home-based access to online services. These studies demonstrate how newcomers from a variety of backgrounds make use of the networked world when they get there, but the studies do not focus on the processes through which people make sense of these new experiences. In contrast to the HomeNet research that analyzes internet usage patterns in terms of demographic, psychological, and temporal variables, we describe the cultural contexts of internet use through qualitative observations of literacy, learning, and community practices.

1.1. Cultural Contact or Notes on Ethnographic Method

Our analysis mobilizes a metaphor of cultural contact based in anthropological theory and method. While touted as a universalizing medium, the internet is actually formed through a set of metaphors (Stefik, 1996), political commitments (Lovink, 2002), and governance structures (Lessig, 1999) that results in a particular set of "information ecologies" (Nardi & O'Day, 1999). Despite the diversity of these ecologies, life mediated by the internet is grounded in a common (though differentiated) *system* of meaning, or what anthropologists would call culture in the most foundational sense (Schneider, 1968). It is the technical architecture of the internet that comprises much of this taken-for-granted system of meaning for the online world. This system of meaning comes to feel "natural", much as we accept certain notions of gender and procreation as "natural" despite the considerable cultural work that brought us these notions in the first place (Yanagisako & Delaney, 1995).

From a newcomer's perspective, the internet seems at first to be a hodgepodge of sites, applications, and services, within which it is not easy to tell the difference between the deeply embedded and more transient or superficial characteristics. Old-timers make sense of the internet as a *cultural system*, albeit an evolving one, rather than seeing it as a set of discrete features and components. Experienced internet participants recognize that certain capabilities and conventions are more stable and widespread than others. Their fluency is based on their adaptation to the taken-for-granted architectures that ground internet experience.

One instructor of an online class we observed encouraged his students to focus their attention on the more durable features of the internet by drawing a distinction between cemeteries and oak trees and black and white cows. He pointed out that in early days of automobile driving, road maps were not readily available to guide travelers to their destinations. Instead, there were guidebooks that used local landmarks as reference points. The guidebooks, he said, were careful to use relatively persistent landmarks, rather than mobile ones. For example, a guidebook might advise a driver to turn left at a cemetery or right at an old oak tree, but it probably would not include a reference to a herd of black and white cows. In any landscape, it is more useful to navigate by some features than others. The instructor urged students to look for landmarks that are both stable and pervasive across the networked world. "If you focus on what button to push," he told them, "you'll be focusing on the black and white cows." He pointed out that the topic of privacy, by contrast, is a cemetery and oak tree that will always be important to internet users, even though the details of addressing privacy will change over time.

It is the challenging task of internet newcomers to discern which features of the online landscape and culture are currently considered long-lived and meaningful to the "locals" of the networked world—those who have absorbed certain local traditions and beliefs and know how to bring them to bear on current practice. In this process, the newcomers are like anthropologists who go out to live in a culture they do not yet understand, asking questions that will help them see how the locals view the world in their particular time and place. To achieve true fluency, they must not only master the tools of the realm such as language and ritual, but also begin to understand the worldview that lies behind the particular utterances and actions of the natives. To make the newcomers' task more complicated, they cannot simply ask the natives to tell them everything they need to know, since the natives usually have forgotten what did and did not make sense when they were newcomers themselves.

An example from a more classic anthropological encounter may bring this dynamic to life. Within anthropology, there has been a controversy as to whether or not certain Pacific islanders recognized the role of coitus in procreation (Delaney, 1986; Leach, 1966–1967; Schneider, 1968). Islanders reported their belief that conception was arranged by the husband's ancestral ghosts, and that coitus was not relevant. As he ponders this debate, David Schneider, in his fieldwork among the Yap, discovers some men removing the testicles from a pig. In the ensuing conversation, he determines that the men recognize that both the testicles and the copulation are necessary for a sow to get pregnant. Why is it, then, that everyone has been telling him that coitus does not make women pregnant? It is the Islanders turn to be confused, until one man finally sees what the anthropologist's problem is: "But people are not pigs!" Schneider writes: "Once that point was made, the rest followed in happy, logical order. I had obviously assumed that biological processes operate for all animals and had included man among them. But they had assumed that no one but a fool would equate people and pigs." (Schneider, 1968)

Like Schneider, students in the classes we observed asked questions to discover local understandings, motivated by their own curiosity and practical objectives. They persisted in their inquiry, although sometimes the categories and distinctions seemed unfamiliar and peculiar. In the process, they questioned the logic of computing systems. The questions have the effect of "denaturalizing" (Yanagisako & Delaney, 1995) our understandings, by refusing to take as given the deeply held structures and beliefs of the networked world. And like Schneider's focus on a "fact" of procreation, student questions will often begin with a seemingly simple particularity, which, when unpacked, reveals striking dimensions of an entire cosmology. Our analysis, in this chapter, is to describe how these apparent confusions about "simple facts" point to naturalized, systemic assumptions that are both obvious and invisible to locals.

We emphasize that the questions the students asked were reasonable and informed, not naive. No one comes to computing as a blank slate. The seniors we met in our study were mature people who had valuable experience with a variety of technologies at work and at home. Sometimes their experience with earlier technologies such as telephones and paper-based mail systems helped them in understanding the internet, and sometimes it provided interference instead. The students' questions illuminate the networked world as it appears to many new internet users (in schools, libraries, senior centers, and homes), and they provide us with material to reflect critically on the design of current computing systems.

1.2. The Internet as a Site of Cultural Change

Although we focus in this chapter on long-lived technological and cultural frameworks that shape user experience on the internet, we do not mean to suggest that the internet is standing still, even for the purpose of our analysis. The distributed technologies that comprise the internet are always in a state of transition, as are network-based business models and legal codes. New technical and social models for the networked world such as web logs (blogs) and the mobile internet have a profound impact on how the internet is perceived and used. Clearly, notions of stability and systematicity must be understood as relative terms when referring to features of the internet.

Rapid change and heterogeneous standards are part of what newcomers have to learn about the internet—they are cemeteries and oak trees. Ongoing learning, therefore, is a necessity for internet users, since even internet old-timers continue to encounter the new and unfamiliar in their online experiences. Because of the pace of change, each successive generation of newcomers is situated in a reconfigured learning context. Even if old-timers could remember each "aha" moment when they elucidated some key ontological distinction in the networked world, their recollections might not translate into useful tips for today's newcomers. While many nuts-and-bolts characteristics of the internet persist over time, the contextual details that color a new user's experience tend to change in ways that render the experience opaque to the next generation.

We argue that the moment of cultural contact with the internet is important and interesting. It is also brief, since motivated newcomers quickly begin to adapt to local ways—the category of "newcomer" is a stage everyone goes through, rather than a permanent identity. Our analysis focuses on the details of newcomers' encounters with the networked world, in order to see more clearly the tacit, embedded models that structure experience for all internet users.

2. THE SENIORNET PROJECT

The SeniorNet organization was founded in 1986 to help seniors gain access to computing technology (*About Seniornet*, 2003). SeniorNet supports robust network communities on the web and on America On-Line (AOL), and it sponsors over 200 volunteer-staffed "Learning Centers" throughout the United States, where seniors can take computer classes on a variety of subjects, including how to buy a computer, how to use financial software, and how to get online. At the time of our research, there were about 25,000 members; SeniorNet now has grown to 32,000. Most SeniorNet members (about three-quarters) are retired, but about a quarter of the members work at least part time. There are more women (58%) than men (42%) in SeniorNet. The age span of SeniorNet members is very broad; anyone who is at least 50 is eligible to join. About half of the members are between 65 and 75. Another 27% are between 75 and 85, and 20% are between 55 and 65. Small percentages of members are in their late 80s and early 90s, and an even smaller percentage in their early 50s. Among the individual members we met during our research, we found that a surprising number were writers or teachers.

In 1998, we engaged in a year-long ethnographic study of SeniorNet. We are interested in the issue of broad access to computing. We chose to study SeniorNet as a case of long-lived, successful computer access among a population that is not commonly thought to be adept at learning new technologies (though the SeniorNet members belie this stereotype). The themes of our research center on understanding the social and technical features that support access and help people become fluent in online participation.

SeniorNet is a distributed enterprise, with activity in different online and physical locations. We carried out observations and interviews in a variety of sites, to develop a better sense of SeniorNet's membership and practices than any single location could provide. We interviewed SeniorNet staff members, observed three multiweek computing classes (each of which took place at a different Learning Center), observed online activity in discussion forums (newsgroups) both on the Web and AOL over a period of months, participated in chat regularly on the web for a week, interviewed 30 members drawn from both network communities, interviewed nine students from two of the classes we had observed (several months after their classes had ended), and interviewed one student weekly, after each of her class sessions. We also posted questions and research themes on an online forum created for us by the SeniorNet staff, to generate discussion among members on topics of interest to the project.

We have research findings in several areas, including access issues, network communities, online fieldwork practices, and learning to become an online participant. In this paper, we focus on the last area: understanding what is involved in learning to use the internet.

2.1. Learning Center Observations

During our study, we observed three classes, each of which took place at a different Learning Center. Two of the classes were introductions to computing. One of the introductory classes took place over 4 weeks and one over 5 weeks; in each of these classes, the weekly class meetings were 2 hours long. One class was an introduction to online access, consisting of 82-hour sessions. All of the classes were taught by SeniorNet volunteers. Each of the Learning Centers we visited was situated within a senior center, where many activities and classes of all kinds were available to seniors.

The Learning Center classes we observed were “hands-on”. Students were assigned to work in pairs on the classroom computers, and they practiced what they learned both in class and at home, if they already owned their own computers. Each of the students taking the 8-week online class already owned a home computer and had home access to the internet through AOL. There were 27 students altogether in the three classes we observed.

To complement the face-to-face class observations, we observed the Newcomers’ Forum, an online discussion group in the SeniorNet network community on AOL, for a period of 1 month. We were interested in learning how the questions posted by people who were already online contrasted with the questions asked by people in Learning Center classes. They turned out to be similar to (and in some cases duplicates of) the classroom questions, so we folded them into our analysis.

3. ANALYTICAL APPROACH

As we observed Learning Center classes, we were struck by the multiple literacies required for online access and by the interesting nature of the students’ questions in class. The questions often struck us as being a bit “sideways” to our own way of looking at the networked world. To understand the students’ perspectives better, we collected all of their questions from our fieldnotes of the four classes we observed and added to this collection the questions from the Newcomers’ Forum discussion group. Here are some examples that illustrate the breadth of topics covered:

If the file was saved, why is it still on the screen?
Does the person who sent you mail know whether you’ve opened it?
When are you supposed to double click?

The questions covered six topical areas: (1) hardware (computer, mouse, modem, memory, printer, keyboard); (2) Graphical user interface conventions and capabilities (dialog boxes, highlighting, scrolling, windows); (3) specific application features (changing margins or fonts, ccing someone on a mail message); (4) social conventions (courtesy, privacy, censorship); (5) computer ownership (upgrades, phone lines, internet service providers, costs, technical support); and (6) networked world (the web, e-mail, downloading). We chose to do a close examination of the questions about the networked world (about 30 of the 125 questions), because they cover new territory that has not been addressed in studies of individual applications or systems.

The students' questions often pointed to areas of complexity or ambiguity, where meanings are unclear and unresolved even to the locals. Usually the questions could be answered with procedural or ontological information—each question was a basis for learning a few more cemeteries and oak trees. But seen in another light, the students' questions point to the technological and cultural frameworks that help us understand how the internet operates. Many of the questions also highlight areas where these frameworks are currently under stress, due to the changing technologies and populations of the internet. As the authors of this paper discussed the questions, we groped for the "right" answers to them. Our answers often felt arbitrary in the technical particulars, but they reflected the broader social and cultural context that organizes the networked world.

We found that the networked world questions clustered into four themes:

Identity and the nature of public participation on the internet;
Boundaries and scope of the internet;
Boundaries and scope of a personal computer; and
Organizing the networked world and understanding the roles of different providers.

We discuss each theme in the sections below through some of the student questions that fit into that theme. As we examine each student question, we try to elucidate its internal logic. We reflect on the inferences students are making as they attempt to link the workings of the internet to other technologies they already understand, and we point to the gaps that are revealed when students' inferences do not hold up. We draw attention to the differences between newcomers' and locals' perspectives, to make visible some of the idiosyncratic features and frameworks of the networked world.

Our analysis in this chapter specifically does not revolve around the notion of the "digital divide", which refers to the demographics associated with whether or not people have access to the internet (NTIA, 2000). Internet participation figures vary from country to country, but it is typical to find that there are more youths than seniors and more middle class than poor people online. Discussions about the digital divide are concerned with how to provide access for groups who currently have insufficient access. Our study focuses on seniors, and seniors are one of these underserved groups; in some of our other work, we look at how age-based identity relates to seniors' online participation in SeniorNet (Ito et al., 2001). However, in our analysis here we do not attribute differences in understanding between newcomers and old-timers (on the internet) to demographic constructs such as gender, nationality, or age. Rather, we argue that it is membership—or not—in the culture of the networked world that differentiates people's understanding of what happens there. Membership does not imply that experienced participants know everything about how the internet works; it just implies that they know enough (and continue to learn enough) to get along in the regions of the networked world they have chosen to occupy.

4. IDENTITY ON THE INTERNET

People who enter the networked world begin to formulate an identity there, just as they do in other settings where social exchanges take place. Using the internet has something in common with other communication media, such as postal mail, telephones, broadcast television, and cable television. Each of these media has its own conventions for establishing who its subscribers are (names, addresses, and other information), and the internet is different from all of them.

Student questions about identity revolve around the idea that an internet identity is persistent and public, and it is constructed in part through the actions you take online.

4.1. Persistent Identity

How is it that you can get e-mail even when you're not logged into AOL?

At first glance, your new computer looks like a telephone. Using your modem, you dial your internet provider. While you're connected, you can interact over the network. It would be reasonable for a newcomer to assume that this active connection gives you a presence on the internet, similar to being present in a telephone call, but using the computer rather than a telephone as a portal. When the portal is not in use, it simply waits to be connected again.

But on the internet, you can receive e-mail even when you are not actively connected. To complicate the picture, if you are an AOL subscriber, you can download your e-mail to your own computer and read it offline, and the students had practiced this activity in class. The student who asked this question was querying the relationship between her mailbox and AOL. In more general terms, this question asks: Where does e-mail live, and what is my role in managing its arrival? The student's confusion results from an assumption that e-mail works in a fashion similar to the telephone. While you are connected (phone is plugged in), you are putting a bucket out waiting for e-mail to be delivered. But if there is no connection, there is no bucket. Both sender and receiver (or an answering machine as a substitute for the receiver) have to be present for the delivery to happen.

However, the locals' assumption is that your identity is different from either your active connection or your computer. AOL holds your identity for you, in the form of an e-mail address. This identity is persistent, independent of your connection. Identity is more than a name on a roster—it can be used to carry out a limited interaction with you even when you are not present. In this case, it can be used to deliver e-mail to you.

4.2. Public Identity

I am getting junk mail on AOL. How did they get my name?
Does the person who sent you mail know whether you've opened it? Can it make junk mail worse to read it?

A more general version of the first junk mail question is: How is my identity made known to others in the networked world? Implicit in the student's question is the idea that e-mail works like postal mail—your own correspondents know your address (and they might sell it to other people), but in general, your identity is not made known to others simply because you are an inhabitant of a particular place.

In contrast, the prevailing notion on the internet is that participating in the internet is a public act and gives you a public identity. It is extremely difficult to have an unlisted number on the internet. It is also easier to send e-mail to a thousand people than to place phone calls to that same thousand people.

Although there is growing concern about privacy on the internet, the technology making up the internet has been instrumental in overriding many of the privacy assumptions people carry over from physical mail or telephone use. Corresponding legal and social protections are not yet available in the online world, although the proliferation of spam traffic is prompting more public discussion and proposals for legal solutions.

The second junk mail question points to another interesting characteristic of life in the networked world. This is an advanced question—the student knows it is possible that her actions may be known to others, though she is not sure about the particular action of reading mail. She is looking for strategies to ensure a certain level of privacy—she wants to reduce, or at least not increase, the amount of junk e-mail she is receiving. Some communication media (such as the telephone) do tell the sender when the receiver is listening, while others (such as physical mail) do not. Since the time of our SeniorNet research, the increasing use of e-mail attachments with active content (and sometimes viruses) has made this an even more pressing concern.

Locals understand that the identity of a net participant is persistent and public, but it is not static. As you perform actions on the internet (such as shopping, reading the news, or making travel arrangements), information about your activities can be broadcast to an unknown audience. Understanding the limits of your privacy and knowing strategies to ensure your privacy are complex, unending issues for residents of the internet.

The fact of persistent and public internet identity points to a general cultural value placed on maximizing connectivity and accessibility. Although this value is being challenged by the commercial internet, it has persisted from the early days of the internet, when uses were largely non-profit, professional, and confined to a comparatively small, homogeneous, and self-governing community.

5. BOUNDARIES AND SCOPE OF THE INTERNET

When you visit a famous geographical site, such as a national park or an important historical landmark, you can usually tell when you get there. You read signs that mark the approach to the site, you cross a border or threshold to enter, and you look around and recognize significant features when you are there. The internet is different. The internet is a desirable destination, but it is not easy for newcomers to the internet to know when they have arrived.

Some of the most persistent and searching questions students asked throughout their courses were those that explored the boundaries and scope of the internet. Where does it begin and end? What does it mean to be on the internet? What does the internet consist of? People are drawn to the internet because they are supposed to be able to encounter novel and useful experiences and resources, but there are few clear markers that tell people where and what the internet is.

5.1. Crossing Over to the Internet

> An instructor noted that you need a certain modem speed to "surf the web." A student asked*, "What about the Internet?"*
> In a message on the Newcomers Forum, an SN member said that he *just knew how to do e-mail and was now "trying to get web or internet."*

The general question here is, "Are we there yet?" People expect there to be a there when they reach the internet, but which are the features that tell people where they are? More familiar consumer technologies correspond to some kind of physical gadget—consider telephones, televisions, and cellular phones. There are invisible signals traveling around to support these technologies, but there is also something tangible to hold onto. The internet does not have the same kind of physical presence, so its nature is more mysterious. Web pages are referenced on billboards, radio, and product labels, but the relationship between the web and the internet is fuzzy. It is easy to see why some newcomers assume that the internet is the same as web content, since at least that is something you can point to.

For locals, the internet is space of possibilities for encountering different forms of information and communication. Although interesting material is part of the internet, the internet is primarily defined by connectivity to a broad set of activities and audiences. The different genres of communication (e-mail, the web, instant messaging, music exchanges, newsgroups) are recognizable as distinct locales, but they are also bound together by being part of the internet as a whole—these different genres both define and are defined by their association with the internet as a new territory.

5.1.1. Geography, Boundaries, and the Net

Is the whole country in this particular chat room?
If you want to send mail outside the country, do you have to use http?

A tangled set of metaphors is commonly used to describe the internet. Sometimes it is a highway, sometimes a library, sometimes a hotline. Often it appears to be some kind of place, as when we talk about visiting a web site or getting into a chat room. How far does this geographic metaphor extend? Both of the student questions above suggest that physical geography goes beyond metaphor, and that physical regions are salient in the networked world. The locals in the technology community would probably agree, though there are differences in the ways newcomers and old-timers bring physical geography into the picture.

The question of whether the "whole country" is in this chat room implies that geography is relevant and that geographic places correspond to virtual spaces. It is a question about scope—who can be here in this chat room, and what are its limits? An implicit assumption in this question is that the relevant limits are spatial.

For the locals in the networked world, the most important limit on participation in chat rooms, multiplayer online games, and other synchronous activities is temporal, not spatial. In a chat room, you can only be together with other people if you are there at the same time. Geography provides relevant information, but need not be a significant boundary on the internet.

The student question about how to send mail outside the country implies that similar assumptions are at work. This question suggests that geography is a significant boundary for addressing e-mail messages. But for locals, the Internet's reach is independent of physical distance; it is just as complicated (or simple) to address a message to someone in a nearby town as to a nearby country. Some e-mail addresses do explicitly refer to geographic entities, especially outside the United States, but this form of addressing is a particular feature, not a generally organizing one. This question exposes a seam where geographic regions and the networked world are explicitly related, though geographic borders are not among the cemeteries and oak trees for locals.

Locals understand the internet through space-based metaphors, but the space and its boundaries are organized by activity and connectivity, rather than physical geography.

Boundaries in the networked world have implications for particular audiences, or who can take part in which networked activities. It is clear from recent technological and legal developments that the locals' sense of audience is subject to renegotiation. Web catalogs (such as those provided by Yahoo and AOL) are useful because they create new localities on top of the Web's chaos, using familiar signposts. (Often these new localities are branded; there is strong competition for capturing users' attention on the web, and meta-sites are one avenue for doing this.) web crawlers and search engines also can radically alter the sense of locality for newsgroups and web sites. We saw an example of this when ancient Usenet news postings became easily searchable on the web; Usenet postings that had disappeared many years ago from their newsgroups acquired new life and visibility when archived versions were made available on the Dejanews web site (and subsequently on Google). The locality of newsgroups can also shift for other reasons, as when a Silicon Valley company's internal newsgroups were subpoenaed by a competitor in a court case. Boundaries on the internet are subject to technological, legal, and social drift.

There are important boundary crossings in the internet, but few of them are marked in ways newcomers can see. They are social and functional boundaries for the most part, rather than physical ones. Native fluency in the networked world involves managing one's own presence, as well as awareness of the presence of others, in an expanding range of synchronous and asynchronous communication possibilities.

6. BOUNDARIES AND SCOPE OF A PERSONAL COMPUTER

The third theme is complementary to the previous one. Just as people work to understand the boundaries and scope of the internet, they also work to understand the boundaries and scope of their own personal computers. Where does my computer end and the network begin, and when does it matter? What makes one personal computer different from another and what are the implications of these differences? In the questions related to this theme, we can see that students are trying to understand the nature of the personal computer. Sometimes a computer is regarded mainly as an entry point for the internet, such as in public libraries or internet cafes. But a personal computer typically is also a site for storing private information and doing personal tasks, like managing finances and creating photo albums. To complicate the situation for newcomers, many tasks (such as paying bills or filing taxes) that people used to handle by installing software on their own computers now can be managed by web-based applications. But even though the boundaries between personal computing and networked computing are shifting, it is still important for newcomers to understand (at least to some extent) what is happening where.

6.1. Locality and Customization

Why doesn't Flashmail work for me at home, but it does in class?

In general, this question asks: How do different personal computers behave differently? Although this student's home computer was the same type as the classroom computer and he was using the same online service as the one used in class, he found that an express method of sending and receiving mail on AOL (called Flashmail) did not work for him at home.

As we saw in the discussion of the first theme, identity (who you are in the networked world) is not maintained on your local computer, but is maintained in its narrowest sense by the internet service provider through which you access the networked world. In a wider sense, identity is maintained through all of your public actions on the internet, which often leave persistent records that collectively say something about who you are. The student reasoned that Flashmail should have worked because he knew that his identity was independent of the particular computer he was using for access. He was the same person, even when he was using two different computers, and he should have been able to read his mail through both access points.

For locals, the networked world operates apart from the computers used for access, but these computers are what enable local intelligibility. In a public library, for example, you can browse the web, but your personal list of bookmarked sites will not be available. Similarly, locals see a distinction between the persistent identity as maintained by the access provider (an e-mail account) and the software used for the e-mail application (Flashmail). The general operating logic is that content and identity are universal (cross-platform), but they need to be endlessly translated and customized to be locally meaningful and accessible. A premium is placed on diversity at the local level, while seamless accessibility to shared content is also highly valued. In fact, locals are known to retain this belief that content should translate across local manifestations in the face of often monumental difficulties in being able to decode content locally. (Witness the difficulties of dealing with e-mail attachments across platforms.)

Customization is an important feature of most current applications, even simple ones. But it is so pervasive that it is virtually invisible. It is often buried in a catch-all menu under a name like "Preferences", "Options", or "Settings"—none of which suggest how crucial it is to do appropriate customization. Customized content is increasingly available from a number of web sites and applications, such as shopping and news sites that recognize repeat users and adjust the presentation according to users' previous interaction histories. This can be quite useful when it works well, but the behind-the-scenes nature of this customization makes it harder for newcomers to the internet to learn which aspects of their online experiences are changeable or controllable. Software designers can help by making it more obvious to the new user that an application has not yet been individually customized, to advertize the fact that there is a distinction between an off-the-shelf or default version of the application and the user's own personal version.

6.2. Residence and Control

Why don't we have to sign onto AOL to see the files we've downloaded?

This is a rather ambiguous question. The student who asked this question had just learned how to download files in class and had also practiced reading one of his downloaded files using a word processing program on the classroom computer. The student might be reasoning that the file is owned by AOL, is still located on AOL, or is in a format that only AOL can decode; in any case, the student's question clearly implies that AOL is the guardian of that file. In general, this question is concerned with the boundary between the local computer and the AOL online service. The student assumes AOL should continue to be involved in accessing files, since it was the gateway through which the files were originally obtained.

> *I use my Favorite Places so much I'm afraid of losing it sometime. Is there a way of putting it on a floppy disk? I've gotten a lot of good links that I'd hate to lose in case of a 'crash'.*
> *Is there any way to read this forum offline?*

These questions ask: To what extent can I manipulate network "stuff" on my local computer? In the Favorite Places question, the user is concerned about what she can or should do to protect herself from losing valuable information, but she is not sure where this information is and who takes care of it. This question is complicated, because it is a case of trying to understand customization as it is controlled remotely (by AOL). In both of these questions, the users are seeking to use the local computer to give them more control over interactions in the networked world.

The rise in web-based applications has led to a partial decoupling of locality and user control, since users usually do have some control over the non-local applications they use. That is, users don't need to feel that information has to be resident on their computers in order to be able to manage it. On the other hand, they do need to understand the limits of their choices and responsibilities in managing their own information, wherever it lives.

It is often not clear to newcomers how information objects can be transported around the networked world. For example, a file in an AOL library or ftp (file transfer) directory can migrate in its current form. A web page can be locally printed (one form of migration) or saved in its HTML source format (another form of migration), but if it is stored locally it loses its identity as an active web page. In general, locals assume is that most online objects should be able to migrate (through various translations), but then the content might cease to be shared and networked and instead become personal and local.

Designers need to help users understand when and why migration of a document is useful from a user's perspective, and whether a document can preserve its "essential" features when it migrates between the networked world and a local computer. Designers should consider ways to mark more explicitly when content is local or remote, and what kinds of translations it might take to make remote content locally intelligible.

7. ORGANIZING THE NETWORKED WORLD

This final theme addresses the various organizations that are involved in the networked world, which include content, service, and access providers, and hybrids thereof. How are the different functions of the internet distributed across and managed by different organizational entities, and how does an internet participant interact with these different organizations?

In the Learning Center classes we observed, students are exposed to a variety of organizations as part of their entry into the networked world. Typically, these include America Online and SeniorNet, as well as particular content providers that students may encounter on AOL or the web, such as Elderhostel or *USA Today*. Some students had already arranged for e-mail accounts through free services such as Yahoo. Through the students' experiences outside of class, they may also be aware of other access and service providers. It is far from clear to newcomers what role each provider plays in the networked world. As we have seen in other areas, the students' questions point to aspects of the internet that are especially ambiguous and subject to rapid change. Locals may take the ambiguities for granted, but newcomers' questions remind us of the fluidity of organizational distinctions in the competitive business environment of the internet.

7.1. Parts and Wholes

Is SeniorNet part of AOL?
If you are on AOL, are you automatically on the internet?
What is the difference between SeniorNet and AOL?

These questions ask: What are the relationships between content providers, service providers, access providers, and the internet? And who plays which roles? Many of the student questions in this area assume a model of parts and wholes to understand the structure of net organizations. For example, is

SeniorNet in a part/whole relation to AOL? Is AOL in a part/whole relation to the internet? Given that the different organizations that comprise the networked world appear to have different scales, this is a reasonable assumption to make. Content may be related as chapters to a book, and organizations may be subdivided in a hierarchical model. Newcomers to the networked world assume and perhaps hope for an elegance of design that would allow them to identify supersets and subsets that are in some logical and accountable relation to one another.

By contrast, locals to the networked world have long resigned themselves to the patchy, *ad hoc*, and chaotic nature of net organizations. Internet users work with a myriad of parts that do not resolve into wholes, and any proposed hierarchy is always under contestation. Service, access, and content providers are constantly jockeying for position and voice while forming fragile alliances that are on always on the verge of collapse, and we call this chimera the internet, giving it an illusion of organizational stability.

The networked world is further complicated when online services such as AOL provide content that is separate and distinct from the internet at large, available only to subscribers. This content is not part of the public internet; instead, it is alongside the internet. The networked world is an assembly of different kinds of parts, and they do not constitute a single whole.

7.1.1. The Medium and the Message

Is USA Today *on the web the same as* USA Today *on AOL*?

Many of the student questions, especially when working from a part/whole model, assume that the medium and content are provided as a piece, and that they are organizationally whole at the point of access. This is an entirely reasonable assumption when beginning with the models provided by other media technologies, utilities, or even destinations. For example, a printed book involves various organizations and individuals in its production and distribution. But at the point of access, the product is unproblematically whole, with the content integrated into its material form. (However, electronic books and audio books do decouple a book's content from its form.) Utilities such as electricity or water are accessed through a single organization, which provides the "content" as well as any associated services, such as repair. Finally, one might consider certain content-based destinations such as theme parks or even libraries, where a single organization again manages the content as well as the service and the space.

The question about *USA Today* is from a student who has already discovered that online content is often organizationally decoupled from the medium. In the networked world, locals are almost always dealing with multiple organizations when accessing any given piece of content. Further, these organizational distinctions matter in the relationship the user has to the content. You may need to “contract” separately with three different organizations to access a given piece of content. For example, you might access the web through a connection provided by your local internet provider, arrange for an e-mail account through a network service provider such as Yahoo, and pay a membership fee to SeniorNet while participating in the SeniorNet network community on the web. In short, in the networked world, access, service, and content are organizationally separable.

7.2. Implications of Organizational Arrangements

> *Could I access SeniorNet on AOL through Microsoft?*
> [When looking up chocolate cake recipes using different web search engines] *What is the role of AOL in all this?*

In general, these questions (and all of the questions we include in this theme) ask: How do different providers affect what I want to do? The ways in which organizations carve up their responsibilities in the networked world reverberate throughout the online experiences of internet participants. Soon after their introduction to the internet, new users realize that these organizational affiliations matter, that it is not simply a matter of branding (Coke versus Pepsi, but you still get cola), or even of choosing a particular informational venue (the *New York Times* has the best book review section). Rather, organizational structure governs in complicated ways not only the brand and content, but also the form, functionality, and general informational access. The newcomers’ questions point to the complexity of these organizational arrangements.

One of the ways newcomers try to understand the role of different organizations is to discern the particular value they are providing to users. A familiar kind of value is exclusive access to interesting content—for example, book reviews you can read nowhere else. But content and access can be related in myriad ways on the internet. The student looking for *USA Today* found that the *USA Today* content was independent of both her access provider (AOL) and a provider of community services (SeniorNet). In the question about Microsoft, the student wonders if both AOL and Microsoft could provide access to SeniorNet content—this is possible, since access and content are separable. But at this time, SeniorNet and AOL were organizationally symbiotic, and the SeniorNet/AOL network community was not accessible through a third party provider.

This line of questioning reveals an even deeper assumption that is held by newcomers to the networked world: organizational affiliation must determine in some way how, whom, and what I can communicate with. Even if you accept that you might be getting access or service through a different organization than the one providing the content, surely the former organization must have some role in determining how communication and information access work. The economic exchange with the access provider must shape content in some logical way, and it seems sensible to assume that you are paying for more and better content. Indeed, what is the role of AOL in all of this?

By contrast, locals to the networked world increasingly see the value of organizational affiliation less in terms of the volume or nature of content that is accessible (all paths lead to the web anyway), and more in terms of how that content is presented. If "information wants to be free", then value must reside in the services that help manage that free-flowing information. Local understanding is organized by the value placed on open exchange of information on one hand, and the desperate need to limit and organize this information on the other. With the ascendancy of networked content like blogs, the operative metaphors are inflected further towards service, filtering, searching, linking, and ranking, rather than content within boundaries.

CONCLUSION

Many of the seniors in our study became enthusiastic and successful users of the internet—it does not take long for newcomers to lose their fresh perspective on the networked world as they move toward becoming locals themselves. But by listening carefully to the questions of these newcomers in their early encounters, we catch glimpses of how the networked world might appear to inquisitive and puzzled visitors from afar. We begin to see curiosities and quirks, as well as deeply held general beliefs that organize the networked world. These aspects of the networked world have become invisible to more experienced users through tradition and habit, but they are strange, interesting, or challenging to newcomers. This perspective can be useful to designers in two ways. First, we should look more closely at the metaphors, explanations, and basic assumptions that are embedded in the user models and interfaces of networked applications, to see where they can be clarified and made explicit to newcomers. Second, it may be fruitful to turn our customary assumptions upside down from time to time, to see if there are new ways of organizing the networked world keyed to increasingly diverse populations and changing technical capabilities. Finally, the underlying approach towards analyzing and denaturalizing internet cultural assumptions is more pertinent than ever if we take seriously the contention that "code is law" (Lessig, 1999). The architectures and ontologies of the internet have far-reaching social and legal implications that extend far beyond the seemingly obscure technical details.

ACKNOWLEDGMENTS

This research has been funded by the National Science Foundation under Grant #SBR-9712414. During the project, three of the authors (O'Day, Adler, and

Mynatt) were located at Xerox PARC and two (Ito and Linde) were located at the Institute for Research on Learning, and this research was also supported in part by these institutions. We are grateful to the SeniorNet staff who supported us in this project, especially Marcie Schwartz and Ann Wrixon, and to all of the SeniorNet members who generously shared their network communities and classes with us. We appreciate the contributions of our Advisory Board members, Claude Fischer, Malcolm McCullough, Sim Sitkin, and Terry Winograd, and our Xerox PARC colleagues Paul Dourish and Steve Harrison.

Chapter 33: The eLibrary and Learning

PETER BROPHY
Centre for Research in Library and Information Management (CERLIM), The Manchester Metropolitan University, U.K.

"I have always imagined that Paradise will be a kind of library . . . "
Jorge Luis Borges

1. INTRODUCTION

. . . although, one might add, not every library will be Paradise!

Discussion of libraries in general and eLibraries in particular can be found across a wide range of literatures, from the professional through the fictional to the fantastical (Terry Pratchett's librarian, it will be recalled, is an orangutan whose limbs are ideally designed for retrieving books from the remotest shelf). The more serious literature may be less far-fetched—although some accounts of future libraries run Pratchett close—but its terminology frequently conspires to compromise communication. In a recent review of the literature on linkages between virtual learning environments (VLEs) and digital libraries, we noted:

> "An immediate problem encountered when searching for published literature was differing terminology. The 'digital library', it quickly became clear, is known . . . as the 'electronic library', the 'virtual library', the 'distance library' or the 'online library'; the VLE as a 'learning management system', a 'course management system' (a subtle difference in emphasis!), a 'managed learning environment' (MLE), an 'online learning system' or 'learning environment', 'instructional management system', 'courseware', 'learnware' . . . ."
>
> (Markland & Brophy, 2003)

Of course, in each case the favored term contains many layers of meaning. They are capable of, and indeed encourage, different interpretations by different observers in different contexts. To give but one example, in the U.K. the concept of the "electronic library" emerged in the early 1990s. But then it became fused with a major funding program in the higher education sector (the *eLib Programme*) which, while generally successful, revealed some of

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 895–913.

the shortcomings of the purely electronic approach. As a result the term now carries an amalgam of negative as well as positive connotations in that country. It will, to the initiated, inevitably bring to mind the Programme's conclusion that a "hybrid" library, delivering both digital and traditional sources, is most likely to meet users' needs. To someone who had never come across the Programme such inferences would be far from obvious.

Yet all this is not to deny the validity of the eLibrary concept (the term will be used generically throughout this chapter). It merely points to some of the connotations the term may carry in certain communities and some of the limitations it may signify. The perfectly valid question remains: How might we define and design an effective "eLibrary" which would contribute fully to the achievement of broadly based learning objectives? What, at its best, would an eLibrary look like? Although some might argue that the starting point should be elsewhere, we can begin to answer that question by exploring more traditional understandings of the "library", examining electronic "equivalents" and then considering the question of and how, and in what manner, such models might be applied in the context of learning and eLearning.

2. LIBRARIES

> "Before the invention of paper the thin inner bark of certain trees was used for writing on; this was in Latin called *liber*, which came in time to signify a 'book'. Hence our *library*, the place for books; and *librarian*, the keeper of books."
>
> (Brewer's, 1970)

It is common, at least in the academic sector, to refer to the library as the "heart of the university". The origins of this phrase are unclear, although Grimes (1998) suggests that it is to Charles William Eliot, President of Harvard University from 1869 to 1909, that the first documented occurrence should be attributed. The metaphor was picked up in the U.K. and used in various reports, including the influential Parry Report of 1967 (University Grants Committee, 1967), which led to considerable investment in university libraries. However, as Grimes points out, the phrase has been used loosely and there is little evidence that it reflects thinking at a strategic level:

> "The metaphor implies that the academic library is of unparalleled importance. Despite its persistence for more than one hundred years, there is a considerable distance between the relationship it implies and institutional opinion and practice. Evidence of this difference is found in a number of areas. . . . Students and faculty alike fail to involve library resources and services in regular learning and instruction,

> turning to the library primarily as an undergraduate study hall or reserve book room. . . . (libraries) remain, for the most part, on the periphery of decision-making and innovative processes. . . . In all, the 'library is the heart of the university' metaphor leads librarians and academics to erroneous conclusions about the real relationships between the library and the university."
>
> (Grimes, 1998)

These are appropriate words of caution, if perhaps a little over-pessimistic, for all too often it is simply assumed that "a library is a good thing" without appropriate evidence. It is also helpful to be reminded that the current position of the university library at the center of the physical campus is a relatively recent innovation:

> "The traditional library organisation was characterised by a decentralised structure in which individual libraries were found in the locations where teaching and research activities actually took place (mostly in the professors' rooms). In order to improve efficiency, to solve logistic problems, and, above all, to cut costs, books and magazines were relocated to central or faculty libraries. Double subscriptions were cancelled. While obviously provoking some protest from among faculty members, this operation was in many cases inevitable.
>
> (Savenije & Grygierczyk, 2001)

Savenije and Grygierczyk remind us that for very many years libraries in academic institutions were highly distributed and the departmental library was jealously guarded by professors, lecturers, and students alike. The monolithic library, though now well established, is but one model for organizing the institution's information resources.

It is both interesting and useful to note that in recent years many commentators have started to see a return to a more user-centered view of the "library", as the emphasis has shifted from a concentration on buildings and on large local collections of physical books and other objects toward a primary concern with the provision of access, whether or not the library owns the information content in physical form.

These ideas have led quite naturally to a model which emphasizes the social role of the library. For Shera

> "A library is . . . a system designed to preserve and facilitate the use of graphic records. It is a social system created to form a link in the communication system that is essential to any society or culture. . . . Its fundamental concern is with the communication of knowledge, ideas, thought . . . ."
>
> (Shera, 1980)

and for Borgman

> "Libraries are social institutions that have evolved over a period of many centuries. They serve the information needs of their user communities, adapting collections and services as those needs change. Libraries tend not to be autonomous institutions. Rather, most are funded by governments to serve a defined community; by schools or universities to serve students, teachers and staff; or by businesses, hospitals, museums, or other organizations to serve their employees and other constituents."
>
> (Borgman, 2000)

The conception of a library as in essence a social organization, entwined within (but not necessarily the heart of) the broader society and community it serves, is a vital one which guards against a mechanistic view which could too easily become prominent within environments which are dominated by technology. Bearing it in mind, let us examine some of the conceptions of the eLibrary (again ignoring for this purpose the terminological niceties), which are revealed in the literature.

3. eLIBRARIES

One starting point is the so-called "digital library", using a term that has tended to be favored mainly by computing science practitioners. Take the New Zealand Digital Library project as an example. It describes the concept as follows:

> "A digital library is made up of a set of collections. Each collection of information comprises several (typically several thousand, or even several million) documents, which share a uniform searching and browsing interface."
>
> (New Zealand Digital Library, 2003)

Here the twin foci are large sets of documents and a common interface. Others stress the importance of the shift from ownership to access that we have already noted:

> "The digital world has . . . caused a shift in the perceptions of users and librarians, and in the underlying paradigms upon which libraries are based, which means that owning and controlling resources on a local basis is no longer the only efficient or effective way of satisfying information needs."
>
> (Deegan & Tanner, 2002)

Arms goes a stage further in his definition, stressing the need for the documents to be managed and organized, and pointing to the heterogeneity of the community served:

> "An informal definition of a digital library is a managed collection of information, with associated services, where the information is stored in digital formats and accessible over a network. A crucial part of this definition is that the information is managed. A stream of data sent to earth from a satellite is not a library. The same data, when organized systematically, becomes a digital library collection. . . . Digital libraries contain diverse collections of information for use by many different users."
>
> (Arms, 2000: 2)

A still more formal definition is provided by the Council on Library and Information Resources (CLIR) in the U.S.A.:

> "Digital libraries are organizations that provide the resources, including the specialized staff, to select, structure, offer intellectual access to, interpret, distribute, preserve the integrity of, and ensure the persistence over time of collections of digital works so that they are readily and economically available for use by a defined community or set of communities."
>
> (Waters, 1998).

Arms' concern that to constitute a "library" the content must be managed is repeated here, and with it comes a reminder that libraries have always made intensive use of human intellectual capacity to make sense of the vast wealth of information resources available. As this potential content has grown in volume in recent decades, and particularly with the explosion in quantity of information in electronic form, the complexity of deciding on appropriate sources, not to own but to point users towards, has multiplied. Of course tools have been developed to assist in this process, but do Google and other search engines really replace this expertise? That is a question to which we must return later. But before moving on, look again at Waters' definition, and note that other roles of the library emerge. Ensuring "persistence over time" occupied much of the effort and not a little of the available budget of the traditional library—here we are reminded that the electronic era does not automatically resolve such questions. Indeed the loss of content, even over short periods, has emerged as a critical issue for the eLibrary community.

But so far the eLibrary has been defined only in functional terms. Just as the traditional library has come to be seen as a social system, so too many commentators have started to examine the role of the eLibrary within its social setting. Owen and Wiercx in the Netherlands, in a supporting study to the European Commission's *Telematics for Libraries* Programme, saw the digital library as a key component of the scholarly communication chain, and suggested that it might best be characterized as a "knowledge mediator". They built on this concept to suggest that the eLibrary needs to perform three related tasks:

- "Making available various types of knowledge resources.
- Providing resource discovery mechanisms, which allow users to identify relevant or requested resources and their locations.
- Providing mechanisms for delivery of specific resources to the user; delivery includes both obtaining a resource when it is not already available in the library, and passing it on to the user in a suitable way." (Owen & Wiercx, 1996)

So the idea starts to emerge that, just as the traditional library is an integral part of its parent social organization, so too the eLibrary, to be fully understood, needs to be thought of in terms of social and personal, as well as technological, processes. This brings us to the question of the relationship between the eLibrary and learning.

4. LEARNING

It is not the place of this chapter to discuss learning itself, nor for that matter eLearning, yet it would be remiss not to make some observations which provide background to the discussion of the eLibrary within its learning community—without a learning intent among providers and users of the eLibrary it would be difficult to find its rationale.

The first point is that since learning is not a monolithic concept, eLibraries must be designed to support variety, actively encouraging a range of approaches to learning both from an institutional and from a user perspective. This suggests that the pedagogical models behind the learning being supported need to be a strong driver in the design of eLibrary services.

Elsewhere in this volume there is discussion of pedagogy in the electronic environment and a number of theoretical perspectives are examined. Among these, the ongoing debate concerning objectivist and constructivist pedagogies provides an important example of how eLibraries need to be designed within a context of learning theory. As I have observed elsewhere, libraries have tended to assume an objectivist approach, perhaps led astray by the intricacies of their beloved classification systems:

> "(objectivism) views the world as an ordered structure of entities which exists and has meaning quite apart from the observer or participant. Much of science and technology is taught on this basis: what needs to be achieved by learning is a closer and closer approach to complete (and

> thus 'correct') understanding. As Duffy and Jonassen (1993: 3) observe, in this understanding 'the goal of instruction is to help the learner acquire the entities and relations and the attributes of each—to build "the" correct propositional structure'. . . . very often an underlying assumption of information and library service delivery can lie very much within this frame of reference—references to 'bibliographic instruction', for example, reveal an objectivist approach in which the student is instructed in the 'correct' view of the world—perhaps that devised by Melvil Dewey!"
>
> (Brophy, 2001b)

If, on the other hand, the challenge comes from constructivist pedagogies, would we expect to find very different eLibraries?

> "learning is a constructive process in which the learner is building an internal representation of knowledge, a personal interpretation of experience. This representation is constantly open to change, its structure and linkages forming the foundation to which other knowledge structures are appended. Learning is an active process in which meaning is developed on the basis of experience. This view of knowledge does not necessarily deny the existence of the real world . . . but contends that all we know of the world are human interpretations of our experience of the world. . . . learning must be situated in a rich context, reflective of real world contexts for this constructive process to occur." (Bednar et al., 1993: 21)

Goodyear (2002) suggests that six characteristics of "good learning" can be identified—learning is "active, cumulative, individual, self-regulated, goal-oriented, and situated"—and recommends (in the context of development activities designed to bring together electronic information services and learning) that these "can help members of a project team discuss and clarify key issues about how the resource on which they are working is intended to help students learn".

Surely the only possible conclusion for librarians, viewing the debates and battles raging over pedagogical theory and practice, is that their role is to act as facilitators for *whatever* learning is taking place within *whatever* pedagogical frameworks teachers devise and students adopt (not at all the same thing, of course!), and that in responding to this call they must be sensitive to the styles, preferences, and approaches of the individual learner. So part of the role may well be to support the delivery of highly structured packages which contain all the information and resources a learner might need to gain knowledge of a specific subject; but another part is to facilitate access, not to a specific, closed set of texts, but to the widest possible range of information resources, providing systems which will encourage users to explore the literature and enhance their learning experiences by engagement with recorded knowledge in all its variety.

It is this concern—to support the reality of eLearning across the full spectrum of its practice—which needs to lie at the heart of developing eLibraries, and it is a central concern to which I return later. What kind of eLibrary might be required to support both objectivist and constructivist—and other—approaches to learning?

5. THE ELEARNER IN THE NETWORKED INFORMATION WORLD

Before turning directly to this question it is worth examining briefly the ways in which learners act in networked information spaces. Much of the evidence for information behaviors comes from the pre-internet age and thus it is to more recent studies that we must turn to obtain clues as to information seeking, information handling, and information using behaviors. While there is not space to examine this literature in depth here, the following functional model summarizes the approach, which has underpinned the majority of recent developments in eLibraries (adapted from Brophy, 2001a).

5.1. Formulate Query

Users begin by formulating some kind of query to represent the information that they require. This representation of their requirements could be in the form of specific terms that describe a subject or an author, or may be quite vague—a "book like the one I had last week"—or could be highly directed, as when the user simply clicks on a likely looking link provided by the tutor within the learning package. The library has traditionally played a role in helping users express their requirements in ways that can be used within the subsequent retrieval system, whether it is human, electronic, or both. Whether or not the user employs a controlled vocabulary may be an important determinant in the success of the subsequent search process; this also raises the question of how users are guided to use such terminologies and the tools, aid and advice that the eLibrary may need to provide.

5.2. Browse Descriptions

Once the query has been submitted to the information system the normal pattern is for a set of descriptions of information objects (the term "information object" is used to denote the generic case) which *may* meet the requirement, and the user examines them. In the physical library this process would formerly have taken place by browsing through a section of the card or other printed catalog; currently the Online Public Access Catalogue or OPAC, together with a wide variety of online indexes and other tools, provides much more sophisticated ways of retrieving bibliographic information. Use of World Wide Web search engines such as Google will involve browsing among lists of descriptions of possibly relevant items, before narrowing down the search. Descriptions may also be delivered to the user automatically, for example, through an alerting service.

The user may not need to go beyond this stage if, for example, the descriptions returned by the system include abstracts or if the query was to establish that a particular author had written a particular book.

5.3. Discover

The next step, closely entwined with browsing descriptions, is to identify a particular item as being of potential interest and finding sufficient data about it to enable it to be identified uniquely. With a "known-item" search, where a user is following up a specific bibliographic reference, this may replace browsing of descriptions. The result is that the user has identified a specific item, which he or she wishes to see.

5.4. Locate

The next step is to locate an instance of the desired item. In the traditional library this could have been within a special collection or in a particular bay of shelving or maybe in the "short loan" collection of items held against heavy student demand. Libraries have usually concatenated subject descriptors with locators to a large extent, so that the Library of Congress (or whatever) classification can be used, with other details, to locate the item. Where the item is not held locally, the library may itself take on the responsibility for identifying a suitable location. In the electronic environment there are a number of issues to resolve, of which one of the most challenging is what has become known as the "appropriate copy problem". This occurs because users may have multiple rights depending not just on who they are but on what they are doing. So access to an e-journal may have been negotiated for students registered on a particular course and undertaking it by distance learning but not for those based on-campus; the publisher might also offer a fee-based article delivery service. eLibrary systems need to detect that rather than offering the fee-based alternative, or pointing to the paper-based version in the campus library, the most appropriate location of a copy for this particular student would be the specially negotiated online "deal". Just to compound the problem, some students might have professional body membership, which provides yet more alternative entitlements to the same journal, regardless of the courses or institutions to which they belong.

5.5. Browse Objects

In a traditional library, once a location had been identified it would be possible to browse through shelves of books or through the issues of a journal, not necessarily to find one in particular, but perhaps to look for ideas. There is some equivalence in browsing through items selected by a web search engine, although in general electronic services are not particularly supportive of this function—it is very difficult to undertake the equivalent of flicking through the pages of a shelf of books on a PC. Line (2000) remarks: "Browsing electronic sources has its own merits, but it is a different process from browsing print; it may prove impossible to offer a good electronic surrogate for book browsing".

5.6. Request

If the identified objects are not immediately available to the user (as they may be if it is simply a matter of clicking a link—or at least one that works!) a request for them has to be initiated. In a traditional library with closed access collections a form may have to be completed to request staff to retrieve the item from the stacks. With electronic services offering access to subscription and other paid-for services, where delivery of a resource depends increasingly on software systems "negotiating" to enable users to be given access, the request function is a core process.

5.7. Authenticate

The system needs to know that the users are who they say they are (authentication) and that they are authorized to access the material requested (authorization). It then needs to ensure that the appropriate "business process" is put in place to deal with the transaction. Is the user a member with a right to request inter-library loans, for example? In the electronic environment, this might include checking that the user has enough credit to use the system (maybe in appropriate cases by taking credit card details), and then setting up a transaction with appropriate non-repudiation features.

The stage at which authentication and authorization are carried out is dependent on a number of factors. Ideally, in the electronic environment, it occurs when the user logs into the system so that the permissions can be carried through until the end of the session. However, there is also a parallel with traditional services where it is desirable to offer free and open access to many resources without requiring users to identify themselves. In these cases the authentication and authorization may be delayed until the user first generates a request for a restricted item—"restricted" in this sense meaning that it is not open to all users without question.

5.8. Deliver

This is the actual process of delivering the requested item to the user. With a book this might involve the completion of a lending transaction; equally it could involve delivering an electronic document via the web or as an e-mail attachment in a form in which it can be displayed at the user's workstation. The electronic environment imposes some additional complexities in that there may be various kinds of incompatibilities and duplication between the objects returned. For example, it is fairly obvious that if a library issues a particular user with a book, a video, and an audio CD then various different types of equipment will be needed to make sense of those objects—such as a pair of spectacles, a video recorder and a CD player. In the electronic environment the equivalent processes need to be handled automatically, and may in addition require methods of synchronizing the delivery of different objects (for example, where a digital video and its audio track are in fact separate "objects" which are only combined when received at the user's workstation). Delivery must therefore interpose some processing in such environments.

5.9. Use

The final process which the eLibrary facilitates is use of the information which has been delivered. "Use" includes the processes of extracting and analyzing information, applying it to specific problems, questions and tasks, personal storage and indexing of files and links, and, in essence, the creation of personal eLibraries with all the processes that they imply.

The above theoretical analysis can be observed in practice in a wide variety of settings, although studies of students' use of electronic information sources suggest that such deliberate searching is perhaps the minority approach. Many commentators have expressed concern that the majority of students do little more than insert a few, often ill-chosen, terms in a search engine and then make what they can of the results. In a report of a national study in the U.K., Armstrong et al. described how few students made use of the more sophisticated information services, such as subject gateways of "quality-assured" resources, provided for them:

> "The effect of the internet on information seeking by students is hugely significant; search engines are the first resort for most academic queries . . . subject gateways are notable only for their lack of mention among students."
>
> (Armstrong et al., 2001: 259–60)

One of Armstrong et al.'s interviewees illustrated the problem nicely:

> "*Interviewer*: you do internet searches for your coursework, is that the most common sort of information source you use? . . . *Student* . . . I don't really use anything else."
>
> (Armstrong et al., 2001: 259)

In a contemporaneous study (Griffiths & Brophy, 2002) we reported very similar findings: "Students either have little awareness of alternative ways of finding information to the search engine route or have tried other methods and still prefer to use Google—a situation we now refer to as the Googling phenomenon". What appears to be happening is that students, faced with time pressures and a huge plethora of information sources, adopt a strategy best described as "satisficing"—what can be found on Google is deemed "good enough".

6. DEVELOPING THE ELIBRARY

> "Information technology makes possible all sorts of new activities and new ways of doing old activities. But people do not discard all their old habits and practices with the advent of each new technology. Nor are new technologies created without some expectations of how they will be employed. The probable scenario is neither revolution or evolution, but co-evolution of information technology, human behaviour, and organizations. . . . Products evolve in parallel with the uses for which they are employed."
>
> (Borgman, 2000: 4)

As we have seen, the eLibrary is, or should be, a complex entity, which is closely integrated with the learning it is intended to support. Borgman is surely right to emphasize co-evolution: we are still discovering the real benefits of eLearning, as well as its disadvantages, and we are still experimenting with different ways of providing learners with access to information resources. A critical issue is to bring the eLearning and eLibrary communities of practice closer together.

As an aside it is worth commenting that one of the curious aspects of the development of eLearning and eLibraries is that the two communities seem to spend so little time talking to one another. Few functional models of eLearning have much to say about the organization of published information—it usually merits a "black box" approach, relegated to the periphery of functional descriptions of VLEs. At the same time digital library commentators seem to spend little time on the actual purpose of their subject—as an example, three key monograph contributions to the digital library debate published in recent years, all with an academic background and referred to earlier in this chapter, (Arms, 2000; Borgman, 2000; Deegan & Tanner, 2002) do not contain a single reference to either "learning" or "eLearning" in their indexes.

It is easy to devise simplistic solutions to the problems of providing integrated access to information resources within VLEs, and Arms' earlier caution that libraries are *managed* collections must be taken to heart. However, since the "space" in which we live and learn is now global, a fundamental question is how a localized service (even if its customers are distributed widely across the globe) can in any real sense manage information resources. The integration of the eLibrary into learning, remembering our earlier emphasis on the library as part of a social system, demands local solutions. There is no such thing as a single, universally implementable blueprint. Yet the context is the global information resource. Global reach within local communities provides the locus of the challenge.

7. TOWARDS EFFECTIVE ELIBRARIES

7.1. Local and Regional and National and Global

The effective eLibrary is local to its constituents—in terms of their relationship to the learning environment rather than physical location. It is engaged with the pedagogical underpinning of the learning which has been designed—the high level pedagogy such as, say, problem-based learning; the pedagogical strategy which includes the broad plans for delivering and engaging in learning; and the pedagogical tactics such as ploys to encourage reluctant learners to participate (see CSALT, 2000). But it is also a window onto the broad universe of information and it sits within a managed framework of information resources. To achieve this it does not stand alone, but plays an active role in creating and maintaining an information environment on which to draw.

A good example of the planned development of a managed information environment is provided by the U.K.'s higher education community, led by its Joint Information Systems Committee (JISC). For over 10 years the JISC has engaged in a program of development which provides shared services and shared content at national level, available to be drawn into local eLibraries and local learning environments as and when required. The technical infrastructure to achieve this is complex and is articulated in the JISC Information Environment Architecture—see http://www.ukoln.ac.uk/distributed-systems/jisc-ie/arch/. In essence it is a collaborative venture in which those services which can better be provided nationally, such as access to large datasets, with all the accompanying user authentication and authorization requirements, are handled at that level while localization ensures fitness for the individual institution, department, course, and class. It is this collaboration—which goes far beyond the warm sentiment and limited action which characterizes so much "collaboration" between institutions—which will mark out the successful eLibrary of the future. In the United States many similar characteristics can be seen in services provided by, or through, longstanding co-operative systems like OCLC with its mission "to further access to the world's information and reduce library costs by offering services for libraries and their users". (see http://www.oclc.org/about/).

7.2. The Importance of Quality

Quality is frequently defined as "fitness for the user's purpose". It requires, in essence, a judgment, which links together the object and the task; the information resource and the learning event. We can provide clues and guidelines but in essence quality remains a matter of individual judgment, of the student or tutor. It may be, as with a refereed journal paper, a judgment supported by experts in the field. It may be judgment informed by prior reputation, as when we accept a reputable publishers' offering over that of an unknown house. It may be mechanistic, as when Google offers hints based on the number of other resources to which a target information source is linked. But at the end of the day there is an intellectual imperative on the user.

The eLibrary helps in two ways. Firstly it tries—and on the basis of long experience hopefully succeeds—to filter out the more obviously poor quality resources. Unlike the mechanistic search engine, it is able to distinguish between the medical paper on "breast cancer" and the web site which offers inexpensive options for the enlargement of body parts! But further than this, it enters into the learning process by providing opportunities for users to develop their own analytical and critical skills—in the emerging argot, to become "information literate". This must be a true partnership activity between those responsible for designing learning and those with particular expertise in the structure and organization of published information in order to ensure that the learning activity is fully situated within the broader domain of interest. As Virkus (2003) has written:

> "information-related competencies may be viewed as context- and content-dependent competencies which are integral elements in a constructive learning environment and are closely related with the characteristics of constructive learners (prior knowledge, metacognition, motivation, and the complex variable 'learning style'). However, the term 'information literacy' might be a useful research construct or umbrella term covering information-related competencies and also as a strategic concept or goal—a political, economic and educational one."

Perhaps it is in the centering of information literacy within the curriculum that the answer to student "satisficing" can be found.

7.3. Personalization

We have already discussed the need for localization of eLibrary services, but there is also considerable activity to take this a stage further by offering the individual personalized access to services. These are seen most obviously in the various "MyLibrary" developments ("MyLibrary@NCState" being the best known and perhaps original example—see http://my.lib.ncsu.edu/) and more broadly in the widespread move to develop portals. Service providers like Yahoo and Amazon are keen to address the individual's needs through personal content, and see this as a way of providing added value. It is also worth noting that the development currently of web services approaches (which enable machine to machine interrogation and retrieval of content for manipulation and presentation) and in the near future of the semantic web (which enables content to carry processable meaning) will provide the means forever more sophisticated personalization. The eLibrary needs to be involved closely in these developments.

7.4. Describing Information

Librarians are used to the lack of enthusiasm of the layperson for the intricacies of cataloging, which can appear an arcane craft with limited benefit to the world at large. Yet the catalog record, or to generalize and bring the terminology up to date, the meta-data, is the key which unlocks the information universe. Without accurate meta-data, complex retrieval which brings together the content of a particular information object (be it book, video, web page, or multimedia presentation) with the need of a particular individual is, to put it mildly, difficult. Libraries have well-established schema, such as MARC (http://lcweb.loc.gov/cds/marcdoc.html), and in the electronic environment the Dublin Core Meta-data Initiative (http://dublincore.org/) is now well established.

Of course it is not only libraries and publishing houses which create and use meta-data; learning systems do too. The IMS and other bodies have expended considerable resources to establish meta-data schema (see http://www.imsglobal.org/metadata/index.cfm), and there is an enormous body of ongoing research on ontologies, vocabularies, and the like. Nor is meta-data purely descriptive—it is used to record information on rights (who may use, who may copy, who may resell, and on what terms), on suitability (the Platform for Internet Content Selection (PICS) system, for example—see http://www.w3.org/PICS/) and for many other purposes.

In seeking to bring together eLibraries and learning systems, considerable work is being undertaken to map the different schema and to reach agreement on common approaches (see, for example, Richardson & Powell, 2003). This is vital work if we are to achieve interoperability between different kinds of object and different kinds of system. Furthermore, among the many challenges is the need to provide persistence, so that the information source my learning object points to today will be the same information source tomorrow—even if it has moved from one server to another, from one university to another, from one country to another. The list of challenges which meta-data poses is almost endless, and the complexities can be mind-boggling. As Pugh (2003: 56) put it: "metadata reminds me of the Schleswig Holstein question in European history: of the three people who understood it, one died, one forgot and the other went mad." Yet it is challenge that we must tackle, and tackle together.

7.5. Preservation: Our Responsibility to Posterity

The networked information world and the eLibrary tend to operate in the present tense. The imperative, as we have seen, is access, and the user wants that access to be instantaneous. It is all too easy to neglect the question of who is going to ensure that the resources we point our eLibrary users towards remain accessible, not just for the short term of our envisaged use—the duration of a course or even the period between major revisions of that course—but for future learners, researchers, and historians.

Part of the answer to that question lies in the role that major libraries, such as the national libraries, have played for many years now, receiving and storing copies of all the works printed and published in their region of responsibility. This needs to be extended to electronic publications. The Chief Executive of the British Library has commented:

> "at the core of the British Library's future relevance and mission to assemble a comprehensive record of the output of the nation and to make it accessible for current and future generations, is the continuing effort going in to ensure that the UK will have an adequate system of legal deposit for an electronic age."
>
> (Brindley, 2000)

However, it is highly unlikely that national libraries will be able to shoulder the whole burden, and in any case the locus of responsibility when so much publishing is global is unclear. Rather, institutions and their eLibraries will have to play a role. There are a number of straws in the wind to be noted here—for example, the movement towards institutional e-print archives and towards repositories of learning objects (one example is the recently established JORUM project—"a practical 'test-bed' investigation into a digital repository for learning materials, one that is both capable of providing the technical infrastructure for storage and retrieval of learning objects, and stimulating the re-use of learning materials for UK further and higher education"—see http://www.jorum.ac.uk/).

7.6. The Human eLibrarian

As yet, the tools which provide the electronic equivalent of the human librarian are in their infancy. We need to remember that some of the characteristics of electronic systems are innately problematic and that it will be a very long time before these limitations are overcome. The problems can be illustrated by reference to what is known as "brittleness", which in essence is the concern with whether a system is capable of responding when faced with a situation outside its core domain, and whether as the difficulties mount the system degrades "gracefully". Human beings are very good at handling problems outside their core area of expertise. Ask a human being who is playing chess where you can get a cup of coffee and you will get directions to the drinks machine or a suggestion as to who else to ask for directions—well, you will if you are not berated for interrupting at the crucial moment! Ask a chess-playing computer where to get a cup of coffee and you are liable to be told either "P-Q7" or "Error 6935462: rebooting"! Human beings are extremely flexible, and librarians are trained not to pretend to have all the answers, but to know where to go—and how to find the answer when they get there.

In eLearning environments it is also important to remember that learners are human beings too. There is ample evidence to show that some individuals cope better with online environments than do others—as a simple yet by no means trivial example the CSALT report referred to earlier pointed out that synchronous "conversation" in online environments may proceed too quickly for some students and too slowly for others (CSALT, 2000). We cannot assume that putting in place monolithic services, and removing the flexibility of human support, will adequately answer the learners' needs.

CONCLUSIONS

This Chapter has discussed the development of eLibraries within the context of VLEs, suggesting that the essence of the eLibrary lies in its ability to become an integral part of the localized, and essentially social, learning environment while at the same time mediating between the individual learner and the global information universe. The eLibrary will be built on the foundations of the libraries which have served learners so well for so long—but which need to be renewed and reinvigorated. The strategic, managerial, and technological difficulties are daunting, yet around the world innovative librarians and teachers are rising to the challenge.

Perhaps the late Rob Kling of Indiana University can have the last word: "The libraries of your future are not "out there" waiting to be discovered. They will develop as they are envisioned and developed by librarians and others. These visions and developments are likely to be local, incremental and opportunistic." (Kling, 2000)

ENDNOTE

1. I should perhaps note here that the discussion in this Chapter does not attempt to address all the possible roles of a 'library' beyond the support of learning: for this broader discussion the reader is referred to Brophy (2001a).

Chapter 34: Beyond Museum Walls: An Exploration of the Origins and Futures of Web-Based, Museum Education Outreach

KEVIN SUMPTION
Powerhouse Museum, Sydney

> "*An effective educational museum might be described as a collection of labels bearing instructions, each of them illustrated by a carefully selected specimen.*"
> *George Brown Goode, Assistant Secretary at the Smithsonian, 1896.*[1]

Although Goode's assertion may look naive by contemporary pedagogical and museological standards, I still sometimes wish that the process of museum education was indeed that easy. However, in truth I know that such assertions are anathema, as both the primacy of museum objects, and our understanding of learning, has advanced considerably in the last 100 years. The museum emerged in the mid-19th century as a general archive, enclosing in one place, all times, all epochs, all forms, and all tastes.[2] Established in 1879 my museum, the Powerhouse Museum, embodied this vision. Up until the 1940s our displays used evolutionary narratives, to move visitors forward through predominantly artifactual learning environments. However, the preponderance of artifacts and their position within the exhibition medium began to change after World War II. An influx of cheap, pulp mass media, and later the arrival of television, significantly altered visitor's media preferences. To keep pace, we quickly assimilated within exhibitions; photographs to give objects a sense of time and place; posters to provide ambience and atmosphere; and electro-mechanical interactives to increase visitor participation. Since the 1940s, the discipline of exhibition design has further evolved to provide shape, form, and structure to these otherwise dissonant media. Importantly as the discipline matured, the role and value of objects far from diminishing, was enhanced. Traditionally, these media were deployed to enhance and enliven communication between museum objects and the visitor. Then in the space of 10 years video and personal computing technologies inculcated our homes and later museums. And together these dynamic media contrived to tip the balance away from artifactual learning environments. And together propelled contemporary museums to look to harness the exciting potential of interactive multimedia (IMM) learning environments. And, it is the most recent of these media arrivals, computer-based IMM and its assimilation, both within and beyond the Museum's walls that I wish to explore. As we shall see this ubiquitous media has in a few short years had a profound impact on museums.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 915–937.

Within many it is now the pre-eminent interpretive and education media. And beyond the museum's walls—through the World Wide Web—it now provides museum educators and curators, with direct access to homes and classrooms around the world.

Computer-based IMM was born in the mid-1980s, when film, radio, and television converged with computers and gave rise firstly to videodisks, CDROMs, Internet and most recently high definition television. The first computer-based IMM appeared in Australian museums in the mid-1980s and now proliferate to a point where they constitute exhibitions in their own right.[3] The popularity of IMM is no accident and is just as much a consequence of museums' new visitor orientation as it is technological appetite. What attracts visitors and likewise museums is IMM's combination of interactivity and sensory appeal. It is now rare to find any display at the Powerhouse Museum without at least one IMM installation. However, as we move into the 21st century, the impact of IMM on the core business of museums is becoming more profound. Six years after the development of hypertext transmission protocol (HTTP),[4] museums all over the world clambered aboard the latest IMM juggernaut—the web. Museums' were willing to embrace the web for it offered the tantalizing opportunity to simplify and expand distribution networks, as well as lower costs for scholarly outreach. Most public museums in Australia are charged with the social responsibility of engaging as many and varied an audience as possible. Many of our museums are large, centralized entities situated in the middle of major cities and so they have had to tour exhibitions or publish and distribute their research, in order to capture these audiences. These are often expensive and time-consuming undertakings that in Australia are further hampered by the vast physical distances touring exhibitions have to traverse.

So it is not surprising that museums have embraced the World Wide Web. But as an epiphenomenon that cannot be meaningfully located in space or time, the web presents a unique set of problems to institutions whose very existence, is predicated on the primacy of the "real". Consequently, many museums are struggling to come to terms with a medium that is rapidly changing form demands they supplant aspects of their material and permanent selves, with that of the ephemeral, hyperreal, and transient. These demands are confronting as they seriously question whether or not the education and media practices, carefully crafted in the museum over the last 100 years, can or even should be, carried over into the realms of the virtual. In addition, museums are increasingly catering for the tastes and preferences of younger audiences. Many of these young people make few distinctions between mediated and primary experiences. Thus, for these particular audiences, museums are having to renegotiate the role and value of their collections in new digital domains. In so doing they are being forced to examine the effects of the voracious web medium on "the status of objects . . . and hence their authority to speak within a hegemonic system of representation."[5] What follows is an exploration of one museum's journey, my museum, as we confronted these challenges. Looking back we, like many, had our fair share of successes and failures trying to design and deploy effective online learning environments. Drawing on these historical lessons from across the cultural sector an array of virtual learning typologies is beginning to mature. And many of these now exhibit cognitive strategies, affordances technologies, and original content, that I believe have considerable worth to others, outside of museums, charged with creating digital learning environments.

1. AUSTRALIANS—EMBRACING THE WORLD WIDE WEB

The consensual hallucination imagined by William Gibson in his visionary text *Neuromancer*, is now a reality, with over 930 million people using the internet in 2004. As well as being a ubiquitous publishing, communication, design, and research tool, the internet has emerged as a powerful teaching medium. As such museums are not alone in exploiting this potential. However, the learning products and services they have created have been truly unique. This is a consequence of the distinctive partnership museums have forged with this epiphenomenon, where over 100 years of object-based teaching has melded with the interactive affordances of chat rooms, multiuser dimensions, news groups, e-mail forums, and videoconferencing technologies.

The term affordance was coined by the psychologist James Gibson to describe the potential for action, the perceived capacity of an object to enable the assertive will of the actor. The term is now commonly used, particularly in new media and industrial design, were it refers to an object or system that has been specifically designed to work with the intentions, perceptions, and abilities of users. Working within these parameters, good affordance technologies reduce the probability of confusing or non-productive user behavior. Thus, they specifically promote efficient, productive, and ultimately creative interventions by users. Technology and media are affordances to the extent that they promise extended human capabilities of seeing, hearing, and uttering.[6] However, as we have seen the successful deployment of these is predicated on an intimate understanding of user needs, perceptions, and abilities. However, the problem for museums, like many institutions, is that until recently we knew very little about our online audiences. Not surprisingly then many museums struggled to develop and deploy affordance technologies to support online learning.

Before, we can explore the history of museum web affordances, we need to acknowledge the differences between the web and the traditional museum as sites of communication. As a communication agent we should place the real museum in the same company as newspapers, photography, and cinema. Like these illusionary mediums, the traditional museum, (one not incarnate with IMM), is unidirectional. That is, its messages go one way from the museum to the visitor.[7] In contrast, the web's combination of mimetic and collaborative affordance technologies, offer the possibility of delivering highly personalized information that can promote learning by engaging learners in a dialog of minds-on, problem solving.[8] In essence web affordances offer the exciting possibility of delivering a genuinely constructivist learning experience.

So not surprisingly the World Wide Web has captivated the imagination of many working in museums. As a communication medium the web allows educators and curators to enter the homes and schools of students without them ever needing to visit the museum. In 2004, over 13 million Australians surfed the Net and depending on age, between 40% and 60% used the internet to engage in some form of learning. Many chose to visit museum websites and last year the Powerhouse Museum received over 1.5 million unique visitors. It could be argued that all of these partook of a virtual learning experience by simply accessing the museum's website. However, a closer analysis of browsing preferences revealed some intriguing trends. The vast majority of our current virtual visitors used the website to help them plan a visit to the real museum. Only 25% are currently attending to education services to conduct online research or partake of a digital exhibition. However, this still represents over 300,000 visitors and compares to the 320,000 students and teachers currently visiting the Museum building and its exhibitions and programs. Significantly, the number of virtual education visitors is also growing by over 30% a year and so we are constantly looking to enhance the efficacy of our online education services. To achieve this has required a process of reinvention and self-exploration, as the museum has turned in on its self to find models, theories, processes, and work practices that could provide a way forward.

Next to the United States, Australians are the second largest user of internet services per capita. This enthusiasm continues a long tradition of embracing technologies that help straddle what we Australians fondly refer to as the tyranny of distance. By the turn of the century Australians had earned a reputation as prolific users of telegraphic services and by the early 1960s led the world in television consumption per capita. In the first 4 years of television in Australia, from 1956 to 1960, over 1.2 million Australians, out of a population of 10 million, purchased TV sets. This compares to the 2 million TV sets sold in the first 4 years of television in the U.S.A., from 1946 to 1950, with the U.S.A.'s population of 150 million.

The advent of broadcast television in Australia in the 1950s not only fed this insatiable appetite, but also fast-tracked the development of a domestic television production industry. And like the U.S.A. and Britain, early Australian television borrowed extensively from other older media like theater and radio, to create new and popular forms. From these, television consciously assimilated familiar formats and symbols, to develop program schema for news services, current affairs, variety shows, etc. Similarly early Australian education television consciously borrowed didactic instructional, as well as factual and interpretive questioning techniques, from traditional classroom teaching practices. Over time these techniques were synthesized, adapted, and enhanced to form the basis of today's distinctive television genre.

And so history repeats itself. If we go back to the early days of the internet we see the very same process of recycling and assimilating the signs and symbols of older media. In the late 1990s, both formal and informal education sectors attempted to develop their own distinctive set of online education services, in large part based on their own teaching and learning heritage. Through this process museums began to develop a set of distinctive website typologies, which by the late 1990s had coalesced to form three basic typologies. The first of these, the *electronic brochure*, was primarily a marketing vehicle, whilst the other two were specifically designed to support informal learning.

2. THE EARLY YEARS—THREE MUSEUM WEBSITE TYPOLOGIES

The three major museum website forms of the 1990s made varying use of imagery, text, and interpretational techniques, much of which was originally created for the corporeal and its exhibitions and print publications. The most common form of museum website, then and still today, is the *electronic brochure*. Typically between 1 and 10 pages, these sites characteristically contained scant details, other than information on museum opening times, location, public programs schedules, and a basic collection overview. The market orientation of these sites was a derivative of the "just in case" reasoning espoused by the first wave of e-businesses. Just in case a visitor surfing the web wished to visit, then information was available to persuade them that their impulse could easily be realized. The major distinctive characteristic of these sites tended to be their reference to, and reliance on the real museum. These were websites that operated primarily to encourage people to visit and use the real museum. As such they rarely provided rich, or what could be described as learning environments. This function was wholly the preserve of the first-generation of museum *tour* and *interactive* websites.

Tour websites typically employed more complex information structures than *electronic brochures*, as they deliberately sought to simulate the informal education experience that one might encounter within an exhibition or gallery. *Tour* websites often used especially composed images and text to give an accented, albeit abridged overview of the museum. Typically, they attempted to provide a sense of the corporeal through expansive use of images of exhibitions. For this very reason the Powerhouse Museum chose this form, when it launched its first website back in 1997.

3. FIRST-GENERATION ONLINE LEARNING ENVIRONMENTS

In 1997, we estimated that internationally there were approximately 8000 other museum websites. Ambitiously the Powerhouse Museum set out to create a site that would operate as more than just a promotional vehicle, and importantly offer regional, education outreach services. In addition the site was intended to fulfill an important institutional objective—to increase access to the museum's collection by establishing a representative virtual collection. In essence, the challenge for the site's designers was to use digital simulacrum of the museum's exhibitions, to allow virtual visitors to learn about Australian history, science, and design.

Despite the proliferation of online museums, few at the time had attempted to reconcile both intra-institutional collection objectives, simultaneous to providing education outreach services. In the absence of a suitable web model, designers turned to the real museum. This selection was naively based on our assumption that the web, like exhibition media, was simply a text and pictorially driven medium. Thus, it seemed by using labels and images originally created for exhibitions, it would be a straightforward task to simulate and place online all the museum's exhibitions. The primary vehicle we used to achieve this was a series of 200 captioned images of significant objects from our permanent collection.

Looking back the Powerhouse's decision to adopt artifactual images as signifier of the corporeal, demonstrated a fundamental confusion of reproduction and simulative media. By simply placing online images of artifacts the museum overlooked the fundamental pedagogical shifts that occur when artifacts are mediated, first by the camera and later by the computer screen. To the authorial intervention of the lens and photographer, is added the compromising intervention of at least two external, or user, determined factors. Back in 1997, the majority of the museum's web users, particularly in schools, utilized low resolution, small-scale (14″) screens. In addition most were incumbered by second generation browser technologies that commonly distorted the layout of webpages. Together these contrived to significantly distort the appearance of artifacts onscreen. Reduced to such shallow simulacrum, it is inconceivable that this qualitative diminishment did not have an impact on the learning efficacy of these early digital collections. Museums are now acutely aware of this diminishment, but to this day struggle to find appropriate ways to represent collections. This is because a website devoid of digital artifacts calls into question not only the role and value of the real collection but the value of the museum's extensive teaching and learning heritage.

3.1. THE HERITAGE OF OBJECT-LESSONS

For all but 8 of its first 100 years the Powerhouse Museum was a part of the New South Wales Department of Education. Thus, it was almost exclusively concerned with education, through the process of collecting, conserving, and displaying material culture. Epistemological interest in the use of objects in teaching and learning at the museum has a long and diverse history dating back to the mid-1890s. At this time the approach to public teaching in Australia was in part predicated on the *tabla rasa* theories of learning, espoused in the writings of John Locke and Jean-Jacques Rousseau. The "object-lesson" was a feature of schooling across many curriculums and thus it is no coincidence that in the 19th century, small collections, cabinets, and museums were established in secondary education institutions,[9] and in the case of my museum in 1893, in the grounds of Sydney's Technical College.

For over a century, object-based teaching has been central to Powerhouse education practice. However, our understanding of the complex interplay among visitor and object that gives rise to learning has changed markedly as epistemological and pedagogical research has evolved. From this a number of education theories have developed, of which the direct-experience-based model is the one most widely used, especially within the United States and European science and technology museums. Direct-experience-based learning divides our world into two distinct realms: the physical world where objects exist and events happen, and our minds, which are capable of memory and conscious thought. By allowing visitors to encounter real objects, labels, and a variety of media, museums traditionally immerse visitors in a physical world, where they see, hear, touch, taste, smell, and do. It is human nature that visitors should then seek to understand these direct experiences. This means they must use their minds to find regularities and relationships between these new primary experiences and existing concepts and principles.[10] The Powerhouse Museum is rich in such direct experiences. Parents and young children standing beneath our Boulton and Watt engine will hear and smell an 18th century steam engine, whilst a secondary school geography class, studying navigational aids, can examine the face of our Strasbourg Clock to elucidate how 16th century navigators used the stars to guide ships. These direct experiences with real objects, help visitors develop a range of skills from observation and reporting to deduction. According to Sue Wilkinson, real objects provide a concrete experience that illuminates or aids abstract thought . . . they are real rather than abstract, and thus they aid the memory . . . [and] may remain much longer in the mind than word or simple image gained facts, ideas, or reproductions.[11] Exponents of the direct-experience model contend that it is the tactile, spatial, and visual stimulus of these primary experiences that promotes learning by engaging visitors in ways that other methods and media fail to do.

Whilst I am not suggesting that it is impossible for the over 200 digital object images on the museum's original website to have significantly contributed to some kind of learning experience, it is inconceivable that their lack of detail, inconsistent coloring, and loss of tactility, along with misrepresentation of scale and weight, would not have had some qualitative impact on learning. After all simulations and models are basically analogies, and are meaningful only if there is prior experience that allows the analogy to be understood. Take for example, the simulated Strasbourg Clock that back in 1997 appeared on the museum's highlights page. Recently, reviewing the archive record I was struck by the manner in which the web had compromised both the aesthetic and intellectual integrity of this magnificent object. Reduced to 72 dpi, unaccompanied by a volunteer's interpretive oration and scaled down to 1/200 of its original size, the digital facsimile bore little resemblance to the original. Looking back we can clearly see that these simulacrum are no substitute for the real thing. Indeed, they can be dangerous as they propagate false and misleading interpretations. Quickly we realized that some virtual objects, similar to some IT objects, are afflicted by a major interpretive dilemma, what in the text *Simulations* Baudrillard saw as the inevitable consequence of the eruption of the binary scheme. And in more recent times has become known in museums as the diminished authority of digital objects.[12]

3.2. THE DIMINISHED AUTHORITY OF DIGITAL OBJECTS

> *The eruption of the binary scheme . . . renders inarticulate every discourse. It short-circuits all that was, in a golden age come again, the dialectic of signifier and signified, of a representing and a represented. It is the end of objects whose meaning would be function*.[13]

In *Simulations* Baudrillard riles against the captious forces of then emerging digital media. He warns that these will perpetrate confusing ambiguities that blur the distinction between object and representations and things and ideas. This confusion was apparent at a recent Loebner Prize. This AI competition challenges human judges to distinguish between natural language processing programs and people. Of the 10 judges, 5 believed that the winning DataFlex C++ program "Albert", was a 30 something Monty Python fan, hailing from Cedartown, Georgia, U.S.A. Such misreadings lend weight to Baudrillard's assertion that if left unchecked digital technologies propagate a potentially dangerous confusion of the real and the imaginary. What is more, the degree to which people will accept computer simulations as being equivalent, and in some cases preferable to, raw experiences, raises important questions concerning the relationship of virtual environments to the real world. And poses significant challenges for the traditional custodians of the real, namely museums. After all in a digital age objects, images, and resources all have equal status. But critically—as we have seen—they are not all equally valuable.

As well as being cognizant of the diminished authority of digital objects, the Powerhouse Museum's current web design has learnt further lessons from these early experiments. Just as we are now acutely aware of the need to carefully construct digital representations of our collection, we are also mindful of the imperative to better understand the needs and motivations of learners. The museum's preference for the *Tour* form back in 1997, was in part based on the promise it held out to meet the perceived needs of students, teachers, historians, and academics, and specifically those that had never visited the museum before. In attempting to place on line an overview of the museum's exhibitions and collections, we had sought to overcome the geographical and logistical obstacles we assumed had hindered them from visiting the museum in the first place. Fundamentally this approach presumed that people in the past that had been unable, or unwilling to attend the real museum, would instead find the virtual compelling. What is more the kinds of learning environments we naively developed for their consumption, took as their primary metaphor, the exhibition. Of course, we now know that the social and the cognitive complexity involved with a visit to a real exhibition cannot in its entirety be replicated online. As Falk and Dierking observed when defining the parameters of an effective educational visit, each is determined by the visitor's unique personal, physical and social attributes, and contexts. Each one of which is mediated by senses engaged by the material reality of the visitor's social and physical surroundings. Thus, the direct replication of real with virtual experiences is a questionable undertaking. After all would we accept that a family visit to the Louvre could be reasonably simulated and replaced by a television documentary? We know that it cannot. However, there are attributes of the television documentary which are unique and privileged, even above that of a real visit. A television camera can take us inside the working components of an exhibit, or provide an expert oratory taking us behind-the-scenes of an exhibition. It is these privileged affordances, often unique to individual media that we are now aware, must be sought to create effective online learning experiences.

Looking back it is easy to see how many frustrated by the web's perceived lack of sophistication, retreated to the safe, and familiar territory of their collection. However, these primitive learning affordances were not a barrier to all cultural institutions. And significantly many of the early pioneering works that did emerge were not conceived by either museums or galleries, but science centers. Science centers are primarily concerned with the teaching of scientific principles and theories through instructive technologies and few if any use artifactual collections. One of the most innovative was and still remains, the Exploratorium in San Francisco. In the late 1990s, the Exploratorium provided an important lead in the search for effective online learning models and was a pioneering exponent of the first-generation of *interactive* websites.

The Exploratorium sits adjacent Bernard Maybeck's masterpiece The Palace of Fine Arts, in a pavilion left over from the Panama-Pacific International Exposition of 1915. Within it are housed 200 exquisitely crafted mechanical and electro-mechanical interactives and it was to these the Exploratorium turned for inspiration. In essence, the Exploratorium recognized that even within the then limited affordances of the web it was still possible to create a set of basic, but compelling interactive learning experiences. The result was a website structured around a series of web-cast programs and internet chat rooms. In August 1999, the Exploratorium dispatched a team to Turkey to film a solar eclipse. Hearing of this I visited the site and eavesdropped on a group of science teachers watching the eclipse unfold. I was enthralled to see how images of a solar eclipse could generate such animated and rich exchanges. In the same year, the Exploratorium conducted a series of web casts on the occasion of the 10th anniversary of the Loma Prieta Earthquake, and later hosted a web-cast program on the science of wine.[14]

It is now difficult to appreciate what a breakthrough the Exploratorium's early experimental web programs represented. But inspired by these achievements and supported by a maturing web medium, this relatively simple *interactive* form has, as we shall see, quickly burgeoned into an array of complex online learning typologies. In part these relatively new metacenter; creative play; electronic field trip; learning network; and videoconferencing forms, have emerged on the back of new web programing and animation technologies. Chief amongst these are Flash programs that for the first time are allowing the interactive microworlds created online, to also be used within exhibitions. In essence these programs are breaking down the distinctions, between the real and virtual museum. However, it is no accident that when we examine the operation, structure, and education effectiveness of these contemporary online learning experiences, we find yet again that they are unique to the cultural sector. This time instead of aping collections and exhibitions, they have sourced the forms, concepts, and theoretical approaches, found in computer-based IMM, which now thrive within many museums.

Since the pioneering work of McLuhan and Parker in the 1960s, museums have recognized the value of creating media rich, stimulating environments for visitors. This awareness spurred the development of a specialist design trade, one focused on the creation of mechanical, electro-mechanical, and more recently computer interactive installations. In part the emergence of this new IMM design discipline in museums, paralleled the rise of mass media within western society and shifts in our appetite away from textual, toward visual literacy forms. Importantly, for this polemic in order to fully understand how museums have arrived at their current array of web-based learning environments, it is imperative to understand what makes the task of designing interactive experiences within museums unique. It is only when we can comprehend the challenges designers face creating computer-based IMM within museums that we can understand how these have come to influence the unique IMM learning environments museums now deploy beyond their walls.

4. INTERACTIVITY WITHIN THE MUSEUM'S WALLS

IMM is neither a specific technology nor a product. Instead it is a visual communications system; a mechanism of delivering information in intuitive, predominantly graphic ways. However, it is neither the aestheticism nor quality of its images that have helped it usurp the role of traditional pictorial or text media. Rather it is IMMs unique malleability, editability, or what we more commonly refer to as interactivity. The animations, photorealist images, and special effects that dominate contemporary IMM are dynamic. That is they provide an active stimuli that elicit responses, which in turn changes either audio or visual content. As such interactivity in museums is not just about person to machine dialog, but also refers to the exchanges that take place amongst museum visitors. It is the essence of human communications, an essential ingredient of face-to-face teaching and learning.[15]

Whilst this face-to-face interactivity remains an important component of the museum visit, nowadays this is not the kind of interactivity that many, particularly younger visitors, seek in museums. They are much more concerned with automated or mediated interactivity. Mediated interactivity in museums has been popular since 1969,[16] when McLuhan and Parker first demonstrated how new communication technologies could enhance visitor participation in exhibits. They asserted that visitor understanding and interest in linear artifactual story lines was limited. This discovery marked a turning point in curatorial and exhibition design practice. To increase visitor interest they advocated bombarding visitors' senses with a variety of media to stimulate them into absorbing more information. Critically, McLuhan and Parker's faith in IMM was not merely as an entertaining alternative to artifacts. Rather they believed it operated in ways that reflected how people think. This was not the first time this fit between cognition and media operation had been articulated. Vannevar Bush's seminal article, "As we may think"[17] was the first to raise the idea of using IMM technology to help us learn. In it Bush described a fictitious machine called the MEMEX which would allow a user to quickly and easily access any information they needed through an intricate web of associative links. Bush envisioned the MEMEX to be a multimedia machine equipped with a keyboard and microfilm reader. Importantly, it could store and link vast amounts of information in the same way he understood people to think, that is by association. With one item in its grasp, it snaps instantly to the next that is suggested by the association of thoughts, in accordance with some intricate web of trails carried by the cells of the brain.[18]

This associative analogy to learning is one of the main reasons why IMM has become so popular in museums. However, it is an oversimplification to state that all IMM technologies have manifestly the same learning or entertainment potential. It would be like suggesting that cinema and television operate identically as they share a common audio and visual form. As semiotics and psychology have so ably demonstrated, the social, narrative, and structural symbolism of cinema and television are fundamentally different. Similarly, it is an oversimplification to assume that there is one discrete set of lessons museums have learnt developing IMM. The assumption that all museum-based IMM and the web are similar and thus techniques interchangeable is a compelling one. But this interchange is predicated on a perceived parity between internal and external computer use. That is computer-based IMM in the corporeal, has the same function and attraction to visitors as that of the web. Nowadays, there is an increasing awareness that this is both a simplification of the complexities inherent in museum-based IMM, and at the same time overlooks the sophistication of contemporary web affordances.

An interactive exhibit is a device in which the visitor's response . . . produces a change in the exhibit[19] and is explicitly designed to focus visitor attention and therefore increase their interest. Although Bitgood limits his definition to physical rather than mental interaction, his three categories of interactivity are those we still use to classify exhibits in museums. These are *Hands On*, *Participatory*, and *Interactive*. Simple *Hands On* refers to exhibits like the "Touch and Feel" children's trails found throughout the Powerhouse Museum. Here, we utilize clothing swatches and fake animal fur etc., to provide visitors with tactile feedback. Alternatively, those interactive experiences Bitgood describes as *Participatory* are designed to intellectually stimulate visitors to make comparisons between their own instinctive responses and those of a programed norm. An example of this type is an activity that invites visitors to identify an advertizing jingle. Here, an audio loop from a television advertizement is activated by a visitor who is invited to select the product they think was advertized by the jingle. An unsuccessful selection results in a pre-recorded voice asking the visitor to try again. This kind of *Participatory* experience is the most common found throughout contemporary museums and currently makes up over three quarter of all the Powerhouse Museum's interactive installations.[20]

Of critical importance when considering the popularity of the *Participatory* model within museums is that its selection is driven by the practical considerations of how museum educators want visitors to use IMM in museums. Because within physical exhibitions there are often space considerations, which limit numbers of interactive installations, controlling the time any one visitor spends on an interactive is important.

In part the popularity of the *participatory* model within museums is a consequence of their structured approach to knowledge creation i.e., philosophically they are explicitly instructional (also known as Objectivism) devices. Consequently, they tend to have closed-architectures, where interactive dialog is deliberately curtailed to arrive at a set of pre-conceived outcomes. However, since Jonassen's paper *Objectivism versus Constructivism*.[21] The education effectiveness of such instructional perspectives has been seriously questioned. Jonassen argued that in attempting to simplify learning in order to improve instructional efficiency and effectiveness, instructional systems may be short-circuiting the relevant mental processing required in learners. Jonassen also believed that if designers continued to simplify learning they risked ignoring its inherent complexity.

In the last 10 years an alternative teaching and learning philosophy has emerged within museums to challenge instructional IMM design—constructivism. As a faction within cognitive psychology, associated with Piagetian learning theory, constructivism is characterized by discovery and experiential learning. Rather than attempting to map an external reality onto learners, constructivists attempt to assist learners to construct their own conceptual framework. Those museum educators and designers favoring the constructivist approach have sought to tap the computational power of modern personal computers, to create environments in which learners can experience and develop sophisticated ideas from a variety of domains. As a consequence of the extensive in-built choices and diversity that these systems require, constructivist IMM exhibits, or what Bitgood describes as truly *interactive* installations, are still rare within museums. At the Powerhouse Museum there are few that support a truly dynamic dialog between visitor and display.[22]

5. RECONCEPTUALIZING THE COMPUTER—FROM TOOL TO MEDIUM

Despite McLuhan's and Parker's contention that IMM operates in ways sympathetic to how people think, it is often unclear exactly what computer-based IMM adds to a museum visit. Do they or could they enhance existing interpretive practices by making learning more effective? Can they lead to new educational paradigms in which the traditional roles of curators and visitors are reversed? Common to these questions is the metaphor of computer as tool. As a tool the role of the computer in the museum is to help visitors learn and enjoy by creating something, including the solution to a problem. However, as with *participatory* IMM, the dynamics of the interactive process are often constrained. This is because designers of IMM in real museums often have to work within the technological confines of existing software and hardware, and the attention-span and time constraints of visitors. Thus as we have seen, designers often have little choice but to adopt closed-architectures. Consequently, visitor experiences of most computer-based IMM within exhibitions are characterized by a set of discrete and limited outcomes that ordinarily have limited interactive or communication potential.

It is this re-conceptualization of the computer and with it the web, as a communication rather than unidirectional presentational medium that has begun to take place beyond the museums walls. Viewed as a medium, the computer can enhance the very nature of how and what we communicate. Critically such a re-conceptualization also allows the museum to cross-over into the constructivist arena of online learning. As a medium the computer not only facilitates inter-subjectivity, that is communication between learners, but also intra-subjectivity, which is, communication between the learner and him/herself.[23]

As we have seen museum web developers face a dilemma. Whilst artifactual simulacra modeled on the real museum can be ineffectual, simulacra modeled on computer-based IMM are also problematic. Whilst their multimedia content and dynamic interactivity are certainly improvements, the inherent objectivism of most *Participatory* models limit their usefulness online. So where if anywhere can the museum turn for an effective model? In truth there is no single model and instead museums have assimilated all these interactive archetypes, along with their object-based learning heritage and constructivist aspirations, to create a series of hybrid learning environments.

6. LEARNING ENVIRONMENTS BEYOND MUSEUM WALLS

Since the privatization of the internet here in Australia in 1995 museums have increasingly sought to use the web to service the learning needs of predominantly secondary school students. To do so they have harnessed the communication affordances of personal computers, *via* the web, to create a plethora of learning environments. These environments strive to attract and hold students by supplanting the inherent pedagogically weak "digital object" with more engaging interactive experiences. This shift away from artifacts has liberated many museum educators who can now concentrate on the development of education products, at the center of which are not just objects, but students themselves. For evidence of this shift one need look no further than the education winners of the Best of the web. In 1998, the *Odyssey* website (www.cc.emory.edu/CARLOS/ODYSSEY/index.html), utilized museum object images and stories to "inform" students of the daily life of Middle Eastern and sub-Saharan peoples. In 2003, the Smithsonian Institute's "Campfire Stories with George Catlin" website, (catlinclassroom.si.edu/) equipped students with research tools to interrogate and extrapolate historical data to help them build personalized interpretations of the life of Native Americans in the early part of the 19th century. This shift from seeing the web as an information medium, to that of a dynamic learning environment, now abounds. Now more than ever, museums are creating web-based learning environments within which users, not just educators, are empowered to make decisions about the tasks, content, navigation, presentation, and assessment activities they undertake. Thus, it is not surprising that a diverse range of learning web typologies has begun to emerge. These typologies range from mature education metacenter products, which continue to utilize digital object images and records, through to expository resources. As we shall see what distinguishes one typology from the next is not just content and affordance technology, but also the cognitive strategies each employs. These are the generative, problem-based, creative play, and expository methodologies that assist learners to build on their own knowledge structures (schema) in order to construct new knowledge and understanding. As we have seen many of these schemas are consciously, and sometimes unconsciously, borrowed from the experiences of the designers and educators in the real museum.

6.1. EDUCATION METACENTERS

Of the six museum education typologies currently identified, Education metacenters, along with Creative play environments, are still predominantly concerned with teaching and learning via museum objects. However, best practice in both is now exemplified by activities that subjugate the diminished authority of digital objects. Most now utilize complex Online Public Access Catalogues (OPAC), to provide access to collection images and information. However, we appreciate that the mere accessibility of raw data alone does not in itself guarantee learning. And in order to move beyond the limitations of objective physical form and function, museums have augmented artifacts with affordances that empower users to create useful intellectual content. To accomplish this many education metacenters utilize interrogational tools with which students can convert raw data into useful and highly personal knowledge products. A good example is Museum Victoria's *Butterfly* site (www.museum.vic.gov.au/bioinformatics/butter/). This website allows middle and upper high school students to access a database of 40,000 Victorian butterfly records via seven discrete searches. Each search is designed for students of a particular age, studying a specific syllabus. At the culmination of each search, students undertake a series of comparative activities that allow them to mentally experiment (generative) by overlaying data sets. In *Butterfly*, this generative experience is supported by a java-based mapping tool. This application allows species distribution data to be overlayed onto vegetation, altitude, river, and zoogeographic information. The result is a unique schematic of species and topological data, which students can endlessly modify and interrogate. Potentially this allows them to develop learning outcomes built around their own interests, which in turn can result in a deeper conceptual understanding and affinity with the subject.

6.2. CREATIVE PLAY ENVIRONMENTS

It is a peculiar anomaly that nearly all online museum learning environments are targeted at secondary and tertiary students. Disappointingly there are few museums developing learning environments for under eights. One of the exceptions is the Museum of Modern Art, New York (MOMA). MOMA has led the way with the development of online resources for this age group and through their website, *Art Safari*, has helped define a learning approach I call Creative play. *Art Safari* (artsafari.moma.org/) uses paintings and sculpture from MOMA's collection to help children develop their observation skills. *Art Safari* has been specially designed with activities that encourage students to examine and creatively respond to the forms, stories, and characters that populate the artworks of Rousseau, Kahlo, Rivera, and Picasso.

Early childhood learning research points to the value of activities that stimulate and support creative play. Creative play is an important part of young children's learning and describes those experiences that encourage them to explore and test ideas through the process of making. Most project-based websites offer some degree of creative play if they allow students to create original written or oral compositions. However, for young children drawing and painting-based activities are often the most effective. *Art Safari* supports this kind of activity by helping children draw a portrait of a pet or fantastic animal, using a downloadable palette. Young children find this specific activity very stimulating, particularly as it allows them to explore subjects that are close to their hearts. Pets, parents, brothers and sisters, etc. are all subjects of deep personal interest to young children, and when combined with creative play, excite children to keep on investigating, listening, talking, designing, constructing, asking questions, reading, and writing.[24]

6.3. ELECTRONIC FIELD TRIPS

Where Creative play learning environments are ideal for helping develop observation and hand eye co-ordination skills, electronic field trips are best suited for teaching complex cyclic or relational concepts, by immersing students in credible microworlds. Credible microworlds convincingly "transport" students through time to historical sites; through space to the museum; or through their imagination to fictitious and fantastic worlds. The effectiveness of this transportation is in part dependent on the utilization of audiovisual materials and interactive technologies to realistically simulate an experience or environment. Be they imaginary planets, tropical rainforest or a civil war battlefield, all these microworlds need to not only capture the attention of students, but also engage them in activities that are stimulating enough to sustain attention for long periods of time. To achieve this, many *electronic field trips* utilize anchored instruction techniques.

Anchored instruction activities borrow extensively from *participatory* IMM from within the museum and utilize sets of interconnected problems to encourage users to activate their reasoning, deduction, and investigative faculties. An excellent example is Brookfield Zoo's *Go Wild* field trip (www.brookfieldzoo.org). *Go Wild* challenges students to overcome the problem of finding a safe way through the Ituri forest of central Africa. To help solve this problem developers have provided four avatar guides who drive the narrative by bombarding users with questions. As with all anchored instruction activities, *Go Wild* challenges are based on real problems, be it using a compass and map, making bark cloth or choosing suitable forest foods to eat. The realistic nature of these problems is imperative, as it can encourage students to take ownership of their dilemma, and in turn, responsibility for actively overcoming their problems.

6.4. VIDEOCONFERENCING

Like electronic field trips, videoconferencing activities utilize the connectivity of the web to transport students and teachers beyond their classroom or home.

However, unlike current electronic field trips, videoconferencing can utilize synchronous affordance technologies to connect students and teachers to the real museum's staff and exhibits, in real time. Here, the microworlds created are not based around animations, but utilize the performances and "scenery" of staff and exhibits. And ultimately it is the photogenic nature of these displays, together with the affability and open-endedness of the student presenter dialog, which determines the level of meaningful engagement.

Videoconferencing consciously builds on the breakthrough web-cast work of the Exploratorium and similarly is dependent on the availability of significant bandwidth. For maximum image quality and minimum image lag, museums ideally have to access high-speed networks, like that of the New Jersey Department of Education's Distance Learning Network. This statewide ISDN/ATM network allows schools from across New Jersey to link to the state's principal science center, the Liberty Science Center (LSC). As well as specially equipped videoconferencing facilities, students can access LSC exhibits *via* a series of e-connection programs, e.g., the aquatic ecosystems package. This videoconferencing activity links a class of upper primary students studying river ecosystems to a biologist based in the LSC's Hudson River aquarium. After a brief introduction a camera scans tanks of toadfish, eels, and spider crabs. A series of carefully choreographed activities follow to prompt students to ask questions about the habitat and behavior of each species. Quickly a dialog begins as the biologist moves from presenter to conversation facilitator. As well as the presenter's conversational ability, their in-depth knowledge is essential if a rich and open-ended dialog is to ensue. To achieve this, research has demonstrated that digital resources need to be sophisticated enough to: (1) encourage children to respond in thoughtful ways; (2) offer response to children's answers; (3) offer variations that are child-controlled; (4) cater for individual children's ability, cognitive development, and computer skills; and finally (5) take into account the child's cultural background and language competencies.[25] For all these reasons human facilitation of genuinely open-ended learning experiences is irreplaceable.

6.5. MUSEUM LEARNING NETWORKS

In internet terms, museum learning networks have been around for a relatively long time. But surprisingly they have yet to flourish. The problem is that most museums are still pre-occupied with developing resources for independent students working either from home or within a classroom. This is understandable as the complexities of building resources to accommodate multiple and simultaneous learners are considerable. Learning networks characteristically provide aggregated access to an array of field trip and expository resources, themed around a single discipline like science, contemporary art, or environment. In 1996, 12 science centers from across Asia, Europe, and the Americas pooled content and expertise to develop the Science Learning Network (SLN). Within SLN (www.sln.org/), students are able to conduct a series of genetic, solar, aviation, and oceanographic experiments or participate in one of three collaborative projects. One of the most popular is *Monarchs and Migration* (www.sci.mus.mn.us/sln/monarchs).

Conceptually, *Monarchs and Migration* uses the natural phenomenon of migration to encourage an international community to build a rich textual, artistic, and photographic record of Monarch butterfly migration. Students in the U.S.A., Mexico, New Zealand, and Australia, use online picture galleries and tracking tools, to share observations and photographs of migrating butterflies. However, whilst offering excellent content and tools, *Monarchs and Migration*, like many learning network activities, is still limited in the genuinely collaborative opportunities it offers.

Over the last 10 years museum researchers, including Falk and Dierking[26] and Uzzell[27] have successfully demonstrated that families and children in school groups, use *real* museums as important collaborative learning environments. In 1993, Uzzell published the results of a series of museum visitor studies, which compared and contrasted the accuracy of students working alone to those in groups. Uzzell observed that group performance was significantly superior to individual performance. Uzzell found the social interaction and exchanges facilitated in groups allowed students to move beyond individual experience and could equip them with the accumulative interpretations of others. The scope and value of this co-operative learning approach is only just beginning to be acknowledged by educators working online. Jamieson MacKenzie's Virtual Museum[28] project for upper-secondary students is one which led the way in using asynchronous and synchronous IRC, see-you-see-me and e-mail technologies to encourage collaborative problem solving. Already his research is pointing to the education potential of a number of specific collaborative activities, including information searches, electronic process writing, and sequential creations. All these are activities that foster co-operative solution finding, through continuous communication. Ideally, this kind of collaboration is best facilitated *via* face-to-face meetings, or in chat rooms, within which the process of creating a joint product is negotiated. An excellent example of a museum-facilitated, collaborative learning experience can be found on the National Museum of Science and Industry's STEM (Students and Teachers Educational Materials) website. (http://www.sciencemuseum.org.uk/education/stem/stem/stemintro.asp).

The STEM project is a learning network with a difference. Instead of museum educators and curators producing content, students and teachers do this work. Students and teachers who visit one of the National Museum of Science and Industry's three museums are invited to compete with one another to create a web resource based on their visit. Invariably those teachers and students that take up the challenges, work in teams both real and virtual. In this way, STEM students create products that explore issues, ideas, and problems that have their roots in their own unique experiences, interests, and opinions. As with any learning activity, given the opportunity to directly control content, students are much more likely to be internally motivated to explore issues and ideas close to their heart. The bonus is that these very same issues are much more likely to be of interest to the resources' intended audience—other students.

6.6. EXPOSITORY TEACHING ENVIRONMENTS

Often found on science and technology museum websites, the closed architectural approaches of expository teaching resources are analogous to in-house *participatory* IMM. Primarily developed for children 12 or younger, expository resources ordinarily comprise a series of highly structured, computer-directed activities, through which a set of principles, laws, or theories are taught (expository). The Australian National Science and Technology Centre's *Funzone* is typical. *Funzone* (http://www.questacon.edu.au/fun_zone.html) features a series of Flash-based puzzles, activities, and laboratories, wherein students can conduct web-based experiments. One of these experiments asks students to observe a series of animated lines moving across a screen. After 60 seconds the lines stop moving, however students observe a motion-after-effect. That is the lines "seem" to continue to move across the screen, because their brain is so accustomed to the movement.

Interaction with other students, and the Flash animation itself, has been deliberately constrained in *Funzone.* Where this may seem at odds with constructivist learning principles, these "closed" learning resources are not without merit. Potentially they can alleviate some of the metacognition problems often encountered by young children. Metacognition problems can occur when people lose sight of, or can no longer accurately monitor, the success or failure of their own learning because activities are not stimulating, or are too complex. A number of studies have indicated that metacognition problems can also arise when students fail to develop clear-cut learning goals because they are given total control of learning experiences. However, metacognition problems can be addressed through careful navigation and interface design, coupled with rigorous remedial evaluation.

Therefore, the dilemma for expository environment developers is to find solutions that accommodate both a student's explorative preferences and need for learning guidance. Whilst there are no easy answers, one possible approach is to try to enrich "experiments" with layers of additional activity. In the case of *Funzone*, students could have been offered extension exercises, wherein different colored lines, or lines moving at different speeds, could if the student desired, have been introduced. This kind of "value adding" to expository resources has the potential to lessen the likelihood of metacognition problems as it supports limited student exploration. Critically, this layering also has the potential to expand student understanding, as it clearly defines the limitations within which phenomena such as motion-after-effect operate. An excellent example of this kind of expository layering is the National Museum of Australia's *Ann Fibian* website http://www.nma.gov.au/education/ann/index.htm). Here students investigate soil erosion and deforestation phenomenon via a series of expository activities. Critically these activities provide the student with a set of incrementally more challenging exercises, or alternatively the ability to opt out at any time. Either way valuable results emerge from the interaction.

6.7. DO THEY WORK?

As these typologies demonstrate, there is no such thing as a sure fire way to guarantee learning or teaching, only methods or devices which together facilitate the individual's endeavor.[29] Indeed, the deployment of any one of the cognitive strategies discussed is not in itself a guarantee students will mindfully attend to any of these activities. The best museum educators and designers can do is to carefully combine pedagogically appropriate content and affordance strategies. But even then we recognize that learning is still a process beyond the total control of museums, and one predominantly invested in the learner herself. So even when this mix has been carefully prepared, work can still be undone by the relatively unknown impact of users' unique cognitive, environmental, and cultural characteristics. This is why it is imperative that we continue to support research activities, particularly remedial and summative evaluations. Without these we have little chance of building understanding and ensuring the efficacy of future online learning environments.

Where the responsibility to better understand learners and their needs is incumbent on all of us working with IMM, museums have another particular responsibility if they are to negotiate this challenging period. If museums are indeed to make a successful transition from predominantly artifactual, to IMM learning environments, they will need to continue to renegotiate and reinvent the role of the artifact. I do not believe that these two learning environments are mutually exclusive because the increasing virtuality of our world seems to demand its own counterpoint in the materiality of those objects that have withstood time. Far from diminishing, the multiplication of IMM will surely intensify the need for emblematic objects that signify the extraordinariness and ever-rarer primary human experiences. This desire I believe will secure the future of object-orientated museums. However, I am not so conceited to take this for granted. For in an increasingly mediated world there is little doubt that *virtual* museums will continue to thrive alongside the *real*. But is this separation sustainable? When I look at our current crop of learning environments, I suspect not. So long as we continue to allow learning typologies, particularly the electronic field trip and videoconferencing forms, to evolve in the absence of a collection, then I suspect we could be left with rather shallow simulacrums.

That is why from a cultural historian's perspective, it is imperative that we continue to find affordances that reuse, recycle, and revisit the intellectual capital of museum collections. If we cannot I wonder what if any useful role virtual museums will play in increasing society's knowledge and understanding?

ENDNOTES

Chapter 35: Genealogical Education: Finding Internet-Based Educational Content for Hobbyist Genealogists

KYLIE VEALE

1. INTRODUCTION

The hobby of genealogy is today one of the most popular leisure pursuits for everyday people. Not since the mid-19th century's period of fluctuating genealogical popularity (Taylor & Crandal, 1986) have we seen so many people in the western world tracing their family tree. In the United States alone, Maritz reports a rise in genealogical interest from 45% in 1996 to 60% in 2000 (genealogy.com, 2000), and since that date, the figure has been steadily rising to 75% in 2003 (Pew Research Centre, 2004). Not only are people of all ages, from all over the world, adopting the hobby as their own, many (Hornblower, 1999; Tedeschi, 2001) report that millions of genealogists use the internet for their research. Although, as Wellman and Haythornthwaite (2003) declare, the internet has grown to be of common use in our everyday lives, it has also "revolutionised genealogy" (Willard & Willard, 2001); a catch phrase utilized no less that four thousand times on the internet.[1]

Genealogy is the science of studying family origins, generally utilizing pedigrees. A genealogist is, at the very minimum, one who collects vital statistics about birth, marriage, and death events and organizes these facts into pedigree charts and family trees. The hobby can be a personal endeavour and social phenomenon; though it is also extremely methods- and learning-based; a fact-finding and information-seeking pursuit requiring knowledge in family structures, life records, history, and methods. This education need is generally not satiated by reading one book or attending one course; genealogical education is constant (Hinckley, 2003a). In fact, the hobby requires continual increase and upgrading of skills as different geographic regions, time periods, and family scenarios present themselves during the genealogists' research. Therefore as genealogists today are using the internet to conduct their genealogy research, are they using the internet as an environment to learn genealogical methods? Is the internet a forum for genealogical education?

In the words of Neustadtl, Robinson, and Kestnbaum (2003), "the internet is many things to many people", and as an educational environment, evidence abounds of it's use. Organizations (Fry, 2001), schools (Foster, 2003; Lopez,

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 939–959.

2003), e-commerce (Joia, 2002), and healthcare and medicine (Beer et al., 2002; Gray et al., 2000) are amongst the many genres using the internet as a virtual learning environment (VLE). For hobbies and leisure pursuits, of which the genre of genealogy can be considered a part, there is minimal scholarly literature about the use of the internet for education.[2] The popular press however have been discussing online hobbyist education for many years (see Cohen, 1999; Munro, 2003; Pollak, 2001; Thomas, 2003) and a brief empirical investigation for the purposes of this study finds thousands of online courses and educational content in this genre. Book binding (Jones, 1995), wood burning (Dulaney & Dulaney, 2003), ribbon crafting (*Offray Ribbon: How To's*, n.d.), quill pen making (Safran, n.d.), and cold process soap making are amongst the many hobbies using the internet for education. Perhaps due to hobby searching being a popular activity in the online world since Pew Research Centre (2003) started measuring in March 2000, many education providers have set-up suites of online courses and learning directories for the hobbyist genre. One such provider, Universal Class (*Classes in Crafts/Hobbies—Online Learning*, n.d.), offers over fifty different online courses for hobbies as diverse as decorating, cooking, Aromatherapy, and trick horse training.

While the above discussion indicates the internet can be used as a forum for general and hobbyist learning, we return to the purpose of this study and the online education of genealogists. As one participant in the newsgroup soc.genealogy.britain explains:

> I know everyone has to start somewhere, but trying to participate in genealogy on the internet before you have familiarised yourself with the basic methodology of . . . research and sources is like trying to drive a Formula 1 racing car before you've learned to ride a bike.
>
> (Stockdill, 2000)

As a result, a study was completed using a grounded theory approach to find and categorize current practices for internet-based education for genealogy. A discovery methodology such as grounded theory was chosen for the study as genealogy is a topic that can be considered a broad and general phenomenon: As demonstrated in part by the fifteen million websites returned by google.com containing the term "genealogy". Grounded theory allowed the study, as Myers (2004) in citing Martin and Turner (1986) explains:

> . . . to develop a theoretical account of the general features of a topic while simultaneously grounding the account in empirical observations or data.

Using theoretical sampling, an initial case of data for the study was created from evolving search engine queries at google.com, commencing with "genealog* education" and "genealog* learning". Online content found to appear as items of genealogical education were recorded in a spreadsheet, and the following descriptive characteristics evolved: title, author, content, learning mode, and learning outcomes. A grounded analysis of this first case led to a subsequent sampling in the form of the available literature on the subject of online GE, in addition to the comments of over 330 genealogists about their online education experiences, obtained during the week 27 April 2004 to 04 May 2004.

2. RESULTS

The grounded theory approach of the study allowed online GE to be interpreted as three emerging themes—scholarly, topical, and ad-hoc—in conjuction with three underlying learning paradigm shifts: class- to session-oriented; subject- to task-oriented; and fact- to problem-oriented learning, respectively. Scholarly education is described as formal courses and lessons provided by reputable organizations. In turn, topical education is generally separate, though sometimes linked, units of information that are topic- or task-based. Lastly, ad-hoc education represents the need for "just-in-time" help and knowledge.

2.1. Scholarly Genealogy Education

Genealogy societies, universities, and motivated individuals currently offer a number of online genealogical courses, adhering to a broad set of common characteristics interpreted as the theme of "scholarly". They are generally fee- and module-based; prescriptively paced; inclusive of online assignments, exercises, and quizzes; and can also include facilitated interaction between the tutor and other students. They address a broad need of genealogists for formal, theoretical education about genealogical methods and records, and they can be interpreted as a paradigm shift from class-oriented learning to session-oriented learning. Scholarly GE range in structure from two-step theory/exam presentation, to fully-functioning courses, and it is with their structure that I begin the discussion.

In the first instance, at a minimum, the structure of scholarly GE content can be described as a two-step process: provide theory, and then test the learning. For example, the National Genealogy Society (commonly known as "NGS", the largest genealogy society in the United States), offers three online courses: Introduction to Genealogy; Federal Population Census Schedules; and Special Federal Census Schedules.Course content is delivered as a step-by-step series of web pages containing text and images. There are no provided assignments or homework, though tests of student learning are conducted via a mandatory interactive exam or "quiz" at the end of each lesson, requiring a 70% or greater grade to pass. Certificates of completion are mailed to the student once all exams are passed.

At the other end of the structure scale, the National Institute of Genealogical Studies (n.d.) or "NIGS" provide fully functioning courses for their students. Although course content is limited to text, images, and downloadable PDF files, interactive bulletin boards are available to enable students to discuss weekly study topics with their classmates. "My Briefcase" functionality allows for a central repository of course, homework and assignment material; formal assignment and exam grades; and links to the aforementioned discussion groups. Similarly, the Genealogy Online Training Courses by Myfamily.com (2004) provides interactive chat and scheduled online class meetings to complement their text- and image-based course content to provide immediate feedback. The Genealogy Classes (genealogy.com, 2003) within Genealogy.com's Learning Centre, broaden the immediate learning environment to the internet at large by including links to relevant reference material and website tools. Finally, the Basic Genealogy Course (Gould, n.d.) is delivered completely via Yahoo! Groups,[3] allowing the publishing of course material, management of students, provision of handouts, and collection of assignments in a manner similar to a traditional classroom environment.

The aforementioned examples of genealogical learning demonstrate online scholarly courses provided by genealogical societies, companies, and virtual genealogy organizations. Though if we consider the debate about academia and history versus genealogy (see Mills, 1983; O'Hare, 2002), it is surprising to find several of the scholarly GE are by universities. In 1983, Elizabeth Shown Mills declared "the academic advancement of genealogy . . . needs the wholehearted but judicious participation of . . . colleges and universities". This study found six universities offer GE, and three of those in two countries offer their complete courses online. The University of Toronto offers "the world's oldest comprehensive web-based certificate programs in genealogical studies", in collaboration with the NIGS. The programs are similar in structure to university courses, to "support the needs of both amateur family historians and aspiring professional genealogists, for reliable and comprehensive education". Thus each of their certificates is divided into three levels: basic, intermediate, and advanced. Students can major in the records of a specific country or librarianship by completing a minimum of eight 6-weeks subjects or "courses" for that country, and subjects can also be completed individually without the end result of a certificate. Brigham Young University and the Open University follow in NIGS's footsteps by also providing university-based scholarly GE online.

Education in the scholarly theme generally requires payment, as represented by the 60% found in the sample, though not all are available for a fee. The aforementioned Basic Genealogy Course by journalist, writer, genealogist, and guest speaker Carolyn Gould is completely free to the student, as she explains (*Bio—Carolyne Gould*, n.d.):

> A very special cousin helped me with my genealogical research when I was just starting out", Ms. Gould said. "This is my way of paying him back and honoring my ancestors—by passing on that help to others.

Moreover, Brigham Young University (*BYU Independent Study*, n.d.), located near the genealogical Mecca of Salt Lake City in Utah, offer their suite of Independent Study courses for free.

Online scholarly GE was also found in this study to be largely theory-based. That is, the underlying basis is in the theoretical cornerstones of genealogical methods, rather than practice-based research advice—a very different characteristic to the audience in the other two themes. The objectives stated for Introduction to Genealogy (National Genealogical Society, 2004) for example, demonstrates a learning baseline from which the participant can obtain general methodological GE:

> . . . record genealogical information; get started with information in family and published sources; find twentieth-century vital records; find birth, death, and marriage information for ancestors who lived in earlier centuries; use online finding aids and library catalogs; and write source citations for birth, death, and marriage information.

Likewise, Beginning Genealogy (MyFamily.com, n.d.) commences with a lesson entitled "Mapping the Course and Equipment for the Hunt", with later topics devoted to more specific and advanced theory on country-specific civil registration. Lynn Mann (personal communication, April 29, 2004) offers her view on how an online scholarly course built her genealogical theory knowledge:

> Recently I did the Open University short course No. A173, Writing Family History. Probably more suitable for people like myself who had already started some research and had some of their own materials to use as example in the assignments. It went into far more than just building a family tree, but aimed to help you think about how you conducted different types of research and what their value would be.

All students are given a class-like environment in the GE of this theme, we see an example of an underlying paradigm shift from class-oriented learning to session-oriented learning, given the asynchronous availability of the courses. That is, the student does not have to physically sit within the bounds of a classroom for the complete lession, as per traditional offline class-based learning. Genealogists can now complete theorerical coursework in one or many sessions at their computer, absorbing the material at their own pace, though still within the time limits of the specific course.

Genealogists are motivated by the need for formal theoretically based education in this theme, however the comments of some genealogists seem to indicate the existence of barriers to their use of online education within this theme. Issues such as internet connection service or the level of computer expertise of the student may be a reason for topical and ad-hoc GE to be used instead of scholarly. For example, Anita Walker (personal communication, April 29, 2004) advises:

> I did look into doing a course online at one stage, but our internet connection wasn't too good at that time so I gave up, before I started.

Additionally, Guy Howell (personal communication, April 27, 2004) offers this insight into possible frustrations with interactive scholarly GE:

> The course was interactive and one was required to answer questions and group talks. As a slow two finger typist and elderly person I felt that I could not keep up with younger computer literate students and gave up.

Further research is required to uncover if and why genealogists are using online scholarly GE as presented in this theme, though it is outside the scope of this chapter. Such research could uncover whether these issues or others lead genealogists to pursue other themes, such as the following topical theme.

2.2. Topical Genealogy Education

A large number of companies and individuals offer content online under the theme of "topical" GE. This study finds separate, though sometimes hyperlinked units of educational information for genealogy that are theory-based, lesson-based, or structured by topic or access, in ways that are more informal than the scholarly theme. They manifest more as an online reference system than a prescribed once-off course, are almost always free, and are examples of an underlying paradigm shift from subject-oriented learning to topic- or task-oriented learning. The ease of publishing to the internet is found as a possible explanation for the personal research experience of the author influencing some content in this theme.

In the first instance, topical GE on the internet can be lesson-based, though not as formally as the scholarly theme. Specifically, although topical GE can facilitate the formation of a methodological process, as some linear structure is implied through presentation, each "lesson" is generally a stand-alone webpage that can be accessed via a search engine and utilized individually as topic-based learning. The Courtenay and District Museum Tutorial (*COURTENAY MUSEUM: Genealogy Tutorial*, n.d.) is one such example. The tutorial is presented to the genealogist as a series of four lessons: Preparation and Documentation; Search at Home; Paper Trail; and Guide Lines. Clicking through to each lesson however uncovers a stand-alone webpage containing text, images and hyperlinks. Similarly, web pages such as Genealogy for Beginners On and Off Line (Curtis, 1997) organize their topical content in numbered lists, suggesting the content is teaching a methodological step-by-step process. On closer inspection however, numbering is conveniently separating and ordering the display of the content, rather than building a research process. To explain, each "step" could be taken individually, in a random manner, and the genealogist could still gain important educational content at each numbered paragraph.

In the second instance, topical GE on the internet can be structured by topic, task, access, or even randomly, in ways again informal in comparison to the linear-structure of the scholarly theme. Firstly, while scholarly GE is obtained through a specific course of lesson-based or module-linked theoretical content, topical GE is found as libraries of articles bundled by task, to more informal informational and advice-based items bundled together in online and e-mail newsletters, columns, and streaming radio. For topic-structured topical GE, the genealogist may be presented with high-level categories of information from which they can click through. One such example is the A–Z of British Genealogical Research (Emery, 1999), a topic-based portal to hypertext and articles on researching British ancestry. In the same way, GenHelp (Partridge et al., n.d.) uses categories to organize and structure their growing library of task-related help articles. Other web sites (see Isaacson, 2003; *USGW—Help for Researchers*, n.d.) employ a portal concept for access to GE topics. Secondly, topical GE can be structured by the very mechanism it is delivered, in the form of push or pull newsletters, Internet Radio, and web logs or "blogs". In this respect we find genealogists seeking or receiving topical education as ongoing GE, as Margaret Read (personal communication, April 29, 2004) explains:

> The greatest help for me as a beginner, even after taking a . . . class . . . , was to receive a "daily dose of genealogy" online with suggestions, sites to visit and articles. Becoming familiar with what is available online and how to use what you find is an important step in learning how to work in genealogy.

The Global Gazette (Global Heritage Press Inc., n.d.) can be read online or pushed to the genealogist via subscription, and is "filled with helpful family history 'How-To' articles and heritage news for everyone interested in genealogy and history". Other newsletters (*Family Tree Magazine Update*, n.d.) send newsletters containing hyperlinked pointers to online educational content. The online Expert Advice series in Family Tree Magazine has in the past included task-based content on grave markers ("Expert Advice: Types of

Grave Markers", 2003), slave ancestor identification ("Expert Advice: Solving Slave Surnames", 2003), and how to search a census ("Expert Advice: Census Research Strategies", 2002). Similar in nature to newsletters, topical GE is also delivered via the streaming audio of Myrtles Family History Hour (http://www.dearmyrtle.com/). Pat Richley, the presenter, interviews guests and refers listeners to the best places to learn and do genealogy on the internet, while supporting the radio program with her own columns and task-based lessons. A show by Dick Eastman (Good, 2002) is a similar for-fee internet radio program. Additionally, blogs have become popular outlets for genealogical research progress and news in the last 6 months, as "tools that can ignite knowledge contribution and sharing in many different settings" (Heritage Creations, n.d.). Genealogy Blog, (Brandi, n.d.), Geneablogy (Lythgoe, n.d.), Family Preserves (Zdenek, n.d.), and a blog at Enriching Lives with Ancestral Ties (2002) offer alternative and topical ways for genealogists to keep up to date with the latest genealogy announcements, news, and tips.

Finally, topical GE may be randomly structured by way of individually authored web pages, accessed via search engines or direct URL. One such manifestation is the web site of Mary Trevan (2002); in part a repository her genealogical research output, and in part topical GE through her pages titled "Basic Approach to Genealogy". Deborah Russes (personal communication, April 29, 2004) explains that a majority of her genealogical learning has come via visits to different web sites and reading. In fact, this type of learning is Trevan's motivation for providing such a personal contribution to online GE:

> Over the few years since people have found my web site on the Trevan family history I have received a small number of emails asking how to do family history. Then in the first week of the new millen[n]ium 3 separate people asked me! Rather than reply in separate emails I decided to write these pages instead.

This chapter to date has generalized that all learning structures in the topical theme can be lesson-based, or topic, task or access-based, though before moving onto the third characteristic of topical GE, there are examples of more structured learning within the topical theme which warrant discussion. For example, using the Genealogy "How-To" Guide (Family Tree Maker, n.d.), a genealogist can access a library of hundreds of task-based how-to articles via any search engine (assuming their query links them to the topic of the article). Though if they access the library via the company's specific guide home page, that we find an implied though informal structure is evident. The umbrella "Step 1-2-3" concept acts as a portal to hundreds of genealogy task-based how-to articles. Each article is hyperlinked to others, allowing the genealogist to further hone their requirement for learning on a specific topic or set of tasks. It is important to note however that although there is a hyperlink structure to the content in this example and all other content in the topical theme, it is non-prescriptive in nature, which separates it from the scholarly theme. That is, education in the scholarly theme is rigid and linear, whereas using the example of the Genealogy "How-To" Guide, the genealogists' experience is topic-based, indirect, and more personalized, as they choose their path through the content.

Returning to the characteristics of the topical theme, in the third instance, the above examples of topical GE support a finding that the internet is a vast library of educational items, an example of an underlying paradigm shift in learning from subject-oriented to topic- or task-based learning. Just as Wellman & Haythornthwaite (2003: 4) explain the internet is "embedded in everyday life", and Neustadtl et al. (2003: 186) describe the internet as "the world's largest library", genealogist Mary Fyock (personal communication, April 29, 2004) describes her use of online topical GE as an often visited library resource:

> Most reputable websites have great tutorials for the beginning researcher. I have used them off and on when I strike an area of research that I am most unfamiliar with.

Similarly, Marilyn Whiteman (personal communication, May 01, 2004) often bookmarks articles from Ancestry.com newsletters, to make a handy topic-based reference notebook. Jan Carr's (personal communication, May 01, 2004) experience is similar:

> I have been an avid and regular [reader] of a wide variety of "how to" articles published by Ancestry.com for about 4 years. Many of these articles I've downloaded and keep in a file for future reference.

The above examples of GE theory used on a needs basis demonstrates that the topical theme can be interpreted as a blend of the scholarly theme's "whole picture" theoretical perspective, in addition to "just-in-time" topic- or task-based problem solving. To be exact, in the fourth instance, genealogical learning on the internet can be informal and theory-based, while also offering informal methodological education. General topic-based news articles about the hobby of genealogy have become high-level theoretical pieces with informal task-based methodological underpinnings, such as one written by Siân Busby (2000) for the *Financial Times*. While Busby commences her article as a summary of the motivations and process of the hobby, the article itself evolves as a reference piece for the genealogical process: headings include "Start with what you know", "Primary sources and vital records", and "Public records—the basics". Likewise, articles such as one created for Americans of Swiss descent (Zentralstelle für Genealogie, n.d.) outline in-depth theory and background for genealogists researching a specific topic, though in the format of an informal task-based How-To article.

While topical GE online is a blend of the scholarly themes theoretical learning and a step in the direction of just-in-time learning, it is with the final theme, ad-hoc, that this chapter reports the greatest concentration of personalized, just-in-time education online for genealogy, and an example of a shift to problem-oriented learning.

3. AD-HOC GENEALOGY EDUCATION

In 1998, Robin Mason declared free-for-all open discussions had largely been abandoned for serious teaching purposes, although they continued to flourish in social areas. Lavooy and Newlin (2003) cite Dede and Kremer (1999) that student–student interaction is especially crucial for the development of web-based learning communities that increase student learning. Both statements are especially evident in the ad-hoc education of the online genealogical community. Rootsweb alone hosts over 28,000 genealogical mailing lists; GenForum (http://genforum.genealogy.com/) has thousands of online forums, and the author counted over forty genealogy newsgroups on her local news server. Genealogists use the internet to access the combined expertise of the online genealogical community and to obtain personalized "just-in-time" education. GE was found in the form of discussions about current events, controversies, readings, common experiments, and many other genealogical issues. GE in this theme is used by genealogists to present and describe their research to others, and as a forum for seeking feedback or advice on their research from other participants. The third and final theme of GE, "ad-hoc", has little or no structure or planning, and is generally based on the personal advice or experience of individuals. It is found to be less a part of the "whole picture" and very much motivated by immediate usage for specific activity problem solving; an example of an underlying paradigm shift from fact-based learning to problem-based learning.

Firstly, in comparison to both the scholarly and topical themes, ad-hoc GE on the internet can be described as having little or no pre-planned structure. While it can be said that the technology of the internet behind such education is certainly structured (in terms of setting up newsgroups, forums, and IRC channels, for example), the mode of learning conducted in this theme is not. That is, the act of learning creates the content in this theme, rather than the content coming first and leading the learning experience. To further explain, this study found two instances in which ad-hoc genealogical learning can be considered—at the very maximum—to be influenced by structure; by the topic of the ad-hoc forum; and netiquette.

In the same manner that topical GE on the internet was found to be topic- or task-based items of information, ad-hoc genealogical learning can be structured at the very highest-level by the topic or task of the forum of learning. Every newsgroup, mailing list and online forum is characterized by the setting of a topic that sets the tone of the forum. While the topic guides (and sometimes restricts, as the discussion on netiquette will point out) the interaction and content within the forum, it is important to say that it does not imply a structure to the learning experiences of the genealogists within the forum. As one anonymous genealogist (personal communication, May 02, 2004) explains:

> I have learned not through reading genealogy tips on websites but from being on the lists with the people that do this or have done this for years. Sometimes it goes, as they say, "off topic", but eve[r]yone is still sharing experiences.

Additionally, this study found that most genealogical newsgroups have FAQs published on the internet and regularly posted to the newsgroup, reminding participants about behavior (netiquette), the topic of the forum, and outlining common questions that have reached the newsgroup in the past. Although it could be argued that by guiding genealogists to read a FAQ, their online learning experience in the ad-hoc environment is altered, this scenario requires further research. However, despite this possibility, many genealogists (see Mouallem, 2003) still post to specific forums they participate in, sharing what they have learned about getting the most out of ad-hoc GE. Similarly, another anonymous genealogist explains (personal communication, April 29, 2004):

> [Mailing lists are] far more useful than . . . faq's as specific questions that are often locality based are answered quickly at zero cost by experts in the area.

Returning to the second characteristic, ad-hoc GE on the internet is generally limited to advice, personal lessons learnt, and personal adaptations of pre-learnt theory; an environment as an example of problem-based learning. For example, a posting to soc-genealogy.jewish describes one genealogist's lesson learnt in contacting long lost family:

> I believe the best approach, beyond e-mail, is to send a personalized letter via snail mail to this person (if at all possible). In my experience, I have gotten the best results from my mailings. I think most people just tend to delete emails that are not from someone familiar, but letters are somewhat more intriguing and less threatening. (see "How to request help", 1998)

While another example demonstrates a genealogists' personal experience in response to a request for information about problems researching Cherokee ancestors:

> Oh, and regarding Cherokee ancestry; in my experience, which granted is limited to my own family and the families of those Cherokees whom I know personally, tracing the maternal line is exceedingly easy as it's usually well-documented. It's much harder to find a paper trail for my father's paternal line, which is not Cherokee. That's another reason I can't help but be skeptical [sic] of all the legions of people who claim Cherokee ancestry but can't find proof. In my experience, Cherokees have been meticulous record-keepers, and that includes all those who stayed behind when the others were forced to undergo the long walk.
> ("Re: Re: Cherokee Ancestors", 1999)

One participant in a study by Duff and Johnson (2003) suggested that general conversation between genealogists can result in the sharing of knowledge about records and research techniques. As a result, and in comparison to the theoretically based scholarly theme, and the hybrid theory/topic-based learning of the topical theme, ad-hoc GE exposes genealogists to more informal though personalized learning from other hobbyists and interested professionals who wish to share their learning experiences. Several other genealogists concur:

> As far as the chat room is concerned, people are pretty good about offering ideas of places to look for info if you hit a roadblock. (Deborah Russes, personal communication, May 04, 2004)

> I [use] message boards for help with individual questions that I can't find an answer to in published articles. (Kate Young, personal communication, April 27, 2004)

Thirdly, in having access to the combined expertise of the online genealogical community, it is the range of expertise that is found to vary greatly within the ad-hoc theme in comparison to the other two themes. As any interested genealogist, expert or beginner with internet access can join and participate in a newsgroup, chat or online forum, that person can also become a provider of GE to the community. On the one hand, for example, Everton's Family History (n.d.) provide the service Ask-a-Pro, an online forum with which genealogists can ask questions and receive personalized responses from a panel of genealogy experts. In contrast, some genealogists like Michael Harding (personal communication, April 29, 2004) have their own informal private network of online genealogists to address their ad-hoc GE needs:

> I have hundreds of people I can contact over a variety of genealogy subjects, places and people.

Furthermore, thousands of everyday people participate in thousands of newsgroup and mailing lists available for genealogy. Given the quantity of input to the ad-hoc theme, it is perhaps not surprising in the final characteristic of the ad-hoc theme that many ad-hoc GE forums are being archived. In the case of the aforementioned Ask-a-Pro service from Everton's Family History, past question and answer sets are added to their online database so that others may search for topical help, and those general enough for the larger audience are also published in Family History Magazine. Ad-hoc GE can also be published in discussion forums with motivations fitting the topical theme. That is, genealogists contribute ad-hoc educational material in anticipation of someone needing it now or in the future:

> I have just run across the following web site for Hungarian genealogy. It is quite comprehensive, including a User Guide to the Archives, information on the Hungarian data bases available at or from the site, an index register of Hungarian names, a bulletin board for posting requests for help, help with finding professional genealogists to do research, advice for doing research in Hungary, a set of international links for genealogy throughout the world with an extensive listing all in one place, and more. (Esterson, 2000)

In 2001, Google.com finished archiving 20 years of newsgroup messages ("Google archive opens up internet history", 2001), and since that date, has captured every message to pass through to present day into an online searchable archive at Google Groups (http://groups.google.com). Genealogists can therefore search for topical GE as reference material that started out as ad-hoc GE, as one online GE theme comes full circle to represent another.

4. DISCUSSION

This study has interpreted online GE as one of three themes—scholarly, topical, and ad-hoc—and briefly intimated examples of learning paradigms underlying each. The presence of structure, fees, and genealogical theory and methods is most saturate in the session-oriented learning of the scholarly theme, and these characteristics lessen as we move from scholarly to topical GE, and then from the topical to ad-hoc theme. Ad-hoc GE has its strengths in personalized learning experiences, immediate availability due to sheer numbers of people powering the effort, and a problem-oriented learning environment, though it lacks the assurance of correctness and authenticity that scholarly GE provides. Topical GE allows genealogists to learn with specific topics or tasks in mind, a shift in the direction of task-oriented learning, in ways that are more informal than the scholarly theme, though more formal than ad-hoc. Both topical and ad-hoc GE (through the archiving of ad-hoc content) are available as reference items to the genealogist on the internet, though scholarly learning must be considered once-off, unless paid for again. With these findings in mind, how do they compare to the available literature? Is the internet being used to the best of its potential for online GE?

Despite the 1999 audience profiler survey of over 11,000 visitors to the rootsweb.com website ("Who Are We? Preliminary Survey Results", 1999) which reports 53% of participant's time online was dedicated to GE, the available literature to compare to the results of this grounded theory study is minimal. This chapter already reports in the introduction that the popular press has published the widest body of knowledge on online education for hobbies and leisure pursuits, and the same can be said for online genealogical education. Thus we introduce some of the available literature for comparative analysis for this study, by genealogical journalists Mark Howells and Kathleen Hinckley.

In his most recent article about online GE, Mark Howells (2002) declares the genealogical community is not utilizing the internet to best teach genealogy, and that genealogical content only emulates traditional forms of instruction. Evidence from this study supports Howells' view—GE for the most part does not extend past direct manifestations of traditional or pre-internet forms of instruction. To explain, using Howell's examples of traditional GE, we see his first example of traditional one-on-one instructional content emulated in the scholarly theme in this study. His second, "self-read materials on methods, skills, and record types" certainly matches the content found in the topical theme. And the third, "skills refreshment through practice or by assisting or instructing others", is demonstratable in the content of the ad-hoc theme. Similarly, the three themes found in this study align with a three-part GE series by Kathleen Hinckley. The scholarly theme aligns with her discussion on online tuition course content (Hinckley, 2003c); topical GE is represented in her article regarding magazines and journals (Hinckley, 2003a); and the communicative nature of the ad-hoc theme is addressed in her article about national conferences, institutes, and societies (Hinckley, 2003b).

While Howells thinks that a more advanced use of the internet for GE would see the genealogical community "use the strengths of the internet to the advantage of the educational process, instead of simply duplicating traditional teaching methods in a new medium", we first look outside of the genealogical community to get an accurate understanding of what could be considered advanced learning.

Using Twigg's (2001) assessment of the problems with online courses, we find firstly that existing GE cannot be considered advanced learning:

> The vast majority of online courses are organized in much the same manner as are their campus counterparts . . . [and] most follow traditional academic practices ("Here's the syllabus, go off and read or do research, come back and discuss".)

Twigg's viewpoint is supported by the comments of course producers such as Ken Innes (personal communication, April 29, 2004) who advise the format of his course Introduction to Genealogy on the internet (Innes, n.d.) derives from the content of original, hard-copy course notes. Additionally, online GE does not seem to have evolved in line with the research of Glenn, Jones, and Hoyt (2003):

> Browser-based delivery has evolved in less than ten years from static HTML pages coupled with e-mail and list-serves to integrated course management suites.

Furthermore, online GE also fails to demonstrate three of the five key features Twigg offers as indicators of improvement in the quality of learning beyond traditional forms of education. Addressing two of Twigg's indicators, some scholarly themed resources in this study demonstrate built-in, continuous feedback and varied kinds of online human interaction such as e-mail, message boards, and chat; and the course suite offered by University of Toronto demonstrates the beginnings of individualized study plans. However this study finds no GE online with an initial assessment of each student's knowledge of skill level and preferred learning style, nor feedback in the form of audio or video. Additionally, no GE resources in this study can be described as having Twigg's fifth characteristic—an "array of high-quality, interactive learning materials and activities"—with the exception of the Free Web Courses by Brigham Young University (http://ce.byu.edu/is/site/special_offers/freecourses.dhtm). These scholarly courses are paving the way for other courses in the provision of Flash-based animation content to help explain genealogical concepts and principles. By placing online GE within the domain of general online learning, this study finds current online GE falling short of improved or advanced education.

Returning to the literature on genealogical education, the resources found in this study also fall short to address Howell's notions of advanced online GE. He expects advanced GE content such as animated map graphics showing how to walk a cemetery for recording purposes; video clips on tombstone rubbing; audio clips of how to interview a relative; or even interactive demonstrations with circles and arrows showing how to cite particular sources. He also states a specific example in guided discovery—a series of statements or questions that direct the learner step by logical step, into making discoveries, which lead to an answer. Although this study found four instances of this "advanced" form of online GE content (Barry, n.d.; genealogy.com, n.d.; Intellectual Reserve Inc., n.d.; *Irish Ancestors / Where to start*, n.d.), they are outliers to the sample of this study, thus GE cannot be generally labelled "advanced" learning.

More over, in an article by Krasner-Khait (2002), various genealogical visionaries prophesise about the future of online GE. Matthew Helm envisions increased interaction through technology, and believes that genealogists should be able to input information on ancestors when using online census records and be guided to a relevant piece of content. Accredited genealogist and instructor Janet Reakes predicts:

> The multimedia aspect of computers will change the face of genealogy classes. We will soon be able to talk to each other via camcorder in a chat room. Already there is voice chat and visual interaction will be next.

Michael Leclerc adds:

> In the not-too-distant future, we'll be able to use the capabilities of graphics and streaming video, and live lectures through webcast.

It is evident from the words of these genealogists that "tailoring an approach with customized, interactive programs" is the future direction for online GE, and an inroad to making Howell's notions of advanced online GE content come true. The broader genre of hobbies and crafts is certainly paving the way, incorporating animated graphics and Flash demonstrations to teach other budding hobbyists about their craft (*Animated Chinese Characters*, n.d.; *Knitting Techniques*, 2001; *Painting Interior Rooms*, n.d.; *A short guide to star hopping*, 2004; *Shutter Bee, The Animated Online Camera Tutorial*, 2003)

The challenge for GE however, as Krasner-Khait concludes, is to meet the hunger for instant gratification while simultaneously teaching problem-solving. Thus the more interactive the content and experience, genealogical educators will be able to draw people with limited experience in basic methodologies and increase the general online education level within the hobbyist genre.

> . . . The learning never stops [in genealogy. And] the internet has changed the way we research. It will also continue to change the way we educate [in the future].

ENDNOTES

1. Entering the query "revolutionised genealogy" and "revolutionized genealogy" through google.com retrieves 556 and 4285 search results, respectively.

2. One of the very few scholarly studies on the use of the internet for hobbies and leisure pursuits reports that amateur radio enthusiasts "have learnt tricks of the trade from video magazines and the internet" (Isomursu et al., 2004).
3. Yahoo themselves entered the VLE market in 2002 with Yahoo!Education (Wilson, 2002).

Chapter 36: Downtime on the Net: The Rise of Virtual Leisure Industries

JACKIE COOK
School of Communication, Information and New Media, University of South Australia, St Bernard's Road, Magill, South Australia

When Manuel Castells in 2001 came to focus on the culture of the internet, attempting to describe its curious amalgam of origins and influences, and their persistence in the values present in its manifold operations, he suggested that it was in many ways a culturally schizoid medium. On the one hand, as maintained for instance in the many myths of its APARNET military foundation, it presents as a scientific, pragmatic, rational, communicative instrument; a standardized, and so regulatory set of operations to facilitate and accelerate data flows. But at the same time, given its long conception in a largely informal and highly collegial set of laboratory backrooms and University graduate-assistant work zones, it has inbuilt elements of the sorts of libertarianism or radical communitarianism identified by Bauman (2000). It retains a playfulness, a feisty independence, and an innovative edge, among the enduring marks of its operations.

Perhaps then it should come as less of a surprise that we have come to see leisure pursuits: pastimes popularly conceived as belonging in the personal domain of self-expressiveness, private recreation or "downtime" sociability; as prominent agents of the Net's development. In some cases, whether desired or not as part of any "official" history of this currently central cultural medium, online recreation or "virtual leisure" has been positioned among the dominant elements within the internet's development. Consider for instance persistent suggestions that the technologization of online pornography has contributed new forms of interactivity to webcam and online video use (Slater, 1998; Williams, 1990); innovations introduced at least as early as those for scientized telemedicine for instance, and rather more widely used. In some of the very earliest academic analyses of online content and services—often published in screen journals, before the rise of more specialized publishing sources—analysts and researchers were already aware of powerful online communities working around such "unrespectable", unproductive or even illicit activities as sex, game play, or just plain sociability.

What remains surprising then is the very slow rise of interest in the full range of leisure pursuits on the internet as itself a site for study. Here is a topic with the potential not only to alter public and even policy-framing perspectives of what the internet "is", or to alert business to new interactive-communications paradigms and opportunities arising from the creativity of the private user,

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 961–998.

but also able to open a whole new set of perspectives around ideas of leisure, recreation, self-expression, popular culture, and social life. While each of these elements has evoked in its own ambits a wide range of debates, theorizations, and academic interest, by focusing them all through the lens of the current drive in the leisure industries toward a rich mix of public events, private responses, and merchandised resources, a new and useful field for examining the role and power of the internet itself, as agent of their interaction, is exposed.

What then "counts" as virtual leisure? And are there already industries and consumer groups which could be considered to be operating, principally or in significant ways, through the "disembodied" interactive networks of the internet? What is it about such new zones and experiences which make "virtual" leisure any different from existing forms? Are we talking about one, or many, models of "virtual leisure"? Are there clear typologies or developmental pathways arising which characterize all online recreative pursuits, or are there multiple modes and stages? And what above all, makes this a worthwhile way to constitute inquiry into 21st century patterns of leisure use?

These are the questions which most immediately arose when, in 1998, I was asked to consider ways of structuring graduate curriculum around the then new idea of Internet Studies. I immediately proposed a course focused on virtual leisure industries. In some cases, this term was used to accommodate study of existing recreational pursuits then rapidly extending into online presences of various forms (sport, gambling, shopping, sex). In other instances, it enabled new forms of scrutiny of activities evolving from already-mediated leisure formats from within related electronic fields (video games for home or arcade use; mediated chat moving from talkback radio or telephone "conference call" lines; fandom; self-expressive display spaces for art, photography, writing—whether DIY or wannabe professional). The immediate response was hesitant: Was this a field for serious analysis and study? How would a university react to a course which specialized in the study of computer games; fan activities, pornographic websites? In Australia, this nervousness had added salience from rising degrees of public-media criticism over research into "private" or popular-culture activities and products:[1] right-wing political attacks through the media, on published or funded research into issues of everyday culture—including of course, inquiry into internet-based pursuits. Above all, how could this be argued as suitable to the graduate-level preparation and research training of senior professionals within the communications industries?

In turn, I found these responses surprising. Those industries which had already, and so quickly, entered virtual leisure fields were not only being widely acknowledged as major sectors of the new economy, but also constantly held up around the world as among the most central and innovative.[2] Indeed, many of the most dominant global communications and media enterprises were at that time intent on mergers, takeovers, and vertical-integration ventures with Net-based VLIs.

These charges of non-seriousness, leveled at both leisure activities and popular or private internet uses, seemed to me indicative of a persistent miscueing of web-based activities, within both the economy and society at large. In an ironic reprise of Frankfurt School responses to the rise of Modernist forms of screened, sound recorded, and broadcast popular media, Net-based activities outside the direct regulatory control of the "old" economy and its institutions were still being read as trivial, if not dangerous, private pursuits. Perversely, at the public level at least, those very forms of old media industries (print, radio, television, cinema) most ardently promoting and themselves taking up the digital hardware and infrastructure which enabled large sweeps of the population to access the new media, were the same ones denouncing its private uses as immoral, illegal, unhealthy, anti-social, anti-educational, or unproductive.

Immediately, this raised for me the still-intriguing issue of the positioning of the leisure industries—online just as elsewhere—within a privatized and consumerist ethic. Here was a field that crossed two problematic social and cultural divides: the public/private, and production/consumption—with all of the complex articulations each has been shown to accommodate. But above all, and here specifically within the Australian–Asian regional context in which I live and work, how could it remain possible not to acknowledge the key social and economic development focus on new media and especially online industries as both annexing old, and developing new, leisure industries. Surely this was at the core of the creative industries movement so strongly expressed within Australian Cultural and Media Studies, and even more powerfully, within the national development policy frameworks of the Asian "Tiger economies"?[3]

I outlined a course in which graduate students, at every stage selecting a focus of interest and research which suited their own professional needs and personal interests, would review both this emergent centrality of "private", self-tailored or "pull" uses of the new media *via* the internet, and the relative degree to which a given industry was fulfilling, acknowledged or otherwise, the demands of Government, commerce and community alike, for new media content, creative product and an open, responsive, "enterprise" culture.

I began by suggesting that students take up the last contributions of re-theorization research into the idea of the "active audience" from traditional Media Studies [see especially Ang (1996) and Nightingale (1996) on active-response television viewing, and Tulloch (2000) and Jenkins (1992) on active fan culture] which had helped to position the theorizations and methodologies behind emergent online-ethnographic studies of the central new-media concept of interactivity. Within this conceptual frame for observation of actual Net practices and behaviors, I created opportunities for my students to examine not only what was available for the pursuit of leisure online, but also how this was taken up, and how it differed from or was continuous with activities pursued in the physical world. The very title: *Virtual Leisure Industries*, played across this complex set of paradoxes, to set up from the outset an analytical project—one which would be forced to confront ongoing cultural beliefs and separations between private life and production, public commerce, and personal modes of consumption. Not only are these increasingly untenable in an era of interactive and mobile communications, given the enhanced capacities of digitized communication platforms such as the internet and related technologies to penetrate domestic and private spheres of life, but also the very divisions between them move, re-form and are themselves taken up in ways which actually promote new technological interventions, applications, and services.[4] Indeed, this newly exposed role for a collaborating and co-productive "pro-sumer" public within commodity and service innovation and the ever-accelerating cycles of fashion and product obsolescence has been central to the rise of the new economy. As Lury (1996, 2004) has pointed out, without the capacities of the new CMC technologies to deliver very fast feedback-loops into style culture, the older consumer industries would not have achieved the market massing which has kept profitability levels high enough to support a growing middle class of leisure and style consumers. Within this, it is the ever-accelerating "trend" drive which maintains forward momentum; which keeps product-desire evolving—and along with it, the many 1990s/2000s myths of online product innovation and crossover from private leisure pursuit to commercial innovation and profit. From *Geekgirl* to Matt Drudge (The Drudge Report), Jennicam to SaveToby.com, individuals have successfully moved their obscure personal pastimes to international prominence, and even to entrepreneurial success.

Studying virtual leisure industries thus requires an examination of a set of fields in which leisure pastimes, or recreational opportunities, or activities in support of them, are offered online, *via* the internet, or related activities within mobile telephony. Open-ended, the course has potential for the clip-on of further industries, or consideration of activities with potential for commercialization and industry uptake: for instance, animation, animatronics, and cinematic special effects; digital broadcasting; recreational applications of online imaging and remote sensing; the authoring of webpages, webcams, blogs, online journaling for fun or profit, software modding; even those spin-off activities from online contact which move back into and impact upon the physical realm: warchalking, moblogging, Lomo. But in each case, it begins by examining four different ways in which an understanding of online experiences benefits from study of internet uses and behaviors, and leisure and recreational institutions and practices, more generally.

Overall, the approach to the idea of VLIs is founded on use of a backgrounding series of texts and studies, each of which in itself may or may not focus upon consideration of the internet, or even on digital-media content and practice. Instead, it might introduce broader issues, relating for instance to our current understandings of leisure, or of symbolic versus material culture, or of creativity and innovation, and the commercialization of ideas. This works to extend attention beyond the rapidly accreting "research literature" around the internet; to build-in a form of inclusivity and range, and to keep this field alert to the new and disregarded. If Castells is even partly right in his analysis of the characteristics of internet culture, it is from here that the most interesting, least likely innovations arise—in the "trivia" of personalized, social, non-corporate activity.

Each segment of the course also, however, seeks to build a sensitivity to both the innovations and the cultural continuities apparent on the internet: The degree to which any newly observed Net-leisure pursuit is "new" as both a conceptual totality, and as simply another example of an existing set of products, services, applications, or capacities. In this it seeks to illustrate Castells' (1996) call for a renewed focus on what he terms the "applications and specifications" levels of the new CMC industries and their institutional and corporate structures. These are the upper-mid-level decision-making spaces of today's "information-era" workforces; those working to position the innovations of research and design into markets, professional uses, communities, populations. It is here that the creativity unleashed through the internet's direct-appeal to a "testbed" of users can be registered and recognized, aligned with market goals, fostered in the release of new hardware/software technologization or services licensing and franchising. And it is here that my graduate students, whether in Government, corporate industry, specialist cultural/subcultural communities, or those new forms of SME/consultancy "indie"-enterprise productivity enabled by the efficiencies of digital media contact, are for the most part positioned. They work as the interpreters of the technologies to the markets, and *vice versa*: What Lefebvre (1991) once called the *decoupeurs et agenceurs*, who move between concept and practice, idea, and product.

In sequence, I ask this group to consider from the perspective of their own agency: their own professional power to activate innovation opportunities; a range of those social and cultural changes occurring alongside the rise of the internet, and impacting upon the structures and potentials with which it has come to be invested. These are not by any means exhaustive, and can be replaced as focal-shift requires, but in the first instance include the following four issues:

- *virtuality and disembodiment* as conceptual markers of a major shift from material to symbolic productivity;
- "*remediation*" of internet "content", or the view that it predominantly reprises existing formats and genres, rather than inventing totally new forms;
- *online leisure* as taking up those forms already oriented toward the symbolic, as opposed to irreducibly "physical" or material recreational activities;
- "*Creative Industries*" as a key concept organizing the new, digital, informational economy, and online leisure's already-evident centrality to both their content and their operations.

Firstly, how might those issues most dominant in study of the new digital media experience: virtuality and disembodiment, be positioned by reviewing how the often very physically centered activities of leisure and recreation are being arrayed and practiced within them?

Further, even where online-mediated leisure activities appear relatively unaffected by disembodiment—as in the case of online games, chat, or blogging—how has the enhanced privacy of "virtual" participation from within secure personal or domestic spaces been reported, diagnosed, and positioned for re-integration into new applications or service design? Should we understand the "virtuality" of these pursuits as perhaps a temporary phase, to be "corrected" by later technological moves (voice enhancement; improved broadband capacity allowing richer visual "habitats"; improved simultaneous language translation; non-intrusive interface design; 4G telephony; and ultimate portability)—or do the popularity and fascination of these processes inherently depend upon their technological distantiation? Rather than side effects of early, primitive forms of CMC interactivity are the various forms of "virtuality" more than spurs for remedial creativity? Do they have things to tell us about our own favored forms of sociability?

Early visions of internet experience focused intently on the capacity of the "virtual" or symbolic spaces of electronic communication to disembody users: to replace physical contact and activity and the identity formations produced within them, with far more malleable forms of textualized and graphic digitally mediated contact. For some, this was immediately a preferred state of being:

> For couch potatoes, video game addicts, and surrogate travellers of cyberspace alike, an organic body just gets in the way.
>
> (Morse, 1998: 125)

Even within less extreme formulations of this new mediated interactivity, the number of online transactive spaces and procedures that arose and the speed of their popular uptake suggest that the "virtual" as a space conceived of as between the two "lived" spaces of communication was something familiar, rather than something entirely new.[5] The virtual, whether encountered in game play, the computer-enabled simulated spaces of theme parks or entertainment arcades, online MUDs, MOOs or Habitats, can be argued to have been extending already existent tendencies in consumer culture and the mediated symbolic culture of traditional media, toward recreation of the self.

This identity play, once commodified and recoded into its myriad forms: games; chat; the *bricolage* of self-selecting online shopping; personalized MP3 compilations or mobile phone pop-tune ringtones; "privileged" reader–viewer news services or behind-the-scenes "director's cut" DVD movie previews, then became an even more high-status activity. Where once only

Hollywood stars or the very wealthy could re-invent themselves; act out new social roles; express personalized style across a wide range of daily activities, now it seemed everyone could.

Electronic communications seemed to have created a new "space", where many of the social rules—even physical restrictions—ceased to operate. The reality of the internet user: the physical self, did not appear to be "uploaded" into the system. When we went online, "the meat" was left behind (see endless discussion of this in the 1990s new media magazine *Mondo 2000*)—or so it seemed. New "old-media" attempts at imagining, or creating, virtual beings—such as the simulant newsreader Annanova; sci-fi novelist William Gibson's *Idoru,* or Hollywood's versus Japanese anime's various attempts at the enacting the cyborg,[6] all acted as models of a new experience, shared at some level by many ordinary internet users: the sense of "making contact" with others, without physical presence, or at least full physical presence.

Already, as researchers were quick to point out, a paradox had opened inside the idea of achieving the disembodied, infinitely changing self of cyber space. To dream such dreams took a society and a culture so obsessed with the physical, as to want to perfect it, even if only in the symbolic form of images or fantasy narratives. In other words, a medium which was said to be about non-body was obsessed by the body—as counter-commentaries constructed over ethnographic work on web-use began to prove. Even on the internet itself, ordinary self-expressive users began to use their upload facilities to "broadcast physical self" in various forms. From the "Jennicam" phenomenon to the rise of the "a/s/l" introductory convention in IRC, the body had proven itself irreducible.

There were, however, other hints at the interconnection between "disembodiment" and already existing experiences of mediated self. This was not the first medium which had offered the dream of re-writing, or re-scripting, or re-imagining the self – processes learned in advertising promises, infinitely deferred; in entertainment centered on glamorous performers, ultra-fit elite athletes, impossibly beautiful fashion models, obsessive body builders. Whether securely in the physical side—sport and fitness—or in the image culture of film, TV magazines, fiction, the "recreation" we are promised in all the various forms of leisure has come to center on "re-creation"—on dreaming or constructing new selves, at the level of body. And as those dreaming, desiring, and constructing activities moved from the artifacts of the physical world to the digitized image-and-text universes of the new media, the "recreation" mode went with them.

Other paradoxes abound. While cyberspace was in fact being set up as a place we all worked in, and through (e-mail, online banking, file transfers, data bases: as Castells (1996) expressed it, a "real virtuality" of everyday use) it was at the same time being "imagined" as a free, "new frontier" space, in which it seemed anything and everything was possible: even the dissolving of our physical selves, and the chance to "transform" into something else.

Was this then a space for more of the same, rather than for something inherently new; in Foucault's terms a slow and broken continuity, rather than a new beginning? Castells (1996) describes the development of a digitized, informational economy, both in its industrial and its personal-private manifestations, as a stage in a much longer process: a movement from high-volume/low-value production (iron ore, wheat, wool) to low-volume/high-value services (data management, information and promotional industries, new media content)—what Bauman has called the commodities of a "liquid modernity". Many "soundings" or observational studies of this general phenomenon of entry to a symbolic or "weightless" economy have been extracted throughout the past two decades—any of which can serve as a departure point, providing cases and concepts and a vocabulary for discussion of this "symbolization" or "disembodiment". Taking any one of a range of book-length studies; for instance Morse (1998), on media, art, and cyberculture; Springer (1996) on cinema imaging of virtual sex; Bukatman (1994), on scifi and cyber-self, or Turkle's (see for instance Turkle, 1995) various studies into online identity-play, it becomes possible to locate and analyze powerful examples of internet sites and contemporary user-behaviors, within existing repertoires of cultural explanation.

To this degree, study of online pursuits and virtual leisure is consistent with existing scholarly repertoires, and provided by them with a rich set of explanatory resources. But does this indicate a dangerous accommodation: an appropriation of something as yet unexplored, into the structures, definitions, and pre-dispositions of existing fields? Is this simply to describe the new on behalf of the old: to carry over the concerns and issues raised in one field, into another? Will it lead us to miss as much as we catch?

One way of raising that possibility, and testing it against how online leisure is practiced, is to consider the second conceptual base proposed for this area: whether or not Net pastimes have in fact "created" anew, in the sense of introducing entirely novel concepts, activities, and content—or whether they are re-applying and innovating within existing formats.

2. DO NEW MEDIA "RE-MEDIATE" OLDER MEDIA?

This initial focus in itself raises the question of whether critical and analytical perspectives established for and within older conceptual frames may or may not capture all of the nuances or potentialities of new media use. The course sets out to examine how, and how far, digital media and internet practices replicate or transform established aspects of symbolic culture: how far "new" media are in fact new. Calling on Bolter and Grusin's (1999) suggestion that the textual and graphic modes at least around which internet sites are designed "re-mediate" already established text and image genres, this section of study suggests that students submit those websites most promoted as exceptional creative departures to the sorts of analysis Bolter and Grusin model.

For instance, students are invited to take on close analysis of the structure and design of a range of websites, by transferring analytical schemas evolved elsewhere. One example involves work by Kress and van Leeuwen (1998), which suggests that tabloid print-news formats have settled into a predictable structure of left-to-right, top-to-bottom viewing perspectives. This can be used in cross-over mode to challenge website design for the same or similar conventions, to review multimedia design texts, to establish how far the recurrent structures observed online arise from informal cultural consensus, or are in-built within design software. Returning to now-classic pre-digital media analysis of the rise of such once-dominant cultural text-forms as the novel [see for instance Watts (1951), *The rise of the novel*], it is even possible to evoke consideration of whether any communications genre or format arrives in the world *ex nihilo,* rather than, in its early phases at least, being constructed from an amalgam of existing forms.

Once past the glamorous myths of innovation which accompany most new scientific endeavors and into an appreciation of the longer, slower historical evolution of technologies (see especially Winston, 1998) it seems logical to position VLIs, at least in their current manifestation, as somewhere within this "re-mediation" phase of new media development: a moment in which older and existing genres, formats and uses are being re-positioned for online application.

The Bolter and Grusin "re-mediation" hypothesis, however, is worth investigating not simply to help with scrutiny of the evolution of various online text-and-graphic genres (website design; e-mail; webcam use) but as a means for considering the broader online activities and services the internet has fostered. Are these inherently new, or extensions of existing behaviors?

Brody (1999), assessing the progress made so far in the development of multimedia design, suggests that we have yet to find the person or people who can really push these media to their limits: who can make them work to the edge of their potential, creating totally new products, activities, or experiences. He points out that in the early days of movie production, it took decades for the arrival of the Russian film maker Serge Eisenstein, who invented ways of editing and sequencing shots into the sorts of expressive and dramatic narratives we see in film today. Brody asks: where is the Serge Eisenstein of multimedia?[7]

Put these comments together, and we have to consider the possibility that we are still working with a major set of limitations in relation to new media communications—and not just technical ones. Culturally, have we yet really learned what is possible in this new communicative "space" for the play of symbolic activity? Is it the total breach with the past we have been led to expect, or just an intensified stage of a process in train over centuries: from speech to writing, to print, to film and radio and recorded sound, to television, which combined them all, and so to the internet and multimedia, which allow us to interact with, and through, our multiple-image spaces.

This tends to suggest then that those activities we are accustomed to within physical space will recur, and versions of them be reproduced, in virtual space—at least in a transitional moment, but maybe permanently.

And if the recreation of the self, imagining, or even reforming identity into the images and behaviors and social contacts we learn to desire from our engagement with the dreamed selves of our symbolic world of media, is actually the same as the recreation activities we are encouraged into during our leisure time, then the new media are just another space for these activities. We should perhaps already stop thinking of "virtual reality" as a second-order or unreal place, and instead use Castells' term "real virtuality". That suggests instead the more accurate view that since we spend more and more of our work and our leisure time online or in mediated symbolic spaces, then these are in fact our new "real".

3. LEISURE AND RECREATION AS "TIME OUT"

A third consideration of online culture focuses on this already well-established reputation for leisure as engagement in a lesser, or less productive "real". It is here that it is especially interesting to engage these charges of secondary status, or triviality, leveled at online pursuits, with similar conceptualizations bedeviling the fields of leisure and recreation.

All of the words contemporary society uses to discuss leisure time reveal something interesting about its connection with ideas of "time out" from the serious pursuits of life: work, productivity, politics, public activities.

Look for instance at the following:

- Holiday: the "holy days" or religious festivals marked by a break in work, or even by bans on productive work.
- Vacation: a "vacant" or emptied period.
- Leave: an abandonment of the "normal" round.
- Break: a breach in the usual pattern of activity.
- Retirement: falling back from important or central activity: literally, to "draw away".
- Retreat: often used in religious communities, but also in military strategy, as a move away from fully active engagement.

In other words, there has long been a deep conviction that "real" life is mostly about work and production. Any change in this is seen as a temporary state of abandonment into the less-serious private space of play and self-indulgent pursuit of pleasure.

This focus requires attention to contemporary theories of recreation and leisure, as they have developed in industrializing economies. In part, such theorization rests on Marxian accounts of socio-economic history in Western economies, relating to the split in how households and businesses were arranged, as productive work moved from the subsistence economy of the family household, or the skilled artisan's "workshop household" of the pre-industrial period, to the mass "manufactory" or mill, or the specialist banking house, shop or store. It addresses the rise of a renewed gendered and age-differentiated social order, removing the wife and children from the daily round of productive labor, into patterns of domestic consumption which included recreative pastimes (health regimes, educational and spiritual programs, and the practice of folk arts and self-expressive crafts). Sociability itself, within the cultural historical work of Western commentators, was included in this gendered division of labor: from the coffee-house public-forums of the *homme et citoyen* who drove economic life (see especially Habermas, 1989), to the formalized "visits" and "conversaziones" and "routs" of 18th and 19th century gentry entertainments (consider the ongoing categorization of the works of novelist Jane Austen, whether in print or screen format, as forms of superior "Mills & Boon-ish", "chick-flick" material).

As this arrangement crept down from the wealthy middle class business owners of the 18th and 19th centuries and into the homes of all, production appeared to have become locked into the public world of work; consumption into the private world of the home. Even more significantly, the pre-digital mass communication systems arising across the 20th century, in particular, are now commonly seen to have promoted and preserved such divisions (see especially Thompson, 1995). They maintained a "stay-at-home house-wife" for the mid-century period at least, by "de-sequestering" the consuming female from the isolation of those dormitory suburb developments enabled by public transport, reconnecting her to consumption activity through radio and magazine marketing, visits by traveling salesmen, and introducing the domestic telephone for discussion of consumer commodities and entertainment events.

Is leisure then inherently feminized—a product of unproductive, interior, affective, domestic space, considered only as an element of consumer behavior? The work of Celia Lury (*Consumer culture,* Cambridge, Polity Press, 1996) suggests that it has been, but that—along with the added "de-sequestrational" powers of digital media including the internet—it is no longer.

"Holidays", originally centered on festivals of consuming: special food, special clothes, special objects such as extravagant lanterns, or floral decorations, or non-productive "artistic" creations or activities: dancing, music, art, had been mostly produced inside the home, and so outside the world of productive (financially rewarded) work. These had been objects and activities disruptive to the cycle of productive work. They meant a short period of non-productivity, which served to mark the usual daily working round as even more central and important. They were domestically and community based, and associated with women and children: the non-productive labor categories.

Across the 20th century however, they too became "industrialized" and certainly commercialized; repositioned inside the consumer industries, as brands moved to insert their products into peak-period "holiday" domestic consumption, and festival originating organizations—including religions—commercialized and merchandised their locations, activities, and souvenirs. As spiritual centers from Lourdes to Mandalay became surrounded by organized commerce, commodity producers such as Coca Cola inverted the process; for instance re-imaging the figure of Santa Claus to place a popular leisure beverage within the celebration of Christmas, by dressing its central gift-giving figure in its red-and-white brand livery. The chocolate trade moved to specialist identification of products with specific holidays, including Easter, Halloween, and Valentine's Day.[8] In contemporary Malaysia commodity production is booming around the Islamic festival of Aed Al Fitri, celebrating the end of Ramadan. Singapore releases an annual video pop-anthem for celebration of its National Day. Australia has adjusted the timing of the annual Melbourne Cup horse race to accommodate international TV audiences and web-based punting. Each in its distinctive historical time and cultural space signals the re-appropriation of "time out" leisure activities into the commercialized enterprises of productive economic development.

This re-appropriation of the private into productivity is of course reliant on the contrast-formula which defined its position as a space reserved for non-economic activity in the first place. Bakhtin's (1981) formulation of "the carnivalesque" as a period of symbolic but praxical "mis-rule", where for a brief time masters serve servants, or bulls run loose in the city streets, or the country comes to the town, or office staff spend the afternoon watching a horse race on TV, drinking, eating, betting, and wearing silly hats, encourages a (temporary) emphasis on breaking the usual social rules, but it ultimately restores the normal social order, and so serves to show how "necessary" those rules must be. But such a revelation also has much to say of how far the concept of leisure as "time-out" is equally filled with unexpected inversions. The seemingly enduring distinctions between leisure and private life, work and public, were eroded well before the capacities of the internet to dissolve physical boundaries.

4. LEISURE ORGANIZED ON BEHALF OF INDUSTRY

As wages and disposable income increase in advanced industrial nations, so does the availability of leisure activities for those now massed in housing in urban areas. Workers living close to workplaces, are far from the traditional spaces for "holiday". Increasingly, these new mass societies move away from shared cultures of celebration of old rituals, as religions, language groups, and people from different origins mix in the new industrial cities.

Such massed populations were seen as dangerous—in much the same ways unregulated internet users have been—if not always organized and controlled. Both are considered especially dangerous during breaks into "carnival". An industrial economy set up ways of controlling the carnivalesque: typically, by turning it into another industry—called "leisure".

The space for non-production—the time for consumption only—itself became formed into productive industries. One after another, the types of celebratory activity that were always connected with recreative pleasure became organized into new industries.

4.1. Organized Sports

Games, once played in different traditional ways in different locations, but mostly loose in their organization and participant activities, became codified into "sports" for the masses—along the lines of the "sporting gentleman's" life. Those un-productive time-consuming activities which had once been for the aristocrats: hunting, shooting, fishing, riding—became re-structured: shooting clubs, weekend fishing on the industrial canal banks instead of in expensive trout streams in Scotland, bicycle riding instead of horses . . . "Royal tennis", played in a complex purpose-built courtyard, became a weekend game in public parks or middle-class family gardens. Football, cricket, hockey, and many others evolved from village rituals or children's games into health and fitness activities, and then into mass spectacles for huge industrial urban populations.

As the 20th century arrived, providing mass print, audio and visual media to expand those audiences and introduce profitable cash flows, professional sports people and sports industries arrived. So powerful did sports spectatorship become: physical sport experienced vicariously through national or local heroic performances and organized annual rounds of competition, that entire national regimes felt compelled by mid century to set up "participation" institutions as well—from totalitarian health and fitness organizations to campaigns such as Australia's 1970s "Life: Be In It" promotion, with its "keen sportsman" "Norm", finally persuaded to abandon the couch and TV for a little therapeutic walking.

4.2. Organized Travel and Tourism

Travel and tourism, once the preserve of the rich, also spread out as disposable incomes rose—especially at the end of the 19th century, as first the railways and steamships, then road transport, then air travel, made more and more destinations available for a reasonable cost, and in a reasonable time frame—for instance, the 2 weeks of annual holiday most industrial and commercial workers had now negotiated through the labor Trades Unions. Where originally travel had been long term, modeled on the "Grand Tour" undertaken by the sons of wealthy English aristocratic and gentry families seeking education and "improvement" from contact with European art and high culture, usually a 2-year trip with a private tutor, now ordinary people set out for a week at a seaside resort, or a "charabanc" daytrip to a pleasure spot. But the idea of "improvement" from travel remained—as it does to this day. Views that "recreation leave" renews the spirits and the energy for work are central to promotional discourses within the travel industries, as well as within medicine and fitness, while longer trips—such as the young person's "gap" year of travel between school and work, or Prince Harry's "work holiday" in Australia—are thought to teach maturity and self-reliance.

4.3. Recreation Through the Self-expressive or "Imaginative" Arts

The imagination, or the private and introspective "fancy", as opposed to the pragmatic and public "reason" had been considered the part of the mind which led to indulgent daydreaming—licensed in creative artists or artisans such as poets, painters, or musicians when they constructed their works, but not advisable for ordinary people, who had manual or skilled work to perform in their public lives, and family support activities in the private realm of the home. The rational mind was thus superior, and the imagination released only in exceptional persons (persons possessed by "genius" in a process disturbingly close to insanity). But as sectors of the social order were one after the other removed from productive labor, the imagination became a space which they were encouraged to enter in order to "recreate" or occupy time (preferably by consuming some new "imaginative" product there—from sheet music for the piano to penny-dreadful novels and cartoons and comic books for the urban masses; from parlor board-games to sketching or amateur photography; from pre-printed embroidery patterns to assembly kit radio "crystal-sets" or "Meccano" construction kits for boys . . .).

Fantasy became a part of this "space of the imagination", opened first to children, as fairy stories (Hans Christian Andersen, the Brothers Grimm), children's books, films, animated cartoons, elaborate mechanical toys, radio, and TV for children came to have their own special market. The "imaginative spaces" of symbolic texts and products (books, comics, TV shows, recorded music) were added to with public physical space for play: pleasure gardens, playgrounds, theme parks, games parlors, franchised restaurants such as MacDonalds—and then multimedia products, designed largely with a child audience in mind.

So in terms of both time and space, leisure has been positioned as the "not everyday": as the place where productive work is suspended, and the self is "recreated" by a change of place, a change into imagination and fantasy and out of physical reality and rational thought, or a "simulated" place for unproductive and potentially disruptive and dangerous body activities such as sport—or sex for pleasure, or chat for sociability.

As the social order produces new media activities for internet consumption, it can be seen to "re-mediate" these older forms and spaces and their contrasts between production and consumption; the rational and the imaginative; the everyday and the holiday. Those very technologies that most unsettle old divides between private and public, work and holiday, productive and consuming activity are still re-working activities and genres established in much older spaces and cultures. From *Mortal Kombat* to *The Sims*, online games still present heavy degrees of gender-division in their design—even where they are played by both males and females. IRC spaces, notorious for claims of cross-gender deception, show heavy levels of gender-segregation in both their searchable topic selections and their online "chat" styles. And while the click-count registrations, which rate websites for the calculation of advertising revenue returns, act as a powerful acknowledgement of how far even recreational internet use is now linked in to productivity, the degree to which this remains a covert technologization, invisible to website visitors, maintains the old distinctions between "work" and "leisure".

How then might these distinctions be overcome—and is internet experience, itself technologizing a re-integration, able to signal the importance of that move? Are we aware of what we are "doing" online—and, as many online commentators have suggested, are we giving too much away?

5. LEISURE AND THE CREATIVE INDUSTRIES

New media industries, their operations carried by the penetrative powers of the internet, drive further in than ever toward private, consuming spaces—retracing them as "symbolic" spaces of recreation; spaces given over to activities promoting "affect" or intangible emotional and imaginative responses. This new amalgam of the organized leisure industries and "personal" interests, with emphasis on identity work or transformation of "the self", makes their operation part of the newly conceived "creative industries".[9]

The "new economy" produced within the "information society" is, as Castells (1996, 1997) tells us, about information, global connectedness of production and consumption, and networking. This constructs inter-penetrability, able to carry desire and demand outwards ("pull") and supply and promotion inwards ("push"). Knowledge—or at least information—is thus important in all sectors of both production and consumption. Only such a weightless form can drive "push" and "pull" at the speeds needed in the new economy. The internet, along with its many peripheral forms, is prime platform for these new flows.

The "culture industries", a term which in the mid 20th century referred to "popular culture" or "mass media" such as movies, music recording, fashion, the media, magazines, and advertising, were originally conceived as providing commodified, debased, inferior, and reproduced art and leisure pursuits for the recreation of the industrial masses. But by the later 20th century, these products, and the style and taste codes schooled by them, had become increasingly dominant, building up successful bricks and mortar industries and business corporations, as agents providing the key symbols of personal, national, and cultural identity. With media industries among the giants of the global economy, "symbolic" production itself was becoming dominant. No longer seen as a secondary space of trivial play, it was now an aspirational space for both work and recreation.

This new role meant that the "recreated" self was now commodified in "leisure industries", such as tourism, entertainment, fashion and design, food and hospitality—and the growth of the services sector in world economies demonstrated how powerful this sector had become.

As design and style spread out: no longer just the marker of the wealthy, but used across the social spectrum, an estheticization of everyday life becomes central. Consumer finance and so the industries to service it turn increasingly to issues of "style". Material needs are largely met, so consumer desire turns instead to "the aesthetic", or versions of beauty, image, and fashion. And Governments seeking to develop industrial production in a saturated commodities market also have to take this turn toward the symbolic product. Terry Flew, in *The new media,* Allen & Unwin, Sydney, 2002, shows how for instance the Blair Government in Britain moved to the development of "creative industries" in 1997:

> The role of creative enterprise and cultural contribution, is a key economic issue. The value stemming from the creation of intellectual capital is becoming increasingly important as an economic component of national wealth. Industries, many of them new, that rely on creativity and imaginative intellectual property, are becoming the most rapidly growing and important part of our national economy. They are where the jobs and wealth of the future are going to be generated (Smith, 1998).

New high-value enterprises include content provision for improved, high-speed but content-hungry broadband services: old and new media linking together in producing content that crosses media platforms (and will do so more easily once radio and TV join print and graphics in a wholly digitized technology). Flew shows how in 1997, copyright became the USA's largest export earner: 414 billion dollars worth of books, music, films, TV. The Spice Girls and associated products were Britain's biggest export that year. Pop culture rules.

But creative industries are still not fully engaged in the economic models and systems which drive national economies—and according to Flew, may never be. He cites Caves (2000) who has outlined seven reasons for this:

1. Problems in assessing demand for creative product, where selection by consumers is subjective, based only on experience of the commodity after it has been produced.
2. Satisfaction flowing to creative producers from factors other than profit: artistic expressiveness for instance—yet the need to reconcile this with profits and income and deadlines and auditing and accountability.
3. The large creative teams needed for creative media products, with many different specialist skills, often arising in different value cultures (to test this note how long the credits are on today's major movies, as opposed to those of only 30 years ago).
4. The huge variety of products both within categories (e.g., individual music tracks) and across categories (music on CDs or DVDs). How do consumers remain expert enough to choose? Or even to choose experts who advise?
5. Vertically differentiated skills: there are hierarchies of talent, and disagreements on how it is assessed.
6. Co-ordinating different creative activities in tight production timelines. There is often loss of cult style power in long productions runs, or over long celebrity careers.
7. Durability of products, especially in new media technologies, which have the potential for taking up archived and re-issued product, and so a capacity to extract new profit over longer periods.

Each of these leads to specific instances of major risk and uncertainty within the creative industries—one reason why public funding or corporate sponsorship is still sought. Such problems then move these creative production activities to models outside the standard industry experience. Creative industries may always be "special"—not like organizations involved in physical commodity production.

Do they then suffer from the same sorts of "unpredictability" as the internet: victim of their own accessibility, variability, and potential for fast-feedback and obsolescence? And are they, like the layers of failed "Big Enterprise" ventures already littering the new economy, doomed to share the "one project" lifespans of traditional arts and creative ventures? Certainly, as Flew points out, new media are mostly produced in start-up or SME companies (small-to-medium enterprises), and not in big industries, such as Hollywood movie companies, or the big music recording labels. The much smaller new-media firms contract to larger mixed-media corporations, who in turn manage their risk, marketing, advertising, and so on.

Is this a slow movement toward establishing large industries? Are we just looking at a stage in the "new media" industries? Media history tells us that film and radio developed in just these ways—as the start ups and SMEs of their era—although TV demonstrated elements of the giant media-company structure, founded on its predecessor industries, film and radio. So is the "creative industries" view correct or are media giants such as PBL or Time Warner already stepping in?

One argument in the "creative industries" account of new media productivity centers on debates over the fact that information flowing through the new digital networks produces little, until "communities of practice" establish to apply this knowledge. This means that the "volunteer" labors of internet users—such as those people who write reviews for Amazon.com, or advertise on eBay—are crucial to the work of these sites and services, and to the image of the internet as dynamic and busy. Does this "voluntary" interactivity show the next step forward in networked symbolic productivity? And if ordinary users contribute, should they do so for free?

Flew cites the work of Andy Pratt (1998), who adds to Castells' characterization of the internet by showing that information as a symbolic entity is not only "weightless", but also socially embedded. Its products and activities arise from and are engaged back into communities of users. Cultural activity increases where people cluster to use and apply knowledge: in the physical world, mostly in cities, and mostly in groups focused around younger adults (18–35). Such groups are heavy users of symbolic products, as they perform identity-formation work around style and aesthetic expression. See for instance Hebdige (1988), for the "revolt into style" hypothesis, which suggests that as younger adults and children are progressively moved out of the world of productive labor, they take up identity formation around consumption of symbolic product, creating "selves" through film, TV, magazines, fashion, music, and cult activities such as being in "cool" places or using trendy communicative technologies—most recently the mobile phone and internet.

Pratt sees post-internet generations of young adults as already expressing new values, formed around new experiences vectored through digital interactivity and speedy communication access. For this key group, symbolic consumption and physical productivity are already the same thing. Pratt itemizes the various cultural values which signal this new departure:

- making culture and making money are seen as the same activity;
- work time and leisure time are not distinguishable: both are co-present and have the same value;
- informal networks and not established institutions pass on the most valued information;
- intuition, emotional involvement, enthusiasm, and immersion in the field are valued; and
- cultural producers want to work for themselves and not in regulated, hierarchical nine to five institutions or corporations.

Each of these new values can be interestingly illustrated and exemplified in experience of internet-enabled new media use. What remains to be calculated is whether these values remain exclusive to the "Y generation" (1980–2000) who grew up with video games and the beginnings of the information economy—or will hold good for an entirely new cultural direction and economic system. Part of the study of VLIs involves amassing evidence for that debate.

Is the "communalism" of these groups established by the new networks, or *vice versa*? Is the flexibility of production arrangements seen among Pratt's young new media producer–consumers a response to the new set of circumstances within creative industries, where styles change quickly and new SMEs and start-ups form and reform—or will these new media enterprises become large establishments and corporations, in time?

With these considerations in mind, any one of a still-evolving and extending list of virtual leisure activities or "industries" can be selected and considered. Given the "re-mediation" hypothesis, and the focus on considering continuities or cultural contexts and so longer than usual periods of development, each will have its own circuit of origins and influences, accessing the primary dimensions of "online" status differently, and with different results. Student interests and backgrounds to date have taken them across an array of fields, from sex to sport; fan culture to family genealogy; gambling to gaming. The list is ever-growing, and indeed one of the concerns of the field is to test whether new activities identified during a period of study are already "within" the ambit of established creative industries, or are contributing something taxonomically different. (For instance, will experts at online "modding"—re-writing aspects of games software to suit the tastes of online communities—be integrated back into games companies, or will they set up fee-pay online services themselves?)

To illustrate some of the ways in which online pursuits activate the range of ideas outlined above, I will conclude by indicating how just two examples of current VLIs drawn from informally and formally constituted "Creative Industries": sex online and sport-related internet sites, create an "interrogation" of both their own field, online leisure more generally, and the internet.

In the first instance, examining online sport, I will show a little of how the hypertextual structures of online study-delivery promote an interrogative or exemplar-generative approach to study, interrupting a study of the major developmental features and concepts of leisure and sport. As the online "discussion stimulus" topic-boxes for self-directed study arise on the site, each is inter-spaced with a series of questions, inviting the reader to conduct online searches, locating examples, and critiques to reconceptualize the "mainstream" account of sport as leisure, within the new experiences offered by its online variants.

In the second instance, online sex, given the difficulties within the field and its near-eclipse by associated matters of governance (regulation and censorship; psychologistic regimes of pathologization), the materials instead move to consider the ways in which a specific field of online use, such as sex-services, can achieve prominence within the social and cultural domains producing and directing a medium such as the Net, in the absence of real research evidence on its uses. Here, the study itself moves back a little, to consider the power of one field of Net use to regulate and control all of the others. This in turn is used to open the entire concept of VLIs to the suggestion that it already contains incommensurable and unequal fields: that it, like the internet itself and the social order producing it, is a space of and for contestations, re-articulations, and often surprising convergences.

6. EXAMPLES OF VIRTUAL LEISURE INDUSTRIES

6.1. Sport

In moving to examine sport online as just one concrete example of practices surrounding online leisure and recreation activities, it is useful once again to test existing accounts of the development of sport-as-leisure against the "new" practices offered to online sport enthusiasts—whether practitioners or spectators. Does online sport continue, or depart from, those patterns of development reproduced in contemporary accounts of sport-as-leisure-industry? Which aspects of online sport-related activity dominate, and might be said to innovate or reinforce established developments?

This section takes up a recent study by David Rowe, *Sport, Culture and the Media*, Open University Press, Buckingham, 1999, into the role of sports media in controlling social and cultural uptake of sport-as-leisure through the strength of sports spectatorship. His account of the mediation of sport across the 20th century is used to invite analysis of new online sport sites and activities. What this sets up is the opportunity for "interrogation" of this largely historical account, testing against it contemporary practices, which may or may not sustain its hypotheses and findings. To reproduce this "interrogative" form of study, I intervene into my own précis of Rowe's text, to introduce issues from online sports activities, sites and behaviors, so addressing some of the questions formulated above—and hopefully both modeling and evoking in students/readers the sorts of interactive, even hypertextual practices central to both online practice in general, and internet study in particular.

Rowe begins by reminding us that sport itself is a surprisingly modern concept.

Although most societies have traditional games which structure play in some way, these were rarely organized into the sorts of regulated, competitive, team-identified cycles of events for mass spectatorship, which we consider to be sport today.

Search online for examples of traditional, non-mainstream sports which to your knowledge have not yet been commercialized.

These may arise in traditional ritual, ethnic communal activities, isolated regions outside the industrialized economies, societies resistant to industrialization for religious or political reasons, or because they have the

status of being minor variants of otherwise "mainstreamed" sports (for instance, women's cricket or "Kalikiti" in the Pacific nation of Vanuatu).
At what stage might any or all of these become "commodified" in the ways Rowe outlines?
Are there examples of minor sports currently undergoing such development?
What roles are being played by online mediation itself in these processes?

Even when large mass spectacles did emerge—the prime example being the ancient Olympics—these had now-forgotten significances, such as artistic or religious celebration, attached to them. And they disappeared, along with the cultures which produced them: the modern Olympics were introduced only in 1896.

Revisit the Athens 2004 Olympics websites and examine their accounts of connections between the ancient and the modern Olympic movements.
How far did the visual codings used to characterize and promote the Athens 2004 Olympics capture the iconography of the traditional Olympics?
Can such iconography be cut away from the beliefs and ritual activities of its origins, to be applied to global media audiences, without entirely altering its significance?

David Rowe states that:

> *sport as a recognisable social and cultural institution is not universal but emerged in a particular location (Britain) at a particular time (early industrialisation)*
>
> (Rowe, 1999: 13).

Rowe attributes this emergence to features which had existed for some time in British social life, including:

- longstanding traditions of rough physical competitive play [Rowe cites Elias & Dunning (1986) for their descriptions of village contests which took the form of games rather like disorganized forms of football];
- activities for both competitive participation—often with prizes—and spectator enjoyment, and sometimes betting on outcomes, but which happened only on special occasions [Rowe suggests Clarke & Critcher (1985) for accounts of boxing, wrestling, cock fighting, and horseracing on religious holy days or market days]; and
- examples of Court or Government edicts that such unruly behaviors during leisure should be organized into "useful" military skills competitions, such as archery.

How far are these motivations and regulatory demands still evident in contemporary discourses surrounding sport? Can you find arguments being made for online technical, social, or competitive skills as part of the skills or attitudinal base for "useful" military, industrial, or commercial activities?

Is the intention of diverting excess energies into "useful" skills such as para- or proto-military fitness completely eroded by the "virtual" status of mediated sport, or are there still arguments circulating that online games are good for developing "strategy skills", or "hand-eye co-ordination", or "competitive spirit"?

Is sport online wholly a mediated, virtual experience, or does it also have ways of attending to physical skills development? Can you find examples of highly mediated sports, such as golf, or tennis, or sports with high degrees of online chat and/or image exchange, continuing the specifics of "training" for excellence through advisory coaching video, graphics, texts, dialogues . . .

Are there any examples of new sports or fitness activities which combine the visual/data feedback loops, or non-proximate interactivity via the Net, with physical action?

Rowe cites Weber (1930: 167) to comment on how those who controlled society most often saw sport as a form of dangerous and un-controlled behavior:

> Sport was accepted if it served a rational purpose, that of recreation necessary for physical efficiency. But as a means for spontaneous expression of undisciplined impulses, it was under suspicion; and insofar as it became purely a means of enjoyment, or awakened pride, raw instincts or the irrational gambling instinct, it was of course to be strictly condemned.

Traditional public media have perpetuated many sport-specific forms of these "moral panic" discourses. See for instance "football hooliganism" in the United Kingdom especially, or "ugly parent" syndrome in children's organized competitive sports. Are these behaviors also practiced in online media and discussion sources for sport activities?

Rowe comments that many of these sorts of fears of the "un-control" of games—another form of the carnivalesque—are now licensed or even encouraged within organized sport. He details, for instance, the ecstasy of victory, pride in a team, shouting and barracking, wearing crazy clothing and make-up in team colors, the crowd euphoria at witnessing a scoring move, violent mass action such as riots or "hooliganism" after team losses, the loss of self in mass activity, such as "the Mexican wave", and the risk of gambling on outcomes:

> Sport can be seen to be an important symptom and a partial cause of a move away from a social order founded on the repression of physical play, and its pleasurable accoutrements, to one which not only accepts such pursuits, but also promotes and makes "capital" out of them.
>
> (Rowe, p. 15)

Select any two mainstream contemporary sports and examine online merchandising associated with one high-profile club or team.
What is under offer?
How are the commodities promoted, in the cause of advancing which practices, behaviors, images or values?
What is being "expressed" about the club, team, or even nation?
View a major sports event, either live or on TV, while simultaneously keeping an eye on its web promotions, streaming, news reporting, chat groups.
Are the values fore-grounded at the game, on the TV presentation, and online, the same? What is fore-grounded in each?
What are the particular pleasures available in each—and in the combined experience?
Trace the media and new media input required of one selected sports practitioner during a major event: on the field, via the traditional media, and online.
What do you learn of the "persona" presented by a single individual, through each of these locations?
Is this person always, and everywhere, exactly the same? Are the same insights and issues covered in all these media, or do some appear to be offering different or specialized perspectives?

It is important to consider what caused these changes from unregulated to "organized" sports—and formed sports audiences in various ways, moving them on to "identification work", immersing their own identity into the values and symbolic codings of their preferred sports and teams and players. This new focus on sports spectator–consumers prepares us to witness even newer online forms of spectating and consuming sport—ways which, because the primary activity (playing the sport, or attending the game) is less and less available, compensate through the rich layers of commodity made available for repeated, self-selected, and identificatory "participation".

Rowe outlines the traditional argument: that a massing of workers for the new industrial cities after 1780 caused concerns about "uncontrolled" groups roaming free while not working—and likely to engage in riotous sports, risking civil order and injury (the 18th century word "mob" is a short form of the word "mobile"—which then meant a loose and dangerously unpredictable group of people).

Shift-working factory labor, industrial city living, new democratic and revolutionary political ideas all shifted sport from being a dangerous activity to be suppressed, to one which could be controlled, directed, and useful—both for keeping bodies fit for hard manual labor, and minds directed to the sorts of organized timetables and cycles arising in mass manufacturing work, as well as promoting the competitive spirit of capitalism.

Boys' schools began to promote sport not as immoral and undisciplined, but as part of the formula for "the healthy mind in the healthy body". These were the sorts of manly, semi-militaristic virtues required to run businesses and rule empire. The "amateur" or "lover" of sport demonstrated "selfless devotion to the sport, fellow team members and competitors" (Rowe, p. 17). But while "gentlemen amateurs" were initially opposed to the base practices of professionals (for instance, pugilists or bare-knuckle fighters, as opposed to boxing and the Marquis of Queensbury rules); working class mass spectators began to demand the superior skills and the monetary rewards of professional sport. See, for instance, the code-division into amateur rugby union and professional rugby league in Britain and France in the 1890s, and the rise of soccer in the British industrial cities.

Do these historical trajectories for the development of what are now mainstream "sports industries" still hold for sports which are emerging today: for instance, the "extreme sports" developing in modern urban street culture, such as skateboarding, in-line skating, BMX, or one-on-one basketball?

Many of these new sports, not yet fully organized as industries, have achieved a "cult of cool" which has seen their best proponents provided with digicams to collect video for dance clubs and advertising use. How far do they also achieve online presence?

Are these examples of the sorts of "image culture" which Pratt identifies as dominating today's virtual pastimes?

Rowe sees the rise of sport in Britain as the first industrialized nation, as directly implicated in the new organizational features of manufacturing: the separation of workers into specialized skills, and the segmenting of the working day into shifts and timetables to suit the production process—which left "tired" workers to be "recreated" in non-work or "leisure" time.

What then is being "recreated" in workers in their online "downtime", through the provision of online sports-related consumption activities?

To what extent are online sports activities continuous with the "developmental" goals of today's industrialized sports activities: regulation of *crowds; distraction from more dangerous or enervating activities; compensation for too much focus on expressive-imaginative "feminized" or domestic forms of consumption . . .*

Is online sport purely about consuming the same product in a different and more accessible sphere, or does it involve other elements?

The standardization and rule-embedding of a "safe" and "efficient" work practice spilled over into games and sports as well (injury at sport could also impact on skilled work).

How far are sports injuries or unsafe sports practices part of the discourse of sport graphics, reports, and discussions?

How far do the attractions of sport: its speed, daring, and physical risks—rely on these "unsafe" qualities, and how do these get taken up in online communities—whether fan or journalistic sites.

At the same time, sport became enclosed into commercial venues, so that spectating could be sold. Rowe shows that finally a "whole economy of sport" evolved, including the following features:

- Clubs and societies were organized, with subscribing members—allowed to play, and with privileged spectator access.
- Competitions were organized, with prize money.
- Imposing venues were built for large crowds.
- A labor market of sports professionals grew, to value and transfer players.
- State funds were allocated to develop sport for national prestige.
- Sportswear and other merchandise were developed and marketed.
- Specialist media were devoted to promoting sport.

Find examples of online activities supporting each of these, within one selected sport.

At what stage of this developmental line does a hierarchy of value and causation: real sport, and then spectatorship; reverse. Does spectatorship now follow from, or bring about, an interest in sport? Does real power shift to fans and consumers once sport is mediated—and is this sped up and intensified through internet sport?

How far does such a reversal have to develop, before it could be said to have achieved a "virtualization" of sport?

How does the interactivity enabled by online digital media feed back into the physical sport itself? Consider for instance digital TV and camera angle changes; the use of video and sensors in coaching; electronic scoreboards and line-call mechanisms such as "Third Umpires"; the fine-tuning of performance times to the millisecond; the feedback-electrode *scans used by athletes to adjust their bodies to achieve better performances and skills.*

Given the expense of a professional sporting life, and the need for commercial media-based sponsorship, is the sporting body also already virtual through its required mediation? How far is internet access intensifying that mediation?

Initially, sport had been about participation.

By the end of the 19th century, it was about physically present spectatorship.

By mid 20th century, it was about mediated spectatorship: radio, TV.

By the late 20th century, it was about mediated spectatorship and identification *via* merchandise, gambling, fan activities—and information flows on websites.

Is this then a movement away from the physical to the symbolic—or back again?

What does the internet add to this trajectory of "cultural uses" of sport?

Is internet sport or virtual sport changing the nature of sport "participation"? Is this a new direction, or "more of the same" but in a new medium? Consider new activities arising through virtual media—for instance the Korean pad-interactive game called JumpDance, which has now developed into a popular competitive sport. How far is this "not" a sport, in that it is a computerized game? How far away is it from athletes competing against their own electronic performance records, or "correcting" their stance or strokes through use of video or animated models?

All of these de-stabilize distinctions between the embodied and the virtual. But are these entirely new directions? Ten years ago Australian researcher Nightingale (1992) found examples of spectators watching Australian Rugby League at home on TV, enacting each of the key plays in the living room, with their own football. Was this mediated, or physical sport? Satirical TV sports commentators "Roy Slaven and H. G. Nelson" have shown video footage of young children playing "mediated football": speaking out the radio or TV commentary as they play their own game of Australian Rules football on the school ground. These intriguing examples of an "immersive" sports experience: one which merges mediation and physical participation, suggests that Pratt's new generation of media users who see material and symbolic as fused, are already at work in the sports culture.

6.2. Pornography and the Sex Industries

In the first piece of Australian research involving online ethnographic evidence for the actual uses of online pornography, McKee (2004) has revealed the popularity of the internet for the downloading and viewing of pornographic material. Of his research team's sample of 612 Net users invited to comment on their uses of pornography, 316 reported sourcing materials *via* the internet, as opposed to 6 *via* pay sites, 190 by purchasing videos, and 169 DVDs, 136 by purchasing magazines and 41 selecting novels.

As is common in so many surveys of online uses, six of the 10 top internet sites for Australian men provide pornography. The estimate is that by 2002, 2.5 million Australians per month were visiting adult sites (the entire national population is around 20 million). McKee estimates that online pornographic consumption is worth about $A43 million per year, and already about 11% of the total national pornography market.

Pornography is a complex field, since the definition of what it actually involves is elusive, and changes according to the reader/viewer. Australian culture at least cannot even agree on a single term, using the following in various forums:

Pornography—*Porne:* Greek for whore; + *graphein:* to write: = "to write about whores".

Obscenity—*ob:* Latin for "to"; *caenum*, Latin for "filth" = "to direct us toward filth".
Erotica—*Eros:* the Greek God of Love = "writing and images about matters to do with the act of love".

Pornography is a necessary central concern in a discussion of VLIs because of its prevalence within—and some argue, influence on—multimedia and the internet generally. According to some public-media accounts, the internet is about little else but sex . . .

Certainly pornography indicates, better than any other issue, fears about the erosion of distinctions between public and private spaces, and of the power of traditional public institutions to control or regulate even "private" consumption activities. This erosion is produced, as in many previous instances, by interactive media and the arrival of self-selected access to full international information flows of texts and images and anonymous social contacts, moving into the private spaces of "home".

Pornography more than most other media forms forces us to clarify issues of how we have come to consider that reading text and looking at images is not just about seeing them, but about what they in turn might "do" to us as we look. Creed (2003) reminds us that the visual materials brought to us first by cinema, then television, and most recently personal-use materials *via* VCR, DVD, and the internet, combine two disparate yet powerfully entwined levels of experience. She speaks of screen-culture's

> . . . two seemingly contradictory elements: its unique ability to capture 'the real' and its unusual power to present the world as if it were a dream, to screen images and activities which flow across the screen not necessarily in terms of narrative logic but as if they had risen from the depths of a reverie, fantasy or nightmare. Through editing film can yoke together disparate images to create atmosphere, mood, sensation, eroticism, desire. The evocative power of the cinema is perfectly equipped to suggest, reveal and display those desires considered perverse or illicit (p. 24).

It is this power to recombine and to evoke which most unsettles social controls on what is or is not considered legitimate for general viewing: which provokes fears of uncontrolled response. And there are conventionally three positions taken up on this "see-and-react" position: on the traditional "effects" views of mediated material as it intersects sexually explicit visual-media content:

Conservative-moralist, which considers that viewing of "obscene" materials produces sexual arousal in individuals, and should be either controlled or banned outright; that it offends cultural or religious views, and de-sensitizes individuals to immoral acts in general.

Pornographic—more recently often *feminist*—which believes that materials used to promote (most often male and heterosexual) sexual arousal devalue women to promote the sexual pleasures of men; that pornography is thus not about sex, but about power, and that it allows men to internalize messages about women's sexual pleasure being suppressed in the service of men's sexual pleasure, and so leads to real acts of sexual suppression or violence by real men against real women.

Liberal-erotic views, which see mediated sexually stimulating materials as about harmless fantasy, potentially at least artistic, sexually pleasurable, and possibly even sexually liberating and therapeutic.

Each theory in its way suggests both that there is an effect from uses of sexually explicit media, and that the broader society should decide about how we all should use or be able to use such products. In other words, regardless of the hypothesis or explanation favored, each view of pornography posits that what happens within a "virtual" zone, technologically mediated, involving representation, such as video/audio or even text pornography or sexualized chat on the internet, impacts in some way upon what happens in the physical world. This in itself is an interesting circumstance, given the varying positions taken up on this issue elsewhere.

Each hypothesis depends of course on values established elsewhere in society and culture: values about social power and how it should be framed and managed; about morality, social control, political intervention, gender relations. None of these concepts can it seems be fully empirically tested or scientifically "proven" on the humans who hold them (despite McKee's hopes for an ethnographic means of establishing empirical data on online uses of pornography), so that each explanatory frame remains in social science terms a "normative" theory: it depends on the consensus or "norms" located within various social and cultural populations.

In a multicultural society, and especially on a global medium, each of these sets of ideas, and all of the specialized sets of beliefs associated with each of them, will be contested and represented.

But for the purposes of inquiry into what pornography on the internet reveals about the operations and nature of VLIs, the major interest is once again with the "virtuality" of the mediated-sex industries: the way that symbolic materials—images, sex-chat, videos, texts—are designed to have physical effects on users—even if these effects are dependent not just on body stimulation, but on the complex social and psychological narratives and "ways of seeing" learned within a culture.

Two issues to consider, as sexual material moves online:

Research into the history of "screened" sexual material—the whole development of filmed pornography up to the internet era—is discussed by U.S. researcher Williams (1990), who shows that this industry has actually been responsible for innovative ways of representing the objects under the viewer's gaze, and for optimizing the inter-activity implied in screened images and narratives.

Is pornography then a technically more innovative industry than has been supposed? Has the relatively direct relation between the viewer and the image; the user and the activity, been important in the development of the new media more broadly?

Have some of the directly relational services of the internet (e-mail, chat, image exchange) linked themselves to the pornographic/sex-services practices established elsewhere, to "activate" whole new groups of users?

One Australian researcher comments on how her research field of pornography users, not considered a suitable topic of conversation by her middle-class colleagues when she began, is "no longer the scary and/or embarrassing secret they hid under their beds" (p. 196). She suggests that more and more Australians are using mediated sexual materials on a regular basis: that this is normalizing socially.

Review some of the options available on the internet for DIY sex: see for instance e-mail affairs (Stretton, 1997); sex and identity and home pages (Kibby, 1997); the representations of "techno-sexuality" used in computer games and techno-magazines (Luke and Luke, 1997).

Is there evidence for the strengthening of a DIY approach to sexual representations and to the establishment of a wider range of sex-relation work online—or are older established forms also increasing their presence?

Springer (1996) showed in the early 1990s how the initial "disembodiment" idea of virtual media as a disconnected space of "mind" has been worked into narratives of sex-in-cyberspace, producing even general-consumption materials showing the internet and cyberspace as saturated with euphoric, even orgasmic, "free floating" states of sexual pleasure, and available for fantasy sexual encounters and play across physical sexual identity. Has the pornographic new-media field alerted us more clearly than other new media activities, to the way that the "free space" of the internet and related multimedia representations of cyberspace actually connects the physical and the symbolic?

In a recent Australian collection on new developments in the ethics of online communities, Albury (2003) has revealed emergent formations around uses of online pornography as a "DIY" exchange, suggesting that in at least some cases internet pornography is legitimizing not only the downloading of pornographic materials for personal use, but also an entire "domestication" of the field, "allowing porn fans to become amateur pornographers in their own bedrooms" (p. 197).

> Most importantly, it allows those who feel left out of mainstream explicit and non-explicit media representations of sexiness and sexuality to create the kind of porn they want to see. As one of my interviewees, a lesbian-porn producer/performer, put it, producing this kind of cottage-industry or DIY porn 'is like a freedom to wear sexy clothes, or get naked or be exhibitionist . . . but do it . . . where our sexual preferences lie' (p. 197).

Is the internet "democratizing" pornography, spreading its repertoire?

Creed (2003) also suggests this kind of broadening effect from online technologies:

> With the development of virtual sex, players/viewers will be able to construct their own voyeuristic scenarios in order to satisfy their individual desires. This may well lead to a decline in public forms of popular entertainment and pornography as individuals assume greater autonomy—and perhaps, responsibility—for their erotic lives. It may also lead to the emergence of new narratives, fantasies and sexual scenarios . . . (pp. 125–126).

Perhaps this is just online pornography's moment of over-enthusiastic optimism for the new technologies: a kind of sexualized version of Rheingold's "virtual communitarianism". Certainly, Australian sex-industry advocate Fiona Patten, (in Lumby and Probyn, 2003) reminds us that the Australian pornography production and provision industry seems unlikely to die out any day soon:

> . . . what we have at the heart of the industry in this country are two very public companies which are listed on the stock exchange . . . . Surveys consistently show that most people favour making explicit sexual material available to adults. The last survey put that figure at 85% (p. 215).

In 1997, reacting to the July 1995 *Time* magazine cyberporn issue, which they describe as a "moral panic" formation, Evans and Butkus set out to test how far internet services reflected the "porn push" reported in *Time.* They discovered that these sites were in fact easy enough to locate, using only popular search engines and standard search terms ("pornography", "sex", and "hardcore"), and even easier to access, without fees. But they also noted that sites were surrounded by admonitory warnings: logos and links to family censorship software such as "Net Nanny"; "entry condition" statements to which one must comply; anti-censorship organization links; even advertisements for missing children. Evans and Butkus argue from these findings that internet sex sites are, like all Net compositions, mixed and multiple constructions, pointing in many different and even contradictory directions. They conclude that "fears of the structural reconfiguration of public sphere communication may well be a key element in the cyberporn panic" (p. 66). In other words, they too see the availability of accessible material online as "democratizing" and "domesticating" the uses and user-range of sexual materials, but by creating a kind of textual promiscuity: one which re-mixes the genres and styles of public and private text access and consumption, and so of online morality.

Repeat the Evans and Butkus search strategy. Using their three search terms and your usual search engine, see what is available, and whether the "mixed" and contradictory links and messages they found surrounding sex site access are still evident.
Compare your findings with a range of "moral panic" articles for popular media. Do your experiences online bear out the claims?
Review current censorship provisions for both online and off line sexually explicit materials in your location. From the base of your own online experience with such materials and their accessibility, is online censorship (1) possible? (2) desirable? (3) working?
Does the Evans and Butkus finding of a social debate over sexually explicit materials, actually evident even at the point of download and use, make any difference to such arguments?

There seems then to be not only a broadening of pornographic uses being reported—at least by Australian researchers of online media—but of attitudes taken up toward the social "positioning" of pornographic materials, and possibly to the general view that this is, as it has been in the past, still an "underground", high-circulation/low-quality media format. With professional public advocates and industry managers; increasingly high-profile performers and growing cross-over into mainstream media, and above all the new personal selectivity, private use and interactivity and DIY productivity of internet services, all forms of pornographic materials are shifting cultural status, somewhere in the diverse cultural matrix.

As contact with these materials becomes more random, and more in line with other everyday consumer activities, online pornography services and products are more likely to hybridize even further into other sectors, than to remain sequestered into specialist zones. Indeed, there is plenty of evidence that this has not only already happened, but that the rise of many forms of moral-panic debate around online pornography or sexual materials may indicate, as Evans and Butkus suggest, social response not to sexualized materials, but to their presence on a medium itself at once public, and private; randomly accessible, yet intensely personalized. In ways that we may only just be beginning to understand and analyze, the internet may be re-mixing our *non-virtual* social/selves in ways which we are only just becoming able to discern. Virtual leisure industries could prove to be not those anti-social "retreats" from "the real" which initial cultural responses claimed; cul-de-sacs of cultural inertia, retrogressive social formation; frenetic but unproductive labor; but instead co-drivers of newly emergent sociabilities, activities, and identities. In the field of digitized sport, a number of Formula One Grand Prix drivers have already confessed that they cruise the next-day's race circuit on the game simulators, to practice the curves and tactics of the track. Perhaps, Florian Brody's "Internet Eisenstein", the creative genius to take us to the next level in virtual image creation, will be an online pornographer. *Game on!*

Finally, one note of advice for those considering inclusion of pornography sites and materials in courses of Internet Study, or for specialist study of VLIs: given the contentious nature of this particular industry, and the many possible responses to the idea of pornography within modern societies, it is necessary to consider the ethics of the use of such topics inside educational materials and curriculum.

As with racist or terrorist websites visited for the study of online practices, your online visit to a sex site will probably be recorded by that site, and possibly used to justify the "popularity" and so validity of the site's views and practices.

Visits may also incur unsolicited "push" materials sent to your e-mail and websites, and this is often very difficult to block or remove.

And both you and your students or co-researchers will have your visits to such sites noted by at least your institution's systems operators—and you may be called to account for them.

The solution to at least this latter problem is to pre-warn of these possibilities, and to provide something akin to the following statement:

Note: this section of the course/research is entirely optional.

If you are likely to find the study of sexually explicit materials offensive, you may disregard this section—without penalty, either in assessment, or in coverage of the course/research project. There are other sections of the course to choose from.

While there is nothing in the course materials provided here which is likely to offend, it is entirely possible, in fact highly probable, that those who wish to study this topic will perform online searches, download files and access sites which will, either deliberately or accidentally, include *explicit sexual material at many levels of acceptability. Searches in this area are notorious for attracting inappropriate links. For these reasons, those who choose this topic should prepare by alerting their lecturer/supervisor to their topic theme.*

On no account may students/researchers use open, public University computer labs or Library terminals for searching or downloading material for this topic. A closed lab is available, with private printer, so that others may not be accidentally exposed to what they might consider offensive materials. Students/researchers should also consider taking similar steps to protect family members or housemates if they are researching at home or in halls of residence. Terminals in the closed lab are registered with University systems operators, who are aware that this section of our course exists. Use of other terminals in the University for such searches and downloads will be noted and monitored, including use of dial-in facilities, and the University's protective arrangements to prevent unethical practices may be evoked.

Please do not attempt to evade these provisions. The University is currently prepared to permit serious study of these matters. Abuse of this status in any way or at any level, could mean that permission will be withdrawn.

Perhaps, the final mark of maturity in assessing the development of virtual leisure industries will be whether as online culture develops, such statements of ethical concern—online "self-protective" behaviors—become more, or less, of a concern.

ENDNOTES

1. See for instance ongoing academic discussion of direct Australian media attacks on those topics within funded and doctoral research in Australian universities, which center on popular media content and/or leisure pastimes, at www.csaa.com.au.
2. In Australia, the 1994 Federal Government policy document *Creative Nation* attempted just such an exposition of how new digital media could help to re-configure the role of media more broadly, operating as an integrator for the streaming of popular cultural content into a wide range of production and consumer uses. Similar policy frameworks were proposed, and some implemented, around the industrialized world See however Goggin and Lovink (2004), for a discussion of how politics destroyed this scenario within Australia, between 1996 and 2004.
3. Despite the much-reported Asian economic "meltdown" of the late 1990s (see Castells, 1998 for a pre-crisis account of where key Asian economies had been heading with their "new economy" planning) at least the

central nation–states and economic zones (Singapore, Malaysia, India—Bangalore, China—Shenzhen, Korea, and especially China-Hong Kong), are back on track in relation to their development of online economic activity. See for instance a wide range of new Hong Kong based research publication relating to Hong Kong new-media culture, produced by Hong Kong University Press (available in English).

4. Consider for instance ongoing developments within mobile telephony as it increases the range of internet-based services packaged into small mobile hand-helds or hands-free devices. The very mobility which has motivated their rapid uptake has created a seemingly never-ending series of moral-panic social debates over what is, or is not, acceptable public use of this very "personalized" form of communications access. A range of regulatory technologies has accompanied these debates: from auto-cancel devices to block mobile phone signals in theatres, to use of GPS chips in mobile phones as a personal back-up for maritime rescue services. Somewhere behind each of these arises a new-economy industry.
5. It is interesting to examine the impact Internet Studies has exerted upon previously disregarded and under-studied forms of communication technology, such as telephony and talk-radio. It is as if the sudden irruption of internet technologies into the social re-ordered the entire communications universe, introducing not only a new critical lexis, but also an apparatus of research infrastructure which has extended to older forms as well as new ones.
6. Annanova is still providing a news service—albeit tabloidesque and celebrity-centered—at www.annanova.com. William Gibson's 1996 novel concerns the "marriage" of a digital-simulant—in Japanese an "idol" or "idoru"—to a living celebrity—among other new-media directed activities. Japanese anime is noted for its view of the cyborg as a networked sentient entity, informational in nature, rather than robotic, heroic and personalized, as in the Hollywood version. For a discussion of this see Claudia Springer, *Electronic Eros.* For a Japanese anime with English soundtrack centered on cyborg issues, see especially Masamune Shirow's *Ghost in the shell* sequence.
7. While I have some problems with the "great men of history" view behind such a comment, it does signal very powerfully the adaptive and appropriative phase new media design is largely still in.
8. In Australia, where Easter Bunny figures are problematic given the status of the rabbit as a major agricultural pest, there have been recent moves to select an alternative marsupial figure in the confectionary business. See the South Australian Haigh chocolate-producer site for a view of the "Easter Bilby".
9. See Flew (2005) for an account of the theorization, policy development, and industrial innovation behind the re-organization of media and content production and commerce around this notion.

Chapter 37: Education, Gaming, and Serious Play

SUZANNE DE CASTELL AND JENNIFER JENSON
Simon Fraser University, York University

1. INTRODUCTION

Attention is a critically important consideration in the design and development of virtual environments for learning, in fact, their very existence depends upon it. Unlike the independent reality of material classrooms and teachers and textbooks, virtual educational realities must address learner attention as an essential condition of their functioning. For just as digital texts are "written" only as they are read—appearing as readable text only when users scroll through them—so for virtual knowledge-artifacts, their very existence is conditional upon user attention. In this respect, a virtual tree falling in a digital forest is not at all like a real tree falling in a real forest. The latter, we may at least argue, still makes a resounding crash, whereas the former's silence makes the virtual tree no tree at all—neither sound nor forest nor tree itself comes to "life" until some user activates the would-be event with eyes to see and ears to hear.

An information society, a society in which information is designated the primary commodity to be produced, marketed, and consumed, has attention as its primary currency. Education has always sought to cultivate a "knowledge society", and has therefore always had attention as its primary currency: In this respect, if in no other, education is a step ahead in the "information society" game, having given considerable thought and paid considerable attention to the culture and management of attention. In schools, attention, both of students and by their teachers has been "traded" for marks, for disciplinary action, for praise. It is captured and held by compulsory schooling laws and, more traditionally, by fear—fear of failure, fear of corporal punishment, and fear of disapproval. And Teachers typically positioned themselves as the center of attention, at the front of the class, "all eyes forward", and as the central figure in the distribution of information (text books, worksheets, library) and knowledge (subject matter).

Today, attention in schools is altered by political and technological conditions which have disrupted the traditional distribution of "information" and thereby knowledge, where, at least in schools, the role of the teacher has been central. As well, there has been a pervasive cultural shift toward progressive, "learner-centered", and more recently constructivist orientations to education. The norms and their legitimating principles which once regulated a stable universe of authoritative texts and authoritative teachers are losing their

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 999–1018.

hold on public sentiment about education. Structures of perceiving, thinking and feeling which kept students attentive to teachers, tests and texts are being challenged directly (students attend—as they always have—to something other than the teacher, writing notes, sending text messages, making faces at each other, staring out the window) and more and more indirectly through popular cultural media, which satirize and/or disregard all together the importance of "paying attention" in school.

What is different is children's sense of entitlement: Whereas under earlier conditions, students had to earn, to merit, to "deserve" their teachers attention, nowadays increasingly today the tables are turning; it is the teacher who must earn or "deserve" the attention of her students—or they will turn it elsewhere. Further destabilizing authority relations between teachers and students, new technologies have afforded children far greater power and therefore far greater choice in what they can see, think and do, because now their attention, as we seem to like to say, "adds value". Under conditions of massive information surplus and saturation, attention acquires its own independent worth. As education's monopoly over credentialism is broken, from outside but also very much embraced by schools and universities, terms of value between private and previously public sectors increasingly converge. Children take economic control with political consequences: whereas children's rights had always been grounded in age-restricted legal rights, an attentional economy has no "age of majority", and children are enfranchised as full citizens the moment they gain access to the global mass media industry already actively working to attract their attention. Culturally, children's frames of perception and significance are being (re)formed by entertainment-oriented media driven by a global advertising system, as it seeks to capture and to hold their attention.

Children, quite literally, *pay* their attention to new multimodal tools, which undermine singular modes (like text) so completely that even technologies like the telephone, once tied to boxes and switches, have broken free both materially and symbolically: Cell phones disengage users from wires, and phones are no longer just for verbal communication but for textual. When we pay attention (as we talk on the phone, for example), we may often be "multitasking" (chatting on the computer and/or watching a movie and/or playing a game). The school's traditional forms of authority to command student attention, along "uni-modal", text-based lines, offer diminishing returns to both teachers and students in such an economy: The technologically supported transformations of both individual and collective attentional structures towards multimodality and multitasking impacts most profoundly on youth, who have never known the text-bound world from which their elders have come.

What we argue in this piece is that the technological infrastructure of the new economy brings in its wake an unprecedented challenge to formal education's traditional monopoly over the mass-scale acculturation of youth: A new "*attentional* economy" in which anyone, adult or child, with "access" (to television, movies, advertising, and computer games, but above all, the internet) owns and controls a full economic share of her/his own attention. Education, which has always been in the business of capturing and holding attention, has sustained serious blows to its capabilities as core values, along with traditional tools, means and purposes have been progressively troubled, destabilized, and finally unseated by new literacies, digital epistemologies. Complexly, a corporate-owned, profit-driven means of educational production transplanted to the heart of the public school: Networked digital technologies of construction, representation, expression and communication.

One powerful result of this new attentional economy and its attendant but very real increase in children's rights, freedoms, and powers has been the ability—and the notable success—of popular culture to school a mass audience in patterns and practices of consumption, which has had economic consequences in the evolution of a mass entertainment industry extending deeply into every aspect of children's (and their teachers') lives. This collision of the hitherto relatively disconnected spheres of education and entertainment has changed how both teachers and students can "do" schooling.

2. VIDEO GAMES AND POPULAR CULTURE

Very much unlike children before them, students at school today have grown up with structures of meaning and of feeling defined by global and local commercial advertising systems and delivered through corporate-controlled communication networks. Even very young children, for example, enjoy and find significance and identity in commercial products and commercialized activities of consumption, and are indeed seen as their own "market" in North American, capitalist economies. At the same time, vastly increased attentional demands on parents, as boundaries between labor and leisure erode and work intrudes into "private" life, means children are growing up with diminishing parental time—a consideration which ought to challenge received understandings of the home as the site of primary socialization. Moreover, for many children today, population density and unstable patterns of "community" growth mean increased dangers and diminishing physical space for embodied, non-virtual play, particularly for boys (Jenkins, 1998).

So for children, if not also for teachers, there is little worthwhile that is left of the traditional separation between education and entertainment. Incontrovertible is the fact that video games have been the most successful medium at grabbing the attention of millions of young men and boys and some girls and women, worldwide (cf. Gee, 2003; Kent, 2001; King, 2002; Poole, 2000.

We therefore see it as valuable to consider what may be learned from a study of computer games as virtual learning environments, and from looking, in particular, at emerging structures and forms of attention within computer-based play to consider their implications for new structures of knowledge. This is a perspective which sees educational promise in computer gaming for "serious play" (de Castell & Jenson, 2003; Reiber, 1996). A cultural form highly successful at attracting and maintaining human attention, commercial gaming's spectacular success may have much to tell us about developing, gaining and keeping audiences both engaged and immersed. Important, too, under conditions of diminished external control and increasingly self-regulated and "voluntary" attention is figuring out how games frame information so that it engages players' attention in ways that give pleasure. What conceptions of learning, and what contents and practices of teaching and learning, do entertainment-oriented computer games appear to have?

In educational contexts, as learning continues to migrate from teachers, texts and classrooms to virtual interactions regulated by learners, there is a need to create learning resources capable of attracting and equipping novices with basic operating skills to mobilize program content, and of motivating and supporting for experienced users the kind of sustained learner engagement required to pursue demanding and sophisticated intellectual activity. To learn more about attracting, capturing, and holding the attention of multimodal, fast-paced, and interactive media, we are likely to learn most from the best tool digital technologies have thus far developed possessing both of these properties: Computer-based gaming.

Studies of teaching and learning in the "new information economy" pay increasing attention to computer-based gaming not least because this field represents the area of greatest financial investment in multimedia design and development. The return on that investment is that state-of-the-art games today embody the most sophisticated technology, and the most fully developed applications of programmers capabilities, that we are available in the public domain. These resources enable games to support a thriving network of users, many of these children/youth, making gaming today's most successful and widest-reaching global subculture, one which comes closer to a "virtual community" than any other "cyberculture" to date.

Gaming's ability to generate a culture which immerses and fully absorbs its participants makes it threatening to many parents and teachers. And in many ways, it is. Today, For example, as a direct result of the proliferation of digital technologies in education, in work and in social life, children in the same physical spaces inhabit different worlds from their parents, speak in new languages, write in new forms, and communicate using media in ways and for purposes their parents can scarcely comprehend. Understandable as a repudiation of computer gaming may be, however, the benefits to education of engaging with and learning from commercial gaming's phenomenal success, popularity, *and effectiveness as a learning environment*, might far outweigh the benefits of attempting myopically to ignore or suppress it, something which is in any case unlikely to succeed in the longer term.

The rich potentials of learning from games and play are of course by no means entirely unrecognized in education which has, however, largely reserved play-based approaches to teaching for the child's earliest years of schooling. For the most part, and for many teachers and parents, playing is the *opposite* of "school", and it's probably safe to say that few teachers would embrace the idea that game-based learning offers a useful and appropriate medium for their students[1]. Supporting a devaluation of play (as "distraction"), or its relegation to the child's earliest years and to non-significant content, other educational uses of gaming and play have limited its role to an extrinsic-motivational one. Any sustained attempt to grasp the profound epistemic and socio-cultural significance of play is rare. In industry, though, corporate trainers have been quick to capitalize on these new possibilities, as evidenced by the burgeoning digital game-based learning for the workplace (Prensky, 2001).

However, educational theory and research has only very recently (Gee, 2003) begun to explore what education may have to learn from the successes of entertainment oriented commercial game development about how to engage and "immerse" people in a virtual universe which develops, through play, both psychomotor skills, and a host of analytic processes, including socio-cognitive attitudes and understandings. Currently, these processes are most commonly being engaged in by men and boys: As has been repeatedly observed (Cassell & Jenkins, 1998: 14) boys' early and continued involvement with gaming has been a key factor contributing to their greater interest in and competence/confidence with new technologies. This early gaming experience amounts to a "head start" for boys which accrues incrementally for the duration of schooling and beyond, such that we continue to see a dramatic and indeed an increasing under-representation of women in computer/technology focused subjects and fields.[2]

So it needs stressing that commercially based entertainment oriented gaming, for all its technological sophistication and cultural power, has been and continues to be inhospitable to women and girls, and proclamations[3] of gaming's "virtual equality" which identify the largest percentage of gamers as adult single women depend on our ignoring the vast differences between playing solitaire "online" and playing Everquest. As soon as we look at differences in computer-based play by gender, it's clear that the vast majority of women and girls remain at best marginal participants in gaming activities as well as in gaming's larger cultures. To look to computer-based gaming for new means of re-tooling public education's knowledge production, representation and dissemination possibilities, *without* taking gender seriously into account is to compound girls' disadvantage with respect to developing competence and confidence with new technologies, a consideration worth returning to.

3. THE ECONOMICS OF ATTENTION

A key to gaming's spectacular success has been its savvy engagement with and its ability to map absorbing and pleasurable activity on to the new structures and functions of attention being taught to youthful consumers for attending to and interacting with information and experience in multimediated virtual environments.

While principles of the economics of attention were initially formulated several years ago by Canadian psychologist Walter Thorngate (Thorngate, 1988, 1990, 1997; Thorngate & Bagherian, 1999), the concept of attentional economy has been further and differently elucidated within contexts of economics, business, rhetoric, and education, each of which helps to map out a significant dimension of this construct. It should be noted, however, that much of the work seems much less oriented to education than to advertising, business and entertainment contexts and that, when and if it is taken up and used as a construct relevant to the field of education, concepts and theories of attentional economy need to be developed more specifically with that field in view, not merely "imported" and unproblematically related.

Writing for a corporate/business audience, Michael Goldhaber's analysis sees attention as indexical to originality, and prophesies a replacement of monetary economies by attentional economies. He writes,

> . . . attention can ground an economy because it is a fundamental human desire and is intrinsically, unavoidably scarce . . . . We search for meaning in our lives especially once pure material needs are already given to us with little effort on our part. Why are we here, and how do we know that we are somehow worthwhile? If a person feels utterly ignored by those around her, she is unlikely to feel that her life has much meaning to them, and since all meaning ultimately is conferred by society, one must have the attention of others if there is to be any chance that one's life is meaningful.
>
> (Goldhaber, 1997: 2)

A flaw in this argument is of course that while many people may indeed crave unlimited or at least large amounts of other peoples' attention, by no means everybody does, even in a culture such as ours in which we have been taught that attention-seeking is perfectly acceptable and in fact a highly pragmatic disposition for an entrepreneurial, self-promotional employment culture. From Greta Garbo to Harry Potter, personalities both real and imaginary have begged to be left alone. Possibly it is true for business ventures that they crave maximum attention of maximum numbers of people, in which case it is an odd choice to construe this desire as a deep-seated *psychological* need. Whatever the case, the presumption is false, as indeed is Goldhaber's reciprocity thesis: In order to get attention, you have to pay attention. This principle supports his idea that what we all have to learn is how to give "illusory attention", making others believe we are giving them fair attentional exchange, so they will give us theirs. However a number of culturally significant practices absolutely depend upon assymterical attentional relations, most obviously sabotage, surveillance, stalking, "intelligence" and so on, in all of which it is critical that one pay attention without having attention "paid back". Interestingly, this analysis, proposed as having economic implications concerned with innovation, again grounds its understanding of economies of attention in the fundamentally psychological terms of the emotional needs of persons for recognition.

It follows from his essentially psychologistic way of looking at the matter that, for Goldhaber, "The limits on real attention per capita are absolute" (Goldhaber, 1998, n.p.). This "zero-sum" viewpoint is shared by fellow attentional economist, Thomas Davenport, who explains that " … though information continues to grow, attention remains a fixed resource, simply because to 'pay' attention is to 'spend' time and nature does not expand lifetime to fill the information available. The result is an attentional economy in which attention is exchanged for the production and consumption of information and in which an abundance of information creates a buyer's market" (Davenport, 2001, n.p.).

Although real "lived" or "embodied" time is certainly a fixed resource, Herb Simon's oft-cited argument about the dramatically altered ratio of information to attention under conditions of information proliferation ("infoglut") can be read two ways. Simon argues that "What information consumes is … the attention of its recipients. Hence a wealth of information creates a poverty of attention" (Simon, in Lankshear & Knobel, 2003: 109). On one view, the poverty information creates is a poverty of attention as intersubjective recognition; on the other view, a glut of information creates a poverty of intellectual engagement. The differences between intersubjective recognition and intellectual engagement prove to be, educationally, very significant indeed.

In the first place, even though there is a dramatic drop in the relative amount of attention *vis-a-vis* information, and an absolute limit to human lived/experiential time, it by no means follows, as the "intersubjective recognition" view of attention supposes, that while "The size of the attention pie can grow as more and more people join the world audience … the size of the average slice can't … [and that] the total available attention per capita (per mind) is simply not going to change" (Goldhaber, 1997a, b, n.p.).

Such a view presupposes that "Technology … doesn't alter what human attention is or how it works in any very basic way, but by changing the conditions under which we can give it, and to whom, it alters how it gets distributed and how important it can be for us" (Goldhaber, 1998, n.p.) Granted that much depends here upon what is meant by "basic", it can nevertheless be demonstrated in respect of many contemporary cultural activities—computer gaming prominent among these—that the ways attention is deployed, as well as the subjects and objects of attention, have already altered greatly, and technology has played a substantial role in the ways these changes are occurring and will occur—with real prospects for an enlargement of human information-processing capabilities.

4. MULTITASKING

Born into a culture of information surplus and time scarcity, many young people have developed information management capabilities that often amaze incredulous parents and teachers. Of course it was always true that students, through a kind of "illusory attention"[4], have paid less than their full, focal attention to their teachers, texts and tasks. But now we are seeing, not sub-optimal attention/competence, but in fact highly efficient *and* effective deployments of partial, subsidiary and intermittent attention strategies routinely used by students who have learned to do homework while watching TV and listening to music on headsets—with that homework being done on a computer whose multiple screens are simultaneously at work and play, between internet researching, chat, word, processing, emailing, and online game play, users switching between screens to minimize loss of time wasted waiting for processing, loading, connecting, etc. If we hark back to Phillip Jackson's landmark ethnography of schooling, *Life in Classrooms*, or subsequent similar studies, we can recall the then-sobering observation that what students learn to do most of all at school is wait (Goodlad, 1984; Jackson, 1968). How much more absurd it must seem to today's students that they should spend so much time simply waiting on teachers—and not at all surprising that they often do not. This attentional restructuring has presented particular difficulty for teachers trying to adapt to instruction in computer lab settings: Students at computers do *not* just "wait until the teacher is ready", they do their e-mail or surf or chat or draw. They do not keep their "eyes front", but on their personal screens, as teachers compete with the infinitely engaging capabilities of networked computers.

These are pre-eminently technologies of communication and production, and user agency is an essential constituent in technology enabled learning. Given that, it's interesting that Goldhaber metaphorically construes intense attention as a species of enslavement. He writes:

> Someone who "enthralls" an audience is in quite a real sense temporarily making the audience members her "thralls"—or, slaves. The very act of paying attention may seem voluntary, but often it is not completely so. There is a definite element of compulsion involved. It's no coincidence that people say things like, "I have to check out that web site," "You've

gotta watch that show," or "That book is a must read." And each of those activities takes physical as well as mental effort.

(Goldhaber, 1997a, b, n.p.)

On this view, agency drops out, and bewitchment takes over, making this a less than useful conceptual framework for investigating the impact and implications of new attentional economies for education, concerned as it is with how people might be supported in learning how to operate, to manage, channel, conserve and control their own attention as an increasingly required commodity, over which they retain and exercise sovereignty.

5. ATTENDING TO EDUCATION

The above discussion briefly outlined current understandings of attentional economies primarily oriented towards a business audience, and attempted to show the ways in which those analyses break down when applied to education specifically. In this final section, we more fully elucidate what we see to be the *educational* implications of an analysis of attentional economy, drawing on the work of Richard Lanham. Here we are most concerned with showing the importance of this analysis for developing a framework for understanding epistemological impacts of new technologies (and their resulting economies) as the field of education struggles generally to "make room" for these new ways of knowing, these "new literacies" for knowledge production, representation and transmission (Gee, 2003; Kress, 2003; Lankshear & Knobel, 2003).

Less "corporate" in its values and orientations and markedly less prophetic in its style is Lanham's analysis of attention economy, whose focus on the epistemic conditions and consequences of attentional economies in an information society makes Lanham's a rather more promising theoretical resource for building an *educational* theory of technology than one focused on psychological needs for recognition.

In a path-breaking paper published in 1994, Lanham construes attention as "the action that turns raw data into something humans can use" (Lanham, 1994, n.p.), and he proposes that under conditions of information "saturation" the work of human attention is primarily enframing, selecting and organizing from the vast stores of available "raw data" those elements which enable the movement from information to knowledge, to understanding, to, in his terms, "wisdom". Echoing educator A. N. Whitehead's critique of "inert" knowledge, Lanham points to the tendency, in a so-called "information economy", for the accumulation of fundamentally meaningless and useless data in repositories whose only purpose is collection, urging and elucidating the kind of intellectual work needed to make information meaningful.

Lanham's later work (Lanham, 2001) develops a rhetorical theory of attentional economy that demonstrates how digital technologies, far from installing a new framework for the operation of human attention, have in fact enabled a return to older, pre-literate attentional practices. New forms of multimedia information display—he gives examples from avionics, in which complex images combined with alphanumeric displays in airplane cockpits, and of CD-Rom versions of books in which an author can appear with, within, and superimposed upon her text to assume multiple roles, not least the hitherto quite separate roles of author and critic simultaneously—mean that "Text is being put back into three-dimensional space" (Lanham, 2001, n.p.). "Text", he explains, "seeks to monopolize our attention" (Lanham, 2001, n.p.). In Lanham's view, new multimodally grounded attentional structures break up the attentional monopoly of the text, eliciting a series of bifurcated responses, for example,

> Response to text and its argument vs. response to voice, gesture, clothes, lighting. Response to a fixed two-dimensional space from which the distractions of ordinary 3D behavioral space have been carefully sieved out vs. response to exactly that world of ordinary 3D behavioral space that floods the margin when Prof. Minsky [the author, in Lanham's CD rom-book example;] is allowed out of his box. Two different kinds of space, 2D symbolic vs. 3D behavioral . . . contend often in the attention structures through which digital text is finding its way.
>
> (Lanham, 2001, n.p.)

These new attention structures are what reinstate the rich rhetorical traditions, suppressed and rendered unconscious by text-based attentional demands, back into our cognitive repertoire. As Lanham points out, "The expanded palette of textual display offered by digital expression again and again pulls us back into the history of Western notation. The whole weight of these alternative display modes recaptures this history instead of, as the media prophets of doom argue, repudiating it" (Lanham, 2001, n.p.).

To further explain the reductiveness of the two-dimensional symbolic space of textually oriented attention versus the three-dimensional behavioral space of attention to multimodal representational forms, Lanham invokes arguments by Hellenist Eric Havelock about the ways this reduced alphabetic notation, the form of notation which has reigned supreme over all others so far as modern education is concerned, functions to render us less rather than more conscious of our informational environment, excluding as it does all manner of semiotic modes and messages—and their "play"—in favor of a literal, "logocentric" approach to knowledge and experience (see for example, Derrida, 1978). Echoing Havelock, Lanham explains, "the Greek alphabet underwrote Western literacy because it was simple enough to learn in early youth, and thus to internalize totally. It became transparent to the conceptual arguments it set forth. The letters themselves, bleached by the very force of thought, lost their visual content. In serious, genuinely literate reading, they had no calligraphic power, *never* made you think about them at all (Lanham, 2001, n.p.)". For Havelock, this paradigmatic cultural shift from orality to literacy was greatly facilitated by the alphabet's easy internalization, since the less consciousness needed to be paid to the tools and means of communication, representation, and expression, the more attention could be paid to its contents. Culturally, this "reorientation of the sensorium" (Ong, 1982) from medium to message (McLuhan, 1964) enabled an explosive growth in the production and transmission of knowledge. Relieved of the burden of attending to form—a necessity for ease of memorization and recollection in cultures without writing—and with cultural knowledge now able to be preserved in written form, human intelligence was "freed up" as intellectual resources were increasingly diverted from memorization to knowledge creation. Written language allowed the preservation, and thence the criticism and growth of knowledge (Goody, 1977).

Modernist education has embraced these new capabilities afforded through text-based literacy: Post-modern education begins to detect certain limitations. Lanham sees this easy internalization of alphabetic literacy as effecting a repression of our consciousness of the reductiveness of text, a reductiveness inevitable in the epistemic shift from 3D to 2D perceptual frames. Confounded by our cultural reliance upon texts and writing as vehicles for knowledge, we have been unable until recently clearly to perceive that, as Lanham puts it, "The history of Western alphabetical notation has constituted one long flight from such self-consciousness" (Lanham, 2001, n.p.). An important loss here is both the vast repertoire of communicative tools and supports afforded by situated human embodiment and, with that, the loss of any reflective consciousness of the ways that a choice of text as the means of representing the world represents a decision to misrepresent it. Like all rhetorical decisions, this choice, if consciously apprehended, has ethical and not just communicative implications, a point of some significance in considering educational conceptions of attentional economy.

Far from diminishing our traditionally text-driven intellectual accomplishments and abilities, new multimodal technologies of representation, Lanham suggests, can actually consolidate, extend and improve upon our literate capabilities. For, Lanham continues, "The alphabet in digital 3D space returns us to the world Havelock dismissed. It *makes us think*. We ask, for a start, questions that never occur to us in conventional reading . . . . How does spatial awareness work as the fundamental reading skill in this kind of literacy? What architectural disciplines are needed to illuminate such an expressive field? To what expressive ends might such a notational space work?" (Lanham, 2001, n.p.). These are questions suppressed by our literate biases, questions which have become increasingly important as education finds itself having to work with media around, over and above the alphabetic text (for recent discussions on the importance of a multimodal literacy see Alvermann, 2002; Gee, 2003; Kress, 2003; Lankshear & Knobel, 2003.

Lanham's proposal for rhetorical analysis of attentional economy is thus a proposal for more self-conscious, accountable and ethical communicative practice, and we argue that his is an approach to understanding the new attentional economy more salient to education than the alternative economistic and psychologistic models characterized earlier, because it stresses, as both a cognitive and implicitly also as an ethical imperative, the need to *think*, to engage "mentally", as we like to say, with both information and the medium of its transference.

Education's ideological allegiance to "intellectual engagement" as a central human value and as a formative and transformative force for the flourishing of both cultures and individuals is what distinguishes education from schooled consumption. Its imperatives are not oriented towards recognition of individuals except as their development can be grounded in and potentially contributory to the advancement of human knowledge, and attention, on such a view, is an intellectual, not an emotional need and value.

6. EDUCATIONAL IMPLICATIONS OF AN ATTENTIONAL ECONOMY ANALYSIS

This is not, or not yet, the way attentional economy has been elucidated in educational contexts. Lankshear and Knobel's (2002, 2003) extensive consideration of the consequences of digitization for a thorough rethinking of epistemology (a rethinking, they explain, of knowledge, knowers, processes of coming to know, and the relative importance of knowledge-forms) offers a detailed, thoughtful and provocative look at the very different ways the school's traditional attentional economy is managed by students and teachers, and how attentional economy is reconfigured with emerging ways of managing attention under new technological conditions. In their characterization of alternative conceptions of attentional economy, they note that "These differences will result in varying implications for formal education" (Lankshear & Knobel, 2002: 20).

Concentrating, in particular, on how Lanham's perspective differs from Goldhaber's, Lankshear and Knobel rightly conclude that "Rather than focusing on how to gain and maintain attention, Lanham is concerned with how to facilitate or enable attention to data by developing new attention structures for attending to the flood of information-as-data that we face constantly" (2002: 24). However, given the choice between a focus on attracting and a focus on structuring attention, theirs is an analysis which privileges the former, recognition-oriented conception, centered on "paying, attracting and maintaining attention" (2002: 20), rather than Lanham's epistemic conception of intellectual engagement in the creation of post-literate forms and structures of attention. Important to notice here is attention's very different object: In illustrating the role of technological literacies in transforming school-based attentional economies, Lankshear and Knobel report with approval how the boys in their classroom-based study of new technological literacies succeeded in attracting and maintaining their teacher's attention, something they had been unable to do in traditional text-based lessons. But in this elucidation of the transition from privileging propositional knowledge to privileging performance and production, the authors unwittingly neglected any consideration of the intellectual values of such an accomplishment. We are left asking what, besides gaining the fuller attention of their teacher, has this performance-oriented pedagogy actually enabled for other than besides a stronger sense of their own agency?

While agreeing entirely with Lankshear and Knobel that "schools ought to be paying more attention to attention" (2002: 37), and that this challenge entails taking seriously into account a range of "new literacies", we would urge a different road from theirs, and argue that a concentration on those "new literacies" which create opportunities for gaining and maintaining attention, is had at the cost of a relative neglect of those that frame and structure attention. This is a viewpoint which, while important and illuminating, is not *educationally* sufficient and it may be that we do better to build upon Lanham's analysis of attentional economy if we hope to get at specifically *educational* ends. For what Lanham's analysis would have us do, by contrast, is to re-focus the boys' attention, not on themselves (something many boys are already very accomplished at doing in classroom settings), but on their work, on the organization of their own doing and thinking and learning. Lankshear and Knobel, while offering a thorough and useful account of both[5] viewpoints on attentional economy, in their own analysis subsequently leave Lanham trailing behind; they themselves proceed to follow Goldhaber (1997a, b) in construing social relations within an attentional economy in terms of "Fans versus Stars", "winners and losers" and "insiders versus outsiders". Lanham's alternative view, which doesn't presume a finite quantity of attention in a zero-sum game, offers, by contrast, a more "democratic" scenario in which any individual's own attentional capabilities can and must get refined, enlarged, reconstrued in the process of learning, significantly including processes of technologically re-mediated learning.

Aligning with an economistic perspective which seeks to bring teachers up to date with what youth know, can do, and will be required to do beyond school, while salutary in its practicality, can thus be seen to be partial at best as an analysis of attentional economy with educational significance. For as much as we might want and need to attend to mass media, new cultural forms, globalized economies, and the like, education, (if not, of course, actual "schooling") should got to involve more and other than that. Finally, there is nothing particularly impressive about four boys arranging scheduling to give a class help in learning technology skills (Lankshear and Knobel's main illustration of what the boys accomplished). We may presume that far more went on than this, educationally, for these four boys and yet we learn little of what that was, as if attracting and maintaining attention were an end in itself.

It maybe be so in many arenas of contemporary cultural life, but it is not so in education.

If this critique is justified, then it is to a consideration of new forms, frames, organizations, and structures for attention that we should turn in considering what a theory of attentional economy has to say to education. And, funnily enough, this brings us squarely back to gaming as exemplary of the ways new attentional structures are at work in play, where, as in education, the concern is far more with absorption, immersion, and the payoff of one's own attentional efforts in a maximally efficient assimilation of new knowledge, new skills, and new ways of thinking, than with gaining and keeping the attention of other people.

7. PLAYING ATTENTION: THE EDUCATIVE POSSIBLITIES OF VIDEO GAMES

By way of concluding, we will briefly outline here how we view the ways in which video games capture and hold the attention of their players as pivotal for attempting to begin to theorize the impact of new technologies on structures and forms of knowledge, including the resulting destabilization of text as the primary communicative medium. In the past, texts held our attention as a kind of "conduit" for imaginative expression, news, personal feelings, documentation, religion, and argumentation, among many other things. Today, all sorts of "media" compete for our attention: Think here of the popularity of *Harry Potter* which is not simply generated by mass-scale excitement about serial children's books, but the "spin off" toys, candies, movies and video games—Harry has our attention *outside* of the text in ways Madame Bovary never could imagine. In schools and in classrooms, our attention is no less bifurcated, no less hybridized, and yet, in those places, text is still precariously perched as the dominant medium of expression, and this is in direct conflict with knowledge and experience of the "real world" in which textual sovereignty is no longer the case. This conflict creates new tensions in classrooms, tensions that we argue are related directly to new economies of attention in those places. While it would be inaccurate, for example, to describe the teacher and/or the curriculum as ever having held the full attention of students or those who were meant to attend to it, it was most often the will of the students to "pay attention" to both. But in our new Western cultures which have been radically and rapidly transformed by technological advances, ideological, cultural, and economic change, and resulting widely available and easily harnessed access to "information", our attention has "value" in ways it never did, as a kind of "commodity" which holds not just intellectual worth, but economic worth as well.

In economic terms, video games now capture more money and presumably more of our attention than the film industry. We would follow Lanham in pursuing a theory of attentional economy in which attention is directly related to intelligence, as it is when and where attention is "paid" that intelligence is mobilized in whatever forms that might take. In video games, the attention of the player is central: She must first *choose* to play, and then, once playing, the game encourages her to continue to play through both sophisticated and simplistic reward structures which help her to *learn quickly*. Finally, the game itself, its environment, its tasks, puzzles, quests, its rewards, need to have some kind of *contextual meaning* which continues to capture the attention of the player beyond the manual skills required to be successful at the game. The player has agency, and, in more than a trivial sense, significant meanings have "play" (de Castell & Jenson, 2003; Derrida, 1978). These devices, among others, are part of the reason why video games are so successful at capturing and holding the attention of their players, and here we'll show what education might "learn" from the attentional structures of video games. We focus, thereby, on the following in education: Pleasure, choice, and immersion; speed and efficiency of learning; and finally, meaningfulness of topic, subject matter, and experience.

In what is still considered a "radical" treatise on education, Jacques Ranciere considers what might happen to education if we assumed that intelligence is *not* something which one individual has more or less of and that, in fact, everyone is equally intelligent, given how widely distributed is humanity's capacities to put their mind, intellect, effort, and attention to accomplishing their various goals. The implications of this argument are that everyone is *capable* of learning whatever they put their minds to, without the "aid" of an instructor, tutor or institution and that their *choice* in what they learn is key to their realizing their goal, which is simultaneously pleasurable (something the will actively wants to accomplish and does) and immersive (the problem is engaged with behaviorally, not merely symbolically, and so it is engaged viscerally and/or cerebrally and/or emotionally). In the first 12 years which mark compulsory schooling in North America, "choice" is parceled out in the later grades in terms of choosing among a limited range of available subjects, and even there, as in all other subject-based learning throughout all the grade levels, there is little if ever "choice" about what to focus on in any given day, and rarely time given to any task without interruption from the teacher, other students, or the institution which rings a bell to move to the next class or subject.[6] It is no wonder then, given the "real world" importance (and economies) attached to their attention that the attention of students in schools is becoming increasingly difficult to attract and hold. This is not to say (as Ranciere argued) that students should only study what they choose to, but that until now, schools have somewhat successfully monopolized student's attention, but because under contemporary conditions structures and forms of knowledge have shifted, so too have the "terms of engagement". Lankshear and Knobel (2003), for example, quote one of the boys in their study we mentioned above as choosing not to attend to school work when he is unable to solve a problem, but instead to focus his attention on the music he likes to listen to: "Mr Y . . . . just tells me to sit there and do nothing if I don't know how to do it. So I just sit there and get my Walkman out . . . " (p. 203). Here, the choice is to "do nothing" or to do something which is usually pleasurable (listening to music) in the absence of being helped or of being attended to, meantime, the student's learning is "on hold" while he waits for his teacher.

Video games, as James Gee (2003) has recently chronicled, are extremely adept at helping their players "learn" quickly. Schools and teachers, by contrast, as the above quote implies, are notoriously poor at facilitating and/or enabling learning which does not follow the prescribed curricular rate of achievement—don't learn too quickly or you will be bored or asked not to participate, and don't learn too slowly or you'll be quarantined from the rest of the class to "make up" the work. That everyone is equally intelligent (à la Ranciere) and that each and everyone of us "learn" at whatever rate we are able given shifting constraints like time, attention to the task, experience, interest, etc. is, in a way, precisely what video games do presume—that anyone who plays the game can learn to fight, to drive, to jump, etc. so that variation in ability is, more than anything, a byproduct of time spent within the game's structures, that is in the acquisition of skills and "intelligence" particularly as it relates to the game, and decidedly *not* to some extrinsic standard or notion of what it means to be "intelligent". This is very different than school-based assumptions of learning and "intelligence": There the standards are always "outside" and performance, competence and skills, to be found "inside" learners whose "talents" and whose "intelligence" are already largely pre-determined, are judged based on "models" and "standards" that even teachers themselves claim to have neither a "stake" in nor "control over". What we see represented in video games, therefore, is the fundamental principle at work in Lanham's analysis of attentional economy: That intelligence is *always adverbial to attentive action* (Ryle, 1949).

Finally, video games, as implied in the above discussion on learning, embed skills, tasks, narrative structures and even "learning" within the environment of game, and each is seen as part of the "play" of the game, which means each is especially relevant to the context of the game more generally. Steven Poole (2000), author of *Trigger Happy*, a book on video game playing, puts it this way: "A well-designed videogame . . . can approach the condition of a work of art simply by virtue of the way such rich, protean transformations in the game's very structure are linked together for the gameplayer's pleasure" (p. 176). So the structures of the game are predicated not only on whether or not they are relevant, but also on whether or not they are "pleasurable". In education, pleasure, as we have said, does not figure prominently, and neither, we would argue, does relevancy or context. Schools and governmental policies still prioritize (in print), and teachers still enforce in practice, a kind of "old-fashioned", text-only literacy (Luke, 2002), despite well-worn arguments and new theorizations which have taken the term to mean much more than reading and writing text (for a recent discussion see Kress, 2003).

How relevant is it, then, given a multimodal literate context, that a teacher of English would worry that her students were using "internet" spelling/s in their journals and fret about whether or not they knew how to spell the words "correctly"—even though she acknowledged that those words were "spelled correctly" for the environment of internet chat? What does it mean to the students in her class that she "outlawed" that kind of spelling, even in their personal writing, because it was "wrong", even though that is certainly not the case outside of school? It seems ever more important to have an attentional economy which reaches within school walls to make all the more careful connections between "what is taught" and "how that relates to the world" than it ever did in the past, as it is also very much the case that our students will not attend to it; there are just far too many other things to which they have both the power and the right to turn their attention.

As long as education still claims to be "in the business" of the intellect, then we would argue that we need to turn our efforts to finding ways of better supporting that kind of playful engagement with what it is we want to "teach" which presumes and engages intelligence, and which enriches and extends the now-impoverished literalness of schooled literacy to recapture for our instruction—as well as for our delight—the deep and rich fields of play, both semantic and semiotic. These are fields which modernist schooling's narrowly textual preferences have so readily abandoned in the name of "standards, pre-specified "learning outcomes", and myopic visions of "educational accountability", which have far more to do with counting than educating.

We therefore argue for a kind of engagement in which dynamic, multimodal learning environments are animated by students' deliberate and sustained attention: An engagement which allows for choice and the freedom to be immersed in an intellectual effort without interruption, regulated less by rigid and indifferent learning goals and schedules, and more by learners' own intelligent attention. To develop attention of this educative kind, we look to play to learn.

ACKNOWLEDGEMENTS

An earlier version of this chapter was published in *Educational Theory*. This chapter is partially based on research from a 2-years study of formal and nonformal learning environments, "Charting Emerging Educational Discourses", funded by the Social Sciences and Humanities Research Council of Canada.

ENDNOTES

1. Not that game-based learning offers a useful and appropriate 'motivator' or a 'support' for existing learning goals, but that it offers an environment

and a set of tools to learners, and so armed, it's very likely that they will want to think and to do very different things than the curriculum guide prescribes.

2. As well as being a socio-culturally powerful disincentive to female participation in technology based subjects and fields.
3. One recent case of this kind is The Pew Internet & American Life Project's report, "Let the Games Begin: Gaming technology and entertainment among college students." which found that "women are more likely than men to be regular players of computer and online games—approximately 60% of women compared to 40% men reported this, while about the same number of men and women reported playing video games." Full report available at: http://www.pewinternet.org/reports/toc.asp? Report=93.
4. Goldhaber's term for ways of giving others the impression that one is paying attention to them, when in fact one's attention is directed elsewhere. Goldhaber argues that since giving attention is necessary in order to get attention, we will effectively get more attention that we give only insofar as we can devise convincing forms of "illusory attention".
5. In fact they describe three perspectives, however we take the third drawn from advertizing's concern with gaining consumer attention, to be sufficiently similar to Goldhaber's (1997) to justify treating both within one perspective, that focused on seeking, gaining and maintaining attention. Whether that securing of attention is for individual satisfaction, or whether for corporate gain, seems more a difference of degree than of kind.
6. In this regard we see a possibly very significant difference between pedagogy in non-formal versus formal educative environments. In schools curricular objectives, scoped, sequenced and timetabled, regulate prescriptive attentional economies; in non-formal learning environments, it is more often the learner's attention, its focus and its duration, which shapes the way learning activities are regulated. For more extensive discussion of the centrality of learner's attention in the formation of non-school-based pedagogies, see "Its all happening at the zoo: Attentional economies in non-formal learning environments" (de Castell and Jenson, Forthcoming).

1. INTRODUCTION AND RESEARCH QUESTIONS

The increasing diffusion of learning environments mediated by computers, or Virtual Learning Environments (VLEs) (Wilson, 1996) is a phenomenon of enormous visibility and significance for the society and individuals living in the Information Era.

In the health care context, there is no question that the diffusion of VLEs has profoundly changed education and practice. Medical training on "real" patients is no longer acceptable (Gallagher & Cates, 2004) and there is an increasing demand for simulation-based medical education. Continuing advances in Virtual Reality (VR) technology and computer-based Simulations Devices, available at increasingly low cost have opened new frontiers in teaching since the end of the 20th century.

Disparities in medical information and education are a major determinant of health practice inequities in developing communities. The recent diffusion of the internet[1] is facilitating the creation and circulation of "new" VLEs in the health-care field, that overcome traditional boundaries of "space", "time", and "place". Yet, online learning environments bring along huge opportunities for learning and knowledge exchange among multiple users in remote areas of the world, but also new barriers.

The *validity* of the new internet mediated learning environments has still to be tested, especially for what concerns their ability to: (1) overcome "traditional boundaries" characterizing the learning experience and consequently change medical education and profession and (2) Help educate patients and "health seekers".

2. THEORETICAL BACKGROUND

Several authors in this book have highly contributed to the discussion about the importance of learning in our life, and have shown how our daily experiences and interactions are mediated and located in "learning environments". But what are learning environments?

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1019–1038.

Wilson (1996) defines a "learning environment" as an instructional metaphor, "a place where learners may work together and support each other as they use a variety of tools and information resources in their pursuit of learning goals and problem-solving activities". When this happens, a classroom, a conference, or an operating room become learning environments.

According to previous literature (Ahmad et al., 1998; Jonassen, 1991; Jonassen et al., 1993; Wilson, 1995, 1996) any "learning experience" follows, implicitly or explicitly, two opposing learning models: objectivism and "constructivist". "Objectivism" originates from the behavioral theory, and "constructivism" originates from the cognitive theory. The two models differ profoundly. The Objectivism model assumes that uncritical learners simply absorb facts from the instructor or a source of knowledge. On the contrary, the major assumption of "Constructivism" is that individuals learn better in an information environment where the teacher provides support and individuals discover things themselves rather than receiving directions (Ahmad et al., 1998).

2.1. VLEs—Computer-Mediated Learning Environments

Following a constructivism theoretical approach Wilson defines the VLEs as "computer-based learning environments" (1996).

Online, the "traditional boundaries", historically characterizing the learning experience, are overcome. When VLEs became available online, multi-space and poly-synchronous accessibility is granted to multiple users beyond geographical constraints. What is interesting is that with the diffusion of the internet, learners interact with "other networked participants, and with widely disseminated information tools" (Edelson et al., 1996).

Significant differences emerge between "online" and "offline" VLEs; therefore, it is necessary to introduce a theoretical differentiation between "offline" VLEs and internet mediated Learning Environments.

2.2. E-LE—Internet Learning Environments

I define "E-Learning Environments" (E-LEs) as internet mediated or located learning environments, which overcome traditional boundaries of "space" "time", and "place", and are accessible by using the new Information and Communication Technologies (ICTs).[2] Cellular phones, last generation of palmary devices, and new integrated media equipments—including computers—are all media that allow users to access E-LEs.

E-LEs present several advantages compared to traditional VLEs (Ahmad, 1998; Winn & Jackson, 1999). However, as VLEs also E-LEs "carry their own set of design challenges and concerns" (Wilson, 1996). As we will see in this chapter, although learning environments available online can enhance or obstacle the knowledge experience, VLEs and E-LEs present new tremendous learning potentials and challenges for both doctors and "health seekers".[3]

3. E-LE AND HEALTH-CARE PROVIDERS

In the last century, medical advances are perhaps humanity's greatest achievement (WHO, 2004).[4] Since the diffusion of early electronic processors during the 20th century, computer-based learning environments have highly contributed to medicine's accomplishments in every discipline, from epidemiological studies to organ replacements trials and from designing of diagnostic machinery to DNA engineering, including cloning.

Starting from the 1960s, but more intensively from the 1980s , VR[5] technology and highly sophisticated computer applications are offering extraordinary VLEs to exchange knowledge and educate doctors.

In addition, the recent diffusion of the internet and the concomitant integration of several important factors, including systems costs reductions, have allowed for revolutionary transformations in the medical daily practice, research, and education for physicians.

3.1. First, Do No Harm

"... primum non nocere"
(... first, do no harm. Hippocrates, Greek Physician. Circa 460–370 BC)

Advanced tech and VLEs in medical education have become a "must". International patient safety movement and policy makers demand that simulation-based medical education become an ethical imperative to "first do no harm" (Ziv et al., 2003). In the last 20 years, VLEs have offered important contributions to the medical research and education. In particular, 2D and 3D technology simulations of human body have created innovative opportunities for learning in "reproduced", "enhanced", and "true" VLEs.

In medical training, "often the appropriate patient is missed or he/she can not be demonstrated to all students because of practical or ethical problems" (Ruderich et al., 2004). Computer-based patient simulations (CBPS) provide an effective instructional virtual environment for medical trainees, which acquire highly specialized medical skills by practicing on "virtual" subjects.

VR simulations offer several benefits for learners, in terms of quality and security in training, including risk-free practice—avoid to hurt real patient—and endless case reproducibility for improved skills acquisition, that may help shorten the learning curve early in training of diagnostic and treatment procedures (Ogan et al., 2004).

In the surgical field, Grantcharov et al. (2004) showed in randomized double-blind trial that training by VR significantly reduces student's errors in laparoscopic cholecystectomy—key-hole gallbladder surgery—and, therefore, should be implemented in surgical training programs, confirming previous findings (Ali et al., 2002; Seymour et al., 2002). Several other authors (Ahlberg et al., 2002; Torkington et al., 2001) validated the usefulness of VR in medical training, while Gerson and Van Dam (2003) findings suggested that medical educators should always associate innovative VR based endoscopy simulator with traditional—real patients—teaching protocols. VLEs should be implemented in the medical educational programs. However, Gallagher and Cates (2004) observed that further empirical evidences are required "to convince the more conservative members of the medical community".

3.2. E-LE and Medical Education

In the past pre-internet phase, VR technology has offered invaluable educational advantages, but still within the constraints of the "traditional" learning experience. In this context, the more recent concept of "online" learning environments has promised to push medical education armamentaria further ahead. Thanks to the combination of several factors—political, economical, and social, including new ICT—state-of-the-art simulation tutorials and new learning environments for medical education are increasingly available for the first time via the internet, offering new possibilities for learning in the health-care field.

Accessing E-LEs are becoming normal practice among an increased number of networked users. Web-based university courses to train medical students and postgradate practitioners[6] are recently developed in several Western countries (Grunewald et. al., 2004; Marescaux et al., 2000). In France for example, WeBS-Surg, offers an E-LE for medical education and successfully makes available VR based applications to train medical students living in remote areas (Marescaux et al., 2000).

Medical educators are under considerable pressure to enhance the quality and safety of medical care. In Emergency medicine for example, medical education materials via the internet and advanced tech are becoming "educational standards", especially when invasive or very rare procedures that are difficult for trainees to "see and do" in real clinical practice need to be acknowledged (Vozenilek et al., 2004).

The usefulness and effectiveness of the internet in teaching medical students has been tested and proved in several field, including cardiology, radiology, and pathology (Gomez-Arbones et al., 2004; Grunewald et al., 2004; Marchevsky et al., 2003).

In Australia, Kumar et al. (2004) described the successful implementation of teaching microscopic pathology with online virtual slides, to closely simulates examination of glass slides with a real microscope for the study of both histology and histopathology. E-LEs like CAMPUS help German speaking students acquire advanced skills for diagnosis by examining online medical cases, by offering personalized learning experiences on the basis of users' characteristics (Ruderich et al., 2004).[7]

When we look more specifically to the young generations, literature shows that medical students are highly familiarized with the use of computers and the internet. Surveys demonstrate high student demand for computer-aided instruction and anatomy applications offered on the internet (Jastrow & Hollinderbaumer, 2004).

Literature has shown that E-LE can help develop standardized teaching and design methods for long-distance medical education and training.

The development of sophisticated E-LEs like CAMPUS often means a lot of work for designers. Collaborative VLEs (Wilson, 1996) emerge from E-LE designers, who need to stimulate and integrate users feedback into practice to improve current system development in medical training (Ruderich et al., 2004).

3.3. E-LE in Medical Practice

E-LE can offer applications for knowledge exchange in the professional medical practice and research, and ultimately benefit patient's care.

Not long ago, treatment decisions were based on personal experiences, anecdotal reports, and a few case reports. VLEs and in particular E-LEs are offering encyclopedic breath information that can ultimately benefit patient's diagnosis and treatment. VLEs and E-LE are increasingly integrated in the medical consulting practice by using e-mail, videoconferencing, online presentations, virtual offices, instant messaging (Kropf, 2003), and new telemedicine devices. Many benefits may result from the use of E-LE in medical daily practice, including, decreased errors in exchanging patients records, less interruption of own daily practice, access to high quality specialized consultancy, and more efficient dissemination of knowledge, including Teleproctoring—long-distance supervision during surgical procedures in disadvantaged or remote areas (Pande et al., 2003). From a more practical standpoint, thanks to improved ICTs, patients, their families and—to some extent—consultants benefit from reduced travel time and travel expenses.

Patients appear to benefit the most, at the present, from the use of advanced technologies in the medical field: for example, 1000 patients living in rural areas of United States needing post-burn visits, saw their doctor at several miles of distance. Teleconsulting resulted a highly cost-effective alternative for patients and their family, but still a financial burden, and in part inefficient, for health-care providers (Nguyen et al., 2004).

In psychotherapy, online VR are used to cure patients suffering from anxiety. Since 1995 VR Exposure Therapy was shown (Rothbaum et al., 1995) to be very effective in reducing acrophobic—subjects that fear heights—anxiety and avoidance of heights. Through virtual environments patient are gradually exposed to feared situation: in a context that is nearer to reality than imagination. Online VR environments are successfully used in Experiential-Cognitive Therapy (ECT) to treat several psychological conditions, like panic disorder, agoraphobia (Vincelli et al., 2002)—and eating disorders (Riva et al., 2002).

Rizzo et al. (2004) describe a system that is currently being used to deliver virtual worlds over the internet for training safety skills to children with learning disabilities, and patients needing rehabilitation.

As regards medical procedures, thanks to the Robotic Technology, skilled surgeons can even operate via Telesurgery systems on patients located in remote and distant areas of the world (Pande et al., 2004; Semere et al., 2003a;) while comfortably seated in a chair, in comfortable clothes, without risking to contaminate the surgical field (screen).

3.4. Collaborative Learning Environment and Advanced Medical Research

In the scientific research practice, the diffusion of new E-LEs benefits medical knowledge exchange. The National Library of Medicine offers free access to "Entrez",[8] an integrated text-based search and retrieval system that allows users access the major medical databases like PubMed to retrieve scientific articles, but also online books, and even the whole Genome sequence.

E-LEs facilitate the creation, exchange, and delivery of new findings within interdisciplinary and international study groups in many areas of medicine, like in gene studies,[9] to find solutions and treatments of life-threatening conditions like cancer, HIV, multiple sclerosis, and heart disease.

In 2004, the British National Cancer Research Institute (NCRI) has launched an important initiative to bring together international scientists in a virtual community to access, analyze, and share findings in a common format across disciplines about cancer research, from genomics to clinical trials (Pincock, 2004).

3.5. Validity of E-LEs for Health-Care Providers

Literature has largely shown that E-LEs are convincing means to overcome traditional boundaries of the learning experience, and secondly that they are profoundly changing medical education and practice, particularly in Western countries. Medical students learn from multiple channels, including E-LEs. Virtual and E-LEs can contribute—still with limitations at the present—to develop standardized teaching and methods *for long-distance medical* education, also in developing countries. Medical daily practice and research is increasingly but profoundly challenged as well. These phenomena have no precedent in the history of health care.

The new E-LEs available for the health-care field potentially have a wide range of advantages over “offline VLEs” and “real” environments (e.g., convenience, flexibility, lower costs, currency of materials, increased retention, transcending geographical and barriers, and multisincronicity) (Ahmad et al., 1998; Winn & Jackson, 1999).

In spite of the tremendous impact that VLEs and E-LE are having on the health-care field, many clinicians and surgeons remain unaware or skeptical of their actual potentiality in medical training and practice, and their possible future applications (D’Ancona, 2001; Grantcharov et al., 2004). In reality, new E-LEs are already changing doctor’s professional and private lives, giving to many of them—especially the young generations—the possibility to quickly transfer, to colleagues and patients, educational and research information.

3.6. Cultural and Digital Medical Divide: What Opportunities for Developing Countries?

From a more global view, new technologies and “educational agents” should help the international medical community reduce the disparities in information and education that most often are a major determinant of health inequities in the developing countries (Filho, 2002). The Virtual Health Library[10] takes advantage of the potential of ICTs to foster access to state-of-the-art medical information and democratization of knowledge, and consequently promote equity in health.

In the developing countries medical students with access to the internet but with low abilities to use ICTs might not be able to access E-LEs for medical education and training. In this regard, a U.K. study (Samuel et al., 2004) has assessed the ICT skills of medical students in Tanzania. Interestingly, a period of approximately 5 hours of peer—U.K. students—online mentoring training produced an approximate doubling of competence scores. Similar telementoring experiences should be further developed to improve ICTs skills and improve access to E-LE in the developing countries.

4. CAN E-LE EDUCATE PATIENTS?

Adequate medical information is a crucial mean to prepare, sensitize, and educate patients before and after medical intervention (D’Ancona et al., 2001). With the rapid growth of the internet, not only doctors but also the general public of “health seekers” is able to access medical information of encyclopedic breath by surfing the WWW, and learn about health-care online.

The internet can help patients and their family better understand their disease and treatment in the convenience of a multisynchronous fruition, transcending geographical constraints, and in the comfort of their home. This is an unprecedented phenomenon, not in the "needs" to learn medical information but in the "ways" people do it.

Prior to the internet, and particularly, the WWW, family doctor, television, book magazines, and other printed publications were the most common sources of medical information for health seekers. Time-consuming trips to the library to consult books and journals on a topic, and related subjects were the usual research method for most of the people.

With the diffusion of the E-LE, going online to search for health related information has become the third most popular activity that almost 100 million internet users in the Unite States—especially women—perform online, after e-mailing and searching for a product or service before buying them (Fox & Rainie, 2000, 2002). In Europe (Murero & Nash, 2003) health seekers are exponentially growing, but empirical research is still scarce.

The internet is a powerful tool that can help patients and health seekers retrieve medical information and increase knowledge about innovative procedures and treatments (D'Ancona et al., 2002; Ferguson, 2002; Murero & D'Ancona, 2001, Murero et al., 2001). As an example, in the heart surgery field authors have dedicated their attention to analyze the pros and cons of E-LE patient education (Scherrer-Bannerman et al., 2000).

In an original study entitled Rural Online Cardiac Education Project (ROCEP), Scherrer et al. analyzed the effectiveness of the internet and other traditional methods of medical education in a group of patients awaiting cardiac surgery. Interestingly, the web-based method offered increased social support, decreased anxiety, improved lifestyle, and more positive attitudes toward the impending surgery. Leaffer and Gonda (2000) demonstrated that senior citizens could easily acquire computer and internet skills to search for medical information on the web. Moreover, the elderly use this tool to assume an active role in their personal healthcare.

4.1. Collaborative Learning Environments for "Health Seekers" in E-LE

Patients and their family or friends are pioneering new forms of collaborative E-LEs. A stunning example has been proposed in the literature (Larson, 2004): a woman with leukemia needing a rare bone marrow match found a donor online, after her family and friends built an online registry to help her and other donors find a proper match. The operation allowed for testing more than 12,000 people in 14 weeks, and finally finding a proper match.

The diffusion of "collaborative" E-LEs, made possible for the first time by the internet such as online Virtual communities, mailing lists—including e-mailing—or bulletin boards, allows health-care seekers to retrieve, acquire, demand, share, and medical information in innovative modalities. It is a new significant phenomenon in the history of health care. This very interesting but vast phenomenon will be specifically analyzed in future publications.[11]

4.2. Threat to Validity of E-LE in Patients' Education

Presence of medical terms and lack medical culture may act as significant barriers to online education when sample underwent in-depth interview conducted by their physician (D'Ancona et al., 2002). In an online multiple-choice quantitative survey Taylor (2002) found that American respondents, along with French and Germans participants gave internet-based health information positive marks, in terms of quality and readability, while Japanese resulted the most skeptical.[12]

Accessing online information does not mean understanding and *learning it.* In our in-depth analysis, we found that 83% of the sample report some difficulties in fully comprehending the information found on the web, especially when medical "language" was used. This caused, in some instances, increased level of anxiety especially in patients waiting for life-threatening procedures such as heart surgery.

All patients agreed that medical information on the WWW should be reported using simpler language in order to make it more accessible to the majority of the web users. Interestingly, the degree of college education had no correlation to the level of understanding of information provided by medical Websites. Pre-existing medical culture facilitates health seekers' proficiency in finding, understanding, and sharing medical facts online.

In order to help health seekers understand medical terminology the Medical Library Association,[13] offers reliable information online, including several resources like the "Top Ten" most useful consumer Health Web Search.

4.2.1. Too Much Information Online? The Overwhelmed Consumer

Using a search engine and entering a medical condition can often result in thousands of results. Literature shows (Al-Bahrani & Plusa, 2004; Murero & D'Ancona, 2001) that overwhelming data retrieved by the internet can, in some instance, result as a confounding factor in promptly and efficiently acquiring the desired and specific information online users look for. A very recent survey (Al-Bahrani & Plusa, 2004) confirmed that the internet provides enormous amount of patient-oriented information, but accessibility and quality of information is highly questionable. Medical doctors who run the analysis simulated patients' searching strategies. By entering few words in popular search engines (Google and Hotbot) thousands of sites were retrieved and 400 were selected to assess accessibility and quality of information.

Results confirmed that the "best sites" for consumers' education are very difficult to distinguish among the thousands of sites returned by search engines.

4.2.2. *Poor Quality in E-LE: The Risk of Online Misinformation*

When health seekers and patients search medical information by using E-LE there is a concrete risk that they access poor quality, limited, or distorted medical information (D'Ancona et al., 2002). Health seekers risk not to access certified info in medical E-LE, *invalidating the learning experience*.

Significant concern should be raised about the correctness, credibility, and origin of medical information available on E-LEs. In order to increase the credibility of the information presented online and the quality of the learning experience.

4.2.3. *Digi-Cultural Medical Divide*

Although the diffusion of the internet is increasingly expanding and the number of health-care seekers rapidly growing in Western countries—especially in the United States—patients that could mostly advantage from E-LEs, and particularly from online health related medical information, are often unaware of the potential and actual benefits of learning about their medical condition on the internet (D'Ancona et al., 2002).

Since the introduction of E-LEs, we observed an emerging digi-cultural divide between e-health seekers that access E-LE and the general public offline. The latter does not have access to the internet and is not able to access neither the internet nor low costs, rapid, and encyclopedic breath medical information, in convenient settings and modalities, and therefore is not able to access new cultural opportunities to improve medical knowledge and education.

4.3. Validity of E-LE for Patient's Education

Patients have shown increasing need for self-management skills and efficacy in using E-LE to acquire medical knowledge (Molfenter et al., 2002). In many cases, E-LEs resulted as powerful tools to learn medical evidences about innovative procedures and treatments. We should not forget that although there are controversial issues to resolve, several studies show that health seekers and patients benefit from online information (D'Ancona, 2001; Fox & Rainie, 2000, 2002; Murero et al., 2001; Taylor, 2002).

In many cases patients and their families are still unaware of how to correctly use E-LE to retrieve medical information from which they could, eventually, largely benefit in terms of education, and decision-making. Non-medical public cultural barriers, internet "overwhelming" information, and online misinformation *can invalidate* the learning experience for online users.

5. PATIENT–DOCTOR: A CHANGING RELATION?

5.1. Meet the "Empowered" Patient!

> They [patients] are arriving to your clinic armed with information they have found on the web, with a preconceived idea about their diagnosis and treatment options, more demanding regarding convenience and ease of access. They want to actively participate in therapeutic decisions and want all the decisions to be informed and intelligent. Meet the new empowered patient!; empowered by the information technology and its benefits.
>
> (Akerkar & Bichile, 2004)

Before the diffusion of the internet, patient tended to simply listen and comply to doctor's indications. The centrality of the doctor was undisputable. More recently, patients are able to retrieve, for the first time in history, thousands of health care related websites, and as a consequence tend to confront their doctor on the basis of internet conceived notions.

According to a 2002 research on the American population (Fox & Rainie, 2002) web medical information changed patient's decision about how to treat their illness in 70% of cases, or on circa 70 millions Americans, while for 28 millions "health seekers" web information influenced their decision as to whether or not to visit a doctor.

When describing e-patients dealing with their doctors after being exposed to online notion acquisition, Akekar (2004) distinguishes among "informed", "impatient", and "lobbying for care" patients.

Recent studies show that online learners are more prone to ask clarifications to their doctors, but also are able to find themselves online answers to embarrassing questions (Molfenter et al., 2002). Literature confirms that patients go to their doctor with more confidence, more capability to discuss alternative treatments, or simply ask for explanations. Patients "come with data, but are still searching for meaning and right action" (Klass, 2004).

When "health seekers" access comprehensible and reliable information within E-LE they can properly learn medical information and benefit from it. However, as we emphasized, patients not always completely understand the retrieved information, but in some cases they are stimulated to discuss it with the doctor to find alternative explanations and treatments to their conditions, or try to "lobby their solution" on the basis of the notions acquired in medical E-LE.

5.2. The Enhanced Role for Medical Specialists

In the literature, *doctors* are reported as, in part, complaining, and in part, welcoming this new phenomenon (Akerkar & Bichile, 2004). Doctors may become annoyed when patients are misinformed or misunderstand online medical information, or have a large cultural divide, but tend to be open and welcoming toward—correctly—informed patients that are less afraid to discuss alternative and consequences of medical decisions.

The majority of patients who have internet access are exposed to a wide array of medical information on the internet without the tutoring of their physicians (Fox & Rainie, 2002). Literature has shown that patients would benefit from accessing internet-sites directly developed by their immediate health-care provider (D'Ancona et al., 2002; Murero & D'A'ncona, 2001; Semere et al., 2003b).

Medical *doctors should do more to help* maximize, optimize, and direct health-care information available via the internet for health seekers—their patient and family—to help correctly address conditions that could be life threatening. Medical doctors should help rather than obstruct this process and guide patients to quality sites to avoid confusion, misinformation, and poor judgment, including negative consequences on the patient–doctor relation.

The facilitating role of medical specialists in maximizing the online learning experience can help validate E-LEs as multiple sources of education for "health seekers", and represent a "convincing factor" for the skeptical medical community.

6. CRITERIA TO ASSESS QUALITY IN MEDICAL E-LEs

Non-medical population is increasingly able to retrieve virtually the same information that doctors access online. As the interest and the request for health information mediated by the internet is proliferating, there is a growing need for objective, reproducible, widely accepted criteria that can regulate the publication of medical material on the Net. Criteria for evaluating—and diffusing—internet health information have been presented in a policy paper supported by the Agency for Health-Care Policy and Research (Mitretek, 2002). Among the most important criteria are "credibility, content, and disclosure" of web-based medical information.

The Health on the Net Foundation Code of Conduct (HONcode[14]) for medical and health web sites is helping standardize the reliability of medical and health information available on the WWW by elaborating eight principles that are increasingly adopted by medical website developers. Among the most important criteria for E-LE designers are respect of personal data, clear indication of sources of information, and transparency. Interestingly, the first principle of the HONcode states that: "Any medical or health advice provided and hosted on Websites site will only be given by medically trained and qualified professionals unless a clear statement is made"(principle of Authority); the second principle (Complementarity) recite that medical and health information available in E-LE—Websites—should "support, not replace, the relationship that exists between a patient/site visitor and his/her existing physician. The HON-code principles were implemented in a very important EU policy act (2002).

The adoption of criteria of conduct for medical and health Websites is very important; they can help learners assess credibility and reliability of online medical and Health information, and improve the validity of E-LEs in educating patients and health seekers in multiple contexts.

Although the internet is a powerful tool for improving health-care decision-making process, users should be aware of the potential for incorrect information and should always assess the quality of the information that is provided in the internet, therefore including e-mail, mailing lists, and online forums or "community". Quality of online "patients networks" need particular attention (Ferguson, 2002).

7. FUTURE SCENARIOS

7.1. The Next Revolution

In the last decades, computers and more recently the internet have revolutionized the way society and individuals operate in every day life, including medical education. The next step in this evolution will allow for E-LEs accessibility to libraries of VR scenarios as a likely form of distribution and use (Rizzo et al., 2004).

In future years, molecular scale research like Nanotechnology,[15]—or the creation of devices, materials, and systems through the control of matter on the nanometer scale—is believed to transform our society (NASA, 2004), including the health-care field[16] and environments for teaching and learning. In this scenario, the integration of new ICTs, Bio-Technology, Genetic Engineering combined with "Nanomedicine[17]', and new frontiers in medical achievements, will transform even more the health-care field. In the meantime, the integration of computer and statistical sciences along with biometric and biomedical research, for example, is breaking new ground for researchers that are working to create "truly virtual" patients, which they say could 1 day replace real people to whom administer placebo in some clinical trials for the development of new drugs and the cure of severe diseases like multiple sclerosis (Cleaver, 2004).

New miniaturization technologies and media integration, along with increased quality of medical information available to the general public could facilitate the development of "sophisticated" Learning Environments that will help accelerate the diffusion of medical education and discoveries all over the planet, bringing along new threats and opportunities for learning and knowledge exchange, for both health-care providers and receivers.

CONCLUSIONS

Challenges introduced by VLEs and E-LEs in the health-care field have no precedents in the medical history. Literature has largely demonstrated that E-LEs are convincing means to overcome traditional boundaries of the learning experience, and are profoundly changing medical education and practice, particularly in Western countries, but still with some limitations. The financial barriers to internet access in the developing countries are still enormous. Many clinicians and surgeons remain unaware or skeptical of their actual potentiality in medical training and practice, and their possible future. We are only at the beginning of a highly promising revolutionary process. In the future, E-LEs and ICTs can help overcome health inequity in the developing countries.

Patients and health seekers acquire new means to access encyclopedic breath medical information on the internet, with huge benefits in terms of decision-making and empowerment in the relation with their physicians. However, cultural barriers, and online misinformation can invalidate the learning experience within E-LE.

It is in the interest of health-care providers and possible internet-content providers, to always post on the Net only high quality information accessible to past, present, or future "health-care seekers". Future collaborations among medical doctors, health-care providers, website developers, and communication experts adopting international guidelines for medical Website producers, like the HONcode may help improve the quality of medical information available in E-LEs, diffuse proper education among health-care learners, and close the digi-cultural medical divide. Positive effects on the patient–doctor relation, and ultimately on patient's health can be foreseen in future scenarios.

SUMMARY

Improved health-care is perhaps humanity's greatest achievement of the last century. Increasingly sophisticated VLEs have largely helped this achievement.

VR technology and computer-mediated learning environments—or VLEs (Wilson, 1996)—have profoundly changed the offer and demand of medical education and knowledge. Medical training on "real" patients is no more acceptable at the beginning of the new millennium.

In addition, the recent diffusion of the internet is *revolutionizing the Health-care field by* increasingly facilitating the diffusion of E-LE, or Learning Environments located or mediated by the internet and accessible via new ICTs.

E-LEs overcome the traditional barriers of "place" "space", and "time" characterizing traditional learning experience.

New means to create, deliver, and exchange medical education, experience and interaction are now increasingly available online. As a result, the medical practice itself is rapidly changing, including new means to exchange medical research findings for the international community, and for the developing countries. However, we are at the beginning of a new phenomenon; financial and cultural barriers are still limiting the diffusion of VLEs.

Moreover, with the recent diffusion of the internet, not only health-care providers, but also health-care "seekers" can benefit from "new" learning opportunities. Although the non-medical public can impressively access online medical info of encyclopedic breath in few seconds we should ask ourselves: can the internet educate patients?

Adequate medical information is a crucial mean to prepare, sensitize, and educate patients before and after medical or surgical intervention. Although the benefits of proper and adequate patient education are enormous, a large number of patients remain unaware of how and where to retrieve medical information suited to their needs. Although the internet is a very powerful tool for assessing health-care decision-making (Fox & Rainie, 2002) users should be aware of the potential for misinformation and should always assess the quality of the information that is provided. When patients and their family USE the internet, new VLEs for the health-care offer them huge benefits for learning and knowledge exchanging but on the other hand, at the present stage (2004) they also create new barriers and risks for users, including misinformation, privacy, and security concerns.

For the better or the worse, the doctor–patient relation is changing as an effect of the exposure to the medical information available on the internet.

On this base, we should foresee a reshaped and more focal position for the doctors in the next future, but also an "empowered"—in part—patient as well.In order to overcome present risks of online misinformation and digi-cultural medical divide, health-care providers and interdisciplinary collaborations should play a future key role to educate patients, their family, and health-care seekers by suggesting "safe" websites where they can find certified information and acquire information.

ENDNOTES

1. "The internet is the publicly available worldwide system of interconnected computer networks that transmit data by packet switching over the IP (Internet Protocol). It is made up of thousands of other, smaller business, academic, and government networks that provide various information and services, such as by e-mail, online chat, and on the graphical, interlinked World Wide Web (WWW). Because it is the largest, most

extensive internet (with a small i) in the world, it is simply called the Internet (with a capital I)". *Source:* wordiQ, retrieved on 27 Oct, 2004 at http://www.wordiq.com/definition/Internet. Furthermore, according to a definition from the United States versus Microsoft case, the internet is the "global electronic network, consisting of smaller, interconnected networks, which allows millions of computers to exchange information over telephone wires, dedicated data cables, and wireless links. The internet links PCs by means of servers, which run specialized operating systems and applications designed for servicing a network environment". *Source:* US versus Microsoft, 84 F.Supp.2d 9, 13 (DDC Nov 5, 1999)

2. "ICT (information and communications technology—or technologies) is an umbrella term that includes any communication device or application, encompassing: radio, television, cellular phones, computer and network hardware and software, satellite systems and so on, as well as the various services and applications associated with them, such as videoconferencing and distance learning. ICTs are often spoken of in a particular context, such as ICTs in education, health care, or libraries. The term is somewhat more common outside of the United States". *Source:* SmallBizIT Glossary, Retrieved online on 20 September 2004 at http://searchsmallbizit.techtarget.com/gDefinition/0, 294236,sid44_gci928405,00.html.
3. The population of "health care seekers" that access and search medical Websites includes patients that have already undergone or will undergo medical or surgical treatment, and people that do not have personal health related problems, but might need to find medical information online to help a third person.

Chapter 39: E-Democracy: Media-Liminal Space in the Era of Age Compression

MARK BALNAVES*, LUCAS WALSH†, AND BRIAN SHOESMITH‡

*Professor of New Media, School of Communications and Multimedia, Edith Cowan University; †Research Fellow, Faculty of Arts, Deakin University; ‡Associate Professor, School of Communications and Multimedia, Edith Cowan University

> Whether direct internet democracy is good or bad is, however, quite beside the point. It is inevitable. It is coming and we had better make our peace with it. We have to better educate ourselves so that we can make good decisions. Restricting the power of the people is no longer a viable option. The internet made it obsolete.
>
> (Morris, 2000: 31)

When Morris says that "direct democracy" is inevitable and "restricting the power of the people is no longer a viable option" he is arguing that traditional distances between representational governmental structures and the voter or citizen have changed because of the internet and that representative democracy will change as a result. The internet, however, is operating in a political and governmental climate where there is a "civic deficit" involving increased complexity of communication between citizens and increased citizen disengagement from the traditional processes of communication (Putnam, 2000). Consequently, the relationship between the democratic potential of the internet and the institutionalize axes of power that currently shape representative democracy need to be teased out. In an age of digital and interactive communication, there is a change in the way citizens collaborate. It is this change that challenges many of the preconceived ideas about the nature of contemporary democracy, hence the enthusiasm of Morris and his kind.

But we can take Morris's point further. It is not simply the internet as a medium that is changing political relations but the learning environments that are made possible by the new media. Indeed, concepts like "ergodic media" and "electracy"—computer programmed environments that require users to make choices—have emerged to describe these environments, the new literacies required for those environments, as well as the potential changes to social and political relations (Aarseth, 1997; Weight, 2004). Thus we have a complex triangulation emerging where the medium, the learning environments in which citizens learn to use the medium and the actual uses to which the medium is put begin to shape our understanding of e-democracy. Once we go down this path, we see that a theory of e-democracy will not only include a mechanism of choosing and authorizing governments, but also describe a kind

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1039–1053.

of society, “a whole complex of relations between individuals” (Macpherson, 1973: 51).

In this chapter, the authors will look at the ideas of e-government and e-governance and practical examples of how new media are being used to enhance decision-making in democratic societies. The authors argue that the learning environments that have emerged from interactive entertainment and other contexts signal a change in the nature and role of liminality—the transition to citizen and civic engagement—in modern society.

1. e-GOVERNMENT VERSUS e-GOVERNANCE

Definitional and conceptual issues in e-government have not gone unnoticed within the public sectors, national and international. The United Nations report on uptake of internet technology defined e-government as “utilizing the internet and the world-wide-web for delivering government information and services to citizens”. (United Nations Division for Public Economics and Public Administration American Society for Public Administration, 2002). The stages of e-government were then classified by levels of sophistication in adoption of the internet, including (i) “emerging” (an official government online presence is established); (ii) “enhanced” (government sites increase: information becomes more dynamic); (iii) “transactional” (users can actually pay for services and other transactions online); and (iv) “seamless” (full integration of e-services across administrative boundaries). The United Nations report then proceeded to create an e-government index, based on a mean figure derived from the web presence, telecommunications infrastructure, and human capital measures. Table 1 gives the ranking of leading countries based on that index.

Riley (2003: 14) goes a step further and distinguishes between e-government and e-governance. Riley (2003) draws on Kettl’s (2000) work on the historical analysis of American public administration, especially the idea of government as an institutional superstructure in society that translates politics into policy and legislation. Governance in this context is the result of communication between government, public service, and citizens in the whole cycle of policy development and service delivery. Riley’s model, above, sets up an initial framework for understanding the differences between e-government and e-governance (Table 2).

Riley (2003) argues that government and governance are both about getting the consent and co-operation of the governed. E-government is a formal apparatus for this objective, whereas e-governance is the “outcome as experienced by those on the receiving end”. e-Government, therefore, as superstructure, could clash with e-governance, as participatory process, especially when expectations of participation are heightened. Riley (2003) says that e-democracy/e-government/e-governance are a discipline in their own right

Table 1. Global leaders in e-Government

Source: Benchmarking E-government, A Global Perspective: Assessing the Progress of the UN Member States (2002).

because new media provide a distinct role in participation that was not available under other forms of representative government.

Riley's ideas on e-governance need to be broken down further. That is to say, the processes of participation need to be teased out. E-governance can involve e-government providing information to citizens, which is engagement and participation in an important but a superficial way. The UN benchmarking is a rating of e-government in this sense. However, activities in the area

Table 2. Differences between Government and Governance

Government	**Governance**
Superstructure	Functionality
Decisions	Processes
Rules	Goals
Roles	Performance
Implementation	Coordination
Outputs	Outcomes
e-Government	e-Governance
Electronic service delivery	Electronic consultation
Electronic workflow	Electronic controllership
Electronic voting	Electronic engagement
Electronic productivity	Networked societal guidance

Source: Riley (2003).

of "electronic governance" can range from government-led initiatives to improve transparency and participation to citizen-directed experiments in participatory democracy. Some of these experiments may be more traditional, like voting in local elections, but others may operate on the fringes, like e-activism or hacking. E-governance is the space where people will form their identities as active citizens and learn to mobilize resources for decision-making.

It is also worthwhile describing some of the activities that involve the mobilization of resources. First, there is the use of electronic media, such as email and databases, to enhance the administration of government and there is the use of media by government to disseminate information to citizens, corporate bodies, interest groups, and so forth in a one-directional, "top-down" fashion (administration and efficiency). Second, there is the use of technology such as the internet and interactive television to enhance citizen participation in government decision-making especially at the "grassroots" community level. Third, there is broadcast activity that encompasses the use of electronic media for the diffuse dissemination of information amongst citizens and government for general news and entertainment purposes. Finally, there is political mobilization and e-activism (together with "hacktivism"), where the internet and related technologies are used to mobilize public opinion in demonstrations against perceived government injustices or to disrupt networks for purposes of civil disobedience.

Once we think of e-governance as processes of consent in new media contexts that lead ultimately to policy and legislation, then we can better understand the tensions between superstructure, the elaborate mechanisms of government decision-making and service provision, and e-governance, the engagement of citizens and organizations in democratic decision-making. Before looking more closely at the different types of mobilization of resources it is necessary to briefly examine the learning contexts that will affect e-democracy formations.

2. AGE COMPRESSION, NEW LITERACIES, AND THE TRANSITION TO CITIZENSHIP

Myths and rituals, in traditional and non-traditional societies, are often associated with "rites of passage" from one status to another. There is a separation (divestiture) phase, a transition (liminality) phase, and an incorporation (investiture) phase (Turner, 1995). During the separation phase, the person who is to be subjected to the passage becomes separated from their previous way of life. During the transition phase, the person separated from their previous environment experiences the liminal condition. During the incorporation phase, they enter a new group and a new life.

> The ritual subjects pass through a period and an area of ambiguity, a sort of social limbo which has few . . . of the attributes of either the preceding or subsequent profane social statuses or cultural states.
>
> (Turner 1982: 24)

Victor Turner, the anthropologist, coined the term "liminal", from the Latin limina for "threshold", to describe transitional phases where myths and rituals became important in confirming the identity of a person and their future role in society.

> Myth treats of origins but derives from transitions . . . Myths relate how one state of affairs became another; how an unpeopled world became populated; how chaos became cosmos; how immortals became mortal; how the seasons came to replace climate without seasons . . . and so on. Myths are liminal phenomena: they are frequently told at a time or in a site that is 'betwixt and between'.
>
> (1968–1979: 576)

The idea of liminality is relevant to this chapter because we contend in modern societies, more than at any other time, learning and consensus building are taking place in a liminal condition created by modern media. Turner (1982) argued that traditional liminality did not exist in modern society and called the quasi-liminal states "liminoid". Contemporary authors have also expanded on this notion in the context of computers and learning (Weight, 2004). The authors will call this liminal condition *media-liminal* space (Balnaves & Tomlinson-Baillie, 2005) because it more accurately reflects what is happening with digital media and the extensive many-media saturation. Turner is not alone in his idea that there are existential spaces in society that have properties conducive to creativity and communitas (the sense of community) but which are problematic in relation to other structured spaces of social organization. Post-modern thinkers such as Foucault called these spaces *heterotopia* and Deleuze and Guattari territorialized, where differences could be played out that were not allowed in normal social routines. It is the games phenomenon in modern society that best exemplifies this produced subjectivity.

The age compression phenomenon, the disappearance of childhood, is an example of how the entertainment business is taking advantage of extended liminal states, or what the industry calls KGOY—Kids Grow Older Younger. KGOY works on the basis that modern media allow children to develop higher order cognitive skills faster and younger. Toys and other goods, normally created for older children, are now being sold to younger children on the basis that their higher order learning skills are more advanced than in past generations. The KGOY philosophy involves introducing the staggering 565 million urban population of 5–14-years old to the new media literacies as soon as possible so they can start playing games (McDougall & Chantry, 2004).

A small picture of children's activities gives an insight into the extent of media involvement. Ninety-nine percent of modern children aged 5–14 years old say that television is their favorite activity, with most spending 22 hours every fortnight watching TV or videos. Seventy-one percent of all Australian children (5–14 years old) spend between 5 and 9 hours per fortnight playing electronic games and spend $450 million on software, $250 million on hardware, and $300 million on peripherals (Australian Bureau of Statistics (ABS) Media Release #4901.0 Date: 30/01/04, Sunday Telegraph, 29/2/04, p. 32; http://www.theesa.com/EF2003).

Companies like Konami produced YuGiOh! as a many-media game and have explicitly designed their games in a way that takes advantage of the media saturation, myth and ritual symbol and, indeed, the idea of intrinsic motivation (which enhances the uptake of the new literacies required by digital media). In the first quarter of 2004, Konami sold 3.5 million copies of YuGiOh!

	2004 Billion Yen
YuGiOh! Card Games (Japan, Asia)	9.5
YuGiOh! Card Games (North America)	18.5
YuGiOh! Card Games (Europe)	3.5
Other Cards	0.5

When boys play Yu-Gi-Oh, they are temporarily removed from normal society, this is further reinforced by the episodic game play on the television show where the players go to the shadow realm to play. Hence boys are continuously imitating the show and playing in "the shadow realm" or a place totally devoid of normal rules and normal "life". They are transforming themselves from the young and immature Yugi into Yu-Gi-Oh. Yu-Gi-Oh is not solely internet-based. It is a good example of an activity that has gone beyond play and brings together the very characteristics of liminal space described by Turner and others (Czarniawska & Mazza, 2003).

Those like Calvert (2003) are currently exploring the link between digital entertainment media and intrinsic motivation and individual interest. According to Calvert (2003), the properties are (i) the capacity to allow control over the learning environment, (ii) responsiveness, and (iii) high production values. These properties in turn provide a context in which identity can be explored through personal involvement in content. Identity development through a character or superhero allows children to have a role model for social participation and develops their confidence to interact with peers. Interest appears to be an even more compelling way in which to discuss student learning than prior knowledge or content (Askell-Williams & Lawson, 2001: 386). Individual interest implies intrinsic motivation, intrinsic motivation leads to multisensory three-dimensional learning that leads to stronger learning outcomes for children. The intensive and extensive engagement of children in media related, or media-tied, activities are linked to improved learning outcomes.

The phenomenon of age compression—drawing children into media-liminal space at earlier and earlier ages—will have an effect on how people learn how to mobilize resources in a digital world. Interactive games, at one level, entertain and provide children with the opportunity to role-play and enhance their learning skills. However, at another level, the whole games phenomenon is successful because of its capacity to replicate a liminal-like space (much like the ketai lifestyle in Japan). Once we intersect the games phenomenon with citizenship, we start to get an insight into the future citizen. The media-liminal space does not lead to a defined role or status, but it does allow people to explore and create and work in peer environments. E-governance will include, therefore, the types of activities described below, but it will also include media-liminal spaces, many of which we see emerging not only in games but also in blogging and in the coming together of smartmobs.

In contrast to this informal education sphere that is essentially private in its scope, there is a vast formal education sphere that is struggling to come to terms with the media-liminal (Reed, 2000). By "formal education sphere", we mean that vast apparatus, both private and public, that has been set in place to educate and socialize the young. Here, the liminal is either feared or discounted as it does not conform to the cognitively based curriculum that sees child development in terms of clearly defined steps and outcomes.

3. ADMINISTRATION AND EFFICIENCY

It would be safe to say that almost every democratic government is or has recently reviewed its use of electronic media, such as email and databases, to enhance its administrative function. This includes the use of electronic service delivery and electronic information infrastructures to co-ordinate organizational activity, and daily government and parliamentary work (Grönlund, 2002; Gibson et al., 2004).

The increase in government information and services provided online during the last decade has been tremendous. For example, one United Nations report found that during 2001, there was a greater expansion in government online presence than the previous 5 years combined. It has been estimated that between 1996 and 2001, the number of official government homepages grew from less than 50 to well over 50,000 official government websites. Furthermore, the *nature* of the information developed from "website content and online applications progressed from static, public affairs 'e-brochures' to virtual information centers where the interaction between citizen users and the public sector is continuous" (ASPA & UNDPEPA, 2001: 5). For example, one U.K. e-government initiative launched in 2004 is *Directgov*, which seeks to offer citizens direct access to public information and services concerning topics such as employment, motoring, and people with disabilities (http://ukonline.direct.gov.uk/). This site sits within a broader initiative, U.K. Online, which was launched in September 2000. Other more locally oriented websites offer services in which citizens can transact with government (e.g., lodge their tax online) (Cross, 2004). A U.K. Government White Paper established five base line principles of e-government related to this type of activity:

- build services around citizens' choices;
- make government and its services more accessible;
- facilitate social inclusion;
- provide information responsibly;
- use government resources effectively and efficiently (White Paper cited in ASPA & UNDPEPA, 2001: 6).

A 2001 survey of 22 countries or territories including Australia, Hong Kong, Ireland, Japan, Malaysia, New Zealand, and Britain found that Canada, Singapore, and the U.S.A. offered the most extensive online government initiatives seeking to provide services to citizens via the web (Saywell, 2001). But the motivations behind these e-governance initiatives are not always driven by the public interest. As one commentator remarks, a key problem with e-government is that "the web is seen primarily as a delivery mechanism for more accessible, efficient and cheaper-per-unit transactions between government producers and citizen consumers" (Hobsbawn, 2003).

4. LEARNING ENVIRONMENTS AND PARTICIPATION

The most promising use of technology in e-governance is the use of electronic media, such as the internet and interactive television, to enhance citizen participation in government decision-making and "grassroots" development. This type of activity has extremes ranging from citizen polling and consultation with government, to a more direct democratic model of participation based on the "electronic town meeting", in which media such as televoting and the web are used for mass decision-making by plebiscite (Abramson et al., 1988).

Much of the recent activity using the internet to encourage citizen participation has taken a moderate approach to complement representative democracy, rather than replace it with a more direct participatory model of democracy. Brazil's city council of Porto Alegre uses email and the web to facilitate a degree of direct democracy by enabling citizens to discuss and vote on issues (Hobsbawn, 2003). Minnesota E-Democracy also hosts online public spaces for citizen interaction on public issues (http://www.e-democracy.org/). This non-partisan citizen-based organization seeks to increase participation in elections and public discourse in Minnesota through the use of information networks. Through e-Citizen Estonia, citizens of Estonia can use an online consultation process to comment on draft laws and suggest new ones (http://tom.riik.ee) (ASPA & UNDPEPA, 2001: 71). The Netherlands' Minister for e-Democracy matters has engaged discussion with the public through online chat rooms. In North Jutland, Denmark, a Democracy Project has attempted to counter low voter turn-out by using ICT to make regional decision-making process more understandable to its citizens (www.nordpol.dk). Similar and varied projects are also taking place in Australia. The New South Wales government sponsors the "Community Builders" network of policy implementation, in which an interactive electronic clearing house is used for community level social, economic, and environmental renewal (www.communitybuilders.nsw.gov.au). Using the web to enable online community consultation, e-petitions and to broadcast parliamentary activities, the Queensland Government established an e-Democracy Unit to explore how ICT can enhance the community's access to government and its participation in government decision-making. The *Citizenscape* website of Western Australia also seeks to promote citizenship-related activities and involvement in decision-making (www.citizenscape.wa.gov.au). These projects have experienced varying levels of success in both disseminating resources from government to citizens as well as engaging greater citizen involvement in representative government (Parliament of Victoria, 2002: 57–63).

It is argued that the growth and convergence of the new telecommunication media will consolidate and extend the nature of participation by citizens in the formation of policy in desirable ways. For Grossman (1995), this trend towards direct democracy is inevitable; the important question for him is *how* this process will be managed.

5. BROADCASTING

Issues of the nature, ownership, and impact of mass media continue to be significant. Sweden has formally recognized the "problems with the

Swedish mass media in contributing to the public sphere by fulfilling the democratic indicator of enlightened understanding . . .” (Rothstein et al., 1995). The growth of the World Wide Web has generated further issues and possibilities. For example, unlike the present system of heavily centralized broadcast television, the web can decentralize political discourse and has the potential to give citizens greater choice and access to information.

The development and adoption of digital television has further implications for e-democracy because of its likely integration with other ICTs such as the internet. The convergence of ICT such as the internet with mass entertainment media, such as interactive television and radio, has been underway for some time and offers tremendous opportunities for civic engagement and greater interactions between government and citizen. For example, information services such as teletext are widely available through television. Popular radio stations simulcast on the web and provide transcription services of broadcast content. The widespread adoption of a database-driven approach to websites has enabled web-content to be more dynamic and relevant to specific user needs, by using mark-up language such as Extensible Mark-up Language (XML) to enable multichannel systems that deliver web-content to conventional PC browsers, interactive TVs, PDAs, and smart phones. Television and home-entertainment systems now come equipped with their own hard-drives, whose basic functioning is not all that dissimilar from those contained within a typical PC. As televisual, audio, and computing technologies converge, they facilitate greater interactivity and new opportunities for the dissemination of information.

Interactive television has been in popular use in countries such as the U.K. for some time now, ranging from spot-polling (e.g., Sky-digital) and popular entertainment, such as game shows. Indeed, the uptake of interactive television in countries such as the U.K. now exceeds that of the internet (Towler, 2001). Recently, trials have begun in the U.K. and U.S.A. involving the use of interactive television. In the U.K., for example, a trial group of voters were given a PIN number and the chance to take part in an e-voting pilot scheme via interactive digital television, the internet, telephone, and special kiosks (BBC News, 2003). In the U.S.A., the technology is now available to use digital TV to cast election ballots (Featherly, 2003). What is truly significant about this technological convergence is that it has as its corollary a convergence of information and entertainment, market, and polity.

All the above examples are based within the law. E-governance also has proponents who mobilize public opinion for civil disobedience or hack networks for what are perceived as public interest purposes. “Hacktivism” has led to a new form of activism, combining political activism with computer hacking.

Civil disobedience was one of the first activist tools to be translated into an electronic context. The Electronic Disturbance Theater (EDT) is considered by many to be the first true "hacktivist" network. The EDT coined the term "electronic civil disobedience" and was the first to implement it as a "hacktivist" event (Pearson, 2000: 16). The EDT actively supports causes such as the Zapatista movement in Chiapas, Mexico, and its members were the creative and technical force behind actions such as SWARM. But it is important to grasp that the flow of information and technique has not been all one-way. Activists who have come from "real-life" protests are also adopting the tools and techniques of the hackers when working for a cause. Activists are finding that by coming online they expand not only the range of tools at their disposal, but also the ways they can connect with like-minded individuals and groups. "As a result, radical groups are discovering what hackers have always known: Traditional social institutions are more vulnerable in cyberspace than they are in the physical world. Likewise, some members of the famously sophomoric hacker underground are finding motivation in causes other than ego gratification" (Harmon, 1998).

Table 3 highlights some prominent "hacktivist" targets, with notes on the issue and the tactics used by the "hacktivists" involved.

There is of course significant e-activism activity that is not illegal and does not constitute civil disobedience. Hacktivist activity, however, does raise e-governance issues as it is a subterranean attempt to influence policy and legislative outcomes. "Hacktivism" is not a shift of power to the citizenry, although like any protest or act of civil disobedience it can be seen as an exercise of rights within democracy. The extent to which that protest or disobedience contravenes formal laws and the extent to which the state will respond as a result of breach of those laws (positive rights) will continue to be a significant issue within the shaping of an e-governance of the future.

CONCLUSION

Modern democracy has two faces: (i) e-government and e-governance as its critical participatory processes and (ii) the underlying social phenomenon of a generation that is immersed in the digital entertainment world where intrinsic interests are appealed to and where deep learning is occurring. Hacktivism is already an example where people are competent in the new literacies and the potential of collaborative and peer-based networks in influencing decisions. Media-liminal spaces—where individuals become immersed in these new learning environments—are not benign.

Table 3. Major hacktivist targets

Target(s)	International Issues/Tactics	Hacktivist(s)
Balkan press	Defaced Albanian, Croatian and Serbian websites relating to Kosovo	Kosovo Hackers Group/Black Hand/Serbian Angel
China	Government censorship. Removed content filters. Warn activists about imminent arrest. Defaced websites. Domain hijacking. Planted Trojan horses	Blondie Wong/Hong Kong blondes Bronc Buster and Zyklon/Legion of Underground
France	Anti-nuclear protest Denial of service attack	Strano network
India/U.S.A.	Independence for Indian-controlled Kashmir. Defaced Karachi stock exchange, U.S. military and commercial sites, including Disney	Dr Nukor/Pakistan Hackerz club/Muslim online Syndicate/GFORCE
India	Protest nuclear bomb testing. Defaced websites	Milworm and Ashtray Lumberjacks
Indonesia	Independence for East Timor. Alleged human rights abuses. Defaced websites	Secretos/Kaotik team
Mexico	Independence for Chiapas. Alleged human rights abuses. Denial of service attack using floodnet utility	Ricardo Dominguez/EDT
Myanmar	Political identity (Burma). Alleged human rights abuses. Defaced websites	Danny-Boy/X-ORG
NASA	Anti-nuclear protest. Computer virus or worm	Wank
Sri Lanka	Independent homeland for ethnic Tamils. Email bomb	Internet black tigers
World Trade Organization	Various agendas. Denial of service attacks	Electrohippies collective and many others

Critiques of the actual and potential impact of communication media on democratic processes are mixed (Abramson et al., 1988; Cronin, 1989). Grand visions of democratic revitalization through the use of information, communications, and interactive media continue to be tempered by scepticism and even derision. (In his humorous scenario of electronic democracy in the future, Anzovin (1992: 11) envisages daily televoting as a regular episode in the evening “infotainment line-up”.) Nevertheless, developments in communication technologies are profoundly affecting communication between governments and voters, lobbyists, and the use of opinion polling. Some argue that the use of electronic technologies should be restricted to the dissemination of information and not actual voting activity. Citizens, it is argued, should still have to physically vote at a polling place (The Economist, 1995b).

Shifts of political power to the citizenry facilitated by technological development—both real and imagined—lead one commentator to wonder whether representative democracy is nothing more than a 200-year bridge from the direct democracy of ancient Greece to the teledemocracy of the future (The Economist, 1995a). While interesting as an idea, this notion pre-supposes that enabling greater participation will necessarily bring about *greater* participation. This is by no means guaranteed. And as e-democracy initiatives seek to enhance and extend governance, these activities face new but familiar challenges.

There is a real danger that much of the interest in using new media to enhance and extend democracy arises out of a desire for technological panaceas. But as commentator remarks, "One thing's certain, though: e-government is as inevitable as the next generation of citizens who treat the free flow of digital information like oxygen. As Xerox innovator Alan Kay once noted: 'Technology is only technology for people who were born before it was invented' " (Hobsbawn, 2003).

The authors in this chapter have explored "thin" democracy, e-government, and procedural issues like information-delivery, voting and administration, and "thick" democracy, participation of the citizen in the social and political world. It is the intersection of these two in the world of e-governance that will determine the nature of tomorrow's citizen.

Chapter 40: SonicMemorial.org—The Virtual Memorial as a Vehicle for Rethinking Virtual Learning Environments

MARK SHEPARD
University at Buffalo, State University of New York

1. THE SONIC MEMORIAL PROJECT

Shortly after September 11, 2001, a group of radio producers, artists, historians, archivists, and the public broadcasting community came together to collect and preserve audio artifacts of the World Trade Center, its neighborhood and the events of 9/11. Lost & Found Sound and National Public Radio (NPR) set up a toll-free phone line to record people's stories and collect audio contributions reflecting the life of the buildings before, during, and after the attacks.

The initial response was overwhelming. People from around the world were contributing a wide range of material: Voicemail messages from those who worked in the towers that day, tapes of weddings atop the World Trade Center, police and fire radio communications immediately following the attack, recordings of the buildings' elevators and revolving doors produced for a documentary film, home videos made by a lawyer in his 42nd floor office, sounds of the Hudson river front, recordings of late night Spanish radio drifting through the halls as Latino workers clean the offices, an interview with the piano player at Windows on the World, and so on.

Toward the end of that year, a series of meetings were convened in New York to discuss ways by which this material could be re-introduced to a broader public. Lost & Found Sound was already working on a series of radio programs to be aired on National Public Radio, but wanted to open the project up to other modes of distribution and access. Among the many ideas put forward, the idea of creating a website by which the public could access and contribute to an archive of these sound artifacts gained early support. The website offered an alternative to the linearity of a radio program, and provided an opportunity for a nuanced, meditative, non-linear experience as visitors browsed through sounds that piqued their interests.

SonicMemorial.org (http://www.sonicmemorial.org)—produced through the collaborative efforts of New York-based new media architects dotsperinch and web documentary studio Picture Projects—was conceived as a vehicle for mobilizing a number of the project's aspirations. First and foremost was its role in cultivating an oral history of the lives and activities of the buildings' inhabitants to assist in the interpretation and the understanding of a tragic

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1055–1065.

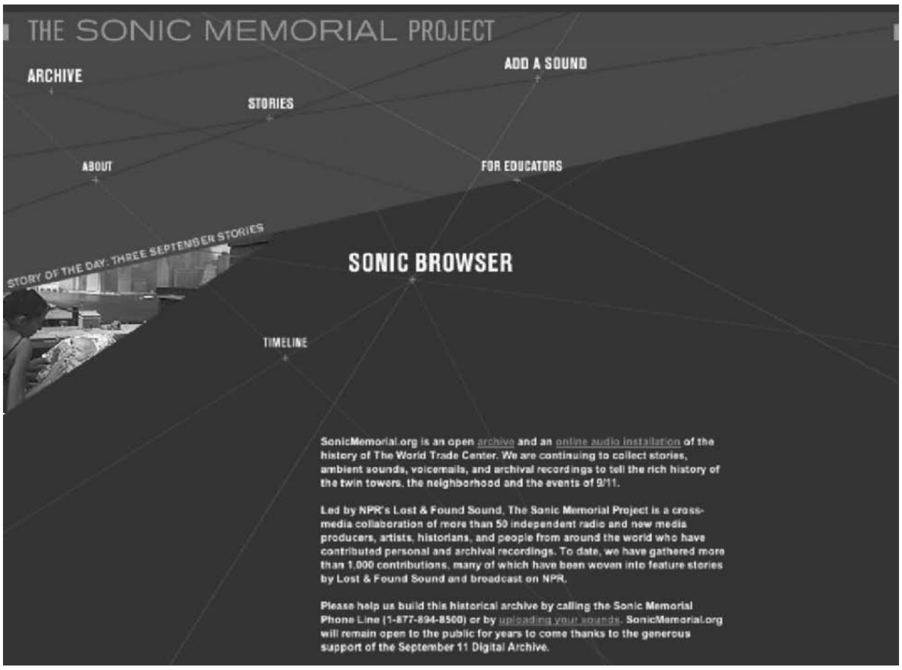

Figure 1. SonicMemorial.org, home screen.

historic event. This was to be an open, participatory project where the public would be invited to continue to build the archive by contributing sounds and stories online *via* a web-based interface. Further, the vast amount of material already collected needed to be cataloged, indexed, and preserved for future generations of visitors to the website, radio producers seeking material for future productions, researchers and historians interested in oral histories, and artists seeking to make creative use of the material for independent projects. Finally, the website was to be a memorial—a place of remembrance, commemorating the life of the World Trade Center as it existed before, during, and after 9/11 (Figure 1).

The website produced consists of two distinct interface modes by which this archive is accessed by the public. The first was designed to support traditional methods of searching an archive, and displays a list of descriptions of sound files based on keywords or themes input by the visitor. From this list, the visitor can select and listen to a specific sound and view images associated with it. This interface mode was designed for people seeking to locate specific sound files efficiently, such as radio producers seeking material for future productions, researchers and historians interested in oral histories, as well as the general public interested in specific material (Figure 2).

The second interface is the Sonic Browser. With the Sonic Browser, the visitor is presented with a more meditative space—one where sound itself

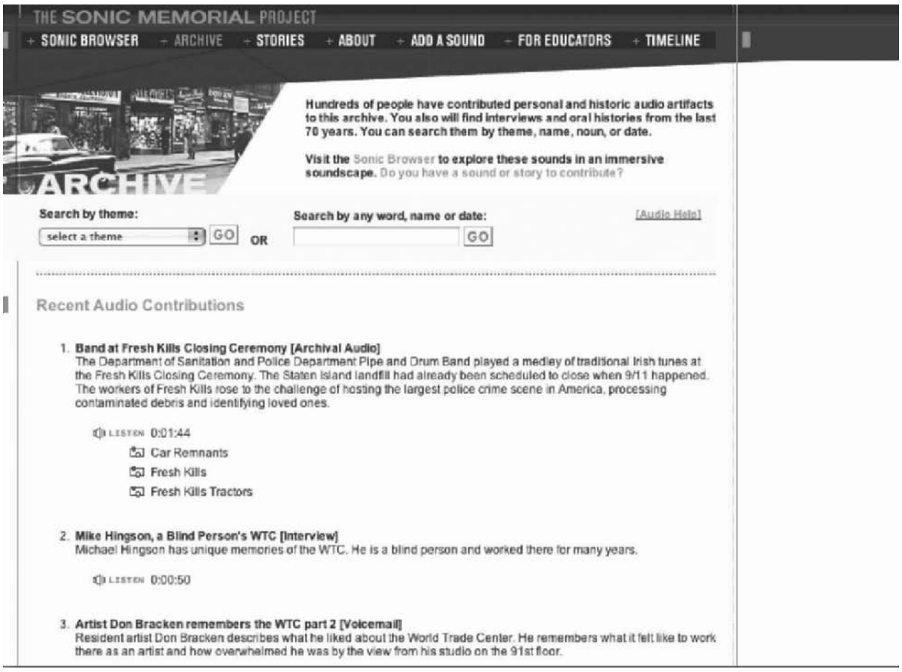

Figure 2. SonicMemorial.org, archive interface.

becomes a compass by which the archive is explored and navigated. Upon entering the Browser, the visitor is presented with a minimal space containing a series of vertical lines drifting across the screen. The lines appear from one side of the screen and disappear off the other, implying an extension of the space beyond the frame of the window. Visitors can pan this frame left or right to explore sounds outside the initial view. As one moves the mouse over one of these lines, the line twitches slightly and a title appears identifying a specific sound file. Upon selecting the line, the sound begins to play, and the line transforms into a dynamic animation reflecting a sound wave with a set of keywords appearing to its side. By selecting one of these keywords, visitors are subsequently able to "gather" sounds related to the one they are listening to, and further navigate the archive based on their specific interests (Figure 3).

The website also provides a simple form that enables anyone to contribute sound artifacts or stories online *via* a standard web browser. Additionally, contributors are able to add descriptive annotations, photographs, graphics, transcripts, or other documents they want to include with their sound. These materials are uploaded directly to the server and are subsequently available to visitors to the archive. That this memorial was to be constructed primarily of sound artifacts, coupled with the fact that these artifacts were to be contributed by a distributed public *via* the internet, offered an opportunity to

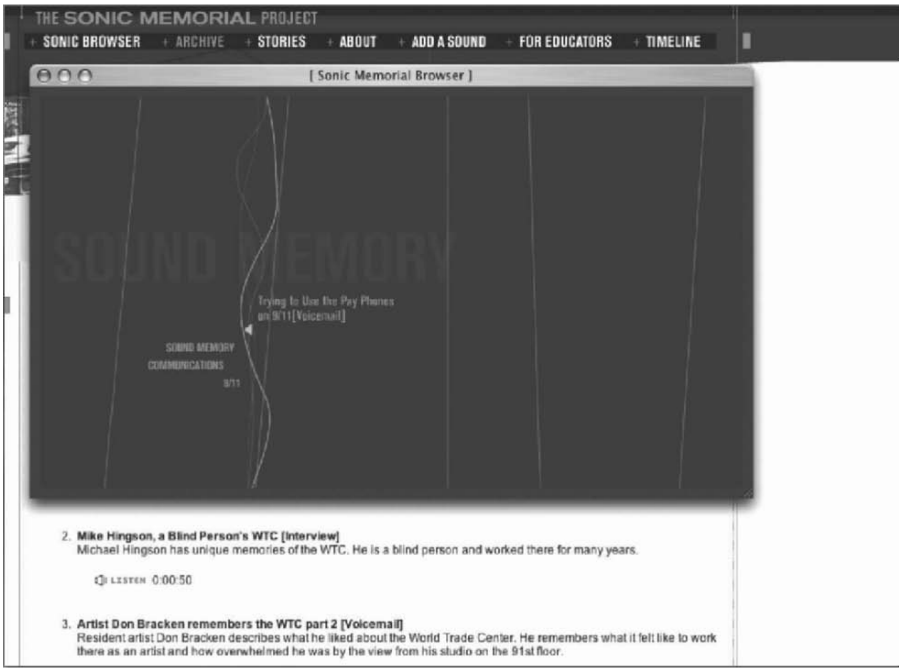

Figure 3. SonicMemorial.org, browser interface.

rethink conventions of memorial making within the context of virtual environments. In the process, notions regarding both what constitutes a "memorial" as well as what has come to signify the "virtual" were revisited in light how each potentially re-informs the other. In the following pages, I consider how SonicMemorial.org, through its use of sound and embrace of public participation, refigures conventional notions of the memorial as stable and timeless and of the virtual as ephemeral and temporal. I begin by reviewing traditions of memorial making and concurrent critiques of monumentality that have been developed by artists, architects, and cultural historians throughout the 20th century. This provides a critical context for a subsequent discussion of SonicMemorial.org with regard to the ways in which traditional notions of memorial making are destabilized through the use of sound artifacts and participatory structures enabled by network technologies. Finally, I explore the implications of these strategies for broader questions concerning of the design of virtual learning environments (VLEs).

2. MEMORIAL MAKING AND THE CRITIQUE OF MONUMENTALITY

Traditionally, memorials have consisted of a physical edifice that is built of stone, often classically adorned, fixed, and timeless. Their role in the physical world is commonly understood as that of both landmark and portal to a person or event that is no longer present, one that we wish to remember for generations to come. In this sense, memorials are a special kind of monument. They serve as vehicles by which someone or something lost is rendered "present" through interplay between the mental processes of memory and imagination, and the physical architecture and artifacts that constitute the memorial construct. These memorials traditionally operate as redemptory sites of mourning and national instruction. They dispense an "official history" for the consumption by the public at large. Nowhere is this more evident than in the memorials built to commemorate wars or public figures. Here, the narrative embedded in the articulation of form, space, and material aspires to summarize the meaning of the person or event in an authoritative manner, once, and for all.

For example, consider the recent construction of the World War II Memorial in Washington D.C. Almost 60 years after the war had ended, and after more than 15 years after the idea was first proposed in Congress, the memorial was unveiled to the public on Memorial Day, May 31, 2004. The memorial's neoclassical arcades and central open plaza, constructed of various kinds of granite, were designed to commemorate those who served in the war—"the greatest generation", heroes all, who fought the "last great war". And though that war has sparked controversy over Japanese American internment camps, the use of the atomic bomb, the firebombing of Dresden, none of this is reflected or even hinted at in the memorial's design and construction. "World War II is, in a sense, a glorious war—a triumph of democracy over totalitarianism", stated Friedrich St. Florian, the memorial's architect, in 2000 (Kennicott, 2004). Yet viewed in the context of a country presently embroiled in not one, but two wars of highly questionable pretext, it becomes difficult not to read the memorial's use of arches, for example—outside the vernacular of a properly American memorial architecture—as suggesting the whiff of something Roman, something imperial, something more to do with military conquest than liberation. "The World War II Memorial", writes Hebert Muschamp, architecture critic for the *New York Times*, "can be seen as a monument to the military-entertainment industry complex, our new enforcers of the global Pax American Pop Culture" (Muschamp, 2001).

The critique of the desire to "set history in stone", and thereby produce an official narrative for mass consumption, is by no means new. Along with other forms of cultural production in the 20th century, the process of memorial making and the form of public monuments have undergone radical transformations, reflecting both the political and the esthetic revolutions of the times as well as a broader crisis within representational practices following the century's major wars and conflicts. As James Young (2000) notes, one can trace a transformation in the monument from the heroic, self-aggrandizing figurative icons of the late 19th century celebrating national ideas and triumphs, to the anti-heroic, self-effacing, conceptually driven constructs that mark the national ambivalence and uncertainty of the late 20th century.

In his chapter “Memory, Countermemory, and the End of the Monument”, Young sketches an historical overview of critical responses to the concept and institution of the monument, of which I will briefly summarize here. “Away with the monuments!” declared Friedrich Nietzsche, calling for an end to the “monumental history” of 19th Century German Historicism that “oppressed the living with stultified versions of the past”. This call to arms was further developed throughout the 20th century, primarily through the voices of artists, architects, and cultural theorists associated with modern movements in art and architecture. “The notion of a modern monument is veritably a contradiction in terms”, wrote Lewis Mumford in the 1930s. “If it is a monument it is not modern, and if it is modern, it cannot be a monument”. In articulating a common thread in modern architecture that privileged change and transformation over the illusion of permanence, he writes, “Stone gives a false sense of continuity, a deceptive assurance of life”. He goes on to suggest that often it is the least effectual regimes that choose to shroud their ineptitude in self-aggrandizing stone and mortar.

The words “set in stone” suggest that an idea, or a fact, has been placed in its ultimate form, beyond emendation and, often, beyond debate or contradiction. Yet to the extent that public monuments are inevitably constructed in particular times and places, contingent on the political, historical, and esthetic realities of the moment, the very idea that monuments can themselves preserve the memory of a person, place, or event for eternity is in itself a contradiction. Often, as the German historian Martin Broszat points out, monuments do not so much preserve memory as bury it beneath the layers of national myth and explanation that make up the “official history” the monument is designed to narrate. Art historian Rosalind Kraus goes further in suggesting that the modern period produces monuments that are unable to refer to anything beyond themselves as pure marker or base. Explicitly self-referential, the modern monument is thus rendered incapable of referring to events outside itself, and is “left motioning endlessly to its own gestures to the past”.

Others have argued that rather than preserving public memory, monuments displace it altogether by supplanting a community’s memory-work with its own material form. Pierre Nora writes, “The less memory is experienced from the inside, the more it exists through its scaffolding and outward signs” (Nora, 1989: 13). One might say that to the extent that we encourage monuments to do our memory-work for us, we become that much more forgetful. Here, it is the very act of remembering someone or something—understood as a form of interplay between a physical edifice, personal memory, and an active imagination—that is considered important to preserve.

Of the number of “counter-monuments” that this critique has produced, perhaps the most influential is that of Daniel Libeskind’s winning competition entry for the Berlin Jewish Museum Extension. Faced with the daunting challenge of “giving voice to an absent Jewish Culture without attempting to speak for it”, as called for in the competition brief, Libeskind focused on reifying this absence in the design of the building itself. “The new extension is conceived as an emblem where the not visible has made itself apparent as a void, an invisible . . . The idea is very simple: to build the museum around a void that runs through it, a void that is to be experienced by the public.” (Libeskind, 1991: 63). This “void” consists of a straight linear slot that is cut through a bent and meandering bar that contains the building’s programmatic spaces. As one moves throughout the twisted and zigzagging building, one repeatedly encounters this discontinuous void—empty and unusable—that in its form and articulation, becomes the primary element around which the building is organized.

3. SONICMEMORIAL.ORG

SonicMemorial.org builds on elements of this critique by positing a memorial that is constructed primarily of sound artifacts contributed by a distributed public *via* the internet. From the start, the design team was interested in the ability of sound to create for the listener an aural “presence” that in face of such a monumental visual “absence” in lower Manhattan where the towers once stood, provided a way to sustain identification with a place and the people who occupied it that directly involved personal engagement. The idea of a distributed public body engaged in the memorial’s construction offered new ways by which the process of remembering, interpreting, and understanding could remain the domain of the people for whom the memorial is created, and not a product of an “official history” to be consumed en-mass by the public at large. Bergson, in investigating relations between matter and memory, describes the process of recollection as a movement from the virtual to the actual:

> “Whenever we are trying to recover a recollection, to call up some period of our history, we become conscious of an act *sui generis* by which we detach ourselves from the present in order to replace ourselves, first, in the past in general, then, in a certain region of the past—a work of adjustment, like the focusing of a camera. But our recollection remains virtual; we simply prepare ourselves for receiving it by adopting the appropriate attitude. Little by little it comes into view like a condensing cloud; from the virtual state it passes to the actual; and as its outlines become more distinct and its surface takes on color, it tends to imitate perception.”
>
> (Bergson, 1988: 133)

The perception and interpretation of sound requires the active participation of a listener. It is one thing to hear a sound, quite another to listen to it. Listening requires focusing attention on what is heard. Hearing is simply the act of perceiving sound through the stimulation of auditory nerves in the ear by sound waves. Sounds have the capacity to create a sense of "presence" for an active listener—the ambient sound of a public plaza, for example, provides us with the sonic material from which we can imagine the space itself. Through listening to recorded or remote telephonic sounds, we are able to transport ourselves to places we may have never been. This "virtual" presence is the product of an interplay between the sound fragment on one hand, and the memory and imagination of the listener on the other. SonicMemorial.org is constructed from recordings that document aspects of the people and spaces of the World Trade Center. In the absence of the physical structures, these recordings exist as a particular kind of evidence of the buildings' spaces and the lives of the people who occupied them—simultaneously lost & found sounds, partial and fragmentary. From these fragments, the buildings and the people who occupied them are continually reconstructed through the active participation of an imaginative listener. It is in this sense that the memory-work critical to the process remembrance resides within the person's participatory relationship to the memorial, not within the memorial itself. The result is a memorial to a place that is sustained through the memory-work of those engaging it, and not through the consumption of an official narrative "set in stone" for all time. This participatory structure was further extended by opening up the process of contributing sound artifacts to anyone—not only people from New York wanting to contribute their answering machine tapes from that day, but also people living in remote parts of the world who composed, for instance, a song or poem from their memories from visiting the place years ago. This not only ensured that the "narrative" of the memorial was not the product of an individual or "official" group of people, but also provided for the collection of sounds to be constantly evolving. The idea was that at no single point in time would one be able to experience the memorial as a complete whole with a definitive story to tell. Rather, it would be the potential limitlessness of the memorial itself that would maintain the act of remembering in the present tense, and tie it to ongoing acts of contribution and discovery.

4. RETHINKING THE VIRTUAL LEARNING ENVIRONMENT

Currently, most VLEs are designed to augment traditional classroom-based learning by extending this learning model to students participating remotely *via* the internet. VLEs commonly provide controlled access to individual curriculum modules, communications systems such as bulletin boards, instant messaging, and e-mail, as well as a suite of administrative features for managing, tracking, and assessing students. Yet while these environments may facilitate distance learning through the use of electronic network technologies, and are quite adept at automating accountability and related control structures within learning institutions, I would argue that they ultimately fail to consider some very basic opportunities for the design of learning environments that the "virtual" affords. Bergson articulates the process of recollection as a movement from the virtual to the actual, as an action akin to focusing a camera, imitating perception. Audio artifacts imply an active listener, a participant in the production of a virtual presence. Perhaps the most promising thread for exploring the opportunities latent in the virtual *vis-à-vis* learning environments is that of rethinking existing learning models with respect to what the virtual affords—beyond the mere facility provided by electronic networks.

To do so, we need to consider the VLE in the context of a broader set of informal modes of learning such as visiting a museum, watching a documentary film on television, participating in a reading group, or checking out books from a library. These informal learning environments (ILEs) offer people opportunities for lifelong learning that extend beyond the purview of the classroom or workplace. As Falk and Dierking note, the most common form of lifelong learning is what they call "free-choice learning" (Falk & Dierking, 2000). Free-choice learning is the type of learning guided by a person's needs and interests—learning people engage in throughout their lives to find out more about what is useful, compelling, or simply interesting to them.

The Contextual Model of Learning (Falk & Dierking, 2000) grew out of a framework that John H. Falk and Lynn D. Dierking developed (Falk & Dierking, 1992) after tracking thousands of people throughout their visits to museums, observing them in specific exhibitions, and conducting innumerable interviews (Falk & Dierking, 1992; 2000). This model suggests that three overlapping contexts—the personal context, the sociocultural context, and the physical context—contribute to and influence the interactions and experiences that people have when engaging in free-choice learning activities. Thus, the experience, and any free-choice learning that results, is influenced by the interactions between these three contexts.

The personal context involves an individual's motivations and expectations, interest, prior knowledge, and experience, and is greatly influenced by an individual's choice and control over what, how, when, and with whom they learn. The sociocultural context acknowledges that learning happens within sociocultural groups, is facilitated through mediation by others, and influenced by all of the cultural overlays of what learning means in a society, who engages in it, and what institutions participate. The physical context addresses the importance of advance preparation in orienting learners to the environment and its expectations, the setting and design of this environment, and subsequent reinforcing events and experiences that over time reinforce the accumulation of understanding. Simply stated, this model suggests that (1) learning begins with the individual, (2) learning involves others, and (3) learning takes place somewhere.

The following design strategies are offered as sketches toward rethinking the VLE in terms of the potential of the virtual in the development of new forms of learning environments. In doing so, the aim is less to provide a formal set of guidelines than to map out preliminary waypoints for further investigation. Ultimately, the design of a VLE provides an opportunity not only to rethink existing learning models but also offers a vehicle by which the ways and means by which we learn can be explored and evaluated.

4.1. Create a Distinct Space/Place

Each structure, virtual, or physical, requires an architecture that defines its relationship to itself, its surroundings, and the space it both occupies and displaces. This architecture carries with it protocols by which we locate, orient, navigate, communicate, and interact with others within the environment. In creating an information architecture, one creates a set of relationships that we "learn" through the way they locate, orient, and position us, both in relation to the information at hand as well as to others taking part.

4.2. Let the Learner Drive

Often we learn best when we are in control of what, how, when, and with whom we learn. Enabling a learner to choose the pace, depth of information, and degree of interaction/feedback of the experience is critical in providing an environment conducive to a range of learning styles and preferences. Intrinsically motivated learners tend to be more successful learners than those who learn because they feel they have to.

4.3. Offer Multiple Points of Entry

By providing multiple points of entry into a particular subject, one enables the learner to enter into a learning situation along paths specific to his or her interest, familiarity, and need. Learning environments offering a variety of ways by which information is accessed are more effective in engaging the unique needs of a diverse group of learners.

4.4. Engage the Learner As a Participant

Cast the learner in an active role *vis-à-vis* the learning environment. Involve the learner not only in contributing material to the environment but also in making meaning from it. Participatory structures not only help learners establish a personal connection to the material, but also a means by which to share that connection with others.

4.5. Foster Social Collaboration

Support and facilitate social interaction and exchange within the environment. Peers build social bonds through shared experiences and knowledge. Social groups often utilize each other as vehicles for deciphering information, for reinforcing shared beliefs, for making meaning. Such settings create unique milieus for collaborative learning to occur.

Chapter 41: "Why don't We Trade Places . . . ": Some Issues Relevant for the Analysis of Diasporic Web Communities as Learning Spaces

VERA NINCIC
OISE, University of Toronto

1. INTRODUCTION

Understanding the learning process as an aspect of the participation in various communities of practice (Lave, 1996; Lave & Wenger, 1991) helped educational researchers to explore learning contexts beyond school-based environments. In that sense, the participation in diasporic web communities could be interpreted as a particular learning experience: by participating in diasporic online spaces dispersed people learn and re-learn what it means to be an immigrant, how to understand and interpret immigrant experience, or imagine a relationship between the homeland and hostland. The identity-changing nature of online participation warrants a close analysis of web communities, which, along with other online/offline environments, could be involved in the construction of immigrant experience. For this reason, web communities, produced by socio-economic, cultural and migration flows, and mediated by the development of internet technologies, should attract attention of educational researchers. However, there is a need to address various issues that emerge in the way we are approaching the issue and conceptualize such a communities.

While the problematization of discourses advocating the transformative potential of web communities has been prevalent in the recent literature, the discourses of political and cultural promises and troubles of diasporic online networking are still being relatively unchallenged. Popular images of diasporic web communities as spontaneous and natural, and "an obvious goldmine" of the Net need to be problematized, as Jones (2002) points out, since they presume the deterministic nature of ethnic ties, allowing us to forget that "communities are very much constructed no matter how organic they may seem" (p. 371).

Discussing diasporic practices in online spaces requires a difficult balancing act among a variety of discourses that surround cyberspace, diaspora-related themes, and their particular configurations (Shohat, 1999). On the one side, it would be necessary to take a critical stance toward celebratory discourses that understand the promises of diasporic uses of computer technologies only in terms of their potential to weaken further the power of nation-states and

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1067–1088.

political borders, as well as the gradual dissolving of the place-bound identities. With such an approach, one tends to overlook both the material effects of the power of nation-state and the situated nature of diasporic online practices. As Shohat (1999) suggests, such discourses disregard "the ways in which material geography and history shape complex production, consumption, and usage of technology" (p. 219). On the other side, we need a critical stance toward overtly pessimistic discourses that understand diasporic online practices as completely entrenched in homeland nostalgia, and, as such, easily susceptible to comodification by homeland-based economic or political interests. Both approaches might disregard diverse, changeable, and context-dependent online practices, and the heterogeneous composition of diasporic web communities.

Several themes explored in this chapter aim to contribute to the discussions that problematize assumptions about diasporic groups and their online practices present in popular discourses and academic writings. For example, a diasporic web community has been frequently understood as a more or less spontaneous product based on ties that tend to produce and maintain the nostalgia-based relationships toward the imagined or real homeland. Framed this way, all diasporic online practices are seen being similar in nature and oriented toward virtual remake of the left or lost homeland. By re-thinking the concept of diaspora in terms of the heterogeneous nature of immigrant social networks and the diversity of uses of diasporic spaces, as well as by challenging the assumed sameness of diasporic experience, it could be possible to understand not only the diasporic online practices as situated, context-dependent and changeable, but also the meaning of the "homeland" as contesting and shifting.

Moreover, certain academic texts focused on the appropriation of computer technologies by "ethnic" groups tend to raise the issue of hegemonic nature of internet-based technologies in terms of being an obstacle to the "cultural expression" of ethnic groups. Such a standpoint assumes that online technologies, by being a product of a particular culture (American, Western, or English-speaking one), possibly hinder the "expression" of local, cultural, and linguistic practices. While such a stance is careful to take into account the political and cultural implications of computer technologies, it simultaneously reproduces the split between Western and "other" cultures by promoting the idea of some distant, exotic, and unspoiled-by-technology "ethnic" culture in need to be "expressed" in a particular way. By looking at the process of the production of diasporic online spaces, it should be possible to problematize such a separation of technology from diasporic practices by understanding them as mutually dependent and co-shaping.

The discussion about above-mentioned assumptions of diasporic online networking—spontaneous production of diasporic online spaces and homogeneity of diaspora, as well as the separation of technologies from diasporic practices, might help us conceive diasporic web communities in more balancing terms. Using the case of a Serbian web community—an online, non-English speaking network of both Serbian (and ex-Yugoslavian) immigrants and Serbians currently living in the homeland(s)[1], I aim to present a more complex picture of an ethnic online group, its online practices, and its communal online space. At the same time, by discussing the situated nature of a diasporic web community, I hope to be able to argue the importance of such communities for the educational researchers interested in diverse sites implicated in the identity-changing learning experiences.

2. THE PRODUCTION OF WEB COMMUNITIES: THE CASE OF A SERBIAN WEB COMMUNITY

The Serbian diasporic web community, a relatively stable and highly populated website of Serbian-speaking immigrants, will celebrate nine years of its existence in the Fall of 2005. This "ethnic" web portal, with the servers physically located in Toronto, Canada, is completely presented in the Serbian language. Web-based statistics (Alexa.com) suggests that this particular site represents one of the most visited websites for Serbian diaspora and Serbian speakers in general. That means that despite the site's major focus on an immigrant audience, it has an appeal to people living in the homeland(s). While we should be skeptical about traffic statistics based on online "hits" to particular sites published by the web companies that generate results for particular purposes, the available statistic, however, suggests certain tendencies. The Serbian diasporic web community, as the results suggest, is a highly visited web location among Serbian speakers with growing number of users every year.

Similar to many diasporic websites this one offers the predictable web content that should appeal to Serbian immigrants: daily updated homeland's news, business advertizements of goods for immigrant market (homeland's food products, air tickets, videos/CDs), and web links to news agencies, newspapers, radio, and television programs available online in the Serbian language. Beside the "standard" diasporic offerings, the site is hosting over 50 discussion boards and several chat rooms that support contact and communication in the Serbian language, as well as the web search engine that searches through the "Serbian-only" websites in both diaspora and the homeland.

A casual visit does not reveal much about the site's authorship. It is hard to find any reference about the people who produce and maintain the site, or about the geographical location of the servers that materially support the entrance of the portal page. A detailed search reveals that all advertizements on the home page belong to Toronto-based companies selling their products to the local immigrant market, and that the site has been developed and operated by a company located in Toronto. It could be assumed that there is a certain profitability of the site (the Toronto immigrant market obviously pays well for homeland-imported products) because it has operated relatively smoothly for years. It has not changed its web location or interrupted its service despite a huge influx of visitors in certain circumstances. For example, an increase in online participation during the Kosovo crisis in 1999 did not interrupt website operation. Rather, it had put this web portal among the thousand of most visited websites in the world for that year. The stability of this web location could be assumed by the site's ability to progressively accommodate increased numbers of visitors year by year.

I mention the importance of the Kosovo crisis because this tragic offline event had helped in establishing the site's visibility and its influence among virtual Serbian diaspora. It seems almost trivial to say that the important events happening in the homeland tend to mobilize diaspora in particular ways. Homeland's wars and violence, in particular, heighten attention of those who emigrated (Kolar-Panov, 1997). The existence of web technologies that offer 24/7 monitoring of the homeland's events through message exchange, allow us to assume that immigrants with a computer access could frequently use those technologies, if for nothing else, then to fill in the lack of information left by "transnational storytellers" such as CNN, BBC, and others (Shohat, 1999).

In some cases, it is not coincidental that internet-based technologies are readily chosen for diasporic participation. For immigrants coming from the territories of Former Yugoslavia (among them are Serbian-speaking migrants), especially those belonging to the migrant waves that followed the Balkan's wars in 1990s, online communication might be of particular significance. According to Stubbs (1998), "[t]he wars of the Yugoslav succession from 1991 are, perhaps, the first 'wars with computers' in which reactions to a real war were multiplied immensely by the possibilities of new communication technology". From the first days of Yugoslavia's deconstruction, followed by broken telephone lines, fax, and postal service between parts of the country and coupled with distrust and skepticism toward the official media, those with computers and modems maintained contacts and exchanged information over computer-based networks (BBSs). It could be argued that many of those who used online technologies (the technologically literate and highly educated) at that time had emigrated out of the territories of the Former Yugoslavia (especially when we consider the market value of technically literate immigrants and immigrant recruitment practices of Western countries during the "high-tech boom" in the mid-1990s).

The Kosovo crisis in 1999 provoked significant increase in online activity, both in diaspora and in Serbia. For example, discussing the web use in Serbia during the Kosovo crisis, Bacevic (2002) suggests the importance of online communication for those in the homeland in "creating a sense (illusion) of greater control over the situation" because it "eased the frustrations and alleviated the sense of rejection, isolation and threat" (Bacevic, 2002: 8). Increased online participation during the war situation has been suggested by others as well (Antonijevic, 2002; Stubbs, 1998).

Suggestions about increased participation at the times of the homeland's crisis are important for a website aspiring to become an influential diasporic informational node on the web. The website needs an infrastructural stability (the same web address, always “up and running”) and careful moderation to accommodate the increased number of people. Moreover, it needs to offer information exchange by linking various internet media (online press, audio, and video files) so that information about the homeland could be re-checked and analyzed from several perspectives (Nincic, 2000). Understood in those terms, after the Kosovo crisis the Serbian diasporic site had managed to establish itself as one of the most popular websites in the Serbian language for both immigrant and homeland audiences.

While many of the Serbian diasporic websites have struggled to attract and maintain the immigrants’ attention in the competitive online diasporic market (by advertizements, content, emphasis on offline context), it is not by accident that this one managed to realize such a goal. With continuous financial and technical support, the site has maintained its web location for 8 years, barely changing its content and visual layout. It has established a certain stability of traditional “walls” necessary for the survival of any “virtual community” (Kolko & Reid, 1998). For the Serbian web community, as I mentioned earlier, the local, Toronto-based and immigrant-targeted businesses represent a necessary building block. In that sense, as Bleecker (2003) argues, it is not easy to discern the web community’s building aspects from those that make it market-ready. Diasporic local businesses have financial stakes in supporting homeland nostalgic online imaginary, which is being tightly linked to the marketable value of their products (from air tickets to homeland crackers).

It would be misleading, then, to treat a diasporic web community only as a spontaneous product of immigrant experience and longings for the homeland. Instead, a well-financed, skillfully maintained, and stable online environment represents an infrastructural basis necessary (but not sufficient) for community building. Beside the business-supported infrastructure, other aspects of Serbian diasporic web organizing play a role, such as assumed commonality based on the shared language, territory, and immigrant experience, the relative recency of immigration, immigrant conditions of hostlands, and the access to the web technologies.

Appadurai (1996) argues that diasporic web communities—or “virtual neighborhoods” as he calls them—could be understood as actualized, spatially produced, situated localities—the effects (material and symbolic) of a general technology of localization. Being concerned with the techniques by which locality is produced, Appadurai understands locality as a structure of feeling, as a sense of belonging that may have real, material effects and which cannot be understood apart from actual realized settings through which social life is produced. Diasporic groups, by using techniques for the spatial production of locality, construct a “material home”—a place constantly produced, reproduced, and maintained by “ritualized” practices. Massey (1998) offers similar suggestion by pointing out that we should be aware of a constant engagement of people to "territorialize, to claim spaces, to include some and exclude others from particular area" (p. 126). Such a desire for territorialization, she furthers her argument, could be understood as an attempt "to tame the unutterable complexity of the spatial: it is a way of gaining some control (. . .) by constructing an ordered geographical imagination through which to frame our worlds" (p. 126).

The immigrant's need for "placing" or "rooting" surely is not new. Certain aspects of the practices of territorialization have been widely studied among immigrants such as "ethnic clubs"—claimed cultural spaces that are supposed to alleviate feelings of cultural marginalization and also as a necessary bridging point for the slow process of acculturation (Kolar-Panov, 1997). While diasporic online networking might be perceived as different from older "ethnic clubs" in its mediated technological quality, it is important to note that any form of diasporic organizing employs some form of technological mediation (e.g., telephone, TV, newspapers). Or, as Poster (1998) reminds us not to treat ethnicities "through a binary opposition of immediate or mediated but through different configurations of mediation" (p. 196). In that sense, similarly to widespread ethnic clubs, organized and maintained in the "host" countries by immigrant groups, these "virtual ethnic clubs", with a potential to provide a cultural and social space for diasporic groups, might represent a diasporic response to social/cultural changes in the broader "network society" (Castells, 1998). "Taking over" the socio-cultural functions of ethnic clubs, understood as "a kind of substitute kinship base for the newly arrived migrants" (Kolar-Panov, 1997), diasporic online places offer a basis for diasporic networking, solidarity, and support.

Although migrant networking is frequently described in terms of the particular migrants' practices in overcoming fear of isolation, complexity of new land, a new language, and of a new culture—economic conditions in which immigrants live in hostlands should be also taken into account. In that context, to avoid less-paid and dead-ends jobs many immigrants must establish and maintain their social networks (Portes, 1996). From that perspective, it could be said that immigrants might bind together to enjoy privileges of "social capital" embedded in social networks (Putnam, 2000). In that sense, online diasporic networks could be thought of as "the imperfect means by which dislocated people who lost their geographic home retain their home imaginary, while also struggling for a literal and metaphorical place in new countries" (Shohat, 1999: 226).

3. DIASPORA, ETHNICITY, AND HETEROGENEITY

As Cohen points out (1999), the concept of diaspora seems to be a trendy "buzzword", too frequently used "as an overarching concept or model to map every kind of traffic in populations, cultures, or ideas" (p. 19). Such a prominent use of the term should be linked, as Anthias (1998) suggests, with the debates about the processes of economic and cultural globalization, increased migration of people, and the new information and communication technologies that all have problematized the traditional concepts of "ethnicity" and ethnic identity.

The traditional discourses about ethnic identity understood it as "based on shared claims to blood, soil, or language" (Appadurai, 1996: 140) and as an expression of "original" ethno-cultural characteristics shared by an ethnic group. The discourse about ethnic identity, objectified as a fixed "unity", had overlooked its processual, situational, and changeable nature as "never complete, always in process, and always constituted within, not outside of representation" (Hall, 1990: 222). Thus, ethnicity had been understood as a primordial and shared set of traits with which only certain groups are endowed. Such an approach could not attend to the issues of diversity that exist inside of ethnic groups, such as "class and gender location, distinctive trajectories of migration and settlement, and internal differences of power, position or claims" (Anthias, 1998: 559). The theorists that hold such a view, might look for the implications of online technologies on ethnic identity as some pre-given, fixed repertoire of ethnic characteristics.

Another view of ethnicity, understood as socially constructed and changeable, assumes that ethnicity figures as a site of the constant struggle between external and internal forces that are dependent on "the individual's perception of its meaning to different audiences, its salience in different social contexts, and its utility in different settings" (Nagel, 1994: 155). According to Nagel (1994) the process of identifying with a particular ethnic category is not simply a matter of personal choice, but is limited and influenced by socially and politically defined and imposed ethnic categories. The social, political, economical, and cultural aspects of the identity construction of an individual or a group, from that perspective, play the crucial role in the process of self-identification. As such, ethnicity has been thought of as being useful for explaining differences among different ethnic groups inside of the nation-state borders.

However, as Anthias (1998) argues, the concept of ethnic identity, despite now being fashioned as having constructed quality, still tends to focus our attention on ethnic groups inside of the nation-state, on the relationships among ethnic groups, as well as on the processes of marginalization, assimilation, exclusion, and inclusion in the country of settlement. Although those are all important issues, Anthias maintains, such a perspective cannot allow us to explore the variety of emergent or established links that an ethnic group maintains with other groups outside of the borders of the nation-state.

For example, as a way to understand migrants' networks, Winland (1998) suggests that we need to challenge the idea of a permanent rupture between the immigrants and their countries of origin and explore the variety of ties that immigrants maintain with their homeland, particularly as these ties have been enabled by the new communication and information technologies and transportation: long-distance communication, frequent travels to the homeland, money sent to family members that stayed in the homeland or political interest in the homeland's issues. In that context, Winland (1998) points out, beside emotional attachments and nostalgia for the homeland, diasporic groups establish and maintain the real, material links that go beyond the borders of the nation-state.

Such theoretical orientation toward transnational links maintained by diaspora has been followed by the rise of a new vocabulary better suited to theorize contemporary migration processes. The concepts such as transnationalism (Basch et al., 1994) and transnational communities (Portes, 1996) allow us to focus on migrants' social networks that cut across geographic, cultural, political, and economical borders. Seeing immigrants as being in constant relation with at least two countries, as Brah (1996) points out, we should focus our attention on the "networks of transnational identification" (p. 196). This suggests that migrants, supported by modern technology and with more affordable travel, have been able to maintain their social networks regardless of the nation-state borders, and, thus, continuity rather than rupture is a more appropriate descriptor of the contemporary migrant condition.

In this sense, the concept of diaspora might serve as an important analytical tool to address the issues of transnational migration and identifications in the context of cultural and economic globalization flows. As Anthias (1998) suggests, the concept has been useful in terms of its focus on "a connection between groups across different nation-states whose commonality derives from an original but maybe removed homeland; a new identity becomes constructed on a world scale which crosses national borders and boundaries" (p. 559–560). In that sense, people in diaspora are able to "maintain important allegiances and practical connections to a homeland or a dispersed community located elsewhere" (Clifford, 1997: 286).

Still, despite its usefulness, the concept of diaspora tends to be over-used and under-theorized (Vertovec, 2002). It relies too much, as Anthias (1998) argues, on unproblematic attachments that migrants maintain with their homeland, which constructs migrants as belonging to a "natural community" that share the same political project. From that perspective, the diasporic group becomes homogenized, Anthias (1998) maintains, even if it has been done now on the transnational level. The intra-group differences (based on social class, gender, different reasons of migration, different experiences with country of settlement) have been overlooked, particularly how those differences relate to homeland and home imaginings. To save the usefulness of the diaspora concept, it would be necessary to re-conceptualize it in terms of transnational, heterogeneous, and temporarily made social networks—since there is no such a thing as unified diasporic experience (Anthias, 1998; Stubbs, 1999).

To summarize, the concept of diaspora has helped in refocusing the theory from the processes of inclusion/exclusion of "ethnic groups" inside of the borders of nation-state to a broader view of transnational attachments and social networks. Such a point of view resonates better with contemporary economic and cultural flows and migration processes, challenging at the same time potentially oppressive practices of the nation-state. Yet, such a theoretical shift has to be accompanied by careful attention on both intra-group heterogeneity and the practices of nation-states.

Cultural hybridity has been another important concept used to problematize the notion of "ethnicity" as a fixed set of cultural traits. It has been frequently employed in the discussions about migration and cultural dislocations as a way to point out the implications of cultural encounters that migrants face in the countries of settlement. Immigrants have been usually conceived as responding by "taking on some aspects of the new culture but retaining older cultural habits" (Wise, 2000). In that sense, a diasporic group could be understood as being in constant struggle to build a "hybrid" culture, while constantly re-negotiating the links with homeland. However, the important point that Massey (1998) emphasizes is that not only diasporic cultures, but also all cultures should be conceived as hybrid ones. Traditional conceptualization of "culture" "as locally produced systems of social interaction and symbolic meanings" (Massey, 1998: 123) needs to be challenged because the processes of importation, adoption, and adaptation constitute all cultures. Taking this standpoint does not allow us to think of cultures in terms of "neatly ordered boxes labeled urban, regional, national" (Massey, 1998: 125) that tend to fashion migrants as coming from some closed, fixed-in-time, technologically unspoiled "local" culture that has been progressively "hybridized" by migration and settlement.

Such problematization of cultural hybridity could be helpful in addressing the issues related to the appropriation of computer technology by migrants in the context of different conditions of migration. We may ask, for example, how contemporary immigration processes might be different than those, say, of 50 years ago? And how has the development of online technologies coupled with economic globalization flows linked to contemporary migration? The question of "new diasporas" has been addressed by Mitra (1997), who suggests that the migration processes in the last two decades have produced the "new wave" of immigrants—usually well-educated professionals employed in North America, Australia, and Western Europe. As Mitra suggests, they might be different from earlier immigrant waves looking to settle close to their "ethnic enclaves" in big metropolitan areas in the Western world. Instead, modern immigrants in diaspora are "scattered across the Western hemisphere, working in similar professions but spatially distanced from each other" (p. 57).

The changes in the immigration practices of the Western nation-states in terms of the constant import of educated professionals (for example, as a response to the development of computer industry) have certainly been implicated in particular technological and diasporic configurations. Although we should be careful with the claims that emphasize novelty of the contemporary processes, there is a need for detailed research that would take a longitudinal approach that addresses the several phenomena simultaneously. Without such an approach, the detailed analyses of the use of new technologies by diaspora might employ certain "old" assumptions regarding migrants by overlooking the changes in immigration processes along the way. If we take into account Massey's argument about the hybrid nature of all cultures and problematize the idea of some local, pure, undisturbed-technologically cultures from where immigrants come, then we might understand the uses of technology by "new" diasporas as interlinked, co-shaping and not so easily separated. For some Serbian immigrants, the use of the diasporic website might start well before the immigration. The discussion boards dedicated completely to the issues of the immigration process (visa applications, transport, settlement) can serve as a proof: Those experienced in such issues (another diasporic business involved) regularly provide resources for those who plan to immigrate, making the immigration process and settlement less ruptured than it could be before the web technologies has been involved in the diaspora–homeland relationship.

4. HETEROGENEITY OF A DIASPORIC WEB COMMUNITY

The Serbian diasporic web community gathers Serbian immigrants that differ across gender, age, class, level of education, or a country of settlement. Moreover, it also includes those who currently reside in the homeland. The survey taken from the community web page suggests that one-third of online participants currently reside in North America, one-third in Europe and Australia, while one-third log on to the site from the homeland. When geographic location of the participants is concerned, this web community is obviously quite diverse. How, then, does the website attracts and maintain such a diversity?

The spatial configuration of diasporic website shapes experiences of its online participants by teaching certain "ethnic" pedagogy. It embodies "nationness" by promoting particular images and narratives that make online visitors to "feel-at-home (Fortier, 2001). Visually, as mentioned earlier, this diasporic website represents itself with an image of a professional, informational web portal that at the "entrance" page offers the links such as money conversion, world news, and weather forecast. Such online presentation problematizes a usual rendering of diasporic online spaces as highly nationally narrativized. Instead of the usual visual display of "ethnicity" (e.g., flag, national memorabilia, homeland pictures), the language in which the site content is displayed obviously serves as the mechanism of inclusion and exclusion of online participants. Even more, among many Serbian-related, immigrant-targeted websites this one belongs to a small group of sites without the openly nationalistic character. It could be argued that by mimicking the layout of a business-casual “portal” and dropping the typical diasporic memorabilia, the website manages to appeal to the widest possible audience of Serbian speakers both in diaspora and in the homeland. The shared language within web community and a relative recency of emigration of the majority of participants makes sure that the homeland is not forgotten and that business advertizing has its own audience. It is important to emphasize that for the use of this web portal the knowledge of any other language beside Serbian is not necessary—majority of web links (including the search engine located on the site) lead to the web content produced in the Serbian language. In that sense, the language of the site encompasses all possible intra-group differences.

The heterogeneity of the diasporic web space is created by numerous online groups that are more or less tightly attached to the main site. The main ethnic portal serves as a broader online territory, a stable infrastructure that acts as a “diasporic umbrella” to various online groups that appropriate parts of the common space (a discussion group, a chat channel) for some time and in a specific way. In that sense, it could be more appropriate to talk about the diasporic network of web communities, than of a single community. Only detailed ethnographic research, by closely following the segmentation of web space in time could suggest how the inter-group differences have been used for a sub-community building and membership regulation within a larger diasporic network.

The heterogeneity of Serbian diasporic web community, beside the differences related to gender, level of education, territory of emigration, or age, reveals also in the way in which the location and the experience of migration have been played out in community discourse. For example, the differences between those located in the homeland and those living in diaspora (as immigrants, refugees, students, guest-workers); between refugees and voluntary (“professional”) immigrants, or between participants immigrated to Western Europe and U.S.A./Canada/Australia could be particularly relevant. I mention those because not only they tend to be frequently invoked in online narratives, but also because they are sometimes overlooked in the research studies of online diaspora.

The narrative practices of participants in the website textual environments (discussion boards and chat lines) are the important component of the diasporic online culture. For those involved in online communication the perceived differences among participants might serve as the basis for the community segmentation or re-connection so that sub-communities frequently emerge, change their form, and diminish depending on many factors. For example, stereotyping, as a way to attach certain differences to particular people, has frequently been used by participants in online diasporic discourse as a basis for the segmentation of community. Thus, some Serbians accessing the online community from the homeland label the rest of the community as “dishwasher immigrants”—working in dead-end, low-paid jobs (“washing dishes”) despite their claimed university credentials. Similarly, those who stayed in the homeland tend to be labeled as "those whom no country would accept", and those who migrated under refugee class might be stereotyped as "lazy" by being forever "on welfare". Such textual otherings, reflecting the local (both hostland and homeland) political and cultural narratives have been frequently invoked and reproduced in online textual spaces, and possibly implicated in further community segmentation.

5. SHIFTING OF NOSTALGIC NARRATIVES

As mentioned earlier, diasporic web communities tend to be perceived as sharing the same unproblematic orientation toward the homeland. A diasporic online space, jointly produced by those who finance and support the community infrastructure and participating immigrants dispersed transnationally, has been used frequently as a research site of online-displayed homeland imaginary. While nostalgic narrativization of the lost or voluntarily left homeland could be a frequent diasporic practice and easily found theme of online diasporic texts, it has been sometimes over-addressed and rarely problematized.

Understanding diasporic online spaces only through nostalgic lenses implies the sameness of diasporic experience and disregard intra-group differences that are constitutive of all diasporic groups. Without knowing who produce such narratives, in which context, when—especially if we take into account moderation of online discourse (why such narratives get more visibility then others?)—we might not be able to fully address diasporic online practices. For example, one-third of the regular participants of the Serbian web community (according to the community web survey) are without a job. We might ask, then, how certain conditions of settlement (such as the lack of employment, loneliness, poor knowledge of host languages) might be implicated in the production of specific online narratives. Such questions situate online practices in everyday immigrant life, and help us to understand them as produced, the result of various factors, rather than as a spontaneous expression of a diasporic experience.

In diasporic discourse, the notion of "homeland" has much more complex and ambiguous meaning than it is frequently implied (Anderson, 1998). While for some immigrants the homeland might refer a particular geographical and political entity, for others the homeland gets more narrow or wider meaning depending on many factors. In the case of Serbian web community, the location of country of settlement in relation to the homeland could be implicated in homeland narratives. For those immigrants settled in North America or Australia, for example, online narration of the homeland frequently addresses "Europe" as a broadened reference of the homeland. For example, the frequent theme underlying online postings in the Serbian web community is summarized in a phrase—"I live in the US (or Canada/Australia) for some time and I feel that I miss Europe and European lifestyle". "Europe" is fashioned both as "home" that have been missed and longed for, and as a signifier of an imagined "lifestyle" (luxurious life, cafes, strolls, "high" culture). Such narrativization of "Europe", frequently simulating the hostland's media discourses (TV, Hollywood, magazines), is implicated in detaching the homeland from its precise geo-political location, shifting of "Europe" as a backdrop for re-imagined homeland memories. On the other hand, for Serbian immigrants settled in Europe the homeland might stay secured within its geographic borders, because they are constantly reminded of their "Eastern-European-ness" in daily, offline life. The meaning of "homeland" or "origin" of those diaspora, as we can see, could shift depending on the country in which immigrants settle. The host land imaginary might provide the point of reference from which immigrants narrativize "homeland", negotiate its meanings, and understand their cultural belongingness.

When discussing the implications of the heterogeneity of diaspora on homeland imaginary, it is important, then, to account for diverse migrant experiences, different conditions of migration, as well as many other contextual conditions of diasporic location. The case of the Serbian web community suggests that this website gathers both refugees, those expelled from their cities and villages, who lost their home without possibility of return, and also "voluntary" immigrants who "applied" for acceptance, waited for several years for visas and are in possession of two passports, and able to choose between two countries to live. We might ask, then, how the possibility that the "homeland" as a point of return or a traveling destination, might be implicated in production of homeland imaginary? How the existence of active social ties (parents, close families, friends) might shape homeland imaginary? But also: How those violently expelled from "homeland" might narrativize it differently?

While it might not be possible to fully understand the production of homeland imaginary without extensive ethnographic research, I want to point out some possibilities that online diasporic spaces offer regarding the nostalgic narrativization of the homeland. As I mentioned earlier, the ways in which the shared "homeland" is fashioned is a contested terrain in online spaces. Depending on immigrants' location, the experience of migration, age, or gender, among other things, the produced image of the homeland might not correspond to the political borders of the nation-state. Nostalgic narratives produced online can take many forms—narrated memories of home, city, people, memories, and childhood could be incorporated in online messages in response to any of various themes. The online diasporic space, by offering the space for collective memory exchange, gives a chance for those in diaspora to bring something new, a new detail that fills in the "memory-mosaic". As a group performance, "the nostalgia talk" serves as "bait" for attracting others who share such memories. By producing nostalgic immigrant stories, the immigrants could temporarily alleviate daily struggles with new socio-cultural environments in sharing comforting personal memories of the places, peoples, and times left "back home".

Narrativization of the homeland in the Serbian diasporic web space displays characteristics similar to any other nostalgic "talk"—the homeland is narrated through memories of "good old" friends, holidays spent on the Adriatic coast, mother's kitchen, first love, soccer games. However, the online presence of those who are currently located in the homeland or frequently travel there, as the analysis of the Serbian web community suggests, could interrupt such nostalgic performances and produce a conflicting image of narrated memories. As an example, I provide three excerpts from a long online thread that could be labeled as a "diasporic nostalgia talk". It is important to note that the thread is taken from the Serbian web community discussion board during the Kosovo crisis in 1999—the time when offline events happening in the homeland had been frequently replayed in online practices (Nincic, 2000). First excerpt is the opening post of the thread, followed by two online replies that illustrate the production of conflicting images of the homeland and homeland-related memories. A participant, currently residing in the United States, starts the thread with:

> I feel like a tree that was pulled-out, and then planted upside-down. Here (as anywhere in the West) I see my next-door neighbor once a year, others I never met, I don't know anybody from whom I can borrow an egg, for example. Even if I die, nobody will notice. I don't hear music here (only during weekends, when everybody behaves like crazy), birds don't sing, children don't speak (they sit at home at computers), people meet in bars (if somebody invites you to their home, that's pretty intimate!), there are no parties I could go. Here, I can't get that phone call I miss so much—"Put the coffee pot, I'm coming over". There is nothing that reminds me on us.

One of the replies to the message above comes also from an immigrant who recently traveled to the homeland, and who, by offering a "first-hand" experience and narrowing the homeland to the particular city (Belgrade, the capital of Serbia and Montenegro) potentially disrupts the presented image.

> I also miss old Belgrade. THAT Belgrade where we would go out almost every night. I miss 'our' clubs, you know, were we would find each other, places like "Cvetic", "KP", "Natan"... I miss my old Belgrade's circle of friends whom I could listen over a coffee for hours. I miss its parks, rivers, streets ... but ... all of those things have disappeared. The last time I traveled there, I had finally understood that my hometown doesn't exist anymore. People I met are not like us, they dream of other things. Belgrade I remember isn't there anymore.

Already challenged "nostalgic talk" becomes even more disrupted by the participation of those currently located in the homeland. The next message, written by a participant from the homeland's capital illustrates the point:

> Dear people far away from Belgrade, you are such hypocrites! Yes, I can understand how "burdened" is your life. Yes, I felt that during the bombing, too. It was painful for you! You were "supporting" us when we were out of electricity and water, with the bombs all those nights. You were "trembling" with us, saving your money for your new cars and the third television set. You were "crying" while putting your children in bed, knowing that ours are in shelters. And now, you are "suffering" when you're buying milk, knowing that we don't have any. Really, it's not fair that you suffer so much! Who wants to come back—I'll give him/her my job as a software engineer and the room in my parent's house, and all that food you miss so much—which I couldn't afford with my salary of $50 per month (when it comes). For a change—I'll take your job and all your problems so that I could suffer a little! So, why don't we trade places, you come here, I'll come there . . . so we could ease your suffering!

By refusing to participate in the narration of "old" comforting memories that are characteristic for diasporic talk, online "voices from home", sometimes as silent, sometimes as fully visible audience as in this excerpt, could interrupt the tone of nostalgic narratives and challenge their decontextualized flow. The imagined "homeland" becomes now contested terrain—the presence of participants from different locations, especially those from the homeland, might produce various images that challenge the idealized, imagined, and unitary "homeland". Only detailed ethnographic research of diasporic online spaces could show how and in which ways homeland imaginary becomes problematized in online diasporic context.

6. HOME AND HOMELAND ONLINE

The concept of diaspora, as previously mentioned, is closely linked and frequently used in the context of the immigrant experience of a search for a new "home" after loosing the "original" one. For the traditional migrant theory, the concept of "home" has been understood as a place of a particular geographic location, assuming unproblematic emotional ties that bind an immigrant to his or her former "home".

The recent discussions of the meaning of home from the exilic and diasporic perspective have suggested that "home" could be conceived as imaginary, temporary, and situated. As Naficy (1999) argues "[h]ome is anyplace; it is temporary and it is moveable; it can be built, rebuilt, and carried in memory and by acts of imagination" (p. 6). The imaginary quality of home and the desire for rebuilding it when the home is left or lost could be particularly important for those migrated, exiled, displaced. While a homeland might be implicated in the production of an imaginary of the "home" that has been left, there is no reason to assume that migrants imagine and produce meaning of a "new home" as tightly linked to the homeland. As Wise (2000) writes, "[h]ome is not an originary place from which identity arises. It is not the place we 'came from'; it is a place we are" (p. 29). If we understand the production of a "home" or the desires for "homing" (Brah, 1996) as the most important migrant practice in the context of dislocation, it is important to think about where and how the home is built? How is the experience of mobility, border crossing, and migrant travel implicated in the process of making oneself "at home"? Should we think, as Fortier (2001) asks, of migrants as being "at home in 'migranthood'" so that the new identity project builds upon experienced mobility?

There is a certain tendency present in scholarly work to imagine today's ethnoscape (Appadurai, 1996) as "border-free" in which we all feel as "nomads"—the concept that "denies the dream of a homeland, with the result that home, being portable, is available everywhere" (Peters, 1999: 31). The nomadic discourse, inspired by the migrant condition, has been conceived as producing borderless identities, employing "a kind of cosmopolitan chic—taking the allure but none of the pain" (Peters, 1999: 35). Such romanticized understanding of the "movement", as Cresswell (1997) maintains, tends to sum up all experiences of migration, travel, and movement under the concept of "nomad". Movement is frequently taken up as the most important experience of contemporary migration, thus, there is "a recognition that not only can one be at home in movement, but that movement can be one's very own home" (Rapport & Dawson, 1998: 27). As for diasporic groups, Fortier (2000) problematizes such privileging of mobility over "homing" by arguing that migrants are produced through both movement and attachment.

While experience of expulsion, migration, and cultural and social dislocation is constitutive of migrant condition, there is no reason to assume that geographic places, locales, and nation-state borders are becoming irrelevant. Borders crossings, citizenships, and passports are of still real consequences for many (Shohat, 1999). Even if globalization flows tend to weaken hegemonic imaginary apparatus of the nation-state, we should not forget that it has been weakened only for some. As Bhabha (1999) warrants, the power of the nation "to determine the lives of its citizens through national economic policy and political regulation should not be underestimated" (p. ix).

The practices of the country of settlement in which immigrants have found new home actively participate in the symbolic construction of homeland imaginary by playing the role of a "significant Other" (Fortier, 2001), which frames homeland images (e.g., "coldness" of hostland makes the warmness of homeland comforting). Frequently overlooked in diasporic writings focused on the maintenance of the ties with the homeland, are the hostland's practices of inclusion and exclusion, as well as the opportunities and resources to which immigrants have an access. In that context we might ask how the multiculturalist paradigm, officially adopted in certain Western countries, has been implicated in the processes of constructing and maintaining the fixed differences of ethnic cultures (Bannerji, 2000)? Or, how immigration procedures that divide immigrants along ethnic lines might actually channel all differences among immigrant groups only in the cultural domain (folk songs, food, fashion, dance)? Such issues have to be taken into account if we want to contextualize diasporic practices in the process of establishing and maintaining of social networks, which make one to feel "at home".

The "place called home was never an unmediated experience" (Massey as quoted in Morley, 1999: 156). The search for a place, for a territory, is frequently presented as a reactionary practice, similarly to a search for roots and fixed origins. However, as Massey argues, if we begin to think about place as a "point of intersection" in a broad networks of relations, then we would be able to understand "place" as particularly linked to other places that gives such place an identity, a meaning (Morley, 1999: 157). The process of searching for "home" will always be the product of migrant's active social networks and not necessarily linked to the imaginary of left homeland. In that sense, the concept of diaspora "offers a critique of discourses of fixed origins while taking into account of a homing desire, a distinct from a desire for a 'homeland'" (Brah, 1996). In some way, the practices of making home and constructing home imaginary rely on the links and attachments established and maintained to both homelands and hostlands, which are constantly being reconfigured in the context of everyday life.

From that perspective, a diasporic online network could be conceived as a temporary, changeable, constantly shifting product of the desires of "homing"—desires to "feel at home" in one's known language, in the familiar referent system, or in the comforting ideas of community belonging.

7. TECHNOLOGIZED DIASPORA: SOME LANGUAGE-RELATED ISSUES

The scholarly interest in the social and cultural aspects of online communication, while producing interesting and valuable work, tends to produce the split between technologies and social practices. The focus on online diasporic practices frequently emphasizes, Poster (1998) argues, technological mediation as a novelty, implying technologically unmediated nature of diasporic communities that existed before the introduction of the internet. To overcome the split between diasporic and technological we might focus on the process of the simultaneous development of both by asking how, in this particular case, the Serbian web community has been developed and established as a diasporic location? Such questions could help us better understand how a certain diasporic group developed specific practices that could not be realized without the particular technologies.

Every social network established online could be understood as a product of "a dynamic process of appropriation in which participants invoke structures to create meanings in ways that researchers or system designers may not foresee" (Baym, 1998). Furthermore, Castells (1998) argues, the common language represents, more than ethnicity or territoriality, "a fundamental attribute of self-recognition, and of establishment of an invisible national boundary" (p. 52) to which certain group might retreat as an act of resistance to globalization flows that threaten to the group identity. In the context of migration, following Castells, a group that shares same language might invoke it as the boundary mechanism of inclusion and exclusion of others from the group. In the discussion of language clash that immigrants might experience in the process of re-settlement in hostlands, Gunew (Spivak & Gunew, 1993) asks, "if you are constructed in one particular kind of language, what kind of violence does it do it to your subjectivity if one then has to move into another language, and suppress whatever selves or subjectivities were constructed by the first?" (p. 201). However, research on diaspora concerned with the processes of inclusion and exclusion "tended to be restricted to those 'ethnic minorities' that are constructed in 'race' terms" (Anthias, 1998: 558) and not to consider language as a boundary marker.

Theoretical discussions that address the issue of cultural homogenization of internet technologies frequently remind us of the inability of computer software to support written languages that are not based on the Latin alphabet. This has a particular importance if seen in the light of the constant increase in the internet users that come from non-English speaking countries. Some theorists argue that such English-oriented online environment might completely discourage or disable the communication in languages other than English one.

However, as the case of the Serbian online network suggests, the English-language dominance regarding online technologies has been overcome on the local level. Serbian-speaking participants in the English-based software environment use the modified version of Serbian written language in Latin alphabet. While Cyrillic has been accepted as the official alphabet, both Cyrillic and Latin versions of the language have been used (Vitas & Krstev, 1999). Although in the last several years it has become possible to use Cyrillic alphabet for online communication so that all 30 letters could be used in writing, it has been rarely done (most importantly, at this point, because of the complexity of the procedure). Thus, online communication in the Serbian web community has developed an "online Serbian"—using the "reduced" Latin alphabet (without w, x, and y) and Serbian without five letters. For example, to write on discussion boards or on IRC chat lines Serbian speakers require 30 letters, but they can only use 25—that is the number of letters that Cyrillic and the Latin alphabet language share. Similar tendency of using a "restricted" version of written language has been found in other non-English online environments. For example Pargman (1998) offers the case of Swedish-speaking MUD community and Voiskounsky (1998) reports of Russian speakers that use both Cyrillic and Latin version of Russian language in online context.

Such situations in which certain "embedded" traits of technology require that users modify their practices (in this case online participants use written form of language by using one letter instead of the other) might serve as one among many points of critique of the oppressive nature of technology. However, what sometimes tends to be overlooked in critical approaches of that kind, is a balanced analysis of the possibilities that have been opened up (and not only closed off) by appropriating specific type of technologies. Only extensive research of diasporic online participation in a particular context could possibly suggest if and how computer-mediated communication has been simultaneously facilitated and hindered by the use of online technologies. More specifically, we need answers on questions such as, who among Serbian speakers might be excluded from web community and how language practices used online have been implicated in that exclusion. While there is a tendency to attribute online spaces an "agency" to influence language choices, such as the prominent use of English words in online communication in a native language (Voiskounsky, 1998), there is a lack of research that shows how such language choices in online communication might be related to other factors beside the internet (hostland practices, for example).

This case serves only as an example of how a certain socio-technological configuration (such as the diasporic web community) might be seen through the lenses of its development, as a construct of the processes of negotiation of all actors involved (local diasporic market, diverse diasporic population, the homeland-based participants, characteristics of technologies). To isolate only a particular point in that configuration ("language unfriendliness" of technology, for example) requires that we talk about online environment in an abstract way, out of the context in which it has been developed.

CONCLUSION: TROUBLES AND PROMISES

In this chapter, I have attempted to present some of the issues that sometimes tend to go unnoticed when diasporic web communities have been taken up in the literature. I tried to suggest, by agreeing with Anthias (1998), that the problematic nature of the diaspora concept emerges when we assume the "sameness" of a diasporic group by focusing on the group commonality and prioritizing the fixed homeland imaginary. The discussion in this paper suggests that a diasporic network could be produced "as much in difference and division as it is in commonality and solidarity" (Anthias, 1998: 564), and that intra-group differences in online diasporic networks, especially when enriched with the participation of people from the homeland, might interrupt "fixed", unproblematic links toward imaginary or "real" homeland.

The production of diasporic online place having the shared community language as a mechanism of inclusion and exclusion, represent a long process in which many actors become actively involved: the local practices of countries of settlement, immigrant business, dispersed diasporic groups, diverse technologies, and active involvement of the people from the homeland. All of those actors actively participate in the production of the online diasporic space. Moreover, the local conditions, such as economical, cultural, or political practices in both hostlands and the homeland have been actively involved in such production.

By taking the standpoint that focuses on the parallel development of diasporic practices and their technological mediation, we might start to get better understanding of particular diasporic web communities and their role as the pedagogical space that teaches those who participate and produce the place—who, why, and with what purpose should be counted as "being in online diaspora".

ENDNOTE

1. The former homeland, Yugoslavia, is now Slovenia, Croatia, Bosnia and Hercegovina, Serbia–Montenegro, and FRY Macedonia.

Chapter 42: Exploring the Production of Race Through Virtual Learning Environments[1]

MELISSA ALTMAN AND RADHIKA GAJJALA
Bowling Green State University

1. INTRODUCTION

Virtual space, suggests Sally Munt, cannot exist without a perceiver (Munt, 2001). Likewise, techno-mediated subjectivities cannot be understood unless the observer enters these spaces and tries living in them, working with them, doing things with and in them.

The early promise of Gibson's cyberspace as limitless, ungrounded, an escape from the "meat" of the body, a space where the virtual has no connection to the real, has been disappointing. The notion that there is no race or gender in cyberspace has long been contested (see works by Lisa Nakamura, Coco Fusco, Alondra Nelson, and others) by critical scholars and inhabitants of online spaces. Although analyses of static[2] texts are proliferating, fewer scholars are actually observing the processes of production of culture within such online spaces. This is what this project focuses on—the actual production of cultural experience and materiality of virtuality, as it is experienced by participants in online environments.

Even in these virtual environments, participants do not leave their bodies behind. Hence, the virtual/real distinction sets up a false binary that cannot be substantiated when we analyze engagement with online environments. Part of what our analysis does is to try to unravel the dichotomy between the virtual and the real.

Physicality of the body is expressed through everyday material practices, even when those practices involve online production of self. The practice of *engaging* such a technological environment produces the subject/agent. Meaning, therefore, is made through doing—doing in this case is coding, programming, typing oneself into existence, and building objects.

Race in a global cyberspace is nuanced and complex. We are therefore concerned with the designing of diverse, embodied, and dialogic encounters for the effective use of virtual learning environments in order to study complex processes of meaning making in digital/analogue contexts that shape and are shaped through post 1990s globalizing processes. Thus, our overall work is an extension of the work on race in cyberspace and is based on research examining the production of techno-mediated subjectivities at various interfaces both in traditional classroom pedagogical settings and other online settings.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1089–1105.

Virtual learning environments are implicitly and explicitly based in globalization processes that bring together workers, educators, students, and employers from multiple socio-cultural, geographical and economic histories, and with varying personal histories as well as skills and literacies in relation to digital work. We examine these in the context of digital technology use and consumption. In this chapter, we argue that, between the presences and absences of such raced bodies—produced through layered, nuanced and contradictory workings of class, interpersonal culture, literacy, and language—"race in cyberspace" can benefit from a much more complex analysis and response than what has been pursued thus far by scholars studying race in cyberspace.

Further, in previous work examining South Asian and Asian Techno-mediated subjectivities (which will inform the present piece) one of the authors has argued that race, class, caste, gender, geography, and specific located histories of colonization INTERSECT with specific place-based configurations of access to various literacies associated with the communities of production (within which the internet becomes important), to shape constructs of identity and ignorance. These constructs of identity and ignorance in turn reproduce existing socio-cultural patterns of inclusion and exclusion, thus intersecting with geographically, culturally, historically, and nationally produced *place-based* configurations of race to produce contradictory manifestations of racism and acts of silencing online (see Gajjala, 2000; 2001).

This book chapter is based on efforts to interrogate these issues through controlled environments in classrooms, and is exploratory. It is part of a larger project that we are working on in an effort to open up different ways for examining issues of race in cyberspace and to provide a variety of possible pedagogic interventions and practices to engage the problem of racialization within cyberspace that is clearly situated in unequal power relations manifested within current "global" economies.

2. PEDAGOGIES FOR VIRTUAL LEARNING ENVIRONMENTS IN A DIVERSE WORLD

In the present chapter therefore, we have drawn on our experience with the use of online synchronous and asynchronous environments, as well as other digital media such as digital video and software associated with digital imaging such as Adobe Photoshop, in attempts to design pedagogies of dialogue and diversity within virtual learning environments. The discussion draws on a period of 8 years of experience on one of the co-author's part using digital internet-mediated tools and environments in pedagogical settings. Scholars involved in distance teaching and learning have always been interested in the use of new technologies for teaching and learning processes. Issues of digital divide, gendered access, race, and other forms of diversity including disability in relation to access and use of such virtual/real technologies (both in classroom settings and in cyber-based environments in general) have also been discussed by various researchers (see for instance, Blair & Takayoshi 1999; Kolko et al., 2000).

This research focuses on these two types of questions, and the implicit and explicit purpose of the assignments introduced in the courses that we discuss in this chapter[3] tend to focus on such explorations:

1. First, questions about how identity, subjectivity, and power are produced in virtual learning environments. This research explores how race, gender, class, and other characteristics of identity are produced or enabled through:
   - the design: of the virtual learning environments;
   - varying kinds of access to the virtual learning environments; and
   - the ways in which various users design, access, and utilize particular learning environments.
2. Second, questions are asked about pedagogical strategies in VLE.
   - What teaching strategies and course designs enhance learning through digital environments?
   - How can teachers and learners foster learner interaction, motivation, and engagement?
   - What strategies are effective for particular media?

The increasing availability and access to various synchronous and asynchronous interactive communication tools online has instigated much discussion and experimentation during this past decade or so regarding the potential for the use of these interactive tools for both on-campus university classes as well as for distance learning. It has been said that the information communication technology revolution will lead to significant changes in the way classes are taught. With the proliferation of online software, students and faculty are forced to continually redefine notions of "classroom", and "teaching". The use of online technologies in instruction changes the way students and teachers interact in both structural and social ways. With classes increasingly being taught in computer labs and in online spaces created by web-based technologies, Multi-User Dungeon (MUDs), MUDS Object Oriented (MOOs), and e-mail listprocs, the nature of all interaction between teacher and students (including both face-to-face and computer-mediated communication) is different, to say the least. Of course the difference in modes of interaction and the continual reinvention of what it means to be in a classroom does not necessarily mean that the quality of education is better. The mere use of technology in the classroom or in any teaching environment, as we all know, does not enhance the teacher's pedagogical skills and methods. Nor does the use of technology in itself ensure that students will become more self-motivated or intellectually and technologically savvy (whatever that means).

Here, we use specific examples from our course contexts to talk about shifting digital/analogue hierarchies in virtual learning environments, based in varying degrees of access and levels of literacies of students, as well as to extend discussions concerning racism and cyberspace by addressing issues of the production and reconfiguration of subjectivities through the encounter between students and specific technospaces. In our larger project, the interfaces included are MOOs, Digital Video, websites, and course management tools such as Web-CT and Blackboard. In the project from which this chapter is drawn, we attempt to investigate questions regarding race, gender, class, sexuality, and geography in digitally mediated cultures through a discussion of exercises and resulting reaction papers, journals, face-to-face discussions, blogs, and other student observations in relation to virtual/real learning environments in which these issues were raised. Based on these, we argue for a nuanced and radically contextual examination of race in cyberspace. In doing so, we argue that it is essential that we link issues of race, class, caste, gender, geography, culture, and literacies seriously with the economics of cultural production and technological design (hardware and software as well as business and pedagogical environments based in various technologies associated with virtuality) that are situated within processes of globalization.

3. DESCRIPTION OF THE DEVELOPMENT OF ASSIGNMENTS USED FOR CASE STUDIES

Below is an explanation of the course assignments that led to our analysis of the production of race in cyberspace. In the initial phase of the project, which was conducted in a Graduate Seminar on Computer Mediated Cultures held in spring of 2003, the environment and objects were pre-constructed by the instructor. The students participated in the interface as guests, a way of interacting which granted them only opportunities to interact with existing structures and objects, not the capability to build their own objects and spaces. Thus, the students were more like tourists/voyeurs, and their experience was shaped by a limited ability to code and shape the interface. After the students proved more apt at negotiating and learning MOO coding and culture in a short period of time than initially hoped, the second course seemed an ideal time to assign students more extensive abilities to build rooms and objects.

In the second class, Humanistic Research Methods in Communications (spring 2004), the project was intended to help entry level graduate students learn the importance of situating themselves and to problematize subject—object relations in Research Methods. For the MOO Ethnography and Research Methods assignment, students were asked to build rooms and explore the MOO. The site was LinguaMOO. At various stages of the MOO ethnography, students were asked to program objects and items to illustrate theoretical concepts and personal location in relation to their objects of inquiry. After the exploration and building stages were done, students were to form groups and write research proposals based on their examination of the MOO and understanding of various methodologies introduced in the course. The rationale for the use of the MOO in this manner was explained using the following quote from Jenny Sunden:

> Even though the border between physical and virtual locations is continuously crossed in online experiences, there is also a separating distance between the two. This distance is on one level introduced in text-based online worlds through the act of typing, and further reinforced by the mediating computer technology itself. By actively having to type oneself into being, a certain gap in this construction is at the same time created. The mediation between different realms, the very creation of texts by the means of computers, makes the interspace that always exists between myself and the understanding of this self particularly clear. Following the idea of a subject that can never have a direct and unmediated access to herself, that the I writing and the I written about can never be seen as one, cyber subjects are always at least double. This distance can in a similar way be used for methodological purposes, to form a reflexive understanding of research procedures and of the way that oneself as a researcher is always intertwined with these processes. It can be used to create room for reflection on how I, the researcher, am not only a producer of texts, such as this one, but also always a co-producer of the reality that is being written.
>
> (Sunden, 2003)

Along with the MOO assignment we were reading essays on communication and critical theory, critical ethnography, feminist epistemologies, postcolonial theory, and the books "Virtual Materialities" by Jenny Sunden and "Object Stares Back" by Elkins.

4. DISCUSSION OF ISSUES RAISED BY STUDENT PROJECTS AND THE PEDAGOGIC STRATEGIES

Specifically for this analysis we're going to focus on one pedagogical situation that utilizes the MOO.

The MOO has three important attributes. First, it is a text-based environment. It is also a multi-user domain and an object oriented space. This means that the MOO is not merely a chat space like AOL Instant Messenger. The MOO interface is predicated on building text-based virtual locations and objects to serve as the context of interactions between users. Although LinguaMoo (http://lingua.utdallas.edu) allows for some images that can be used as backgrounds or character or object icons, the space is navigated primarily by text entered by the user.

It should be noted that the text-based MOO is a comparatively older technology (even though Lingua MOO has a more current web-interface, it is important to note that most of the object building/programming and interaction with objects usually takes place in the text-based, text-coded environment). MOOs are used consistently in English classes that teach writing skills. However, students in both communication studies classes were unfamiliar with it and did not understand why we were using it. This lack of familiarity with the software or the specific LinguaMoo interface is important to the production of the self in a particular online context. The lack of familiarity produces a contested dynamic techno-mediated space, unsettling notions of digital technology as fostering immediacy and efficiency in a world defined by the rhetoric of "Progress". Not only are these in-between and dynamic in-formation spaces in the way they are used, in allowing for uncertainty of participant experience and encounter, they are also sites for the explicit contestation and negotiation of co-produced and technologically mediated meaning-making processes and of the pseudo-binaries of "Virtual" and "Real". Further, the fact that MOOs require the user to establish an avatar and description for their character creates, as Beth Kolko points out, "explicit engagement with identity . . . [that] makes them fertile ground for exploring how identity and interface interact." (Kolko et al., 2000: 214).

It should be noted that theorists such as Kali Tal have suggested that cyberspaces usually suffer from an "unbearable whiteness of being". Because most online environments (including LinguaMOO) do not explicitly include race as an avatar characteristic (unlike gender), race is not an automatic character attribute. The following explanation of gender on a MOO is taken from Lingua MOOs help menu. Note that there are various possible "genders" offered.

```
Syntax: @gender <gender>

@gender

The first form, with an argument, defines your
player to have the gender <gender>. If <gender>
is one of the standard genders (e.g., `male',
`female', `neuter',...), your various pronouns
will also be set appropriately, making exits
and certain other objects behave more pleas-
antly for you.

The second form tells you the current
definition of your player's gender, your
current pronouns, and the complete list of
standard genders.
```

```
It should be noted that some of the ``genders"
on the standard gender list need verb conju-
gation in order to work properly and much of
the MOO isn't set up for this (...yet). For
example, you should expect to see `they is' a
fair amount if you @gender yourself `plural'.
Your gender is currently female.
Your pronouns: she, her, her, hers, herself,
She, Her, Her, Hers, Herself

Available genders: neuter, male, female,
either, Spivak, splat, plural, egotistical,
royal, or 2nd
```
[4]

However, as Kolko and others have noted, the MOO does not allow the user to set a "race" category. Kolko writes, for instance, "in the case of textual worlds, race tends to be missing as an element of virtual identity" (Kolko et al., 2000: 214). In her work, she describes, "how race as a category has been elided in such media through various design choices," while investigating "how the construction of 'raceless' interfaces affects the communicative possibilities of virtual worlds". She goes on to describe efforts at reintroducing race as an articulated notion on MOOscape in order to "ask how an explicit marking of race online might affect the social environment".

Because of work done by previous researchers on race in cyberspace, we have come to understand that in many online environments, explicit mention of race becomes an anomaly, unless used as a particular kind of identity tourism (Nakamura, 2002), for which it is employed nearly completely stereotypically. In fact, Kali Tal goes as far as to assert that

> In cyberspace, it is finally possible to completely and utterly disappear people of color. I have long suspected that the much vaunted "freedom" to shed the "limiting" markers of race and gender on the internet is illusory, and that in fact it masks a more disturbing phenomenon—the whitinizing of cyberspace. The invisibility of people of color on the Net has allowed white-controlled and white-read publications like WIRED to simply elide questions of race.
>
> (Tal, 1996)

As critical race theorist Adrian Piper demonstrated with her "calling card" performance art, the explicit introduction of race counters cultural expectations that race should remain unremarked. Because the MOO interface elides racial identities, the introduction of race by participants could conceivably be considered "socially inappropriate" in the same way that the very "white-looking" mixed race Piper experienced any self-reference to her racial identity:

> Dear friend,
>
> I am black. I am sure you did not realize this when you made/laughed at/agreed with that racist remark. In the past I have attempted to alert white people to my racial identity in advance. Unfortunately, this invariably causes them to react to me as pushy, manipulative, or socially inappropriate. Therefore my policy is to assume that white people do not make these remarks even when they believe no blacks are present, and to distribute these cards when they do.
>
> I regret any discomfort my presence is causing you, just as I am sure you regret the discomfort your racism is causing me.
>
> (Piper, Calling Card #1)

Piper passed out the calling cards in a variety of settings as a performance art piece, disrupting the comfortable elision of her own racialized self. In addition, at exhibitions Piper made the calling cards available and encouraged others to use them, regardless of their racial self-identity. Piper's goal was to move away from essentialization of race as a static category of identity or as an articulated notion, while at the same time draw attention to discrimination based on particular racialized identities.

In employing the MOO pedagogically, our goal was not so much to reintroduce race-as-an-articulated-notion as a textually recognizable label or category, as it seems to have been in Kolko's invaluable experiment, but to engage the apparent invisibility of being raced, in the way of Adrian Piper's work, specifically in online textual environments. Our strategy was to create a racial awareness implicitly and explicitly in our face-to-face class environment. In an effort to refuse to allow race (and other nuances of identity grounded in the body) to remain unremarked, students entering the MOO textual environment had been sensitized to issues of race, sexuality, geography, and class within the face-to-face classroom environment, in face-to-face group discussions and through class readings. Thus, when they entered the textual environment the analytical and conceptual lenses they engaged in trying to make meaning of their encounters with the MOO—as their identity and MOO interface were explored—led them to be very aware of racial, sexual, and cultural codings in interpersonal and socio-economic contexts within both their daily lives and in their online activities in class.

Part of the goal of this project was to conduct auto/ethnographic observation and analysis of the ways that the self was produced at the intersection of the face-to-face classroom, MOO classroom, and MOO analysis. Although we are co-authors and collaborators, we occupy different points of entry in relation to the classroom experiment. Radhika is the faculty member who will both grade all the assignments and has ultimate say on how the assignments are framed. She experiences her position of power in contradictory ways as both a woman of color in the U.S. academy and as someone who has had the privilege to deliberately follow non-traditional (and therefore often confusing and unsettling to students used to more mainstream, top-down ways) ways of teaching and assertion of power in her classes. She also very clearly understands and uses her privileged location in terms of the academic culture and literacy. In addition to being a graduate student who participated in the Research Methods class, Melissa has been a student in several other of Radhika's graduate classes that employed the MOO and other digital technologies in this self-reflexive way. In addition, Melissa assisted in teaching an undergraduate class that engaged the MOO. Although fully a student (receiving a letter grade and credit for the course) and an advisee of Radhika, Melissa is also engaged in ongoing research about production of the self and the use of technology to disrupt everyday notions of identity. Engaging the research process from these two different participant perspectives is a key strategy of the cyber-ethnographic methodology employed for this research (Gajjala, 2004).

4.1. Unsettled White Male Privilege?

> "The very idea that a mediated form of communication technology could serve to disguise identity and even prevent those of privilege from asserting their identity (particularly white, European-American males) became a center to my engagement with course materials. . . . Such technology has shown to have the ability to disguise one's true identity . . . . The main issue underlying all of this is that there are certain forms of technology within the realm of communication that in some form or another make it difficult for people to assert their physical identity."—"Ray" graduate student in Research Methods Course.[5]

What is interesting to us here is that Ray's experience does not match what theorists such as Kali Tal would suggest about whiteness as the default category of identity in cyberspace. Ray failed to realize that even though the visible physical markers of his identity are not present, the seemingly ubiquitous white maleness in cyberspace marks him with the unmarked default category of white male. According to other research on race in cyberspace, we should expect his privileged race/gender position to be preserved even though HE cannot see himself that way—he is still going to be read that way. Our research suggests that the "whiteness of cyberspace" functions as an extension of the whiteness of everyday life that Adrian Piper's work examines. In addition, a closer look at how race was used and functioned in this classroom environment shows that:

1. The function and definition of race and privilege is radically dependent on the context and specifics of the interplay of online and offline spaces that are being considered.
2. Multiple understandings and experiences of race are employed in online and offline spaces with which they intersect.

To understand his experience, we have to look at the real world context in which he engaged the technological interface—as described above, the classroom context was designed specifically to try to counter the insistence that race remain unremarked. First, the visible identity markers of the instructor, which identify her as a third world woman of color. Next, the context of the course readings were heavily influenced by critical theory and post-colonial feminist theory. Third, we have the makeup of the class room participants—Ray was one of only two white males, and the other class members included three international students (two Chinese and one Indian), one African-American and one "out" lesbian, and several straight appearing white women, all of whom were fluent and articulate in the theoretical language of post-colonial feminism and critical theory used in class readings.

We see from the beginning that the MOO was "Rad-eee-ka's MOO"—most students couldn't pronounce Professor Gajjala's first or last name. Thus, the space became racialized in a very particular way. Students were required to program an object that would illustrate a concept coming out of the readings, and then asked to analyze the effect of the object they programmed. This created a reflexive space.

Because of the context and design of the real life space in which students encountered the MOO, the MOO space was racialized, creating a reflexivity on the production of the students' own racial identities (and other characteristics of identity) in the space.

> "I'm sitting in front of this terminal trying to figure out what in the world I'm supposed to be doing for this class. What are these commands? I'm supposed to create a home? I'm supposed to generate artifacts that represent me? I can't figure out the basic functions of this MOO. I hate this assignment."—"Ray"

This student goes on to describe how he would rather use the Moo at home even though his access is an older, super-slow, dial-up connection, compared to the relatively speedy direct connections he could access at the university computer lab. His anxiety about identity and meaning manifest themselves in this choice, evoking not just the absence of visible physical cues about his everyday self, but also the lack of validation of his identity that he is granted from others in his everyday life.

"Here, I have the smell of home, the taste of my wife's cooking, and the security that she is there for me. She knows who I am—she can see me, she understands me, and she knows all of my quirks."—"Ray"

In addition to this idea of the way the MOO was raced/affiliated in this context, we see how critical it is that students were unfamiliar with this technological interface. The technological interface, because of its design, can force us to negotiate cultural cues that function differently in familiar everyday life. This can make the process of producing the self visible.

"A personal encounter with a technology that strips me of much of my everyday privilege. This is a way to sum up my personal encounter with the MOO. Let me explain—I am a white, European-American, male, of middle-class status. These very marks of identification have been taken from me during this encounter . . . . I noticed my desire to assert some sort of privilege on this technology. Can't they see I'm white? Can't they see that I'm male? Can they see anything about me at all? I couldn't seem to produce the privilege that I seemed to take for granted."—"Ray"

Ray's is also a kind of racial anxiety. What we observed was how he was more anxious about the presence of his body than someone who was more confident about his ability to communicate wholly through text might have been. After examining some of his responses and articulations, we wondered if his anxiety around the absence of his white body to assert his privilege in a social space may have been linked to his obvious struggle with academic articulation. Thus, while his own analysis of his encounter with the anonymity of cyberspace *via* the MOO might suggest that he was a white male—privileged in many ways in comparison to other students in class, he may indeed have been slightly more disadvantaged in terms of particular kinds of academic or cyber-literacy when compared to some of the other students who may have appeared more disadvantaged socially based on their race-based, gender-based, sexuality-based, and geography-based locations.

Lori Kendall states that

[C]lass background may be the single most important factor influencing online participation. Over 60 percent of internet participants (63–75 percent, depending upon the data source) hold some form of professional, technical, managerial, or other white collar job . . . Yet in their depictions of interactive forums such as muds, online researchers rarely discuss class, usually focusing instead on gender. This tendency reflects online culture itself, where gender and sexuality are much more frequent topics of discussion than class or race identity.

(Kendall, 2002: 183)

If race is expected to be an invisible category, in everyday life and in cyberspaces—class is even more so. Both these categories are often subsumed under discussions of the "digital divide", where the specifics and complexities of race and class in relation to the internet examine issues of access and literacy in non-problematic ways as purely economic, geographic, or a combination of both (as in, "the poorer regions of the world experience the [singular] digital divide"). In actuality, both existing connected populations as well those who are on the unconnected edge of the digital divide are variously raced and classed, and likewise have varying cultural competencies in different online spaces. The particular pedagogic process we engaged in here were designed to reveal the complex interplay of race, class, sexuality, gender, and geography in relation to the negotiation of online environments. As is visible in the two examples discussed, issues of literacy, access and class were as much a factor in the production of hierarchies as race and gender.

Thus, we used a practice of pedagogy that relies on dislocating students out of privilege, then asking them to reflexively analyze the loss of privilege and the everydayness of the privileges they experience. This practice resulted, as we will see in the next example, in helping students articulate the different cultural competencies and literacies that impacted their experiences in the VLE.

But how might this pedagogy of dislocating students out of privilege work with an Asian female student who had come to the United States to study only about a year prior to taking this course? What sorts of privilege or lack might this encounter reveal in relation to her? In what ways does her gendered, classed, and raced experience reveal the nuances of techno, academic, language, or other literacies that impact virtual learning environments?

Yahui Zhang, a female Chinese student in the class was very silent when the MOO assignment was first introduced as a requirement. Her non-verbals indicated that she was not particularly happy. As it turned out, she later went to meet the instructor in an effort to learn to "MOO". During this meeting, she gently questioned the need for the MOO exercise in a course that was supposed to be about "research methods". Upon being asked if she felt angry at being asked to do this assignment and if she was could she please articulate that anger in discussion *via* the online course discussion space so that we could raise the topic in class discussions, she did so. Below, we reproduce the post that she contributed regarding her response to the MOO.

> **Subject:** Power and new literacy
>
> I have always considered myself to be literate because I can not only read and write in my native language, Chinese, I am also quite proficient in English. However, my literacy is completely challenged in the MOO world because here I don't know the codes, the commands, and the icons.

Suddenly I realize that I'm illiterate in this world. To be confident, I have to learn the MOO language which takes time. I feel kind of embarrassed for sleeping all the time in MOO. Not only that, I accidentally built my room in auntpearl's room and infringed on her private space. To make things worse, I even didn't know that I was sleeping in somebody else's room right from the first day I had a room in the MOO. Now with the help of the patient professor, I was able to apologize to auntpearl and move my room to my territory. The technological illiteracy (not knowing the MOO language) renders me powerless in this already built and sophisticated world. My impotency makes me suffer from inferiority complex and unnamed anger. Never before have I felt so stupid for a course I' took. I feel angry with myself and the MOO. I am angry with myself because after several attempts to explore the MOO world, I still feel as almost dumb as the first time and I don't seem to make any progress as far as understanding and mastering another language is concerned. On the other hand, I feel angry with MOO because it is MOO that makes me feel stupid and inadequate.

My frustrating MOO experience leads me to the thinking of power structure in terms of entry for the time being. In an already established power structure, the order of entry does matter. The later you come, the more puzzlement you have to experience and the more failure you have to endure. However, there is still some hope. My present situation reminds me of a book Woman/Native/Other. Somewhere in the book, the idea of using the master's language to defeat him is discussed. Whether it is an appropriate analogy, there is the hope for me to know the language and use it for something good. Actually, I did some ethnographic work on my mother's and sister-in-law's life and I'm still working on it. Although they come from different educational background (While my mother is completely illiterate, my sister-in-law can read and write), both of them feel inadequate in articulating their voices. They entrust me with the job of telling their stories, stories of ordinary, everyday Chinese women to the audience in the West. Thus, I become the agent of their voices in a foreign land where I have to constantly struggle with my place of belonging. The world of academia to them is what the world of MOO to me. But here, I cannot find an agent to do the talking for me and I have to make it out myself (Yahui's post ends here).

diaspora now is writing diaspora in her own abode—developing practices and literacies for coping with this situation. . . . (part of the instructor's response to Yahui's post) Yahui certainly got the point of the exercise!

Using the methodology we have developed in this project (reflexive, participatory, and autoethnographic) for studying virtual learning environments has multiple benefits—one of these is that we can understand how the learner herself experienced the socio-cultural space we are studying. Yahui's reflection on what happened for her in the MOOspace reveals nuances we could not have surmised from watching the product of the socio-cultural exchange. In addition, asking students to reflexively consider their experiences in virtual learning environments creates opportunities for the learner herself to better understand the ways that privilege and power are nuanced.

In Yahui's case, understanding the MOO encounter was about considering "power and new literacy". She uses literacy in more than one way in her explanation—and her careful articulation makes it clear that to understand how race, privilege, and power interact in VLEs we must reach for a finely nuanced analysis.

It is obvious both from Yahui's participation in class and from her carefully written post quoted above that she is highly literate in English as a language. Additionally, we can see her fluency (or literacy) with academic language, the language of theory. In fact, Yahui's position as a non-native, Chinese woman living in diaspora made her feel comfortable in a classroom steeped in the language of post-colonial feminism, and we saw this proficiency both in classroom discussions and in her written work.

In Yahui's case, however, she cites two other kinds of literacy that need to be considered in order to fully understand her experience on the MOO. First, she suggests that her lack of comfort with the particular technology, her "technological illiteracy" with the language of the MOO, makes her feel angry and uncomfortable—lost in a world without the right language. Although Ray clearly expresses similar feelings of inadequacy and frustration (and in fact nearly all students first introduced to the MOO in this classroom said the same, including the student co-author of this chapter), Yahui's post articulates this frustration as technological illiteracy.

In later assignments, Yahui realizes even one more kind of literacy that impacts her experience on the MOO—her literacy with the "soft parts of American culture". A world traveler who is extremely fluent in both Chinese and English, who has studied life in the United States and has been teaching students to be prepared to successfully communicate in U.S. English for several years, pop culture references in the MOO made her feel like an outsider—lost not only in the MOO techno-language but also in the everyday culture references used as students built objects that referred to popular bands, movies, TV shows, and so on. As a student who is native to the United States, not living in diaspora, and the same race as most of the students in the class, the student co-author of this chapter and Yahui had similar experiences—it took her half a semester to realize that auntpearl as a screen name was a reference to the band Pearl Jam. Thus, "literacy" in soft culture is not necessarily based just in nationality and race.

The ways in which Yahui nuances literacy can help us build a framework for analyzing what happens in VLE. When we juxtapose Yahui's varying literacies with Ray's, we see a complex interaction of cultural competencies and/or literacies that allow/produce privilege at the intersection of cyber/real spaces in the classroom.

5. CONCLUSION

Although subjectivity is grounded in the body and the way that body moves in the world, the identity markers culturally available to us to use to remark those differences cannot adequately help us to understand or theorize those differences. The power of the MOO exercise is the way it reveals differences that are about *not just* *race, skin color, gender, or some other standard category, but also get to the heart of questions about subjectivity and cultural competencies—which can have as much, or more, to do with our experiences in the world and the way we negotiate them as do oft essentialized constructions such as race, gender, sexuality, etc. The MOO is no more "artificial" than the real world—in each we take ourselves (the accumulated history and bodily materiality that makes up the person) into a pre-existing cultural/social structure and try to produce a self that reflects what we understand about ourselves. Like face-to-face interactions, we are more or less successful based on what we bring with us, what our materiality offers us, the structure of the interface, our cultural competencies, and the others with whom we interact. Technological mediation of race and racial anxieties, like everyday meaning making, is nuanced in the situation, in the culture, AND in the individual* (From Melissa's MOO autoethnography).

Virtual Learning Environments offer great opportunities to develop innovative pedagogies, as well as plenty of challenges for researchers trying to understand and theorize these interactions. This work attempts to begin to expand our existing understanding of how race functions in cyberspace, as well as to help us to develop a working vocabulary that we can use to theorize and explain the intersections of real and cyberspaces that become more common everyday. Three important considerations found here include methodology that engages the process and experience of the user/learner, consideration of the physical, local, theoretical, and academic context in which the VLEs are engaged, and nuancing our understandings of specific cultural competencies that impact the production of subjectivity and socio-cultural interaction in VLE.

Firstly, it is important that the methodology of studying virtual learning environments that we use engages the process, not just the "outside gaze". Although a great deal can be learned from looking at transcripts from interactive spaces like MOO and chat as well as examining e-mail and other static texts, understanding the subjective experience of the participant is vital to effective analysis of cultural creation and interaction. By engaging in the production of culture and subjectivity, the researcher can develop a more finely tuned understanding of the ways that meaning is being made in a particular context.

Secondly, to understand the way race, gender, class, and other characteristics of identity work in virtual learning environments, we must contextualize the analysis by considering the intersection of cyber/real spaces, the everyday context in which users access the virtual learning environment, and the specifics of the classroom context of engagement in cyberspace. Because of the way in which the self is *produced* in VLE, our understanding of these categories of identity need to consider the ways that that identity will be constituted *in the context of* and *in response to* a specific context. While Ray's physical body looked and moved the same in the world before and after his MOO experience, the carefully contextualized MOO exercise offered each learner a way to reflect on how privilege is built and maintained in varying cyber-and real-spaces. Unlike MOOs researched in other contexts—race did not remain unremarked or unconsidered. Although it is important to consider the technological features of VLEs such as design and synchronicity, it is also important to consider how specific VLEs intersect with real life learning environments often seen as discrete and distinct from VLE.

Lastly, when considering race and other characteristics of identity in cyberspace, it is important to look at the specific cultural competencies and literacies that produce/allow privilege(s) at the intersection of these cyber/real spaces. To understand what goes on in VLEs, we must consider the ways in which particular subjectivities are produced and maintained by multiple cultural competencies and literacies.

ENDNOTES

1. The authors wish to thank members of the courses—Computer-mediated Communities (Spring 2002) and Humanistic Research Methods (Spring 2003) for permission to use their assignments, discussions, and insights. We also thank Chris Bollinger and Yahui Zhang (both Radhika Gajjala's doctoral advisees) for their valuable work connecting to the larger project of which this article is a part. See also the publicly available blog discussions at http://cyberdiva.typepad.com/coauthoringproject/
2. In online contexts, text can be static and frozen in time on website and blogs and listproc archives, while during interaction, whether synchronous or asynchronous, the same texts appear "live" and dynamic to users. This is why we use the notion of static text as opposed to text in production in this instance.
3. The examples taken are from Radhika Gajjala's courses. While the general discussion spans a period of approximately 7 years and include courses taught by her in Bowling Green State University since Fall 1997, the

specific examples are based on three courses—Computer-Mediated Cultures and Organizations (undergraduate), Performing Digitally Mediated Identities (undergraduate), Computer-Mediated Communities (Graduate), Humanistic Research Methods (Graduate). Melissa Altman was a student in the graduate courses and assisted Radhika in an undergraduate course.

4. This exerpt was taken from Lingua MOO's help menu on gender.
5. In this section, we have not used the real names of some of the students we are discussing. We do however have their permission for use of their assignments in scholarly publications.

Chapter 43: Engaging the Disney Effect: The Cultural Production of Escapism and Utopia in Media

PETER PERICLES TRIFONAS
Professor at Ontario Institute for Studies in Education, Univeristy of Toronto

1. WHAT THE SIGN OF DISNEY TEACHES

What does the sign of Disney teach? What are the sources and openings of its symbolic violence? Its effects? The extent of its pedagogy? How does Disney inform the subjectivity of culture and the living text of social practices? In short, how can we engage the symbolic violence of the sign of Disney and its effects?

I will now begin to take up the question of the relations between the media, education, and the empire of signs as sites of socio-ideological contestation and cultural reproduction.

In a recent book, *The Mouse that Roared: Disney and the End of Innocence*, Henry Giroux (1999) analyzes the intentionality of corporate culture-making. That is, the "organization and regulation" (p. 2) of a political economy of signs as driven by a multinational media conglomerate that touches and teaches the everyday lives of children and adults alike. *The Mouse that Roared* presents a critical yet balanced view of the educational force of "[m]ass-produced images" (p. 2) that inform the "most intimate perceptions and desires" (p. 2) of our daily existence. As Giroux (1999) quite correctly explains, it would be too easy—unfair and unethical—to concoct conspiracy theories portraying Disney as "part of an evil empire incapable of providing joy and pleasure to the millions of kids and adults who visit its theme parks, watch its videos and movies, and buy products from its toy stores" (p. 4). There is an inconsolable temptation to overdetermine and therefore to overstate and simplify the efficacy of its role as an active agent of truth construction and a purveyor of a pedagogy of diversion. But there is also another side to gauging the influence of such an enormous media and entertainment company and investigating the way the signs it produces have functioned to educate the cognitive and affective dimensions of subjective agency in the shaping of popular culture. By using a critically balanced approach, Giroux (1999) provides the theoretical and methodological grounding and analytical framework for examining the ethical and moral force of Disney and its rendering of culture as a byproduct of "media culture" without dismissing the complicated value of its "public pedagogy" (p. 4) as a means of constructing a pleasurable escape "from the drudgery of work" (p. 5). The veneer of images Disney spins out simulates reality and stimulates the imagination. It garners responses. Here we must probe

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1107–1119.

beyond the surfaces of corporate signs to show how the logic of representation is thoroughly and deeply infused with traces of ideological force and political power. Disney's illusion is neither naïve nor innocent. As in all means of media production and representation, there is an element of intentionality involved. However, the creative impetus of the means of representation is neither technical nor technological as much as it is an instance of artifice that is poietic in nature. This extensional production is a neglected or understated aspect of media. It produces something other than the technology of itself, that is not remote controlled by the technology itself. We could not even call it technological because it is an independent production of meaning spawned from its interpretable nature. The medium is the message. Yes. Marshal McLuhan was correct in this observation. But the medium therefore becomes transparent, that is put in the background, forgotten, in its purely instrumental role as the visible reflection of content. A message has to be produced on a fundamental level to justify the conceptual and material resources expended to facilitate the attempt made at communication (Trifonas, 1998). What is the point of representation if not to engage the other in a reciprocal act of meaning making? This obvious fact of communication theory allows us, like Giroux (1999), to turn our attention to how the ideological impetus of this political economy of signification that Disney engages in facilitates the subjective interpretation of its signs. That is, how it is possible for a corporation to use the media as a pedagogical tool or device in order to convince the public of the redeeming cultural value of its idiosyncratic point of view. The effects of this form of expression constitute the real moments of teaching and learning: In short, they are (mis)educative in nature.

2. DISNEY AND THE CULTURAL IN-CORPORATION OF SIGNS

Disney is a part of a culture industry that runs rampant. The projections of its media exact immeasurable influence on minds young and not so young. It does not discriminate between those possessing innocence and those wanting knowledge in the age of consumer-oriented global economies where the instant gratification of subjective desire is driven by the digital mantra of the day. The sign defuses agency as much as it activates and mediates for responsivity. So it should be of no surprise that the culture industry treats the psyche of the neophyte and the mature reader of cultural phenomena quite equally—with the same amount of discourtesy when it comes to arbitrarily evaluating and commodifying the signs of culture through the media and its simulations of reality. To yoke ethics with representational concerns is only natural for critical educators: For those who practice pedagogy with a body and mind set to raising human consciousness toward the effects of the symbolic violence of signs upon our everyday practices. Especially, if we consider a sign to be an image that we learn through, about, and from. For those who participate in and run the culture industry, it is a means of focusing and obsessing subjective desire in an economy of intellectual and material self-fulfillment based on an empire of signs whose terms and values are to be worked out and actualized at any and all costs. Effects are rendered more crucial than causes. Representation cannot take place without consideration given to the beginnings and ends of response—that is, to meaning making and the consequences of realizing the vision and presence of a possible world emerging from it. As Umberto Eco (1979) has pointed out, a sign has no analogous, motivational, or correlational link with what it represents in reality because it is arbitrarily produced and mediates for our understanding of reality by being an *interpretant* of experience, an idiosyncratically constructed mental tool used to reference and understand the world. The sign is all surface, all projection, all image: Complete in and of itself and for itself. Thus, it has a directive force of its own that defies the reciprocity of a two-way model of communication. It sends the logic of itself and attempts to make plain its *raison d'être* for all to see or perhaps to miss. It re-presents information and dissimulates reality through its power to initiate and sustain a form of symbolic violence upon those who engage in, create and apprehend, the values of the sign as a model of reality. That is, the semiotic force of its re-presentation of information or content enhances the effects of its message as the effects of the sign are internalized and reflected by the viewer/consumer of the image. The viewer/consumer cannot alter the form of the sign but only imbibe and complete its intentionality by aesthetic and cognitive, conscious and unconscious responses in relation to the image. On the one hand, the sign in itself is therefore intransitory, both subject and object, and needs no mediative completion by way of a subjective predicate that puts its meaning into action. It suffices as the symbolic representation of meaning itself. It is readily interpretable. The sign stands for itself and requires no mediative injunctions. On the other hand, because the sign is its own pedagogy, it teaches, but it needs a viewer/consumer to fulfill the intentional and extensional limits of its communicative potential as a meaning-making tool.

Disney's signs are neither innocently conceived nor haphazardly constructed. And we would be naïve to think so. It is in and through and within the political economy of these contradictions produced between sign/meaning correlations, between surface image and deep sense, between imaginative production and interpretative completion, that a corporate agenda can be mystified by overdetermining and therefore complicating—exacerbating yet also simplifying—the tensions between the creative production of subjective responses and the contingency of an interpretative direction upon a media image. For example, it is ironic that Disney calls upon the subject to enact a productive resistance to the adult world of work and the moral banality of the self-absorbing capitalistic drive to achieve social standing through economic status. It more or less denounces the ethical validity of this way of thinking by endlessly reworking themes of escapism and utopia that glorify the attraction of adventure and the joys of play. The altruism of this message however is worth interrogating on its own grounds, the grounding of its own reason. An appeal exhibited and made to such counterlogic of cultural praxis is intended to activate and drive human behavior, through desire, toward the imaginative actualization of a possible world of unrealized childhood hopes, wishes, and dreams in the name of innocence, fun, and purity. After all, who can argue with the pursuit of innocence, fun, and purity as the way to find happiness in life? Since Plato, the quest for happiness has been culturally and philosophically linked to the uncovering of pure and ideal forms of being. That is, the search for happiness is entwined with the ideal ethic of striving for a state of goodness beyond being. This mean rejecting the life world as delusional, an evil simulacra, a flawed education guided toward the supplementation of nature and childhood innocence. This Platonic philosophical dreamscape is the cultural site of Disney's appeal and the affective source of its emotive power and value. It suspends, if even for a short while, the "broader American landscape in which cynicism has become a permanent feature" (Giroux, 1999: 6) and takes advantage of the image of a childhood utopia lost both from within and without. In this sense, Disney functions as an arbitrary mediator of cultural memory and value by enabling a reductionistic reading of reality that is focused and worked out along the lines of images that harken back and reinforce the archetypal vision of an edenic world without subtlety, bereft of evil and of limits, in which anything and all is possible. It teaches by example rather than through example. Disney demands nothing less of its consumers than a psychic capacity to let go of the present and dream of an "other time", a better time when reality could be read like an open book through the eyes of a child. Its existence is tied to this illusion of the possibility of an escape to unmediated sources of experience and reality that it constructs. Disney expects of the subject an unreflexive mimesis of its ethos of ideal remembrance and the phantasmagorical representations of a possible world that reduces the complexity of reality to a binary and hierarchical formula pitting good against evil. We might call this opposition the categorical imperative of Western culture (Trifonas, 2000). You either agree with its precepts or you do not. If not, then you are marginalized and othered as an outsider. Choosing sides *should be* easy because it is obvious that good is preferred over evil. Teaching the utopic landscapes of Western cultural memory is therefore simple for Disney as what is lost of the past must be regained and reproduced via the mnemo-technical procedure of a pedagogy of unquestioning recollection that requires a repetition without difference. There is no supplementation of the signs of memory. Form is content. The difference of interpretation is pre-empted by an oversaturation of the sign that is intended to flatten out meaning. Disney provides the semiotic means for an escape reality via a psychic and material construction of the "good old days of childhood in middle America". But the mediative completion and objectification of such a reality is intended to result in the transformation of the public sphere by making things simple, transparent, and obvious. Its Western cultural and philosophical bias assumes that we will all respond in the same way.

For example, the "nostalgia machine" of Mickey Mouse and his pals, sometimes goofy, but sometimes heroic, counteracts the debilitating effects of pessimism by tempering its perspectival liminality with the hope of a better world, a better place, or "that which extends beyond what the market and commodity-crazed society can offer" (Giroux, 1999: 6). Disney creates the physical and emotional pre-conditions of a "wish-landscape" (Giroux, 1999: 6) by situating the desires of adults and children in exotic settings where powerful themes such as "survival, separation, death, and loss" (Giroux, 1999: 7) come alive through the serious play of imaginative renderings of epiphanic experiences and fictional recreations of the life world in the way it should be. As a moment of teaching and learning, the "Disney effect"—and we must call it that—is thoroughly escapist because it induces an excitement of mind and spirit not essentially rooted in the spontaneous and mundane phenomena of reality. The distraction of enchantment depends upon a vicarious thrilling of subjectivity—a dislocation of being that feeds off of estrangement and produces the need to make the moment of living meaningful (truthful) again. The Disney effect is a heightening of experience that is a simulation of reality and therefore a manufactured occurrence aiming at an ecstatic reaction achieved by the suspension of disbelief. The intellect knows that there will be a "swindle of fulfillment" (Giroux, 1999: 6), but nevertheless is willing to play the game for the sake of distraction. It is willing to undergo its "mixture of alienation and pleasure" (Giroux, 1999: 7) simply for the sake of encountering an "other moment" of being that is completely reflexive to the sources of itself, an epiphany of sight and sound beyond common experience, and in some instances even beyond common sense.

Succumbing to the rapture of Disney culture demands a material, ethical, and psychic investment in the dream of the possible world Disney represents and projects. Giroux (1999) reminds us that "there are no passive dupes in this script" (p. 7). The act of submission has its price, so to speak, beyond the monetary gains of a megacorporation providing the pre-conditions for "play therapy" to those who choose to take up its offer. And it is here that we find the crux of Giroux's (1999) distaste for the media centered pedagogy of Disney:

> How audiences interpret Disney's texts may not be as significant as how some ideas, meanings, and messages under certain political conditions become more highly valued as representations of reality than others—and further, how these representations assume the force of ideology by making an appeal to common sense while at the same time shaping political policies and programs that serve very specific interests.... (p. 8)

Giroux (1999) tells us, much like Edward Said, that "the forces of cultural production and reception are not equal" (p. 9). And they could not ever be. There is a concentration of energy expended in the technical production of images and texts, but this conscious intentionality does not cancel out the independent purposes of interpreting what these images and texts signify and mean when mobilized and circulated through the public sphere by the processes of media in order to promote a response and convey a message. The problem of the social construction of meaning therefore involves questions about the mediation of reality and the political implications of how representation practices bear on cultural practices. Giroux (1999) delivers indispensable insights for media education by providing a "set of tools [in *The Mouse That Roared*] that enable [readers] to inquire into what Disney represents, in a way that they might not have thought about, and to shatter common sense assumptions regarding Disney's claim to both promoting fun and games and protecting childhood innocence" (p. 8). The point of such an approach is not so much about how to do ideology critique as it is about re-evaluating the pre-conditions of norms that are propagated through the channels of the media apparatus and its seemingly benign technologies of reason. The appeal to common sense and its conservative pre-suppositions inform the traditional conception of education in the public sphere. Disney is a part of that machinery that puts an end to the innocence of representation and communication—not that it ever was!—through the cognitive and aesthetic constellations of the signs it disseminates via the media of popular culture. Common sense is a powerful deterrent of innovation and difference and a determinant of the value of the proper, of tradition and its propriety (Trifonas, 2000). It depends upon a conception of an interpretative community as the abode of subjects who are the same, and without difference, think the same, hold the same desires, values, and ideals. Sense is therefore common, readily possessed and easily found. It is transparent and can effortlessly be agreed upon as the arbiter of universal truth. It puts up barriers against the intrusion of any competing interpretations by radicalizing different points of view as other, not commonly held, truths, that are therefore illogical, to be despised, and not worthy of expression. Questioning the accountability of corporations to the public and to the mandates of public education within a democracy, requires serious consideration of the implications of the appeals to common sense that Disney makes and objectifies through the signs, images, and the material manifestations of its media products and events within American cultural life.

3. TOWARD A POLITICAL ECONOMY OF THE SIGN OF DISNEY

The emphasis of *The Mouse That Roared* is on three interrelated points regarding a critical assessment of the role Disney plays (1) "in shaping public memory, national identity, gender roles, and childhood values; (2) in suggesting who qualifies as an American; and (3) in determining the role of consumerism in American life" (p. 10). There is a pedagogical crux to the subject of the analysis that centers on the importance of finding ways to "democratize the media" (p. 12) by providing a means to interrogate the cultural politics of signs (Trifonas, 2000). Representation is always already ground in the logic of itself and what it tries to teach. Giroux's (1999) purpose involves inventing and engaging in new modes of reading practice aimed at a critical reexamination of the role of multinational, media-based corporations such as Disney in the public sphere via the political economy of its signs. The ethical impetus of the search for methods of engagement aimed at the task of emancipation, social responsibility, and critical citizenship is what links pedagogy to democracy. *The Mouse That Roared* challenges us to rethink the innocence of Disney, the ground of how and what it teaches through the political economy of its signs. In it, Giroux (1999) provides a way to critically approach the "struggle over meaning and institutional power" (p. 11) by opening up to scrutiny the technologies of reason that mediate and produce the ideological conditions of meaning-making in the public sphere. That is, how the production of meaning is rationalized, grounded, and institutionalized, its processes disseminated and given the unquestionable force and power of common sense via the appeal to the socio-cultural and ethico-political value of universal truths. As media conglomerates invade the "noncommodified spheres of our public culture" (Giroux, 1999: 12) and intrude upon the private sphere of experience, the limits of the individual capacity for participating in social reconstruction are increasingly placed at risk. The overdetermination of the conceptual field of practice by commercial interests makes the imaginative constitution of "vocabulary and imagery available for defining, defending, and reforming the state, civil society, and public culture as centers for critical learning and citizen ship" (Giroux, 1999: 12) more and more difficult. Although, as Giroux shows us in the *Mouse* that Roared, it is not at all an impossible task.

For example, Disney culture is fully invested in the concept of innocence. Its founder Walt Disney, realized the value of cultivating an image of purity that was centered and grounded in the "security and romance of the small-town America of yesteryear" (Giroux, 1999: 17). According to Giroux (1999), this semantic linking of image with content in the public consciousness has made Walt Disney and his company "synonymous with the notion of childhood innocence" (p. 17). The emotio-psychic influence of the corporation and the living expression of its values and ideals is therefore difficult to resist because the lure of Disney is rooted in a sentimental view of the American past that is cognitively and affectively grounded in the logic of itself. The appeal of a utopian cultural historicity secures, reinforces, and predicts the ideal of a future where anything is possible and happiness is "just around the corner". But in order to find fulfillment in the promise of a return to the "golden days" of middle America, the memory of the past must be protected as a discreet image of human being because it is the source of identity. Giroux (1999) teaches us how to read the mnemo-technical pedagogy of this signifying ground of cultural historicity. Disney makes a connection between entertainment and education so as to fuse together the public and the private spheres of subjective being and memory according to an image of innocence that "had to be constructed within particular maps of meaning in which children and adults could define themselves through a cultural language that offers them both modest pleasure and a coherent sense of identity" (Giroux, 1999: 18). It is a question of a corporation having power over the cognitive and affective mediation of signs and their historicity in the public sphere and more or less regulating the subjective production of collective of "popular memory" through them. Because of its film and television companies, its involvement in the radio and music industry, and the reach of its publishing empire, Disney cannot be anything but a "teaching machine" that exerts tremendous influence on the shaping of American culture. Its undeniable commercial success, Giroux (1999) reminds us, "represents, in part, the power of the culture industries to mediate and influence almost every aspect of our lives" (p. 19). By regrounding public memory in a celebration and remembrance of a utopian view of the American nation, nationhood, and its reliance on the nuclear family unit as the seed of childhood innocence and its source of knowledge, Disney reconstructs and transforms pedagogy into a public site of cultural practice worked out in relation to the mediation and representation of signs. The space and place of media representations is where the formation and transformation of subjectivity is directed toward the aim of continuing the social historicity of knowledge constructions through the disciplines and also reinforces acceptable models of behavior with respect to the role of the citizen in a democracy.

The problem is that the scene of teaching—as Disney redefines it by enjoining entertainment with education—comes to be permeated by commercial interests not necessarily motivated by or connected to principles of pedagogy. The appeal to the rightful innocence of the nostalgic quest to find the vestigial remains of the "inner child" masks the motivations of the corporate agenda and the madness of its economic reason that is happy to turn America into a toy store as Giroux (1999) puts it. How can we find this commercialization of ethics and values not problematic? Giroux (1999) alerts us to an obvious yet overlooked marketing strategy that Disney propagates with effective yet disturbing results. By equating learning with entertainment and the innocence of childhood and play, the corporate agenda is infused into educational goals since teaching and learning are linked to the commercial means and apparatuses of producing and consuming a pedagogy from distraction or diversion as a form of public instruction. This correlation of entertainment and education banks on the image of teaching and learning as a dull cerebral activity. That its cognitive and affective effects cannot be achieved without the instrumental intervention of pedagogical aids. For Disney, forms of education without the distraction of entertainment are overly serious, monotonous, and cannot be made to be "fun". Even if we accept this pre-supposition, it does not mean that the scene of teaching is a disinterested space. The appropriation of innocence as a catalytic force for motivating educational actors strives toward the articulation of a "market-based notion of identity, one that suggests relinquishing their roles as critical subjects for the passive role of consuming subjects" (Giroux, 1999: 13). Disney makes questions of social justice, equity, and the public good dependent upon the economic demands and reason of its corporate agenda. In short, its teaching machinery of retail outlets and virtual spaces of multimedia merchandizing enables it to function and act as "the arbiter of children's culture" (Giroux, 1999: 160). Giroux (1999) maintains that the "false happiness" (p. 54) of Disney pedagogy "should be understood as part of a broader assault on public discourse, which dispenses with the principles of autonomy, critical self-reflection, and the power of self-determination" (p. 55). And it is very hard not to agree with him given the wide-ranging examples of corporate self-interest that are copiously documented in *The Mouse That Roared.* Some of the most damaging commentary about the entrepreneurial petulance of Disney and its unethical business practices comes from its present and past CEOs. These examples—that include influencing the course of news reporting, engaging in public shaming rituals when dismissing employees, and refusing legal and moral culpability for injuries individuals have suffered on its theme park rides—have the effect of cleaving the aura of innocence from the public persona of Disney and exposing the unethical bathos of its commercial protectionism. It is anything but a celebration! And there is a certain poetic justice in that. For what Disney teaches is exemplified by the town its imagers created under the name of Celebration and the "progressive school" it has established there.

Giroux (1999) examines the logic and the circumstances leading to the founding of this vision of community and its mobilization and enactment of a philosophy of public schooling governed by the "instrumental logic of the market" (p. 64). Disney's search for a "grab bag" of best instructional methods has set in motion the need for a curriculum emphasizing "technical over civic competencies" (Giroux, 1999: 73) to facilitate the commodification of knowledge as a means to safeguarding the future and profitable participation of the student in the virtual machination of the global economy. The notable experts chosen to actualize the vision of the Celebration School—Howard Gardner and William Glasser among them—are "largely grounded in educational psychology" (Giroux, 1999: 75) and the pedagogical necessity of developing a climate of therapeutic instrumentality in school cultures where problem solving and flexibility reigns supreme. As Giroux (1999) notes, it is not surprising that the progressive logic of the Celebration School is tied to a view of community under girded by a focus on personal relations, self-discovery, relevance, and adapting successfully to change via self-discovery and cognitive adjustment. We have to be wary of the dangers of such a discourse of educational reform that is inherently solipsistic and inwardly projected at the ethical expense of acknowledging the difference of the other. In stark contrast to Giroux (1999), Andrew Ross (1999), who has written an ethnography of Celebration, is firmly under the spell of the enchanted world Disney has arbitrarily manufactured to simulate reality and improve upon it, but without the trappings of the critical values necessary to sustain a democracy society by securing the possibility of expressing a counter-logic to that of the status quo. The arguments made in the book take on the qualities of more or less a subtle hagiography of social reconstruction and the "life-worth-living-according-to-Walt". Ross documents the material realization of a binary vision of the world where the existence of what is good is self-evident and always opposed to what is bad, without giving any sense of "how to challenge the substantive injustices in a society founded on deep inequalities" (Giroux, 1999: 75). The book does not present an even-handed reflection upon the phenomena and experiences chronicling the everyday goings on in the community of Celebration. Ross persistently defends Disney against its critics and surprisingly attempts to reclaim its democratic and corporate right to sprinkle pixie dust on the bleary and hopeful eyes of American citizens who want nothing more than the common sense ambition of securing a better future for themselves and their families that is far removed from the social realities of crime and poverty. There is nothing wrong with wanting to improve the conditions of one's life. But what are we willing to give up for this? We must remember that a community is a gathering of some at the expense of others. That is, its distinguishing characteristic is the taking up and sharing of arms, or munitions, both literal and figurative, against the threat of others (Trifonas, 2000). An undercurrent of authorial frustration permeates *The Celebration Chronicles: Life Liberty, and the Pursuit of Property Values in Disney's Town* as if Ross is trying to convince himself (and his readers) of the authenticity and value of the community he is temporarily living in as well as what he is experiencing and writing about. The effects of these latent, nagging questions of conscience looming below the surface of expression disrupt the coherence of the narrative and what is required by way of a structural corroboration for the examples constituting proofs of the argument the text puts forward. This does not mean that the book necessarily belies its trustworthiness as much as it is unreflexively one-sided. Although such myopia is not unexpected given the length of time Ross spent in Celebration and the personal and social relationships he struck up with its inhabitants. What is the critical point of this elaborate attempt at ethnography? Is it to simply assert, as the synopsis on the dusk jacket of the books does, that despite the elaborate façade of order and harmony we find in Celebration there are "real people" who live there with "real problems". Therefore, we should not be too critical of Disney and absolve it of any ethical responsibility for what is happening in the town. *The Celebration Chronicles* illustrates the well-known problems of doing ethnography as experiential reportage or participant observation. Ross presents no sustained critical perspective on method through which to triangulate the catalytic validity of personal observation and responses therefore we quite naturally challenge the sources of their inspiration and presentation and must question their motivation. In the end, I do not think that we can agree with his conclusions without taking the pre-occupations of his method into account.

Giroux (1999) makes his critical intentions clear with respect to reading what Disney teaches and attempts to operationalize through the cultural politics of Celebration:

> The most important form of education fosters self-reflection and public responsibility, two qualities that, in the Disney ideology, are secular sacrilege. The "naturalized" world of Disney, with its squeaky-clean image, false happiness, and cartoonish social imagery exacts a high price both politically and ethically. (p. 54)

One of the issues at stake pedagogically is the pursuit of social justice and educational equity. There are numerous examples of Disney's skillful navigation (manipulation?) of the political system and the democratic process to achieve the level of control it desires to construct an exclusive community that would mirror and reflect the nostalgic image of the regaining of childhood innocence and the renaissance of traditional American ideals. The corporate practice of territorialization is justified by a "decoupling [of] the language of politics from the discourse of community and substituting security, conformity, and regulation—referred to in Disney language as 'Family Friendly Planning'—for the risk filled dynamics of democracy" (Giroux, 1999: 69). It is necessary to question the methods and the criteria used to achieve the reality of this utopia. For it surely is not a coincidence that Celebration is a predominantly white, middle-class, community where public behavior is heavily regulated in order to inculcate the appearance of similitude and homogeneity, a non-offending environment of good sense and sensibility. Grioux (1999) states,

> Nobody can get lost in Celebration. The rules include not being allowed to hang the wash oput to dry, keeping the grass cut, not being able to live elsewhere for more than three months at a time, holding only one garage sale in any twelve-months period, displaying only white or off-white window coverings, and using only approved house paint colors. (p. 68)

The regimentation of the private sphere of individual freedoms and choices is necessary for the sake of perpetuating the image of community values Disney puts forward as a philosophy of being predicated on the meaningful lack of diversity and difference. Celebration is an objective correlative of the return to childhood innocence and its memory that Disney keeps alive. But the pedagogical symbolism of this community is not immediately apparent. Its paternalistic decision-making structure and the inflexibility of its laws mitigate the power of the individual to actualize authentic states of self-determination. Subjective agency is severely diminished, if not totally taken away, in some instances. Celebration unwittingly reproduces what is a most obvious fact of childhood innocence and the necessity for pedagogical intervention: That is, the innocence of childhood is characterized by a state of powerlessness and is marked by the inability of the child to act against its oppressors in order to establish subjective agency. Yes, Disney does teach. Giroux (1999) is right. Yet, on a fundamental level, through the prohibitions of Celebration in the name of community, it treats those who uncritically espouse to reproduce the spirit of its image as powerless children in need of tutelage.

To some readers, this conclusion may seem severe, or even unfair to Disney as a "cultural corporation". What I mean by this term "cultural corporation", is a commercial enterprise that is in the business of interacting with, representing, and affecting the historicity of cultural forms and practices in some way through its control of the means of media production. And I am not stating that Giroux's (1999) reading of Disney asserts the conclusion I have drawn above. He is more critically balanced in his view, more open minded and less extreme perhaps. Giroux (1999), in this sense, praises the inventiveness of Disney as a cultural corporation "in its attempts to reconstruct the very grounds on which popular culture is defined and shaped" (p. 95). Its early experimental films such as *Fantasia* were eclectic and unique in their scope of rewriting cultural forms of expression and representation via the media of motion pictures. Although I would not necessarily consider Disney's technological innovations completely laudable from a strictly aesthetic viewpoint, they did further the development of animation films through the mixing of literary genres with interactive narrative techniques and catchy songs. We cannot deny that. But a more important concern is what children learn from Disney films. And it is here, on this problem of affectivity and reception, that Giroux's analysis is very clear, precise, and most powerful.

The themes of memory, culture, and social responsibility organize the structure of such a critique with a view to submitting Disney texts to counter-readings for the purpose of exposing the contradictions between expression and content, image and message, idea and ideology. For example, deconstructing the pre-occupations of animated films such as *Pocahontas, Aladdin, The Little Mermaid, The Lion King* as well as feature movies such as *Good Morning Vietnam* and *Pretty Woman*, Giroux (1999) shows us how the cinematic experience is not without self-interest, not innocent but invested with purpose. The production of aesthetic responses demands the psychic and somatic involvement of the viewer, on many levels, with what is being viewed (Trifonas, 1998). This enables the suspension of disbelief that follows a heightening of the critical faculties where the subject is absorbed in the evocation stimulated by its engagement with the experience of a new possible world. Disney calls for "enchantment". This is another way of saying it is promoting an unreflexive and uncritical responsivity through which "the audience is meant to suspend judgement of [a] film's ideological messages" (Giroux, 1999: 96). Giroux (1999) gives many examples where the films I mention earlier thematize problematic assumptions and their structure "restricts the number of cultural meanings that can be brought to bear" (p. 96) on their interpretation. The following are but a few of them: The sexual ordering of women and their roles as defined by men (e.g., Princess Jasmine in *Aladdin*); the racialization of speech and its connection to the racist representation of "evil" characters as cultural others (e.g., the Arab thieves in *Aladdin*); the lack of references to the legacy of imperialism and colonialism in *Pocahontas*; and the gender stereotyping of *Pretty Woman* as well as its patriarchical logic of the script that allows the female protagonist to be first objectified and commodified as a woman, then transformed and rehabilitated, via male intervention, from "escort" to potential love interest and marriage partner. In reading Disney films, it would be a mistake to concentrate on reproducing pre-determined ideological reading of these films. It would be much more productive to analyze what they represent and thematize to get their message of enchantment across, how they work in, on, and through memory "to secure particular forms of authority and social relations" (Giroux, 1999: 108).

Disney is hard to resist. We have known that since we were children. Sometimes, Disney has shown us a representation of the world as we have experienced it both realistically and allegorically. At others, it has revealed a vision of the world as we would like it to be, a place of innocence and enchantment where all is well that ends well. But if we are to reclaim the space of public memory as an open communal space for negotiating the terms of democracy and critical citizenship through which to achieve equality and social justice, then we must try at the very least to reread the effects of the political economy of the signs and images produced by Disney that pervade our everyday lives and those of children. Perhaps it is not too late to begin.

Chapter 44: "A Small World After All": L. M. Montgomery's Imagined Avonlea as Virtual Landscape

BENJAMIN LEFEBVRE
Department of English and Cultural Studies, McMaster University

In the rental car on this clement afternoon in June, Jenny and I discuss some of the papers given at a three-day academic conference centered on an author whose literary output has been the subject of both my graduate work and hers. It is my fourth such conference here, her third; we talk comfortably over the familiar mixed feeling of satisfaction and regret now that the conference has ended—satisfaction over the chance to connect with new and familiar friends and colleagues, regret that these discussions had to end so soon. As part of the conference package, we have been given complimentary tickets to a tourist attraction a 30-minute drive away. With us in the car is our new friend Cynthia, who is researching an article for *Saturday Night* magazine but who has no way of getting around. The drive is pleasant, the scenery making us feel lazy and contented, the conversation open and frank. Once we arrive at the tourist site, however, we need a moment to adjust to the glaring contrast between what stands before us and the scholarly gathering we have just left behind. For the theme park is "Avonlea: Village of Anne of Green Gables", located on the outskirts of Cavendish, Prince Edward Island, Canada; the conference, L. M. Montgomery and Life Writing (2002), is the fifth biennial conference devoted to author L. M. Montgomery,[1] whose imagined community of Avonlea, described in three novels and two collections of short stories published between 1908 and 1920,[2] has proven socially, geographically, and culturally recognizable to readers around the world for nearly a century.

This "Avonlea Village", part of an ever-expanding tourist industry only vaguely connected to the actual fiction written by Montgomery, is a fenced-in replica of a town square comprised mostly of new but old-fashioned-looking buildings, the majority of which turn out to be stores selling Anne-related products such as multiflavored ice cream and bottles of (carbonated) raspberry cordial. Actors dressed as Montgomery's Avonlea characters wander from building to building, interacting freely with tourists, and even pausing to be photographed. I walk around in a daze, taking pictures of everything and complaining the whole time that nothing in this representation makes sense. Cynthia's article, which will claim that "the theme-parking of the Green Gables site has pushed it even further in the direction of the unreal" (Brouse,

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1121–1140.

2002: 36), will describe this place as "an awkward pastiche of locations from both Montgomery's and Anne's lives" (Brouse, 2002: 39). Indeed, the theme park's collapsing of the worlds of Montgomery and of fictional characters created by her is what vexes me most about this environment: In the actual schoolhouse where Montgomery taught from 1896 to 1897—hauled all the way from Belmont, 40 miles from Cavendish, and one of only three "authentic" buildings here—a Montgomery impersonator "teaches" children seated at desks the details of "her" private life, including the death of her mother, her subsequent lonely childhood during which she was raised by stern maternal grandparents, and her ambitions as a writer and a schoolteacher.

After one of these scheduled "sessions" with her pretend pupils, who appear bored by this performance, the Montgomery impersonator exits the Belmont schoolhouse of 1896 and finds herself in Avonlea, a fictional community that the actual Montgomery would not begin imagining until 1905. Although my friends and I never catch the Montgomery impersonator interacting directly with the characters she would later create, the fact that they occupy the same enclosed space is something I find truly odd, even though none of the fellow tourists around me seem to notice this hole in narrative plausibility. The academic in me, searching for some semblance of "authenticity", is inconsolably bothered by the lengths to which the site goes to erase all cultural and temporal specificity in its attempt to lure and attract a mass consumer audience into its depiction of "the good old days"; in fact, given the Mark Twain and Disneyesque feel of the place, Jenny and I wonder whether the site is designed to appeal specifically to *American* imaginings of the rural past. Still, even though this Avonlea in no way matches the fictional space I imagined after reading Montgomery's fiction, creeping up on me is another feeling, one of excitement over being a physical participant in Avonlea, a place I feel knowledgeable about after more than a decade of reading and study of it. I ask my friends to help me locate some of the actors so that I can have my picture taken with them—"for kitsch value", I add feebly. My friends look at me as though they believe I have lost my mind. The excitement that has snuck up on me against my will gives me pleasure and revolts me at the same time. The sight of the Avonlea children running alongside Montgomery certainly pushes narrative credibility beyond logical limits, and yet I find it fascinating in terms of street theatre: The costumed actors remain upbeat and in character no matter what is said to them. I get my photograph taken with both Montgomery and Anne—or, rather, alongside actors impersonating them. I stare shyly at the woman playing Montgomery while Cynthia fiddles with my camera. "I did my Master's thesis on you", I am tempted to confide to her, but I find I cannot. I am momentarily duped into believing that this actually is Montgomery and am rendered speechless by that realization.

It appears rather difficult to bridge the gap between the academic conference and a tourist site that evokes in me both incredulity and pleasure simultaneously, yet these phenomena are complexly entangled together in the name of one individual creator. Although the published oeuvre of L. M. Montgomery (1874–1942) consists of 20 novels, 500 short stories, 500 poems, as well as journals, correspondence, and numerous miscellaneous pieces, the derivatives of that body of work spill over multiple categories simultaneously—film and television, tourism and commodification, iconic image and cultural capital. The name L. M. Montgomery, itself a trademark of Heirs of L. M. Montgomery Inc., is likewise a commodity that pushes to new limits Foucault's (1997) concept of the "author function", whereby the author becomes a cultural capital that develops, through cultural association, into an ideological entity separate from the actual individual who bears that name. This ideological entity, the implied author behind a series of popular novels that are at times devalued as wholesome and harmless entertainment for girls, clashes awkwardly with the "unreliable narrator" (Brouse, 2002: 34) of *The Selected Journals of L. M. Montgomery* (Montgomery, 1985, 1987, 1992, 1998, 2004), a carefully crafted auto-representation consciously designed by Montgomery for posthumous consumption.[3] What Rubio (2001) calls Montgomery's "own multi-volume 'life-book'" (p. 59) frequently includes narratives of despair and rebellion alongside the more expected descriptions of passionate female friendships, of her negotiation of the social roles expected of a woman of her background, of her responses to the literature that helped shape her writing, and of her particular appreciation for the natural world. Numerous tourist sites in Canada and beyond, like the one described at the beginning of this paper, purport to be shrines dedicated to Montgomery's life and legacy. Some sites go to the lengths of re-enacting key events described in her journals and letters, but are unable to incorporate these unexpected moments of rebellion and anger into their reconstructed record of her life: They must either censor these moments or present the point of view of the detached outsider unable to see beyond Montgomery's impenetrable public exterior. These narratives, which claim to be fact, are in fact fictions.

In her discussion of "Avonlea Village" and similar Montgomery tourist attractions, Brouse applies Baudrillard's (1994) concept of the "simulacrum", which analyzes "copies of things that no longer exist . . . which leave us feeling that nothing is real anymore" (2002: 36). Examining these tourist sites as simulacra is entirely apt: Even though Avonlea itself never existed, and even though the Cavendish of 1905—ostensibly a loose model for Montgomery's imagined community—no longer exists, countless tourists from around the world have traveled to Prince Edward Island since the publication of *Anne of Green Gables* (1908) in an attempt to somehow return to this "original" appealing rural landscape, to see *first-hand* a visual and three-dimensional reality that is represented, through written language, in a literary text. The desire to see and experience this represented space—both imagined and ideological—through a medium other than the literary text has led to several industries of mass-produced commodities that exist alongside the publication of Montgomery's journals, all of which help keep Montgomery commercially relevant almost a century after the publication of *Anne of Green Gables*: A series of multinational television adaptations, including several produced in association with the Disney Corporation, an institution that has been critiqued for its patterns of subtle cultural domination (Bell et al., 1995; Giroux, 1999, 2000; Hearne, 1997; Lefebvre, 2002b); a growing commodification industry that immortalizes dominant images for mass consumption (Lynes, 1998); a network of tourism sites in Ontario and Prince Edward Island concerned more with generalized assumptions about the Montgomery phenomenon than with an "authentic" representation of her fictional space (Fawcett & Cormack, 2001; Gates & Gillis, 2004; Squire, 1992; Tye, 1994); and a growing list of internet sites created to visually reproduce Montgomery's idealized representation of Prince Edward Island landscape and culture for users all over the world and to simulate online virtual communities that have been categorized by previous critics as "metaphor" (Nolan et al., 1998) and as "hyperreal" (van der Klei, 2002). As Devereux (2001) notes, these "supplementary products . . . do not, for the most part, reproduce the text itself, but . . . rely on visual representations of the heroine" (p. 12). Moreover, these complementary products have added implications for audiences who have not read Montgomery's source text: By stripping Montgomery's imagined community of its geographical, temporal, and ideological specificity—including its occasional xenophobia (against French-Canadians, Irish-Catholics, and Americans) and its absenting of religious, cultural, and racial diversity—these later incarnations manage to keep the names "L. M. Montgomery" and "Anne of Green Gables" ideologically accessible and culturally relevant through time, geography, gender, sexuality, and background. In her discussion of the novel's complex dual relationship as a sign of Canadian nation and as a recognizable sign outside Canada, Devereux suggests that "*Anne* is popular in other national and nationalist contexts not because it is Canada, but because it is itself a nationalist narrative" (2001: 20). Beyond their recognizability as signs of Canadian culture (Gammel & Epperly, 1999), *Anne of Green Gables* and its derivatives have also gained tremendous cultural capital in such seemingly unlikely places as Japan (Akamatsu, 1999; Allard, 2002; Baldwin, 1993; Gaudet, 1987; Katsura, 1984; Stoffman, 1998; Trillin, 1999), Poland (Rubio, 1994; Wachowicz, 1987), and Iran (Lefebvre, 2002b: 182; York, 2000). Thus, Montgomery as a cultural capital now refers less to any fiction that she wrote and more to such recreations and transformations of that fiction that make her appear simultaneously traditional or timeless and up-to-date—what Lynes would call "a collision of past and present" (1998: 9).

It would be impossible in the scope of one paper to outline in sufficient detail the complex processes of adaptation, appropriation, transformation, and mutilation that have occurred in the creation of these spin-off products, and it would likewise be impossible to properly overview these films, products, and internet sites that add to the larger Montgomery library. Instead, the main purpose of this chapter is to examine how Montgomery's fiction has proven so potentially malleable, so universally appealing in the first place. And so, rather than limit the discussion to an analysis of how such spin-off simulacra misread the "original" text, I propose to go a step farther and suggest that Montgomery's "original" Avonlea is itself a simulacrum, a *selective representation* of reality, a copy of an original that does not exist. Thus, in suggesting that "Avonlea Village" is not just a simulacrum but a simulacrum of a simulacrum, this chapter departs from the writers and critics who make direct links between the visual pleasures described in Montgomery's fictional texts and the actual geographical space of Prince Edward Island (Davey, 1999; Kessler, 2001; Rootland, 1996). I do not mean that Montgomery's textual descriptions of the physical landscape of Prince Edward Island are somehow faulty or inaccurate, but rather that Montgomery imagined a specific form of selective community in order to make her texts as appealing as possible to readers who had never even heard of Prince Edward Island. In other words, as much as tourist sites such as "Avonlea Village"—which includes at its entrance two "cigar-store Indians" painted over as Anne and Diana—create their own meaning that is completely divorced from its literary origin, this "origin" is not itself an original as Baudrillard defines it; instead, it is Montgomery's selective interpretation of the real that has been interpreted as universally attractive. While this leads to its international relevance and popularity, this selective representation has a downfall when it is read as metonymically representing the nation. An examination of this dual consequence is the goal of this paper.

1. "A PURELY IMAGINARY PLACE": L. M. MONTGOMERY AND SHIFTING LANDSCAPE

In a journal entry dated 1 March 1930, Montgomery copied down extracts of book reviews she had collected throughout her career and commented on some of the discrepancies between them. What amused her especially is that several early reviews claimed that Nova Scotia, New Brunswick, Cape Breton Island, Western Canada, New England, and even Scotland were the setting of *Anne of Green Gables* (1998: 40–41). The inability of these critics to notice or remember that the novel is set in Prince Edward Island is somewhat curious, given that this geographical location is explicitly identified throughout the novel, and especially given the growing number of tourists who had trekked to Prince Edward Island not to see its author (Montgomery had moved to Ontario after her marriage in 1911) but to see the landscape described in her books. In a journal entry recording a return visit to Cavendish in September 1929, Montgomery recorded her impression of some of the esthetic changes and renovations made in Cavendish—including signs announcing "Avonlea Beach" and Green Gables, which in fact was the home of a distant relative—to accommodate the desires of these tourists: "It seems of no use to protest that it is not 'Green Gables'—that Green Gables was a purely imaginary place. Tourists by the hundred come here and . . . no one will ever believe that Cavendish Pond is not 'The Lake of Shining Waters' " (Montgomery, 1998: 8–9). Although Montgomery's categorization of Green Gables as "a purely imaginary place" conflicts with some of her earlier statements about Cavendish as the model for her imagined Avonlea,[4] what does remain consistent is the reader response—one that outweighs the authorial intent—that is attracted *first* to the description of this imagined space in a literary work and *second* to the idea of traveling to the geographical space to see it "first-hand", assuming that the description in the literary text is a "copy" of a "real" geography that still exists. I complicate this notion in a twofold way: (i) again using Baudrillard's terminology, it would be more accurate to claim that, because the literary text came first for readers traveling to Prince Edward Island in search of the "original" Avonlea, the community described in the novel is actually the original Avonlea and (ii) in light of the comments made by critics who have examined Montgomery's descriptions of landscape and community, the imagined Avonlea is a simulacrum because it is a selective reproduction of what existed.

Despite the numerous ways in which *Anne of Green Gables* has been categorized by critics and readers (Lefebvre, 2002a: 92–93), the label that is most appropriate to the discussion here is that of the regional idyll, which MacLulich (1983), borrowing from the earlier work of Pacey (1967: 196–197), describes as "the Canadian version of the local colour and kailyard fiction that was popular in America and Britain just before the turn of the century" (p. 490). While similar novels such as Sara Jeannette Duncan's *The Imperialist* (1904) and Stephen Leacock's *Sunshine Sketches of a Little Town* (1912) refigure the conventions of this form, MacLulich suggests that *Anne of Green Gables* "is a thoroughly conventional regional idyll" and that its strengths stem from Montgomery's "skillful but straightforward use of the literary conventions her age gave her to work with, not from her witty innovations on familiar themes" (pp. 490–491). Although several critics subsequent to MacLulich would contest the notion that *Anne of Green Gables* follows any literary convention so straightforwardly, MacLulich's definition of the regional idyll is quite useful for the present examination of the book's international portability and appeal:

> The regional idyll recreated a simple rural world, usually a *heightened version* of the author's childhood environment. Readers could join the author on a sentimental journey into the immediate past of their own country. The resulting blend of sentiment and nostalgia offered readers a welcome temporary escape from a world grown increasingly urban and industrial.
>
> (1983: 490; emphasis added)

Such a convention fits with Montgomery's wish, stated in a journal entry dated 1908, to be "a messenger of optimism and sunshine" in her creative work, a statement made in light of her mention of "the conditions of worry and gloom and care under which [*Anne of Green Gables*] was written" (1985: 339). It also works in tandem with the work of several critics (De Jonge, 2002; Fiamengo, 2002; Kotsopoulos, 2002; Squire, 1992; Tye, 1994; Willis, 1976–1977) who have examined Montgomery's selective reproduction of late 19th and early 20th century Prince Edward Island reality in her imagined community. Willis suggests that the book attracts a dual audience of adult and child readers due to "its catering to a desire for wish-fulfillment and, on the part of the older reader, nostalgia for a sentimentally envisioned past" (1976–1977: 247) in addition to its distortion of myth and fairy tale. In her examination of landscape in Montgomery's fiction, Fiamengo claims that Montgomery describes Prince Edward Island in a general enough way that would not alienate her readers, whom she saw as primarily American, thus creating what she calls "a transregional magic" (2002: 232). In light of these remarks, it is perhaps less surprising that readers past and present have had difficulty remembering where *Anne of Green Gables* is set (Lynes, 1998: 10), meaning that, for these readers, the geographical specificity of Prince Edward Island is less important than the appealing natural images described through language. As well, as Careless (1992) argues and as Litster (1997) supports, the conflicting historical references throughout both *Anne of Green Gables* and the overall series make the task of conclusively dating specific events impossible. As a result, this imagined community, one with no temporal specificity and whose geographical location sometimes shifts away from the real, becomes a virtual community even before it is transformed for film, television, and computer screens in the century subsequent to its publication.

But what are the values of this "imagined community", to use Anderson's (1983) term—one that, as I will get to later in this chapter, has been interpreted as representative of the nation?[5] What are its dominant meanings and signifieds? Who and what are represented in this imagined space? These questions are especially apposite in the case of an imagined community that represents a selection of reality, not only because this fictional environment has proven so appealing worldwide for such a long time but particularly given Balibar's (2001) point that, "under certain conditions, *only* imaginary communities are real" (p. 221). For Atwood (1999), " 'Avonlea' was simply reality edited" (p. 224), meaning that, while the characters themselves are accurate portraits of people in the environment being represented, not all of reality is included in that representation. Litster (2001) offers the following corrective: "Montgomery tamed the world she grew up in, but also twisted it, exaggerated it, romanticized it, made it more exciting, although never so much so that it ceased to be a recognizable 'real' Canadian scene" (p. 188). Litster's comments, and to a lesser extent Atwood's, fit within MacLulich's discussion of Avonlea as a regional idyll broached earlier in this chapter. But the editing of this reality is far from simple, since Montgomery edits out what little diversity there was in the Cavendish used as her model, a place Rubio (1999) calls "a typical tightly knit nineteenth-century Scottish community, with life organized around its church" (p. 94). Although Cavendish had two churches—Presbyterian and Baptist (Rubio, 1999: 97)[6]—and its surrounding settlements included French and Irish inhabitants, Montgomery's imagined Avonlea does not represent this diversity. Montgomery creates Avonlea to be religiously and culturally monolithic in order to maximize the level of disruption that Anne, a stranger to this community, signifies.

This "simplification" of reality is perhaps most noticeable when placing Montgomery's texts alongside the recent television adaptations that rework and "update" her literary output to make the name "L. M. Montgomery" compatible with more recent imaginings of Canadian nation. While I readily concur with MacLulich's claim that "The enduring popularity of Montgomery's best-known creation suggests that her writing has the capacity to evoke a strong and abiding emotional response in many readers" (1983: 489), I extend this remark to include the many viewers who have responded in similar ways to the television adaptations of this text without encountering Montgomery's actual writing (Lefebvre, 2002c: 165); for these consumers in the post-digital era, it is these recent adaptations and not Montgomery's books that are the cultural capital associated with the name L. M. Montgomery. The *Anne of Green Gables* miniseries from Sullivan Entertainment (Sullivan, 1985) is of especial relevance here, not only because it has received a varied number of critical responses (Berg, 1988; Dickinson, 2002; Drain, 1987; Frever, 1998; Gates & Gillis, 2004; Hersey, 2002a, b; Howey, 2002; Lefebvre, 2000, 2002c; Poe, 2002), but because it is the first of an extensive catalog of television productions that would renew Montgomery's name as a popular culture phenomenon from the mid-1980s onward. An examination of the adaptation process of these texts reveals late 20th century rewritings that make these "old-fashioned" texts more appropriate viewing for television audiences of the 1980s and 1990s. This examination also reveals that the majority of these adaptations remove all examples of female self-sufficiency in Montgomery's novels in order to pressure these stories to fit the demands of heterosexual romance (Lefebvre, 2002c: 151; see also Dickinson, 2002: 9; Sheckels, 1999: 188).

For instance, critics who have examined the cultural prejudices present in Montgomery's *Anne of Green Gables* (Devereux, 2001; Edwards & Litster, 1999; Gates & Gillis, 2004; Robinson, 1999; White, 1995), more specifically its characters' negative attitudes against the Acadian population of Prince Edward Island (a group that both Montgomery and her characters continually refer to as "the French"), inevitably focus on the following extract found in the first chapter of the novel, in which Marilla explains to neighbor Mrs. Lynde the rationale for deciding to adopt a boy from an orphan asylum in Nova Scotia to help her aging brother Matthew with the farm work:

> And you know how desperate hard it's got to be to get hired help. There's never anybody to be had but those stupid, half-grown little French boys; and as soon as you do get one broke into your ways and taught something he's up and off to the lobster canneries or the States. At first Matthew suggested getting a Barnado [sic] boy. But I said 'no' flat to that. 'They might be all right—I'm not saying they're not—but no London street Arabs for me,' I said. 'Give me a native born at least. There'll be a risk, no matter who we get. But I'll feel easier in my mind and sleep sounder at nights if we get a born Canadian.'
>
> (Montgomery, 1908: 6)

As White (1995) notes, the entire premise of *Anne of Green Gables* stems from this extract, given that it is only because young Acadian males are apparently irredeemably unreliable that Matthew and Marilla need to send for an orphan from Nova Scotia to help with the farm chores (p. 65).[7] Examining this extract in the context of national and communal identities, Robinson (1999) adds that Marilla's preference for a "native born"—despite the fact that Prince Edward Island had only become part of the Dominion of Canada in 1873, a decade prior to the general period in which the novel is set (Edwards & Litster, 1999: 31)—indicates her hope in "keep[ing] the risks of foreignness at a minimum" (p. 22) and her conviction that a "native born" will fit the dominant stratum of Avonlea in ways that a Barnardo boy and a native born, French-speaking Acadian boy apparently could not.[8] Devereux (2001) maintains that this scene is "an index of the novel's ideological positioning to a 'white' Canada" (p. 22). The 1985 miniseries from Sullivan Films, which refits the novel not only for the demands of the visual screen but also those of co-production partners in Canada, the United States, and West Germany, reproduces the larger scene almost exactly from the source text but excises this comment from the characters' discussion. This creative decision is in line with an overall project of eliminating material from the source text that, while perhaps historically accurate, would likely offend many television viewers of the 1980s, who presumably would not be able to properly place those attitudes in their historical context. Such an offense could easily result in a loss of international sales as well as the possibility of having a dubbed version of the film marketed to francophone Canada. Despite such a concern, Gates and Gillis maintain that "Sullivan's re-visioning of *Montgomery's* re-visioning [of reality] further removes the audience from a specific Canadian history, as the films reproduce the tensions of contemporary national culture under the guise of heritage" (p. 191). I would add that, at the same time as removing the offensive line about French-Canadians, this excision also removes the very *existence* of French-Canadians from the national terrain.

Gittings (1998) reaches a similar conclusion in his examination of the television series *Emily of New Moon* (1998–1999; 2002–2003), an adaptation of later novels by Montgomery co-produced by Salter Street Films (Halifax) and

CINAR Productions (Montreal). In his analysis, Gittings is concerned less with individual statements from Montgomery's novels excised for television consumption than with the addition of Micmac and French-Canadian characters into a new narrative associated with the name L. M. Montgomery; as he states, "Montgomery's caricatures of Irish difference in the *Emily* books and her absenting of Micmacs from the social terrain of the trilogy [conflict] with contemporary imaginings of a racially diversified nation"; the work of L. M. Montgomery, a "national icon", must be transformed to become "compatible with late 20th century Canadian imaginings of nation" (p. 23). As well, later episodes of the series that aired subsequent to Gittings's study introduce an extended story arc involving one of the lead adult female characters trapped in a disastrous marriage. This and additional episodes focusing on unwed pregnancy, rape, divorce, marital infidelity, and melancholia—themes that Montgomery avoided in most of her fiction—contradict her narrative choices to broach such realities subtly rather than explicitly at the same time as they widen the possibilities of female experience represented in works associated with Montgomery's name.

Of especial interest in a discussion of Montgomery adaptations as representative of specifically Canadian imaginings of nation are those co-produced by the Disney Channel (U.S.), which comprise the majority of total viewing hours in the Montgomery television catalog. In addition to using Montgomery's novels as raw material to create new storylines with original titles, these productions are also very fruitful in terms of theorizing about national images that are recognizable to more than one nation. The miniseries *Anne of Green Gables: The Sequel* (Sullivan, 1987), the film *Lantern Hill* (Sullivan, 1990), and the episodic series *Road to Avonlea* (1990–1996), all co-produced by the Disney Channel and largely successful in that venue, are much looser in their adaptation of Montgomery's source texts—in the case of *Road to Avonlea*, adaptations of unrelated texts by Montgomery—to create new visual productions that, much like Disney's reworking of myths and fairy tales, are now more recognizable as popular culture phenomena than Montgomery's own fiction.

Knelman (1987) suggests that the partnership between the Canadian Broadcasting Corporation, the Disney Channel, and Telefilm Canada in creating these adaptations should be unexpected, given that the Walt Disney phenomenon is supposedly "dedicated to promoting the ideals of Middle America, while Telefilm is supposed to be encouraging the development of an indigenous Canadian film culture and providing a shield against the overwhelming shadow of the Hollywood giant" (p. 148).[9] But *Road to Avonlea* managed to appeal to both CBC and Disney Channel viewers and subsequently to international viewers in part because it created stories and settings that would be familiar domestically and internationally without being bound to a specific geography and history (Kotsopoulos, 2002; Lefebvre, 2002c). As Dickinson (2002) notes, multinational adaptation requires "deemphasizing the gender, cultural, regional, and historical specificities of the source texts", which these

Sullivan/Disney co-productions achieve remarkably well (p. 32). After a series of interviews with key personnel involved in the development of *Road to Avonlea*, Kotsopoulos (2002) concluded that all three parties had similar goals in shaping material by Montgomery for a multinational co-production: (i) the elimination of specific religious, cultural, and regional practices or beliefs that are ostensibly accurate of the culture about which Montgomery was writing but that may offend or alienate mass viewers of the 1990s (similar to the excision of anti-Acadian dialog in the earlier adaptation of *Anne of Green Gables*) and (ii) a refiguring of male–female relations, including the figure of the single woman, that would be more compatible with late 20th century imaginings of gender politics. In order to follow the Disney model of erasing difference to appeal simultaneously to the greatest possible number of viewers (Giroux, 1999), the "Avonlea" of this television series becomes a timeless and universal cultural monolith, one in which an extended family of white Canadians of Anglo-Saxon (specifically Scottish-Presbyterian) origin come to represent all Canadians of the 1990s (Lefebvre, 2002b). Although it would seem as though a CBC/Disney co-production could not be feasible because of each corporation's nationalist agenda,[10] I suggest that *Road to Avonlea* became its own Canadian popular culture phenomenon not *despite* Disney's involvement but rather *because* of it.

As such, the cultural product most recognized as Montgomery's is no longer a body of work that is dependent on the time of its composition but rather a reworking of these texts that purges them of any cultural specificity to increase their relevance and portability across time to nearly every country with broadcasting capabilities. It is also worth noting that the Prince Edward Island visually represented in the Sullivan productions is actually a pastiche of filming locations in Southern Ontario; the minimal stock footage of Prince Edward Island was filmed separately using stand-ins and then edited into the narrative in such a seamless way that most viewers not familiar with the actual physical landscape of Prince Edward Island could not tell the difference. This has worked too well, however; as a result of these television adaptations, numerous tourists from both Canada and beyond have been disappointed that the "real" Green Gables House in Cavendish, Prince Edward Island is not the house used in the film (Squire, 1992: 144).[11] In addition, for internet users of the 21st century, there are a greater number of fan sites devoted to the Sullivan modernizations of Montgomery's characters than those devoted to Montgomery's books themselves (in other words, more site creators see *Anne of Green Gables* as a series of television productions than as a literary text). For those in the former category, the "original" production under reference is one that has been made universally appealing through the Disney machine, one specifically designed to appear timeless and one in which the geographic reality of Prince Edward Island is replaced by a pastiche of locations in rural south-western Ontario that selectively represent the landscape of Prince Edward Island.

This "universal appeal" needs to be examined for the internet users who interact with virtual replicas of Montgomery's Avonlea—an Avonlea that is free of context, free of race, free of history, free of religion, free of nation, and free of culture, thus an Avonlea that is potentially malleable to any cultural context. While this de-contextualization is aided by Disney's intervention in rewriting and transforming Montgomery's texts for domestic and international television audiences of the 1980s and 1990s, the "original" texts were likewise transformed out of their cultural context and adapted for new cultural contexts. The specific details that Anne is a white Canadian and that Avonlea is a monolithic Scottish-Presbyterian community has not proven to be greatly important to citizens of Poland and Japan, for instance, where Montgomery's novel has enormous cultural capital; in these cultural contexts, Anne and Avonlea become allegorical entities, meaning that Anne becomes a representative figure of any outsider who is marked as different, and Avonlea becomes a representative space of any monolithic society that requires disruption and reform. For internet users all around the world who take up the various products associated with the name L. M. Montgomery, this simulacral Avonlea becomes a site of a return to an "ideal" past, one free of all social problems—including racial, economic, or political conflicts—as well as free of geography, history, and culture.

Thus, at the same time that Montgomery's landscape has "transregional magic", it also has transcultural portability when read as metaphorical or allegorical. However, the erasures discovered in this imagined community become more problematic when Avonlea is read as a metonym for Canada, particularly for the late 20th century imaginings of a racially diversified nation that Gittings sees at work in the television series *Emily of New Moon*. The remarks of Adrienne Clarkson (1999), former Governor General of Canada, on the impact that Montgomery's texts made on her as a young refugee from Hong Kong merit a close examination in light of this present discussion, particularly her point about how Montgomery's books gave her a "profound understanding" of Canadian culture: "Through the particularity and peculiarities of Prince Edward Island and these girls' fictional lives, I became a Canadian. L. M. Montgomery educated me at a very profound level about how Canada operated in a rural setting, with smart people, in the birthplace of Confederation" (Clarkson, 1999: ix). Clarkson adds that she could identify with the figure of Anne waiting at the train station—which Lynes calls "one of the most pervasive symbolic images" of *Anne of Green Gables* (1998: 19), an iconic image that is perpetually immortalized in Anne commodities—because it was *allegorically* similar to her own experience as a young refugee (1999: x). Her comment should be read alongside Devereux's understanding of the consequences of seeing *Anne of Green Gables* as a national and a nationalist text, which becomes "a work that is, in ideological terms, seen to be reproducing a particular vision of the English-Canadian nation as a racially constituted community, a branch of the imperial racial organization of 'Saxondom'" (2001: 24). With Devereux's analysis in mind, Clarkson's remarks are troubling because they imply that, to her, "Avonlea" was a pedagogical environment that provided her with a cultural education that was neither metaphoric or metonymic or allegorical but literal. Rather than become allegorical sites of resistance to conformity, Anne and Avonlea were, to Clarkson, literal pedagogical sites of Canadian culture.

2. CONCLUSION: MULTIPLE LANDSCAPES AND CONTRADICTORY MEANINGS

Perhaps Avonlea ultimately remains what Giroux would call an "innate contradiction" of popular culture (1999: 9). Certainly, in terms of the quotation cited earlier about Marilla's proscription of a very narrow range of individuals who qualify as Canadians, Devereux's remark about Montgomery's use of "other" characters "to reaffirm the dominant group's dominance", a strategy that she sees as a "pervasive and fundamental" part of the *Anne* books (2001: 22), is certainly apt. But given the success of "other" cultural groups as well as internet users of any background or location to incorporate this story into their own cultural or virtual context, Montgomery's imagined Avonlea also has the potential to transcend these specificities and become recognizable and malleable universally, both before and after Avonlea is transformed by Disney. Such multiple meanings attest to the complexity of Montgomery and her imagined community as popular culture phenomena.

Ultimately, the erasures in Montgomery's texts stem largely from some of the limits imposed on her at the time of composition of this novel, limits that are beyond the literary conventions of the regional idyll. In many ways, aside from infrequent instances of overt xenophobia throughout the text, Montgomery merely simplifies Avonlea to make her imagined community more manageable as a literary text. Indeed, since she was living in Cavendish at the time of creating *Anne of Green Gables*, this simplification would have been necessary for her, since she could not afford to have people think she was criticizing her neighbors and the community she was living in while she was still living in it. As Litster notes, "When Montgomery first wrote of Avonlea she was living in Cavendish, which restricted the inclusion of material that mimicked local people and concerns (thus surnames were dissimilar, clan networks less oppressive, religious worship unified)" (2001: 211). The later Anne books, particularly those written after Montgomery left Prince Edward Island for Ontario, are less tempered in this respect. As well, given that she was trying to attract an audience consisting primarily of American readers who would likely be entirely unfamiliar with Prince Edward Island culture, let alone its group tensions, she perhaps did not feel it necessary to delve into the long history of such tensions, which, if nothing else, would have taken away from the plots of her novels.

However, this does not mean that the complexities of absence and presence in both Montgomery's novels and its later derivatives should be ignored. The internet sites that idealize Avonlea are actually broadcasting a virtual environment that is several filters away from Montgomery's own filtering of Prince Edward Island. It is, after all, the continuing development of multilayered simulacra that led to the creation of "Avonlea Village". But at the same time, there are implicit dangers in seeing the literal, non-allegorical Avonlea as an "ideal" community that has nothing to do with generalized nostalgia about the "good old days". If Anne and Avonlea are idealized on the allegorical level, then it is generalized values about community, disruption of oppression, and insider/outsider tensions that are idealized, and these can then be applied to any context, either national or virtual; in this way, Avonlea becomes, to quote the theme song that attests to Disney's cultural domination, "a small world after all". But if Anne and Avonlea are idealized on the literal level, then implicit in this idealization is the longing for a white settler community with explicit values of racial purity and xenophobia, one that avoids racial, economic, religious, linguistic, and sexual diversities. The possibility of multiple interpretations stems not only from the interaction necessary on the part of readers, viewers, tourists, and internet users to engage in the environment named "Avonlea", but it also illuminates the extent to which Montgomery's texts can be simultaneously products of their time as well as lively, vibrant, malleable, and evolving texts that are no longer dependent on their context of composition.

ACKNOWLEDGMENTS

I am indebted to Jennifer H. Litster (University of Edinburgh) for her generous feedback on several drafts of this paper. I gratefully acknowledge doctoral fellowships from the Fonds québécois de la recherche sur la société et la culture and the Social Sciences and Humanities Research Council of Canada, which helped make this research possible.

ENDNOTES

1. These biennial conferences, begun in 1994, are organized by the L. M. Montgomery Institute (founded in 1993) at the University of Prince Edward Island <http://www.lmmontgomery.ca>. Themed conferences have examined Montgomery's work and its derivatives in relation to Canadian culture (1996), small-islands literature (1998), popular culture (2000), life writing (2002), interior and exterior landscapes (2004), and conflict (2006). The 2008 conference will mark the 100-year anniversary of the publication of *Anne of Green Gables*. For an overview of the most recent scholarship, see Lefebvre (2004).

2. The novels set in Avonlea are *Anne of Green Gables* (1908), *Anne of Avonlea* (1909), and *Anne of the Island* (1915); a related collection of short stories, *Chronicles of Avonlea* (1912), was followed by an unauthorized sequel, *Further Chronicles of Avonlea* (1920); another sequel partially set in Avonlea, *Anne of Windy Poplars*, was published in 1936. Further novels about Anne after her marriage—*Anne's House of Dreams* (1917), *Rainbow Valley* (1919), *Rilla of Ingleside* (1921), and *Anne of Ingleside* (1939)—are set in a community elsewhere in Prince Edward Island. Montgomery published 12 additional novels about unrelated characters and locales, but it is for the first three *Anne* novels that Montgomery has always been best known.
3. Although Montgomery began her adult journal in 1889, she decided in 1919, after she had become an internationally recognized figure, to transcribe these journals into uniform ledgers, which are now housed at the University of Guelph archives and which form the copytext of her published journals. Although she claimed she was copying these journals word for word, the fact that she destroyed the original documents subsequent to this project makes it impossible to compare the two versions. By 1929, she was increasingly conscious that her journals would be a unique record of a woman's experience and that this "private" journal would one day become a "public" artifact, and she consciously wrote with this eventuality in mind.
4. In the journal entry dated 16 August 1907, in which she mentioned *Anne of Green Gables* for the first time, Montgomery claimed that "Cavendish scenery supplied the background" (Montgomery, 1985: 331). In 1911, responding privately to the incessant question of what aspects of her books mirror the real space of Cavendish, she responded that "Cavendish is to a large extent *Avonlea*" (Montgomery, 1987: 38).
5. See Kertzer's (1999) analysis of Duncan's *The Imperialist*, specifically his discussion of her novel's "mixed genre commingling fact and fiction. Elgin is an imaginary town in a real nation, but the Canadian nation is an imagined community whose emerging sense of identity comes, in part at least, from reading about Elgin and Mariposa and Avonlea" (p. 24). Mariposa is the fictional community depicted in Leacock's *Sunshine Sketches of a Little Town*.
6. Although Montgomery attended the Presbyterian church all her life, and although there was tension between the two churches of Cavendish, Montgomery occasionally joined in the Baptist church's social activities. Interfaith tension was also a part of her later life as a minister's wife in rural communities in southern Ontario.
7. White suggests that these prejudices, which he also detects throughout Montgomery's journals, stem from a feeling of racial and cultural superiority derived from a feeling that, "since the French were supposed to have left the Island when it was ceded to the British, it was possible

to maintain that they had no right to live there except through the goodwill of the English-speaking population" (1995: 67). Although I agree with White's statement in part, I also maintain that Montgomery often satirizes her own prejudices or satirizes the prejudices of her characters without necessarily sharing their attitudes.

8. This xenophobia of this extract is also shifted in the French-Canadian translation *Anne . . . La Maison aux pignons verts*. The "stupid, half-grown little French boys" become "ces stupides petits Acadiens, des demi-portions" (1986: 13).
9. Knelman also claims that the partnership of Telefilm Canada, the Canadian Broadcasting Corporation, and the Disney Channel to create *Anne of Green Gables: The Sequel* is "perhaps the oddest ménage à trois in this country's cultural history" (p. 164), although the film also received funding from PBS/Wonderworks, the Corporation for Public Broadcasting (U.S.), and Channel 4 (U.K.). *Lantern Hill* was likewise produced in partnership with the CBC, the Disney Channel, Wonderworks, the Corporation for Public Broadcasting, and Telefilm Canada. Sullivan Films retained only CBC, Disney, and Telefilm as the major partners involved in the creation of *Road to Avonlea*, although additional funding in later years came from the Ontario Film Investment Program and the Cable Production Fund (see Lefebvre, 2000).
10. Co-production arrangements between the CBC and the Disney Channel have not been exclusive to Montgomery adaptations; earlier projects include the television series *The Edison Twins* (1982–1986), *Danger Bay* (1984–1989), and *The Raccoons* (1985–1992), all of which proved successful and recognizable as examples of "Canadian" television.
11. The television series *Emily of New Moon*, financed solely in Canada, was filmed entirely on location in Prince Edward Island. Sets were built with an eye for future tourism, but the series was abruptly cancelled and such plans were abandoned.

Chapter 45: Slash Fiction/Fanfiction

ROCHELLE MAZAR

1. FANFICTION: VIRTUAL REVISION

Fan fiction (otherwise known as fanfiction, fanfic, or simply fic) is the product of unauthorized writers taking characters and settings from television shows, movies, comics, or books and writing stories about them. In the 1970s fan fiction writers helped to keep Star Trek culture alive and well long after the show itself was cancelled; they collected stories about the adventures of Captain Kirk and his crew in mimeographed and stapled zines and handed them out at conventions. The topics of these stories ranged from simple episodic crusades like those seen on the show itself to heartfelt romances between any and all characters, including, infamously, Kirk and Spock.

Since the explosion of the internet, fan fiction audiences have become crowded places; name a show, book, personality, video game, or other form of pop culture and you can find fan fiction for it. Fanfiction.net[1], which archives fan fiction from multiple fandoms, has hundreds of categories with thousands upon thousands of stories. There are more than 87,000 stories about the boy wizard Harry Potter at fanfiction.net alone.

Fan fiction itself is generated primarily by women of all ages, sitting at home in front of computers tapping madly into keyboards to complete often novel-length stories about their favorite characters. They do not do it for the money, of which there is none to be gotten; they do not even do it for fame, since most fan fiction writers guard their real life identities very carefully. They do it because they love writing their stories, they love the characters that are not theirs, and they develop a commitment to the community they discover when they start to share this love with others.

While corporations are often uncomfortable and sometimes litigious over what they consider to be copyright infringement and misuse of intellectual property, fan fiction communities are possibly some of the richest learning environments online.

2. FANFICTION AS WRITING WORKSHOP

"I've learned a lot from writing fan fiction", says Ivy Blossom, who writes Harry Potter stories.[2] "I used to write a lot when I was in high school but I stopped, and didn't write anything until I found fandom online. I look back

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1141–1150.

at my early stories now and cringe, I've learned things I was never taught in writing classes".

"There are books and books and books written about what writing workshops do to writers and their talent", says Shallya,[3] "and for me, fandom is like a big writing workshop. Just, you know, with a lot more people".

One of the reasons why fan fiction writing can be such an intense workshop is the fact of a built-in audience. Anyone can write fan fiction, and the community of fans often creates spaces where those stories can be archived and shared with others.

Fictionalley,[4] which owned and maintained by Heidi Tandy, a copyright lawyer in Florida, has an upload interface where Harry Potter fan fiction writers can describe their story and submit it to the moderators for archiving. If accepted, it will appear online, on a site where, every day, thousands of users turn their browsers to read stories just like them. Other archives, like Level Three[5] in the Smallville fandom or the multifandom archive Skyhawke,[6] have automated archives where writers upload their stories and they appears online immediately, without moderation.

One of the hallmarks of fan fiction many communities is their emphasis on feedback; archives like fanfiction.net and fictionalley have database systems or message boards in place specifically to house the reviews for stories they archive. Other archives, lacking such technology, add a note at the end of every story encouraging readers to respond to the author directly, and posting their e-mail address for that purpose. In practical terms, this means that stories written on personal computers anywhere from Singapore to Idaho are readily available and organized within hours of being posted, and are open to commentary.

Many fan fiction readers are notoriously critical. They are not likely to pass over spelling or grammatical errors in silence. Destina, a writer in the Smallville fandom, writes, "Many grammar rules are not really flexible. Nope. Not really. You can break them, but first you need to understand them, and you need to break them in a way that makes *sense*. Especially the rules about punctuation. Don't wade into the deep water of 'this isn't really a rule' or 'but XYZ does this in her stories all the time' unless you know what you're talking about".[7] Submitting a story to fans is a serious proposition, and requires serious preparation.

A fanfiction writer is not only writing a story when they write fanfiction; they are entering into territory inhabited by many other fans. The characters writers animate are well-loved by their audiences, and the universes whose rules they bend and twist have housed thousands via television shows, books, comics. Every reader has a sense of what is legitimate (or "canon") behavior; when rules are broken or mistakes made, a fan will always notice. Readers and writers take these stories very seriously, and spend hours dissecting characteristics and situations, imagining alternative or unwritten scenes, or giving motivations to minor characters and bad guys.

"There are a thousand different ways to interpret even a single sentence that JKR [J. K. Rowling] has written", says Harry Potter fan Erin Miran.[8] "And just when you think every possibility's been thought of, someone comes along with something new". There is a constant drive in fan fiction communities not only to write a well-crafted, carefully plotted, well-written story, but also to have an original take on someone else's universe. Response to a story can be overwhelming if a writer gets everything just right. "Some people may say fanfiction is a good testing ground for insecure writers because it provides that existing universe as background", says November Snowflake.[9] "That's oversimplifying the matter, and does a disservice to the (perhaps surprising number of) experienced writers who make up the fandom. The challenge of fanfiction lies in staying true to canon, while still infusing it with your own vision".

With that pressure in mind, along with a deep thirst for feedback, the stories produced by many fan fiction writers are often astounding and highly creative. All genres can be found within a single fandom, from noir to romance to high adventure and even historical drama. Modern characters can be taken out of their original context and placed in, for example, Victorian England, or Byzantium, or in a Roman amphitheatre. Sometimes characters even morph from men to women, or women to men, who find themselves body snatched and suddenly living someone else's life, or the life they could have lived had certain decisions not been made. These stories are called "AU", or Alternate Universe. Buffy can become a Vampire or a courtly Renaissance lady; Fox Mulder can be revealed as an alien clone; Lex Luthor can avoid going to the dark side and decide to defend Clark Kent instead of trying to destroy him.

In spite of all the creative space available in fandoms to create new stories, the characters themselves are still known quantities. They have "canon" characteristics and back stories that need to be respected and acknowledged in fan fiction. Readers are quick to point out when a character is less than believable, when a point from the original show or book has been left out or forgotten, or when characters behave in ways that aren't consistent with the original source. On a community journal for the Due South fandom, Laura Shapiro posts, "I just don't think it's in character for Vecchio to put a smiley face on an official form. He wouldn't be as uptight about that as Fraser would, but it still doesn't seem like something he'd do. Do you agree?" Posting fan fiction online is an act of offering up one's interpretation of a beloved character to people who not only love him/her, but have read hundreds of other variations on the exact same idea.

"I started writing fan fiction in order to get feedback on my writing style", say Libertine, a Harry Potter writer who moderates a large mailing list for fans called veelainc.[10] "In comparison to the feedback you get on original fiction, the response for fan fiction is overwhelming—people have a genuine interest in what you're doing". Writers and readers have a very open back and forth exchange over ideas, grammar, writing style, and characters. There is no fourth wall in fan fiction; when a writer posts or archives a new story, their highly critical readers will return opinions on it. The reviews of one story written by Ivy Blossom show the wide range of criticism fan fiction can get:

Kami writes: "Ok . . . that was a little weird". Meanwhile, Nupil provides a more grammatical and literary review: "You're short sentences are probably the most effective thing in your piece of writing. It gives a sense of speed and urgency yet at the same time something that's not fully comprehended. Like a start. Stop. Start. Stop feeling to the fiction, that reflects his mind. The first person makes it seem kind of colloquial—you can imagine him telling this story to someone. Also the language is simple—no windy in-depth descriptive sentences, just every day words".[11] Through this dialogue of story and feedback, fan fiction writers have what authors of original fiction can only dream of; an audience of thousands who are prepared to critique their work and suggest ways to make a story better. It's a kind of instant gratification that few other forms of writing can achieve.

One of the characteristics of many fan fiction communities is the serial story; long, multichapter epics that sometimes take years to complete. Like Dickens, authors must learn not only to plot on a grand scale, but to write within the restrictions of their own story in progress, under the eye of sometimes thousands of fans desperately waiting for the next chapter. As any novelist will attest to, large plots are difficult to plan and even more difficult sustain throughout the writing process. Fan fiction writers learn as they go in an open forum, discovering via public feedback what plot elements are most popular and most effective, and how to write stories that can, in the case of Cassandra Claire's Draco Trilogy,[12] total in the hundreds of thousands of words while remaining entertaining and internally consistent. "Though I have no real writing work ethic, I write epic fan fiction", says Libertine. "One of the only reasons I managed to make it to the ends of the stories (one of which is well over 100,000 words) was because of the public support I received".

Writing and posting fan fiction is not an isolated activity at any stage; discussions of ideas for stories, called "plotbunnies", occur on message boards, mailing lists and journals; many writers post what they call "cookies" in public, snippets of the story they're working on that acts as a teaser for their readers. When a story has passed through its first few drafts, it is generally handed over to a trusted editor known as a beta reader. The beta reader edits grammar, word choice, plot, characterization, canon inaccuracies, or whatever else they happen to notice. This process is a learning experience for both the writer and the beta reader, and is the first line of feedback that helps the writers improve their basic skills. Fan fiction resources often provide listings of willing beta readers, and the first goal of a fan fiction writer is to find one that works well with them. The first words out of a reader's keyboard if they see obvious problems with a story are, "get a beta reader". Fan fiction communities expect writers to take their own writing seriously enough to seek out a decent editor, and sloppy writing will always be noted, regardless of age or experience. In this way, fan fiction communities force writers to take stock of their abilities and improve their writing through trial and error.

While fanfiction communities often work as elaborate grammar and plot workshops, this feature is not the only element that serves to define them as highly sophisticated writing communities. In order to write realistic stories set in other times and places, writers dig into all kids of resources to learn how to make their stories authentic. Juliette Torres, writing in the *Pirates of the Caribbean* fandom, says, "I've been reading a lot of articles about pirates, and about 18th century-wigs, and about corsets—everyone talks about the Victorian corsetry, the tight-lacing, because that's the kind that makes for the sixteen inch waists and bent ribs and crushed spines, and it's hard to find information on earlier corsets. I read and participated in a long, technical discussion of the biology of Scarrans and hybrids on *Farscape* which involved use of commercial bananas as an example of a species that's been bred to sterility".[13] Another writer going by the name of Lady Angel says, "I have researched everything from ancient Roman bathing customs and ship routes in the 10th century to German names at the turn of the last century to lasers and heroin withdrawal".[14] Fan fiction writers seek out maps of places they've never been, lists of foods available in certain areas, rail schedules, and even seek out phrases in languages they don't speak to lend authenticity to their stories.

Such detail is certainly appreciated in fan fiction communities; any story set in England but written by an American will be ruthlessly pulled apart by readers known as "brit-pickers": "I still remember the time I referred to eggplant parmesan in a fic", says Ivy Blossom. "To this day I get e-mail reminding me that in the UK, an eggplant is an aubergine".

But fanfiction communities are not only populated by writers and readers; they are also the home of fan artists, who draw their favorite characters and scenes from their favorite fan fiction stories. They create art as a form of feedback, thanks, and as creative expression all on its own. In fandom, artists find a place to hone their skills; they have ready-made models and a built-in audience who will critique or bubble over with joy over their work. With the wide variety of styles already present in fandoms, artists can glean tips from each other by discussing their work or by just admiring the finished pieces of those artists they admire.[15] Fandoms attract a wide range of artists, both amateur and professional. There are even a few tattoo artists in fandoms, etching tribal symbols onto the pristine skin of copyright protected characters.

Much of fandom is defined by sharing creative energy; fans share and debate their original source material, write about and draw the same characters, and develop fandom conventions often called “fanon”. The creation of fandom motifs is a group project in which every member of a given fandom participates. Characters go in and out of style over time, and certain characteristics get applied to characters so often that fandom members become uncertain whether they are part of the original source or not. In that sense, there is a certain fandom zeitgeist in which all writers and artists produce their work; they are constantly in dialogue not only with each other, but with the microculture in which they all exist, the paradigms they must either adhere to or shift.

3. BREAKING ALL THE RULES: FANFICTION TRANSGRESSION AND DISCOURSE

This kind of learning environment, where so much is already a shared creation, can result in tension. Plagiarism is a dark word in fandom communities, in spite of the fingers pointed at them by corporations calling them all plagiarists to begin with. In truth fandom environments come equipped with their own plagiarism watchdogs, often adhering to a more stringent definition of plagiarism than many outside fandoms would.

Any vague trace of original plots and ideas are closely guarded by artists and writers, sometimes too zealously. Penelope Z, who writes in multiple fandoms, notes: “I find it’s very stupid to consider someone plagiarizing a fic just because it shares a common general idea, that is not even a unique thought of the author. I’ve just read a very nice SV [Smallville] where Lex steals Clark’s T-shirt, being obsessed and all. Is this supposed to be a copy of Sweater Stealer [a popular story]? I’m sure the author is not even aware of that fic”.[16] When one artist’s style too closely resembled another’s in the Harry Potter fandom, for example, she was quickly reprimanded and the files of her art were removed from the community where she had posted them. One artist commented, “copying is good for learning, but not for posting online or in a RL gallery. I’m not sure if it’s naivete or enthusiasm that is blinding you, but I get the feeling that maybe you aren’t very aware of how the art world (online and IRL) sees tracing, copying, and appropriation of style”.[17]

Accusations of plagiarism based on style, plot ideas, and concepts as well as word for word copying fly around fandoms fairly regularly, forcing all artists and writers to work extra hard to find their own unique voice. Far from a collection of random fans posting pencil-drawing fantasies and half-hearted erotica to the internet, fandom communities are complex environments where participants are expected to learn not only from their own mistakes, but from the mistakes of others, and to offer something new and thought provoking to a community constantly in flux.

While most fandom communities have a strong fan fiction element, even among fan fiction aficionados there is far more to fandom life than writing or drawing. The nature of writing extra-canonical stories creates tension and argument among fans; one person's interpretations are bound to conflict with another's. One of the issues that cause the most tension among fan fiction communities is the presence of slash fan fiction, a subset which is characterized by same-sex romantic pairings.

The term "slash" comes from the / symbol, which is traditionally used as part of a story header to mark the main pairing in the narrative. Kirk/Spock in the early Star Trek fandom was the first couple to be "slashed", and many fan fiction readers and writers object to what has become known as the slash fandoms. Some homophobic comments in a forum will invariably cause a raging debate in any fandom: What is homophobia? What is and is not acceptable for a fan fiction writer to write about? Are children's books exempt from same sex romantic leads by nature of their intended audience? Is slash fan fiction unfair and disrespectful to the actors who portray television characters? These questions return over and over again as some elements of a fandom take issue with another element, emersing members of a fandom in a timely social debate and providing endless arguments on either side.

Discussion about the source material is always par for the course in fan fiction communities, regardless of whether or not a specific comment has sparked it. In television fandoms, a critical appraisal of each new episode is expected from many fans, and as soon as the credits begin to role they hop online to read and comment on the varying opinions. Thamiris, a writer in a variety of fandoms and an English professor as a Canadian university, posts thoughtful essays on canon material on a regular basis. In her insightful cross-fandom essay entitled "Domestic Penetration", she writes, "There's something undeniably penetrative when one man invites another into his home, when one man invites himself in. *Mi casa es su casa*, Methos says as Duncan enters his house uninvited, a come-on so queer that the set designer's forced to display naked statuesque tits complete with erect nipples beside Duncan's head in a laughably impotent reminder of canonical heterosexuality".[18] Fans will spot metaphors and interpret scenes and dialogue with the wit and skill far beyond that of typical television critic.

Likewise, in response to the release of *Harry Potter and the Order of the Phoenix*, Cassandra Claire writes, "I think part of the bleakness of this book can be explained by the fact that Harry is now in the belly of the beast, to return to the pure archetype of the hero's journey. This is the hero's lowest point, at which he is transitioning between selves. This is the death of the hero's childhood/immature period, and the birth of himself as a new person".[19] Fan fiction writers engage with their subject on a level normally reserved for university classrooms, and these discussions of metaphor and archetype are open to the entire community for consideration and debate.

4. FANFICTION AS TECHNOLOGY WORKSHOP

One of the critical skills that any participant in fandom acquires over time in fandom are technological skills. Even casual writers learn some HTML in order to present their stories properly. Many writers and artists maintain their own websites to showcase their work. Artists scan images they sketch on paper, color them using a variety of graphics software, and post them where other members of their fandoms can see them and comment.

A specialist group of fans known as "vidders" use clips from television shows and films to make "vids", video montages set to music and highlighting themes that interest the vidder, skewing the source material to tell the story the way the vidder wants to see it told. Old school vidders created these forms of post-modern art using a VCR; today more and more vids are being created using video software such as Adobe premiere and imovie. Experienced vidders hold formal and informal workshops to help others learn these skills; there are mailing lists dedicated to tips and tricks of viding. While many broadcasters and corporations are uneasy about such art forms, which make use of often-pirated material, in fact vids provide some of the best forms of advertisement for those same corporations.

Fan fiction archivists seek out web technologies that can help readers communicate with writers; java comments, tag boards, blogging software, message boards, php-nuke, and more. Television without Pity and Panfandom.com, for example, are multifandom message board and newsblog system established by fans who saw a need in various fandoms and learned the skills required to fill them.[20] Fandom members with the know-how also create uploading scripts and database programs to make archiving and story searches easier. Moderating teams are established to maintain mailing lists or design and update webpages and resource lists. Fandom websites are constantly changing to meet the needs of a community whose populations regularly shift and change.

Participants in fandoms use whatever means they can find to communicate and share with each other. One of the fandom activities that requires the most innovative uses of technology is collaborative writing, something that standard software programs don't facilliate well over distances. Different writers collaborate in different ways; some write stories by swapping chapters by turn, passing files to each other through e-mail or file transfer programs. Others write line by line with another writer in programs like instant messengers. Writers Libertine and Ivy Blossom, in Australia and Canada respectively, wrote a story together by taking turns inputting lines into an IRC chat room, and then copying the transcript into a word processing program. Technology for fan fiction writers is a means to an end, and in order to participate and produce the results they can imagine creatively, they need to learn about software and their capabilities in order to use them in non-traditional ways.

CONCLUSION

Fanfiction communities exist on the edge of legality; while currently fanfiction is not strictly illegal, copyright owners have repeatedly sent cease and desist letters to fans in the name of hapless children, decency, and the law. Some authors against fan fiction for legal and moral reasons. Ursula Le Guin says, "it is lovely to 'share worlds' if your imagination works that way, but mine doesn't; to me, it's not sharing but an invasion, literally—strangers coming in and taking over the country I live in, my heartland".[21] After a crack down on fan fiction writers, Anne Rice firmly stated: "I do not allow fan fiction. The characters are copyrighted. It upsets me terribly to even think about fan fiction with my characters. I advise my readers to write your own original stories with your own characters. It is absolutely essential that you respect my wishes".[22]

Certainly not all writers and copyright holders feel this way; fictionalley, a Harry Potter fan fiction archive, is affiliated with Harry Potter copyright holder Warner Brothers. Smallville fans enjoy references to message boards and nods from actors. Many television shows have spin-off novels; a published form of fanfiction.

Chapter 46: A Critical Eye for the Queer Text: Reading and Writing Slash Fiction on (the) Line

RHIANNON BURY
Women's Studies Programme PAS 3010, University of Waterloo, Waterloo, ON, Canada

In the first half of the 21st century's first decade, information and communication technologies, commonly referred to as internet technologies, are embedded into the lives of most middle-class North Americans. According to Nielsen//NetRatings, over 200 million Americans over the age of two had internet access by August 2004. Of those, 137 million were classified as "active" users who accessed the web pages tracked by Nielsen (ClickZ Stats, 2004a). In the United Kingdom, 24 out of the 34 million who have internet access are considered active users (ClickZ Stats, 2004b). Judging by the proliferation of chat rooms, Multi-User Domains (MUDs), Usenet newsgroups, message boards, and electronic mailing lists, what is being sought out is not only information and/or entertainment but interaction with others using both synchronous and asynchronous forms of communication. Scholarly investigation of computer-mediated communication has drawn attention to the complex ways in which identity and community are produced in a range of cyberspaces. While a body of literature that critically examines issues of gender and to a lesser extent, race and sexuality, has taken form, little has been written about class beyond the digital divide between the information "rich" and "poor".[1] At its broadest, this chapter is an attempt to map out the *performance* (Butler, 1990) of gender, sexuality, and class on an electronic mailing list made up of fans of the Canadian television series *Due South* (DS).

Due South was co-produced by and aired on the American network CBS from 1994 to 1996. After cancellation by CBS, two more seasons were made with Canadian, British, and German funding. For those unfamiliar with the series, the lead character is Royal Canadian Mounted Police Constable Benton Fraser who is on assignment in Chicago. He works closely with Chicago police detective Ray Vecchio and then with Stanley Ray Kowalski.[2] Fraser (usually referred to by the other characters and DS fans by his last name) is regularly seen on duty in full dress uniform or at the very least with his wide-brimmed RCMP-issue hat on head or in hand. "Thank you kindly" is his motto, a phrase he offers up several times an episode. While a "do-gooder" and a "goody goody", Fraser is also well read, well spoken, loyal, and not as naive as he appears to be. Both Rays find Fraser eccentric and exasperating but at the end of each episode, they come to see the superiority of his polite, honest, and quirky Canadian ways.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1151–1167.

In 2002, I spend 4 months conducting an ethnographic study with The Militant RayK Separatists (MRKS). Its members, all female with one exception, are readers and writers of a genre of fanfiction known as slash. Writing stories about characters of a favorite television program is a means of extending the meanings and pleasures of the primary text. *Fanfic*, as it is called by those who produce and consume it, can be traced back to the original *Star Trek* series of the 1960s. Although women were traditionally a minority in science fiction fandom, a large base of "character fans" formed around *Star Trek* (Boyd, 2001). These female fans were not necessarily attracted to the themes of space exploration or conflict but rather interested in the relationships between the characters. As existing zines began to include fic and then new zines dedicated to fiction were set up, a space for female fans eager to move beyond interpretation to production opened up. Curtin (2003) did a statistical analysis of zines archived at Temple University and estimated that pre-1967, only 17% of zine publishers were female. By 1971, an astonishing 83% were female. Writing in the mid-1980s, Camille Bacon-Smith estimated that 90% of all stories were written by women (referenced in Jenkins, 1992).

There are several genres of fanfic, including *slash*—stories that involve same-sex relationships between male or female characters who have been written as heterosexual in the series. The term slash came into use because of the typographic symbol signifying the same-sex pairing, as in K/S for Kirk/Spock. MRKS members thus pair Fraser exclusively with the "second" Ray ("RayK"). This private list was founded in October or November 1999 by five members of Serge, a public *DS* slash list that emphasized the BF/RK pairing. It began with 25 members and had grown to 40 by 2002. Twenty-two members agreed to participate in the research project, including the sole male member. After examining the role of the internet in popularizing fanfiction in general and slash in particular, I focus on the pleasures of reading and writing BF/RK slash. I argue that these pleasures are not only related to queer desire but high standards of writing and adherence to the primary text (referred to as "canon").

1. A WHOLE LOT OF SLASHING GOING ONLINE

In recent years, there is growing evidence that slash is moving from the zine to the screen. In her study on slash fiction, Boyd (2001) found that of the 210 adult readers and writers who completed her questionnaire in late 1999, 70% did not limit their publication to print zines. In addition or as an alternative they named websites (personal and archives), listserves, and the sharing of stories with friends through e-mail. To find interested participants for her survey, Boyd searched 364 web pages and 129 mailing lists. I did a search using Google and came up with one site, www.fictionresource.com, which contained 720 links to websites dedicated to some form of slash fanfiction. With no link to the MRKS website, I can be certain that it is incomplete. While my sample is far too small to make a generalizable claim, the participant responses do support Boyd's findings. Only three out of the 13 respondents came to slash through print zine culture:

> I first remember hearing about slash waaaay back in the 1970's when I was in high school. I heard slash mentioned in connection with Star Trek the Original Series (though we just called it Trek because there were no later shows yet), and also Starsky & Hutch. There was a local science fiction bookstore called Lois Newman's which kept a stock of fanzines that you could go in and read at your leisure. I read a (very tame by my current standards) Kirk/Spock story and was shocked. At the time I thought it was weird and strange and kinky and wrong. Hah. Little did I know that two decades later I'd be writing it;-D.
>
> **(Drucilla)**

> In the 1970s, when I was in college . . . friends were writing and editing some of the original Kirk/Spock zines. I thought the zines were fun and silly, but didn't really get that involved with slash until I started reading and writing it in the early 1990s.
>
> **(Marguerita)**

> As a long-time science fiction fan, I caught the second wave of ST:TOS [The Original Series] fever. . . . The first time I heard that people were writing K/S was in one of the 'underground' free magazines—the type that flourish around university campuses. These publications tend to be very liberal on all fronts—sexual included.
>
> **(Estraven)**

It is not the age of these respondents that distinguishes them from the others—all but two were between 36 and 45. Rather, it was their longstanding connection to science fiction and *ST:TOS* fandom. As high school or college students, they had come across print zines in science fiction book stores or on campus.

The rest discovered slash through online forums and/or searches related to a particular fandom. In the case of Phoebe, Clegret, and Tikva, it was DS. Others named were *The X-Files* (Alain), *Star Trek: Deep Space Nine* (Jeanne), Highlander (Meghan), *Sports Night* (Penelope), and *Star Wars* (Thea). Some discovered slash by accident through a search for general fan information; others were referred to specific slash sites by friends and acquaintances from both "real life" and online contexts. Kenzie's story is interesting as she was referred to DS slash by her female life partner:

> My partner found it first and was hesitate [sic] to tell me about it. She finally broached it by telling me she had found some websites where people had written stories about these characters and had made them into couples. And that it was pretty explicit. My first reaction was "oh, so they're writing gay porn about fictional characters?" It was fine that she was reading it, I didn't care. I was writing my dissertation and didn't have time for other stuff. Well, she was going to visit her family one weekend and before she left she said "go to www.hexwood.com". So I did and well, forget the dissertation. I fried my eyes reading all weekend and that was that. I've been hooked ever since.

In light of the above, it will come as no surprise that all participants primarily accessed slash online. Of those who had pre-internet exposure to slash, only Marguerita mentioned that she continued to read print zines, though Jeanne remarked on buying "the odd zine over the years". Some members—Clegret, Tikva, Kenzie—only accessed a few DS archives, author websites, and lists including MRKS while others like Meghan and Marguerita put the total number for all fandoms at a hundred and several hundred, respectively. As for the writers, six out of the nine had produced between two and 10 DS stories by the first half of 2002, and these were "published" on personal websites, sites such as "Exwood" (DS Archive), Due Slash, as well as announced on or posted to MRKS, Serge, and/or Asylum. Drucilla had written the most DS slash with 31 stories and Phoebe was next with 21. Given their long association with fandom, Marguerita and Drucilla had produced the most fanfic overall at 50 and 68 stories, respectively. The former also published in print zines. Moreover, it would seem that print zines are being created as a result of online story production. *Serge Protector* is the first and only zine dedicated to BF/RK slash, yet it also has a web version. At the time of writing in early 2004, four participants are listed as having stories published in the latter.

In light of the above, it is safe to claim that the production of fanfic in general and slash in particular has increased exponentially with the networks of distribution afforded by information and communication technologies. This increase directly correlates to the dramatic increase in the number of women with access to the internet in the past 10 years. In 1994, 94% of users were male, the majority of whom worked as computer professionals (Graphics Visualization & Usability Center, 1994). By 1998, women comprised 33% of internet users and 48% of new users. (Graphics Visualization & Usability Center, 1998). Since 2000, a range of internet surveys have confirmed that gender parity among male and female users has been reached. When I asked the MRKS members about the participation of men in online DS slash forums, all indicated that very few men were involved. Two stated that they would not join a list that intentionally excluded men but admitted that this was not really an issue. Jeanne described slash as a "woman-centric genre".

2. QUEER AS FEN[3]

Slash has been described by Russ (1985) and Penley (1991) as "feminized" pornography that rejects anonymous, emotionless sexual encounters informed by patriarchal relations of power. Lamb and Veith (1986) take the opposite approach, positioning slash as a reworking of the romance that rejects the role of passivity and subordination of the heroine. I argue, however, that slash is best understood as a *queer romance*. Four of the participants said that they particularly enjoyed "first-time" fic, that is, stories involving the realization of the two characters that they are both in love with and sexually attracted to each other. Two also mentioned the pleasures of reading about romance or a romance/sex combination. Similarly, "angst" stories that emphasize heartbreak were thought of favorably by four participants, Thea explaining that it "makes the happy endings all the sweeter!" Alain (not the male list member) made a direct parallel with the published genre of romance:

> This is no different to me except that slash is not work that is likely to be commercially available. In many cases, the quality of slash writing actually surpasses the published work I read, although of course there is a great deal of dreck in both fanfic and published work. It makes me sad sometimes that the brilliant slash writers I read are not likely to find a broader audience unless they write about a more conventional subject.

"Conventional" in this context obviously means "heterosexual". Jeanne and Kenzie, however, emphasized the difference between the published romance and slash, noting that slash had more "depth" or was free of the genre's restrictions. Phoebe stated her dislike of "harlequins" but recognized that some slash did resemble them and that she disliked that type of slash as well. At the same time, members wanted stories to contain graphic descriptions of homosexual oral and anal sex, although most rejected the term pornography:

> Gay porn tends to be, well, different. Less relationship-oriented. More into action than interaction, if you know what I mean.
>
> **(Blue)**

> If there's a relationship and an emotional attachment between the characters that comes through in the story, then it's erotica. If it's pure sex with no characterization or development, or if it's patently obvious that

the writer is only writing to get off, or get the reader off, then it's porn. And neither is good or bad, they just are.

(Kenzie)

Anonymous. Quick couplings of various permutations. Partners chosen strictly by their appearance. Underlying theme that the appearance was enough to insure compliance, since this was a purely sexual act. It was nothing like the slash that I cherish.

(Estraven)

The MRKS position is best summed up by Kenzie who wanted to read about "men being men" and "men having sex with each other within the context of a loving relationship".

Doty (1993) defines queer texts or textual elements as "a range or a network of non-straight ideas" in which the lesbian, gay and bisexual, or other non-normative sexuality are combined (p. xviii). Moreover, he talks about gay, lesbian, and queer pleasures of the texts depending on the location of the reader. For example, he notes, "you might identify yourself as a lesbian or as a straight woman yet queerly experience the gay erotics of male buddy films" (p. 16). Ultimately, "queer reception ... stand[s] outside the relatively clear-cut and essentializing categories of sexual identity under which most people function" (p. 15). All but two participants made direct reference to these queer pleasures of the buddy/action story transformed into erotic romance:

I'll be up front and say it's sexually stimulating. Guys like F/F porn, women like slash. It's nice to 'see' all that maleness—it's [sic] intrigues me. Reading detailed descriptions of some woman's sexual responses doesn't turn me on but reading about some guy's sexual responses? Oh yeah; -D

(Drucilla)

It's hard to define. All I know is that reading about a male/male relationship titillates me.

(Penelope)

The range of queer desire is illustrated by the following two responses:

[I]t's what I told my husband when he finally broke down and admitted that he thought slash and homosexuality were just sick and that I was a lesbian because I liked it. <G> I said, "If one is good, two are better." And that's a big part of it—just that it's two guys. I have decided I'm really pretty heterosexual—guys do it for me, and so do their sexual organs.

> I've definitely become more aware of good looking men and nice bodies since reading/writing slash too.
>
> **(Phoebe)**

> As bisexual women in a monogamous lesbian relationship, it is nice to have some men in our lives!
>
> **(Clegret)**

For Phoebe, her sense of heterosexuality is heightened while Clegret is able to explore the multiplicity of identification and desire, refusing a singular identification as lesbian. Others, on the other hand, gestured toward the imbrication of desire with a gay politics:

> I read and enjoy slash on two levels. At the basic level, it feeds my kinks and gives me a thrill to read really good slash where the author has taken the time to work on the characters. It doesn't have to have a great plot, or any plot. Just good characterization and sex. On another level, there is the whole two men realizing, sometimes for the first time, they are in love with their male partner and dealing with all the ramifications that go with such a revelation.
>
> **(Meghan)**

> Also, it's an undeniable turn on for me to read a well-crafted story with the well crafted sex-scene. I like those in M/F but in the original fiction. It's almost as if once I decide that a pair of guys is a couple, that's a turn on in itself, and I'm rooting for them to overcome, get it right.
>
> **(Estraven)**

The "ramifications" and that which needs to be "overcome" are likely oblique references to heterosexism and homophobia that men who decide to enter into a same-sex relationship "in real life".

3. WHEN QUEER IS NOT ENOUGH

An underlying theme running through the above data samples is the *quality* of the fiction. Part of the "thrill" for Meghan, for example, was reading "really good slash where the author has taken the time to work on the characters." The "turn on" for Estraven was "a well-crafted story with the well-crafted sex-scene". Thus descriptions of two men kissing or engaged in homosex, while queer, were not pleasurable in and of themselves. To date, scholars have paid little attention to this aspect of slash. Penley (1991) is the exception, discussing the importance of "good writing" in relation to "professionalism".

She describes the pleasures of receiving critical acclaim from readers but stops short of linking this discourse with class or, more specifically, with what Bourdieu refers to as *bourgeois aesthetics* (referenced in Jenkins, 1992). This term refers to the ability to maintain enough distance from the text in order to evaluate it critically and "objectively". Fans in particular are accused of what Jenkins calls "sitting too close", that is, being incapable of distinguishing "good" texts from "bad" and simply identifying with the characters on an emotional level. As university-educated women with at least one degree, the MRKS members had strong investments in this discourse and by paying close attention to the quality of the fiction, they marked themselves out as legitimate members of the middle class. In the quotations that follow, MRKS participants unpacked the term quality:

> [A]ccurate characterization, attention to canon and then spelling and grammar, in order of importance, but the key is if they add up to a story that is pleasurable to read for its construction as well as its content. Some of the slash stories I've read are written so beautifully that images and whole paragraphs stick in my mind. As a writer, I frequently have serious "line envy", wishing I could have written a specific piece of dialogue myself.
>
> **(Alain)**

> Writing, writing, writing. I want the characters to sound and act like themselves (voice is vital!). I want the sentences to flow. I like clean, well-crafted prose. I want to see believeable [sic], meaningful situations that play out logically. And, sure, hot sex is nice, but I'd rather read a well-crafted story that merely hints at the slashy elements than a poorly written sex fest.
>
> **(Meghan)**

> I look for characterization first. I have to be able to "hear" the character's [sic] voices in my head when reading slash; otherwise I won't read it. Next most important thing is spelling and grammar. I'm an editor and if I find myself proofreading and correcting a story as I go, I can't get through it. It's literally too much like work. Another important thing is canon. Unless the story is labeled an AU [alternative universe], I expect canonical events and characterizations. Research is also very important. I know that some authors extensively research background events, locations, etc for stories and I appreciate that. I also expect that a story will have been beta'd by at least two people.
>
> **(Tikva)**

Together, these three responses cover the qualities of "good" slash: characterization, part of which involves adherence to the primary text ("canon"), a plausible, logical though not necessarily detailed or intricate plot, verisimilitude achieved through research, effective and accurate use of language and style, and finally editing (referred to in software testing terminology as a “beta”). The references to language use and style serve to highlight their function as *linguistic capital* (Bourdieu, 1977), a form of cultural capital. The “rules” of written expression, reaffirmed through classroom instruction and style guides and manuals, are but one variety of English but have become the standard against which all others are measured. Those unable to meet these standards can be understood as lacking sufficient linguistic capital. By contrast, those who possess high levels of such capital will be considered “good” writers and will thus be recognized as legitimate members of the university-educated middle class.

The issue of “canon” is the one feature unique to fanfiction. In the popular cultural context, the term refers to the characterization and character development across the history of the series. The importance of canon to the members of MRKS cannot be underestimated. When I joined the list, I received a welcoming Frequently Asked Questions (FAQ) detailing life histories, behaviors, and characteristics of both characters established in the episodes. Here is an excerpt around naming conventions:

> *Fraser introduces himself as “Benton.”
> *His father and other family friends and enemies call him Benton or Ben (Quinn, Eric, Buck Frobisher, Gerrard, Buck Frobisher’s daughter, Victoria, Mark Smithbauer).
> *The only person to call him “Benny” is Ray Vecchio.
> *Ray Kowalski calls him “Fraser, and, very occasionally,”Frase” or possibly “Red.”
> *Other policemen at the 27th, including Lieutenant Welsh, refer to him as “Red” or “Big Red,” although Welsh prefers to address him as “Constable.”
> *Thatcher also calls him Ben once (in WATE) when she’s trying to imply an intimate relationship between them for the benefit of Henri Cloutier who is harassing her.

As for Ray, he is called by this name by everyone except his father, an old friend, and his ex-wife, Stella, who call him Raymond. He is only called “Stanley” by his mother and no one calls him “Stan”. The FAQ is also humorous, noting incidents that are a nod to m/m pairing: “Vecchio and Fraser spend a lot of time in a supply closet at the 27th [division] in seasons 1 and 2. Ray K and Fraser never go into the closet in the 27th in seasons 3/4.”

Expectations that slash writers have an extensive and in-depth knowledge of canon may seem contradictory when there is not one scene in *DS* that depicts a homosexual relationship between Fraser and Ray. Yet, as these comments suggest, the sexual orientation of the characters is not as "straightforward" as it may appear:

> In a given work of slash, I could be convinced that either one is gay and has just been closeted (or in denial) for a lifetime, but it would take a damned good writer to make me believe it (unless it's in an AU).
>
> Generally, I do believe that Ray loved his wife (and that was a very long term relationship), and I believe Fraser was . . . well . . . if not in love with Victoria, then at least in lust/obsessed with her. However, I don't see much in the way of chemistry between either of them and most of the female characters on the show (regulars or guest stars) and I *do* see chemistry between Fraser and Ray, so . . . if I have to attach a label, I'd say bisexual is the only sensible label for either of them, most of the time.
>
> **(Jeanne)**

> For the purposes of the fic I write/read, I would have to say bisexual, as each has had at least one serious het relationship in his past (as defined by the show's history/canon). When I watch them on-screen, however, there is only the barest subtext—for all intents and purposes, they are straight. I can and do extrapolate in various ways, since neither has ever said anything canonical about their sexuality. Ray, in fact, has said he'd "try anything once," and Fraser's "only ever loved one woman" in his life . . .
>
> **(Penelope)**

As Jeanne indicated, the only type of story that can legitimately and deliberately play fast and loose with canon is the story that is labeled AU or Alternative Universe.

In light of the above, I argue that knowledge of and respect for canon is a form of popular cultural capital (Fiske, 1989), based on Bourdieu's notion of cultural capital. While Bourdieu was particularly concerned with higher education and "high" culture, Fiske redeployed the term to recognize the high symbolic value that popular culture carries in many quarters in contemporary North American society. As university-educated fans, the MRKS participants had investments in both traditional and popular forms of cultural capital, both of which came into play in assessing all genres of fiction:

> In non-fan based work I still want characterization and plot and relationship development. I want it to make sense. However, in other original work I don't have a context, or a mirror to hold it up against. So I can't read it and say "this character would never do that" because I don't have

> a television show to provide me any past history. In that way, I guess I'm actually less demanding of mainstream fiction than I am of fan fiction.
>
> **(Kenzie)**

What is on offer is a post-modern redeployment of bourgeois aesthetics: slash is not seen as derivative and of lesser value than "original" fiction; on the contrary, it is more highly valued because, unlike other texts, it can be held accountable for its intertextuality.

The result of these investments in critical practices was to create a rift between the MRKS community and the larger DS fandom. In one of the longer list discussions, Phoebe identified the two positions on writing slash as "craft" versus "fun". What particularly irked her was an attitude she has encountered which lumped all women in the "fun" category:

> I have no problem with the concept that there are people out there writing for reasons different than mine. The only thing I object to is when I sense a gathering moral superiority and attempts to make one way the "only" way—that the "fun" way is better than the "craft" way, for instance, or the condescension of "it doesn't matter, it's just fanfiction/for fun/for women," which is actually a pretty damn insidious way of dismissing what we do, and dismissing (by implication) the people who take the craft of writing "just" fanfiction seriously much more completely than those writers who are "fooling around" or writing as an explicit (or implicit) leisure activity.

Oddly, Phoebe associates this anti-feminist position that women are not capable of or interested in bourgeois aesthetics with a feminist one about taking "ownership" of slash. Others contested this interpretation but agreed with her central argument. In another post, she criticized the "just for fun" position as an excuse to avoid the hard work that craft required. At the same time, she recognized that some writers might not have the required levels of cultural capital to produce well-crafted stories. Deirdre agreed with Phoebe, and positioned communities like MRKS who care about quality as a minority:

> Far as I can tell, most *people* are lazy and uncaring about the degree of craft and care they bring to any pursuit. I'm sure in any hobby group or whatever that's mostly male, there's some minority feeling annoyed/disgusted/whatever with the rest of the members of the group who are sloppy/uncaring/'just in it for fun'.

Sylvia's reply reaffirmed the view that the majority of any group will "settle for mediocrity". When Donna joined the thread, she disrupted the consensus around the "us versus them" position:

And I realize this is probably not the forum for disagreement on this issue, but . . . <holding my nose and jumping in> I think posting sloppy, poorly written, poorly characterized fanfic is okay. I personally won't read it, and truthfully I don't know where they're getting positive feedback from, but it's still okay with me that they do it. . . . The folk on the Way Too Intellectual TS Critique list used to take this kind of writing as a personal affront, as far as I could tell.

This participant was clearly concerned about the consequences of expressing disagreement, but a common position was quickly re-established by Phoebe, who asserted that she had no problem with others posting "dreck", repeating the term Donna had used to conclude her message (not quoted). Her objection, she explained, was being put down by those in the "fun" camp for "rewriting a sentence 27 times or agonising over a point of characterisation or dialogue". What was coalescing was a position of "us and them" rather than "us versus them". Angela spoke for the community when she declared, "I'm in the live and let live school, like probably everyone on this list—it's part of being a mature adult".

That said, some participants did not always adhere to this school of thought. Several list discussions revolved around criticizing or mocking fiction perceived to be "poorly written". These discussions are particularly interesting because in pointing out the "bad", what passes as "good" is cast into relief, not always without ambiguity. The sample presented below begins with an overt qualification of the "live and let live" stance:

From: Angela
However, a couple of sentences in an intro will make me run screaming for the hills:

"I've never seen any of the eps, but I've read lots of fic."

"I rushed this together between classes"

"I was supposed to be studying for a <insert high school class here> test, but my friend IM'ed me with a plot bunny <most hated term!> and begged me to write it."[4]

"Beta? What's a beta?" <Different from self-beta'ed>

"I like the name Stanley."

By "intro", Angela is referring to the story notes provided by many authors. Whether these lines are actual quotations from story notes or loose paraphrases is neither clear nor important. They signaled to her that the fiction would be lacking in quality because the author was unfamiliar with the primary text, did not spend any time developing characters, a plot, or even to proofread, only wrote the story as a challenge, is unfamiliar with the custom of having an editor, and weights personal taste over canon ("Stanley" instead of "Ray"). She concluded her message by asking others to add to her list, and a number of members responded. Most were humorous variations of the same themes. Penelope, for example, punctuated the "line" with disapproving "sounds": "Benny <aargh> and Stan <aaargh> go shopping/bake pies/go to the zoo <aaiieee>." Beyond violations of naming convention and non-sensical plots, Penelope, not surprisingly, flagged spelling and punctuation:

> "Ray and Frasser's relationship flourishes and gets a little help from Dief." (Okay, I'm cheating, that's an actual summary from a new F/V fic on due Slash. Spelling is as I found it.) This may be too general, but . . . anything with exclamation points, or ALL CAPS . . . I'm tapped out. Back to writing angst (with Manly Stifling of Tears).

Once the criticisms shift to inspirations for stories, the waters of "quality" become murkier. In two separate posts, Drucilla suggested the following: "I have <insert disease of choice> and thought it would be interesting to see how Ray and Fraser would react if one of them came down with it too;" "After the recent (insert event here) I wondered how Ray and Fraser would react to being in that situation;" and "I just broke up with my significant other and decided to write this story". Presumably, the problem in all three examples is a lack of critical distance/objectivity. These writers are perceived to be "sitting too close": the characters become non-canon mouthpieces for the author's political interests or emotional state/physical condition. For some participants, the line between emotional attachment and critical distance was not so clear-cut. Leah responded directly, noting that the "recent event" inspiration "can work, but it's got to be handled subtly and carefully". As for the "break up" influence, she agreed, "nope, that's never good" but then admitted that she was "guilty of scary author's notes" and gave an example: "I've been listening to George Michael nonstop for ten days. Enjoy". Whether her post was intended to be tongue in cheek is not clear, but it prompted this reply:

> **From: Deirdre**
> I've got to say, this thread is making me think about what *actually* inspired some of my stories and all's I can say is, man, I'm just glad I didn't 'fess to anything too massively stupid in my story notes.
>
> Yikes

This post served to rupture the communal position, blurring the binary between "well-written" and "poorly written" fiction. Drucilla moved to smooth over this awkward moment by teasing her that was okay to have these inspirations as long as one did not confess to them in story notes. Jeanne then joined the thread to re-establish a sense of community by asking members about what inspired their stories. She then provided some personal examples:

> "T", for example, came from a single image floating around in my head: a kiss at twilight in Ray's kitchen doorway—and that ended up being the first scene I wrote (even though it came in the middle of the story). "S" was a combination of things . . . part based on various discussions (privately and on lists) about what constitutes craziness where Fraser's concerned . . . and part based on hearing Patsy Cline's song "Crazy" right after I re-watched "Strange Bedfellows." And "M?" Appropriately enough, I pretty much dreamed it . . . and then wrote it the next day.

Others followed her lead and volunteered their inspirations. Yet the mention of a song and a dream by Jeanne do not seem so unlike the notes that had been criticized for failing to demonstrate appropriate critical distance. Toward the end of the thread, the participants did acknowledge that story notes in themselves were not a useful criterion:

> **From: Drucilla**
> Actually for me it's a combination of factors, but certain types of story notes definitely tend to put me on 'alert status' and the first few paragraphs of a story will usually be enough to tell me if that alert is warranted or not. So do certain author names. So if, say, I saw a story by someone I have read and enjoyed before with a note about—say—it having been inspired by a breakup or a natural disaster, I would probably read it anyway, while if it were by an author whom I have generally found lacking in some way, it might be enough to make me skip it.

To be fair, MRKS participants also meted out praise for fiction by other writers and measured themselves against it accordingly. Below is an excerpt from the thread, "Fic Rec" (recommendation):

> **From: Phoebe**
> Doing my flyby maintenance of due Slash and there's a new story up called "From Afar." It's F/K, post CotW, pretty long, and she can string complete sentences together. Worth a look if you need that bedtime reading.[5]
>
> **From: Drucilla**
> This is a major understatement.
> (off to burn everything I've ever written)

> **From: Phoebe**
> Well, you know me. Very few things actually blow me away. But this was technically well written, a major plus compared to some of the stuff out there lately. Could have used a beta.<G>

As Phoebe's post contained a minor criticism, Drucilla conceded there may have been "one or two small things" but then affirmed being "was too engrossed" to pay attention. Phoebe's response is conciliatory: "Uh, maybe you'll catch 'em on the reread, says the wanna-be copy editor". Drucilla agreed: "Most likely—I tend to notice things more the third or fourth time through. (as you know);-D". Later on in the thread, Drucilla admitted that she had violated her own rules about not reading "unbetaed" stories from a first-time slash writer. To shore up her position as a critical reader in the community, she emphasized that her statement about burning her stories had been hyperbole, a rhetorical strategy she had assumed the others would recognize as such. As well, she reaffirmed her support for the story: "I know my first story ever was a hell of a lot less well done than hers was:-". Leah, by contrast, would only say the story was "nice". Although she played down her lack of enthusiasm by saying "it was not her style", she also offered more concrete criticisms about it being too long and having "wayyy too many adjectives"!

CONCLUSION

It should be clear from the discussion above that the process of making meanings and pleasures out of slash fiction is a complex process. These pleasures are best conceptualized as a Venn diagram. One circle represents the "hotness" of the story, the second the "quality", and the third the adherence to canon. The "pleasure zone" is thus the space of overlap. By pointing out the contradictions in advocating for "quality" fiction, I am not suggesting that the MRKS participants are hypocrites or that no distinction can be made between "good" and "bad" fanfic. Rather, bourgeois aesthetics is a double-edged sword that can cut those who wield it in an effort to make distinctions on the basis of "quality" or "good taste". Upholding community standards based on bourgeois aesthetics too often have the unintended effect of creating an insider/outsider division within the community. Ironically, the importance of upholding such standards for the participants is likely reinforced by the charges of "sitting too close" or perversion made by high culture aficionados and homophobes, respectively. The denigration that they experience as fans in general and slash writers in particular may reinforce their desire to mark themselves out as legitimate members of the university-educated middle class.

Although they may not be obvious at first glance, parallels can be drawn between slash communities such as MRKS and virtual learning communities. For many in the latter category, engagement with a canonical text is also central, and members will find themselves struggling to define the boundaries of "legitimate" interpretation. Given the emphasis on effective and accurate expression in educational institutions, the insider/outsider binary that is the result of differing levels of linguistic capital will always have to be negotiated. At risk of being penalized and/or silenced are those students unable to meet the generally unmarked norms and standards of the community. In contrast, the student who is able to produce "well-written" responses is likely to receive the most attention and praise from instructors and classmates. Hence, the use of mailing lists and discussion boards to extend classroom discussion and then the assessment of the ensuing contributions demand careful thought and attention. Because of the centrality of language in virtual environments—"one becomes a thing of words alone" as Rushkoff (1994) puts it—one's cultural and linguistic resources are, quite literally, on the line.

AUTHOR'S NOTE

A longer version of this paper appears in Bury, R. (2005). *Cyberspaces of Their Own: Female Fandoms Online*. New York: Peter Lang.

ENDNOTES

1. For accounts on gender and cyberspace, see Cherny and Weise (1996), Herring (1996), O'Farrell and Vallone (1999), Consalvo and Paasonen (2002), and Shade (2002). For work on race, see Rodman et al. (2000) and Nakamura (2002). On sexuality see Case (1996) and on issues of digital divide see Van Dijk (1999) and Katz and Rice (2002).
2. David Marciano, the actor who played Ray Vecchio, did not return for the third season, and Canadian actor Callum Keith Rennie was brought in to play by Stanley Ray Kowalski.
3. "Fen" is the plural form of "fan" commonly used in fan communities.
4. "IM" stands for "Instant Messaging; in this example, it is used as a verb to "IM" someone.
5. CotW stands for "Call of the Wild," the title of the *Due South* series finale.

Part IV

Challenges for Virtual Learning Environments

Chapter 47: Chromosoft Mirrors*

JEFF NOON

The dramatic rise and fall of the Chromosoft empire has already been expertly charted, especially the part that Mirrors version 4.2 played in the short and dramatic end. I offer the following story as a more human addendum to the official history. It may illuminate a dark passing, if only with a single beam of truth. Concerned as they are with the bigger picture, none of the extant histories have managed to reveal the actual person responsible for the final terrible error. It was, of course, Chromosoft's policy that all mistakes be veiled by a collective responsibility.

My grandmother, Elisa Gretchen, died before I was born. Any knowledge I had of her life came through borrowed memories, until my discovery of her private journal. I need not go into the details of this discovery, except to say that the primitive nature of the recording medium necessitated the expensive purchase of an antique cd-rom player.

Elisa was on the famous skunk team that came up with the original idea for the Mirrors technology (code-named the "Alice" project), and was active during all stages of its development and demo-testing. Later on she was assigned to the troubleshooting team, which suffered heavily during the fretful launch period. Version 1.0 was riddled with bugs, and the new interface itself so strangely inhuman that the critics were quick to predict the company's demise, especially with its main competitors riding high on the "back to nature" campaign of the fashionable DOS revival. Version 1.1 ironed out some of the problems, and v.1.2 introduced the new feedback loop dynamics. It was the major relaunch, with v.2.0, that really kick-started the product's unprecedented success. With a brand new interface, greater though-recognition software, and an inspired marketing campaign centered around the slogan, "Chromosoft Mirrors—*where's your head today?*", the whole world turned to gaze in on itself.

The problem with Windows—the most famous interface prior to Mirrors—was that the more advanced it became (version 491.7!), the more difficult it was to use. And for all its increasing complexity, still all you ever did was *use* the technology; it never *used* you. Thus was the Mirrors project initiated. A new simplicity was called for, something beyond windows, beyond the blinkered one-way gaze. Although my grandmother makes no claim to inventing the actual concept, she does write that the name "Mirrors" was her

* Originally published as Chromosoft Mirrors (V.4.2) in *Pixel Juice*. London: Black Swan Books, 1998: 125–128. Reprinted with permission of the author.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1171–1173.

invention. It came to her in a flash, one evening in a Parisian hotel bathroom, "after a rigorous bout of continental-style lovemaking", as she puts it in her journal.

It was not the first system to use thought recognition, of course, but the first to successfully marry it with a usable feedback loop. Put simply, previous attempts allowed you to change the screen by thinking of the changes, but only Chromosoft allowed the information to redirect your thinking in turn. The Mirrors system really was a new way of working, a new way of being.

Where's your head today? Gone downloaded.

As it did with the invention of the typewriter and the word processor, a new type of creation emerged from the mirror. Suddenly, "speed of unconsciousness" novels were all the rage. Punctuation mutated into mere rhythm, narrative dissolved, symbols became deeper, more dreamlike, more dangerous.

Version 3.0 introduced the concept of network. Version 3.4, to the Internet. These were radical upgradings, with long-lasting social effects; because, although it was not strictly true that we were all telepathically linked, it certainly felt like it. The Internet's long-promised "revelation of the global soul" suddenly seemed less of a pipe dream, more of a God-given right. Version 4.0 added little that was new, merely a cosmetic repackaging to fend off the latest clones. 4.1 was another tweakjob, and it was this version that became the standard for the next 3 years.

The public will always find its own use for technology, and usually in secret. Nowhere in the Mirrors manual did it warn against remaining connected whilst asleep. Nowhere in the manual did it ever mention that such a thing could be done. And nowhere did it mention the effect this could have on the human psyche: the ability to get up in the morning, simply to access the correct document, and then to view, or rather review, your dreams of the night just gone. Could the company have seen how this would lead to a possible madness, a knowing of one's self that was too deep, too far-ranging?

Where's your head today? Why, it's playing with the burning giraffes, dancing with a turquoise lobster on the top of the grand piano, thank you, Mr. Penguin.

Many were affected by this dream-knowledge, and many did not make the journey back from the twisted, inner world.

I can now reveal that it was my grandmother, Elisa Gretchen, who developed and introduced the *disable dream* switch to version 4.2 of the Mirrors system. Approximately 6% of the world's population activated this facility, before the dangers of it were realized. Could Chromosoft, could my *grandmother*, really have so easily forgotten the feedback loop in the user/device interface? Her journal mentions little of the moment of invention, and even less of the subsequent events, except to note the "burning sense of shame that welled up within me, a shame that persisted even after the corporation had taken control of all responsibility”. Her last recorded entry reads simply: “I can do no more.”

Chromosoft Mirrors was taken off the market by government orders, and all existing devices were recalled, and trashed. By then it was too late for the 6% of who had already succumbed to the censoring loop. Those darkened, veiled unfortunates, who would never dream again.

I need hardly add that my grandmother was one of those unfortunates.

Chapter 48: Net:Geography Fieldwork Frequently Asked Questions

MARTIN DODGE* AND ROB KITCHIN†
Centre for Advanced Spatial Analysis, University College London, London, U.K.; †NIRSA, National University of Ireland, Maynooth, Ireland

1. INTRODUCING THE NET:GEOGRAPHY FIELDWORK FAQ

Q. *What is the Net:Geography FAQ about?*
A. It is a set of answers to frequently asked questions (FAQs) regarding the geography and unseen, "inner", structures of the internet. It provides a practical "fieldwork" guide for understanding the internet, using online mapping resources as virtual learning tools.

- It gives hands-on suggestions of techniques and freely available software tools and web resources that can be used to actively explore both the internal topology of internet connections and the external geography of network infrastructure. By revealing the operation of the internet in terms of where things are located, who owns them, and how data travels, the FAQ helps foster a more critical engagement with the media. The goal is to contribute, in a small way, to changing users of the internet from passive consumers to more informed and active citizens of their network, and potentially more engaged learners.
- It is possible to learn a lot about the internet from critical writing, popular discourses, and secondary published data. However, for real understanding, there is no substitute for doing your own fieldwork.
- It is not necessary to be a network engineer or computer scientist to begin to ask critical questions about the structure and the operation of the internet. Nor does not require a large investment in expensive, specialized tools as the internet can be used to measure and map itself. Many of the tools and techniques used were actually created by engineers for practical purposes of "debugging" network problems. However, they can also be re-used in politically challenging ways in the context of virtual learning, providing tactical knowledge of the media that cannot be gained in any other way. As a consequence, anybody can do Net:Geography fieldwork.
- The practical examples given in this FAQ were tested using a standard PC running Windows 2000 on a university network, but most of the software tools and all of the techniques discussed are sufficiently generic that they should work in most situations.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1175–1202.

- The Net:Geography FAQ comprises four sections: (1) finding out about your place on the internet, (2) determining the location of components of the internet, (3) measuring distance across the internet, (4) charting the routes of data through the internet.

Q. *In what ways is Net:Geography relevant to virtual learning environments (VLE)?*
A. The concept of doing "fieldwork" is very relevant to some of the underlying goals of VLEs—fostering active participation, developing social interaction by engaged learners, and mixing together learning resources and teaching approaches. Further, we would argue that specific Net:Geography methods outlined in this FAQ can contribute valuably to VLE development on three levels:

- Firstly, the practical techniques of network explorations and mapping can be incorporated as pedagogic content in a range of VLEs, particularly those that aim to explain "how the internet works".
- Secondly, the techniques are useful for academics and learners to look at and probe the underlying infrastructures that make their existing VLEs work.
- Lastly, the techniques can be used as part of thorough appraisal and assessment of the value of a VLE. Most obviously this can be achieved through monitoring online interactions and mapping the geography of participants.

Q. *Can I really explore the "inner workings" of the internet without permission?*
A. Yes, even as an "ordinary user" you can begin to explore the structure and operation of the internet. This is because the internet is built and operated in a fundamentally different way to other large communication networks, like telephones or television. These other networks are purposefully closed and proprietary, and, unlike the internet, actively try to keep "consumers" away from the insides of the network.

- The internet was purposefully designed as an open network that encourages active exploration and experimentation. The internet is not a single physical entity, instead it is premised on a public agreement to share data using open protocols. Anyone can use these protocols and as long as users abide by the terms of any access agreement and follow the protocols, they are able to take an active role in producing the network. Many of the most useful internet services widely used today came about through researchers, students, and enthusiastic hackers exploring and exploiting this open architecture to try out new things.
- However, the openness of the internet is always under attack because it is seen as threatening and subversive by many entrenched institutions. Today, with increasing commercial pressures, fears of criminal hackers,

rising levels of spam, viruses and worms, there is a definite "chilling effect" across the Net as security is tightened and the media comes under more surveillance.
- For a lucid discussion on the open design of the internet, see Searls and Weinberger (2003).

Q. *Does the Internet actually have a geography?*
A. Yes it does. In fact, there are several different geographies, although this FAQ focuses on the material geography of the infrastructures of the internet. Other important geographies that can be analyzed include, for example, the social geography of e-mail and the economic geography of content production and distribution.

- The hype around much of the "impact" of the internet, especially in the mid-1990s, was that it was "everywhere and nowhere" and it would make geography less significant in human organization through the "death of distance". This has patently not been the case.
- While the internet has undoubtedly had an affect on the geography of business operation and the time–space patterns of individual communication and consumption, distance is not dead. What is being witnessed are complicated socio-economic restructurings, through processes of concentration and decentralization, across scales.
- The idea of the internet as being somehow "anti-geographical" is based on three key notions: fantasy, denial, and ignorance
  1. Internet geography was assumed not to materially exist. This is founded on the anti-corporeal, cyber-utopianist *fantasy* that somehow the virtual communities of cyberspace can be produced in a realm divorced from material existence.
  2. Internet geography was assumed not to be important, so could be *denied*. The failure of many e-commerce ventures in the dotcom boom, we would argue, was based in part on ignoring the grounded, geographic, realities of computer-mediated communication, logistic networks, and labor markets.
  3. Internet geography was assumed to be not measurable. Because it was hard to do, it was *ignored*, especially in the heady days of bubble growth.
- The medium of communication might be virtual, but the internet is dependent on physical infrastructure and human labor, most of which is invisible to users. The computers are small in scale and are usually hidden from view in anonymous server rooms and secure, windowless buildings, while the cables are under floors, in ceilings and in conduits buried under roads.
- The banal technicalities of internet infrastructures are easily overlooked (just like for other essential utilities of water, electricity), but they are not naturally given. The geographical structure and operation

of networks that service modern living have politics. Net:Geography fieldwork can help in grasp some of these grounded politics first hand.

Q. *Why is understanding the geography of the internet useful?*
A. There are several pragmatic reasons why being able to find out about the geographical structure of the internet is useful. Most importantly, the internet is a global system, but it is always locally produced. Understanding the local variability enhances the understanding of the whole system.

- The social production of the internet is contingent on cultural, legal, and economic forces that vary from place to place. In communicating with people, it is often useful to be sensitive to language, customs and time-zones differences for example.
- The production of the internet is subject to myriad of different legal systems, which vary by territorial geography. It can be important to know the legal jurisdiction where the user is located as this may impact the types of consumer protection enjoyed, the particular obscenity laws enforced, and so on.
- The freedom to surf the web is not universal. Governments in many countries try to impose varying degrees of censorship in the production and the consumption of information of their citizens. For an authoritative catalog of censorship efforts across the world, see Reporters without Borders (2003).
- In economic terms, internet availability (as measured by access speeds, reliability, and cost) remains uneven across space and across different social groups. This has been characterized, often overly simplisticly, as the "digital divide" and, for a nuanced analysis, it must be considered geographically.
- Knowing where things are located is also useful analytically because variations in spatial patterns can often give researchers an insight into underlying processes. Geographic location is one of the most effective means of indexing internet data, enabling linkages to be made to a vast array of existing secondary data, such as demographic statistics from censuses and surveys. Geography also provides a familiar frame for presenting data about the internet, giving context and additional meaning to numbers. Conventional geographic mapping remains one of the most powerful means of information presentation available (e.g., showing the locations of learners in a VLE).
- Lastly, in a world of evermore information and services on the internet, geography proves to be an invaluable way of segmenting, filtering, and prioritizing people's attention. As a rule, people tend to be more interested in information that is local to them, rather than things that are distant.

We start the exploration of Net:Geography with some local fieldwork investigating how individuals are connected to the internet, and what is happening in their local internet neighborhood.

Q. *How am I connected to the internet?*
A. You are connected to the internet via specialist software and the settings that identify your location to the rest of the internet. It is quite easy to find out these details using diagnostic utilities of the operating system to display the current internet configuration for your PC.

- Technically these are the Transmission Control Protocol/Internet Protocol (TCP/IP) settings. TCP/IP is the basic lingua franca of the internet. If your computer is connected to the internet, it is "speaking" in TCP/IP.
- The ipconfig utility will show the TCP/IP settings. Run it by typing "*ipconfig/all*" from the command prompt. This gives the following type of output (Figure 1). (To open the Command Prompt, click Start, then Programs, then Accessories.)
- The output looks technical (and it is to some extent) but all it shows is the range of settings that allows the PC to get online. The most useful parts to note are the name of your PC on the internet (*Host Name: mini-ferret*) and the *IP Address (128.40.59.54*), which is the globally unique location of the PC in terms of the Internet's internal topology. No other computer on the internet can (legally) share the same address.

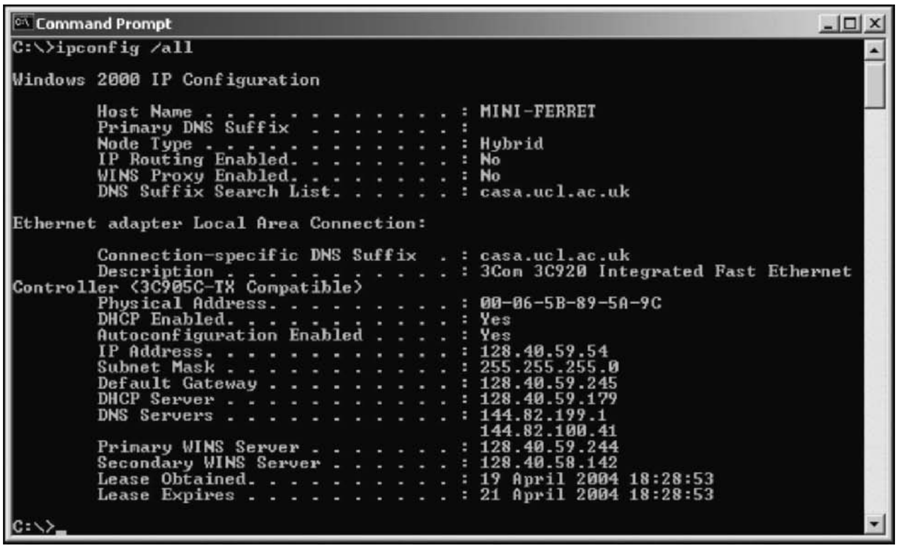

Figure 1. TCP/IP settings reveal the structure of your local Net:Geography.

- Details are also given on the type of connection, in this case through a local area network using Ethernet, with the make and model of the card (*Description: 3Com 3C920*). The physical address of the card, a globally unique id code number that identifies this piece of hardware (*00-06-5B-89-5A-9C*) is also shown.
- Lastly, the output lists the IP addresses of the *Default Gateway (128.40.59.245)*, which passes traffic from the local area out to the wider internet, and the *DNS Servers* (*144.82.100.1 ; 144.82.100.41*), which are important components in the internet for translating domain names into numeric IP addresses.

Q. *What is the speed of my connection?*
A. You can easily obtain the speed (and other useful statistics) on your current internet connection.

- Open the Network and Dial-Up Connections menu (accessed from Start, Settings). Right click on the active network connection and select the *status* option (Figure 2).
- In this case the connection is running at *10 Mbps* (megabits per second). This is typical for an office environment and is quite a lot faster than the average home internet access. Also displayed is the duration of the session and a basic indication of activity in terms of the total data transferred in and out.
- The speed of connection is important because it determines the bandwidth available for internet interactions. Bandwidth is the capacity to shift data measured in bit per second and is crucial to what can be

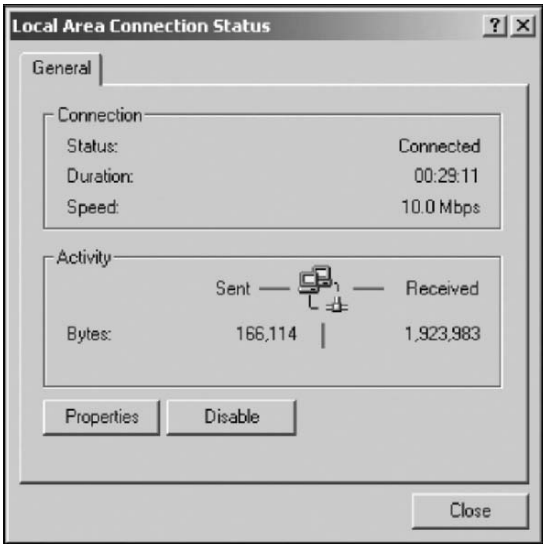

Figure 2. Network status showing the speed of connection.

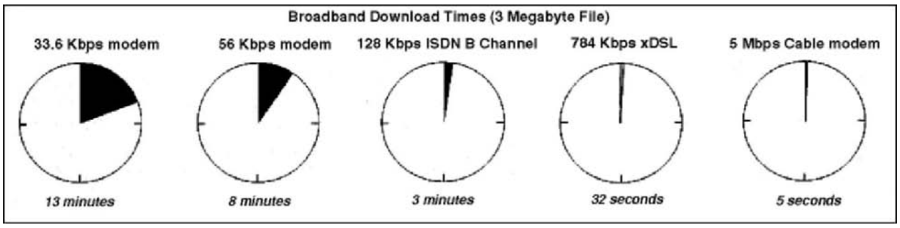

Figure 3. The importance of bandwidth.

done and how long it will take, as illustrated by Figure 3. Some internet services are simply not viable over low bandwidth connections.

Q. *What is going on in my local internet neighborhood?*
A. It is possible to see in some detail the inner structure of a local part of the internet, observing the activities of other users, using network monitoring tools.

- There are lots of different tools available. One of the most capable is the Ethereal Network Analyzer. It is a free, open-source application, downloadable from http://www.ethereal.com.
- Ethereal is a network monitoring tool that does "packet sniffing". This means it can watch all the traffic "going past" your PC on a local network. This traffic is in the form of streams of individual data packets flowing between different machines. The data packets can be captured by Ethereal for processing and detailed analysis.
- Figure 4 shows Ethereal monitoring a small local area network of an office at a university. It was able to "sniff" quite a lot of activity nearby. This screenshot only shows a snapshot of a few seconds of the data packets flowing by the monitoring PC.
- The display looks complicated as it shows a very detailed view of internet activity that most people never see. The result is simply a long list of all traffic "sniffed" rather than a summary graph or a map. Ethereal does not "know" anything about the physical structure of the network or the actual locations of the users. However, it is able to identify the different types traffic and, most importantly, the source and destination of the traffic.
- The top window in the Ethereal interface displays one data packet per line. It takes some care and skill to interpret what is going in terms of user activity because it can be fragmented over many individual data packets. As an example, one data packet, number *2449*, has been selected. The data was sent from PC identified as *casa198.bart.ucl.ac.uk* (Source column) to *newswww.bbc.net.uk* (Destination column). The destination is the web server for the BBC News service. The protocol of the data packet was *http* (hypertext transfer protocol used by web browsers) and

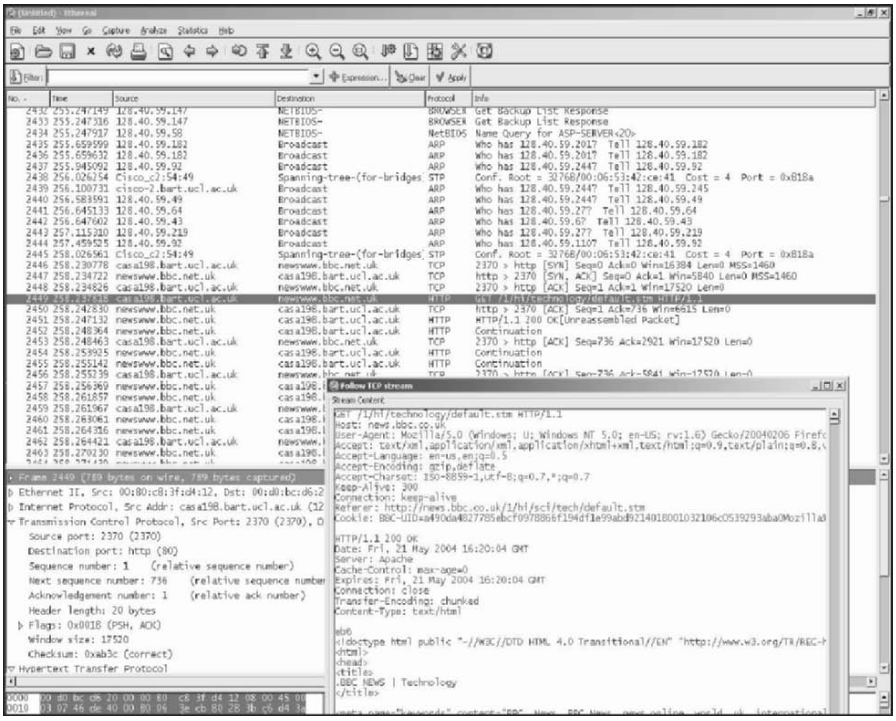

Figure 4. Ethereal Network Analyzer capturing packet-level detail on the traffic flows of a local network environment.

the *GET* command Info column reveals it was a request for a web page. Ethereal can connect together all the related packets of data for this particular web transaction, shown in the *"Follow TCP Stream"* pop-up window, enabling us to see the actual web page content (in raw html form). In this case Ethereal was able to reveal exactly the web page this user was looking at.

- Ethereal, and similar network monitoring tools, have the power to reveal a great deal about individual user's activities. This is particularly so because most data flowing across the internet are sent unencrypted and can be covertly read by anyone who is able to tap into the network flow.
- Beyond the practicalities of running network monitoring tools like Ethereal and interpreting the output, there are clearly some more thorny ethical issues to confront about covert "spying" on the activities of your neighbors. Good ethical practice for researchers would require that prior informed consent is obtained from *all* people on the network being scanned. Active network scanning for benign Net:Geography exploration can also be deemed improper behavior by system administrators, so you need to be prepared to justify your actions.

Q. *What do I reveal about myself to the rest of the internet?*

A. Connecting to the internet means necessarily revealing some details to network providers and leaving traces in the logs of the services you interact with. At a most basic level the IP address must be known to send data to the correct location.

- Any online activity leave traces, but using different services and different client software results in different amounts of potentially personally identifiable data "leaking" out.
- Surfing the web in particular results in a considerable amount of information being revealed. Even if you have not formally registered with websites and feel that you are browsing anonymously, you may be surprised the degree to which you are trackable.
- There are number of free web services that test what is revealed about your PC and web browser configuration. Figure 5 shows an example produced by the BrowserSpy service (http://gemal.dk/browserspy).
- The "basic information" that BrowserSpy is able to extract is perhaps not that surprising; it can determine the type of web browser and version, as well as the operating system. More interestingly it could tell the connection was via a modem. BrowserSpy is also able to gather many more details from a typical web browser (e.g., plug-ins available, drive letters, screen resolution, time-zone settings). In many ways this is technical and very banal information, but taken together this voluntary "leakage" can paint a detailed picture of your PC. These data are useful for websites in building profiles and tracking their users,

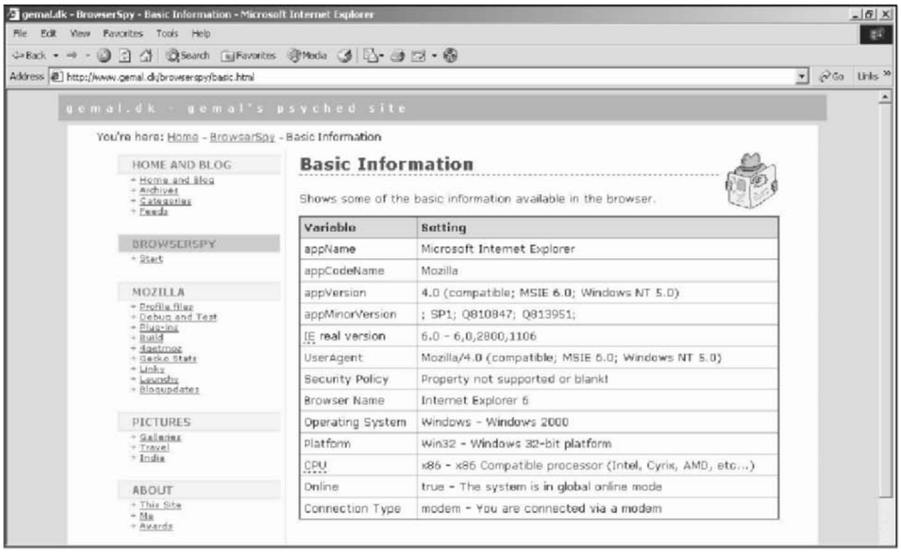

Figure 5. An example of some of the possible "hidden" details that you can unwittingly reveal to websites.

and also for automatically presenting tailored content to suit different users (e.g., less graphics for those on low bandwidth connections). It can also be exploited by more unscrupulous people to identify potential vulnerabilities in your PC through which to attempt to break in.

- Browser cookies are particularly pernicious tool in web surveillance, although we do not have space to discuss their role in actively tracking individual browsing patterns. However, as a very simple test of their prevalence, try setting your browser so that it has to request permission from you every time a website wants to set a cookie. You will quickly see just how many are set!
- Further technical reading on what data are known about you when using the internet see Clayton (2001).

3. LOCATION ON THE INTERNET

We now look beyond the local neighborhood to methods that allow a wider exploration of where things are located on the internet.

Q. *How is location in the internet defined?*
A. Knowing where things are located is crucial to most activities, including in the internet. However, the internet is concerned with topological location (where things are located in terms of connections) and not with physical geographical location, defined by x, y co-ordinates.

- The internet comprises a robust and scaleable system to specify location uniquely so that data can be correctly transferred.
- As demonstrated earlier when discussing *ipconfig*, globally unique locations in the internet are based on two key systems—IP addresses and domain names.
- Typically when people give out an internet location this will be some kind of domain name address (e.g., a website address, *http://www.jasonnolan.net* or an e-mail address such as *jason.nolan@utoronto.ca*). Domain names are always associated with an IP address.
- IP addresses are little seen or used by typical users. They look a little like telephone numbers, such as *64.246.60.38*, identifying the *http://www.jasonnolan.net* website. The unique allocation of IP addresses is the key to the successful delivery of traffic across the complexity of the global internet.

Q. *Why don't internet addresses specify a geographic position?*
A. This is how they were designed. Basically, the internet protocols at the core of the network were never designed to make details on its geographical structure explicit to users. The successful transfer of data through the internet requires knowledge of a topological address, not geographical location.

- In many ways the internet was designed to deliberately hide the underlying physical geography. This split between logical locations and physical locations is actually very useful. It is part of the reason why you can surf across websites scattered across the world and not have to worry about where the data are physically located.
- Because the internet is a network of networks, rather than a homogeneous entity, its means of control are decentralized and its structure is fluid. Even though "no one owns the internet" as a whole, each one of its component parts is owned and operated by many millions of different organizations and individuals. In consequence, no one single institution has a synoptic view of the whole internet and, therefore, no one is required to maintain a register of where all the components are physically located.
- However, it is often useful to be able to determine the geographic location of parts of the internet, for example the location of a website as a part of assessment of whether they are credible sources of information or before entering credit card details. Many websites might not be physically where you think they are. However, because there is no one central register to do this mapping, you have to use a range of different fieldwork techniques (detailed below).

Q. *What types of geographic location are relevant for Net:Geography fieldwork?*
A. Understanding the nature of the geographical location of components of the internet is interesting because different parts can be in different places. There are five obvious kinds of geographical location which are important in terms of the web:

1. A website is where it is published, that is where the server is physically located (hardware geography).
2. A website is where the author/maintainer is located (production geography).
3. A website is where the legal owner is located (ownership geography).
4. A website is where the readers are located (audience geography).
5. A website is where the content refers (lexical geography).

- In some cases all five locations will be coincident. But it is easy to imagine plausible scenarios in which you have a web page about Maynooth, Ireland that is written by someone in Canada, hosted on a server in London and read by people from across the world.
- The geographical precision of these different physical locations can also vary. Sometimes location might be determined as the precise x, y position (e.g., street address of the building with the web server), other times one might only know the city or legal jurisdiction referred to.

Q. *How can I tell where an internet address is geographically located?*
A. Unfortunately, determining the precise geographic location of an internet address cannot be done easily or in an accurate, consistent fashion. However, there are some techniques that can be used to try to determine the geographic location, at least approximately, of a website for example.

- The first point to note is that different techniques will tell you about the five different locational types. Most of the techniques described here will identify the production or ownership geography.
- The first, and most obvious, method is to use lexical location as the proxy. Here, the content of the website is browsed to try to find an "about page" or "contacts page" that provides a postal address or telephone number of the owner. Other cultural and linguistic clues (e.g., flags, symbols) in the content of a website might give useful indications of the "real-world" location.
- If you only have the domain name of a website to work with, the first place to start is by "decoding" it. Many domain names are allocated on a country-by-country basis with their name ending with the appropriate two letter ISO country code (e.g., *.ca* for Canadian domains, *.ie* for Irish domains, and so on). One can infer the geographic location of an internet address based on the country code in its domain name. A useful list of all the country code domain names is available at http://www.iana.org/cctld/cctld-whois.htm.
- However, there are limitations in relying on country code domains.
    1. There are several domain name types (the so called "global top-level domains") that are not related to countries. The biggest of these are *.com*, *.org*, *.net* and *.info*. The *http://www.jasonnolan.net* website has a *.net* domain name which does not allow any inference on its location to be made. A *.net* domain could be located anywhere in the world. (Note, the top-level domains *.mil*, *.edu* and *.gov* are allocated only to U.S. institutions, so one can be fairly safely assume they are located in the U.S.A.)
    2. The level of geographic precision is obviously crude with this technique, particularly so for large countries. A *.ca* domain name could be anywhere in Canada.
    3. Lastly, just because a website uses a country code domain name does not guarantee that the website is actually within the country indicated. The ownership, production, hosting, and use of that website could well be in another country or several different countries. For example, the amazon.de and amazon.co.uk websites are published on servers physically located in the United States and not in the United Kingdom or Germany as indicated by their domain names.
- Moving beyond decoding the top-level domain names, you can try to exploit other parts of the domain name to infer geographic location of the address. This works when e-mail addresses or websites

are part of an established, easily identifiable company or institution that can be traced to city in which they are located. For example, we could deduce that Martin Dodge's e-mail address at ucl.ac.uk links him to University College London (UCL) and could then infer that he is physically located in central London, on the site of the main university campus. Again, there are limits to the level of precision in this method, and it is also prone to error for large organizations, like transnational companies, which operate from many sites, over extensive areas.

- The last thing you can do with a domain name address is to find out whom it is registered to. All domain names have a legal owner and the registration databases for this usually contain contact details. You can freely consult this registration information from the domain name system using a *Whois* query. (Note, not all domain registration databases will publicly give out the full address details of the owner.)
- A *Whois* query can be easily run from any number of websites. Below is the results of a *Whois* query to find the registered owner of *jason-nolan.net* domain name using the free service provided by AllWhois (http://www.allwhois.com) (Figure 6).

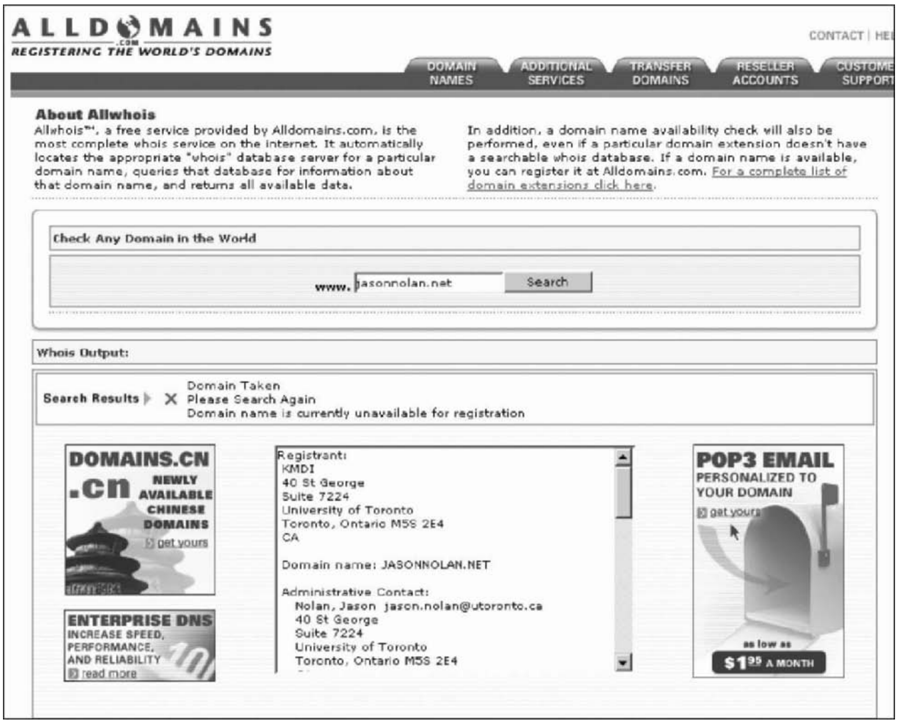

Figure 6. Looking up the domain name registrations details on jasonnolan.net using Whois.

- The registration information from the *Whois* query identifies the owner of *jasonnolan.net* to be located in Toronto, Canada. The full street address is given. This could be looked up and a detailed map obtained giving the precise location.
- The results of *Whois* queries can be very useful in finding out where the registered owner of a domain name is, however they are not always accurate. Firstly, registration details held on a given domain name may be out of date, incorrect, or deliberately false (spammers, for example, try to hide their true geographic location and would be unlikely to complete the registration honestly). Secondly, ownership details may only tell you one of the five possible geographies of a website. We can see that *jasonnolan.net's* owner is located in Toronto, but the site may be produced, published, and consumed elsewhere. Thirdly, the registrations for large organizations often give a single postal address (their headquarters) and thereby mask where individual domain names are actually being used.
- If you do not have a domain name to work with, you can also lookup the ownership of IP addresses. These are generally allocated in large blocks to ISPs rather than to individuals or companies. You can do this query by doing a *Whois* query to ARIN (http://www.arin.net/whois). The IP address of the server which publishes *http://www.jasonnolan.net* is *64.246.60.38* (Figure 7). Looking up this address yields details on the registered owner, a company called Everyone's internet Inc., with a postal address in Houston Texas.
- Another strategy is to test where a website is connected to the internet by tracing traffic flows. Details on how to do this real-time probing are discussed in the last section of the FAQ.
- There are a number of firms that provide commercial services to convert IP addresses to geographic locations. For example, Quova, Inc. (http://www.quova.com), IP2Location (http://www.ip2location.com).
- To find out more on the technicalities of relating internet addresses to geographic locations, see Lakhina et al. (2002) and Padmanabhan and Subramaniann (2001).

Q. *What else can I do to find out more about a website's ownership and location?*
A. Taking a different perspective, you can also explore the "virtual" position of a website in terms of its visibility in the information space of the web.

- Counting the number of hyperlinks to and from a website and analyzing whom the links come from can reveal the informational structures of Net:Geography. The results can be used to infer a website's position in terms of social networks and power geometries; a well-linked site could indicate that its creator has power and influence. This kind of hyperlink analysis has many parallels to citation analysis used to assess influence in scholarly research. Much of the success of the Google search engine

Figure 7. The results of a Whois lookup on the IP address of the web server that hosts http://www.jasonnolan.net.

in terms of relevance ranking depends on its analysis of hyperlink structures to indicate the most credible sources of information.

- It is possible to obtain appropriate data to give a rough approximation of hyperlink structures using some of the large web search engines. These will report link statistics (usually available as part of their advanced search options). For example using Google you can find out the number and origin of incoming hyperlinks made to the *jasonnolan.net* website using the search command *link: jasonnolan.net* (Figure 8).
- The Google search engine index reports 346 web pages with hyperlinks to *http://www.jasonnolan.net*. This is a respectable number of links.

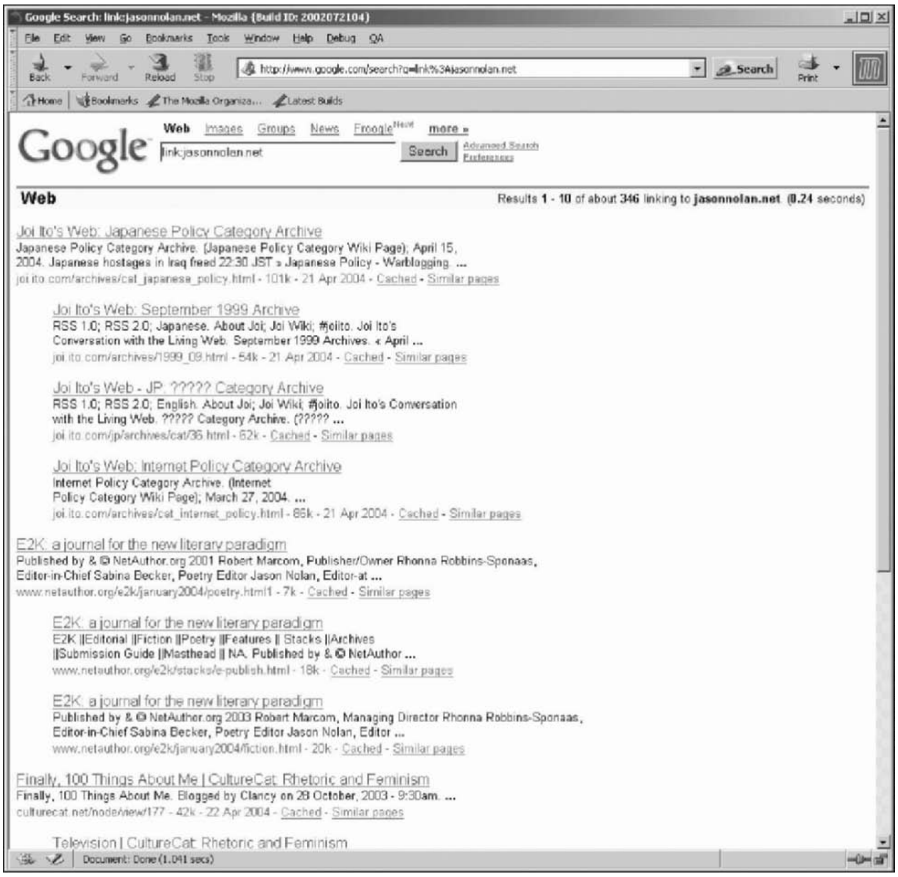

Figure 8. Incoming hyperlinks to http://www.jasonnolan.net website according to the Google index.

From a limited understanding, many of them appear to come from blogs citations. This is perhaps not surprising as jasonnolan.net is also a blog.

- These types of informational structures can also be viewed as graphs, where the web pages are nodes and the hyperlinks are connecting lines. A nice example of this is available using *GoogleBrowser*, an interactive tool produced by TouchGraph (http://www.touchgraph.com). It allows the active exploration of a website's location in terms of the virtual economy of linkages. Figure 9 shows an example of the GoogleBrowser view of linkage network immediately around *http://www.jasonnolan.net*.
- For those interested in exploiting the tactical power of hyperlink analysis to expose the hidden politics of Net:Geography, the research of Richard Rogers and colleagues is well worth consulting (http://www.govcom.org).

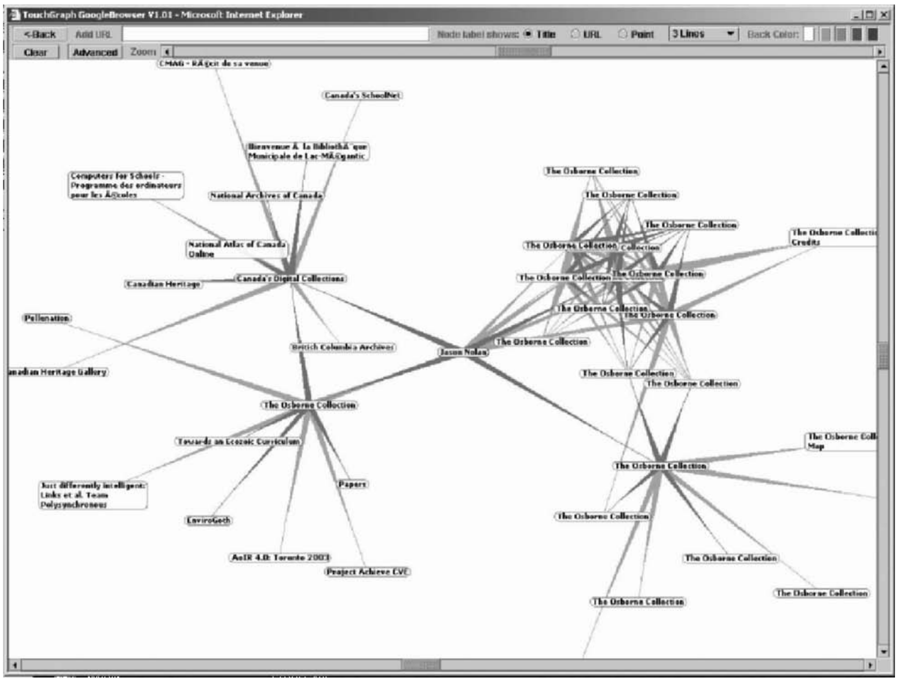

Figure 9. GoogleBrowser view of the local web neighborhood of http://www.jasonnolan.net.

4. MEASURING DISTANCE ACROSS THE INTERNET

Q. *How is distance across the internet defined?*
A. Simply put, distance is measured in terms of time inside the internet.

- Within the topological structure of the internet, physical distances between places have little meaning or relevance. Instead relative distances are measured using the "journey" time taken to transmit and receive data.
- This "journey" time is called latency. Increasing latency implies increasing relative distance between two places on the internet. Latency metrics serve the same purpose as physical distance on road signs and maps, that is they tell you how "near" or "far" apart things are. It is important to note, however, that there can be many different technical factors (e.g., types of hardware and network configurations) that effect latency.
- Of course time, and associated costs, are also widely used in the "real" world to express distance. Most people assess a journey in terms of the time it takes and not linear distance on the ground (e.g., a 10-minute drive to the shops, a 4-hour flight to a holiday destination). Time-based distance measures are useful to people because they match subjective perceptions of closeness, relevance, and importance. Near things tend

to be judged as more important because people's exposure to them is more direct, immediate, and frequent. Far away things take longer to experience and thus tend to be less familiar (e.g., people speak a different language) and are perceived as less comfortable and perhaps even as more risky.

- An interesting point of analysis, both on the internet and in the "real" world, is to compute the relationship between distance on the ground and time distance for different places. This relationship is not always linear because of barriers, lack of connectivity, and poor accessibility. Sometimes the quickest places to reach are not always the closest physically. Analyzing the variable patterns in time accessibility can sometimes give insight into underlying structural processes.
- Distance can also be measured by the complexity of the journey, such as the number of interchanges encountered. In terms of the internet, the least-complex distance would consist of the minimal number of different networks crossed or switching points negotiated, which may or may not be the same as the quickest route. The next section of the FAQ demonstrates how route complexity can be plotted by tracing traffic flows.

Q. *How can I actually measure latency?*
A. There is a useful utility called *ping* that can measure latency (the travel time of data) on the internet. Ping is easy to use and available on most PCs.

- It is a network measurement tool primarily used by engineers to diagnose connectivity problems. Basically, it reports whether a particular place on the internet is "live" and accepting data.
- Ping takes its name from the sound that submarine SONAR uses. Conceptually it works in a similar fashion by sending out small packets of test data to a target host and listening for a response. It is useful for distance measurement because it reports the round-trip time of these data packets.
- Figure 10 shows an example of measuring the distance from a PC in London, U.K. to *http://www.jasonnolan.net* using ping.
- By default on Windows, ping sends out four test data packets. The time each took to go from London to *http://www.jasonnolan.net's* server and back again is reported (in milliseconds). The last line of the output reports the overall statistics. According to this, the average "distance" for this particular journey across the internet as measured by latency was 340 ms, while the slowest data packet took 391 ms.
- This type of time distance measurement is very susceptible to changes in conditions on the internet, especially congestion in traffic flows. Internet distances measured by latency are never fixed. However, this

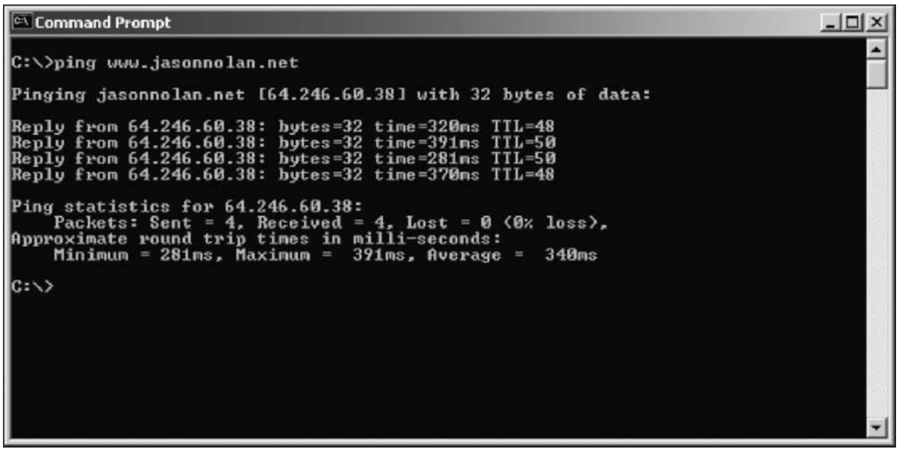

Figure 10. Using ping to measure time distance between two points on the internet.

variability is actually useful as it can be used as a way of quantifying the fluctuations in internet conditions, much like measuring car speeds gives an indication of the level of road congestion.

Q. *What else can I do with ping?*
A. There are several ways that "pinging" internet distances can be used to learn more about Net:Geography.

- First, and most obviously, a sequence of pings to the same place at different time periods can be used to build up a comprehensive longitudinal profile of latency. This might reveal interesting temporal patterns in the variation of latency as places on the internet move nearer and further apart in a predictable fashion. Sudden changes in latency that do not fit the profile can reveal serious problems (e.g., a physical cut in a key fiber-optic cable).
- Another useful extension is to take pings from different places on the internet to triangulate in on a particular target point. For example, one could take measurements of latency to *http://www.jasonnolan.net* not just from London, but from other geographically closer or more distant points. The practicalities of doing this type of triangulation are made easier because there are a number of websites which allow you to run pings from their location. (To find them use a search engine to look for "ping websites".)
- By triangulating from different points it possible to get a sense of the relationship between latency and physical distance, assuming that the (approximate) geographic location of the origins and target are known. It is possible to get the physical distance (measured as the great circle distance) between the cities using a websites distance calculator (e.g.,

John A. Byers's site http://www.wcrl.ars.usda.gov/cec/java/lat-long.htm).

- Knowing the latency and physical distance also means you can approximate the speed of data transmission. Indeed, the use of ping has been taken further in a classroom physics experiment to calculate the speed of light. For technical details see Lepak and Crescimanno (2002).

5. ROUTES THROUGH THE INTERNET

Q. *What route does my data take through the internet?*
A. You can answer this question using *traceroute*, a network engineer's tool that allows you to "lift the lid" on the internet and get a "packets-eye" view of its working structure. It is undoubtedly one of the most useful tools available for Net:Geography fieldwork.

- Traceroute works in much the same way as ping but it provides much greater detail. It maps out the path that data packets take between two points on the internet, showing all of the intermediate nodes traversed, along with an indication of the speed of travel for each segment of the journey.
- Traceroute was invented in 1988 by Van Jacobson at Lawrence Berkeley National Laboratory in the United States. The utility often comes as part of the operating system. The Windows version is called *tracert* and is used simply by typing, at the Command Prompt, *tracert [internet address, e.g., www.jasonnolan.net]*.
- Although, traceroute is primarily for network engineers to "debug" routing problems, it can also be used in a more tactical fashion by researchers to expose the political–economical structures of the internet. It reveals the hidden complexity of data flows, showing how many nodes are involved (often more than twenty), the seamless crossing of oceans and national borders, and the sometimes convoluted transfers through networks owned and operated by competing companies.
- To illustrate how traceroute "maps" the internet, it was used to chart the path from a PC in London to the *http://www.jasonnolan.net* website. Figure 11 shows the result.
- It is important to note that the view of data routing that is "seen" by traceroute is quite a generalized, "high-level" summary of the network in terms of topological connections. Below the traceroute view, there is a much more detailed level of routing in terms of the geography that lies between each node, based on the types of wires and their physical pathways in the ground. Sadly, this level of detail is not measurable using present Net:Geography fieldwork techniques.

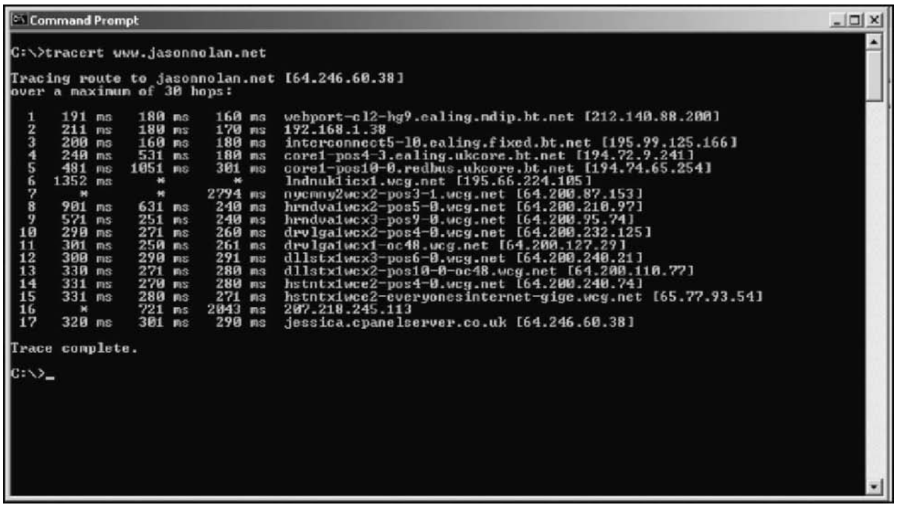

Figure 11. Traceroute from London to http://www.jasonnolan.net.

Q. *This does not look much like a map, can you explain what it means?*
A. The end result of a traceroute does look rather cryptic at first sight, but it is in fact a kind of one-dimensional map of how the data flows, with each node traversed listed on a separate line.

- The "map" gives a complete linear route listing showing how data packets traveled through the internet starting in London and ending at Houston in the United States–the apparent location of the web server which publishes *http://www.jasonnolan.net*. The three time measurements in milliseconds–such as *211, 180, and 170 ms*—are round-trip times for that segment and give a useful indication of the speed of each link.
- Each node traversed is identified by its domain name and numeric IP address. Not all nodes have a domain name (e.g., *192.168.1.38*). Also, notice that many nodes have strange, long domain names (e.g., *dllstx1wcx3-pos6-0.wcg.net*). These are routing computers at the core of the internet and their domain names are not normally seen by users. With a little bit of "decoding" these router domain names can yield useful information, such as the type of node hardware, the bandwidth of the link, the name of ISP that owns a node and often a node's approximate location (usually at the city level). Fortunately, for traceroute explorers, many of the large ISPs apply a consistent naming convention throughout their network infrastructures (as you can see from the domain names of nodes owned by *wcg.net* in Figure 11).
- The geographic location of the node is often represented in these types of domain names as an abbreviated city name. For example, *dllstx* at

the start of segments 12 and 13 (Figure 11) could sensibly be guessed to mean Dallas, Texas. Some ISPs use the familiar three letter airport identification codes (e.g., LHR for London Heathrow) as their city naming convention. (There are lists of these airport codes available on the web, for example, at http://www.orbitz.com/App/global/airportCodes.jsp.)

Q. *How do I interpret the actual route to http://www.jasonnolan.net from the traceroute output?*
A. The first thing to note is that data traveling from London to *http://www.jasonnolan.net* had to pass through 16 intermediate network routers to reach the end of the destination (node 17). At least three different networks were traversed—British Telecom (BT), Williams Communication Group (WCG), and Everyones internet.

- Reading the route line by line, it begins with the first node—how a user's PC is connected to the internet. From the domain name we can see that it belongs to *bt.net*. From local knowledge, it is known that *"ealing"* in the domain name is also an area in West London, so we can take this is an indicator of its likely geographic location.
- The next "hop" in the journey to node 2 is rather mysterious with no domain name to decode. We have to assume it is a node within BT's network in London.
- Node 3's domain name indicates it is another BT node in Ealing, London.
- Node 4 again says *"ealing"* and BT. The node also states *"ukcore"* which we might reasonably take to mean this node is within BT's core network for the United Kingdom.
- Node 5 is also in BT's "*ukcore*" network. Notice the increase in latency as measured by the RTT at this point in the journey.
- At "hop" 6 in the journey the data leave BT's network and is handed off to another ISP called wcg.net (Williams Communication Group, now part of Wiltel corporation). The cryptic abbreviation at the start of the domain name ("*lndnuk1icx1*") can reasonably be decoded as London, U.K. The convention on this ISP's network is to start the domain name with a four letter abbreviation of the city, followed by a two letter code for country/U.S. state. Note the big jump in RTT and the appearance of * for two of the times (this means timed-out, no response) at this point, probably due to traffic "congestion".
- The next segment in the journey sees the data packets cross the Atlantic to New York, most likely on an undersea fiber-optic cable. The start of the domain name for node 7 is *"nycmny"* which can be decoded as New York City, New York. The RTT increases greatly at this point, again with two * timeouts.
- From New York the data travel on wcg.net network to *"hrndva"* at nodes 8 and 9 that are in Herndon, Virginia (one of Washington D.C.'s

satellite towns which has a great deal of internet infrastructure related companies).

- The next two steps in the journey on wcg.net's network are in *"drvlga"* which is somewhere in the state of Georgia. However, it is not immediately obvious which town *"drvl"* refers to. Perhaps it is a suburb of Atlanta, the main internet hub point for the state.
- We are now approaching our goal, as the data move on into the state of Texas, going through Dallas (*"dllstx"*) in nodes 12 and 13 and then to final destination, the city of Houston, Texas (*"hstntx"*) at node 14.
- At node 15, the wcg.net network exchanges the data to a new company, EveryonesInternet (Everyones Internet, Inc.).
- Nodes 16 is most likely on EveryonesInternet network but does not have a domain name, so it is hard to know for sure.
- Node 17, somewhat confusingly called *"jessica.cpanelserver.co.uk"*, is the domain name of the web server that hosts *http://www.jasonnolan.net* website. It is unclear why this server in Houston has a *co.uk* domain name!
- It is important to realize that internet routing is dynamic, it can change minute by minute. The "map" that is produced by traceroute is a live scan and always represents a one-off snapshot of Net:Geography at the point in time it was charted. Running the same trace at a future time is quite likely to give a different map.

Q. *Can I run traceroutes from different places?*
A. Yes, just like ping you can "triangulate" the internet using web-based traceroutes.

- These make it possible run traces from many different starting points, including on different networks and in completely different continents. web traceroute gateways are very useful for active exploration of the Internet's topology from across the globe and illustrate the degree to which routes vary.
- There are several hundred freely available web traceroute gateways in many places. Thomas Kernen maintains a good list of them at http://www.traceroute.org.
- As an example of traceroute triangulation we ran a trace from Australia to *http://www.jasonnolan.net* using a gateway provided publicly by Telstra, the main Australian telecoms carrier. Figure 12 shows the output "map" from the trace. (Note that the formatting of this output is slightly different to that produced by Windows tracert.)
- Again, with a little bit of decoding work, reading line by line, it is possible to follow the data packets on this new journey. The traceroute utility is installed on a *telstra.net* server located in Canberra, Australia indicated by the domain name for node 1. The next two nodes in the trace were also within Canberra, according to their domain names.

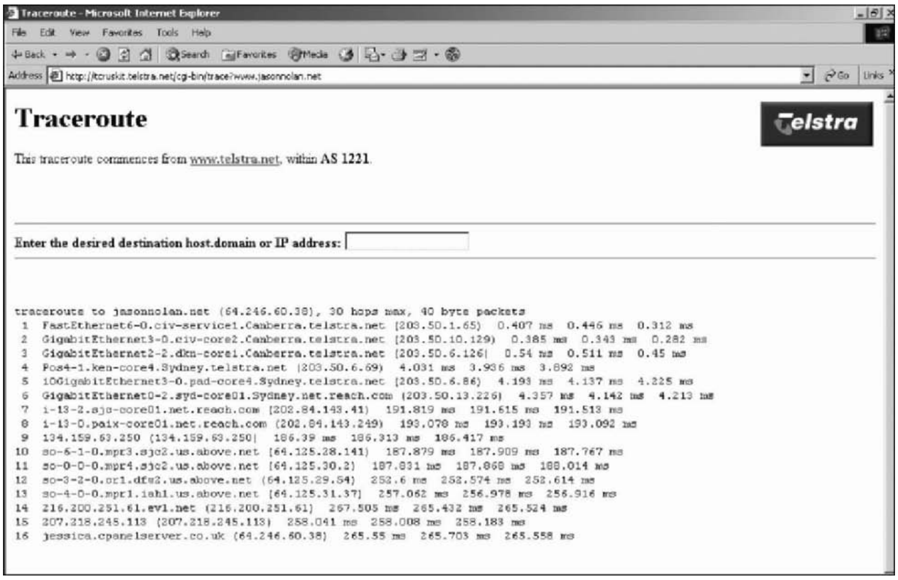

Figure 12. An example of a web-based traceroute from Canberra, Australia to http://www.jasonnolan.net. (Available at http://www.telstra.net/cgi-bin/trace).

- At node 4 the data moved a couple of hundred miles on the *telstra.net* network from Canberra to Sydney. The data are then passed through three nodes in Sydney before leaving the Telstra network for the *reach.com* network at node 6.
- The big trans-Pacific hop in the journey occurred at node 7, as the data went to *"sjc"*, the airport code for San Jose, California. Note, the marked jump in the RTTs at this point in the journey, caused in large part by the 7500-mile distance across the Pacific Ocean.
- Node 8 on the *reach.com* network is located at *"paix"*, the name of a major internet exchange point located in Palo Alto, California. Node 9 is cryptic. At node 10, the data left PAIX for a new network, that of *above.net*.
- Nodes 10 and 11 on above.net's network were located in San Jose, California as indicated by the *"sjc"* codes in their domain names.
- The data moved on from California into Texas, going to Dallas-Fort Worth (*"dfw"*) at node 12. It moved onto Houston, Texas (*"iah"*) at node 13.
- The final stretch into *http://www.jasonnolan.net* took place at nodes 14 and 15, which are likely to still be in the Houston area.

Q. *Can I geographically map traceroute output?*
A. Yes, an obvious refinement of the regular traceroute list output is to try to plot the route visually on a geographic map. There have been a

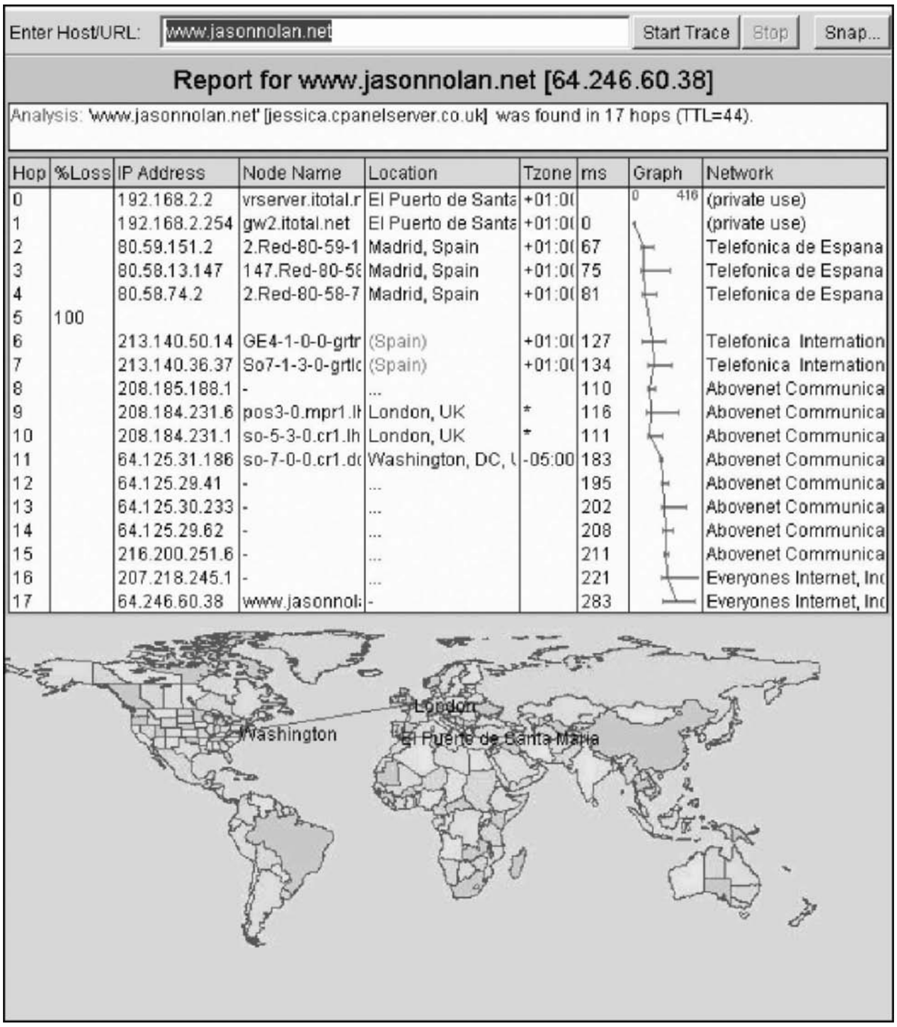

Figure 13. An example of a geographic traceroute produced using VisualRoute.

number of attempts at a geographical traceroute, with varying degrees of success.

- Figure 13 is a screenshot of the best geographic traceroute program currently available, called VisualRoute (http://www.visualroute.com), tracing the data route from a server in Spain to *http://www.jasonnolan.net*. The top half of the display is table presentation of the trace results. The approximate locations (where known) of the routers are plotted on a rather crude map below.
- The particular advantage of this application is the ease of geographic interpretation of routing. For example, it can provide direct visual

evidence of the Internet's business "logic" of data routing following the cheapest paths rather than the geographically shortest. Much international internet traffic is still routed through the United States as the cheapest means of transit between regions. This can result in sometimes quite anomalous looking, circuitous routes being chosen.
- However, automated geographic traceroute is far from perfect. It is very hard for software to reliably "decode" the router domain names, as this often requires local knowledge, human intuition, and a bit of guesswork. The large number of gaps in the "Location" column of the traceroute results table in Figure 13 clearly show the limitations.

Q. *What else can I tell from traceroute results?*
A. There are practical things you can use traceroute data for. It can also be used for more political "debugging" of the Internet's structure.
- Traceroute can be really useful for deducing the approximate location of internet hosts (such as websites) in terms of "hardware geography". The output can tell you the location and identity/owner of the "upstream" network provider even if the final destination of the server is unclear. If the data travel into a certain city and does not leave it again, it is probable that the target is located there. For example, deducing that *http://www.jasonnolan.net* is published from a web server in Houston, Texas. Also, the "upstream" network providers may keep logs for identifying a host that is of interest (this is of particular concern for law enforcement agencies in tracing the source of illegal activities).
- Traceroute has also been used in a physics classroom experiment to measure the size of the earth. See Kicovic et al. (2002).
- Running multiple traceroutes to lots of different points across the internet has also been used to gather data to chart the topology of the core of internet. The results of which have been impressively visualized as huge abstract graphs, providing some of the most evocative representations of Net:Geography. See for example Lumeta's Internet Mapping Project (http://lumeta.com/mapping.html) and Branigan et al. (2001).
- Traceroute can also reveal something of the hidden political economy of the internet. The patterns of traffic routing show the transit agreements and mutual peering relationships between competing companies. Details on these deals are often deemed commercially confidential but are revealed by necessity in how and where the actual networks interconnect to share data. The routing of traffic reveals the structuring of business relationships in terms of who connects to whom and the hierarchy of these connections (from periphery to center to periphery again). It can also show which telecommunications carriers dominate the transfer of traffic between certain countries and between continents. These companies are likely to be influential in the structuring of global

communications and tracerouting could provide an alternative way to quantify the extent of their power.

- Traceroute can show potential vulnerabilities in the structure of the internet. Are there particular choke points in the routing of data flows? Is there only single route into a region or between two cities?
- Lastly, the output from traceroute provides a useful way to assess the number of international borders crossed and determines which different territories (i.e., separate legal jurisdictions) the data transit. The more "points of contact" in the flow from origin to target, the more potential there is that internet traffic could be intercepted and subjected to local regimes of monitoring, filtering, censorship, and data retention. For example, does an e-mail message transit through a third-party nation that has hostile intentions. Particularly in regions of conflict, being able to identifying territories that are transited might be vitally important in terms of the reliability of communication. For example, does an e-mail to someone in Palestine transit through Israel?

CONCLUSION

Q. *So what is the future of Net:Geography fieldwork?*
A. As the internet grows in size, expands in scope, and becomes increasingly embedded as a banal and invisible background to everyday living, it becomes more important to understand its politics. We would argue that understanding the geographies of the internet, through Net:Geography fieldwork using the techniques and tools described here, provides one of the most valuable avenues into network politics, allowing you to gather information firsthand and critically question network operations directly.

- Net:Geography fieldwork is likely to become easier as new and more powerful software tools for scanning the structure of internet become available. This will be a benevolent outcome of the experience in the design of the current plague of internet worms and viruses and ways to counter them. Also, as search engine tools develop they will increasingly provide new ways to do Net:Geography fieldwork in terms of mapping the information structures of the internet. Of course, researchers will continue to have to tread carefully along the ethical boundaries between critical fieldwork and potentially criminal hacking.
- Yet, at the same time, Net:Geography fieldwork is also going to get harder and riskier to do. Individual networks on the internet are increasingly being designed and operated in a much more closed fashion. For example, the university networks of the authors have recently begun blocking ping and traceroutes as a security precaution against malicious scanning. Other areas of the internet are also using the cover of greater security as a way to try to develop more proprietary and profitable

business operations. While many internet users, for example on peer-to-peer networks, are likely to be using software tools in future that encrypt and cleverly attempt to mask their activities and their locations to preserve confidentiality of communication in the face of evermore draconian monitoring by corporations and governments. This will also have a side effect of frustrating Net:Geography fieldwork.

- Despite these changes, Net:Geography provides a very useful set of virtual learning tools for interrogating the media that supports virtual learning itself. They can reveal important details about the geography of infrastructure, the linking of information, differential access to resources, and so on. They therefore constitute a useful resource to those interested in virtual learning.

Chapter 49: Hacktivism: The How and Why of Activism for the Digital Age

MICHELLE LEVESQUE
Toronto, Ontario, Canada

On the main floor of the Munk Centre for International Studies, a formal reception is taking place: The topic of discussion is internet accountability. The political figures that are participating in the reception have arrived at the University of Toronto wearing suits and ties, and gather over appetizers for a chance to speak their piece. Below this formal event—one floor down, in the basement of the Munk Centre—heavy rock music is blaring. A crew of well-caffeinated undergraduates are coding programs to probe international computer networks. Over the loud music and between the flurry of fingers against keyboard, they are having the same discussion as the formal reception one floor up: internet accountability. This is the Citizen Lab and its inhabitants call themselves hacktivists.

Understanding the history of hacktivism helps us to understand its current manifestation. Once its history is understood, it is possible to appreciate some of the issues that hacktivists tackle, such as internet censorship and online surveillance. These issues are often otherwise neglected, as they tend to be too technical for a strictly political group to understand, and too politically involved to interest most technology-driven groups. And yet they remain some of the most significant issues surrounding the internet today, because they affect our privacy, freedom of speech, and the free exchange of information. It is through education and raising awareness about these issues that these freedoms will be preserved, and this is what makes hacktivists so important.

Hacktivism evolved from a diverse set of groups who are in part represented by two very distinct cultures: hackers and activists. Nart Villeneuve, a hacktivist and member of the Citizen Lab, believes that "it is necessary to understand their respective backgrounds in order to analyze this historic merger and to examine [hacktivists'] challenges and future capabilities" (Villeneuve, 2003). First, it is important to make the distinction between hackers and crackers. Crackers are those who break into computers in order to achieve destructive ends. Though the media will often confuse the two terms, hackers are very different. "Hacker" was originally a term that was coined to represent an individual's deep understanding of computer systems and networks. Hackers use their skills to invent, modify, and refine these systems, often creatively using computers to achieve a goal for which the system was not originally intended.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1203–1214.

The history and philosophy of hackers is thoroughly explained in Steven Levy's book *Hackers: Heroes of the Computer Revolution*. Levy (1984) explores the original hacker ethic that "access to computers should be unlimited and total" and "all information should be free". It was this ethic that spawned the Free and Open Source software movements and the General Public License (GPL). Software released under this license, such as the GNU/Linux operating system and over 40,000 applications (OSDN, 2002), may be freely used and modified as long as the source is made available to others, so that future hackers are free to tinker with these programs. This same ethic also creates a natural antagonism between hackers and those who would seek to monopolize, control, or censor the internet, as hackers believe very strongly in free access to information.

While the hacker community was growing and expanding, activists were beginning to integrate internet technology into their decentralized networks. In the mid-1980s, while the internet was still young, the first version of PeaceNet was released, enabling political activists to communicate across national borders with relative ease and speed. Since then, as the internet expanded and flourished, so too did the activist networks that were based on it, because the internet provided for many of their needs: "The internet has boosted the intellectual capacity and interconnections of citizen activists enormously" (Deibert, 2000). It facilitated these activities by providing a lost-cost transport layer for sending the vast amounts of data necessary for activist collaboration and mobilization (Denning, 1999). It also offered a safe place to co-ordinate illegal or dangerous protests because messages could be posted outside of that country's borders, such as protest.net. Michael Dartnell, a political science professor at Concordia University, believes that the internet changed how the world played the game of politics: anti-government groups were now able to use this advanced communication technology to establish alliances and coalitions that were previously impossible (Denning, 1999). But most importantly, activists realized that the internet was ideal for transporting messages to a wider audience. It cost relatively nothing in order to publish messages to a public forum or website, compared to the considerable costs involved in operating a radio or television station or printing a newspaper: The internet thus was enabling the democratization of the media.

It is from these politicized hackers and techno-savvy activists that hacktivists evolved. Villeneuve (2003) states that "the evolutionary progress of both communities has put them in a position where they can compliment each other because they face the same techno-political opposition: the repressive use of laws and technologies by private corporations and governments to increasingly monitor and control the internet". The issues that interest individual hacktivists are varied, as are the techniques that they use for fighting for these issues. But since freedom of speech is a recurring theme in hacktivism, two of the largest issues that they undertake are internet censorship and online surveillance. Both of these issues are fairly technical in nature, but have profound political implications, which makes hacktivists the ideal candidates for exploring them.

Internet censorship is when a government body intentionally filters internet content in order to prevent that content from being viewed or posted. The nature of the content being blocked varies. Sexually explicit content is filtered in Yemen, Singapore, U.A.E., many U.S. libraries and schools, Thailand, etc. The Turkish Internet Service Provider (ISP) NetOne blocks international news websites. Dissident websites are blocked by Myanmar, Saudi Arabia, Iran, and several other countries. And even human rights information is sometimes censored, for example in Syria, Vietnam, and China (Villeneuve, 2004). Figuring out exactly what content is being blocked—as well as how it is being blocked—is the first step to examining internet censorship. But it is not an easy task. There are many levels of complexity, and it is important to distinguish between being unable to access a webpage because it is filtered, and being unable to access a webpage because of a network hiccup, or because the webpage is currently offline for a moment.

When a webpage is being blocked, there are several possibilities of what a user might see, depending on how the filtering was set up. Sometimes the user sees a "404 Page Not Found" error, or a server error; the exact same error that they see if they try to visit a website that does not exist. Sometimes they are redirected to a fake webpage, which has some of the content removed. Sometimes their internet connection suddenly stops working, and then access returns only after a few minutes have passed (Zittrain & Edelmen, 2003). And sometimes a user sees what is called a "block page": A signature from the filtering software to inform the user that they are attempting to view banned content and have been denied access (Figure 1).

There are also several locations where the filtering can occur: Anywhere along the connection between the user and the target website. For example, if you are connecting from a University residence in Ottawa, and trying to visit a website in Edinburgh, the connection might look something like this: your computer connects to a router on the floor of your residence, which connects to your residence's main router, then to the University's server, to the ISP of your University, to a larger ISP in New York, across an international line to London, to an ISP in Edinburgh, to the webpage's server. At any of these nine locations (including both your computer and the webpage server itself) data filtering could be taking place.

This blocking can also either be centralized or distributed. Centralized filtering usually occurs in countries with few international access points or ISPs. This filtering is centralized and co-ordinated nationally, so the same filtering behavior can be expected no matter where you are in the country. However, when a country's internet population grows, it often becomes too unwieldy for a single governing body to implement this filtering, and instead the implementation is delegated to individual ISPs. When this happens, there are often variations in the blocking behavior. When new lists of webpages to

Figure 1. The block page that a user from Myanmar would see if they attempted to visit http://www.freeburma.org. This block page identifies the filtering software being used as DansGuardian.

block are released, the time that it takes an ISP to update their system varies, so the population that they serve will temporarily have a different set of websites blocked than the rest of the country. And sometimes there is not a specific list of websites provided to the ISPs: They are simply told to block categories (like sexually explicit material, gambling websites, etc.) and it becomes the ISP's responsibility to implement the filtering. When this happens, ISPs often turn to commercial providers.

There are many internet filtering packages available, such as Cyberpatrol, BESS, SmartFilter, SquidGuard, and many more. These applications usually offer an easy way for a user to select the website categories that they would like to block, without having to worry about the implementation details. For example, the product SmartFilter offers 30 categories, such as Nudity, Gambling, and Hate Speech, but also Arts/Culture/Heritage, Educational/Reference, General News, Non-Profit Organizations/Advocacy Groups, Politics/Opinion, Search Engines, and others (SecureComputing, 2004). Thus, an ISP can block its users' access to all General News websites (such as CNN and Google News) with only a single mouse click (Figure 2).

There are several important issues that should be discussed when countries and ISPs are using third-party software to assist in internet censorship, but one of these important issues is that many of these filtering products have closed-source lists. This means that the exact specification of which websites will be blocked when you choose to block "Politics/Opinion" is the undisclosed

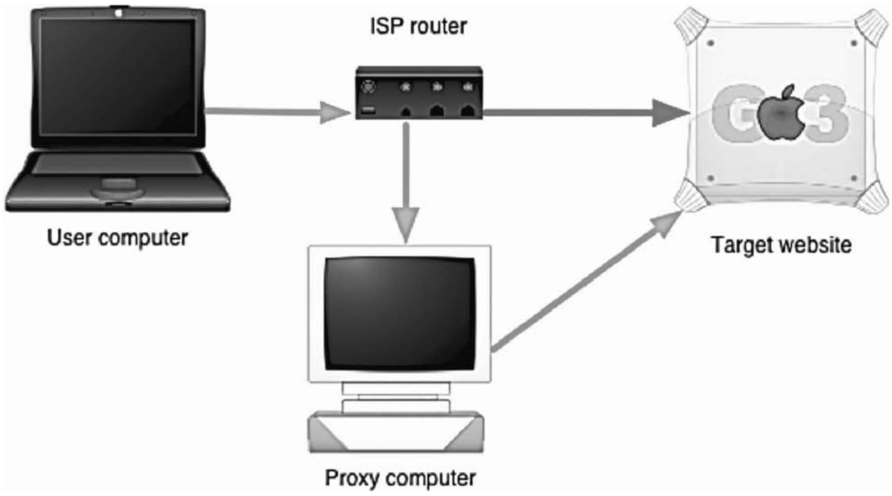

Figure 2. Although an ISP may deny access to a specific website, if the ISP does not deny access to a proxy computer, a user can surf through that proxy computer to visit the website, uncensored.

intellectual property of the company that owns the product. Therefore, governments and ISPs that are using these products for internet filtering are putting their citizens' access to information into the hands of external corporations. If a filtering product miscategorizes a website, something that occurs frequently, the entire country could be unable to see that website's content. For example, 40% of U.S. schools filter their internet with a product called BESS to prevent access to sexually explicit websites, however, BESS also blocks access to some teen advice pages because it classifies them as "sex". Saudi Arabia was found to be blocking multiple gay and lesbian rights websites, because they were using SmartFilter to try to block pornography, and SmartFilter miscategorized these websites as porn. Likewise, the Kuwaiti ISP QualityNet blocks teenpregnancy.org/teen as a result of SmartFilter's miscategorization of this portion of the site as sex (Villeneuve, 2004).

Upon examining how these filtering products work, it becomes obvious why miscategorizing is common. The three most common methods are: blacklist (every website may be viewed except for a few explicitly chosen ones), whitelist (only explicitly chosen websites may be viewed), and keyword searching (blocking based on whether certain keywords are present in the URL or in the page itself). However, none of these methods work flawlessly. Google's SafeSearch, an option that Google's search engine provides so that its users can remove all pornographic content from their search results, warns that "no filter is 100% accurate". The problem with blacklists and whitelists lies in the vastness and dynamic nature of the web: The internet is in a constant state of flux, and a webpage that advertizes computer parts one day may turn into a blog about golfing the next day. The problem with keyword searching is that the URL of a webpage does not necessarily describe its content, and thus over-blocking frequently occurs. For example, the pornography filters in place by a product called Anonymizer blocks keywords like "ass", "hot", and "breast" (OpenNet Initiative, 2004). Among many actual pornographic websites that this blocks, it also blocks websites like usembassy.state.gov and www.grass-roots.org (because they contain the word "ass"), www.hotmail.com and www.hotels.com (because they contain the word "hot") and www.breastcancer.com and breastfeed.com (because they contain the word "breast"). These examples are just some of the many that illustrate that keyword searching is often an inaccurate filtering technique.

Similarly, blacklists and whitelists are often inaccurate because there are simply too many websites in existence—and new ones are constantly being created—for it to be feasible to manually visit them all. Therefore, these lists are often generated by computer programs that try to automate the categorization of websites. Like keyword searching, this automated method tends to over-block webpages. When these blocking techniques affect which websites citizens of a country can and cannot view, studying their inaccuracies becomes an important part of studying internet censorship as a whole.

Hacktivists and others have taken an interest not just in studying these many cases of internet censorship, but also in developing mechanisms for those in censored countries to circumvent the filtering. There are many initiatives that are currently developing applications for internet censorship circumvention. Most of these initiatives are based on the idea of providing a proxy between the censored user and the content that they are unable to access. A proxy is an application that visits a requested website and returns the content. For example, if a proxy is running in San Francisco, a user in China can connect to the computer in San Francisco and request content from www.falundafa.ca. The proxy computer visits the requested webpage and gives the content back to the user in China. The ISPs and the national backbones between China and San Francisco only see the connection to the proxy computer, not the final destination, so the connection is not blocked.

There are several types of proxies. The most common are webserver, CGI, remote account, and content duplication. Webserver proxies are when web servers (the same that are used to serve webpages) are configured to serve external webpages. So instead of connecting to www.example.com and requesting the page /index.html (which would retrieve the webpage www.example.com/index.html) or the page /sample.html (which would retrieve the webpage www.example.com/sample.html), a user can connect to www.example.com and request the page www.google.com (which would retrieve the webpage www.google.com, despite the fact that the connection was to www.example.com). CGI proxies are webpages that contain a form where a user can type in a URL, and that URL's content appears. There are several CGI programs which provide this service, such as CGIProxy and PHProxy. Remote account proxying is when the user has a shell account on a computer in another (preferably uncensored) country and can telnet or ssh to that computer and surf the web from that computer. Lastly, content duplication is when webpages mirror each other's content, so that if only one of the webpages is blocked, users may be able to access the other sites and thus still access the content.

A variation of content duplication is to provide web content through different ports. For example, having web content e-mailed to you, or sent to you *via* your favorite Instant Messenger client. There are several services available that will e-mail any given webpage to you, and these are used by many Iranian citizens who want to access blogs that have been blocked by Iranian ISPs (Derakhshan, 2004). An application called RSSinator allows users to mirror RSS feeds from news sites and blogs, such that those in countries that block these sites can still use their favorite RSS aggregator program to browse these websites.

Using a proxy is usually an effective way to circumvent internet filtering, but it has several problems. The largest problem is how to let citizens in censored countries know where they can find these proxies. One approach has been to spam these proxies to e-mail addresses within the country, but this approach is often ineffective because as soon as the citizens find out about these proxies, the government usually finds out too, and the proxy computers are then added to their blacklists, so they are no longer useful. A second approach is being taken by an application being developed by the Citizen Lab called Psiphon. Psiphon is a personal proxy that users can easily install on their computer for friends in censored countries. It is then the responsibility of the Psiphon user to inform his/her friends of where they can find this proxy. By using personal communication networks as opposed to mass broadcasting, it is much less likely that censoring governments will discover and block these proxies.

However, all of these techniques for censorship circumvention are simply temporary solutions. Once they reach a critical mass of effectiveness, it becomes worthwhile for censoring governments to invest time and effort to block these mechanisms, and then new circumvention technologies must be developed. Also, they are only effective for users who are willing to research circumvention applications available, and who are willing to go against their government's policies to have these websites restricted. The only way to permanently end these blockings is for censorship policy to change.

The other major issue tackled by hacktivists is internet surveillance. Online security, privacy, and surveillance have become hot media topics, but few individuals are aware of how much or how little internet surveillance is actually taking place. The surveillance problem affects more than just individuals' privacy: Many non-governmental organizations (NGOs) fear that their online activities are being monitored by local and national governments and that their security has been or may be compromised. Compromised security in some contexts can result in arrests, imprisonment, or even death. In many parts of the world, ISPs are being required by law to keep logs of users' activities, and some are doing so of their own initiative. This information could be sold to advertizing agencies, handed to the government, or used for identity theft.

Not only is there a lack of substantial internet surveillance policies, but a lack of understanding of what is going on and a lack of information being given back to the public. A 1999 paper that deals with the issues involved in explaining cryptographic systems to the general public states: "Many people use debit cards to pay for goods, where money is transferred directly from their bank account to the store's. In the process, the bank finds out where the purchase is being made, and could build up a profile of the person's shopping habits . . . . Most people are quite unaware that cryptographic protocols exist which enable the transaction to be carried out reliably without the bank being able to identify who the money is going to!" (Bell et al., 1999).

Points of potential internet surveillance are basically identical to points of internet censorship: Anywhere in between (and including) your computer and the target computer, surveillance could be taking place. Unfortunately, there is no accurate technological means to determine whether or not this is actively taking place. It is similar to sending a postcard: There is no way to find out if any of the post office employees read the postcard while it was in transit. Because postcards are open to be read by anyone who handles them, most people do not (or at least, they should not) write sensitive data like credit card numbers on the back of postcards. Similarly, although there are an uncountable number of online transactions taking place every day (and it is improbable for them all to be manually monitored), as disk space becomes more affordable, it becomes easier for institutions (ISPs or governments) to log all of these transactions and run programs to gather the data that might be of interest to them. Therefore, if you 'are sending data over the internet that you would not feel comfortable having the employees at your ISP read, you should be using encryption techniques to secure your communications.

Safe, unread, untampered online communication is really two problems: authentication and secrecy. Authentication is proof that the two parties involved really are who they say they are (and that they are not a malicious third party), and secrecy is the desire to keep the message secret. Both of these are necessary in order to establish secure communications. To illustrate why, it is necessary to turn to the example trio often used in cryptography demonstrations: Alice, Bob, and Eve. Alice is trying to send Bob a message, and Eve is a malicious person between them. Apart from just listening in on the message, Eve can also change it in some way: delete it so that Bob never gets it, insert a new message that Alice never sent, change the order of messages, or record it and send it to Bob later. Encryption prevents Eve from reading the message, and authentication prevents Eve from tampering with the message. Bruce Schneier, one of the leaders in cryptology, says, "Never confuse the two concepts. Encrypting a message does not stop manipulation of its contents, and authenticating a message doesn't keep the message secret. One of the classical mistakes in cryptography is to think that encrypting a

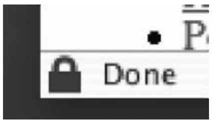

Figure 3. An HTTPS connection, as shown by the lock icon.

message also stops Eve from changing it. It does not." (Ferguson & Schneier, 2003)

Fortunately, most users do not have to worry about implementing their own encryption techniques because there are already protocols programs and that can be used conveniently and securely. PGP is a common method of securing e-mail communications. It can be installed in any Operating System, and used to encrypt e-mails so that they look like garbled text to all but the intended recipient. "PGP can also be used to apply a digital signature to a message without encrypting it. This is normally used in public postings where you don't want to hide what you are saying, but rather want to allow others to verify that the message actually came from you. Once a digital signature is created, it is impossible for anyone to modify either the message or the signature without modification being detected by PGP". (Slegers, 2002)

Also, most common protocols have a secure version to complement the plaintext one. For example, HTTPS is the secure version of HTTP, and SSH is the secure version of Telnet. When a lock appears on the corner of your browser, it is an indication that you are surfing through HTTPS, and that your communication is secure (Figure 3).

If encryption options exist for most internet activity, why is internet surveillance still such an active concern? There are several reasons. First of all, just because these options exist does not mean that they will be used; most sensitive traffic continues to be plaintext because users are not aware of the alternatives, or simply do not believe that it is likely that their activities would be logged. Secondly, since security shortcuts are often taken to save on time and money, there are some circumstances where encrypted traffic is not fully secure.

The most common attack on encrypted traffic is called man-in-the-middle. This is a general term for any attack where Eve intercepts the message between Alice and Bob (for example, if Eve is Alice's ISP). A real life version of man-in-the-middle occurred in April 2004: "A woman posts an ad requesting a nanny. When a potential nanny responds, she asks for references for a background check. Then she places another ad, using the reference material as a fake identity. She gets a job with the good references—they're real, although for another person—and then robs the family who hires her. And then she repeats the process". (Schneier, 2004). This woman, like Eve in a man-in-the-middle attack, inserts herself between the two legitimate parties: The real nanny sends her references to this Eve, because she believes Eve to be a real employer, and the real employer verifies the references and when they are valid, completes the transaction, unaware that the references do not belong to Eve. This is a form of man-in-the-middle attack that, in some circumstances, is still possible today.

Man-in-the-middle attacks do not have to take place on a network. An example of a physical man-in-the-middle attack is keystoke logging: Intercepting information between your keyboard and the rest of your computer. Keystroke logging is when every key pressed on a user's keyboard is logged to a file. It is possible for this to be a piece of hardware, or an application running on the user's computer. Since it records every key pressed, it also records passwords, encrypted e-mails, and anything else that the user types. The logs can then be remotely transmitted to whoever set up the keystroke logger. If the keystroke logger is hardware, whoever setup the logger would require physical access to the computer, but this can include the vender who sold it to the user, the computer manufacturers, etc. If the keystroke logger is an application program, it requires for that program to be installed. One method that it can be installed through is a trojan (a program that pretends to be friendly, but that runs malicious code). Another is by building the keystroke logger directly into the computer before selling it to the public. Many ISPs require their users to install and run various programs in order to use their internet connection: These programs could, in theory, contain keystroke loggers. The FBI used keystroke logging in the case against Nicodemo Scarfo Jr. (Villeneuve, 2004) in order to intercept the password for various encrypted files that he had on his computer. Since keystroke logging has been used by government agencies in the past, it is a very real possibility that it may be used again in the future.

Being cautious is the best defense against internet surveillance. Encryption programs should be used whenever sensitive data are being transmitted, and applications should not be installed unless you trust their source. Since it is impossible to know if your internet traffic is being monitored, it does not hurt to take a few extra steps to ensure your privacy. Educating everyday internet users about encryption technology is the best first step toward rendering internet surveillance meaningless: If the watchers cannot read what is being said, there is little point to watching it.

These concepts are important for the general public to understand because they threaten their privacy and the free exchange of ideas. Furthermore, many hacktivists believe educating the public about these issues is the first step toward change (Villeneuve, 2004). Other hacktivists seek change by writing software like Psiphon and RSSinator that allows users to circumvent censorship that is being imposed on them. Some hacktivists launch electronic protests, for example, conducting a virtual sit-in on a website by having protesters repeatedly reload the website content at a specific date and time. This spike in internet traffic, called a Distributed Denial of Service attack (DDoS) will cause the web site's server to slow down, and possibly even crash, under the force of many people repeatedly visiting the website. The level of acceptable hacktivist behavior is an issue under debate, but has roots within the activist community. The hacktivist who defaces web pages for his cause is the electronic equivalent of the activist who smashes windows or graffitis the sides of building. In both communities, however, destructive activity is not the norm. What *is* the norm is the desire to educate the public about the issues at hand, to help out those in need, and to try to find ways to convince the state that these are policies that need to be changed.

These issues are just some of the areas that hacktivists tackle on a regular basis. In many countries, dealing with these issues is illegal; in many more, what they do is in the "fuzzy gray area" of legality. But they are working in support of broader principles of human rights by forcing governments to be held accountable for their internet policies, and by helping citizens to access a free exchange of information. Because the internet changes so rapidly, many of the facts discussed here will become obsolete in the upcoming weeks, months, and years. However, though the details of who is censoring and surveilling whom will inevitably change with time, the underlying principles will remain the same. In fact, if there ever comes a day when everything said here is irrelevant and obsolete because censorship and surveillance are practices that are no longer acceptable in society, then hacktivism will have truly achieved its goal and we will have won.

Chapter 50: Weblogs and Collaborative Web Publishing as Learning Spaces

ALEXANDER C. HALAVAIS
School of Informatics, University at Buffalo (SUNY), Buffalo, New York, U.S.A.

Weblogs have received a great deal of public attention recently, accompanied by a certain degree of hyperbole. Software designed to maintain weblogs is little more than a simplified content management system. The excitement surrounding weblogs has less to do with flexible systems that ease the process of web publishing, and—like many technologies that allow for virtual interaction—more to do with the cultural practices that have evolved using these technologies as a foundation.

As with any other educational technology, the success of weblogs and other web publishing technologies in an educational setting depends heavily on the specifics of their implementation and use. The following pages explore the exciting potential of weblogs and related tools for student-centered education, provide some indication of how they might be used most effectively to meet the needs of learners, and discuss the inevitable difficulties of engaging the kinds of radically open and democratic education that collaborative web publishing engenders within existing institutional spaces. The assessment of such approaches remains guardedly optimistic, and it is hoped that readers will actively contribute to refining these technologies to allow for more effective and rewarding future learning environments.

1. COLLABORATIVE WEB PUBLISHING AS A TECHNOLOGY AND A PRACTICE

It seems clear that weblogs existed well before they were named. These days, there are nearly as many definitions of weblogs as there are weblogs. Most of these relate to the formal presentational structure of a genre of web pages. Jill Walker's (2003) definition, for example, notes that:

> A weblog, or blog, is a frequently updated website consisting of dated entries arranged in reverse chronological order so the most recent post appears first (see temporal ordering). Typically, weblogs are published by individuals and their style is personal and informal.

While Walker goes on to suggest some of the behaviors and motivations that lead to this formal presentation, as with most weblog definitions, the focus is

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1215–1235.

on the web page itself. Such definitions certainly capture many of the features that are frequently found on weblogs, but by no means are these observable attributes always present or clear.

Rebecca Blood's (2000) history of weblogs describes what sort of material is usually placed on such pages. The original weblogs, according to Blood, were websites created to keep track of and publicize other pages found on the web. In some ways they resembled public, annotated "bookmark files", cataloging and identifying websites that the author thought were particularly interesting in one way or another. At least one of these sites also linked to other sites with a similar aim, and this cross-linkage is what would later evolve to become a "blogosphere" of interlinked blogs.

A second type of blogger then emerged, growing rapidly in numbers by 1999, according to Blood. Rather than the outward focus of the public linkers, these weblogs were composed of short diary entries in which authors would make note of their thoughts and experiences, sometimes several times throughout the day. In order to support these new bloggers (and helping to drive the development of blogging) a number of content management systems were developed that aimed to make updating a weblog easier. Naturally, there is no clean line between these two types of blogging; those who primarily provide links often provide reviews of the sites to which they link, and those who publish essays or their short observations often accompany them with linked materials. Rather, these two pure types of blogging help define a spectrum of approaches.

These two ways of identifying weblogs—by their formal organization and by the kinds of content that they contain—may have been adequate during the earliest days of blogging, but as blogging has grown as a phenomenon, it has become clear that part of what makes a weblog is whether and in what ways it is linked to other weblogs. What drove the rise of weblogging was not just a desire to increase the frequency with which personal web pages were updated. When weblogs began to link to one another, bloggers were increasingly able to self-identify as a group, and—potentially at least—as a community. Weblogs exist chiefly as a part of a larger "blogosphere", a term that has been employed in various ways (cf. Hiler, 2002) to describe this collective hyperlinked subweb. That is, one of the most important ways of discovering whether a page on the web is a weblog is whether it links to other weblogs and whether other weblogs link to it. Unlike the earliest examples of weblogs, more recent examples engage in an exchange with some subset of the millions of other weblogs being published.

This focus on the aggregate nature of weblogs begins to indicate that blogs are more than simply a genre of web content, they represent a social practice. Restricting the definition to purely a description of the web sites generated is difficult because it misses so much. The only seemingly vital element of weblogging is a public forum (the World Wide Web) in which bloggers are able to associate and self-assemble into groups. The attraction to weblogging has less to do with the software involved and more to do with the kinds of social groups that emerge from interactions among weblogs and their authors. These practices provide for serendipitous, unstructured learning, as differing perspectives and discourses come into contact with one another.

In our discussion we should include tools that perform similar functions, and provide for similar venues for social interactions. Wikis, for example, are web pages that are easily updated by (usually) any person who encounters them on the web. While not as familiar as weblogs, the success of projects like Wikipedia—an online collaborative encyclopedia project with nearly a quarter million articles in English alone—has brought collaborative hypertexts like wikis wider recognition. Related systems that allow for the sharing of personal information among networks and friends, often referred to as "social networking systems", as well as machine-readable forms of weblogs, wikis, and social network information, form a larger information ecology that allows for the traffic of ideas within a community.

While several alternative labels for these technologies have been suggested, all represent some form of collaborative web publishing; that is, all support the addition and editing of relatively short pieces of text, sometimes images, audio, and forms of media, in a way that invites multiple authors to link their ideas together. Of course, while these changes may be small (resulting in what is sometimes referred to as "microcontent") the impact is often anything but. As the example of Wikipedia above demonstrates, in the aggregate, such efforts can yield a substantial collaborative text. Nonetheless, because the text can be addressed and constructed in very small pieces, it allows for the kinds of communicative give and take that are more often associated with synchronous environments.

It would be a mistake to assume that there is a single culture that pervades the blogosphere to the exclusion of all others. Indeed, the variety of bloggers allows for niche communities of interest that would be far more difficult to maintain without the openness of the blogosphere. Bloggers have inherited a core set of values, common to the early computer hackers, and passed on through earlier virtual environments. Pekka Himanen notes in *The Hacker Ethic* that hackers' (and here he means computer enthusiasts) relations to the idea of networking, though present in the 1960s, "received a more conscious formulation in recent years" (2001: 86). He traces some of the virtues cultivated by hackers, including passionate engagement in their work, autonomy from government and others, pursuit of social position (sometimes to the exclusion of financial gain), and perhaps most importantly, an active and caring approach to communication on the Net (pp. 139–141; Levy, 2001, lists similar attributes).

These virtues are not difficult to identify within the blogosphere. Mutual aide and open exchange of information are encouraged as norms. Although the commercialization of blogging recently has begun in earnest, many tools remain freely available. The Creative Commons movement, an effort to provide a more flexible intellectual property regime to encourage the sharing of information, has enjoyed a warm welcome from many in the blogosphere. Many of those who engage in blogging become interested in extending and changing the tools they use, and this kind of amateur tinkering is at the heart of the hacker ethic. Respect from one's peers is highly valued. In many ways, the practices of the blogosphere resemble nothing so much as the scholarly exchanges common in academic settings, and the number of professors and students that choose to take up blogging is therefore not particularly surprising.

Given the nature of collaborative web publishing, it is sometimes difficult for non-participants to understand. Of course, all technologies have considerable social components, but a television, for example, has a fairly limited and easily described range of uses. Weblogging is essentially an evolving collective and social practice, and therefore easier lived than described. In what follows, we will examine ways in which the social technologies that drive collaborative web publishing may be effectively leveraged in educational settings.

2. WEBLOGS AS REPLACEMENT TECHNOLOGY

Technologies provide a "valence" of potential uses, to borrow the terminology of Carolyn Marvin (1990), writing in the context of the early adoption of the telephone. What we think of as the telephone today is the result not only of the initial development of the technology, but a complex evolution of social practices over time. Examples of telephone systems used for news broadcasting, or Edison's decades-long delay in accepting the use of the phonograph for music recordings, remind us that a technology does not choose its own use, though it may suggest some uses. In part, this is because new communication technologies are inevitably initially fit into existing ideas of how communication takes place. Depending on the metaphor with which blogging is approached, it may seem fairly obvious how such a technology is to be employed. Nonetheless, new communication technologies also have the capacity to violate our expectations, and usually do (Nord, 1986). Having our expectations disrupted need not be a bad thing; indeed, it is central to the process of learning. Nonetheless, the earliest applications of collaborative web publishing in educational contexts have aimed to replace existing analogues.

Despite the range of ways in which weblogs might be employed, the two general types of weblogs identified by Blood, above, suggest the most obvious potential uses. Diaries and journals are a longstanding fixture of writing and foreign language classes. Journals are also commonly employed in other subjects, including lab notebooks in the sciences, and sketchbooks and portfolios for teaching the arts. Teachers often encourage students to keep notes of their own, and sometimes use these notes as an additional indicator of their progress. The earliest uses of weblogs thus far have been as replacements for writing journals. Despite difficulties, there are several advantages to the use of weblogs in this setting, especially in that they provide a more immediate and social environment for writing (Kajder & Bull, 2003), which when combined with the improvements to student writing that seem to accrue simply by moving to a computerized form of journals (Goldberg et al., 2003), represents an obvious area for experimentation.

There has been a move over the last decade toward using portfolios of student materials to improve evaluation and learning. Such portfolios not only provide a richer understanding of student abilities and progress than do narrower evaluative approaches, but also provide a way of allowing students to better monitor their own progress and become more active in the learning process (Frazier & Paulson, 1992; Lamme & Hysmith, 1991; Tierny et al., 1991). The involvement of students in their own education, not surprisingly, often results in a better understanding of the material, when compared with traditional evaluation methods (Finlay et al., 1998). Portfolios can also be used to communicate progress to parents and others (Flood & Lapp, 1989), and to help teachers evaluate their own efficacy (Hiebert, 1992). There are a variety of ways in which portfolios may be organized. Some students assemble their best work, and provide an overarching narrative to frame that work in a "showcase" portfolio. Others use learning portfolios: Records of progress and achievement in a field of study. Portfolios have gained ground in areas outside of education as well, and much of the work relating to school portfolios applies equally to professional and personal portfolios.

There have been various efforts to move portfolios online and create electronic portfolios, or e-portfolios. This has been particularly popular at the tertiary level, with a number of universities promoting e-portfolios for their students. E-portfolios provide the advantages of traditional portfolios, but in many cases also provide a way of moving beyond the student-teacher dyad. When a portfolio is placed online, it provides an opportunity for parents, friends, and others to view the work of the individual. Making the portfolio electronic has the further advantage of allowing for a variety of multimedia and interactive content, depending on the skills of the student both in creating such material and, not insignificantly, making it available via the web. While there is much excitement over e-portfolios at the moment, and a number of incipient projects, it seems that effective supporting software remains a stumbling block (Young, 2002). Moreover, the approach is much more akin to traditional publishing models: Portfolios may be updated, but rarely incrementally.

Weblogs are a natural extension of online portfolios. As noted above, weblog software is little more than a simple content management system, a way of placing work online with little effort. Such software can provide an easy way of managing online portfolios, and often the term "e-portfolios" is now used in the same breath as "weblogs" (or as "blogfolios"; Levine, 2003). While it does, at some level, provide some of the same functions as an online journal or portfolio, generally, an implementation using weblog software will bring with it certain expectations in terms of the length and permanence of the materials, the connection to the audience and other online content, and the motivation to publish.

Before examining some of those differences in more detail, we might turn briefly to the other form of blogging: Those websites that focus on selecting and annotating links to information found on the web. In 1945, Vannevar Bush described what many have suggested is one of the earliest visions of hypertext, and suggested that mapping information space would be a primary way of transmitting knowledge in the future. He writes that the associative process of research through the literature of the world could be recorded as a "trail" of a researcher's linkages and annotations, "and his trails do not fade". The processes of discovery, as well as the records that make up that discovery, are easily recalled in this "enlarged supplement to his memory".

Students at all levels often turn first to the web when called upon to do research, only later reverting to the library, if at all. Given the increasing availability of authoritative information available on the web, using this information effectively is a worthwhile skill. The process of annotating their search, using a weblog or wiki, provides a window on research, an opportunity for teachers to intercede in the process, and for the student to be more reflective about their own efforts. Students can use this process to learn to manage information effectively. Also, linking to their sources helps to avoid problems of plagiarism and provide a venue for understanding copyright, as students come to a greater appreciation of the originality of their own work (see Oravec, 2002).

Finally, especially at the college level, teachers have experimented with using weblogs for course management. Because of the flexibility of many weblogging systems, they may be customized to this end relatively easily. Readings, handouts, and assignments may be distributed through a weblog, but weblogs are even better suited to providing a central location for news and discussion related to the course. Many of the large, commercial course management systems have been experimenting with collaborative web publishing systems of various sorts. It remains to be seen whether such systems will retain the cultural practices that have led to the success of weblogs and wikis.

To draw on a metaphor already applied elsewhere in the context of blogging (Frauenfelder, 2000), the automobile began as a replacement for the horse-drawn carriage, and was for some time the "horseless carriage" before it was clear that it not only provided for new kinds of uses, but shaped social interaction, the built environment, and a national culture. Weblogs can certainly serve as replacements for existing educational technologies, but their potential reaches far beyond this. Weblogs provide an environment amenable to decentered, distributed, experiential learning. One of the greatest differences between collaborative web publishing and other computer-mediated forms of educational interaction is that weblogs, wikis, and similar technologies encourage public engagement, interaction with a broad community, experiential learning, and an extension of the learning process beyond the physical and temporal boundaries of the classroom.

Etienne Wenger describes what he calls a "learning architecture", based upon certain needs:

> 1) places of engagement
> 2) materials and experiences with which to build an image of the world and themselves
> 3) ways of having an effect on the world and making their actions matter.
> (1998: 271)

The following sections suggest that collaborative web publishing can help to provide for these three needs. By creating virtual places of engagement, and in combination with directed self-discovery, students can use weblogs, wikis, and related technologies to engage in an active, communal learning process.

3. THE OPEN CLASSROOM

The most obvious difference between keeping a traditional journal or portfolio of work and keeping a weblog is that the former is likely to remain relatively private—shared between the author, a teacher, and perhaps friends, parents, or in some cases an employer. Weblogs have the potential of being far more public. In the extreme case, a weblog entry might attract millions of readers. But it is not quite right to place these two media on opposite sides of a public/private dichotomy. Weblogs exist in a gray area, the unfiltered expressions of a private individual, within reach of a broad audience. Some have compared their role to the salons of 19th century France: A fundamentally public sphere, but relying on personal interactions and dialogue to arrive at understanding (Habermas, 1991; Mortensen & Walker, 2002).

The word "public", especially in contemporaneous usage, suggests some form of broadcasting is taking place. A better word might be "transparent". The interactions between the teacher and the students, and among the students, are radically open to observation. For those students who are already steeped in a culture of open discussion in the classroom, this might feel familiar, but especially within large universities, this openness of exchange is a relatively novel and exciting experience for many students.

This transparency is initially and primarily among the students in a class. In many cases, despite public accessibility of course websites, dialogue with those outside the class is comparatively sparse, especially when students are just getting started. It might seem that a student would be most concerned with what a teacher thinks about her work, but students are often far more concerned with how their peers view their work. In some cases, of course, this can be a difficulty. A student may be apprehensive about sharing her own work with her classmates, but the advantages to open work can be enormous. Students are generally interested in helping one another succeed, and when presented with assignments that invite collaboration, they find the work both enjoyable and fulfilling.

Some see the absence of school walls as removing a protective barrier to the outside world, particularly for younger students. Clearly, students should be made aware of dangers in their environment, and guidelines should be established to ensure their safety and privacy. Since the protective walls (and firewalls) of the school are only temporary, it is important that students learn the skills needed to protect their privacy online and off. At the beginning, students may not realize how widely their voices carry, and the influence they can have. With that power to influence comes the responsibility to wield it appropriately. One way to protect students' privacy is to make certain topics or identifiable information off-limits. A further measure is to have students create an alternative identity. This comes at the cost of making the virtual environment even less real and more virtual, but in order to maintain the safety of students, this may be a necessary price to pay.

4. TRIPS WITHOUT THE FIELD

In early 2004, Elizabeth Lane Lawley toured Japan and China with her son, and he brought his fourth-grade class along virtually through his weblog. He described visiting the *dai-butsu* in Kamakura, and a night of *kabuki*, while his class commented and asked questions. These kinds of virtual field trips have a bit of a history, and a number of initiatives aim to make virtual field trips more easily accomplished (see, for example, the Remote Accessible Field Trips project: http://www.raft-project.net/). Having a student or group of students act as the agent of a larger class provides a unique translation of the world to the classroom. Students exposed to these kinds of hybrid field trips have a special advantage of being able to interact with their environment in a very social way, and likely took much more from their experience because of it.

Naturally, one of the reasons to remove the walls of the classroom is because it provides the opportunity for students to experience the world more directly. That experience can mean a number of things. As Rousseau noted in *Emile* (1979), we learn from nature, from other people, and from things, and only when these three masters are in harmony do we gain understanding. Experiential education is most often seen as somehow distinct from more academic kinds of classes and confined within service learning experiences, internships, practica, and outdoor adventures or museum trips. The ways people learn outside of classes is different from the ways they learn within traditional classrooms, and instead "tend to emphasize wider goals better captured by terms like enculturation, development, attitude, and socialization" (Schauble et al., 1996).

The bridging of public and private engendered by collaborative web publishing provides a unique opportunity for students and teachers to actively engage global, networked communities while remaining on school grounds. As much of our work continues to involve the manipulation of text and symbols, and as our everyday social lives become entangled less within local physical communities and more within global networks, the kinds of interactive experiences to be had online constitute a valuable and expansive space for learning.

While writing in a personal journal represents an exercise of a particular skill, it does not reflect the experience of using that skill; studying French conversation is not the same as having a conversation in French. Some have suggested that what is vital about a "real world" experience is that it has consequences, often in terms of connections or relations to those outside of the classroom (e.g., Bell, 1995). Others take the view, originating in part from Vygotsky (1980), that all knowledge is an internalization of interactions with others, and that a broad exposure to such interactions is thus beneficial to learning. Those who take a more psychological than social approach to cognitive constructivism might favor experiential learning because it connects education with physical involvement. For Vygotsky, a pioneer of social constructivism, using language as a tool is the defining characteristic that makes us human, and through the exercise of conversation we learn about our world.

Interacting with people in places other than the classroom, people who live in different circumstances and different cultures, provides an opportunity for students to engage in expansive social networks, and by doing so become more self-aware and self-reliant. While it may be counterintuitive, it is through these interactions that students become more self-directed and seek out autonomy. As Robert McClintock (2000) notes, today's youth live within a globally interconnected network, where the urban connections of the past are brought together in the new form of networked communications:

> As the oldest of the new media, the city is the place where people form and exercise their powers of choice. "Stadt Luft macht frei". Youth, coming of age within the city, has this task of forming distinctive powers of choice, building chosen skills and preferences, making a place within the great mélange of human achievement. The city concentrates together human possibilities. The young must choose and master, exercise their elective affinities. In this process, they strive to achieve a persona, a recognizable presence accorded to them by a community of peers. In the city, people shed ascribed characteristics, striving instead to take on acquired, achieved ones.

To place them within an institution that artificially keeps them cloistered for many of their waking hours does them an extraordinary disservice. While there is certainly a need for formal instruction in certain areas, the balance that Rousseau speaks of is lacking in education at all levels. The interactive nature of collaborative web publishing provides the opportunity to engage the global community, and to learn by *becoming* a member of that community rather than by learning *about* that community.

5. NEW APPRENTICESHIP

There is something inherently different between the "student" and the "newbie". Even in the most democratic classroom, social roles introduce discontinuities between the student and teacher that remain static. The newbie is simply a less experienced person within a particular field, a neophyte, a temporary category that applies only while someone learns the ropes. The student, no matter how familiar she becomes with the material, is always a student. Weblogs allow for learners to engage a larger social network, and to participate actively within that network, and to become localized experts.

As noted above, to a greater or lesser extent, weblogs provide the opportunity to link to source information and ideas. But linking to ideas in the massively collective hypertext of the World Wide Web often means linking to individuals as well (see Nilsson, 2003). The brief, timely pieces of text that make up collaborative web publishing encourage engagement by neophytes. Collaborative web publishing allows those who research within a narrow academic specialty to more easily cross traditional disciplinary boundaries (Aïmeur et al., 2003). Because it is so difficult to determine the audience for a particular short entry, the author must assume very little context. As a result, even the weblogs of experts in the field provide links and explanations that might not appear, for example, in a scholarly journal within their own field. This ease of entry also encourages students to become involved as producers of knowledge from an early stage, and to make provisional statements of ideas and knowledge with the hope that these will be engaged, challenged, and worked out in dialogue. That is, the newbie makes knowledge, even when she only makes mistakes.

Apprenticeship, abandoned at the end of the 19th century in favor of mass schooling, emphasized learning by doing. The vision many associate with apprenticeship—in part because this is where apprenticeship remains strong—is craft skills like masonry or cabinet-making. Plato's use of dialogue to teach, or to learn together, also represents a form of apprenticeship. This approach to learning was all but eliminated in the United States at the turn of the last century in favor of homogenized education for immigrants, standardized curricula, and credentialing, especially at the college level (Popkewitz, 1987). Large schools also came to reflect the bureaucratization and Fordism of mass industrialization. As part of this transformation, empty exercises have come to replace "authentic activities" that reflect the kinds of tasks found outside of the classroom. The process of reading about a skill and then taking a standardized test relating to that skill has replaced the process of exercising a skill and gaining proficiency.

There are a number of factors that make an activity "authentic"; here we examine three (Honebein et al., 1993). Authentic activities imply students' ownership of their own tasks. The nature of many exercises in a school setting implies that the student is doing something *for* the teacher, who then signals her approval or disapproval. One of the ways in which collaborative web publishing provides students with ownership, ironically, is by making them answerable to a larger audience. When students put their name on an exercise for a teacher, they are identifying themselves, but when they post to a weblog, they own their words and are making a gift of their work to the community. Authentic activities are usually project-based, and the complexity of the activity represents the kinds of tasks that are often undertaken outside of the classroom. Rather than simply demonstrating that they are familiar with certain reified facts or operations, students must demonstrate mastery over a more global task, within a larger context. Collaborative web publishing allows for and encourages links between assignments within a class and items in the larger information environment. Finally, the work should embrace multiple alternative perspectives. The open nature of collaborative web publishing means that everyone's assignments must not only be different, but must highlight how they are different and complementary to those of their peers. Not only is work marked by the personal voices of its authors, by hyperlinking to alternative perspectives, it situates itself within an ongoing conversation, representing a multiplicity of viewpoints.

The idealized vision of a student in the blogosphere is one in which the student moves from specialist to specialist, drawing from disparate sources to assemble their own base of knowledge. Achieving this ideal requires a period of practice within the classroom in order to become competent in sharing information. While this might seem to be something that is inherent—all students naturally know how to share information—the idea of knowledge transmission that is at the root of most schooling has trained students to expect knowledge to be fed to them by experts. They are not familiar with the idea of engaging in dialogue to co-construct understanding.

Partnering with those outside the classroom should be modeled with information sharing and peer mentoring within the classroom. The creation of environments that allow for information sharing requires coordination between assignments, the research process, and informational give-and-take among peers. The course assignments and the evaluative procedures should focus on the outcomes of these collaborations, but they should also be designed to encourage such collaboration. Working in a group is a learned skill, and since many students will have had unfortunate experiences in the past with group work, it is important to provide some process-related instruction. But even more important is setting clear proximate objectives for the groups to achieve (Brown & Campione, 1996).

Often, by presenting expectations and then establishing an environment in which peers feel free to discuss the issues, students will establish their own patterns of understanding. Jim Gibbons discovered this while teaching an engineering course at Stanford University (Brown & Duguid, 2000). When engineers from Hewlett-Packard found it difficult to come to campus to attend lectures, Gibbons had the lectures taped and the engineers watched the tapes together on the HP campus, stopping at various points to discuss the issues and come to consensus before moving on. The students who were afforded this discussion space were better acquainted with the material than those who had attended the lectures in person. Certainly, there are things that can be done to encourage discussion (particularly by modeling such discussion in other contexts), but it is often enough to simply provide what Erving Goffman called "open regions, where participants have a right not only to engage anyone present but also to initiate face-engagement with self-introductions . . . " (1963: 135).

Once groups have become comfortable interacting with one another and doing collaborative research, they are much more likely to approach specialists. This became obvious to me while teaching an undergraduate course on communication theory. Without prompting (at the time, I had no expectation that our work would carry beyond the classroom), two of the student groups writing textbook chapters as their final assignments in the class contacted theorists associated with the theories they were explaining. They most likely would not have considered doing this if they were reading a textbook and had a question, but two factors made it easier for them to approach the subject experts. First, they were confident of the knowledge they had assembled on their own. Other members of the groups served as checks, validating one another's understanding of the topic. They felt, if not equals to the researchers who had written on these theories, at least that they were well-informed acolytes. They could be confident in their knowledge because they had developed it interactively by questioning each other, the teacher, and the literature until they felt they had some fluency. Second, they knew that their product—a chapter for a textbook had the potential at least of being read by others and aiding their understanding. As translators for other students like themselves, they felt that they were doing more than seeking knowledge selfishly, they were helping their community.

The ability to work in global teams becomes increasingly important in a global knowledge society, and the skills required for this kind of distributed collective work are best learned through practice (Knoll & Jarvenpaa, 1995). Moreover, the kind of grassroots politics and social ties that once could be assumed to be local are more and more played out in global networks (Castells, 2000; Garrido & Halavais, 2003). Knowing how to use these networks is, naturally, an important skill. But more important is for students to understand how they might affect institutions and social relations. The Deweys saw this as a vital part of educating students for industry: "Unless the mass of workers are to be blind cogs and pinions in the apparatus they employ, they must have some understanding of the physical and social facts behind and ahead of the material and appliances with which they are dealing" (1915: 246).

6. TIMELESS EDUCATION

The weblog extends education beyond the school in time as well as in space. Already, many have begun to talk of a record that is self-managed, and records important (and unimportant) segments of one's life over decades. One effort toward this end is the Minnesota eFolio project (http://www.efoliominnesota.com/), "a multimedia electronic portfolio designed to help you create a living showcase of your education, career and personal achievements". E-portfolios are available to all Minnesotans, student or not. This raises interesting questions, from a technical perspective, but also provides an exciting connection between education, career, and community. With a similar goal in mind, the University at Buffalo's School of Informatics, when creating a weblog system for their graduate program (http://blogs.informatics.buffalo.edu), decided that students should be allowed to keep their weblogs indefinitely. The hope was that this would establish an electronic network that connected alumni to current students, to the benefit of both groups. Already, some graduates have taken on a mentoring role, helping new students to follow in their footsteps.

As with the removal of the classroom walls, the record without end comes with a potential price. There is the potential for ideas recorded as a student to then return to haunt the graduate. Recently, a former graduate student in the informatics program requested that his blog be removed in its entirety. As a student, he had written about what he saw as deceptive practices of a particular marketing firm. He had recently been hired by a company that counted the marketing firm among its clients, and they asked that he remove the site. There is sometimes a virtue in forgetting. While a weblog makes plain growth and learning, it often presents a balanced picture of the individual. Later, when a more favorable image is desired, mistakes—especially those taken out of context –can be ripped from the past and brought to the present.

This difficulty can be mitigated entirely by pseudonymous publishing, as noted above. And students should always have the ability to edit and remove their own work. However, the best way to avoid the problems of a public record is to place student bloggers in the shoes not only of their audience, but of their future audience. Would you publish something that you didn't want to see a decade or a century in the future? Naturally, we cannot always predict what our future selves will be proud or ashamed of, but by blogging for an audience that may include their future selves, the authors once again place their learning within a very broad context.

7. SOME PRACTICAL IMPLEMENTATION ISSUES

I have been using weblogs and wikis in my courses since early in 1999. Over the last five years, I have used weblogs, in various configurations, for undergraduate and graduate courses of a couple dozen to a couple hundred students. None of these courses were exclusively online; all had a significant face-to-face component that included some form of in-person group discussion. None could be considered an entire failure, and none could be considered a complete success. Overall, however, students have responded favorably to these collaborative web-publishing systems by the end of the course, and many continued using similar systems professionally and personally after completing the courses. This section will address some of the approaches taken and the lessons learned.

Collaborative web publishing brings with it some of the same problems that e-portfolios do. Trent Batson (2002) writes about its greatest drawback: "Moving beyond the familiar one-semester/one-class limits of managing student learning artifacts gets us into unfamiliar territory". With that unfamiliarity comes a certain degree of confusion and frustration, both antithetical to educational aims. Encouraging self-directed learning does not mean setting students adrift. They should understand the objectives at hand, and participate in the process of identifying these objectives. Successfully teaching with collaborative web publishing means changing what is taught, how it is taught, and how students learn. Simply "adding" blogging to an otherwise unchanged class is unlikely to produce anything other than confusion. However, using collaborative web publishing-based approaches does not require a complete departure from the traditions and practices of existing institutions. Implementation will be impossible if the formal strictures of the institutional environment are not addressed, and more importantly, without some of those formal elements it will be difficult to ease students into new ways of thinking and learning. Good teachers know that students enter a class not as empty cups, but with the total sum of life experiences that they bring to the process of learning. It is important to remember that they have also had years of experience that influences how they approach learning and their expected role in that process.

It is possible to adapt collaborative web publishing in small steps, but each of these small steps must be carefully thought out and integrated with the rest of the class. Simply providing a collective weblog, and urging students to make use of it, will likely produce little in the way of results. It is the virtual equivalent of attempting to have a discussion in person without any ground rules and little guidance from the teacher. Changing the focus to student-centered learning requires that the teacher take on a role as facilitator (Collins & Berge, 1997). That means preparing students before engaging in collaborative web publishing, acting as a model for their work, and guiding interaction. It also means planning to include weblogs or a wiki in such a way that it is more than an auxiliary to the main content of the course. For it to be valued by students, you must demonstrate its value.

However, beyond this initial introduction, the teacher must be willing to serve in a supporting capacity, as a resource for students who are seeking out knowledge. The continuing authoritarian presence of the teacher in online discussions at some point serves to inhibit engagement. As soon as practicable, students should be placed in the role of moderator and facilitator. Rourke and Anderson (2002) discuss the advantages of placing peers in the position of leaders in online discussions. In addition to this process, students should be provided the opportunity to seek out their own discussion leaders and engage in their own online communities. Learning is most likely to occur at the juncture of these communities, where differences in perspective are most likely to lead to critical thought and interactive understanding.

Given that the technology is still in its earliest stages, there are a wide variety of ways in which it is being implemented. Many early implementations of weblogs make use of the software simply to host the materials of the class and to make announcements, with the added ability of students to comment on these announcements. While a simple first step, this can be a powerful way to encourage interaction and increase communication between the teacher and students. In smaller classes, it may also be possible for students to play a more active role in managing content on the weblog, or helping to edit it. As a replacement for existing course (or learning) management systems, the weblog represents an interesting alternative. By opening the course weblog to the world, the teacher opens a window on the world of collaborative web publishing and models the kind of open interaction that can take place.

To realize the more extensive benefits discussed above, the students need to have more direct access to the tools themselves. Many instructors have now experimented with moving discussions onto public weblogs rather than closed discussion boards or e-mail lists. The advantage, beyond the open engagement, is that it encourages an ongoing dialogue on particular topics. There is an upper limit of perhaps twenty students beyond which these unthreaded discussions become unwieldy, and the advantages of discussion are lost; as David Weinberger has noted, “on the web, everyone will be famous to 15 people” (2002: 104). While there is some hope that collaborative filtering like that found on large public weblogs like Slashdot might be one way to manage these large discussions, experimenting with such systems so far has led to only limited success (Halavais, 2001, 2002).

Increased involvement in large classes usually means providing weblogs for individual students or student teams. Both have advantages. Individual blogs may provide students with an opportunity to extend blogging beyond the classroom and engage in self-organized learning. They also allow students to integrate their work from other classes. I have encouraged this in my classes, suggesting that assignments and research done for other courses, if identified as such, is included in my evaluation of their work. Students have found this integration with other courses to be very helpful, and I have received comments from instructors in other courses indicating that the students become more active and interested in their work in those courses when they can share knowledge between classes.

This can also occur with group blogs, though these are likely to be abandoned at the end of the course unless the groups are fairly permanent. There are several ways to allow students to comment on other groups, while encouraging participation within their own groups. When combined with group assignments, and a chance for peer group discussion during the class, this can be very effective. Aggregation systems (which collect recent entries from each of the weblogs and present them in a single web page), allow the teacher or students to track all of these conversations, and concentrate on those that are of particular interest.

Wikis also represent an opportunity, both in large and small classes, to contribute to a collective work. In several of my classes, I have asked students to collaborate on an open textbook for the course, based on their research and on lectures. In others, I have had them participate in creating an encyclopedic reference of terminology, legal cases, and communication technologies. The likelihood that they may gain an audience larger than just the professor has led to consistently better written and designed work in each of my courses.

Moreover, there is the impression that there is at least the possibility that the work is not "disposable"—that it will live beyond the end of the semester. As noted above, beginning last year, graduate students in some of our programs receive a weblog when they first enter, and continue to update it throughout the program. One intention was to create a more cohesive cohort experience. The weblogs have allowed students to provide help and encouragement to one another, and share events and news of interest. They also serve as a collection of work from which they can draw when working toward their culminating projects.

For blogging or wikis to work, students must be provided a good introduction to the technology, as well as to the social practices. The software that supports blogging changes constantly, but there are a wide range of systems available, many of them inexpensive or free, and some more complicated than others. No matter which software is chosen, it is vital that students become familiar with the technology itself before engaging in assignments or learning tasks. In many cases, teachers wrongly assume that students of a certain age must be thoroughly familiar with computing and networking. While they may be familiar with using computer networks within existing institutional and social frames, collaborative web publishing represents challenges to their existing understanding of how computers are used, and the time invested in preparing them use a weblog or wiki, will be time well spent. Failure to do so will lead to significant student frustration and disengagement (Hara & Kling, 1999). This is particularly true when these technologies are used in a distance education setting.

Students must be made aware of what the expectations are. Especially at the university level, many students are both familiar and comfortable with traditional means of assessment. Much of what has been learned in portfolio-based assessment can be applied here. At early stages, provide a set of requirements in terms of the quality and frequency of their participation, as well as the tone and boundaries of the discourse. As students become more comfortable with self-directed learning and writing for an audience larger than the classroom, they will begin to collectively establish new goals and objectives that move beyond the guidelines the teacher has instituted. This approach to learning will be unfamiliar to students, and with some preparation, the students will be motivated by the opportunity to interact with a wider group. To ensure this occurs you must be prepared, especially at the earliest stages, to help acclimate students to the environment and to the expectations.

The most enduring lesson of these last five years is that small changes have large impacts. The approaches here tend to take more time for both the students and for the instructors. As such, it is important that the objectives of the course, and the place that collaborative web publishing takes in that process, be clearly communicated to students. There is a natural tendency among students and teachers to rely on successful patterns, and introducing a new way of thinking about learning to a classroom can be expensive in terms of time and effort. Even minor adjustments to the way the technology is introduced, or the way the expectations are framed, can mean the difference between thrilling successes and chaos. When it works, the outcomes are sometimes staggering: I still receive comments from students in prior classes who have found their work in collaborative web publishing to have had an enormous impact on the professional lives. The hope is that by continuing to refine the use of collaborative web publishing and open learning, this kind of success will become the norm.

8. COLLABORATIVE WEB PUBLISHING IN A DEMOCRATIC KNOWLEDGE SOCIETY

We have moved from the most practical and direct applications of collaborative web publishing technologies as replacements for existing educational artifacts to an idealized vision of the blogosphere as a continuous collaborative large-scale conversation. A conversation entails a process of give-and-take, of co-learning. The technologies at hand provide tools for leveraging conversations over time, space, and scale. They are what Sebastian Fiedler (2003) has termed "reflective conversational learning tool[s]", encouraging a shift in emphasis from teaching to learning, from lecture to conversation. But more than this, collaborative web publishing provides a set of tools for citizens, a way for individuals to engage more fully in a democratic knowledge society.

Paolo Freire recognizes the power of dialogue, the power of naming and understanding the world. "Only dialogue, which requires critical thinking, is also capable of generating critical thinking. Without dialogue there is no communication, and without communication there can be no true education" (1993: 73). Freire sees the process of learning how to communicate as coterminous with the ability to live justly in the world. To put this in a different way, there is a significant difference between *training* and *learning*; the latter implies that the subject maintains a stake in the process and the outcome. Democracy begins in the classroom and the community. Students who direct their own learning can do so only by engaging the community. Just as it is impossible to learn effectively without engaging in discussion, consensus, and collaboration, it is equally impossible to engage in democratic collective action without a learning community. As John Dewey (1916) notes, free interaction among social groups and an interest in mutual goals are integral to both good education and good democracy.

It is easy to ascribe power to new technologies. The current excitement surrounding collaborative web publishing, regardless of the ultimate place weblogs, wikis, and related technologies serve in education, appears at a certain moment. For now, the future form of these technologies is unclear and untethered. While it still remains to be seen whether the potential of collaborative web publishing will be realized, there is reason for hope. Ithiel de Sola Pool (1983) argues that certain communication technologies have more potential to be used in the service of freedom and self-government; particularly those technologies that encourage exchange and dialogue rather than amplify the voice of a small elite. One of the reasons that collaborative web publishing has received so much attention lately is because it has the potential of being a very powerful cultural tool, if appropriately wielded. Henry Jenkins sees it as the counterpart of, if not the antidote for, the concentrated broadcast media: "Broadcasting will place issues on the national agenda and define core values; bloggers will reframe those issues for different publics and ensure that everyone has a chance to be heard" (2002).

Many have decried uncritical descriptions of new educational technologies, technologies that are often presented as educational panaceas. The description presented here remains optimistic about the possible application of these new learning tools. The claims made here are not that the application of these technologies will yield a better learning environment. As we have seen repeatedly in the past, new technologies do little on their own to improve schools. It is suggested, instead, that these socio-technologies of collaborative web publishing represent tools that can be a part of an effective change in pedagogy, a change that focuses on dialogue and participatory engagement. Such changes can be accomplished without information technologies—and they should remain an objective apart from questions of educational technology – but collaborative web publishing may prove to be a useful tool to use in this transformation. The only way it will be successful is if it is employed and critically evaluated within teaching environments. Over the next few years, we must pursue refinements in the use of these technologies, and we must be as acutely aware of the failures as we are of the successes.

Chapter 51: Procedural Discourse Networks: Weblogs, Self-organizations and Successive Models for Academic Peer Review

BRANDON BARR

> Our official culture is striving to force the new media to do the work of the old.
>
> —Marshall McLuhan (1967: 91)

By now, its become somewhat *passé* to comment that metaphors of old media shape—and often constrain—our conceptions of new media. Over 40 years ago, McLuhan first pointed out our natural tendency to attempt to understand new media through metaphors derived from older media: "these are difficult times because we are witnessing a clash of cataclysmic proportions between two great technologies. We approach the new with the psychological conditioning and sensory responses of the old. This clash naturally occurs in transitional periods" (McLuhan 1967: 91). In the intervening decades since McLuhan's pronouncement, the development of digital media has served as a perfect case study. Our computer screens simulate the organization of the typical office, complete with desktops, file folders, mailboxes, and clipboards. "Scrollbars" virtually extend a window of text while paying homage to perhaps the oldest form of paper medium. The typical Word Wide Web browser changes the computer window, which has its own history in the genealogy of perspective art (Bolter and Grusin 1999: 79), into a "webpage". Digital publications extend the metaphors of print technology with indices and tables of content, particular structures of organization developed for print materials. These print metaphors shape our conceptions of digital projects—leading to the creation of electronic books, electronic archives, and electronic journals complete with dated volumes and issues.

Bolter and Grusin call this process of using metaphors of old media to understand new media "remediation". It is important to note that remediation is not just an effect; it is also a cause. That is, it does not simply shape our end experience with media technologies. It also shapes those technologies—and the discourse networks that those technologies help shape. Academia, as a discourse network, needs to be particularly wary of remediation because academia is one of the few communities where the dynamics of text and profession intersect. In academia, remediation has real and vital effects within two sets of networks: the textual and the professional. The last century has figured professional academia in a way in which there is a one-to-one

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1237–1249.

relationship between these two networks—a relationship steeped in elements of print culture. Success within the textual network (which is accomplished through the successful publication of articles within peer-reviewed journals) is key to success within the professional network (which uses peer-reviewed publication as one measure of academic stature in tenure reviews). So when we rethink our methods of publication to account for digital media, we inherently must rethink not only how digital media may reorder our texts, but also how it may reorganize our professional lives. When we assign the moniker "electronic journals" to publications within digital media, we remediate new media within the metaphor of periodical publications. That choice is fraught with implications. When we attempt to digitally recreate what we are used to without questioning whether or not the structures of print periodicals are, in fact, outdated and outmoded, we avoid both risk and opportunity. The onset of digital media is a risk to the *status quo*, but it also gives us the incredible opportunity to re-examine the *status quo*—to determine whether or not it is something we really want to keep.

Over four centuries of developments in print media helped to shape the academic textual and professional networks that were in place in the latter half of the 20th century. Tracking one media form that is vital to academia, the scholarly journal, highlights both the historical and current purposes of scholarly communication within print media.

Ideally, scholarly publication is about sharing information. That, after all, was its original *raison-d'être*. From its origins in the 17th century through the great expansion of the 19th century, the publication of scholarly journals was primarily a method of maintaining academic communities at long distances—of sharing knowledge in different fields of inquiry through regular publication of the proceedings of academic societies. From the beginning, the media form of academic journals has been shaped by the economics of distance and volume. The physical cost of printing and transportation creates a need for editing; even today, it is that editing process that reinforces the traditional linearity of a communication model such as Shannon and Weaver's (Figure 1).

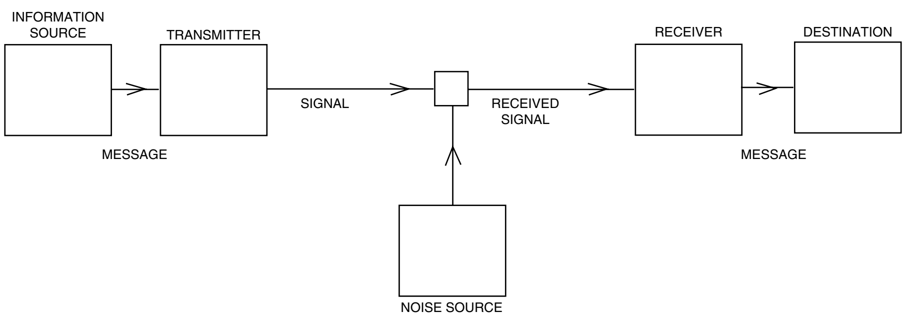

Figure 1. The linear communication model described in Shannon and Weaver's A Mathematical Theory of Communication *(Shannon 2).*

Though Shannon and Weaver developed their *Mathematical Theory of Communication* to explain information transfer within electric media such as the telegraph and radio, mapping the communicative arc of scholarly journals onto their model is relatively straightforward. The channel of information transfer is the physical printed journal; transmission and reception incorporate both the printing processes and distribution of material goods. In any media, the encoding of the message adheres to two considerations: the limitations of the channel and the intended audience. In scholarly journals, the intended audience is a "like-mind"; hence, the message undergoes little lexical translation during encoding. The integral element of the encoding process instead becomes the process of filtration carried out during the editing process—a process which becomes integral because of the physical limitations of the print journal.

The numbers of both publishing scholars and specialized academic fields exploded in the 20th century; according to *Ulrich's Periodicals Directory*, there were over 240,000 active periodicals at the end of the 20th century, with thousands appearing and disappearing each year. The professionalization of academia has led to an increase in academic specializations, which in turn has encouraged the development of new academic societies—and ultimately new clusters of journals geared toward specific fields. This explosion has resulted in a stratification of information and a decrease in the effectiveness of the scholarly journal as a method of sharing research. Because print media (like broadcast media) have no efficient method of audience feedback, the peer-review process has become not only a filtration device but also an *ad hoc* organizational tool focused on the creation of commodities which like-minds will find useful. But the sheer number of current publications now undercuts the value of the peer-review editing process. For example, an Americanist interested in feminist and queer theory—in order to actually keep up with publications in her areas—would have to wade through 29 journals on feminist theory, 4 journals specializing in queer theory, and around 90 journals devoted to the study of American literature. However, she may only find a few articles in each issue to be particularly compelling—a print version of Bruce Springsteen's critique of cable television: "fifty-seven channels and nothin' on". Academic research has become the textual equivalent of channel-flipping; researchers are ultimately forced to use online databases to keep up with their field—reading information that is inherently at least 1-year old, drowning in information.

The 20th century, then, has seen academic publication undergo a strange reversal. Academic journals were created to share information; the cost of print technology imbued printed information with a value ("this article is *worth* sharing"). The professionalization of academia during the middle of the 20th century formalized the worth of published information by making publication a part of the tenure-review process. This created a congruency between textual and professional networks. Paradoxically, it has also led to an explosion in journal publication, and ultimately a decline in the efficiency of scholarly journals as information channels. If the original purpose of academic journal publication was to share knowledge, its purpose today seems to be to act as a measure of academic prestige. Professional researchers in all fields are measured by how often and where they are published, with little regard for whether or not the system of serial publications is still an effective way to share knowledge. That is, the peer-review publication system has sacrificed the efficiency of its textual network in the creation of its professional network.

> The electronic book must instead have a shape appropriate to the computer's capacity to structure and present text.
>
> —Jay David Bolter (1991: 3)

The challenge, then, is to establish publication models within digital media that create textual and professional networks that both serve the needs of modern-day academia and highlight the native power of digital media: procedurally. Procedurality derives from the fact that digital media make feedback an implicit part of textual presentation. In digital media, feedback no longer passively shapes the work; feedback *creates* the work. Computer-based media operate on a slightly more complicated paradigm than the one represented by Shannon and Weaver.

Philipe Bootz's diagram (Figure 2) clarifies the unique quality of digital texts. For Bootz, the "text-to-be-seen" (what the reader experiences) is a result of complex processes of text generation and feedback. The computer, ultimately, is a parsing and representing machine and any digital text is the resultant output of programmed processes. That is, any digital text depends on layers of invisible functions that happen behind the reading process. Even a rudimentary knowledge of computer programming and architecture reveals that the procedures required to present even static text on a computer screen (or to represent cursor location based upon mouse movement) are far more dizzying than those required by any web-like hypertext. It is in the structural capabilities of those invisible processes that the true strength of digital text lies. Procedurality at this level is highly precise: instantaneous messages operating behind the on-screen text take predictable paths with myriad encodings and decodings. When networked, though, procedurality can also be highly variable:

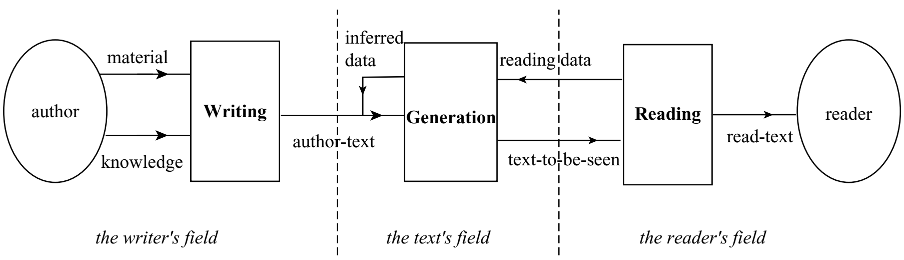

Figure 2. Philipe Bootz's procedural model of communication (1999: 307).

the parsing and representation of information varies widely from computer to computer, something any web designer is aware of. Multiple "texts-to-be-read" exist within code; which text is revealed depends upon the method of decoding. Read even a standards-compliant website using a Macintosh with Safari, a PC with Netscape Navigator, and a PC with Internet Explorer, and you read three different versions—even if the information delivered is similar. It is possible to see this variation as a type of noise; indeed, feedback tends to be read as "noise" from the music industry to the cable industry. It is also possible to see this variation as an identifying characteristic of the digital.

Current theories of digital text have centered on one type of procedurality: hypertextuality. Hypertext introduces a feedback loop at a narrative level, so that choices of the reader shape the narrative. Each choice is fed back into the functional process, and helps to generate the next "text-to-be-seen". As Espen Aarseth has pointed out, this type of feedback loop existed prior to computers, and is not necessarily unique to digital literature (1997: 18). Choose-Your-Own-Adventure books introduced the possibility of branching narratives in the 1960s, but authors have experimented with non-linearity and intertextuality for hundreds of years. While hypertext depends on a type of feedback that computers process very efficiently, it is not a uniquely digital form of text. Bootz's model, while allowing for hypertextual procedurality, more aptly models texts which are programmatic—texts which generate themselves by taking some form of feedback from the reader and incorporating it into the procedures which control the generation. The feedback loop occurs here not at a narrative level but at a lyric one; audience feedback is used to shape moments, not stories. Whether the reader's feedback is active (*via* mouse movements and clicks, for instance) or passive (for example, *via* cookies that communicate data such as the reader's operating system and IP network address), the feedback *activates* the work—momentarily shaping the text the reader experiences and, in turn, reshapes.

These two types of procedurality—hypertextual and programmatic—describe not only the structure of discrete digital texts but also digital textual networks. As previously discussed, print-based academic textual networks use the peer-review editing process both to filter and organize the network; because of the nature of print media and the cost of publication, this process occurs prior to the distribution of text. In digital media, the organization of textual networks is procedural and generally occurs after publication and in reaction to feedback from network users—either through database queries, user preferences, or hypertextual linking. As Paul Levinson puts it, digital textual networks "do away with gate keeping and maintain the appraisal, or transform the gate from a filter to a valuator" (1999: 127). The migration of academic textual networks to digital media, by definition, is a referendum on the process and politics of peer review. The referendum does not need to be a complete revolution, of course. The current structure of academia is based on the one-to-one relationship between its textual and professional networks.

By examining implementations of digital media in which textual networks and professional networks collide, academia can establish models of digital publication which work toward the ideals of scholarly publication while exploiting the strength of digital media. Currently, procedural textual networks have two different types of organization: exogenous and endogenous. Each type establishes a different relationship between its respective professional network. Both types offer a glimpse of what lies beyond peer review: a move from gate keeping to valuation. As Charles Bernstein put it, “authority is dead. Editing begins” (2001).

> The image of the electronic library as a community of writers in instant and effortless communication—this image will persist, and it will define the next age of writing.
>
> —Jay David Bolter (1991: 103)

Exogenous procedural networks are primarily hypertextual. In them, many discrete texts and personalities organize and evaluate themselves with a web of external hyperlinks. Weblogs are perhaps the clearest example of how exogenous textual and professional networks develop. A weblog, or blog, is a web-based journal that generally utilizes some form of content management software that allows frequent and easy updates. Generally, blogs are a practice in impermanent permanence; the ease of publishing encourages writing that is dialogic and even informal, yet every entry of a blog is archived and given a permanent URL address for reference purposes.

The front page of a blog serves as a sort of index; it generally features a chronological column containing the last few entries, with the most recent at the top. The margins of a blog’s front page usually contain both internal links to archived posts and a “blogroll”, which contains external links to other recommended blogs—traditionally, the blogs frequented by the blog’s author(s). The margins, then, serve to organize a blog’s internal texts, but they also serve to place the blog within particular textual and social/professional networks (Figure 3).

Indeed, they actually create and organize those networks; the blogroll serves an editorial function that uses hypertextual links to organize an exogenous network rhizomatically. The weblog, as a writing technology, creates implicit connections between the activity of reading and writing (connections which did not adequately exist within print technology or within earlier digital writing technologies—such as the static webpage—that were trapped by print metaphors); the blogroll, then, is used by both readers and writers. For readers, it serves a bibliographic and editorial function, helping the reader to generically “place” a blog and helping them find other similar blogs; for writers, it serves both as a bookmark and a ruler—keeping the community of blogs the author reads frequently close-at-hand while helping other blog authors gauge the impact of their own blogs. If procedural organization shifts

Figure 3. An example template of the front page of a blog. Most blogs feature identifiable features on this front page: a chronological column of recent entries, links to search and browse the archive, and a blog-roll of suggested links ("Georgia Blue").

its organizational schemata from pre-publication filtration to post-publication valuation, then the valuation in exogenous networks, such as networks within the "blogosphere", develops through a currency of links. Jill Walker describes this economy of links in terms of barter: "reciprocal linking and link exchange are common practice, and are loosely organised as favours or more systematically in web rings and blogrolling. . . . These informal exchanges and the prolific linking in certain communities, especially among weblogs, may be a method of subverting Google's objective measurement of links" (2002: 78). In the world of the web, links give value to a text by serving as a vote of confidence—not unlike the vote of confidence given in a peer-review process:

"this text is worth reading". In so doing, they increase a text's visibility, both in the textual networks of blogs and in search engines such as Google (which algorithmically process incoming links to determine a page's placement within search results). The currency of links in exogenous networks occurs in two types. Links to blog entries contained within the content of other weblogs serve to create and valuate the textual network (they say, "this *text* is worth reading"); links to other blogs within a blogroll serve instead to organize and valuate the professional network (they say, "this *colleague* is worth reading").

As a successive model for academic publication, weblogs have a lot of potential. Because there is no external pre-publication filtration such as a peer-review editing process, the resultant textual and professional networks are inherently more open. This openness is characterized both by the inclusion of and interaction with new voices (for instance, tenured professors carrying on equitable dialogues with students or non-academics) and the movement away from academic specialization and toward a spirit of interdisciplinary generalism (because the editorial decisions of blogrolls are based as much on personality and voice as subject matter). Because blogs are, as mentioned earlier, a practice in impermanent permanence, the resultant textual and professional networks seem more in-tune with the original goal of scholarly publication: sharing information. Blogs are not about permanent statements; they are instead about the dialogues, missteps, corrections that ultimately move toward shared knowledge. But because of their form, weblogs also share (and in some ways exacerbate) many of the constraints of scholarly journals. Their primary internal organization is even more hyper chronological than scholarly journals, ordering monthly archives into a chronological listing of entries. Though the chronological ordering of weblogs is by design instead of an arbitrary result of a publishing model, it still creates a dearth of information that is difficult to navigate. And because each blog is in essence its own publication, weblogs have resulted in an even more alarming stratification of the textual network. It took several centuries for scholarly journals to reach the point of unmanageability due to volume. Weblogs have in many ways reached that point in less than a decade.

If exogenous procedural organization uses hypertextual feedback to shape textual and professional networks, endogenous procedural organization uses programmatic feedback to instantaneously organize myriad documents. In an endogenous textual network, the "text-to-be-seen" can change for every reading; documents in the network are sorted based on some preset feedback from a reader and an algorithm that uses that feedback to determine the presentation of the "text-to-be-seen". Unlike search engines, which programmatically sort exogenous texts, endogenous textual networks generally exist as one site that collects and organizes information internally. Message boards and forums are endogenous textual networks. So are community-oriented news and commentary sites like Slashdot and Kiro5hin. The most progressive implementations of endogenous procedural organization are the most programmatic: self-organized textual networks. “Self-organization” is actually a misnomer, since all textual networks are self-organized to some degree; the term refers to information systems which order and present themselves on-the-fly based upon some form of feedback. For example, the welcome page at Amazon.com analyzes a user’s prior purchases and fills the screen with individualized recommendations. This is one-to-one marketing at its most programmatic, and it is a glimpse of how endogenous procedural texts are unique to both the digital environment and the contemporary mindset. As Bolter reminds us: “Today we cannot hope for permanence and for general agreement on the order of things—in encyclopedias any more that in politics or the arts. What we have instead is a view of knowledge as collections of (verbal and visual) ideas that can arrange themselves into a kaleidoscope of hierarchical and associative patterns—each pattern meeting the needs of one class of readers on one occasion” (1991: 97). Unlike exogenous networks, endogenous textual networks publish all material in a central location, then evaluate and sort that material programmatically during the reading process; those evaluations are generally based upon ratings systems or individual reader preferences.

Probably the clearest example of a programmatic endogenous network is Epinions.com, a site that allows anyone with a user account to share their reviews of consumer products. Interestingly enough, Epinions.com evaluates its texts in a similar fashion to weblogs. As stated earlier, weblogs use links as a sort of currency to give “votes of confidence” to both individual entries and blogs as a whole; Epinions.com similarly evaluates texts by soliciting reader feedback and then using that feedback to organize its textual and professional networks. As members read others’ reviews, they rate each review on a four-step scale. If they find someone whose viewpoint they consistently respect, they add them to their “Web of Trust”, Epinion’s equivalent of a blogroll. The site organizes itself on-the-fly based on these ratings. In any given subject area, readers see reviews written by people they trust (or people the people they trust trust) first, followed by reviews by highly trusted people and highly rated reviews. The site’s database is continuously and immediately updated, and the organization of texts in the database is personalized for each individual reader. Epinions.com, then, is less a publication than a network; it does not create an identifiable product; instead, it creates a self-organizing consumer community designed to foster high-quality reviews. Good reviewers find themselves with an immediate and large readership. Bad reviewers find themselves with a much smaller audience. And each reader gets his or her own personal publication sorted out from all available material (Figure 4).

This model is particularly appropriate to academic publication because, like weblogs, it creates a strong tie between textual and professional networks. Because the organizational process is automated and programmatic, however, the professional network tends to dominate the user experience of endogenous procedural networks—unlike blogs, in which the organization of

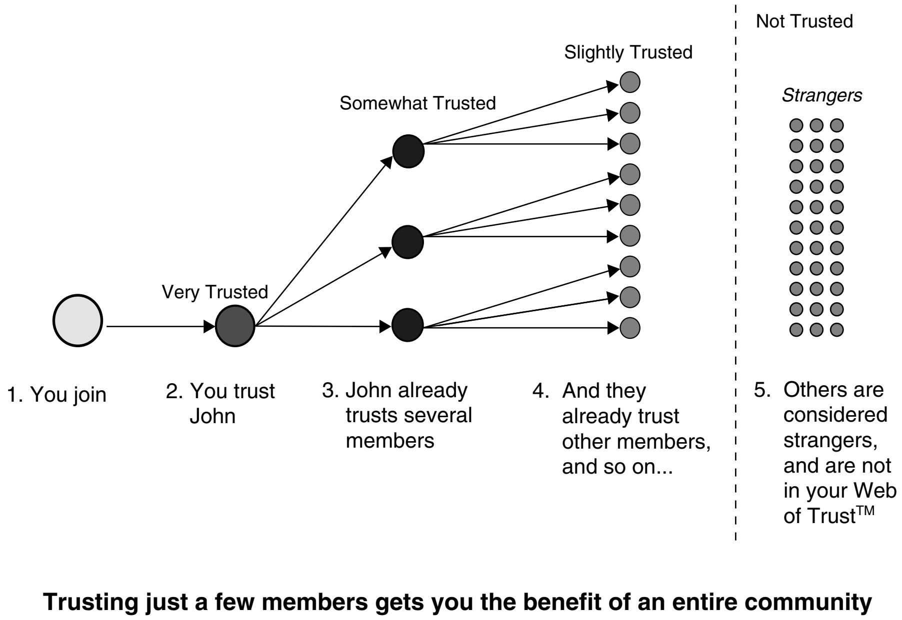

Figure 4. Epinion.com's Web of Trust organizes data for a reader based upon authorial relationships ("Web of Trust").

professional networks is quite literally marginalized. In endogenous procedural networks, the professional network becomes the valuator and organizer of the textual network; authorship and power become intrinsically tied to every reader experience. To that end, endogenous procedural organization seems to most readily accomplish the more recent goal of scholarly publication—the evaluation of a researcher's professional success of a researcher. After all, knowing that an author is trusted by 237 of her colleagues is in many ways much more precise than knowing that 14 editorial boards have seen fit to publish her articles. Endogenously, procedural textual and professional networks are less open than their exogenous cousins, but they are also less stratified; their databases structure their contents from the top down, allowing for better standardization across the textual networks and more efficient archival and retrieval of information.

Practically, the best model for procedurally organized digital scholarly publication will likely implement an amalgam of endogenous and exogenous organization. Webloggers understand the organizational limitations of exogenous networks; the phenomenal growth of weblogging has spurred development of numerous tools to organize, map, and represent its various textual and professional networks and to navigate along those networks. Sébastien Paquet's call for structured blogging is both an indictment of the implicit organization of exogenous procedural organization and a yearning for the sort of ordering one finds in endogenous networks:

> Right now what we have, globally speaking, is pretty much a huge pool of blogposts, each implicitly tied to a particular weblog author and with a date slapped on. Now, say I've written a review of the latest Radiohead album into my blog. I'd like others who are interested in Radiohead, or in music reviews in general, and who may not know me, to be able to pick out my review from the common pool in a simple way. Interesting people may come my way because of this. What we're talking about is getting people to put more metadata on their content. Now allowing it is one thing, and fostering it is another. And I'd say the latter is the bigger challenge.
>
> (2003: 2–3)

The stratification of exogenous networks makes it difficult to implement organizational structures from the top down. The inclusion of metadata creates voluntary structures, only structuring posts from weblogs that use its standards. Paquet's suggestion, then, that these structures "put control more firmly in the hands of contributors" seems a bit paradoxical. Paquet is understandably wary of the corporate underpinnings of sites like Epinions.com and Amazon.com, and it is true that current implementations of endogenous procedural networks tend to be commercially oriented structures. But they need not be. As an example, let us imagine a non-commercial academic endogenous network; let's call it Academedia. It could resemble endogenous networks such as Epinions.com or Amazon.com's review database, but Academedia's database could be more flexible than that of Epinion's or Amazon's, allowing authors to use an entry within the database to present simply text or link to another object (a blog entry, a PDF document, a Flash animation). Academedia's textual network could then be parsed programmatically according to its endogenous professional network, allowing a professional network of comments, ratings, and webs-of-trust to be overlaid on a flexible textual network. A system such as Academedia, if ever brought into fruition, would create a form of academic communication that is both open and structured: the breadth of material published would increase, the reader's experience of that material would become more efficient, and a system for determining the quality of academic research would remain in place.

Regardless of the specific form that procedural academic networks ultimately take, it is clear that they pose a threat to the current notion that blind peer review is the best way to determining the quality of academic research. Any post-publication valuation of text that occurs in procedural networks (whether exogenous or endogenous) implicitly occurs within the context of the professional network; that is, every node of a textual network is read with a knowledge of the author and the author's place within a corresponding professional network. This has at least two effects on procedural textual and professional networks. First, success within the professional network tends to drive success in the textual network regardless of the value of the content; for instance, when established authors contribute to procedural networks, their presence is immediately felt even if the content published within the procedural network is sub-par. Second, hyperawareness of their place within professional networks can ultimately alter the textual practices of authors, leading to such practices as link-slutting [as Walker defines it, "shamelessly selling one's integrity for links" (2002: 79)] and link-promotion (trying to raise one's profile by linking to popular authors or leaving a comment on a popular node with the sole purpose of driving traffic to one's site). There is an implicit danger in such a direct connection between textual and professional networks; however, there are also great benefits: procedural networks create an open exchange of research in which every participant is an evaluator—leading ultimately to a more accurate valuation than currently available with the peer-review system.

It seems clear that text published in digital media need not be in a new hypermedia form to take advantage of the processing powers of the computer. Perhaps, the most important aspect of digital media lies not in how different text may look but in how differently it is distributed. Digital technology is forcing us to think beyond peer review, to investigate the ways in which the development and implementation of procedural publication models will reconfigure academic textual and professional networks. As we restructure the ways in which we filter research and organize knowledge, we have a tremendous opportunity to take the best elements of the past and refigure them to harness the unique properties of digital media. Procedural organization will likely be a part of any successive publishing model in digital media. Which type of procedural organization we as researchers ultimately favor will determine the shape not only of our collective knowledge but also of our professional lives. As academics, nothing else could be more worthy of careful consideration.

Chapter 52: Wikis: Collaborative Virtual Learning Environments

NAOMI AUGAR, RUTH RAITMAN, AND WANLEI ZHOU
School of Information Technology, Deakin University, Australia

1. INTRODUCING WIKIS

Ward Cunningham used the word wiki (the Hawaiian word meaning quick) to name the collaborative tool he developed for use on the internet in 1994. Wikis are fully editable websites. Users can visit, read, re-organize and update the structure and content (text and pictures) of a wiki as they see fit. This functionality is called *open editing* (Leuf & Cunningham, 2001). All a user needs to edit and read a wiki, is a web browser. Consequently, the wiki has great potential for use as a collaborative virtual learning environment. Wikis abound on the internet. A well known wiki is Wikipedia an online collaborative encyclopaedia, where anybody can read, edit, re-organize and update the encyclopaedia content (Wikipedia, 2004). The homepage of Wikipedia is depicted in Figure 1.

1.1. How Wikis Work

Wikis have two different writing modes, or styles of usage. The first is known as *document mode.* When used in document mode contributors create collaborative documents written in the third person. Authors leave their additions to the wiki document unsigned. As time passes, multiple authors edit and update the content of the document and gradually the content becomes a representation of the shared knowledge or beliefs of the contributors (Leuf & Cunningham, 2001). The second wiki writing mode is *thread mode.* Contributors carry out discussions in the wiki environment by posting signed messages. Others respond leaving the original messages intact and eventually a group of threaded messages evolves (Leuf & Cunningham, 2001).

Wikis have two states, *read* and *edit*. Wikis are in *read* state by default. *Read* state means that the wiki page looks just like a normal webpage, as is shown in Figure 2. When the user wants to edit the wiki page, they must access the wiki's *edit* state. To edit a wiki, a user points their internet browser to the wiki URL (e.g., www.wikipedia.org) and clicks an edit button or link featured on each wiki page. Wikipedia provides a tab style format at the top of each page which contains a clickable link entitled "edit this page" which

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1251–1269.

Figure 1. The Wikipedia wiki encyclopaedia home page.

users can click to access Wikipedia's *edit* state. The "edit this page" tab is shown in bold at the top of Figure 2.

Most wikis use a version of *wiki syntax* that helps users to format wiki content (e.g., bold, underline and hyperlink text formatting). Users need to learn a set of basic mark up or syntax rules. *Wiki syntax* rules may vary depending on which wiki is being used. Some wikis, such as Wikipedia, do not require the user to know *wiki syntax*. Rather, an editing toolbar is provided so the user can type in their content and format it by clicking on the toolbar.

Figure 3 shows Wikipedia in *edit* state, the content in the text editing area has already been formatted using the editing toolbar. Consequently, it contains *wiki syntax* such as square brackets and apostrophes as well as text content. Once a user has added their contribution to the text editing area, they can click on a save button in the edit page to update the wiki content and return the interface to *read* state.

Users can add a new page to Wikipedia by accessing the wiki's *edit* state and formatting the required text using the internal hyperlink tool (third tool from the left in the toolbar depicted in Figure 3). This encloses the text (which constitutes the name or title of the new page) in double square brackets (refer

Figure 2. Users edit Wikipedia articles by clicking the "edit this page" tab.

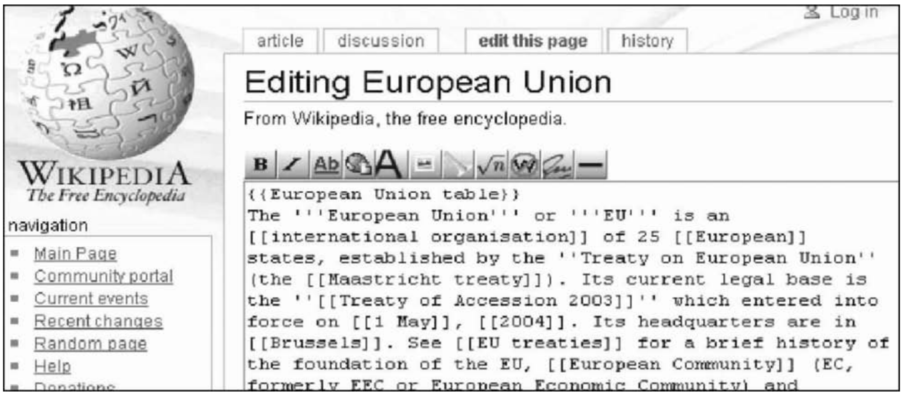

Figure 3. Wikipedia in edit state.

Figure 3), which denote an internal link. When the page is returned to *read* state the newly formatted text appears as a hyperlink. Clicking the new hyperlink accesses the new page in *edit* state, where text can be added to the new page as required. Reading, editing and adding pages to a wiki is a simple process. However, the degree of difficulty for the novice user and the steps involved will vary depending on the wiki being used.

1.2. Wikis and Collaborative Learning

Wikis can be used to facilitate computer supported collaborative learning, CSCL. CSCL, first noted in the early 1990s, is the development of collaboration by means of technology to augment education and research. CSCL promotes peer interaction and facilitates the sharing and distribution of knowledge and expertise amongst a group of learners (Lipponen, 2002). Collaborative learning exercises are student centred and enable students to share authority and empower themselves with the responsibility of building on their foundational knowledge (Myers, 1991).

Considering that e-learning is the delivery of training and education via electronic media (Mohan & Greer, 2003), current research suggests that CSCL is one of the most significantly technological means for supporting e-learning. Positive interdependence is the heart of collaborative activities that define collaboration and transform group work into teamwork (Collazos et al., 2003). This can be defined as a learning process which is conducted in the CSCL environment and which goes through the following four sequential stages (Pan & Hawryszkiewycz, 2004):

1. The composition of the collaborative learning group which consists of assembling appropriate fellow students who will study together. This selection will be based on criteria such as academic strengths, group size, and a varied expertise in the subject matter.

2. The partition of the learning task into subtasks in an effort to allocate each one to a student member of the group. This distribution is based on the learning task, the learning modality to be adopted and the members' individual capabilities.
3. The completion of the individual subtasks whereby each group member attempts to finish their designated requirements.
4. The compilation of all the learning outcomes with a further attempt to present the results as determined by the shared initial group goal.

Wikis can be used to facilitate CSCL in an effort to support knowledge building and collaboration (Raitman et al., 2004). Students can use wikis to create a set of documents that reflect the shared knowledge of the learning group. Wikis can also be used to facilitate the dissemination of information, to enable the exchange of ideas and to facilitate group interaction.

Research undertaken at Georgia Tech highlights three ways in which wikis have been used as collaborative virtual learning environments: *Information distribution, collaborative artefact creation, and discussion and review activities* (Guzdial et al., 2001b).

Distributing Information Students worked collaboratively to gather and share information using a wiki as the repository and vehicle for dissemination. In the process students created an information resource similar to Wikipedia. Students also created a list of links to other useful resources using a wiki, known as a *collaborative hotlist* (Guzdial et al., 2001b).

Collaborative Artifact Creation Students collaborated to create artifacts using a wiki either for authoring or dissemination in the process. Exercises at Georgia Tech have included *collaborative writing,* the creation of a *collaborative glossary,* participation in *cross class projects* (where each class developed different aspects of the artifact), *cross-term communication* (re-using a wiki so it became the artifact which was created as a resource for future students) or finally the creation of a *choose-your-path adventure game* (student assignments involved the creation of multiple linked pages on a wiki where several links were grouped together representing the possible paths which the navigator could choose by selecting one of links and clicking on it) (Guzdial et al., 2001b).

Discussion and Review Activities Students used a wiki to participate in discussions about course content or artifacts. *Anchored discussions* involved staff or students posting links to resources on a wiki which acted as the focus for the discussion. This method was used at Georgia Tech to facilitate discussion and analysis of practice exam questions. A wiki was also used to create a *project case library* where students posted their exemplary work after grading, to act as a guide for the class on how to achieve a high standard in their work. This method was adopted by computer science, math and chemical engineering classes at Georgia Tech and students were given extra credit for participation. Finally, wikis were used for *professional and peer design review* and *close reading* where particular readings were duplicated on a wiki and students hyperlinked sections of text which they felt merited further discussion to pages which critiqued the work (Guzdial et al., 2001b).

Schwartz et al. (2004) examined 24 wikis in use at universities in "... Canada, the US, Germany, New Zealand, Switzerland, and the UK" and noted that these wikis were used as information repositories, discussion mediums and as a mode of communication between students and teachers. Because groups of students can develop a collaborative information resource, which over time becomes the representation of the contributors' shared knowledge, wikis are ideal for the development of virtual learning communities (Augar et al., 2005a, b; Goodwin-Jones, 2003; Leuf & Cunningham, 2001; Schwartz et al., 2004).

2. WHICH WIKI?

Each wiki has a unique set of features which can make it more suited for use as a virtual learning environment. This section highlights several administrative issues that can influence the selection of an appropriate wiki. It also provides a brief overview of common wiki features and discusses how these features can be used for teaching and learning online.

2.1. Wiki Clones and Administrative Considerations

Simply put, wikis are a collection of program files or scripts which run on a web server. There are many different wikis, called wiki clones which can be downloaded free of charge on the internet. Wiki clones are written in a variety of programming languages. The reason for this is that wiki source code is available under the GNU General Public Licence, meaning the code is freely available to be reviewed and adjusted by developers. As a result, developers can translate the wiki code into their preferred programming language, which enables them to manipulate the code with ease. Many wiki clones are written in PHP, a common internet scripting and programming language. However, wikis are written in a variety of languages including Perl, Squeak, Ruby and Java, to name a few.

Wikis have a variety of features, such as user authentication, which are useful in a virtual learning environment. However, not all wiki features are enabled by default upon installation. Implementing advanced features sometimes requires the location and manipulation of individual lines of program code in the wiki source files. Consequently, wiki administrators need to be familiar with the programming language in which their wiki clone is written. This will allow them to change both administrative and installation settings with ease.

Table 1. A comparison of Wiki features.

Wiki Clone	Edit Style	Image Support	Authentication	Tracking	Sophistication
MediaWiki	Toolbar	Uploads and inline	Supported	User and IP	Moderate
PMWiki	WikiSyntax	Uploads and inline	Page password protection	IP	Basic to moderate
PhPWiki	WikiSyntax	Inline	Not supported	IP	Basic

Some wiki clones, such as MediaWiki store wiki site content in a database (MediaWiki, 2004). Others store wiki site content in flat files, as is the case with PMWiki (PMWiki, 2004). Wiki administrators should be familiar with the storage format used by their wiki so they can implement backup and recovery procedures and perform administrative and installation tasks.

2.2. Comparing Wiki Features

Table 1 compares several features of three different wikis written in PHP. These wikis were considered for use in the Deakin University wiki project (discussed later in this chapter), because the wiki administrator was familiar with PHP. The sample presented here is by no means exhaustive, but it is included to compare and contrast the features that impacted on the wiki selection process: Edit style, image support, authentication and tracking.

The edit style of most wiki clones (including PMWiki and PhPWiki) is such that users must know wiki syntax to edit effectively. However, wiki syntax can be confusing to novice users. MediaWiki provides an editing toolbar for users to format their posts, making editing a wiki relatively simple for a novice because they do not need to learn wiki syntax rules.

Not all wikis support the upload of images. Depending on the nature of the planned e-learning exercise this functionality could be a key issue in the selection of a wiki clone. When uploads are supported, as is the case with PMWiki and MediaWiki, users can place a copy of an image on the server that hosts the wiki, for use in their wiki posts. An alternative to this, inline images, requires the user to include a reference to an image stored on another server in their post. PhPWiki only supports the use of inline images.

Most wikis support tracking of wiki edits or updates. Tracking is useful for wiki administrators as it allows all wiki updates to be monitored and student participation to be assessed. Tracking is usually implemented as a “recent changes” page accessible from the wiki’s homepage. This page has a list of all the wiki pages that have been edited in a specified time period. When users are able to login to a wiki and be authenticated, the recent changes page will attribute the changes to a specific user name, rather than the more common method of listing the anonymous user's IP address. Of the wikis reviewed only MediaWiki supported full user authentication and tracking.

Because MediaWiki users can be authenticated they also have access to a signature tool and a personal user page on the wiki. The signature tool appears as an icon in the wiki editing toolbar. If the signature tool is clicked when the wiki is in *edit* state, a signature (wiki username) is added to the editing text area. The signature tool creates a hyperlink that when clicked in *read* state, accesses a personal wiki user page. Signatures and user pages can aid students in building an online identity in the wiki virtual learning environment.

Wikis comprise many and varied features that contribute to their sophistication. Of the three wikis contrasted in Table 1, MediaWiki was considered to be the most sophisticated largely due to its editing style. However, MediaWiki's support of authentication, signatures, user pages, tracking and images also contributed to its being chosen for use in the Deakin University wiki project.

The aspects of wiki functionality discussed here are the minimum set of features that should be considered when choosing a wiki for use as a virtual learning environment. Cost, complexity, control, clarity, common technical framework and many and varied technical features are also highlighted as possible selection criteria in (Schwartz et al., 2004).

3. E-LEARNING AND WIKIS @ DEAKIN UNIVERSITY

Deakin University, in Victoria, Australia offers dual mode delivery of higher education degrees to students. Approximately half of Deakin's student body completes some or all of their degree through distance education (Calvert, 2001). Deakin comprises several campuses throughout Victoria. A given subject may be offered simultaneously at multiple campuses, as well as off campus (Augar et al., 2004).

The School of Information Technology has many units that are offered at two campuses and in both on and off campus mode. Inline with University policy to promote online education, students completing a degree in Information Technology must complete an entire subject online (Deakin_University, 2003). This is achieved through Deakin's virtual learning environment, DSO, Deakin Studies Online (Coldwell, 2003).

DSO is facilitated by WebCT Vista and provides bulletin boards, synchronous chat rooms, whiteboards and the like for communication and collaboration. Static course content is delivered in HTML, PDF or PowerPoint formats. DSO also provides tools for management of assignments, assessment as well as class management (Coldwell, 2003). Deakin is continuously developing its virtual learning environment to enhance the experience of all distance and on campus learners (Augar et al., 2004).

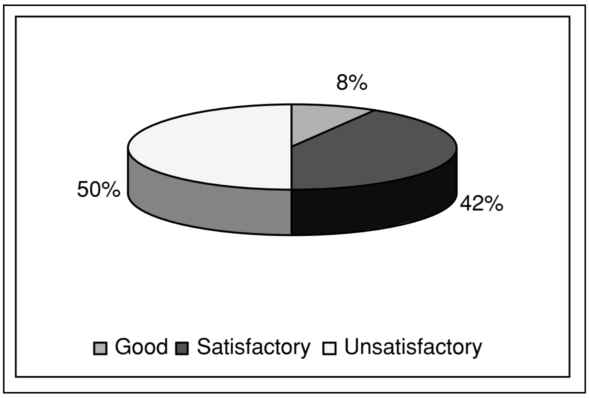

Figure 4. Students' view of learning online.

3.1. Previous Research

Ongoing research at Deakin University uses anonymous student surveys to evaluate student attitudes about learning online using DSO. Participants in a 2003 survey had completed a third year Information Technology subject called "Computers, Society and Professional Ethics" entirely online (Augar et al., 2004). For most students this was their first experience of learning in an online environment. Results showed that 50% of students found the experience unsatisfactory, as shown in Figure 4. Many cited frustration with technology and lack of interaction with peers and instructors as contributing factors to their lack of satisfaction.

Additional survey questions related to the students' participation in the asynchronous discussion forums which acted as online tutorial classes. Students participated in discussion groups of approximately 10 members. They talked about the content of prescribed readings and completed group tasks like compiling documents based on the results of their discussions. Only 42% of students surveyed indicated that all group members participated in the discussions. Of the students that did participate in discussion, almost half joined in on a weekly basis, as shown in Figure 5.

The first task completed by students as part of the subject was the publication of a single page biography in their discussion forum. It was envisaged that group members would read the biographies and use them to as a means to get to know their fellow group members, facilitating ongoing interaction throughout the duration of the subject. However, rather than lively interchange of ideas and construction of knowledge in the discussion forum, many students added a single post just before the deadlines and no real discussion or interchange of ideas occurred.

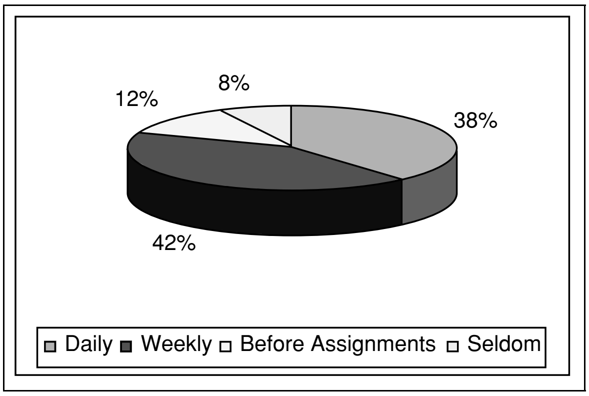

Figure 5. Dialogue frequency.

3.2. Using Wikis to "Break the Ice"

In an attempt to remedy the lack of interaction noted in online discussion groups in previous years, a traditional icebreaker exercise used in classroom situated tutorials at Deakin University was adapted for use on a wiki. The premise for developing the icebreaker exercise was to explore new ways to help students get to know the other members of their online learning groups.

In a classroom situated environment the icebreaker exercise consisted of a list of questions printed on a piece of paper. Sample questions include: "Find someone who has the same colour car as you?" or "Find someone who speaks a language other than English". Students must list the name of at least one other class mate under each of the questions. Usually there are about 15 different questions, 20 students and the activity takes about 20 minutes to complete. Students get up and circulate in the classroom, asking each other questions, to try to locate people who match the criteria outlined in the questions. In completing the exercise they introduce themselves to their other classmates. Because all students are participating the exercise creates a non-threatening way for students to introduce themselves to others in the class. Observation indicates that students respond well to the exercise, establishing new friendships that continue throughout the semester.

The success of this classroom situated icebreaker led to the adaptation of the exercise for use on the School of Information Technology Wiki, or SITWiki. Students participated in wiki groups comprising approximately 10 members. Each group had their own icebreaker document on the wiki to complete as a group. Questions similar to those used in the classroom situated exercise were included in the icebreaker document. Students had 2 weeks to update the document in thread mode so that every question had at least one group member's name underneath it. The icebreaker document was seeded with

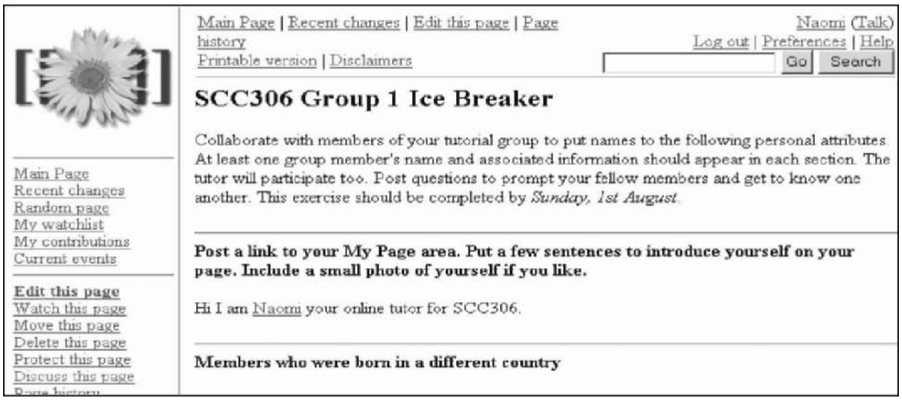

Figure 6. The SITWiki icebreaker exercise.

information about the group's tutor (online group teacher or facilitator). This was done to introduce the tutor to the group, and to model appropriate wiki usage and social presence to group members. A partially completed example is shown in Figure 6.

3.3. Signatures and User Pages

Students were encouraged to sign their posts using the SITWiki signature tool, so that other group members could attribute the posts to the appropriate person and get an appreciation of their character. Students were also encouraged to include a photo of themselves and a few brief sentences about themselves on their user page. Tutors also completed this task to model the process of constructing an appropriate online identity. An example of a tutor's user page is shown in Figure 7.

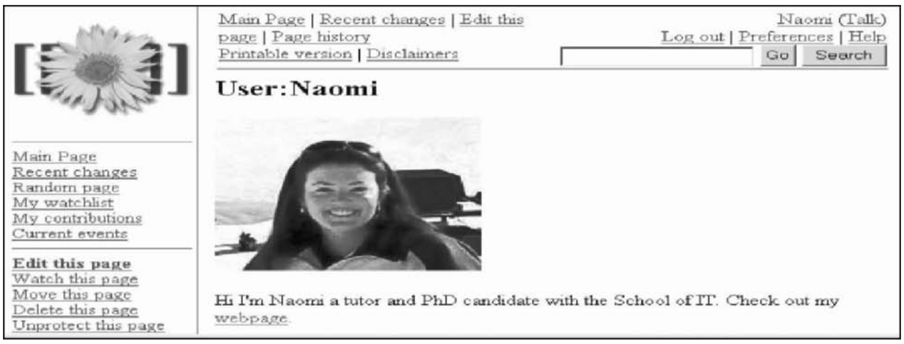

Figure 7. The STWiki user page for Naomi Augar.

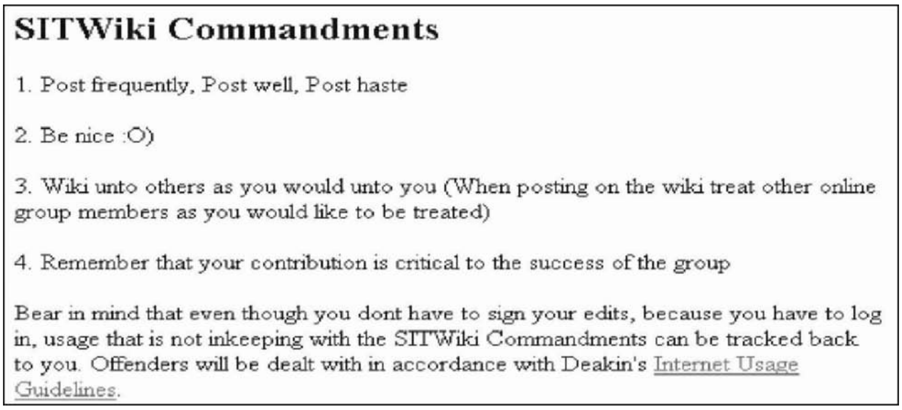

SITWiki Commandments

1. Post frequently, Post well, Post haste

2. Be nice :O)

3. Wiki unto others as you would unto you (When posting on the wiki treat other online group members as you would like to be treated)

4. Remember that your contribution is critical to the success of the group

Bear in mind that even though you dont have to sign your edits, because you have to log in, usage that is not inkeeping with the SITWiki Commandments can be tracked back to you. Offenders will be dealt with in accordance with Deakin's Internet Usage Guidelines.

Figure 8. SITWiki commandments.

3.4. Wiki Security and Tracking

Possible problems faced when using wikis for e-learning include inappropriate posting of content and unintentional deletions. Several precautions were taken by SITWiki administrators to ensure that problems relating to the security of wiki content could be avoided if possible and could be rectified if they did occur.

The first step was the development of a set of four clear usage guidelines. Powazek (2002), advises that usage guidelines should be short, simple and written in a positive tone. Consequently, the SITWiki Commandments were developed and are depicted in Figure 8. The guidelines encouraged users to be considerate of others and be active and friendly in their wiki posts. The SITWiki Commandments appeared in a disclaimers page that is a default feature in MediaWiki. A link to the disclaimers page appears on every page in the SITWiki. In addition a link to the SITWiki Commandments was placed above the “save button” within the editing interface. This ensured that users were reminded about the usage guidelines every time they made a post on the wiki (Augar et al., 2005b).

In addition to the usage guidelines, tracking and authentication mechanisms was implemented to deter students from making inappropriate posts and deletions from the wiki. Because students had to login to edit the wiki, every post or edit could be attributed to an individual student. A note asking students to be aware that usage could be traced back to them was also included as a footnote to the SITWiki Commandments to deter intentional misuse. SITWiki included a rollback feature which could be used by administrators to repair any deletions or misuse as required. The SITWiki database was also backed up nightly to prevent loss of data in case of system failures.

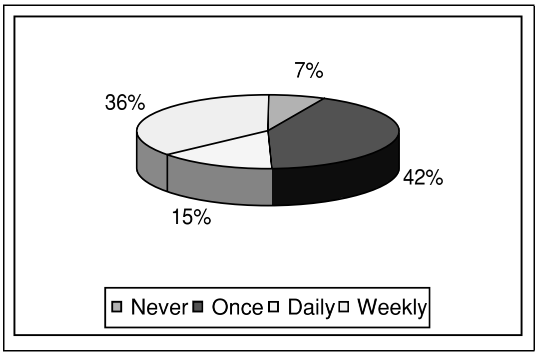

Figure 9. SITWiki edit statistics.

3.5. The Wiki Icebreaker in Review

SITWiki hosted 451 users who actively participated in the icebreaker exercise. Sixty eight per cent of active participants added some text to their user page. All users signed their posts and 92% used the signature tool to do so. However, the remaining 10% of students did type their name in plain text to sign their posts.

Many students added their picture to their user page, a total of 87 pictures were uploaded and displayed by wiki users. A popular icebreaker question asked users to add a post to tell the group if they had pets. Some students chose to upload a picture of their pet instead of a picture of themselves. Many linked the images of their pet to their posts responding to this question, other students added a picture of their pet to their user page.

Students were surveyed at the end of the University semester to explore how they used the wiki and to gather feedback about the experiment. Survey results showed that the majority of students edited the wiki either once, or at most weekly, during the icebreaker exercise, as is shown in Figure 9. However, half of the students surveyed indicated they checked the wiki on a daily basis to review the input of their group members. A further 35% indicated they viewed the wiki on a weekly basis as is shown in Figure 10. Encouragingly, 87% of students felt that the exercise enabled them to get to know their group members at least slightly better. Eighty three per cent of students felt that the exercise helped them get to know their tutor at least slightly better (Augar et al., 2005b).

Virtually all students participated actively and introduced themselves to each other by answering the questions. The School of IT at Deakin University has a very culturally diverse student body, so questions relating to culture were devised bearing this in mind. The students were very candid in disclosing information about their cultural background, such as where they were born, what languages they spoke and what countries they had lived in.

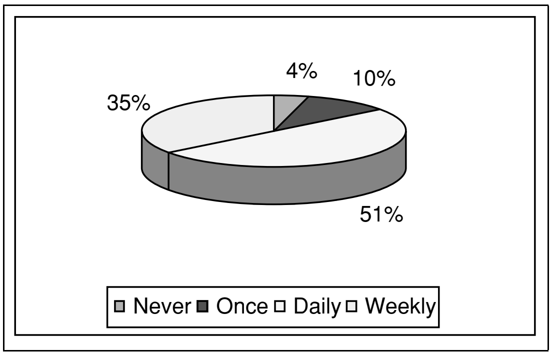

Figure 10. SITWiki view statistics.

Overall the wiki proved to be a good technology for online collaboration. All participating students completed the exercise to a satisfactory standard, proving they could use the wiki in the process. Throughout the 2 weeks duration of the icebreaker exercise there was no misuse or intentional deletions from the wiki indicating that the security measures taken were adequate and effective.

The wiki technology itself proved to be robust, supporting 450 users over a period of 2 weeks with no service outages. When the SITWiki was installed it was seeded with icebreaker documents for 50 student groups, several tutor home pages and many help pages; approximately 100 pages in total. Throughout the 2 weeks duration of the exercise the number of pages increased steadily each day to a final tally of over 1000 pages. Every day the wiki had between 1000 and 2000 page views, or hits. Each day the wiki was edited approximately 150 times and there were over 2000 wiki edits in total.

The wiki exercise presented here is purely social in nature, but it illustrates a possible use of wikis as a virtual learning environment. Another project underway at Deakin University at present encourages students working in project groups to use a wiki to disseminate information to their fellow group members, such as the time of future group meetings and the like. There is no structured task for students to complete on the wiki (as was the case with the icebreaker exercise). Students are able to use the wiki as they see fit to facilitate the completion of their assigned projects. Users of these project group wikis are not authenticated. Research aims to observe whether the lack of authentication and a structured exercise impacts upon the students' motivation to participate in the wiki environment.

Future research at Deakin University aims to use wikis *document mode* to enable students to collaborate in the creation of information repositories. The goal of this research is to further explore the use of wikis as virtual learning environments and to gauge the community building potential of wikis in the process.

4. THE COWEB VIRTUAL LEARNING ENVIRONMENT @ GEORGIA TECH

The collaborative website (CoWeb), originally known as Swiki, is an open source wiki clone written in the Squeak programming language. CoWeb, was developed in the late nineties at Georgia Tech and has been used successfully as a collaborative virtual learning environment, supporting over 120 different subjects by thousands of students since its first implementation in 1998. Its feature set has evolved through a process of constant evaluation and improvement over a number of years. Some of the features that were added to enhance teaching and learning include the ability to be notified via e-mail alert when pages change, multifield templates which allow specific portions of a page to be edited at a time (rather than requiring the whole page be accessed in edit state), and page locking mechanisms (Guzdial et al., 2000a). Consequently, CoWeb is a wiki which has proven success as a virtual learning environment and unlike other open source wikis available on the internet, it benefits from years of rigorous use and testing in the education arena. Swiki, its documentation and the Commanche web server required for installation, can be downloaded at http://minnow.cc.gatech.edu/swiki (Guzdial, 2001; Guzdial et al., 2000a, 2001b).

CoWeb has been used in many different ways (highlighted in the collaborative learning section in this chapter) by students studying subjects such as Architecture, Chemical Engineering, Biology, Mathematics, Computer Science, and English at Georgia Tech. CoWeb has supported a blended learning approach to course delivery, where content and exercises are provided online but students still attend situated classes. The most common implementations of CoWeb have involved students constructing information resources and undertaking anchored discussions (Guzdial et al., 2000a, 2001b).

The ongoing success of CoWeb has been attributed in part to the open minded, enthusiastic teachers who integrated the system well in their courses and promoted its use and benefits to students in situated classes. Teachers were able to learn to use CoWeb with a minimum of training and could implement it in their classes with little effort. This led to creativity on the part of teachers who were responsible for developing many innovative uses for the CoWeb in course delivery. Research indicated that open ended problems with no single answer were best suited for collaborative projects on CoWeb and that students were more likely to participate if their input was assessed. Exercises worked well when they introduced CoWeb, explaining how it worked and how to use it effectively before scaffolding the student into detailed collaborative tasks once they were competent and confident in the new virtual learning environment (Guzdial et al., 2000b, 2001b).

CoWeb research also highlights instances where the system has failed. Interestingly, the researchers attribute the lack of enthusiasm shown by students to their distaste for collaboration in general. Surveys indicated that a negative attitude to collaboration was evident in computer science, chemical engineering and math students who would rather receive a lower mark than collaborate with other students. Students perceived that collaboration would negatively impact on their overall marks because the classes were graded on a curve, making them highly competitive. Surveys also indicated that students enrolled in these courses felt that there was only one correct answer to most questions in their courses, and they preferred to learn independently (Guzdial et al., 2001a, 2002).

The wealth of research that documents the evolution of CoWeb and its successes and failures indicates that wikis can be used to create effective collaborative virtual learning environments. However, the exercise that will be completed on the wiki must be open ended in order to promote discourse and collaboration amongst students. The student body must be eased into the new learning environment via introductory exercises that teach them how to use the wiki effectively before they embark on detailed collaborative learning tasks. Finally, wikis have proven themselves to be easy to use by teachers and students alike, as their ongoing use a Georgia Tech attests.

5. WIKIS @ TRINITY COLLEGE DUBLIN

Wikis were introduced at Trinity College to try and overcome the feelings of isolation felt by distance learners as a result of the individual nature of online learning and assessment. The UseMod wiki clone was used to provide a basic collaborative environment for an established community of post-graduate students who were completing a dissertation required as part of their degree. The wiki was primarily used by students for collaboration and discussion about their dissertations which would otherwise be completed in isolation. Researchers suggested that the post-graduates also use the wiki to evaluate and reflect upon their learning experience in the degree they were completing. The wiki also acted as a vehicle for an anchored discussion about PowerPoint presentations that would form part of a presentation to be delivered in conjunction with the submission of their dissertation (Gibney, 2004).

Support was given to students (who had above average levels of computer literacy) in the form of a *wiki guide* which acted as an FAQ about how to edit and use the wiki effectively. The wiki was protected from unauthorized access via a password, however users did not have to login to edit the wiki and could consequently remain anonymous. The structure and content of the wiki was modified continuously throughout the duration of the experiment inline with the recommendations and feedback of users and staff. Interviews with staff and feedback gathered during the exercise indicated that the wiki was not used to its greatest potential and that exercise would have been improved by catering to the needs of the novice wiki user. However, staff involved felt that wikis had great potential as virtual learning environment to support distance education and inter-University collaboration (Gibney, 2004).

6. WIKI STARTING POINTS

Whilst the use of wikis as virtual learning environments is addressed in academic literature, some of which is cited in this chapter, the internet provides a plethora of resources and ideas for e-learning practitioners looking for ideas and support. Education based projects which use wikis and several different wiki clones are catalogued and contrasted in (Mattison, 2003). Indeed many wikis exist as collaborative online projects which are updated continuously by many anonymous users to detail how to start and maintain wikis for educational purposes. One such wiki is (WikisInTheClassroom, 2004). Technically adept practitioners may benefit from reviewing the large collection of wikis which are catalogued by (WikiEngines, 2004). Another page hosted by the same wiki, lists the experiences and recommendations added by various wiki practitioners from around the world (WikiInEducation, 2004). Online journals often provide detailed articles about how wikis are being used as virtual learning environments (Lamb, 2004; Schwartz et al., 2004). Finally, blogs (dynamic websites that act as personal journals) updated by enthusiastic e-learning practitioners can highlight the latest thoughts and reviews about the multitude of wikis available on the internet (Downes, 2004; Farmer, 2004).

CONCLUSION

This chapter introduced wikis and explained how they work. It highlighted the fact that many wikis exist, each having varying sets of functionality and features. A brief analysis outlined the features that make some wikis suitable for use as virtual learning environments. Selecting a wiki that is easy to use is important; for instance wikis that support a simple *edit* style, by including an editing toolbar, are easier to use than those requiring the knowledge of *wiki syntax*. However, additional features such as authentication and tracking are required for wikis to be suitable for teaching and learning online. Authentication enables all wiki edits to be traced back to the author, enabling the assessment process. Tracking helps to secure wiki content against possible misuse and intentional deletions.

Wikis were used successfully to enable hundreds of students to participate in a collaborative icebreaker exercise at Deakin University. This project illustrated how e-learning practitioners can use wiki technology to enhance social interaction amongst students online. However, wikis can also be used for the dissemination of information to the student body, for building information repositories or for the collaborative production of documents as research at Georgia Tech and Trinity College illustrates.

Wikis are freely available, reliable and relatively easy to use. However, they are not yet widely implemented in the education arena. Projects such as those underway at Deakin University and Georgia Tech at present illustrate how wikis can be used to create collaborative virtual learning environments.

ACKNOWLEDGEMENTS

The authors would like to acknowledge Jo Coldwell, Annegret Goold, James Farmer, and the entire teaching staff involved with the subject Computers Society and Professional Ethics, whose enthusiasm and open minded approach towards using wikis in their subject for the first time made this research possible. We would also like to thank Robert Ruge and Jeff McDonald for their invaluable technical support, and Sally Davey for her role in introducing us to the classroom situated icebreaker exercise. This chapter is an extension of Augar, N. et al. (2004). *Teaching and learning online with wikis*, Ascilite. Perth, Australia, 95–104.

Chapter 53: Partying Like it's 1999: On the Napsterization of Cultural Artifacts Via Peer-to-Peer Networks

JOHN LOGIE
Department of Rhetoric, University of Minnesota, St. Paul, MN, U.S.A.

As we begin to explore the possibilities and potentialities of Virtual Learning Environments (VLEs), it is critical that we understand the historical experiences that inform our students' interactions with virtual spaces. For students now attending universities the technology that first drew them to virtual spaces often was Napster, the first peer-to-peer application to achieve widespread popularity. While Napster and its peer-to-peer successors do not typically function as rich VLEs, they nevertheless are the spaces in which many students first cultivate a sense of the computer as a facilitator of community, communication, and exchange. In short, Napster offered the environment in which many current university students first embarked on virtual learning and their perceptions of contemporary VLEs are shaped by their peer-to-peer experiences.

Indeed, the disappointment that many students acknowledge when operating within commercial (and thus more constrained) VLEs is illustrative of the perceived freedom that students associate with their peer-to-peer experiences. But this freedom was always contested, and when placed within the frame of U.S. law, it was arguably illusory. That said, today's instructors must acknowledge and understand this perception if they hope to encourage students to adapt to the relatively controlled spaces found within many contemporary VLEs. A nuanced understanding of the history and consequences of the Napster case will aid instructors in developing VLE-savvy pedagogies that build upon the knowledge and skills gained during students' peer-to-peer experiences.

It is at times difficult to recall an internet predating the peer-to-peer networking that is now so commonplace, but Napster arrived fairly late in the life of the internet—a full decade after the development of the http protocol that underpins the World Wide Web. Napster was incorporated in May of 1999. The company's website "went live" in August of that year, offering an elegant user interface for locating and downloading music files compressed in the MP3 format via the internet. As word spread among savvy internet users Napster's network experienced exponential growth. Napster's users began transferring not only current popular music but also arcane, hard-to-find, and out-of-print music. Within weeks of Napster's launch, the traffic to and

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1271–1288.

from Napster's servers was becoming a significant problem for network administrators at universities across the United States. Recognizing the significant likelihood that much of this traffic was enabling violations of copyright, the Recording Industry Association of America filed suit against Napster in December of 1999. In January of 2000, after discovering that somewhere between 20% and 30% of *all* the traffic on its servers was Napster-directed, Northwestern University blocked student access to Napster on its networks (Gold, 2000). In April of 2000, the hard rock band Metallica and hip-hop producer and performer Dr. Dre also sued Napster, alleging copyright infringement and racketeering (Borland, 2000). Napster, in the wake of the publicity afforded by these high-profile lawsuits, became far and away the most popular file-transfer service on the internet. This prompted an additional wave of legal go-rounds and injunctions ultimately resulting in the demise of Napster as a free peer-to-peer network, when its servers were shut down in July of 2001.

Today, the striking iconography developed by the Napster Corporation lives on in as the public face of Napster 2.0, a pay-for-play music service offered by Roxio. But Napster 2.0 is demonstrably *not* Napster. Indeed, the Napster 2.0 pay-for-play service eliminates the community-building features (e.g., chat functionality among uploaders and downloaders) that made Napster both distinctive and especially efficient. Napster 2.0 is struggling to find its way as a pay-for-play service. But the Napster cat is out of the bag. As of this writing, the number of users of post-Napster peer-to-peer applications including KaZaA and various Gnutella clients dwarfs Napster's reported peak usage of 13.6 million. And these users are downloading without evident regard for the legal threats posed by the Recording Industry Association of America. Indeed, peer-to-peer users have, by and large, persisted in the same patterns of behavior that they did via Napster, and even extended their napsterization of cultural artifacts, freely downloading film, video, and photographic files via current peer-to-peer applications. And they are often doing so in defiance of the law, as it is commonly understood.

Napster's brief history as a peer-to-peer network points up the United States' failure to develop intellectual property policies that respond in positive ways to the use and transmission of creative work via the internet. Napster's file transfer technologies were, at the time of their initial circulation, largely unanticipated by U.S. law. Because Napster entered a gray area within the U.S. legal landscape, it offered an opportunity for a public policy discussion that might have productively evaluated the widening gap between common internet practices and the "letter" of U.S. copyright law, and generated responsive laws. Instead, to this point, the United States persists in projecting print-directed intellectual property policies into cyberspaces.

In the decade since the rise of the Mosaic browser made the internet a widely available public phenomenon, the U.S. government's response to internet technologies has proven increasingly consistent. When U.S. legislators address themselves to the internet, the result is almost always a decline in opportunities for access, use, and circulation of copyrighted materials. This trend is typified by the so-called "Digital Millennium Copyright Act" of 1998, which, in overly broad language, forbade the circumvention of copy-protection mechanisms without regard for the possibility that such circumvention might be necessary for users to exercise access rights granted under the fair use exception to copyright law. The fair use exception, codified in a 1976 amendment to U.S. copyright law, is the space in which legislators formally recognized the degree to which the activities of educators, journalists, and critics depend on access to and limited use of information. In particular, the fair use exception cites use of copyrighted material for "nonprofit educational purposes" as especially favored, and students and academics have come to depend on the law's bias in favor of non-profit use. The fair use exception facilitates the creation and circulation of digital archives in classrooms and libraries, but these uses are increasingly under attack by the content industries. Indeed, under the DMCA, it is not entirely clear whether an academic librarian who cracked the copy protection on a DVD in order to make a back-up copy would be violating the law or not. This distinction becomes especially important in light of the dramatic uptick in penalties for "crimes" against intellectual property. Just ask Dmitri Sklyarov, who spent weeks in jail and was forced to post $50,000 bail after his demonstration of how to crack the copy protection on the Adobe e-book software prompted a complaint from Adobe.

The need for informed policies with regard to the use and circulation of copyrighted works is critical, not just for the United States, but in an international context, because *the internet itself is (among other things) a peer-to-peer file-sharing network.* While much of the activity on the internet might be described as client-server (and thus predicated on an imbalanced relationship between participants) there are also numerous sites within the internet that depend on a roughly level relationship among participants. The most prominent example is the Usenet news groups (e.g., alt.music.no-depression) that, prior to the advent of the World Wide Web, were, taken together, the most popular spaces on the internet. Usenet is, to this day, a peer-to-peer application, with level relationships among the NNTP servers that store and forward articles to one another. Thus, the policies developed to address music and media file transfers facilitated by peer-to-peer networks like Napster and its successors will almost certainly radiate not only beyond the boundaries of the United States, they will also radiate beyond the boundaries of the relatively narrow debates over the circulation of music and motion pictures to address technologies that enable the internet as we have come to know it. For this reason, it is in the collective interest of internet users to monitor and, at times, attempt to influence U.S. policy on peer-to-peer technologies.

Unfortunately, the Napster case presents a striking example of how *not* to conduct an argument over the transmission of copyrighted materials via peer-to-peer networks. Worse, the polarities established during the debate over

Napster continue to set the terms for the ongoing public policy discussion on peer-to-peer technologies. The Napster case was the foundational conflict in an ongoing effort to come to terms with the consequences of the widespread availability of copyrighted materials via the internet. And the policies developed to "cope" with Napster and its successors will effectively circumscribe the use of copyrighted information in the learning environments we are building in virtual spaces.

In the remaining pages, I will critically examine the flawed rhetorical constructions at the heart of the Napster debate. I will first explain how those who valued Napster failed to successfully frame a powerful argument that might have shifted the debate away from the accusations of piracy and criminality, which dominated popular press treatments of Napster. Napster's fans had an opportunity to first acknowledge and then defend their uses of copyrighted materials, and this might have promoted a better result for Napster and for internet users more generally.

In the next section of this paper, I will illustrate how Napster was felled by a canny one-two punch from prominent musicians who functioned as the public mouthpieces for the recording industry. What is striking about these musicians—Lars Ulrich of the hard rock band Metallica and hip-hop impresario Dr. Dre—is that prior to this point their public personae had been grounded in an anti-authoritarian and anti-corporate ethos which, at least superficially, was at odds with zealous protection of intellectual property via courtrooms and corporate counsel. Indeed, at first blush, it is difficult to understand why the record industry allowed Ulrich and Dre to function as its representatives (as opposed to "safe" performers like Billy Joel or Celine Dion) given the degree to which Ulrich and Dre traffic in music and identity politics which can fairly be described as abrasive, profane, and advocating violence and criminal behavior. But, as I will argue, the "outlaw ethos" that Metallica and Dre had cultivated prior to the Napster controversy proved instrumental in the recording industry's ultimate victory.

Finally, I will review the consequences of the Napster debate for users and developers of VLEs, and suggest that we have yet to move beyond the flawed arguments developed to address the particularities of Napster's case.

To understand the arguments surrounding Napster it is important to first understand the laws involved in the Napster case, and to come to some sort of understanding as to whether Napster should have been understood as a legal technology or as the basis for a community of pirates. Napster, as a tool, enabled distributed file transfers. While other peer-to-peer systems, such as Gnutella, allow users to transfer almost *any* sort of file, Napster's software enabled traffic only in music files encoded in the MP3 musical format. Almost all current computers are capable of easily producing such files, by extracting audio files from CDs and compressing them using the MPEG compression format (a format which was first developed to reduce the size of motion pictures in order to facilitate their distribution via the internet). Napster's focus on music files proved to be a virtue. The software's built-in limitation produced demonstrably superior results for those interested in locating specific music files. For a time, almost every pop song imaginable was available through Napster's service.

There can be no question that certain uses of distributed file-sharing networks like Napster are absolutely legal under U.S. law. This is not to say that the majority of the uses of Napster were aboveboard, but it *is* to say that a small but significant percentage of uses were certainly legal. If, for example, one used Napster to locate and secure a particular recording that was in the public domain, either because it was recorded prior to 1923 or because, for whatever reason, the copyright holder did not meet or maintain registration requirements, that use of Napster would be absolutely legal. On this basis, it is officially open season on Enrico Caruso's recordings (as the great tenor died in 1921). If I was downloading MP3 files of songs which I had already purchased on CD and downloading them, for convenience's sake, from other users who had also purchased the CD, this use might well be legal. And if I could frame an argument that the use in no way harmed the copyright holder's economic interest in that intellectual property, I would have at least the start of an argument that my use was either legal, according to the principles of fair use, or a *de minimis* violation of copyright, a violation so minor and so trivial that it falls beneath the purview of the court system. Most importantly, if I were to secure material for the express purpose of using it in my classroom teaching, that use would probably be legal according to the fair use exception to copyright—though the question becomes more complicated if my use involves a publicly available web space or learning environment.

The hedged language of the preceding paragraph is unfortunately necessary, as U.S. legislators have refused to offer "bright line" distinctions, preferring instead for judges to make the kinds of fine-grained decisions called for in copyright cases. In the absence of case law addressing a precisely parallel circumstance copyright consumers are left to guesstimate whether their uses are legal. Of course, the absence of clear markers means, in practical terms, that those wishing to use material that *might* be protected by copyright must err on the side of caution or assume some measure of risk of litigation. While many Napster users did not engage with the legal questions surrounding their downloads, many more made an informed judgment to assume the low risks attendant to their use of the Napster network. And indeed, there were ultimately *no* personal consequences for the use of Napster—only the Napster corporation suffered.

In March of 2001, the best estimates suggest that 2.8 *billion* music files were transferred over the network Napster facilitated (Graham, 2002). Because the internet is international in its scope and reach it is impossible to determine what percentage of these transfers were made by U.S.-based users. But given the general distribution of computer technology worldwide, it is almost certain that the vast majority of Napster's users hailed from the United States. And this use of Napster was transpiring despite their increasing awareness that the technology at the heart of Napster's network was based on a questionable interpretation of U.S. copyright laws. In fact, Napster users' awareness of the July 29, 2000 injunction threatening to shut down Napster's servers prompted a flurry of downloading in the days prior to the prospective shutdown date (Konrad, 2000). The dramatic spike in downloads suggests that Napster fans were actively indulging in a "last call" prior to the service's shutdown in anticipation of the court ruling Napster to be illegal.

Despite the general presumption of illegality Napster users *did* have an arguable case with respect to their consumption of copyrighted materials. In addition to a generalized fair use argument, which did not really speak to most of the activity on Napster's servers, many Napster users cited the 1984 Supreme Court ruling in the so-called Betamax case as supporting their right to make and keep non-commercial copies of songs for their personal use. In this case, Universal studios sued Sony for having developed a commercial videotape recorder—a VCR—alleging that the primary use of the VCR as a technology was the enabling of piracy and that Sony should be held liable for contributory infringement. While the court acknowledged the likelihood of VCR owners archiving copies of copyrighted films and programs the Court also recognized that the VCR had a significant non-infringing use: the recording of programs for viewing at a later date, or time-shifting, and it ruled in favor of this non-infringing use without directly addressing the problem of archived videotapes harming the markets for commercial releases of copyrighted material.

The question of whether individual consumers can legally record and preserve copyrighted materials for personal use was also addressed by the Audio Home Recording Act of 1991. This Act protects manufacturers of recording devices (in this case the technology driving the law was Digital Audio Tape or DAT) from the charge that their devices were enabling contributory infringement when home users violated copyrights. But this protection came with a price. Manufacturers of DAT players and DAT tapes were also obliged to pay fees designed to address the likelihood that purchasers of DAT tape would be using this high-quality recording medium as a substitute for commercially produced recordings. Unlike the VCR, the DAT was never meant to time-shift broadcasted material—its chief purpose was creating the best possible reproductions of previously recorded material. Nevertheless, the legislative history found in the house reports leading to the Audio Home Recording Act makes it clear that, at least at that time, home recording for private, non-commercial use was not being targeted, in a passage which reads: "In short, the reported legislation would clearly establish that consumers cannot be sued for making analog or digital audio copies for private noncommercial use" (qtd. in Carroll, 1993).

The general import of both the Audio Home Recording Act *and* the holding in the Betamax case is that technologies facilitating both infringing and non-infringing copying ought not be withheld from the public, *even if the* *availability of the technologies leads to infringing uses*. And while Congress offered special compensation to copyright holders for anticipated infringements by DAT users, the Supreme Court offered no such compensation to copyright holders for the expected infringements by home videotapers. If we follow the logic of these policy decisions, it seems clear that the peer-to-peer file sharing system at the heart of Napster *if understood as a technology*, ought to remain available to the public because, like the VCR, the technology is capable of substantial non-infringing uses. The only real question ought to be whether, like DAT, Napster and the machines associated with it ought to be subject to fees that would be distributed to copyright holders in compensation for anticipated infringements.

This was Napster's argument to win or lose. And Napster had the good fortune, at least initially, to be arguing against one of the most widely loathed industries this side of tobacco manufacturers: the record industry. Many music consumers hate the major record labels because record companies have been demonstrably ripping them off for years. (For example, music consumers were initially told that the high list price of CDs was due to the costs of establishing manufacturing facilities, and that prices would ultimately approximate the $8.98 list price for vinyl LPs.) Further, many musicians view the major labels as necessary evils, and there are hundreds of cases of demonstrable unfairness to musicians by the record companies that supposedly nurture and develop them. Among the most notable: Muddy Waters, who fulfilled his contract, in part, by painting the Chess studios (Fricke, 1990); Creedence Clearwater Revival's John Fogerty, who was accused by his record label of plagiarizing *his own work* (Bio: John Fogerty, 2004); and the members of TLC who faced bankruptcy in the immediate wake of a #1 record (TLC, 1999). Two prominent musicians with roots in punk rock, Steve Albini and Courtney Love, have internet-based essays on the blatant unfairness of typical major-label contracts for most recording artists (*see* Albini, 2004; Love, 2000). And if all that were not incriminating enough, the five major record labels in 2004 paid out $67.4 million and $75.7 million worth of CDs to settle a class-action lawsuit addressing price-fixing (Lieberman, 2002).

While the record companies' evident bad faith does not legitimate copyright infringement, it does establish that these companies bring a *lot* of excess baggage to public debates over their intellectual property rights. In short, in their roles as mediators between artists and their fans, record companies have managed to deeply offend significant numbers of artists and fans. In this context, it is perhaps not surprising that Napster's initial forays into cyberspace bespoke an almost casual disregard for the major labels' interests. But it becomes clear that Napster ultimately remained too connected to this ethos—an ethos grounded in the music fan's distaste for the record company's business as usual—and this left the company open to charges of irresponsibility and piracy.

We can see part of the problem in the company's iconography. The early versions of Napster's logo featured a headphone-wearing figure that has been

Figure 1. Shawn Fanning as rebel icon.

variously described as a demon or a cat. It was meant to represent a cat, and, significantly, in the early versions of the logo, this was a black cat, conventionally symbolizing bad luck (but for whom?) The logo was later amended to bleach the cat and thereby reposition Napster as something other than sinister.

Napster also structured its public identity around the figure of the technology's inventor, Shawn Fanning, who developed the software code while a student at Northeastern University. Despite Fanning's having left the University almost immediately after this "Eureka" moment he is often presented in circumstances which reinforce his "dorm rat" persona. In a publicity photo which was featured on the company's website (Figure 1) we see the ballcap-wearing Fanning sitting in front of his record collection and what appears to be a handmade flag (a pirate flag?) looking like a sophomore with more than a touch of rebel attitude.

This positioning was transpiring while the "suits" at Napster were busy preparing for the company's initial public offering, and there is an obvious gap between Napster's attempts to develop into "respectable" dot.com and the maintenance of Fanning's ethos as a combination of college-age music fan and hacker. When *Time* magazine photographed Shawn Fanning for a cover story (Figure 2) and later, for its listing of Fanning as one of the finalists for its person-of-the-year award, its positioning of Fanning illustrates the degree to which Fanning had become synonymous with Napster. Here Fanning inhabits the headphone-wearing pose of the logo, and the accompanying text points out that "Napster" is both the company's name and a childhood nickname for Fanning.

By the end of 2000 Napster had yoked itself to Fanning, despite Fanning having a fairly limited role in the company's business operations. And throughout its first year, Napster struggled to find the balance point between serving the interests of its predominantly dormitory-based user base and the

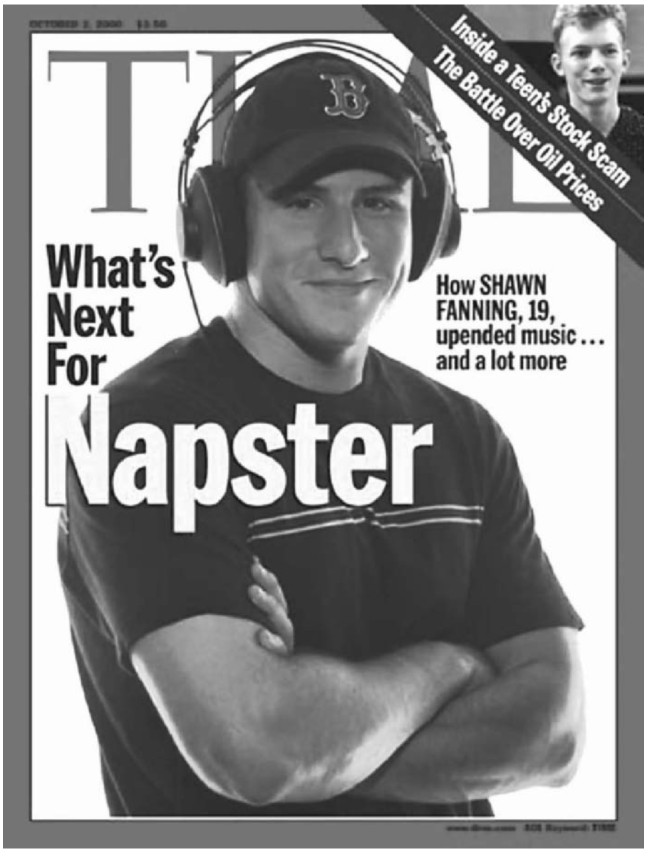

Figure 2. Fanning positioned as the Napster cat.

need to articulate a business model that would bespeak corporate responsibility with regard to copyright.

Fanning was consistent in positioning his work as community-oriented. In an early interview Fanning said:

> I was at Northeastern University playing with the idea and getting feedback from my roommates, and then started drafting a really basic design idea. It was rooted out of frustration not only with MP3.com, Lycos, and Scour.net, but also to create a music community. There really was nothing like it at the time.
>
> (Varanini, 2000)

And indeed, Fanning's software represented an important step forward from other services cataloging and delivering MP3 music files. Napster allowed for direct communication among users of the Napster software, so an individual downloading a particular song might well receive an instant message from the person serving that song to the network. Napster consistently spotlighted this feature. Napster's press releases included a boilerplate phrase claiming that Napster "provide[d] media fans a forum to communicate their interests and tastes with one another."

Napster proved remarkably effective in developing a recognizable company ethos, grounded in the iconic figures of the Napster cat and the cat's human counterpart, Shawn Fanning. But classical treatments of ethos do not wholly account for the ways in which Napster established its connections with an audience. Clearly, Napster's initial stance is not one grounded in the establishment of the Aristotelian triad of good sense (*phronesis*) virtue (*arête*) and good will *(eunoia*), as the company's presentation is grounded, in large part, on a violation of the established order. Indeed, Napster was participating in the same sort of anti-authoritarian stance that has become conventional within the rock and hip-hop genres. As fans proclaimed, "Napster rocks", this rocking obliged Napster to maintain an orientation toward its fans and against the perceived corporate machine even as it strove to stabilize its own corporate machinery.

Coyle and Dolan's "Modeling Authenticity, Authenticating Commercial Models" (1999) illustrates the kind of polarities which rock musicians face when turning toward the marketplace:

> New sounds are invariably proclaimed as liberations from the devitalizing control of industry, even as such proclamations generally inserts the new into an established pattern. Real rock is always a rebellion, always a disrespect to the hierarchy, a blow to the empire. The authentic article is never the commercial article.

To the extent that Napster wished to participate in rock's stance, it was precluded from full partnership with the record industry, because this would have violated the company's ethical obligations to its fan base.

This tension is reflected in Napster's sometime contradictory self-representations. Napster's first CEO, Eileen Richardson, attempted to maintain a position of corporate responsibility when she re-purposed Shawn Fanning's "community" theme as potentially falling outside the bounds of copyright law. Richardson said: "It's about community. Maybe I know about this band just in our local town, and you know about them, too. So it is a known artist, and I can share that with you directly. It is not about known artists like Madonna" (qtd. in Menn, 2003). Richardson was attempting to focus attention on potentially non-infringing uses: the sharing of unsigned bands among tiny circles of fans But at the same time Napster's website stated that Napster "ensures the availability of every song online" and further, that Napster "virtually guarantees you'll find the song you want when you want it . . . and you can forget about wading through page after page of unknown artists." This implicit invitation to what the major labels describe as piracy and theft suggests that Napster's ethos was not grounded in assertions of virtue, but rather in something like Kenneth Burke's identification, which Burke explains most clearly in *A Rhetoric of Motives* (1969):

> *A* is not identical with his colleague, *B*. But insofar as their interests are joined, *A* is *identified* with *B*. Or he may *identify himself* with *B* even when their interests are not joined, if he assumes that they are, or is persuaded to believe so. Two persons may be identified in terms of some principle they share in common, an *identification* that does not deny their distinctness. To identify *A* with *B* is to make *A consubstantial* with *B*.

Burkean identification offers rhetor and audience the opportunity to unite over a shared principle without necessarily verifying the virtue of either party. Thus, by maintaining Shawn Fanning as the public face of Napster, the company promoted an identification with fans of rock and hip-hop music which maintained the anti-corporate, anti-authoritarian stance of those musical genres. And this proved especially damaging when the contest shifted from a battle between Napster and the Recording Industry Association of America to a battle between Napster on one side and Metallica and Dr. Dre on the other.

Metallica describes itself as the "7th biggest selling act in American history". The band's success is grounded in a close relationship with its fan base—so close that when Metallica's members collectively updated their hairstyles, this was seen as a capitulation to the image-consciousness promoted by MTV, but at odds with Metallica's anti-corporate ethos. Metallica's lyrics, too, position the band as vocal critics of a vaguely constructed network of authority figures including record companies, parents, and the U.S. government, a critique which is expressed most directly on the cover of the band's album, "... And Justice for All" which features the iconic figure of Lady Justice being toppled by four ropes (probably corresponding to the four band members). The title's song's lyrics also bespeak a frustration with the degree to which "power wolves" pollute the justice system with money and influence.

A similarly oppositional stance, albeit one arising from a different space within U.S. culture, is everywhere apparent in Dr. Dre's work. Dre's career can be traced back to his membership in the Los Angeles-based group "Niggaz With Attitude" whose breakout single, "Fuck Tha Police", was a withering indictment of the Los Angeles Police Department's racist practices that predated Rodney King and the L.A. riots. A producer, writer, and performer—whom *Rolling Stone* has compared to Phil Spector, the architect of the 1960s "Wall of Sound", and Quincy Jones, the producer of the biggest-selling record of all time—Dre has crafted an identity which balances his success as a performer and entrepreneur with the markers of "street credibility" which allow him to maintain a productive identification with his audience. Thus, while Dre is the owner of a record label, the label was named "Death Row Records", associating his work with the politics of capital punishment, a practice which the State of Illinois suspended due to its evidently racist application. In the lyrics to his 1999 rap, "Forgot About Dre" Dre also, somewhat disingenuously positions himself as a struggling small business owner, refusing handouts because his company is too "little", and because he is too street-smart to be taken advantage of.

Once Dre and Metallica entered the legal arena the Recording Industry Association of America backed away from its aggressive attempts to set the terms of the Napster debate, relying instead on the sometimes inarticulate voices of Metallica's drummer, Lars Ulrich, and Dr. Dre to carry the industry's arguments to the public. At times, this undoubtedly proved excruciating for the industry. In one interview, Ulrich compared Napster's claim that it could not hope to control whether the technology's users violated copyrights or not as the equivalent of the National Rifle Association's infamous "Guns Don't Kill People, People Do", argument. While Ulrich's is correct in pointing to a superficial similarity between the arguments, the comparison also tacitly equates copyright infringement with murder. Clearly, this is not an optimal rhetorical presentation. And Ulrich's Senate testimony was widely criticized by the band's fans as a betrayal. Indeed, the juxtaposition of "Mr. Lars Ulrich" with the gentle questioning of Senator Orrin Hatch was one of the more irresistible pop culture mind grenades since Elvis shook hands with Richard Nixon, and a direct violation of Ulrich's then settled image as a rock and roll wildman. And while Dre is verbally inventive as a writer and performer, his public statements on Napster were disappointingly brief and vague, his press release stated, baldly "I don't like people stealing my music", without addressing the complex questions arising from peer-to-peer technologies (Dansby, 2000). Dre's participation in the argument was further complicated by his position as a hip-hop producer who had made extensive use of sampling technology on his records, sometimes with permission but often without. In fact, at the time of the Napster lawsuit, Dre himself was being sued by George Lucas for having sampled the "Dolby THX" sound which precedes some films, without first securing permission. And given that the sound was followed by a barrage of bong hits and profanity, it seems clear that Lucas, as a family-friendly entrepreneur would have denied permission.

Nevertheless, the industry hung back, allowing Ulrich, in particular, to function in the role of the aggrieved artist, and in so doing the industry transformed the Napster argument from a likely loser into an argument powerful enough to persuade a crucial district court judge to enjoin file-transfers via Napster's site. Because Metallica and Dre so fully inhabited an outlaw ethos which allied them with fans and against the same authoritarian, corporate architecture which Napster had targeted, the industry succeeded in creating uncertainty and debate within a fan base which, prior to Metallica and Dre's entering the argument, was united behind Napster's implied assertions that music ought to be free.

Thus, while Napster initially offered a viable alternative to business as usual within the music industry by crafting an ethos that paralleled rock and hip-hop's superficial rejection of authority and corporate politics, this left Napster with only limited opportunities to position itself as a legitimate business. When, in the midst of this process, it faced a challenge from the very performers who had inspired its existence, Napster faced an argument it could not win without "selling out". In the music industry, this is a familiar narrative. Like many performers in its favored genres, Napster failed to successfully negotiate the difficult task of preserving its authenticity and integrity when the company became an "overnight sensation". But this is not the sort of narrative that ought to lie at the heart of an important discussion about public policy. Napster was allowed to function as a representative for *all* peer-to-peer applications and networks, and its eventual defeat created a circumstance in which even clearly legal uses of peer-to-peer technologies are greeted with wariness (especially by university legal counselors who are compelled to err on the side of caution).

Napster's demise still reverberates throughout discussions of intellectual property in virtual spaces. One of the most striking testaments to Napster's continuing influence is the website "napsterization.org" which defines "napsterization" as "the disintermediation by new technologies and digital media of old economy, incumbent institutions and analog frameworks" (Hodder, 2004). The "disintermediation" referenced here is usually understood as the internet-based elimination of the "middleman" in (formerly) physical and print-based transactions. In conventional transactions there are layers of intermediation, as a product moves from manufacturer to market. But the internet has long been understood as offering opportunities for disintermediation, for streamlining relationships between artistic producers and their audiences. In the case of popular music, the call for disintermediation is particularly pronounced, as the music industry and music consumers have for many years maintained a relationship characterized by suspicion, frustration, and antipathy. The advent of the MP3 format, which made it feasible to transfer music files over even relatively low-bandwidth dial-up connections, was a notable technical breakthrough. But the explosive expansion of Napster was not attributable solely to its leveraging of technology. Napster also offered an opportunity for music fans to demonstrate their distaste for an industry that had often failed to address consumer's calls for products other than the default 10–15 song compact disk retailing for $16.99–$19.99. And indeed, the current reality is that music consumers now have considerably more choices. The prices of compact disks have dropped significantly and consumers wishing to purchase single songs are able to do so via Napster 2.0, Apple's iTunes, and a host of other pay-for-play services. The music industry has responded in positive ways to the implied threat posed by Napster and its successors. And by so doing, the content industries are repositioning themselves.

Despite dramatic shifts in the availability and affordability of popular music, a large cohort of music fans persist in maintaining the Napster model. In May of 2003, Kazaa Media Desktop became the most downloaded software in the history of the internet. By the end of that month, individuals had downloaded over 230 million copies of the file-transfer software. They did so despite persistent reports that the software included "sneakware" and "spyware'—surreptitiously installed applications that would appropriate computer processing power and monitor computer usage, sending the by-products of both back to Kazaa's parent company. Indeed, the description of Kazaa Media Desktop at Download.com, one of the major sources for the software features the following warning:

> **Editor's note:** This download includes additional applications bundled with the software's installer file. Third-party applications bundled with this download may record your surfing habits, deliver advertising, collect private information, or modify your system settings. Pay close attention to the end user license agreement and installation options. For more information, read Download.com's guide to adware.

Further, these 230 million downloads occurred despite the general understanding that Kazaa's software was designed to enable activities generally thought, in the wake of Napster, to be illegal. The U.S. public has demonstrated a voracious appetite for mp3 music files and has persisted in using peer-to-peer networks to download music despite the implicit threats to privacy posed by Kazaa, and the possible illegality of their actions (as implied by the injunction that closed Napster as a "free" peer-to-peer network). While the majority of the public now seems to have been persuaded that their actions might well be proven illicit, they are not buying the larger argument—that they must cease and desist downloading copyrighted files.

The U.S. citizenry's difficulties with respecting copyrights have a long history. But the arguments mobilized in response to citizen's actions have remained remarkably consistent. In the 19th Century, the United States had a well-earned reputation as a nation of copyright scofflaws. At that time, Charles Dickens toured the country decrying the pirated editions of his novels that effectively wiped out the market for legitimate editions. As a British author Dickens was directly harmed by America's refusal to honor international copyright laws. Eventually, many American authors came to share Dickens' views. Vaidhyanathan's *Copyrights and Copywrongs* (2001) devotes a chapter to Mark Twain's vexed relationship with copyright, and his shift from what Vaidhyanathan calls "copyright realism" to plaintive calls for *perpetual* copyright. At one point, Twain argued:

> The limited copyright makes a distinction between an author's property and real estate, pretending that both are not created, produced, and acquired in the same way. The man who purchases a landed estate had to earn the money by superiority of his intellect; a book is a result of the author's own brain in the same manner—a combination and exploitation of his ideas.

Vaidhyanathan rightly takes Twain to task for the speciousness of this argument, pointing out that there is no necessary relationship between having money to purchase property and labor *or* intellect. And yet core appeals of this argument persist to the present. First, Twain's argument hinges on establishing an equivalency between tangible and intellectual properties. While this supposed equivalence is easily deconstructed, it reverberates throughout intellectual property discourse. For example, representatives of the record industry have repeatedly insisted that there is no appreciable difference between an unauthorized download and shoplifting a compact disk. Tellingly, Metallica drummer Lars Ulrich made this case in his July 2000 testimony before the U.S. senate:

> If you're not fortunate enough to own a computer, there's only one way to assemble a music collection the equivalent of a Napster user's: theft. Walk into a record store, grab what you want and walk out. The difference is that the familiar phrase a computer user hears, "File's done," is replaced by another familiar phrase, "You're under arrest."

Ulrich's argument hinges on the elision of the important distinction between tangible physical artifacts and readily reproducible digital files. In Ulrich's hypothetical, the shop owner is harmed, having paid to purchase the pilfered compact disks. In the case of a downloaded file, the uploader and downloader each retain perfect copies. There is measurable harm only when the downloader would have purchased the file in question were it not for its ready availability via a peer-to-peer network. This difference was, for many years, recognized in U.S. law. Physical theft was understood as a criminal matter, with penalties including imprisonment, whereas copyright infringement was understood as a civil matter with financial penalties as the primary remedy.

The second element of Twain's argument is an implied *pathos* appeal, grounded in the notion that the author has worked hard and expended effort (or at least, made use of "superior intellect") and deserves to be rewarded for the expenditure. This argument, too, has a counterpart in Ulrich's testimony.

> Since what I do is make music, let's talk about the recording artist for a moment. When Metallica makes an album we spend many months and many hundreds of thousands of our own dollars writing and recording. We also contribute our inspiration and perspiration. It's what we do for a living. Even though we're passionate about it, it's our job.

But copyright makes no allowance for inspiration and perspiration. Indeed, the law makes no distinction between the by-products of Metallica's "job" and a recording like Jimi Hendrix's "Band of Gypsies", which documents a live performance on New Year's Eve, 1970. In the case of "Band of Gypsies" an engineer simply rolled tape on a live performance. Hendrix's inspiration and perspiration were certainly involved, but they would have been present even if this performance had not been recorded. Further, copyright law does not distinguish between the evident artistry of Metallica and the utter (yet arguably charming) incompetence of a performer like William Hung, who is currently parlaying his infamous audition for "American Idol" into a recording career.

Despite the obvious flaws in these arguments, they have triumphed. So we must account for how it is that Mark Twain and Lars Ulrich mobilized arguments that have demonstrable rhetorical power. Clearly, the most compelling elements of these arguments are the points when Twain and Ulrich speak as working artists seeking fair compensation for their efforts. While the logical foundation of their arguments is shaky, most of the participants in the peer-to-peer debates would stipulate that fair compensation for the creators of cultural artifacts ought to be central to any copyright law (though there would be wide variation of opinion when it came time to define "fair compensation"). The question at present is whether the current debate over peer-to-peer technologies is moving us closer to a system in which digital media prompt fair compensation for creators, or effectively delaying the development of such a system.

The Napster debate was, from a legislative standpoint, largely resolved by the Senate hearings featuring Ulrich's testimony and the court case that closed Napster's servers. But this debate, by highlighting Ulrich's arguments, served to perpetuate a fundamental misconception with respect to users of peer-to-peer technologies: that they are "thieves" (or more commonly, "pirates") of other people's "property". This perception remains dominant despite the absence of precise correspondences to physical theft and real property, as Vaidhyanathan (2002) points out:

> We make a grave mistake when we choose to engage in discussions of copyright in terms of "property." Copyright is not about "property" as commonly understood. It is a specific state-granted monopoly issued for particular policy reasons. While, technically, it describes real property as well, it also describes a more fundamental public good that precedes specific policy choices the state may make about the regulation and dispensation of property. But we can't win an argument as long as those who hold inordinate interest in copyright maximization can cry "theft" at any mention of fair use or users' rights. You can't argue for theft.

Napster's unfortunate legacy is its inscription of users of peer-to-peer technologies as pirates. The positioning of the company's corporate icon, Shawn Fanning, flying the flag of dorm-based rebellion was ultimately understood as emblematic of all users of peer-to-peer technologies. This undermined a more reflective portrait of peer-to-peer users which would include, among others: the classroom instructors who keep their courses current by briefly referencing current artworks; the Usenet users who build communities around shared interest in particular cultural phenomena; and archivists, who are struggling to maintain whatever is most compelling amidst the torrents of data now available via the internet.

The Napster case should serve as a telling indication of how much might be lost if the internet community at large allows the peer-to-peer debate to continue as a contest between "pirates" and "property-holders". Indeed, one of the most compelling opportunities afforded by digital technologies is its destabilization of the once sharply delineated relationships between producers and consumers of digital artifacts. And this has particular resonance for those instructors inviting students to participate in building and shaping VLEs. The process of building rich virtual spaces often involves borrowing existing snatches of code, riding on previously invented wheels, and incorporating and critiquing the massive waves of information that crash down regularly throughout cyberspace. A reasonable reading of the fair use exception would suggest that instructors and students ought to undertake these efforts without fear of legal retribution, so long as they honor the exception's calls for "criticism, comment, . . . teaching . . . , scholarship, or research."

But these opportunities may never be realized if peer-to-peer users persist in partying like it is 1999—downloading without compunction. Thus, it falls to the academy to begin the process of demonstrating the degree to which the educational process depends upon the kinds of use and access to information that are now threatened. Not only must instructors model appropriate use and acknowledgment of others' materials when developing VLEs, they must also directly engage with the laws and policies addressing these uses. Unless those whose work depends upon use of and access to copyrighted materials offer cogent and compelling rationales for their activities, the developing mischaracterization of peer-to-peer transfers as at best suspect and at worst piratical will continue to reverberate throughout U.S. copyright law. And the trend toward replacing free resources with less attractive "pay for play" services will accelerate.

To date, the rhetorical strategies exemplified by Lars Ulrich have carried the day. Surely, the distributed international network of peer-to-peer users, many of whom are among the most educated and technologically savvy members of their communities, can collaborate to produce a stronger argument.

Chapter 54: Virtual Harlem as a Collaborative Learning Environment: A Project of the University of Illinois at Chicago's Electronic Visualization Lab

JIM SOSNOSKI*, STEVE JONES, BRYAN CARTER,
KEN McALLISTER, RYAN MOELLER, AND RONEN MIR

Although numerous virtual reality (VR) applications devoted to educational purposes have been developed at University of Illinois at Chicago's (UIC) Electronic Visualization Laboratory, we focus on the Virtual Harlem project because it is designed as a collaborative learning environment (CLN)—a VR application that is structured as a networked collaboration with the goal of building a model of the subject being studied (see "the Virtual Harlem Project" below for a more detailed description).

Virtual Harlem is a learning environment (Sosnoski & Carter, 2001). Visitors can enter Virtual Harlem and navigate through it as a way of learning about the historical context, the events, the everyday life of persons who were living in Harlem at the time.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1289–1320.

Unlike a conventional classroom in which the subject matter being studied is available to students mostly in textbooks, on blackboards, or in slides projected on the wall, Virtual Harlem is a locale that has to be experienced. Students enter a cityscape that can be experienced, albeit virtually, as if they were tourists visiting Harlem, NY via a time machine. To visit Virtual Harlem is to undergo a virtual experience.

Virtual Harlem is also an historical replica of Harlem, NY. during the Harlem Renaissance in the 1920s and 1930s. Scholars of the Harlem Renaissance direct their students in research that contributes to the model. Their research informs the work of students in computer science at the University of Illinois at Chicago's (UIC) Electronic Visualization Lab (EVL). Many of these students are in the Fine Arts program at UIC and they contribute their skills by creating digital replicas of the buildings, people, automobiles, and other aspects of the scenario.

Virtual Harlem is also a networked project and has been seen at VR sites from New York, to France, to Sweden, to Japan, and to Arizona. Classes in the Harlem Renaissance at various universities, for example, at the Sorbonne in Paris, France are part of the network that use Virtual Harlem to give their students a more holistic experience than books can provide.

The Virtual Harlem project at UIC has been influenced by two important VR educational applications developed at UICs EVL, namely, the NICE project and the Round Earth project. We describe these projects and indicate how they have influenced the Virtual Harlem project in the next section. Then we delineate the pedagogical rationales underlying the project. Next we describe the Virtual Harlem project as a CLN, after which we comment on two of its outcomes, and conclude with comments from our perspective on the significance of the Virtual Harlem project.

1. THE RESOURCES OF THE UNIVERSITY OF ILLINOIS AT CHICAGO'S ELECTRONIC VISUALIZATION LABORATORY

The Electronic Visualization Laboratory (EVL) at the UIC is a graduate research laboratory specializing in VR and real-time interactive computer graphics directed by Tom Defanti and Dan Sandin. Instruction at EVL is a collaborative effort of faculty in UICs College of Engineering, the School of Art and Design, and the College of Liberal Arts and Sciences.

An important focus of EVLs research has been the development of VR systems and their application to both science and art. Current research focuses upon developing the software to support collaborative, virtual environments, and the networking over which these applications are shared. Research is also ongoing to utilize video, audio, and database technologies to provide seamless, collaborative, virtual environments for design, interactive art, and data visualization.

Figure 1.

EVL seeks to provide an infrastructure for educators to collect, maintain, develop, distribute and evaluate virtual environment (VE) tools and techniques used to create learning environments. VE tools and techniques include computer-based models, simulations, data libraries, programming libraries, and user interfaces. The libraries and user interfaces encompass visual, auditory, tactile, and motion-based information displays.

After building first and second-generation immersive VR devices (the CAVE—Computer Automated Virtual Environment—in 1991 and the ImmersaDesk in 1995 Figure 1) to support tele-immersion applications, EVL is now conducting research in "third-generation" VR devices to construct variable resolution and desktop/office-sized displays. The Access Grid Augmented Virtual Environment (AGAVE), GeoWall (Figure 2), and Paris are the most recent VR devices developed at EVL.

Over the past decade, EVL has developed VR applications for collaborative exploration of scientific and engineering data over national and global

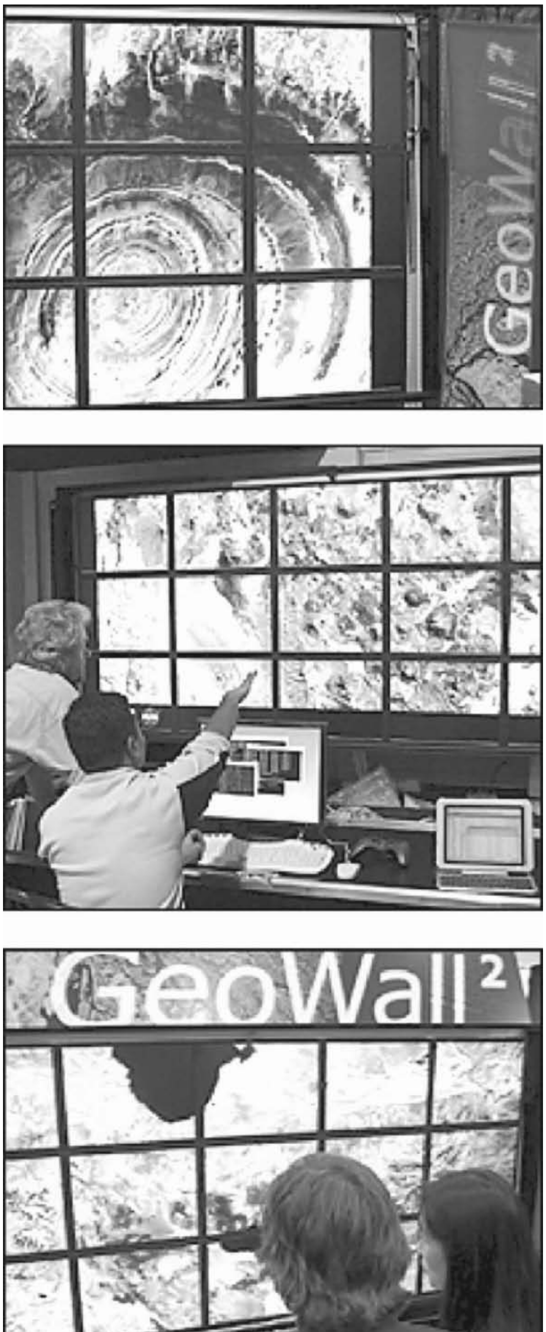

Figure 2.

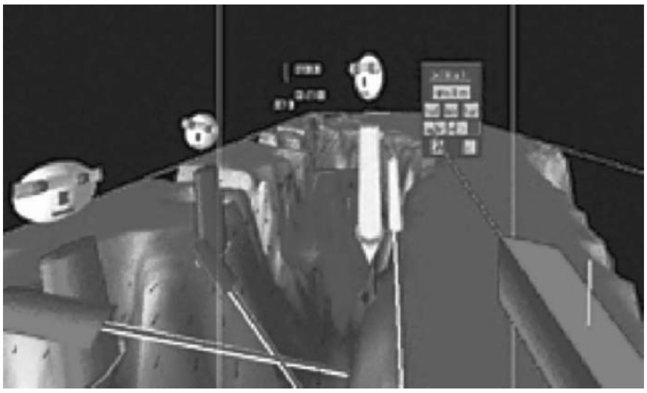

Figure 2. Continued

high-speed networks referred to as "tele-immersion" (Defanti et al., 1999; Johnson, 200; Lascara et al., 1999; Leigh et al., 1999;). Tele-immersion is defined as collaborative VR over networks, an extension of the "human/computer interaction" paradigm to "human/computer/human collaboration", with the computer providing real-time data in shared, collaborative environments, to enable computational science and engineering researchers to interact with each other (the "tele-conferencing" paradigm) as well as their computational models, over distance. Current tele-immersion research focuses on providing easy access to integrated heterogeneous distributed computing environments, whether with supercomputers, remote instrumentation, networks, or mass storage devices using advanced real-time 3D immersive interfaces.

CAVERN, the CAVE Research Network, is an alliance of industrial and research institutions equipped with CAVE-based VR hardware and high-performance computing resources, interconnected by high-speed networks, to support collaboration in design, education, engineering, computational steering, and scientific visualization.

CAVERNsoft is the collaborative software backbone for CAVERN. CAVERNsoft uses distributed data stores to manage the wide range of data volumes (from a few bytes to several terabytes) that are typically needed for sustaining collaborative virtual environments. Multiple networking interfaces support customizable, latency, data consistency, and scalability that are needed to support a broad spectrum of networking requirements. These diverse database and networking requirements are characteristics typically not exhibited by previous desktop multimedia systems but are common in real-time immersive VR applications.

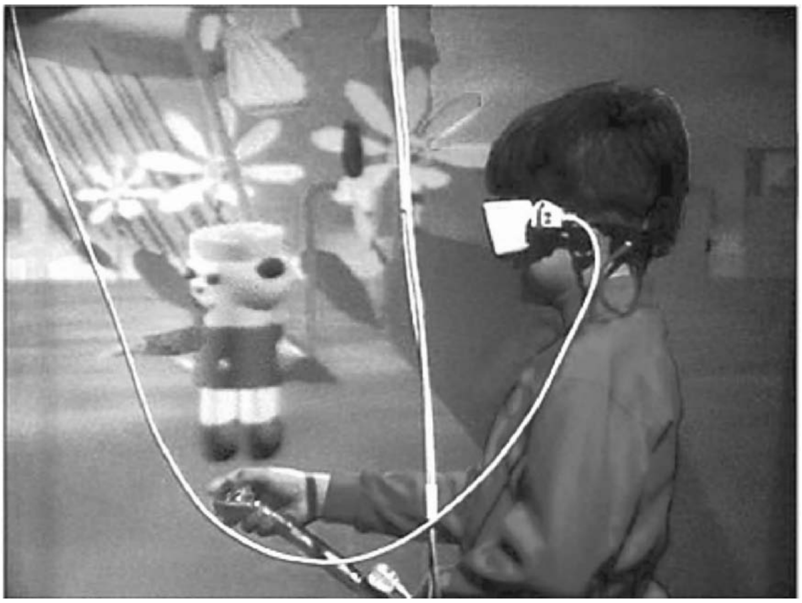
Many of the applications developed at EVL are educational. In the next section, we focus on one of them, the Virtual Harlem project because it is a good example of a collaborative learning network utilizing CAVE technology. We first delineate the pedagogical assumptions underlying the Virtual Harlem project. Next we briefly speak about the educational projects at EVL that preceded and influenced the design of Virtual Harlem. Then we speak briefly about the migration of such projects to different technological settings such as small science museums and gaming engines converted to educational purposes. After describing the Virtual Harlem project, we include a brief interview with Tom Defanti and Dan Sandin, the Co-Directors of EVL, on future directions in VR developments. We conclude with a reflection on what has been accomplished and what work needs to be done on projects like Virtual Harlem.

2. EARLY EXPERIMENTS AT EVL AND THEIR IMPACT ON THE VIRTUAL HARLEM PROJECT

In 1996, NICE was the first collaborative VR learning environment created at the EVL. The team that built NICE was: Andy Johnson, Maria Roussou, Tom Moher, Jason Leigh, and Christina Vasilakis (N-team). The NICE project was a collaborative environment in the form of a virtual island for young children. In the center of this island was a garden where the children, represented by avatars a graphical representation of the person's body in the virtual world—could collaboratively plant, grow, and pick vegetables and flowers. They needed to ensure that the plants had sufficient water, sunlight, and space to grow, and kept a look out for hungry animals which might sneak in and eat the plants (Roussou et al., 1997a, b, 1999; Johnson et al., 1998).

The N-team had just completed a project called CALVIN that allowed several remote users, each standing in a CAVE or in front of an ImmersaDesk, to collaboratively arrange objects in a shared architectural space. Some of these users moved through the space at human-scale while others were giants. The giants were better at moving furniture and walls around, while the humans were better at judging the quality of the resulting space. The design evolved over time so users could enter the space, make a change, leave, and another user could enter the space later and see the new design. When the CALVIN project ended, the N-team was very intrigued by these ideas of asynchronous collaboration and heterogeneous views, and wanted to investigate them further.

Like CALVIN, NICE supported real-time distributed collaboration. Multiple children could interact with the garden and each other from remote sites. Each remote user's presence in the virtual space was established using an avatar—The avatars had a separate head, body, and hand, which corresponded to the user's actual tracked head and hand motions.



This allowed the environment to record and transmit sufficiently detailed gestures between the participants, such as the nodding of their heads, the waving of their hand, and the exchange of objects. Voice communication was enabled by a real-time audio connection.

In NICE the N-team also included avatars that were clearly non-human. Participants could be birds or whales, or bees. It can be rather limiting to always be represented as a humanoid avatar, and there may be advantages to looking like something else. In NICE adults could share the garden with the children without appearing as obvious authority figures. Continuing with our interest in heterogeneous perspectives, the children in NICE could shrink down to the size of a mouse and walk under the soil of the garden. This also allowed a full-size child to pick up one of the shrunken kids and carry them around.

In CALVIN the virtual world only changed when one of the users changed it. In NICE the development team wanted a more sophisticated world that could evolve on its own, even when all the participants had left the environment and the display devices were switched off. NICE's virtual environment was persistent; the server was left constantly running; the plants in the garden kept growing. The plants were simple agents with common rules of behavior based on simplified ecological models containing a common set of characteristics that contribute to their growth. The combination of these attributes determined the health of each plant and its size. This also allowed them to determine the pace at which the world evolved; choosing to see the plants grow very quickly, or extend their growth over several months.

Every action in the environment added to a story that was being continuously formed. The narrative revolves around tending the garden and the decisions taken while interacting with the other characters. These interactions are captured by the system in the form of simple sentences such as "Amy planted a tomato" that go through a parser, which replaces the nouns with their iconic representations and publishes it on a web page. This gives the story a picture book look that the child could print to take home.

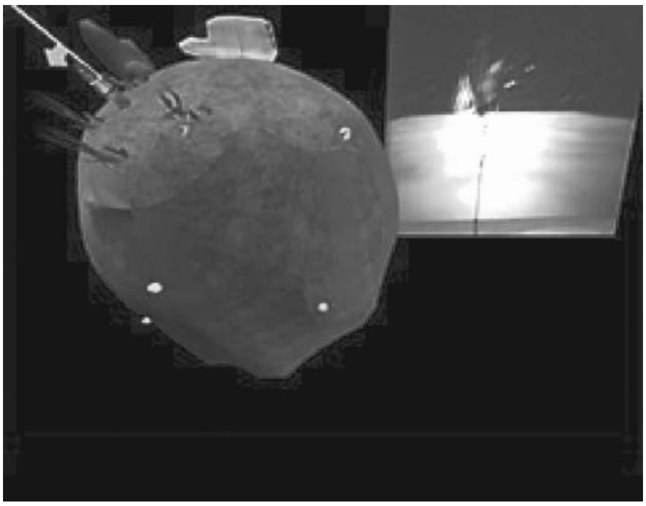
As an educational environment there were problems. The most serious shortcoming was the inadequacy of its science model. The balance among reality, abstraction, and engagement is particularly difficult to achieve; in this case the application likely veered too far from reality. Secondly, instead of directing activity toward the discovery of the underlying scientific knowledge, the N-team assumed that the desired learning would take place naturally through exploration and discovery. This obscured the intended learning goals. Thirdly, the presence of avatars representing remote users spurred social interaction, but did little to structure cooperative learning to fostered positive interdependence among learners, or support reflection and planning. Social interaction became an end unto itself, rather than a mechanism to support learning.

Overall the successes and failures of NICE significantly influenced the design of the Virtual Harlem project. NICE represented an explicit attempt to blend several pedagogical themes within a single application. Constructionism, exploratory learning, collaboration, and the primacy of narrative, reflect several of the most important educational reform themes of the past three decades. These features of the NICE project were incorporated into Virtual Harlem which was designed as a collaborative environment that emphasized the primacy of narrative in that it is a hiSTORY. As in the case of NICE, students were invited to explore Virtual Harlem and to participate in its construction.

Another project that influenced the design of the Virtual Harlem project was "The Round Earth Project". The team that developed the Round Earth project was: Tom Moher, Andrew Johnson, Stellan Ohlsson, and Mark Gillingham (RE-team). This project investigates how VR technology can be used to help teach concepts that are not a part of students' mental model of the world. Virtual reality can be used to provide an alternative view of the world that alters the representation of it based on past experiences. In particular, we compared two strategies for using VR to teach children that the Earth is round when their everyday experience tells them that it is flat (Ohlsson, 2000: 364–368).

The concept of a round Earth is not a simple one for children to acquire. Their everyday experience reinforces their deeply held notion that the Earth is flat. Told by adults that the Earth is round, they often react by constructing a mental model of the Earth as a pancake, or a terrarium-like structure with people living on the flat dirt layer inside, or even a dual model with a spherical Earth and a flat Earth coexisting simultaneously. In effect, children attempt to accommodate the new knowledge within the framework of their existing conceptual models. Unfortunately, holding tight to the features of those prior models inhibits fundamental conceptual change.

One strategy, the "transformationalist", starts the children off on the Earth and attempts to transform their current mental model of the Earth into the spherical model. The second strategy, the "selectionist", starts the children off on a small asteroid where they can learn about the sphericality of the asteroid independent of their Earth-bound experiences. Bridging activities then relate their asteroid experiences back to the Earth. In each of the strategies, two children participate at the same time. One child participates from a CAVE while the other participates from an Immersadesk. The child in the CAVE travels around the Earth or the asteroid to retrieve items to complete a task, but can not find these items without assistance. The child at the Immersadesk with a view of the world as a sphere provides this assistance. The children must reconcile their different views to accomplish their task.



Virtual reality (VR) technologies are used to support both pedagogical strategies. In the transformationalist approach, VR is used to simulate the launching of a spacecraft from the Earth's surface and subsequent exploration within a fixed-height orbit. In the selectionist approach, VR is used to simulate a small diameter asteroid. Thus learners may walk on a body with a curved horizon, see objects "appear" from "below" the horizon, take a long walk around the entire globe and come back to where they started. In both environments, distributed VR technologies are used to provide a CLN promoting positive interdependence among pairs of learners. Although we do not employ the term, "selectionist" in our account, the Round Earth Project confirmed our main hypothesis, namely that virtual experiences can occasion changes in the learner's worldview.

The importance of the Round Earth project for the Virtual Harlem project team was that Stellan Ohlsson's research confirmed that virtual experiences can provide "deep learning" alterations in the learner. Stellan Ohlsson argues that ideas which are fundamental to knowledge domains are acquired through "deep learning". He writes: "Unlike other types of knowledge, fundamental ideas cannot be acquired through discourse or concrete experience, because those ideas are the very tools by which the mind interprets both discourse and experience". Such ideas are acquired through a process he terms, "deep learning", during which the cognitive frameworks (abstract general frames or concepts) persons use to understand their experience in particular knowledge domains undergo a transformation. "New fundamental ideas are acquired by instantiating an abstract schema in a novel way; the new instantiation gradually assimilates pieces of the relevant domain, until it has effectively become the new center of that domain. Abstract schemas, in turn, are generated by combining and transforming prior schemas". His research points to the following observation: Reading about a theory has little impact on students unless they have acquired an abstract schema of the fundamental concept *in another domain*.

Ohlsson's research includes experiments with VR scenarios which provide "another domain" through which students can experience "fundamantal concepts" before they learn them in the context of the knowledge domain with which they are associated by experts. Ohlsson writes: "New technologies for presenting interactive 3-dimensional worlds have been developed at UICs EVL. This technology is a means for presenting students with alternative experiences that contrast with everyday experience in educationally relevant ways" (Ohlsson, 2000).

Working from the circumstance that the "deep learning" process is often highly "analogical", we extended Ohlsson's research into the ways in which persons map their personal worlds. Since Virtual Harlem is a representation of African American culture, it comprises a "sector of a world-map" or worldview (the mental construction of space which persons use to locate their experience of distance from their present location). One hypothesis governing the project is that "sectors" of personal worlds parallel knowledge domains. Unlike knowledge domains, however, such sectors do not provide organizing frameworks to give order to abstract concepts; rather, they provide general narratives, "configurations" of experiences.[1]

A correlative hypothesis is that configurations undergo a process of transformation similar to the one Ohlsson describes with respect to "fundamental ideas". Because configurations are the stories that are fundamental to personal maps of the world, they can be said to constitute a "cultural domain" parallel to a knowledge domain. Such domains are often shared—in the case of knowledge domains by the members of a discipline, and, in the case of cultural domains, by the members of a culture. Theoretically, then, it is possible that a person may replace a stereotypical configuration of African American culture with one that reflects its history more accurately.

The sections that follow—Virtual Harlem, the Small Science Museum, and the Learning Games Initiative projects—came to be associated with EVL through the ASCEND network directed by Jim Sosnoski. ASCEND links UIC to other educational institutions interested in developing virtual learning environments featuring computer modeling. The ASCEND network is an outgrowth of the Virtual Harlem project that has as one of its goals furthering the engaged learning experiences observed in the projects we have described.

3. CLNS AS VR LEARNING ENVIRONMENTS

There are innumerable cultural heritage (CH) projects, including a few initiated at EVL. There are fewer VR projects that are the center of a CLN (Sosnoski & Carter, 2001: 115ff.). There are several reasons for this. Unlike CH projects, CLNs require exacting research into the subject matter as well as into the technology that displays it. In addition, CLNs depend upon a collaborative network that spans a broad range of educational institutions from high schools to museums and Cultural Centers. Further, they require a subject of study that constitutes an environment learners can "inhabit" and to which collaborators with significantly different skill levels, technological savvy, scholarly acumen, and cultural perspective can contribute.

CH projects can be anything from the restoration of a homestead such as those supported by Australia's CH Projects Program (CHPP) to North Carolina's, *Exploring Cultural Heritage Online* (ECHO) whose vision is that "*All of North Carolin's cultural institutions work together to make the state's unique cultural and historical resources accessible for the education and enjoyment of people of all ages in the state, nation, and the world*".[2]

Although CH and CLN projects have cultural sites as their focal points, a CLN has to meet strict academic standards and produce historically accurate representations of the cultural site being modeled. Whereas, it is not very problematic to render an existing site accurately, it is quite another endeavor to render an historical site like Virtual Harlem accurately when the buildings, signs, and persons who inhabited in the 1920s and 1930s are available, if at all, only in photographs or written descriptions. For example, there is a VR project consisting of 16 fullscreen 360-degree panoramas of the existing Vatican's basilicas and surroundings—including St. Peter's, Santa Maria Maggiore, San Paolo Fuori le Mura, and San Giovanni in Laterano. Because the project replicates existing buildings, it is not difficult to construct accurately by using photographs with software such as Maya. However, the fact that the VR application is "accompanied by Gregorian chants performed by Mina Mazzini, Italy's legendary Diva" would be highly problematic to an historian of the basilicas.[3]

UCLA's Cultural Lab,[4] for instance, has also built a VR version of the Santa Maria Maggiore basilica, but under quite different constraints. One of the goals of the lab is the creation of scientifically authenticated 3D computer models of cultural sites. For instance, the Basilica of Santa Maria Maggiore ("St. Mary Major") which was built by Pope Sixtus III in 432–440 A.D. on the highest point of the Cispian Hill is being restored in UCLAs Cultural Lab. Because it is a "virtual model" of the historical building. it requires historical research. For this reason the UCLA Cultural Lab is associated with the Center for Medieval and Renaissance Studies.

Though similar in intention to UCLAs Cultural Lab projects, the Virtual Harlem project focuses on the historical context of the Harlem Renaissance.

4. THE PEDAGOGICAL RATIONALE FOR THE VIRTUAL HARLEM PROJECT

According to the historian David Levering Lewis, the artists and writers associated with the Harlem Renaissance configured African American Culture as a counter to the prevalent racial stereotypes hoping to influence persons who could not actually experience African American culture to reconfigure it in "their mind's eye". As improbable as it seems that narratives of African American culture might have the potential to change the worldviews of persons who had never experienced it at first hand, nonetheless, current research suggests that it can be a very effective tactic for social change (Lewis, 1997: 90).

Recent studies of "narrative impact" support this strategy of social transformation. In *Narrative Impact: Social and Cognitive Foundations*, the editors state that the subject of their book is the impact of public narratives that are aimed at persuasing the public (Green & Brock, 2002: xiii–xiv). Several contributors refer to studies that show the widespread social impact of narratives such as the Bible or Uncle Tom's Cabin. Their remarks are often based on previous research that demonstrates the role narratives have played in social change. In the Introduction to the volume, Green, Strange, and Brock note that "the impact of public narratives on beliefs and behavior has received substantial scholarly investigation in disciplines such as sociology (e.g., Gamson, 1992), communications (e.g., Bryant & Zillman, 1994; Gerbner et al., 1994), humanities (e.g., Booth, 1988), and political science (e.g., Iyengar & Kinder, 1987)" (Green & Brock, 2002: 2). Since psychological research has focused on advertising without reference to its implicit narratives, Green and Brock have conducted a series of experiments involving "imagery-rich narratives". These experiments confirm that prior beliefs can be changed by imagery rich narratives that confirm or threaten their audiences' worldviews.

Research on the phenomenon of "psychological transportation", which is defined "as a state in which a reader becomes absorbed in the narrative world, leaving the real world, at least momentarily, behind" (Green & Brock, 2002: 317), indicates that readers' propensity to experience transportation is dependent upon mental imagery evoked by the narrative. "A mental image is a representation of a particular stimulus that is formed by activation of a sensory system and, thus, is experienced by the organism as having similar qualities to the actual perception of the stimulus" (Dadds et al., 1997: 90). Such sequences of mental images contextualized by a narrative provide the sensations that accompany actual experiences. "Instead of seeing activity in their physical surroundings, transported readers see the action of the story unfolding before them" (Green & Brock, 2002: 317). Such virtual experiences, which are usually "seen" "in the mind's eye", can be remembered. When recalled, they can be applied to analogous situations in an experience transfer. Virtual reality narratives are likely to have similar outcomes.

Green and Brock's "Transportation-Imagery Model", consists of the following five postulates.

- Postulate I. Narrative persuasion is limited to story texts (scripts) (a) which are in fact narratives, (b) in which images are evoked, and (c) in which readers' (viewers) beliefs are implicated.
- Postulate II. Narrative persuasion (belief change) occurs, other things equal, to the extent that the evoked images are activated by psychological transportation, defined (below) as a state in which a reader becomes absorbed in the narrative world, leaving the real world, at least momentarily, behind.
- Postulate III. Propensity for transportation by exposure to a given narrative account is affected by attributes of the recipient (for example, imagery skill).
- Postulate IV. Propensity for transportation by exposure to a given narrative account is affected by attributes of the text (script). Among these moderating attributes are the level of artistic craftsmanship and the extent of adherence to narrative format. Another conceivable moderator, whether the text is labeled as fact or fiction (as true or not necessarily true), does not limit transportation.
- Postulate V. Propensity for transportation by exposure to a given narrative account is affected by attributes of the context (medium). Among these moderating attributes may be aspects of the context or medium that limit opportunity for imaginative investment and participatory responses. (Green & Brock, 2002: 316–317)

Restated as a sequence of cognitive experiences, Green and Brock's "Transportation-Imagery Model" would have the following stages:

1. The experience of a narration
   - which "deals in human or human-like intention and action and the vicissitudes and consequences that mark their course" and in which the sequence of events is both "logical" (cause-effect) and implicitly chronological.
   - and which portray situations that imply beliefs held by the audience.
2. The narrated events stimulate mental images from past experiences
   - that transport the audience into the world of narrative where they lose the sense of their physical surroundings.
   - and that evoke sensations (seeing, hearing, feeling) reminiscent of past experiences.
   - which are accompanied by emotions when the associated beliefs are threatened or confirmed by the implications of the narrative.
3. The narrated events enter the memory system where they can be recalled.

The flow of this "transportation" experience can be applied to VR narrative scenarios since both types of narration depend upon the impact of the mental images evoked. The major difference is that instead of "reading" the audience would be viewing the narrative. This difference is one that is anticipated by Green and Brock when they write: "The term 'reader' may be broadly construed to include listeners or viewers or any recipient of narrative information" (Green & Brock, 2002: 323).

The concepts of "suspension of disbelief" and "in the mind's eye" and both are conditions of "narrative persuasion", that is the use of narratives to change a person's beliefs and attitudes. Narrative persuasion depends upon the phenomenon of transportation. To be engaged by a VR narrative, viewers have to "suspend the belief" that they are in a darkened room looking at 3D images on a screen and listening to recorded sounds. Though readers see the narrated scene's "in their mind's eye", viewers in VR CAVEs, would seem to be looking at pictures directly. However, viewers actively supply "in their mind's eyes" much of the detail missing in the images and they also "correct" unrealistic images "in their mind's eyes". Though both of these conditions pertain to VR experiences, it is less clear that the sense of being "Lost in a book" (Nell, 1988), that is, being "transported" arises from the 3D images in the VR scenario.

In their delineation of the phenomenon of transportation, Green and Brock stress the "adherence to narrative format" as one of the chief conditions for the experience. Many VR narratives, including the current version of Virtual Harlem, do not meet this criteria. Virtual Harlem is a narrative but it lacks "story elements". For the most part visitors to Virtual Harlem experience the sequence of events that occur as they navigate their way through the cityscape as a "tour" a "chronology of events" rather than a "story". Stories set up expectations in their readers or viewers. As narratologists have argued, narratives require "resolution". Because they draw their audiences into identifications with characters in the story, the desires and conflicts they encounter are shared empathetically by readers or viewers. The difference is salient to audiences. In its format Virtual Harlem is closer to the videos one nowadays see on real-estate websites that allow you to "walk" through the rooms of a house or apartment than it is to films like *Fatal Attraction* whose audiences shouted at the screen in the climatic bathroom scene where Alex (Glen Close) attacks Beth (Ann Archer) only to be saved by Dan (Michael Douglas).

Admittedly, Virtual Harlem or its recently developed companion, Virtual Monmartre, are not yet ready to transport their audiences into history. However, it is not beyond the capacity of VR scenarios to do so. In 1999, when we frequently gave tours of Virtual Harlem at UICs EVL bat-CAVE, we liked to follow it with Josephine Anstey's "The Thing Growing", a VR short story. Her website describes "The Thing Growing" as "a work of fiction implemented in VR, in which the user is the main protagonist and interacts with computer controlled characters.[5] It was originally built for a CAVE VR system at the Electronic Visualization Laboratory between 1997 and 2000. We believe intelligent agents are crucial elements for dramatic VR applications. The Thing was our first attempt at building a responsive character—a manipulative creature designed to encourage the user to jump through emotional hoops". As a VR narrative, "The Thing Growing" visualizes a short story Anstey had been writing in which she "wanted to explore a relationship that was cloying and claustrophobic but emotionally hard to escape. An immersive, interactive VR environment seemed an ideal medium to recreate the tensions and emotions of such a relationship".

"The Thing Growing" begins with a stark landscape in which a box is visible. Soon, the audience hears "Let me out" repeated in louder and louder tones. With instructions from the "voice" to use the remote control in the hands of their "leader", the audience frees her with a key that the remote becomes as it is pointed toward the screen. She jumps out and exudes joy, praising the audience. After a few moments, villainous figures appear in the landscape and the voice begs the audience to save her. Again following the voice's instructions, the audience, using their remote device which now looks like a gun, shoots the villains who disappear at they are hit. Again the voice expresses delight, suggesting that she and the audience leader dance. Once again giving instructions, this time by waving her arms up and down, she invites the leader to dance. If the leader does not move his remote in the manner she suggested, she complains loudly that the leader is not dancing with her. Depending on whether the leader "dances" or not, the voice becomes increasingly domineering and emotionally ruthless. After a time, the audience finds itself desperate to get out of the situation. Finally, again depending on the tactics of the leader, the voice is either killed by the remote control which still has the capacity of a gun, or after a lengthy period, she dissolves.

This story does succeed in transporting many of its viewers. Members of the audience have shouted at the screen and demand for her to stop berating them. One viewers shouted, “get me out of here”. Most find the experience disconcerting and even embarrassing if they decide to kill the voice. Some leaders, including women, shot the voice without compunction and expressed delight at being rid of her. “The Thing Growing” website concludes its gloss on the VR story with the following passage:

> We believe that the use of narrative techniques can enhance interactivity in VR. Andrew Glasner suggests that, for the construction of interesting computer fiction, the author should control the sequencing of events, and the creation of a causal chain of action. Therefore the narrative in The Thing Growing has the classical bridge structure of plays and films; act one introduces the protagonists and the goal; act two revolves around struggles to reach the goal; act three resolves those struggles. The difference in our case is that the user is one of the protagonists and in each act she is involved in interaction. The narrative as a whole is moved on either as a result of the user’s actions, or by time.

Although we did not obtain a grant to incorporate stories into Virtual Harlem, we did design a story format, though not as yet a very dramatic one since we did not have the narrative freedom Anstey had because we were doing an historical narrative. We commissioned two stories based on the format we designed. As the project stands, we have some preliminary evidence from surveys we have conducted that visitors to Virtual Harlem have reconfigured their view of African American culture as a result of their experience of Virtual Harlem. The more systematic evidence that The Round Earth project and certain uses of VR in medical fields can produce effective learning experiences combined with audience feedback from Virtual Harlem warrant its further development.

5. THE VIRTUAL HARLEM PROJECT

In *When Harlem Was in Vogue*, David Levering Lewis makes the case that the Harlem Renaissance is one of the most significant eras in African American cultural history. Harlem, NY, is commonly thought to be its cultural center.

> The decade and a half that followed World War I was a time of tremendous optimism in Harlem. It was a time when Langston Hughes, Eubie Blake, Marcus-Garvey, Zora Neale Hurston, Paul Robeson, and countless others made their indelible mark on the landscape of American culture: African Americans made their first appearances on Broadway;

chic supper clubs opened on Harlem streets, their whites-only audiences in search of the ultimate "primitive" experience; riotous rent parties kept economic realities at bay while the rich and famous of both races" outdid each other with elegant, integrated soirees.

(Lewis, 1997, from the back cover of the paperback edition)

Until recently Harlem has been a forgotten site of American cultural history. Even today, its history remains largely unknown. This important cultural locale during the period that came to be known as the Harlem Renaissance needed to be represented as a part of the history of American culture. For this reason, Bryan Carter proposed that a VR representation of Harlem, NY in the 1930s would make a powerful component of courses in the Harlem Renaissance. The Advanced Technology Center at the University of Missouri accepted his proposal, which resulted in the creation of "Virtual Harlem", one the earliest uses of VR technology as a way of telling history.

Virtual Harlem is a digital model of 1930s Harlem, N.Y., at the height of the Harlem Renaissance. At this point in time, the model includes about 10 blocks of Harlem out of the 20 or so that are associated with Harlem during its Renaissance. Virtual Harlem includes buildings such as the Savoy, the Lafayette Theatre, and the Cotton Club; the only building that can be entered. As visitors move through the streets, they can encounter several famous figures-Langston Hughes, Marcus Garvey, and Paul Robeson, as well as several residents of Harlem in the 1930s in routine activities. Cars and trolleys move up and down the streets. Inside the Cotton Club, one can watch several very brief performances. In sum, this seminal model already presents a rich, though incomplete, environment to visitors. The team that began the Virtual Harlem project at the University of Missouri was Bryan Carter, Bill Plummer, and Thaddeus Parkinson. Since 2001, when the project moved to UIC, the team that is now continuing to develop Virtual Harlem is: Bryan Carter, Jim Sosnoski, Andy Johnson, Jason Leigh, Steve Jones, Tim Portlock, Kyoung Park, and Chris White.[6]

The digital model of Virtual Harlem can be accessed through several delivery systems. The fullest version, the immersive CAVE environment (see above) requires visits to a lab such as UICs Electronic Visualization Lab to experience the VR scenarios though it is available to be shown on the Immersadesk as well as on the AGAVE Geowall. Every effort has been made to allow for work done at the higher end to be translatable into programs at the lower end so that it can be circulated at locations that do not have high-end equipment. Even more important is the fact that work done at the lower end can be translated into higher end software. From a practical point of view, this enables students who have relatively modest experience with technology to contribute to the project and find their contributions shown in more sophisticated versions of Virtual Harlem. A 3D version of Virtual Harlem is available on the WWW. Several videotapes of Virtual Harlem tours are available and, upon

request, specific tours can be videotaped for particular groups. CD-ROMs of Virtual Harlem can also be made. Finally, web sites on Virtual Harlem are accessible through standard browsers the network's content.

An important aspect of the project is that it produces many versions of Harlem. This allows for alternative views of Harlem during its Renaissance. Constructing the definite Harlem is not the goal of the project. Instead, showing Harlem's past as one that has been constructed by its proponents and displaying the variety of perspectives that have been used in interpreting the Harlem Renaissance is its goal.

As a virtual experience of cultural history, the Virtual Harlem project serves as a prototype for similar projects being developed of the Bronzeville neighborhood in Chicago and Montmartre in Paris which are also significant sites for African American Culture in the 1930s. What is special about the Virtual Harlem project is that it is designed as a collaborative learning network—the builders of Virtual Harlem are collaborators in a network the aim of which is to learn about the Harlem Renaissance. Persons who are interested in the Harlem Renaissance or Harlem, NY. can contribute to the building of the model(s) as long as they follow the project's protocols. In addition, like other visualization projects (where models are constructed of the subject matter being studied), the cross-disciplinary collaboration is extraordinary (see below). These aspects of the project render it a potential prototype for other endeavors involving new instructional technologies.

As we envision it, a collaborative learning network (CLN) like virtual Harlem—because of its complex structure—requires that persons in the network be both teachers and learners. The technical staff has to learn about the Harlem Renaissance from the non-technical staff. Similarly, the non-technical staff has to learn about the technologies of networking from the technical staff. It may be helpful in understanding the structure of a CLN to introduce the idea of a "learning pathway". Sometimes discussions of learning seem to imply that learning takes place ONLY in a classroom. As we all know this is far from the case. We often learn more outside the classroom than in it about a particular subject. For this reason, and because the Virtual Harlem project requires students to go outside of their classrooms and visit other sites, we describe several typical learning paths (movements from site to site) that occur in the Virtual Harlem project. Let's begin with a student taking a course in the Harlem Renaissance.

If we think of a learning pathway as a journey of discovery, then we might designate a conventional English literature classroom as the site of departure. A student may be assigned to read a work introducing the Harlem Renaissance as a period of literary history from her textbook. This would lead her home or to the library where the reading might take place before she returns to the classroom. This "trip" would be repeated many times in the learning path. At some point, that student may go to the immersion CAVE instead of the classroom and experience Virtual Harlem, followed by a trip to a computer center to record her response to it. If she decided as her term project to take on a research endeavor that culminated in adding some information, say about a building that was yet to built in Virtual Harlem, this would necessitate a trip to the library and/or to a computer lab with internet access in search of photos and accounts of, say, the Dark Tower (an important salon). This decision would likely lead to the preparation of a research paper not only submitted to the instructor but also presented for "publication" in Virtual Harlem. Since a literature student or instructor would probably not be able to build a 3D Dark Tower into the VR scenario, the "publication" of the Dark Tower would be handled by someone who could.

The learning path of the literature student, in all likelihood, would have to intersect with the correlative learning paths of several other students before the Dark Tower could be added to Virtual Harlem. These intersections would "deepen" the learning experience to the extent that the students and instructors involved were in dialogue with each other. Without going into the same detail, I hope it is easy to imagine an engineering student beginning his learning path in a classroom on C++ in the Engineering building and at some later point taking on the project of constructing in 3D code the image of the Dark Tower as his term project. A third student in Fine Arts might start out in a computer graphics class in the School of Art and Design and follow a learning pathway that eventually intersected with the first two students adding an aesthetic dimension to the design. A Women's Studies student might intersect with the group in an effort to portray the women in the Dark Tower setting accurately. If by collaborating they took perspectives on the materials that they would not otherwise have considered into account, this circumstance would enrich their learning experience.

Since it would be tedious to read the details of the many additional learning pathways that might intersect or be juxtaposed to those we have mentioned, we ask you to imagine the likely collaborative learning pathways that would go into building the Dark Tower into the current cityscape. Envision, for instance, students with a history or cultural studies learning pathway intersecting with the learning paths we've identified. Consider students from psychology or sociology or urban anthropology who might be studying the impact that the Dark Tower is having on visitors to Virtual Harlem. And let's not forget the dramatic scripts that creative writers and theatre students need to write and enact in order to dramatize the events that took place in the Dark Tower.

These learning paths would also inevitably intersect with those of students from other universities who were researching the Dark Tower or some of the persons that were its habitual guests. If the learning paths did not intersect smoothly but, instead, clashed and contradicted each other, the learning would take another turn as students would then be forced to encounter perspectives they had never before engaged, a likely scenario as more universities from abroad join the network.

Though the network formed by the intersections of these varied learning paths has the potential to be quite volatile, it is nonetheless governed by the same set of research ideals its professorial constituents are advocating and the situation is potentially a mirror of any lively intellectual or discourse community, which Mary Louise Pratt aptly describes as a "contact zone". All the learning paths come into contact with each other because they all lead to Virtual Harlem. Ideally, all paths are attempts to visualize the past.

Within this framework, everyone in the network is both teacher and learner at some level or with respect to some area of study. The unusual combination of disciplines in the project—African American culture, literary, historical, urban, gender, social, anthropological, artistic, graphic, dramatic studies, communication, psychology, engineering, computer science, and visualization—mandates that no one person in the network will be the master of any one perspective. At the same time, the diversity of perspectives allows each person in the network to view the subject matter and the technology from a previously unfamiliar perspective. Moreover, since the project is based on VR scenarios at the higher end of the technological spectrum, a certain excitement is continuously generated, especially when persons enter the network and view the work that has been completed.

There are several features of the Virtual Harlem project that contribute significantly to its potential as an instruction technology. From the point of view of its subject matter, Virtual Harlem is a learning environment in which participants virtually experience a dramatic, visual history centered in Harlem, New York during its "Renaissance" period. From the point of view of the mode of learning, Virtual Harlem is an environment that enables a subject matter like the Harlem Renaissance to be studied by modeling its historical context as a dynamic system of social, cultural, political, and economic relations, that is, as a "neighborhood". From the point of view of learning outcomes, Virtual Harlem is an environment that configures its visitors as a set of cultural counter-stereotypes.

Because of its subject matter—the Harlem Renaissance—this project has the potential to link scholars and students from all over the world who are studying and researching African American culture into a learning network. At the time of writing, nine universities and one super computer center are associated with the Virtual Harlem network: University of Illinois at Chicago (UIC), Central Missouri State University (CMSU), the University of Missouri-Columbia (MU), the University of Arizona (UA), Columbia University (CU), Växjö University, Sweden, Morgan State University (MSU), Vassar College (VC), the Sorbonne IV, Paris, and the SARA Super Computing Lab in Amsterdam. Several of these universities have already been linked to each other for discussions of the Harlem Renaissance in connection with courses about it. The Virtual Harlem CLN also has the potential to introduce learners to systems thinking and visual thinking, two evolving modes of intellection that have come to the forefront as educational goals due to the increasing availability of computer assisted learning (Park et al., 2001; Sosnoski & Carter, 2001).

As a consequence of interest in the Virtual Harlem project, the ASCEND network was created to link universities to other types of learning centers, for example, to small science museums.

6. VIRTUAL HARLEM AND THE SMALL SCIENCE MUSEUM LEARNING ENVIRONMENT

SciTech Hands On Museum located in (Aurora IL, U.S.A., just west of Chicago) joined the ASCEND network in 2001 to test and evaluate the VR hardware and software developed at EVL. By the summer of 2002 the first museum prototype VR learning lab was established at the museum with a Geowall on loan from EVL. SciTech's VR lab is beginning the process of testing and evaluating VR environment as it applies to museum visitors. Based on initial positive results, it is foreseen that the SciTech pilot implementation of VR will be expanded to other science museums in the near future. The team that is developing VR environments for small science museums in collaboration with EVL is: Ronen Mir, Diana Zajicek, and Sammy Landers from SciTech Hands On Museum, Aurora IL USA. Marcelo Milrad from Växjō University, Sweden, in association with Xperiment Hus, is engaged in extending the project to small science museums in Europe.

In the summer of 2002, VR Technology was brought to SciTech by a team from EVL headed by Andy Johnson and Jason Leigh. The lab for the VR set up is a $17' \times 20'$ room used previously as a computer class. The first thing that we did was to paint the room a dark color to give the feeling of entering a theater. Next, we made and framed an opening in one of the walls in the enclosed space to house the screen. The computer is located in the enclosed space with the projectors. The monitor, the keyboard, and the mouse are out at a station for the operator to use when setting up for a show. The last thing that we did was to install a curtain to keep ambient light from entering the viewing area. In a short time, the renovation of a room to use as a VR lab and the installation of VR equipment was completed.

The VR set up at SciTech has the following specifications:

screen; 5′ long, 4′ high
user area; 9′ × 6′
rear projection (This system looks a lot better and makes a better experience since the viewer can get closer to the screen)
"starter" 3D model viewer application
rear projection requires 10′ behind the screen for the projectors
dark room not necessary, but dimly lit is preferred
best to stand about 4′ back from the screen for viewing
PC (Windows XP and Linux 7.2) platform used at SciTech
This system consists of joystick-controlled navigation of a set of 3D models a stereo projection upon a 6′ screen, viewed with special polarized glasses.

We found it necessary to have a staff member to run programs and assist visitors.

The first phase of VR presentation at our site is ongoing and has consisted mainly of short, less than 30 minutes, VR sessions, in which a trained museum staff member has introduced the concept of VR to a variety of visitors to the museum, museum staff, and board members. This introductory session has included: definitions of VR, a short explanation of the operation of the system in use at SciTech, an opportunity for viewers to manipulate the 3D models themselves. During the exploration of the available models, a trained SciTech staff member provides commentary about the models viewed, and answers questions. At the conclusion of this session, an informal evaluation of the experience is conducted and results recorded.

Since the VR equipment has been up and running, the VR lab has had approximately 500 visitors, a fairly even mix of adults and children, ranging in age from 7 to 75 years of age. Their comments on the experience have included both positive reactions: "Enjoyed it very much"!, "It was a wonderful thing", "Very cool"! "Loved it"!; "It was good"; and critical ones: ". . . makes the stomach queasy if you move around a lot"; ". . . liked all the different models"; "I think you should put chairs (in)". The development of educational programming is underway. Several approaches to the use of VR are being considered. Descriptions of two scenarios follow.

There are noteworthy limitations to the current VR set up at SciTech. Our set-up is fairly rudimentary. At the present time, the number of applications that can be deployed to SciTech is restricted because we can only run environments that are based on OpenGL or OpenInventor. Most of the VR worlds are still built on the Silicon Graphics machines, so there is a certain amount of work needed to port them to a personal computer. On the less technical side, the room in which SciTech's VR set up is housed is small limiting group size to 6–8 people. We find it difficult to stop people from touching the screen, which destroys its ability to preserve the passive polarization. Simulator sickness may be an issue. Projector based systems have a much lower rate of simulator sickness than head mounted displays and having a non-tracked system definitely reduces the amount even further, but a visitor can still get sick from watching a friend play a first-person shooter, so odds are that this will make a small percentage of people sick. Therefore we are showing 3D models floating in space rather than terrain to explore. We need to consider seating or a railing.

As part of SciTech's mission to make technology and science concepts accessible and exciting through exploration and discovery, an experience based on the concept area of perception is one avenue for development. This would include: definition of perception, types of perception, scientific methodology, avenues of investigation, scientific tools, types of models, VR as a tool for exploration, and manipulation of the world around us.

A second area of development focuses on the content related to the VR 3D models at our disposal. At present, these models include: an ant, a bee, Round Earth, The Solar system, The Wright Brothers Airplane, A Human Heart, and Lungs. A model-based experience would address SciTech's goal to enhance the public understanding of science and demonstrate its relevance in everyday life. This experience would be based on exploration of and hands-on activities relating to a pre-selected 3D model, e.g., the heart. The organizational model would be a series of exploration stations through which the learners would proceed in small groups. The stations could include: manipulation of 3D VR heart-lung model, internet virtual field trip; e.g.—a trip down a coronary artery, brief description of circulatory system, perhaps a video, create a poster of the heart and lungs using an overhead projection, create a simple lung model from a soda bottle, balloons, etc., heart rate, pulse and exercise activity web worksheet directed research, students model the heart and blood flow using themselves as parts of the model, tennis ball heart action simulation.

Our long-term VR goals include:

The construction of a dedicated VR environment on SciTech's main floor, and the development of additional educational programs to be used therein.

Expansion of VR experience to include not only science and technology, but also the areas of art, history and entertainment.

Implementation of similar systems in other museums with which SciTech collaborates.

Complementing the ASCEND experiments in non-university learning environments like SciTech, are experiments with non-academic technologies such as computer games.

7. VIRTUAL HARLEM AND THE LEARNING GAMES INITIATIVE

We regard computer games as virtual learning environments. The technology behind computer games runs in parallel with the technology behind VR applications. Virtual Harlem, for example, can be seen on a game engine and in collaboration with the Virtual Harlem project team, we have been considering introducing dramatic elements into the cityscape drawing upon game design. In collaboration with the ASCEND network, the Learning Games Initiative (LGI) team at the University of Arizona (Ken McAllister, David Menchaca, and Ryan Moeller) is working to accomplish three objectives:

1. Study: members of LGI use a variety of multi-disciplinary analytical techniques to reveal and understand the ways in which sociocultural tensions are embedded in, imposed upon, and taught through games;
2. Teach: members of LGI work to develop pedagogies that teach these analytical techniques to students so that as computer games become ubiquitous and their ideologies are naturalized in players, students will have a set of critical skills that they may use to critique them;
3. Build: members of LGI work to develop new games that draw upon their critique-oriented knowledge of computer games in order to generate new and more complex opportunities for game developers and game players.

Each of these areas is deeply informed by a wide range of multidisciplinary research, including sociology, cultural history, graphics programming, audio engineering, rhetorical studies, political science, music composition, media arts, communications, literary studies, philosophy, military science, pedagogy, organizational studies, and graphic design. In the remainder of this section, we will briefly discuss some of the current research and useful practices employed by LGI and others in these three areas.

There are basically two points of entry for the study of computer games: the point of production and the point of consumption. In both cases, there is a wealth of available material for scholars to examine, some of it originating in the academy and some in the materials circulating in the gaming industry. On the academic side, work that studies the psychophysiological nature of computer game playing (e.g., research on how computer games shape players' minds and bodies) is particularly abundant. It is in this area that one finds the dozens of studies attempting to discover causal relationships between computer game play and sociopathic and behavioral problems, the research on a variety of physical ailments caused by computer games (e.g., repetitive motion disorders and seizures), and the research on how computer games may or may not facilitate non-game related skill acquisition (e.g., accurately assessing collision probabilities, effectively interacting with complex dynamic systems, and the improvement of mental focus). Related to this is the application of anthropometrics to the development of alternative input/output devices and channels.

An emerging area of research in the academy focuses on the cultural implications of computer games, and studies, for example, how race, gender, sexual orientation, and class are constructed in particular games. Much of this research is to be found in academic publications like the journal *Game Studies* and *The Journal of Popular Culture*, although there are an increasing number of book-length treatments of these topics. Initially, members of LGI have focused their efforts on studying and applying multidisciplinary approaches to the study of computer games. Additionally, LGI members work to harness the learning elements inherent in computer game play to enhance the study of topics unrelated to game content—for instance, using computer game interactivity to study collaboration, communication, role-playing, task-oriented decision-making, analytical and organizational skills, and so on.

Most academics interested in studying computer games have not had the luxury of formal training in this area (e.g., "game studies"). Rather, they tend to be scholars who are naturally inclined to interdisciplinary work in interactive media, and as a loose collective comprise a rapidly advancing area of research and teaching. Much like the structure of Film Departments to which they are sometimes compared, the fledgling academic programs to which these teacher-scholars migrate tend to combine the technical skills of development with the critical skills of close technical, aesthetic, historical, and cultural analysis. Some programs emphasize certain skills over others due to particular resources available on different campuses: Some programs emphasize game programming, while others specialize in visual studies, narratology, or music. Increasingly, however, academic programs are being developed that consist of multiple tracks that combine basic programming skills (especially the mastery of scripting languages, such as Lingo and Actionscript for Macromedia Director and Flash, respectively) with advanced design concepts, or vice versa: advanced programming skills with basic design concepts. In programs such as these, both tracks culminate in the development of a playable computer game.

The Learning Games Initiative at the University of Arizona takes a somewhat different approach than other programs by focusing first on "reading" games as complex techno-cultural artifacts, then using these "reads" to build provocative educational games. LGI members are concerned with how games manifest various sociocultural dynamics through the design of non-player characters, level and interface design, types of interactivity, placement and content of cut scenes, audio effects and music choices, point of view and camera placement, and so on. This deeply interdisciplinary work requires its members to have a broad range of both analytical and technical skills. For this reason, LGI members rely upon their peer practitioner-scholars to learn, for instance, how an openGL programmer "sees" a game, or how a poet or priest "reads" a game's metaphors and justificatory logics. As a result of their ability to see computer games in such an unusually expansive way, LGI members are then able to teach these ways of seeing to their students.

The mechanisms behind this educational process are straightforward. LGI members participate in collective knowledge building by sharing research and teaching techniques via an electronic forum, and they meet twice a month for "Game Night", an opportunity for LGI participants to gather face to face and closely examine a particular game. From these two practices have emerged a variety of pedagogical tools that concern computer games, including instructional videos, how-to guides, course curricula, conference talks, and the development of educational game mods built from commercial game engines like *Quake* and *Neverwinter Nights*.

The third point of entry to studying computer games exists at the point of production. Here, LGI relies upon methodologies suggested by anthropologists and artifact historians: Investigate the techniques of production in order to extrapolate and interpret the cultural ideologies that support and inform such techniques.[7] LGI incorporates the research and teaching of its members into the actual production of complex educational games using a variety of commercial game engines. LGI wants to know what can be learned about computer gaming and classroom space, for example, especially when the latter has been reproduced digitally, using software designed to support a first-person shooter like *Quake* or a role-playing game like *Neverwinter Nights*.

LGI members hold that participation in the construction process is a vitally important part of gaining a complex cultural understanding of computer games. Such an understanding makes visible the constraints and operating assumptions of commercial game production—including, for example, issues concerning audience, content, timeliness, complexity, and playability. It also provides participants with an intimacy with production techniques uncommon in more traditional artifact studies, which are often removed in time, space, and circumstance from an artifact's method of production.

The study and use of computer games in educational settings works to enable students to develop the skills necessary to critically examine all aspects of game design. By understanding computer games as both commercial artifacts and as components in a much more complex sociocultural dynamic—that is, a material object that is continually reconstructed in play—students simultaneously learn the skills necessary to critique all those other elements of popular and specialized culture in which elements of Vr are used to shape belief and manufacture knowledge.

Since its creation in 1996, the Virtual Harlem project grown into a research network. Our belief is that the project demonstrates the vital importance of VR instructional technology to the humanistic disciplines.

8. CONCLUDING REMARKS: CONFIGURING THE PAST

Virtual Harlem is a visual history. Techniques of computer simulation and visualization have been developed to the point that it is now possible to present historical events in virtual space and time, not only showing the location of the event but also tracking it through a temporal sequence. Virtual Harlem, for example, is the most important historical location for events that comprise what literary historians refer to as the Harlem Renaissance. Technically, it is possible to show temporal sequences, or, for example, one can visit Virtual Harlem during the day and then later at night. Although, the project has not yet developed to this point, we plan to show the historical changes in Harlem from the 1920s to the mid-1930s. Concomitantly, we intend in our design to show the periods within the Harlem Renaissance that correspond to those changes by indicating the development or demise of movements and periodicals, the migration of artists and musicians, the changes in the character of the neighborhood.

Virtual Harlem is a dramatic presentation of the history of the Harlem Renaissance. Scripts of everyday life are built into the presentation to dramatize the historical events (see Sosnoski/Portlock). Students can interact with figures that "live" in Virtual Harlem and whose character and behavior are as historically accurate as we can make it. Though such experiences are fictive by definition, the dramatizations are governed by an effort to interpret what it felt like to live in Harlem during the 1930s and to encounter the many great artists who worked there. While admittedly an unconventional form of history telling, whose historiography has yet to be developed, every effort is being made to give students an experience of the past that matches scholars' interpretation of it. The governing genre in this endeavor is history, not fiction, not even historical fiction. The fictive elements arise from the absence of video or audio documentation. Whereas it is possible to write sentences such as "residents of Harlem could purchase the 'Crisis' at a local news stand, a dramatization of that event requires a specific figure to approach the news stand and ask for a copy of the 'Crisis' ". Since we do not have photographs of that event or recordings of what was said, that figure in Virtual Harlem cannot not represent a actual person who lived in Harlem at the time. Yet, to dramatize the historical generalization (residents purchased the 'Crisis' at local news stands) does not entail the genre of fiction. The stories told in Virtual Harlem are governed by historical constraints.

Hypothetically, Virtual Harlem is a “dynamic system of relations”. Virtual Harlem is comprised of many elements: buildings, people, cars, events, communications, markets, and other phenomenon. These elements can be understood as a “neighborhood”, a dynamic system of relations. People live in buildings, pay rent, buy goods, make decisions, respond to injunctions, talk, sing, dance, drive, and involve themselves in multifarious relations with the other elements in the immediate environment. Computer models allow for the computation of a variety of possible systemic relations and provide a way of understanding the historical period. “Systems dynamics” has been used for years as an instructional technology both in this country and abroad. This approach, as we tried to suggest above, is built into Virtual Harlem.

From another perspective, the Virtual Harlem project is a project in “urban archeology”. We have plotted out the surface of historical Harlem and drawn a map of its topography. At various locations on the map, we have dug deeper into its history to obtain a closer look at the development of that site. For example, whereas some buildings are no more than facades to mark the space they occupied at a particular moment in history, others can be explored in much more depth of detail. What the researchers unearth about a particular place, is then recreated virtually. As a representation of a “neighborhood” in a city, the Virtual Harlem project can be extended to other neighborhoods in New York City. As a representation of a city, the Virtual Harlem project can be extended to other cities and their neighborhoods.

The significance of the Virtual Harlem project is the use of VR technology to model a humanistic subject. It opens the door not only to new modes of learning but also to new modes of historiography and interpretation as well as inter-disciplinary collaboration.

ENDNOTES

1. Configuring is a cognitive process through which persons create virtual experiences by re-assembling their past experiences into one that provides an analogous pattern to the one they are presented in VR applications or other modes of simulation ranging from TV and film to literary and artistic artifacts. See Sosnoski forthcoming.

Chapter 55: Video-as-Data and Digital Video Manipulation Techniques for Transforming Learning Sciences Research, Education, and Other Cultural Practices*

ROY D. PEA
Stanford University, Stanford Center for Innovations in Learning

1. INTRODUCTION

This chapter concerns the theoretical and empirical foundations and current progress of the Digital Interactive Video Exploration and Reflection (DIVER) Project at Stanford University. The DIVER Project aspires to accelerate cultural appropriation of video as a fluid expressive medium for generating, sharing, and critiquing different perspectives on the same richly recorded events and to work with others to establish a Digital Video Collaboratory (DVC) that enables cumulative knowledge building from video-as-data for discovery and commentary. These uses of digital video manipulation are very distinctive from those used in virtual-learning environments today across K-12, higher education, and corporate training (e.g., BlackBoard, WebCT, PlaceWare), which are primarily video clips that are used to illustrate a point or concept during a lecture or a video of a faculty member teaching and using PowerPoint slides.

The DIVER system distinctively enables "point of view" authoring of video tours of archival materials (from video to animations and static imagery) in a manner that supports sharing, collaboration, and knowledge building around

* DIVER™, WebDIVER™, Dive™, and "Guided Noticing"™ are trademarks of Stanford University for DIVER software and affiliated services with patents pending. The DIVER project work has been supported by grants from the National Science Foundation (#0216334, #0234456, #0326497, #0354453) and the Hewlett Foundation. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author and do not necessarily reflect the views of these funders. Roy Pea served as lead author with contributing authors Ken Dauber, Michael Mills, Joseph Rosen, Wolfgang Effelsberg, and Eric Hoffert for portions of earlier versions of some of the text material provided here regarding DIVER. Ray Pacheone, Randall Souviney, and Peter Youngs have been instrumental in our thinking of DIVER in the teacher preparation and certification context. Brian MacWhinney was an additional key collaborator in conceptualizing the Digital Video Collaboratory characterized in Section 8.0.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1321–1393.

a common ground of reference. A fundamental goal is user-driven content re-use, prompted by the desire of content users to reinterpret content in new ways, and to communicate and share their interpretations with others, for purposes ranging from e-learning to entertainment.

DIVER makes it possible to easily create an infinite variety of new digital video clips from a video record. A user of DIVER software "dives" into a video record by input controlling—with a mouse, joystick, or other input device—a virtual camera that can zoom and pan through space and time within an overview window of the source video. The virtual camera dynamically crops still image clips or records multiframe video "pathways" through normal consumer 4:3 aspect ratio video or a range of parameters (e.g., 20:3) for video records captured with a panoramic camera,[1] to create a dive™ (a DIVER worksheet). A dive is made up of a collection of re-orderable "panels", each of which contains a small key video frame (often called a "thumbnail") representing a clip as well as a text field that may contain an accompanying annotation, code, or other interpretation.

After creating a dive using the desktop DIVER application, the user can upload it onto WebDIVER™, a website for interactive browsing, searching, and display of video clips and collaborative commentary on dives. In an alternative implementation, one can dive on streaming video files that are made accessible through a web server over the internet, without either requiring the downloading of a DIVER desktop application or the media files upon which the user dives.

In the desktop DIVER implementation, the dive itself is packaged automatically as an Extensible Markup Language (XML) document with associated media files. XML is the universal language approved in 1998 by the World Wide Web Consortium (W3C) for structured documents and data on the web. The web representation of the dive includes the key frames, video clips, and annotations. A dive can be shared with colleagues over the internet and become the focus of knowledge building, argumentative, tutorial, assessment, or general communicative exchanges. A schematic representation of the recording, "diving", and web-sharing phases is shown in Figure 1.

Much of our primary DIVER work involves scenarios in which a video camera is used to record complex human interactions such as the behavior of learners and teachers in a classroom, or research group meetings. One may capture video directly into DIVER using DIVER's MovieMaker feature with a digital video camera connected by FireWire to the computer, or use DIVER's MovieImporter feature to bring in as source material previously captured video. A 360° camera may also be used to capture panoramic video of the scene—but before discussing the rationale for panoramic video recording, it is important to establish why it is that video-as-data and digital video manipulation techniques such as those that DIVER represents are critical for transforming learning sciences research and educational practices.

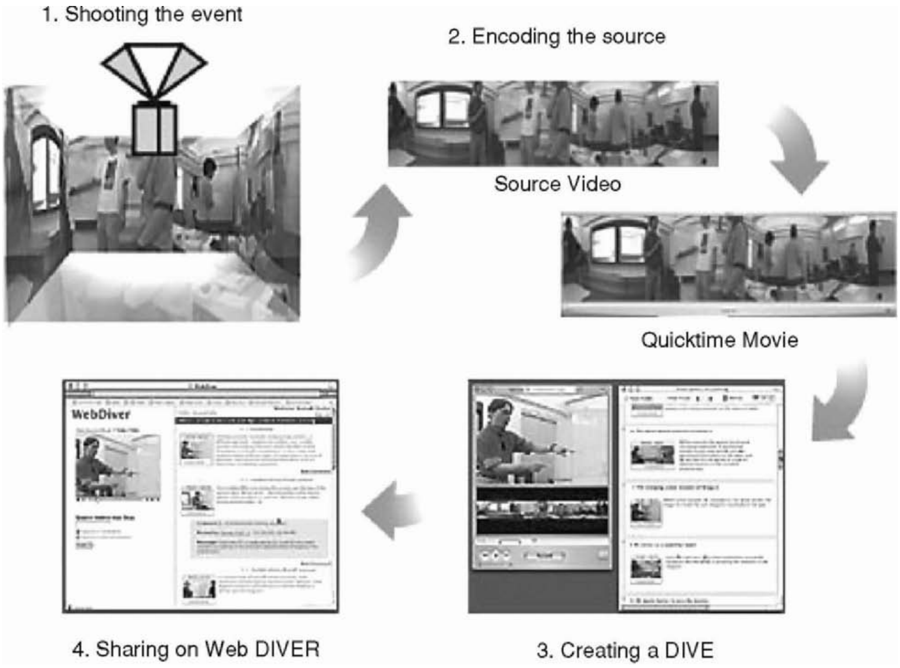

Figure 1. Overview of the DIVER video exploration and reflection system.

2. POWER OF VIDEO-AS-DATA FOR HUMAN INTERACTION ANALYSIS AND REFLECTIVE USES FOR PURPOSES OF LEARNING, TRAINING, AND EDUCATION

2.1. Situated Learning

In recent years, there has been increasing recognition that human activities such as learning need to be understood in the context of their naturalistic situations and socio-cultural environments (e.g., Brown, 1992; Brown et al., 1989; Lave, 1993; Pea, 1993; Resnick, 1987). Over this period, the learning sciences have shifted from a view of learning as principally an internal cognitive process, toward a view of learning as "mind in context"—a complex social phenomenon involving multiple agents interacting in social and organizational systems, with one another, and with symbolic representations and environmental features (Bransford et al., 2000; Greeno & MMAP, 1998; Hutchins, 1995; Pea, 1993).

This orientation to "learning environments"—the concrete social and physical settings in which learning takes place—has led researchers to utilize tools that allow capture of the complexity of such situations, where multiple simultaneous "channels" of interaction are potentially relevant to achieving a full understanding of learning or other human interactional phenomena. For

100 years, researchers have experimented with using multimedia records—first film, then analog videotape, and now digital audio and video—to gather richer and more reliable data about complex social interaction than is possible with traditional alternatives like field notes, participant recollections, and transcripts of audio recordings. These technologies are attractive for their potential in making a relatively complete record for re-use and for sharing among multiple researchers, without the inconvenience and intersubjectivity problems of recording methods like field notes. But capturing and working with video records, until the rapid technological developments of the last two decades, required access to equipment and skills that relatively few researchers sought to acquire. The consumer revolution in video technology has lowered this barrier in making sophisticated, easy to operate, cost-effective recording tools broadly available.

Uses of such audio and video records have been instrumental in theoretical developments by researchers contributing to this "situated shift" in studies of learning, thinking, and human practices. This development was deeply influenced by conversation analysis (Goodwin & Heritage, 1990), sociolinguistic studies of classroom discourse (Mehan, 1978), by ethnographic and anthropological inquiries of learning in formal and informal settings (Erickson, 1992; Lave, 1988; Rogoff, 1990; Rogoff & Lave, 1984; Saxe, 1988; 1991) and ethnomethodological investigations (Garfinkel, 1967) as well as studies of non-verbal behavior such as gaze (Argyle & Cook, 1976), body orientation/kinesics (Birdwhistell, 1970), and gesture (Kendon, 1982). These foundations are evident in Jordan and Henderson's (1995) influential paper on interactive video analysis—in research labs throughout departments of psychology, sociology, linguistics, communication, (cultural) anthropology, and human–computer interaction, researchers work individually or in small collaborative teams—often across disciplines—for the distinctive insights that can be brought to interpretation during the analysis of video recordings of human activities.

Thanks to these socio-technical developments, interdisciplinary studies utilizing video have deepened our understanding in many learning science sub-fields such as mathematics thinking, learning, and teaching (Greeno & MMAP, 1998; Lampert & Loewenberg-Ball, 1998; Schoenfeld, 1992), functions of teacher activities (Frederiksen et al., 1998), international comparative studies of videos of mathematics classrooms (Stigler & Hiebert, 1999; Stigler et al., 1999; 2000); learning of demanding topics in high school physics (Pea, 1992; Roth & Roychoudhury, 1993), informal learning in science museums (Crowley et al., 2001; Stevens & Hall, 1997), interacting with machines such as copiers, computers, and medical devices, suggesting new design needs (Nardi, 1996; Suchman, 1987; Suchman & Trigg, 1991; Tang, 1991), collaborative learning (Barron, 2000; 2003), and of specific roles for gestural communication in teaching and learning (Roth, 2001a, b). The pervasive impact of video studies was in evidence at the 2002 American Educational Research

Association meetings, which included 44 scientific panels and symposia using video for learning research, teaching, and teacher education (with comparable levels in 2005).

The availability of such inexpensive videography equipment and promise of more complete records of complex phenomena than earlier methods has led many researchers to adopt video recording as a primary data collection method. Yet, there is a serious and persistent gap between such promise and the usefulness of video records. Video data circulates rarely and slowly within scientific research communities, even as more researchers use the medium. Video research analyses are typically restricted to text-only displays for presenting findings; original data sources are not made available for re-analysis by other researchers; and it is typically impossible for collaborators working at different sites to conduct joint analysis of shared video records. Several workshops have documented the needs for much better tools for powerful video capture and analysis technologies to support studies of learning and instruction (Lampert & Hawkins, 1998; MacWhinney & Snow, 1999; Pea & Hay, 2003). This gap between the promise and reality of digital video yields continued problems by obscuring the connection between evidence and argument, discourages sharing of video data, and impeding the development of shared examples of exemplary analyses using video that could serve training and socialization functions for novice researchers (Pea & Hoffert, in press).

2.2. E-Learning

Furthermore, over the last several years, there have been a number of projects in research and industry whose goal is to advance the use of video and computer technologies to study the complex interactions underlying classroom learning. For example, the *Classroom 2000* project (Abowd, 1999) developed a system for recording many aspects of a live classroom experience—including the capture of strokes on a whiteboard—and making these recordings subsequently available to students. *Teachscape* (www.teachscape.com) and *LessonLab* (www.lessonlab.com) are commercially available products whose web-based platforms allow teachers and other professionals to study and discuss videos and other artifacts of classroom practice, as face-to-face resources or over the internet. There are many teacher education projects that utilize some form of digital video records to provide case-based learning approaches for learning at different points in the teacher professional development continuum, including Indiana University's Internet Technology Forum (Barab et al., 2001; 2002; 2003), University of Michigan's KNOW system (Fishman, in press), San Diego State University's Case Creator (Doerr et al., 2003), and Northwestern University's VAST tool (Sherin, in press).

In a related vein, Microsoft's MRAS (Microsoft Research Annotation System) has put forward a general architecture for multimedia annotations focusing on use in higher education (Bargeron et al., 2002). There is also a considerable body of work on video annotation that has focused on indexing and browsing video databases (e.g., Carrer et al., 1997; Kim et al., 1996; Lee & Kao, 1993; Mills et al., 1992; Weber & Poon, 1994). Nonetheless, as described below, many of same problems beset this work as they do research on learning and the social sciences using video records.

2.3. Business Meeting Capture and Re-Use

A number of projects over the past 5 years (e.g., Chiu et al., 2001; Fiala et al., 2004; Lee et al., 2002; Myers et al., 2001; Stiefelhagen et al., 2002; Yang et al., 1999; Young, 2001) have explored how to provide business and technology groups with the capability of returning to context captured from rich media records of their meetings, from automatic indexing, and other methods. The general idea is that one can use video to enable persistent context for ongoing teamwork, building in a cumulative way on prior meetings and design decisions, and continuing to excavate information that may come to have subsequent value.

For application to video conferencing meetings and distance education, Sun et al. (2001a, b; also see Foote & Kimber, 2001) have used their FlyCam system (Foote & Kimber, 2000: which produces high resolution and wide-angle video sequences by stitching together video frames from multiple stationary cameras directed at the front of a seminar room) in combination with a Kalman filter to detect the speaker's motion and then use that information to steer a virtual camera for recording a region of interest within the panoramic video stream.

Although not directly concerned with education, at Microsoft Research, Rui et al. (2001) have investigated the use of a panoramic recording system to allow people to "re-experience" face-to-face meetings. Interestingly, they found that users prefer having a panoramic overview—peeled-back video imagery showing 360° panorama—as a mechanism for navigating the scene.

2.4. Reflections on the Need

In summary, there is substantial need, for research in the learning sciences, for e-learning purposes, and for facilitating collaborative work both in face-to-face teams and at a distance, for new methods that foster capturing, navigating, analyzing, re-purposing, and commenting on video as a medium for representing situated practices. Researchers today lack tools for sharing these video data readily with other scholars and practitioners, for building cumulative analyses of research data across investigators, and for opening up these data for public discussion and commentary.

2.5. Prospects of Digital Video Collaboratories

As in other scholarly domains of inquiry, there are fertile opportunities in education and in the learning sciences for developing new methods of work, knowledge creation, and learning that leverage the collective intelligence of the field in ways analogous to the biological, health, earth, and space sciences (e.g., Cerf et al., 1993; Finholt, 2002; Finholt & Olson, 1997). Advances in the physical sciences are inexorably linked to a corpus of scientific data that can be shared, annotated, analyzed, and debated by the community of physical scientists, as well as by developments in the instruments and technologies that are integral to formulating, conducting, and analyzing results from scientific investigations. Apart from the notable example of *TalkBank*, to be discussed, with its emphases on digital audio files and transcripts of human talk, there is no such corpus of shareable audio and video data of human interaction in the social and behavioral sciences. This lack of a shareable corpus of social science data has hindered theory development. The DIVER project is devoted to fill this void by providing social and behavioral scientists with a tool and a platform for generating different perspectives on human interaction phenomena in the form of annotated audio and video recordings.

The psycholinguist Clark (1996) has formulated the important social science concept of "common ground" as what it is people seek to achieve in the work that we do to co-ordinate what it is that we are attending to and/or referring to, so that when comments are made, what these comments refer to can be appropriately inferred. In the learning sciences literature, the "common ground" concept is usually used to examine collaborative or teaching learning discourse and pointing, bodily orientation, and joint visual regard to the focus of a conversation that is being analyzed for studies of learning or teaching (e.g., Barron, 2003; Pea, 1994).

But it is not sufficient only to focus on the non-technology mediated aspects of common ground—for once we look at inscriptional systems (e.g., Latour, 1986) that lay down and layer symbolic records such as text or diagrams or other paper-based representations, we see that they, too, become a focus of pointing and joint visual regard and introduce new problems as transient referents. One may want to refer back to an earlier moment when only a part of a mathematical diagram was present to allude to that state or some part of that diagram, for that is what one wishes to establish common ground around. Similarly, for a business meeting, one may want to refer back to a state of information display on a whiteboard and what it is that the people in the room were speaking about when it was constructed.

I argue that this common ground concept must extend to the dynamics of representations, particularly for the problematic cases when these representations are computer-enabled (e.g., Pea, 1994). One often needs to refer to specific states of information display when using computer tools, so establishing a common ground for discourse and sense-making, what it is one wishes to point to, means capturing what Latour (1986) calls "immutable mobiles"[2] for replay and guided noticing.

Consider the potential but unactualized learning across learning science researchers themselves, with respect to the primary video data they collect of learning and teaching. Here too, we need to facilitate the learning and cumulativity of knowledge construction that can come about through co-building on a common ground. A significant opportunity thus exists to work across researchers on a common ground of video records and annotation tools that is rare today. Without the dynamics of common ground, these results are improbable, and the sciences of learning and education will suffer accordingly.

2.6. Dynamic Media e-Publishing

Finally—a point for subsequent elaboration—the uses of digital video collaboratories in the human and learning sciences call for a new, dynamic publishing and commentary medium, one where multimedia records are integral to the presentation of the phenomena and analyses, and in which precise references to specific facets of behavior or analyses are possible to sustain the knowledge building processes of a research community (e.g., Pea, 1999). Such a call for e-journaling is commonplace (e.g., Harnad, 1991; Varmus et al., 2000), but the importance of dynamic media in such publications is less commonly raised as an issue of importance (for a notable example, see *Journal of Interactive Media Research*, but even here dynamic media are presented but not able to be indexed or commented upon by referring to their features in terms of space–time cropped selections of the interface displays).

3. TOWARD VIDEO AS A SCHOLARLY MEDIUM

Consider the core plea here to be examining what it will mean to make video as integral a scholarly medium as text is today. This aim requires treating video-as-data and has a host of implications that will take us in different directions than are being pursued in today's broadcast-oriented approach to uses of video-as-file in e-learning, movies and sports videos-on-demand, and other cultural pursuits.

There have been diverse efforts to move video data into broader circulation so that it may be re-analyzed by others. While anthropological film's beginnings in 1898 by Haddon in the Torres Straits were only 3 years removed from the birth of the cinema (see Grimshaw, 1997), the tradition of filmmaking in visual anthropology was made salient in part by the classic works of Margaret Mead and Gregory Bateson (especially his book *Naven*, 1936, devoted to multimedia investigations of cultural ritual in Papua New Guinea). Researchers have recently taken advantage of other media to distribute video recordings together with multiple researchers' analyses of these data

[CD-ROM enhanced issues of *Discourse Processes* (1999) and *The Journal of the Learning Science*s (2002)]. These important efforts nevertheless highlight the limits today to bringing video records into a broader collaborative process among researchers and practitioners. Challenging other researchers' interpretations of video analyses typically requires becoming a filmmaker oneself, and either bringing in other material or cutting and splicing materials from the original researcher's work, adding new commentary.

Compare these obstacles to the simpler task facing students of textual literary works, who are able to excerpt and juxtapose passages from their subjects with little effort, and with few limitations as to length or location within the primary work. Even in using the data-sharing innovation of a CD-ROM with video clips that were to be referenced in the articles, the special issues nonetheless decouple video data from analysis, as researchers reference video source time codes and lines in transcripts. To comment on researchers' interpretations of these video data, other scholars must engage in the same referential gymnastics, instead of referring directly, in context, to the video data in their own commentaries on others' video data commentaries.

4. INTRODUCTION: POINT-OF-VIEW VIDEO AUTHORING IN DIVER, GUIDED NOTICING, AND DIGITAL VIDEO COLLABORATORIES

Our approach to addressing these fundamental issues of making video function as a scholarly medium-like text turns on several fundamental concepts, which I briefly introduce here. These concepts, illustrated in Figure 2, are (1) point-of-view video authoring; (2) virtual camera; (3) virtual videography; (4) "diving" into video records; and (5) guided noticing.

The first concept is *point-of-view authoring*. This idea arose for me in thinking about the prospects of panoramic video for enabling fundamentally new kinds of interaction and manipulation of video records. Panoramic video, as noted above, involves using of one or more digital video cameras and mirrors to capture 360° horizontal imagery. Panoramic cameras are being explored for uses in sports, entertainment, surveillance, and business meetings, among other applications. The interesting issue for education and learning research is how to think about navigating and re-using such panoramic video records.

The innovative idea that we developed for the DIVER Project in thinking about panoramic video imagery is that of point-of-view authoring, in which a *virtual camera*, represented by a resizable rectangle (in one instantiation) can be panned and zoomed through that video, and used to "record" a point-of-view movie through the panoramic video array—to which comments and annotations can be appended. Such a virtual video camera makes it possible to enact *virtual videography*, creating any one of an infinite number of possible point-of-view authored films. We describe such path-movie authoring and commenting as "*diving*" into video. The use of a virtual camera to author

Figure 2. User interface for the DIVER desktop application, showing panoramic video. Note that we show a 20:3 wide aspect ratio panoramic video above, but that the DIVER interface can also automatically support Diving on traditional 4:3 aspect ratio video, or multiple video streams that have been synchronized from different cameras.

point-of-view movies within a panoramic video record and to annotate these path movies performs an important action for establishing common ground that I characterize as *guided noticing.* The use of the virtual camera for the framing of a focus within a complex and dynamic visual array directs the viewer's attention to notice what it is that is thus circumscribed, and the point-of-view authoring thus guides the viewer to that noticing act. Finally, DIVER makes it possible for the author to publish their dive to a webpage, using a WebDIVER server, so that others may experience their point-of-view video document and annotations—their dive on a source video. In an alternative implementation, videos encoded for WebDIVER server accessibility may be dived upon as streaming media by authors using any simple web-browser (thus not requiring the downloading of the video itself onto the diver's computer).

As it turns out, these core concepts are extensible from the case of navigating and point-of-view authoring within panoramic video records to the more general case of taking as input to the authoring process I have described any video source, including normal 4:3 aspect ratio video from consumer video cameras, multiple yet synchronized 4:3 aspect ratio video streams (e.g., from different locations in a networked collaboration session), and more generally yet to any dynamic or static visual medium including art, photographs, scanned documents, animations, and other imagery or visualizations, as in science, medicine, or cartography (see Section 7).

I will later develop a broad account of current and prospective scenarios of DIVER use for enabling a broad range of cultural practices across and beyond learning, education, and scientific research. While not intended to be exhaustive, these scenarios will illustrate the scope of applicability of the general framework for guided noticing and point-of-view authoring. Finally, the capability that DIVER enables for any author to point to and comment on any part of a visual display and share that view so that others can experience it, by publishing it as a webpage over the internet with commentary capabilities at its component level, opens up the prospect of *Digital Video Collaboratories*, whereby a scholarly infrastructure is established for integrating video analysis, sharing, and collaboration in research communities (with potential for other cultural purposes). Making video function as a scholarly medium such as text turns on being able to refer to specific time–space co-ordinates in the source video, and in our work with DIVER and in collaborations underway with other researchers we are seeking to develop this vision into a reality.

5. DIVER AND GUIDED NOTICING

What is the activity of guided noticing? And how does it relate to other behaviors and concepts such as pointing, disciplined perception, and professional vision?

Guided noticing is a two-part act for a complex situation/visual scene. First, a person points to, marks out, or otherwise highlights specific aspects of that scene. Second, a person names, categorizes, comments upon, or otherwise provides a cultural interpretation of the topical aspects of the scene upon which attention is focused. In a two-person (or more) interaction, there are also distinctive roles. One is the "author" of the guidance (I guide you to notice what I notice), and the other is a "recipient" of the notice, which is mediated by an environment in which each participant is immersed. In the case of DIVER, and related media such as video and film, such guided noticing is also time-shifted and shareable by means of recording and display technologies. Diving creates a persistent act of reference with dynamic media—a link-addressable artifact—which can then be experienced by others remote in time and space, and which can additionally serve as a focus of commentary and re-interpretation.

Why is guided noticing important? Because achieving "common ground" (e.g., Clark, 1996) in referential practices can be difficult to achieve, and yet is instrumental to the acquisition of cultural categories generally, and for making sense of novel experiences in the context of learning and instruction especially. Clark observes that for one person to understand another person there must be a "common ground" of knowledge between them, and his research and that of others illustrates the complex multitude of ways in which such "common ground" is inferred from immediate surroundings, mutual cultural context, and participants' own prior conversations.

Guided noticing builds on the fundamental human capacity of referring and the establishment of shared attention. As Wittgenstein (1953) observes in his *Philosophical Investigations* in critiquing St. Augustine's view of language learning as achieved by observing pointing and naming of things by adults—unless shared attention between infant and adult is achieved, it is impossible to learn from such ostension. The roots of shared attention and what the philosopher Quine (1960) called the "ontogenesis of reference" are established early. In the 1970s, an influential set of publications empirically demonstrated the advent of shared visual regard following adult pointing or line of visual gaze at approximately 9 months of age (Bates et al., 1979; Bruner, 1975; Scaife & Bruner, 1975) and its role in establishing what Trevarthen (1979) described as intersubjectivity between infant and adult (involving mutually adaptive purposeful activities).

Another reason why guided noticing is important as a human activity is that it facilitates the continual interplay between two fundamentally distinctive but complementary ways in which we make meaning in social activity—what Lemke (1999) calls the typological and topological modes. Typological representations assign a culturally meaningful category to some material form as when a pronoun is viewed as singular or plural, a verb form as expressing one type of tense or another, etc. In contrast, topological representations are visuo-spatial and often continuously variable in their qualities (examples include acoustic-vocal properties of speech such as timbre or sound quality, and visual media, ranging from gesture to graphs).

The obstacles to sharing analyses and commentaries of video data exemplified in special issues of *Discourse Processes* (1999) and *The Journal of the Learning Sciences* (2002) can be contrasted to the basic structure of human visual interpretation that builds on these human capacities for shared attention, and the interweaving of typological and topological modes of meaning-making. This structure appears in what I describe as a cycle of Looking, Noticing, and Commenting (the LNC cycle): I *look* at a visual scene, *notice* a pattern or something of interest, and *comment* upon it. If others are involved, the noticing is followed quickly by a gesture or visual regard that calls out the particular item of interest from the scene as a whole, so that others can connect the comment to the particular topical element that is being referred to. This Look-Notice-Comment (LNC) cycle—familiar to anyone in any field of work and life—is generative and recursive. Others can return to the scene as a whole to offer amendments or counter-comments, all the while noticing and gesturing in order to continue to tie the scene to the discussion and to build a common ground of understanding, or to negotiate differences in meaning. In daily life, this cycle is so well integrated into practice that it most comes to attention when it fails to function. However, in the analysis of video records, there has been no existing toolset to enable distributed communities of scholars or practitioners to readily engage in this kind of interactive commentary on a shared and accessible body of video material with anything like referential precision.

The basic LNC structure is used in early parent–child interaction in helping guide noticing of culturally significant phenomena and their meanings (e.g., Rogoff, 1990; 2003). It is also used in promoting expertise development in the exceptionally broad range of domains in which visually accessible information is critical, toward achieving what the anthropologist Goodwin (1994) calls "professional vision". Examples include learning to appreciate artistic works from specific frameworks of interpretation (Berger, 1972), recognizing diagnostic patterns in dirt at archeological digs (Goodwin, 1994), coming to see important patterns of classroom interactions as a teacher (Sherin & van Es, 2002), detecting tumors in radiological imagery, analyzing a motion picture, identifying mountains on a map, seeing galaxies in telescopically enabled perception of the heavens, and so on. In each of these cases, one is faced with a complex visual array of information to *look* at, comes to *notice* aspects of that visual information (for any one of a number of reasons, such as its being distinctive, relevant to the action at hand or being pointed out in some way by a more expert other), and to *comment* on the meaning of the noticed aspect one has picked out of the looking.

Goodwin (1994) uses the phrase "professional vision" to characterize how, "central to the social and cognitive organization of a profession is its ability to shape events in the domain of its scrutiny into the phenomenal objects around which the discourse of the profession is organized". He presents compelling examples from archeological field excavation and legal argumentation (and oceanography: Goodwin, 1995) to indicate how professions achieve this ontological work by *coding* (in which some structures of the world are captured and other possible ones ignored), *highlighting* (as in saliently establishing a figure against a ground, such as by demarcating graphically or pointing), and *producing graphical representations* to make a case (such as transcripts of talk, diagrams, and frame grabs of scenes recorded on videotape). I wish to argue that the LNC cycle is the developmental base upon which the more academically focused concept of professional vision builds.

For millennia, humans conducted this central human activity as an oral discourse only, situated in the here-and-now of whatever visual information was in front of them (e.g., DeLaguna, 1927) or able to be adduced from memory of shared experiences with others and talked about, and without the benefit of any inscriptional system, that is, a notation scheme that made sensible marks on a persistent and observable surface whose meaning could be shared with others (such as written words or other symbols that express a consistent system of meaning). Extensive scholarship has been devoted to the historical importance of this development in human culture, for the later emergence of logic, mathematics, science, art, and many other fields of human achievement (e.g., Cassirer, 1953–1957; Goody, 1987; Latour, 1986; Olson, 1994; Ong, 1982). For once, humans were able to inspect a persistent record

Figure 3. DIVER's windows: (1) overview ("Look") at bottom, (2) magnified viewing ("Notice") at upper left, and (3) the Dive worksheet ("Comment") comprised of panels.

of ideas and their inter-relationships, and to leave behind a commentary on their topic of attentional focus from which others could learn.

In this broader framework of socio-cultural practices and technologies, the DIVER software goal is thus to provide a tool and a communications framework for augmenting the fundamental and social activity of human visual interpretation and communication about what is interesting or relevant to a purpose at hand—looking at a complex scene, noticing events of interest, and commenting on the focus of attention. As shown in Figure 3, the LNC cycle has informed our design of the DIVER software. Specifically, the DIVER interface consists of three distinct regions, each corresponding to one of the elements in the fundamental LNC cycle of visual interpretation and communication.

The overview (Look) window provides access to the original source material that is the overall subject of the discussion or analysis, and has standard video controllers, for forward, reverse, and pause, which also allow for "time scrubbing" by moving the video player control forward or backward quickly, with a corresponding viewing of the video at accelerated speed (as a quick way to survey the content of a video record). In this overview window, users can return to any part of the original video source and explore it.

The magnified viewing (Notice) window depicts a selection from the original source that the user makes with the mouse by dragging a resizable selection rectangle overlay (the "virtual camera") across the overview window, panning over, and zooming into regions of interest in the scene. We sought to satisfy with this dual overview/magnified-view interface the well-known dual awareness principle of human–computer user interface design, also called "focus + context" (e.g., Card et al., 1999; Furnas, 1986; Lamping et al., 1995; Mills et al., 1992; Rao & Card, 1994). The user can thus zoom-in on an information source's details yet maintain a sense of orientation and context. Related navigational interfaces have been explored in several experimental and commercial applications of panoramic video technology (BeHere.com; Fullview.com; Kimber et al., 2001; Prihavec & Solina, 1998; Rui et al., 2001; Teodosio & Mills, 1993).

As the virtual camera is moved across the video source overview, the viewing window provides a dynamically updated and magnified view of that region of the original video source. Two buttons—MARK and RECORD—turn this viewing area selection into an easy-to-comprehend and flexible authoring activity. MARK takes a temporally tagged snapshot of the contents of the magnified viewing window and creates a new panel for commenting in the third region of the screen—the Dive (Comment) worksheet. A worksheet panel contains a video thumbnail representing a marked clip, as well as a text field for describing what is noteworthy about that selection.[3] If the DIVER user presses the RECORD button, another panel is created. When the record button is pressed again to end recording, the virtual camera's pathway across the video overview window completes its recording of the spatiotemporal selection shown in the virtual camera window.

Thus the user of DIVER can record a dynamic "path" through the original source video and annotate it by entering text in the Dive panel. In creating a unique "point-of-view" virtual tour of the original video source, we say the user is creating a dive (or "diving") into the video record. He or she can then use the dive as a device for storytelling or other rhetorical purposes (e.g., video data argumentation for a research conjecture) by playing back the marked locations and dynamically cropped pathway "recordings" through the original video source as well as the annotations of these records. A dive is subdivided into panels, which serve as containers for the data elements that constitute the dive (see Figure 3). Panels contain the following data elements:

First, static and dynamic time and space video markers: A static marker is a pointer to a frame in the video (temporal co-ordinate) and the location of the virtual viewfinder within that frame (spatial co-ordinates). Dynamic markers are recordings of the space–time path traveled by the virtual camera as the user guided it through the source video.

Secondly, a thumbnail-sized image copied from the source video at the marked time and space is used as a live link for specific time–space video co-ordinates. To make it easy to explore the place of the marked clip in the overview context, dragging and dropping such a marker into the viewing window resets the virtual camera to the space–time co-ordinates previously marked.

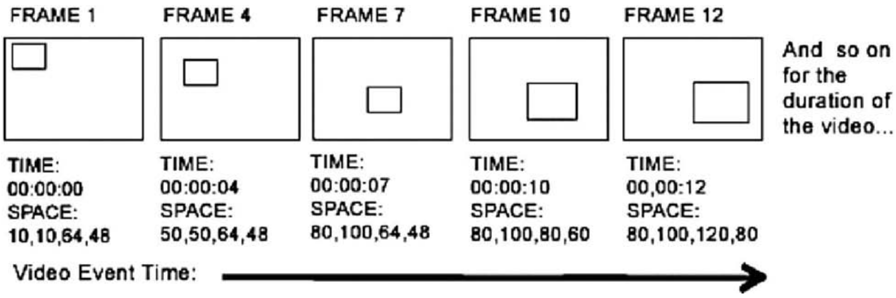

Figure 4. A graphical representation of the .dvc file format.

Thirdly, annotation text that a user typed into the panel is used to provide a commentary associated with the static or dynamic marker.

Fourth, the temporal point or range of video that is contained within a panel selection is denoted by a single time code for a static marker or a range of a time code range for a dynamic marker.

Finally, a time–space cropped video clip is depicted as a thumbnail-sized image in a panel to act as a symbolic representation of the selected portion of the source video segment. Double-clicking a thumbnail (or drag-and-dropping it back into the viewing window) repositions the source video at the corresponding time–space co-ordinates.

The simple and efficient creation of dives is supported by the DIVER file format. As a user drags the virtual camera viewfinder across the source overview window (see Figure 4), a reference to time (the video time) and space (the position of a viewing region within the video's border) is recorded to a list. These time–space recordings (which we call ".dvc files", where .dvc represents "DIVER Video Collaboratory") can be played back by the user; the DIVER system reconstructs the virtual viewfinder's path through the original source video in real-time. What is recorded when the user presses the RECORD button in the DIVER desktop application is not literally a new video, but the .dvc file information needed to replay the dynamically cropped pathway which the virtual camera traced through the original sequence of video frames.

When a .dvc file is played, current video time and space is reset to the previously saved time and space co-ordinates. Prior to displaying each frame of video in the virtual camera window, the video's borders are scaled (in real-time, on-the-fly) to match only the viewing area co-ordinates associated with the same frame (video time) in the recorded virtual camera path. Two key benefits inhere in using the ".dvc" list recording scheme versus re-rendering new video clips: (1) disk storage requirements are greatly reduced since virtual video clips do not generate redundant video files and (2) software performance is vastly improved because no rendering time is required—users can instantly create and play back dynamic path videos. Dives are thus extremely lightweight glosses on original source content. Yet, they can comprise very rich and compelling viewing experiences—they truly provide the interactive experience of *making movies within movies*.

The structure and extensibility of the XML-based ".dvc" file format serves as a metadata container that can allow for the reformatting of DIVEs into many display and interaction environments. For example, on a handheld computer or cellphone supporting only text and image display, the ".dvc" format could be used to extract and display only text annotations and video thumbnail images, or smaller video display if capabilities allowed.

In the desktop implementation of DIVER, a user's video dive can be uploaded to a WebDIVER™ server for sharing, discussions, and collaborations. The content transformation process for the web format takes place in a series of client- and server-side tasks invisible to the user. The user initiates an automatic series of text, image, and video clip transformation processes as he or she chooses the "Export to HTML" menu option in the desktop DIVER application (see Pea et al., 2004 for details).

When a dive is later opened on the WebDIVER site, the content is reconstituted as HTML and JavaScript, so that webpages are dynamically generated from the media files and XML data. WebDIVER browser pages look similar to desktop dives, for they contain the same data and media elements. The

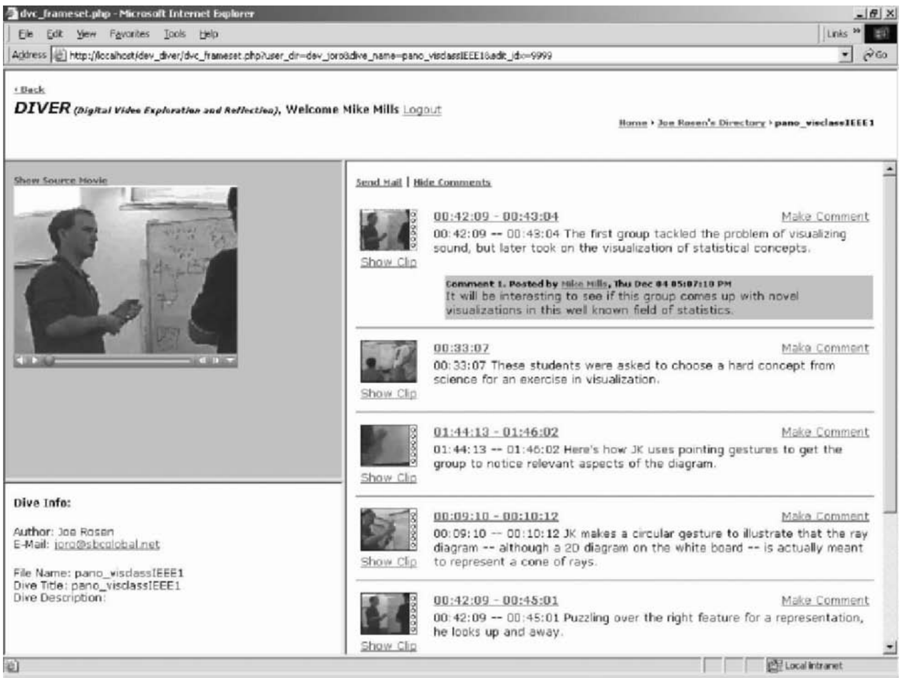

Figure 5. A dive from the WebDIVER site, as seen in a browser window.

WebDIVER window in Figure 5 shows an example (also see Figure 6 for the more recent Flash streaming video implementation interface).

In addition to the original author of the dive, other WebDIVER users can now both view a dive and explore its full source video through any web browser. Moreover, users can collaborate on a dive by entering their own comments on the dive annotations made by the dive's creator for each panel. WebDIVER users can also perform keyword and metadata searches within and across all annotations for all videos and dives that are available.

The paradigm of desktop DIVER use and uploading to WebDIVER of both the media file and the user's dive for access and commentary by others—while very useful and powerful—has several key limitations. One of these is that the time for uploading large video files will often be prohibitive. A second concern is that many use scenarios where one may wish to allow users to dive on videos (e.g., research collaboration, entertainment) recommend a scheme for protecting intellectual property in which a user does not have the video file itself residing on his or her own computer, but where the video simply streams from a web server during the video playing and diving processes. A third concern is that the requirement to download and install the desktop DIVER application (and regularly update it with new versions) may make DIVER far less widespread in its uses than a web-browser-based approach would allow.

To achieve this more demanding objective, we developed a new WebDIVER design that provides many of the key desktop DIVER application functions, but in a fully browser-based approach. The design as of January 2005 is as follows (Figure 6).

One or more remote users use a web-browser on their computers to go to a specific URL where a video file has been encoded in Flash video format and made accessible so that it can be "dived" upon as described above. The new WebDIVER design still represents a dive as made up of a set of panels, each of which has an author and editing capabilities affiliated with it. The panel is a data container for the DIVER key frame that is marked or the DIVER movie that is made with the virtual camera. Multiple users can be connected to the URL at once if they have permissions to do so and can make their own dive panels for the video file, with the MARK and RECORD buttons and the use of the virtual camera viewing rectangle under mouse control in the web-browser version, as on the desktop DIVER application. When they do so, they see their own work appearing in the dive in real-time, and if others are also making dive panels for that video, if one presses the "update" button on the webpage (see Figure 6), the different panels of the DIVE that are being created collaboratively—whether locally or by distributed users—are made visible. Thus, users may be either face-to-face in a meeting room, or connected to the same webpage remotely *via* networking, as they build a collaborative video analysis.

In principle and in practice, there is no need for the users to be watching the same portions of the video at the same time when they work collaboratively;

Figure 6. WebDIVER: Streaming Media Interface for web-based diving.

as the video is streamed to them through their web-browser, they may mark and record and comment at their own pace and as a function of their own interests. The collaborative video analysis activity that uses DIVER can be as planful or emergent as the participants choose to make it; constraints on focus, intent, duration of sessions, and so forth are not built-in to the technology, but a matter of negotiated social practice. Note one important difference: whereas in the desktop DIVER application, two video windows are part of the user experience (one an overview window of the whole video file and the second the zoomed video contents circumscribed by the virtual camera rectangle), the WebDIVER system allows for just one window of the whole scene. The diver achieves guiding noticing by directing the dive user's attention to where the diver points in their dives with the virtual camera rectangle. Thus, when one plays back a dive on the WebDIVER browser version, the viewing rectangle moves across the video and shrinks or expands to represent what the diver pointed to during their dive creation.

Having now provided a basic account of how the DIVER and WebDIVER software systems work and the connections of their functions to socio-cultural purposes of guided noticing and point-of-view authoring, it will now be worthwhile to examine the profound implications of panoramic video when brought into this context.

6. DIVER AND PANORAMIC VIDEO AS A NEW MEDIUM FOR LEARNING SCIENCES RESEARCH AND EDUCATIONAL PRACTICES

6.1. The Need

Because 4:3 aspect ratio digital videos captured with digital video cameras are so pervasive, they will often be the source material for DIVER. However, the use of such video records as data in social science research is hampered by their partial quality. One or two video recorders and microphones produce a record that is partial (since limited by what the operator chooses to capture and what to ignore), and often of low quality, particularly in the audio dimension (Lampert & Hawkins, 1998). The original researcher or other researchers who may be interested in different aspects of the events that transpired cannot recover events relevant to the analysis occurring off camera. These issues drew us to developing for research and educational uses the application of panoramic video and audio capture, navigation, and DIVER application for creating point-of-view authored tours of video records.

Today, panoramic video is often employed for omni-directional vision/sensing applications such as teleconferencing, navigation, and security or military surveillance (e.g., Fullview, 2004; Nayar, 1997; Sun & Manjunath, 2004). Bapna et al. (1998) provided a dramatic demonstration of panoramic video-guided tele-operated navigation of the Nomad robot for 220 km across the Atacama Desert of southern Chile, anticipating planetary rovers. Other panoramic video applications include making available a remote window onto a panoramically recorded event such as a lecture (Kimber et al., 2001), or as one component in an effort to produce an immersive simulation of activities such as a sports game or a concert (Neumann, et al., 2000; Rizzo et al., 2001).

We were attracted to exploring the feasibility and practicality of panoramic video recording for research and education because one can place such a camera in a room, shoot the video, save it digitally, and in post-production, create with DIVER a virtually infinite number of different experiential paths through the video—as if one had multiple cameras in the room at the time of the video shoot. Panoramic video is of special interest in any context where the purpose and application of the video resources are not well defined before recording.

It is hard to wrap one's head around this when seeing and thinking about it initially. The reason may well be that it is easy to have a misleading question, that the video camera is like an eye and therefore must have a "point of view". But in acquiring the images in the 360° surround, the panoramic camera at every moment in time, every frame and pixel saved, provides the raw materials for an infinite number of points of view at once. And for every next frame, one can pan, tilt, and zoom to any one of a very large number of other points of view, and so on, ad infinitum. There are infinitely many pathways that one can explore and then express, using DIVER's point-of-view authoring methods, what one sees and notices in the pathways one crafts through the panoramic recordings.

For uses of video in research on learning, our goal is to capture much more complete event recordings than is possible with usual means, by using techniques such as panoramic high definition video, multiple-phased microphone arrays, and a software and hardware infrastructure to support variable numbers of synchronized data streams from sources such as handheld devices and video displays that may be part of the context of the activity filmed.

6.2. Synoptic Video Capture

We use DIVER as a software analysis tool for selecting and annotating clips from what we have called a "synoptic", or all-encompassing, panoramic view of an event, in order to allow users to gain control over the high volume of data thus produced. Our ultimate purpose is to record events in a way enabling researchers to return as often as they wish to the original event, refining, modifying, or rejecting their conjectures in the light of new interpretations of the recorded activities. This goal stems from the high degree of complexity of learning environments (such as classrooms), defined by the interaction of multiple simultaneous channels of behavior and communication in context of a complex physical and representation-rich environment. It is difficult to determine, either in real-time or in a single viewing, what is important about a learning event. Making sense of an event typically requires repeated viewings, isolating in turn individual components of an event [see Jordan & Henderson's (1995) paper on video interaction analysis]. Conversely, any real-life learning situation can sustain multiple different interpretations, focusing on different factors of theoretical interest and on different aspects of the recorded behavior.

We would thus like to produce as complete a record of an event as is practicable from panoramic recording, so that the DIVER software can support repeated interrogations of the original event from differing perspectives (and with differing hypotheses) about what aspects of the event are significant. Our aim with this synoptic approach is in part to overcome presumptions about inherent limitations of "video-as-data" in how ethnographic records have traditionally been collected with video cameras, for example:

> "Although video technology can clearly capture more than one observer could possibly notice and record, in another sense video technology may capture less. Videographers have options as they decide how to tape a classroom: they might pan across the room or fix on the teacher, depending on the structure and goals of the data collection and the videographer's training. Tapes cannot capture everything that happens in a classroom, and what they miss is typically determined by the position of the camera rather than by a trained observer's instinctive reactions to events as they unfold. Moreover, while video data are less "processed"

than other kinds of data, they are not equivalent to direct observational data. The view of someone watching videotape is constricted; he or she is experiencing what is taped through the frame of a host of decisions made before and as the data were collected".

(Hall, 2000)

These assumptions are challenged with a "synoptic" approach to video capture, that is, the use of multiple perspectives/instruments on the same event in order to compensate for the partial quality of any one instrument. In post-capture interrogations of the panoramic digital video data from a classroom situation, the analyst can choose different fields of view and pathways through them depending on their purposes—in effect, going "beyond being there" (Hollan & Stornetta, 1992) in ways that a single videographer could not have done at the time with a traditional camera.

The completeness of the record is further addressed in the spaces instrumented for panoramic recording, which may consist of a room set-up with multiple audio and video recorders, with the goal of producing a synoptic record of events. We obviate the need to make real-time decisions about what is "important" to shoot by using a panoramic video recording system. We have also demonstrated that it is possible to equip a recording space with multiple microphones to capture with equal clarity interactions occurring at any point in the room (see below). This synoptic architecture is deliberately designed to be open to future enhancements, both by enhancing the recording ability of any particular recording modality (e.g., additional video cameras to deal with problems of occlusion and differential resolution based on spatial position, or moving from standard definition to high definition video), and by adding new modalities (e.g., recording, in addition to the audio and video, the content of displays being used by participants in the space, or other behavioral data streams).

An example of "being beyond there" that ethnographers have found particularly compelling in using DIVER is the capability of creating grouped clips, that are made up of selected regions of the video scene which can then be played in unison to explore relationships between what was happening in different parts of a learning situation at the same time, and annotated accordingly.

A major technical challenge in recording panoramic video is *image resolution* [see Benosman & Kan (2001) for an excellent edited volume on problems and recent solutions in panoramic vision]. In order to be able to zoom into an area of the panoramic video as we do with DIVER's virtual camera and still see sufficient detail, the video must be captured at the highest possible resolution. In principle, panoramic video can be recorded with a single-lens system: a spherical mirror, somewhat similar to a fisheye lens, collects the light from the 360° surround and redirects it onto the CCD chip of a single camera. The digital video stream of the camera can then be processed (stored, compressed, edited) like any other video stream. Such systems are relatively inexpensive and readily available; examples include the BeHere® camera (behere.com) and the camera used in Ricoh's Portable Meeting Recorder (Lee et al., 2002). But single-lens systems have very low image resolution because the number of pixels on the CCD chip, designed for a small angle of vision, must now be distributed across a much wider angle for surround vision. Thus, zooming into an area within the video leads to a very low image quality due to the pixelization of the video data.

To solve this problem, several multilens systems have emerged. They capture a scene through multiple lenses and CCDs with slightly overlapping fields of vision and then construct the panoramic image by "stitching" the frames together (Tan et al., 2004). Examples are the Fullview® camera (fullview.com), the FlyCam developed at the Fuji Xerox Palo Alto Laboratory (Sun et al., 2001a, b), and the RingCam used in Microsoft's meeting capture and broadcasting system (Cutler et al., 2002). Multilens systems address the image resolution problem, but they introduce the challenge of stitching and de-warping of multiple frames in the computer, perhaps in real-time. In addition, multilens systems running at full-resolution generate a very high bit rate, often too high to be transferred over a single PCI bus.

In the DIVER project, we use a Fullview® camera system with five mirrors and five cameras, whose streams are fed into a PC where they are stitched and de-warped at a resolution of 1800×240 pixels, at about 15 frames/second. The panoramic video is written to a file for subsequent processing by the DIVER toolset. We use three parallel PCI buses on the PC doing the processing to accommodate the very high data rate generated by these five digital video streams. We have developed a tape-based alternative recording system (see below) capable of even higher resolution, which is desirable for the repurposing of panoramic video. We have also devised a system for capturing multichannel sound with a microphone array so that panning and zooming with the virtual camera into the overview window on the resultant panoramic video record provide a corresponding audio focusing mechanism[4] (see below).

It is important to ensure compatibility with 4:3 aspect ratio video and panoramic video content at a variety of aspect ratios. As a result, DIVER has been architected to support a general approach for video analysis, collaboration, and interaction allowing for use of a diversity of aspect ratios and resolutions for recorded video material. This provides a flexible approach for users to record, analyze, and share a broad range of video material in the DIVER environment, independently of the specifics of the video material that has been captured.

In order to accommodate even higher resolution video capture than is possible with native FullView® live preview and direct-to-disk video, we developed an alternative full-resolution video tape-based recorder. The output from the FullView® camera array is recorded at full-resolution ($720 \times 5 \times 480$) and full frame rate ($\sim$30 frames/second) to five consumer-quality Digital Video Tape

Recorders. Desired video tape segments are later transferred to a PC, where in a software assisted post-process the multiple recordings are reassembled into seamless full-resolution 3500 × 460 @ ~30 frames/second QuickTime encoded panoramic movies ready for DIVER.

While there are a number of systems that provide panoramic still image capture (e.g., Apple QuickTime VR: Chen, 1995: Pix, 2005), and fewer systems that capture panoramic video, they are all oriented to providing an immersive remote or recorded experience (e.g., Boult, 1999; Neumann et al., 2000; Rizzo et al., 2001), not enabling authoring by the user of point-of-view perspectives on their interests in the visual array of the recorded data. One interesting exception is the FlyAbout system where panoramic video captured by moving a 360° camera along continuous paths is spatially indexed for subsequent interactive navigation so that users can interactively replay video by traveling along paths using a map-like interface (Kimber et al., 2001).

The DIVER software system provides users with capabilities for adding perspective on the digital files that have been collected with a panoramic camera. Diving is designed to be a liberating authoring medium for video, perhaps most evident with panoramic video records, as it is constructivist in nature since any user can create their own annotated point of view on the video that has been captured. Creating one's personal point of view in establishing a dive through a panoramic video recording amounts to what I call Personal Reality Authoring—as a new complement to the recent decade's developments in Virtual Reality (Rheingold, 1992) and Augmented Reality (Feiner, 2002), neither of which are created by the intended user of the medium—because the diver can save his or her path through the panoramic video record. Once saved such a record provides a mechanism for replaying the user's authored path, or guided noticing tour, through the panoramic video recording.

6.3. Panoramic Audio and DIVER Zooming into the Panoramic Audio–Video Array

We have highlighted the common problem in use of one or two video cameras for learning research of poor audio quality for select parts of the video record. DIVER's ability to focus attention on a particular visual area within a panoramic (or non-panoramic) video image—the unique capability for interacting with video which we call "guided noticing"—raises the question of how to handle navigation of the sound field, once captured from multiple microphones in an instrumented recording space. Our current solution is associating co-ordinates within the video visual field with sound tracks, which locations then function like individual physical microphones (although they could also be produced by mixing microphone inputs in post-processing, and vary from the number of physical microphones). In this manner, we can switch to the corresponding sound track as the user navigates the virtual camera through the visual field (as in Figure 2).

DIVER panoramic movies may currently contain up to 10 independent sound tracks. Each is mapped to an associated field of view captured by the FullView® panoramic camera. These multichannel sound recordings are embedded as navigable QuickTime audio tracks within the post-processed panoramic movies. The result is that panoramic sound can be steered from inside DIVER in such a way that only the tracks associated with the current focus of the virtual camera become audible. This mechanism allows for the easy re-purposing of audio recordings and the dynamic creation of infinite virtual audio mixes. The audio remapping process happens continually and on-the-fly, so the user is not required to wait through a time consuming sound re-rendering phase.

7. DIVER VISIONS AND DEVELOPING SCENARIOS OF USE: RESEARCH, DIAGNOSIS, TRAINING, AND COMMUNICATION

7.1. Introduction

We distinguish several key forms of point-of-view authoring made possible using DIVER which we believe will prove useful: (1) tool for *learning research use* for expert analysis and discussion of video data (and other media); (2) *assessment of novices and trainees* in diverse fields, regarding details that they notice in complex visual media and the qualities of their commentary about it; (3) *the "scaffolded" training of novices*, who could be guided in their analysis of a video record by comments designed to stimulate their own perceptions; and (4) *expressive uses* for communication of perspective on complex media records by users in virtually any life sphere. The details of diving will depend on the nature of the cultural purposes of the media on which one dives. I then exemplify these categories for a broad variety of cultural purposes in research in the learning and other social sciences, and then consider prospective DIVER uses across this taxonomic span of purpose types for the physical sciences, art, film and popular culture, sports and other entertainments, e-commerce, and training of all kinds including sales and law. It is worth noting that one can distinguish DIVER use by type of media (dynamic or static), and the dynamic media may be either videos, animations, or dynamic records captured from running a simulation or model, whereas the static media may be a radiology image or a work of art or a photograph of a landscape scene or a microstructure of a plant, to name but a few examples.

7.2. Tools for Research on Learning and Other Media

DIVER has been developed first for use as an expert tool involving selecting and annotating video clips of human learning in diverse contexts from classroom learning settings, to the workplace, to home, community, and more informal learning settings—for the purposes of empirical investigations of patterns and relationships in behaviors, talk, and other levels of analysis. With its use for these purposes, we may study knowledge-in-the-making and examine the ways in which the physical, inscriptional, and social environments contribute to learning and knowledge construction. As applied to teaching, one can do empirical investigations of patterns and relationships in the work practices of teachers, and how they relate to student behaviors and artifacts of their work.

In one notable DIVER extension to be discussed, when applied to the physical, biological, and medical sciences, it is often observed that to investigate and understand many of the interesting phenomena of biological growth, or cellular activities, or dynamics of fluid flow or mechanics in physics, one needs video or simulations that can "play" at different spatial and temporal scales. In this use of DIVER, once one has video in hand, one can select and annotate video clips of the physical or biological phenomena at hand—for the purposes of empirical investigations of patterns and relationships.

7.3. Diagnostic Tool

DIVER also provides an experimental tool for teasing out differences in the ways that novices and experts in the learning sciences "see" or "notice" social and behavioral phenomena captured in the video recordings. As applied to teachers, we can use DIVER as a means of identifying differences in the ways that novice and expert teachers "see" or "notice" patterns in learning, classroom interaction, or teaching. We know that there are extraordinary differences in the perceptions and cognitions of expert and novice teachers. Expert teachers literally notice very different things in the unfolding drama of classroom interactions than do novices, and their perception of these patterns contributes to their ability to make nuanced decisions about what to do next to enhance the learning that will take place (Berliner, 1988; 1994). Teachers need to develop expert models for perceiving instructional opportunities and how the challenges of meeting them are achieved.

For either application, one can do free-field selection of parts/clips of the video recording for annotation on their part, but can also provide highly structured assessment templates, in which the DIVER user's attention is directed to particular spatiotemporal co-ordinates in the video array and about which specific questions can be asked. Teaching mentors may also mediate the novice in role-playing the decision-making role of the teacher depicted in the video—"what would you do next?"

Finally, as discussed later, DIVER may find utility in teacher certification processes, used for teachers to build video-based evidence from their teaching practices and other documents that they use to argue that they meet specific rubrics of evaluation.

7.4. Training Tool

We know from the model-scaffold-fade instructional approach that has been called "cognitive apprenticeship" (Collins et al., 1989) that a powerful mode of learning a complex skill and knowledge base is to experience an expert in the discipline modeling their problem formation and problem-solving processes, "thinking aloud", and to then be scaffolded, i.e., supported as a learner, in the performance of that complex activity. Finally, the instructor then "fades" the scaffolding so that the learner can function autonomously without the aides initially required (Pea, 2004). In applying DIVER for such a scenario, learners who seek domain expertise would be provided with inquiry modeling in structured video dives provided by experts. These dives will highlight with guided noticing and commentary how the expert perceives and interprets the complex environment in which their developed skills are deployed. Then, following experiences with such a modeling phase in the cognitive apprenticeship approach, the DIVER user would be provided with scaffolding support in pursuing their own perceptual activities in the task domain. Such scaffolding can take various forms, including reducing the degrees of freedom affiliated with an interpretive response, or other forms of hinting of prospective solution approach to the problems at hand. In any respect, the DIVER user's dives, once posted to WebDIVER, can be provided with asynchronous commentary/critique from experts concerning the user's learning efforts to detect or notice the patterns in the video records that the experts recognize.

7.5. Expressive Communicative Tool

In this scenario, anyone who can use DIVER and desires to communicate a point of view about a media record (static or dynamic) can author a dive. These purposes can be exceptionally diverse, from day-to-day dialogs with peers or family, to formal certification activities, to entertainment—as in making dives of a favorite movie to share fun parts of it with a friend.

A particularly powerful use in this vein would be to ask children in a classroom to dive on a panoramic video of a lesson and to provide the point-of-view path movie and commentary on what they noticed and thought about as it was happening [e.g., Goldman-Segall (1994, 1998) explores what she calls "point of viewing" by learners about their school experiences]. This stimulated-recall scenario is likely to yield results that will surprise the teacher and others who view the students' dives, because we so rarely understand their points of view on the instruction they receive. Yet what matters is their experience, not simply the experience of watching the teaching an adult provides.

There is a potentially radical activist agenda that could be pursued with point-of-view authoring of DIVER videos as well, that builds on work from the 1960s that began to provide cameras and video cameras to children in

Figure 7. Photo courtesy of Paper Tiger Television (http://www.museum.tv/archives/etv/A/html/activisttele/activisttele.htm).

poverty conditions for their own documentation of their reality (see Figure 7), and in general to provide personal alternatives to mass produced studio television programming (e.g., Halleck, 2002; Shamberg & Raindance Corporation "Guerilla Television", 1971).

7.5.1. Tools for Multimodal Studies of Classroom Discourse

Researchers who study learning and teaching in classroom interactions often capture multimedia records and seek to use them for understanding their phenomena of interest. Problems of the selectivity of video recording are compounded with an additional problem. As Hall (2002, personal communication) has argued, the process of moving from a concrete video to a general proposition with scientific status should be transparent and reversible, in order to preserve the status of video as evidence. He suggested that providing viewers with access to the original video and the means to author their own perspectives might be a useful way to maintain focus on the process of fact and argument construction out of video evidence.

If digital video is to become widely used and accepted as evidence in the learning sciences, it is necessary to develop practices for video-based argumentation, as well as statistical uses of video. Otherwise, oft-heard arguments will remain that the selective capture of video is anecdotal and used primarily for buttressing the beliefs of an investigator rather than for systematically testing scientific conjectures. For example, with panoramic video records that do not bias a point of view in selecting specific students to focus on, and an algorithm for data-sampling, one could do randomized time-sampled or other designs for systematic experimental comparisons of student behaviors in an environment employing designed interventions versus a control classroom.

Ken Hay's Integrated Temporal Multimedia Data (ITMD) Project at the University of Georgia uses a variety of cameras, audio recorders, and computing devices to produce multiple streams of data from event recording

(Hay & Kim, in press). This approach ensures that the event is fully documented, but poses difficult issues in data management and integration. Hay and Kim describe some aspects of a response to these issues, such as real-time coding of "nodes" of event activities. The amount of data generated by the ITMD research approach has led Hay's group to a concept with very broad applicability: The amount of "friction" involved in creating and, most importantly, storing, retrieving, and using video records. Friction refers to the amount of time and, secondarily, expense that is required to make a video record useful. If friction is high, researchers will tend to make relatively less video and to make less use of it in their work. If friction is reduced, then we can expect digital video to be more heavily used. Hay urges that friction be quantified as much as possible, and that attention be directed within the community to reducing the amount of friction associated with digital video inquiry.

There are a plethora of tools for video analysis, editing, and reflection, and it is important to characterize some of them briefly and how they relate to our DIVER work. We found in a recent workshop bringing together leading video researchers in the learning sciences and teacher education that there were 10 different functions of video research that are supported (or not) across these different tools (Pea & Hay, 2003): (1) acquisition; (2) chunking; (3) transcription; (4) way-finding; (5) organization/asset management; (6) commentary; (7) coding/annotation; (8) reflection; (9) sharing and publication; and (10) presentation.

Many of the tools used by research communities have focused on developing only a few of these capabilities, and as several examples illustrate, they vary considerably in their strengths of support for the functions. Video-Paper Builder is designed primarily to facilitate the creation of web-based "video-papers", educational research publications that incorporate video clips (Beardsley et al., in press; Nemirovsky et al., 2001). The CLAN tools that MacWhinney and colleagues (2000) have developed for TalkBank provide an exceptional suite of transcription, coding, and annotation tools but are not oriented to supporting reflection, sharing, or commentary. In contrast, the Teachscape platform for providing school districts and teachers with video case studies of exemplary teaching integrated with online community of interpretation focuses on chunking (there are highlighted sections of each of the videos, for particular instructional purposes), and reflection (as supported by use models of study groups of teachers who exploit the online community features at home, e.g., Lu & Rose, 2003). But while providing transcripts of videos used, it does not offer transcription tools, as it is designed more as a teacher professional development environment than as a research tool.

Other tools are tuned to analyzing video records by coding, creating transcripts for and/or annotating video clips (e.g., *Constellations and Orion*: Goldman-Segall, 1994; 1998; in press; *Transana*, 2004; Derry & the STEP Team, 2003; *Video Analysis Support Tool*: Sherin, 2001), and several commercial tools used for coding and transcripts in behavioral sciences research are available in Nudist/nVivo, and atlas.ti. (There is a long history to video annotation and analysis systems I will not survey here, e.g., Harrison & Baecker, 1992; Mackay & Beaudouin-Lafon, 1998; Roschelle et al., 1990).

Video editing and chunking are often accomplished with commercial tools such as Apple Computer's *iMovie* or Adobe *Premiere* but these are not oriented to coding or reflection, among needed functions noted above.

Reed Stevens' desktop *VideoTraces* system (Cherry et al., 2003; Stevens & Toro-Martell, in press; Stevens et al., 2002; Stevens, in press) is oriented to reflection and presentation, in enabling users of his software to lay down a reflective "trace" on top of a video record (the "base" layer that can be played at variable speeds), consisting of voice annotation and a pointing gesture implemented as a pointing hand cursor. A VideoTraces file may then be replayed so that one hears the audio trace overlay and can see the "pointing at" specific aspects of the video record upon which comments are being made. Stevens and colleagues have used this system in science education museums and in diverse higher education courses including rowing and dance composition, illustrating the value of this methodology for providing a time and space-based interpretive layer on video records. In Cherry et al. (2003), uses of VideoTraces in an undergraduate class in dance composition were revealing. They illustrated how providing a concrete representation upon which pointing gestures and voice annotations could be made: (1) supported students in new ways of seeing dance works in terms of concepts and techniques of choreography; and (2) enabled the instructor to better understand students' intentions in their dance work from their VideoTraces annotation of that work, and to provide individual feedback. Students considered viewing the instructor's traces on their dance work video as the course component that contributed most to their learning.

VideoTraces is guided by Stevens and Hall's (1998) insights on the importance in "learning to see" in specific disciplines, what they call "disciplined perception", in the spirit of Goethe (e.g., Seamon & Zajonc, 1998; Shotter, 2000) and Humboldt from an earlier era who used the phrase to describe the possible objective histories of nature that science enables.

Stevens' use of virtual pointing and voice-recorded commenting within a video record provides a complementary but different mechanism to our use in DIVER of guided noticing for achieving common ground in a referring act in the complexity of a video data stream. As yet the VideoTraces system is a stand-alone desktop application written in Macromedia Director, but at a VideoTraces installation site, a use community can also make a response on a VideoTraces file in the manner of a threaded discussion. Unlike DIVER and WebDIVER, VideoTraces does not involve any video transcoding or path authoring activities for the user, or web-based access to such traces.

Diverse computer-based tools are also used for compiling video materials for teacher professional development (Shrader et al., 2002), including commercial products Teachscape and LessonLab. LessonLab (owned by Pearson Education) provides a client-server solution for K-12 schools to construct their own video case training materials from video that they capture themselves. Related research efforts include the Carnegie Knowledge Media Lab (Young, 2001; see http://www.carnegiefoundation.org/KML/), the Case Creator Project (Doerr et al., 2003), Indiana University's Internet Teaching Forum (Barab et al., 2003), STEP (Derry & the STEP Team, 2003) and Schrader et al.'s (2003) work on pre-service teachers' web-based video cases in elementary literacy.

At a more advanced level of teacher competencies, elaborated documentations of professional vision in teaching have been developed at the Carnegie Foundation for the Advancement of Teaching. The Carnegie Foundation, through the Carnegie Academy for the Scholarship of Teaching and Learning (CASTL) and the foundation's Knowledge Media Laboratory, provides exemplary teachers with resources and technical support to fully document an extensive aspect of their teaching, such as a course. CASTL provides fellowship support to allow teachers to devote themselves for a period of 1 or 2 years to the documentation and improvement of their teaching, in part expressed in richly documented web-accessible video (http://kml2.carnegiefoundation.org/html/gallery.php).

In the Case Creator Project (http://www.sci.sdsu.edu/mathvideo/cc/), teacher educators can create interactive video case studies of teaching by importing QuickTime videos and transcripts, creating an "issues matrix" of many different pedagogical issues that are relevant to the case, add web hyperlinks and/or supplementary text.

As interesting as this distinct efforts are, the most important lesson from our video research workshop (Pea & Hay, 2003) was that, without the use of metadata coding and affiliated XML schema exposing such video analysis metadata to browser search, analyses developed with any of these tools will be stranded in data islands that can only be used and understood within the tool in which they are created.

While the issues affiliated with establishing broadly applicable metadata for video analyses and video cases in learning and teaching are significant, since generic and discipline-specific categories for metadata will be needed, the broader goals of establishing distributed communities that can communicate about their video data productively will be unachievable without such efforts. Productive work in this direction for coding metadata for instructional materials is evident in Gateway to Educational Materials (GEMs) instructional topics hierarchy, and pedagogy elements/values (http://www.geminfo.org/), building on the Dublin Core (http://dublincore.org/), and in the metadata development activities of the OLAC (Open Language Archives Community, www.language-archives.org) initiative, which in turn conforms to the larger OAI (Open Archives Initiative, www.oai.org). The stated goal of OLAC/OAI is that "any user on the internet should be able to go to a single gateway to find all the relevant language resources available at all participating institutions, whether the resources be data, tools, or advice. The community will ensure on-going interoperation and quality by following standards for the metadata that describe resources and for processes that review them".

These efforts are founded on the emergence of the Semantic Web and its uses of the Resource Description Framework (RDF), which integrates a variety of applications using XML for syntax and URIs (Universal Resource Identifiers, which include URLs) for naming. "The Semantic Web is an extension of the current web in which information is given well-defined meaning, better enabling computers and people to work in co-operation." (Berners-Lee et al., 2001). As noted on the W3C site (http://www.w3.org/RDF/): "The RDF integrates a variety of applications from library catalogs and world-wide directories to syndication and aggregation of news, software, and content to personal collections of music, photos, and events using XML as an interchange syntax. The RDF specifications provide a lightweight ontology system to support the exchange of knowledge on the web."

7.5.2. Distributed Collaborative Video Interaction Analysis

We believe that video dives will come to play special functions in interpretive activities when people are working to do sense-making together of the records captured in video, whether it is human interactions, teaching behaviors, or other phenomena of interest. Like designers collaboratively working to design objects (Geisler & Rogers, 2000; Hindmarsh et al., 1998), the makers and users of dives take on special relationships with these point-of-view authored video tours as "boundary objects" (Star & Griesemer, 1989) between their special terms and conceptual frameworks of engagement—but opening up the prospects of building common ground (Clark, 1996). Jordan and Henderson's (1995) paper on the Interaction Analysis Laboratory (IAL) methodology for developing multidisciplinary analyses of video through group viewing of tapes in face-to-face settings illustrates the power of doing better collective thinking when researchers can build video analyses by sharing their perspectives on the observed phenomena and theoretical frameworks that they use to make sense of interactions captured in videos.

Building on the IAL methodology, WebDIVER enables distributed communities to contribute distinctive perspectives that, for example, individual researchers have on a video recorded learning interaction, and to then use the contrasts and convergences to advance their collective understanding of the empirical materials. These needs and an approach for tackling them that we have underway will be taken up in Section 8 on video collaboratories.

7.5.3. Teacher Learning and Teacher Education

U.S. processes of teacher education and certification are in major transformation given concerns with increasing levels of student performance in standards-based instruction spurred in part by the federal *No Child Left Behind Act*. Beyond coursework and student teaching, over 40 states mandate that teaching candidates pass tests of basic skills, subject matter knowledge, and/or pedagogical knowledge for certification (Youngs et al., 2003). Since these certification processes are mostly remote from the actual teaching practices, based on written tests and coursework completion, many teacher education programs and states are turning to performance assessments that include video recordings of candidates' classroom teaching practices to make their certification decisions. Video is a potentially more effective assessment method than a written test in providing an unfiltered (even if selective) view of the teacher candidate directly interacting with students.

However, as already noted for learning research, video suffers from a number of obstacles that impede its usefulness, e.g., such as requiring complex knowledge of video-editing software and techniques. And for assessment purposes, video simply does not support the kind of fine-grained access and reference possible with text. It is challenging for a teaching candidate to reference a particular teaching interaction in a video to illustrate how her teaching meets a specific evaluation rubric, e.g., "I promoted conceptual understanding by supporting student inquiry following the question about non-linear functions from the student in the blue shirt in the front left of the room that occurs about five minutes into the video". A scorer of the teacher's video portfolio materials must then search for this incident, and may find it difficult to uniquely identify the candidate's intended event. Scorers of video have the same problem in efficiently and unambiguously pointing to the elements of teaching practice involved in reaching their judgments. The same features that make DIVER uniquely useful for research purposes—using a "virtual camera" to precisely refer to events bounded in space and time within a video, and then attach text annotations to them—make it a potentially transformative technology in the context of teacher assessment and evaluation.

The effort to use DIVER for performance assessment of video records of teaching events builds on other responses to strengthen prospective and practicing teachers' knowledge of both content and content pedagogy, across a broad variety of subject disciplines and age levels, and on portfolio approaches more generally for documenting the work of teaching (e.g., Anderson & DeMeulle, 1998; Athanases, 1994; Porter et al., 2001; Snyder et al., 1998; Stone, 1998). These responses include videocases portraying teaching dilemmas related to content (e.g., Barnett, 1998; Crismond, 2003; Galvis & Nemirovsky, 2003; Horvath & Lehrer, 2000; Koehler, 2002; Mumme, 2003; Schrader et al., 2003), "video clubs" for teachers to review and discuss one another's work (Frederiksen et al., 1998), computer files containing artifacts of an entire year of teaching (Lampert & Loewenberg-Ball, 1998), and videotapes enabling international comparisons of teaching practices (Hiebert et al., 2003; Ma, 1999; Stigler & Hiebert, 1999; Stigler et al., 2000; Ulewicz & Beatty, 2001). Multimedia records portray teaching that is less filtered by interpretation than vignettes or observations, and avoid the complexity and inefficiency of making sense of multiple observations of different teaching actions that occur when students observe different classrooms.

The use of DIVER provides an opportunity for teacher education programs to reform their practices in ways that increase candidates' ability to construct and apply pedagogical content knowledge, analyze student learning, and reflect on video and other records of practice.

Can video analysis software that permits precise reference into a video and other records (such as scanned student work records) improve the quality of assessment over the use of video and other artifacts without such a tool? Can the use of such software reduce the cost (and thus increase the feasibility) of implementing a performance assessment system for credentialing that includes video? Can teacher candidates' use of DIVER software improve their ability to reflect upon their teaching practices, and to recognize the connection between their practice and state and national standards? Uses of DIVER software for teacher education and certification provide a powerful research opportunity to produce knowledge that can guide teacher education institutions and certification agencies.

We have begun to explore these questions in a partnership with the California PACT (Performance Assessment for California Teachers) initiative, designed to respond to 1998 state legislation (California SB 2042) aimed at ensuring that schools employ only "highly qualified" teachers. SB 2042 required that teacher education institutions use a teaching performance assessment certified by the state Commission on Teacher Credentialing to align with California's Teaching Performance Expectations. Twelve California colleges and universities created the PACT consortium to pilot and implement Teaching Event portfolios in this context, and in 2002–2003, more than 600 candidates (and over 125 trained scorers) piloted PACT Teaching Events in the areas of elementary education, English/language arts, history/social science, mathematics, and science. For each PACT Teaching Event, or unit of instruction, candidates completed several entries including: Teaching context narrative, lesson plans, 1–2 videotapes of subject-specific teaching and learning tasks during the unit, analyses of their students' work, and written reflections. These assessments are presented in terms of a Planning, Instruction, Assessment, and Reflection (PIAR) model whereby the teacher certification candidate uses knowledge of students' skills and abilities, coupled with content knowledge and pedagogical knowledge—how best to teach that content in planning, implementing, and assessing instruction. In 2003–2004, all 12 PACT institutions continued using the Teaching Events, 1000 candidates piloted PACT Teaching Events, and pilot uses of DIVER were deployed in this context. Unfortunately, California's budget crisis has put the SB 2042 requirements on hold, and with it, our prospects for undertaking these collaborative studies with the necessary funding.

Nonetheless, there is great promise inherent in California's development of the PACT Teaching Events, as it is consistent with a national trend in which several states and national organizations have created performance-based assessments for teachers including teacher-developed portfolios, classroom observations, and structured interviews (i.e., the Educational Testing Service [ETS], the Interstate New Teacher Assessment and Support Consortium [INTASC], the National Board for Professional Teaching Standards [NBPTS], and institutions seeking accreditation from the National Council for the Accreditation of Teacher Education [NCATE]). PACT Teaching Events could eventually be used in combination with the NBPTS assessments to establish a professional continuum whereby teachers have comparable assessment and professional development experiences throughout their careers. These assessments have many common aspects in being standards-based, content-specific, and involving videotaped instruction, student work products, and reflective analyses of planning, teaching, and student learning.

We hope to have the opportunity to experiment with DIVER use in embedded assessments during teachers' coursework, which would provide an opportunity to capture additional information about candidates' teaching fitness as they proceed through their teacher education program. Such work would provide the occasion for investigating how digital video provides value added over text in the case studies used today (Shulman, 1992). There is relatively little research about how video works in learning: What is the process by which teachers learn from digital video case materials about what types of events it is important to notice, and how to reason about what should be done in such situations, in ways that lead to improvements in their teaching actions and in student learning outcomes? Our plan in the PACT work was to have teacher candidates use a modified version of DIVER to reflect upon and annotate the videos and other media that they submit as part of their PACT Teaching Event performance documentation. DIVER now presents a blank worksheet to be populated with video clips and annotation, but it can be modified to establish a scaffolded worksheet requiring teacher candidates to identify, through video examples and affiliated media, including a description of their teaching context, lesson plans, student work samples, and written reflections, those facets of their teaching that satisfy criteria or tasks that are part of the Teaching Event.

This approach builds on a model of the teacher education process as developing prospective teachers' ability to think analytically and reflectively about their teaching performance (Grossman, 1990; King, 2002; Schon, 1983; 1987; Zeichner & Wray, 2001). Locating specific classroom events in terms of a body of professional knowledge about teaching is a crucial capability in integrating the general content of teacher education into consistently effective practices of teaching. A performance assessment system thus provides an evaluation of the teacher candidate's ability to both construct an effective teaching performance and to reflect upon that performance in professional terms.

This design approach closes the gap between the assessment criteria and the teaching fitness evidence—the video record of the teaching performance and supporting materials of plans and student work. Evaluators would see a worksheet populated by the candidate with clips, document highlights, and text annotations that express precisely how the candidate believes that he or she has satisfied PACT assessment criteria. The evaluator would use the DIVER worksheet to quickly but accurately assess the candidate's understanding of the standards and his or her performance, and can easily refer back to the full video record of the Teaching Event to settle questions that arise.

7.5.4. User Studies

A large field of use for video is in the human–computer interaction field, a design-oriented discipline in which records of users interacting with software, information systems, or computing devices are analyzed to understand problems users are having that could be improved through user-centered design accounting for forms of support and resources given discoveries about the user's information needs during tasks (e.g., Allen, 1996; Dourish & Button, 1998; Ehn, 1988; Laurel, 1990; Preece et al., 2002; Schuler & Namioka, 1993; Winograd, 1996). The concept for using DIVER in this line of research is tightening the loop between design prototyping, use study and iterative re-design driven by what is learned from use studies. Participatory design methods could also incorporate stimulated-recall sessions with users who reflect using DIVER on video captured of their use of prototype or new technologies in context (inspired by Iacucci et al., 2002; Masten & Plowman, 2003). The DIVER researcher can capture video, and after uploading it to the WebDIVER communication server, can either create dives in the DIVER desktop application or directly on streaming video from the WebDIVER site through a web-browser. These dives could highlight specific facets of the user interactions that reveal problems, and with their web accessibility could immediately enable the designer or design team to review the dive to learn about problems with their design and, if offered by the diver, suggested resolutions.

7.5.5. Scientific Imagery, Visualization, and Models

We have begun to explore DIVER as a tool for diving ever more deeply into the study of visual phenomena apart from human behavior and interaction. The different kinds of applications that we see as fertile fall into a number of different higher-order classes, with extensive branching below in the hierarchy. For each class, we see utility in two broad types of DIVER use—for static and dynamic (time-varying) materials. The higher-order classes I will differentiate here are (1) image analysis at any scale, (2) visualization analysis at any scale, and (3) visual model or diagram analysis.

7.5.5.1. Geo-spatial and Semio-spatial Representations

An additional distinction of note is that between representations that are "geo-spatial" versus "semio-spatial " (see Roschelle & Pea, 2002). Both class (1)—*images* (such as photos)—and class (2)—*visualizations* (such as geographic maps)—are geo-spatial. But class (3)—*visual models and diagrams*—also important scientific representations, are commonly semio-spatial. We define geo-spatial representations (geo = "of the world") by formally specifiable mapping functions from measurable spatial parameters of the physical world (distance and direction, as in terms of height, depth, width) and their representational system counterparts (i.e., inscriptions: e.g., 2D and 3D maps, drawings, photos). These mapping functions are not always isomorphic, as in the renowned Mercator projection for the earth's surface, producing distortions at the poles. Geo-spatial representations are geo-gridded, a common property of many scientific visualizations (e.g., Goodchild, 1992; Gordin & Pea, 1995; Pea, 2002), in that they incorporate latitude and longitude grid "cells", which may vary in their resolution from coarse to minute.

The important differentiation for semio-spatial representations is that their spatial attributes *are not mappable* to spatial attributes of the physical world. Consider several familiar semio-spatial representations by which we may illustrate this important difference: *graphs* of all sorts, and *concept maps* (which represent taxonomic and other typological relations in the form of directed graphs), *flowcharts*, and *organization charts*. Yet, importantly for the human activity of guided noticing, both geo-spatial and semio-spatial representations are usefully exploited for supporting reasoning, argumentation, and deictic functions that are important for establishing co-reference and attentional alignment of different individuals in their communicative purposes.

With this distinction as backdrop, let us now consider the three categories of diving for scientific inquiries that I believe are useful to distinguish (1) image analysis, (2) visualization analysis, and (3) visual model or diagram analysis.

7.5.5.2. Image Analysis at Any Scale

Whether one is looking at a nanotechnology scale at atom assemblies or a cosmological scale involving astronomical images from the origins of the universe, the guided noticing framework of DIVER provides a powerful facility for establishing referential common ground—among scientific experts or in educational communications. We have been looking at DIVER use for a broad range of different scientific applications involving static images: Here we will briefly describe prospects concerning medical, astronomical, and satellite imagery.

Consider *medical imagery*. Whether images are captured with microscopes, X-ray machines, CAT scans, f-MRI technology, or simply cameras, the images

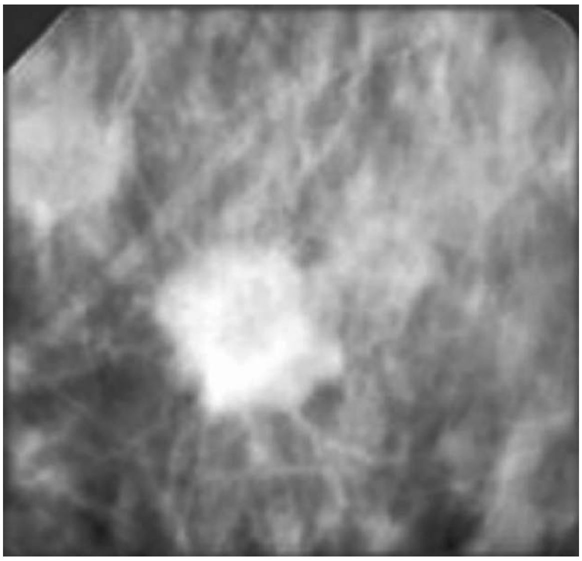

Figure 8. A malignant tumor revealed in a digital mammogram (Electronic Radiation Laboratory).

are complex and multifaceted in nature, revealing differentiation and structure. In radiology, a common issue is diagnosing whether a tumor is revealed, say in a mammogram (see Figure 8).

Use of guided noticing in DIVER provides a focusing and naming mechanism for depicting the malignant organ part in a radiological image, and a DIVER collection of clear cases of tumors, clear cases of non-tumors, and differentiating properties of boundary cases (tumor, non-tumor) could be used for training up diagnostic vision among mammogram analysts.

Consider *astronomical imagery*. In the Sloan Digital Sky Survey (http://www.sdss.org/, http://skyserver.sdss.org), the field of astronomy is collaboratively developing an exceptional resource for aggregating all observations and imagery of the skies visible from the Northern Hemisphere for advancing scientific discovery in the field, with over 100 million astronomical objects already logged in over 200 terabytes (TBs) of data. The virtual observatory in development as SkyQuery (http://www.skyquery.net/) enables interactive queries of astronomical data from the SDSS, so that one can zoom in or out, investigate adjacent phenomena, link through to publications on the astronomical object referred to and so on. Figure 9 illustrates the exquisite spiral of an astronomical object called “NGC 3521”.

We can foresee DIVER use for assembling a database of dives to illustrate for educative or research purposes multiple examples of a particular astronomical categorical type (e.g., spiral galaxies, edge-on galaxies, interacting galaxies), where particular differentiating features of these entities are established using DIVER’s path movies, guided noticing mechanism, and annotations.

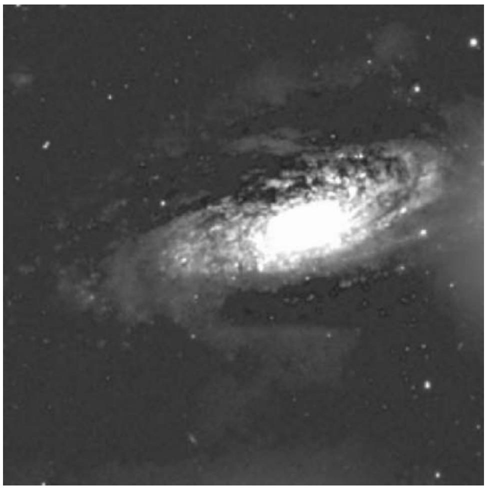

Figure 9. The famous "spiral" astronomical object NGC-3521 from the Sloan Digital Sky Survey (http://skyserver.sdss.org/dr1/en/tools/places/page2.asp).

Finally, consider static *aerial, satellite, and topographical images of the earth's surface*. As in the case of the SDSS, a vast online atlas has been developed—the TerraServer website (http://terraserver-usa.com/ provides United States imagery and http://terraserver.com/ offers European and Asian imagery)—which integrates over 15 TBs of aerial imagery and 1.5 TBs of topographic maps from the U.S. Geological Survey. These photographic images, one per location and averaging 5 years old, are captured with medium resolution cameras so as to identify geographical features (not people, autos, or houses), as illustrated in Figure 10. Another such resource appearing in 2005 was Google Earth.

Using such images with DIVER, one can create "dives" for a variety of purposes involving geographic information. Urban planners and landscape designers can depict flow routes and landmarks, and create dive commentary on their inter-relationships—for historical teaching, for designing based on prior art (or overcoming its limitations), for discussions with citizenry to explore issues and environmental impact concerns of anticipated changes in a city or town's landscape.

My intent here is to be illustrative in sketching medical, astronomical, and geographical imagery that is static in nature but nonetheless provides a rich resource for diving with DIVER, across the expert research, diagnostic use, training, and expressive communicative use categories that were distinguished earlier.

Although I have been focusing here on the values of diving on *static* imagery, dynamic, animated sequences of images, at different time scales, can yield crucially new and different kinds of information to support theory-driven inferences about developmental, causal, and other relationships that

Figure 10. An aerial photo of Stanford University Quad from 1991, downloaded from the TerraServer, with 2-meter resolution.

lie latent in the static image on its own. In my work during the 1990s on scientific visualizations for learning, I was struck by the power of a time-lapsed video sequence of San Francisco skies captured by the Exploratorium Science Museum; it revealed different strata of clouds that were moving in different directions at wildly different speeds, an effect I had never observed in the normal time-course of experience. MIT's Harold Edgerton, through his invention of high-speed photography and film using stroboscopes, brought a powerful new machinery for "seeing the unseen" in the visual world, from hummingbird flight to bullets bursting balloons to the atomic blast (Bruce, 1994; Edgerton et al., 2000). When coupled with DIVER's use of the virtual camera guided noticing mechanism, science investigations of dynamic imagery provide an exciting arena for further development and research.

7.5.5.3. Visualizations at Any Scale

While still geo-spatial in their fundamental nature, scientific visualizations (as distinct from imagery), utilize a geo-gridded framework and superimpose upon it representations of data values for variables that have been either directly captured through observational instruments or inferred in terms of a model for interpolating between the distinct locations where data are collected. A reference point is provided by the commonly experienced graphics from the newspaper *USA Today* and TV news weather reports: The use of a false-color map representing the range of temperature in degrees Fahrenheit or Celsius on a geographic map. While these weather data are useful at a particular point in time, for reading out the actual or predicted temperature at specific locations on the map, it is only from animating a sequence of such visualizations that the patterns of change that indicate "fronts" (highs and lows of pressure that influence temperature and precipitation changes) become evident, among other emerging inter-relationships between the data quantities visualized.

Scientific visualization dramatically changed scientists' practices in recent years by "using vision to think" (Card et al., 1999), exploiting human visual pattern perception for complex investigations within large data sets (e.g., Brodie et al., 1992; Cerf et al., 1993; Nielsen et al., 1997; Tufte, 1997; Wolff & Yaeger, 1993). Such visualization provides an image rendered through high-speed computer graphics that is based on a numerical data set that describes some quantity in the world (e.g., global temperatures). The field of scientific visualization came to broad visibility after a major report provided an integrated account of the productive collaborations that were emerging from the disciplines of science, computer science, and visual arts (McCormick et al., 1987). Such scientific visualizations commonly leveraged uses of color, shape, and motion to provide new visions into the structure and patterns that could be teased out of large and complex data sets. Gordin and Pea (1995) observed that scientific visualizations are generally characterized by how they (1) incorporate massive amounts of quantitative data, (2) aim for verisimilitude with the phenomena they represent, (3) attempt to represent entire phenomena holistically by interpolating from data, (4) employ color and shape to encode the magnitude of variables, (5) use animated sequences to show progression over time, and (6) rely on high-speed computation to generate images.

Gordin and Pea noted that scientific visualizations, while often similar to digital photographs in containing a set of values that can be rendered by mapping each number to a particular color, vary from digital imagery in that the numerical values composing a scientific visualization image commonly represent abstract quantities (e.g., precipitation), not formed from the variable intensities of visible light used in photography. A color range is defined according to which various values of precipitation are assigned specific colors, so that a geographic map can depict a digital image of variation in precipitation across the region displayed. The variations and patterns of color allow one using scientific visualizations to discover underlying patterns more straightforwardly than by scanning over data tables for different geo-locations. They may reveal to the human senses what could readily go unnoticed in a typological representation such as a data matrix or function. Underlying processes may also become visible if successive images over time are animated. By design, scientific visualizations strategically engage color and motion in order to tap the human visual system's capabilities.

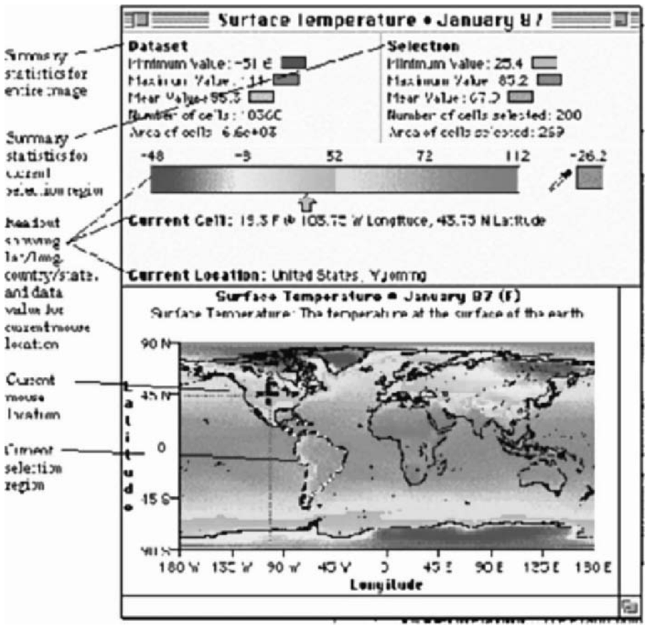

Figure 11. A WorldWatcher visualization window with key to what is represented.

In our Learning through Collaborative Visualization (CoVis) Project (see Pea, 2002; http://www.covis.nwu.edu) at Northwestern University, and the related WorldWatcher software development and curriculum projects (Edelson & Gordin, 1998; Edelson et al., 1999; http://www.worldwatcher .northwestern.edu/), we developed a powerful open framework in which static and animated visualizations could be created for project-based scientific inquiries from scores of public domain geo-gridded data sets as well as personal data. WorldWatcher provided a learning and inquiry environment for students to explore data sets created by the scientific community (and to also create their own data using built-in arithmetic operations and climate models) while providing key features for data display and analysis commonly used in the powerful, general-purpose visualization environments of scientists. For example, the mapping of variable values to colors is used to display 2D global temperature data (as in Figure 11) on a geographical information grid with latitude and longitude border marks and an overlay of a continent outline (optional). When a user interacts with the WorldWatcher visualization, a continually updating readout tracks the user's mouse location and displays current latitude, longitude, country or state/province, and data values.

In their inquiries, users may tailor visualizations by modifying colorscheme, mapping of colors to numerical values, spatial resolution, and magnification. Statistical summaries are provided for regions a user selects, for whole maps by specifying geographic areas (by name), or data values (by ranges). WorldWatcher also offers select operations for mathematical data analysis within an image so that users can add, subtract, multiply, or divide all the values in a region or an entire image by a constant (as well as normalizing values for an image). WorldWatcher users can apply a function at each location in two different images using any of a set of binary operators—addition, subtraction, multiplication, division, maximum, minimum, and correlation—which then yields a new visualization as a result.

WorldWatcher data sets for global climate change for examining the transfer of energy through the earth–atmosphere system (e.g., absorbed/reflected solar energy, surface temperature) are complemented by human and physical geography data so students can examine sources and impacts of climate change. Global climate data on precipitation and relative humidity are provided, as are physical geography data on elevation/bathymetry, soil type, dominant vegetation and ground cover, and plant energy absorption (FPAR). Students may also access global information on population magnitude and density, carbon emissions, and national boundaries.

What is the relevance of WorldWatcher for DIVER's guided noticing framework? It is the pre-eminent example of scientific visualization software tools and data sets used for pre-college education. Yet many practical challenges affiliated with its use in an educational setting arise from the difficulty of establishing common ground to what is being referred to in a learning conversation between individuals that has WorldWatcher scientific visualizations as its source. WorldWatcher users have powerful display and analysis capabilities, akin to those of scientists. They also have very useful notebook facilities that enable users to author text, and paste in visualization window results, animations and hyperlinks to specific visualizations. But even with these facilities, the complex visual arrays of information represented by its visualizations cry out for a complementary tool of guided noticing such as DIVER could provide.

How might this work? WorldWatcher already supports the creation of animations in the form of Apple QuickTime movies from a meaningful sequence of visualizations. Such animation capability is especially useful for time-series data, as in the 12 different visualizations of global temperature data (or insolation), one per month, so as to highlight the patterns of temperature (or incoming solar energy) and their distribution over the earth's surface. But a learner can easily need to refer to specific time–space pathways through such an animation—as DIVER would support for such animated movies—rather than the animation as a whole representing the whole earth's surface. These movies can only be played within the WorldWatcher application today, but we can see how diving into both the dynamic and static scientific visualizations that WorldWatcher enables users to create could provide a crucial enhancement to their meaning-making and expressive capabilities concerning their beliefs and evidence for them in the data analyses that they are constructing. These same arguments apply to other scientific visualization environments that may be used to greater effect for learning and establishing common ground in conversations by use of DIVER's guided noticing capabilities.

7.5.5.4. Visual Model or Diagram Analysis

In Section 7.5.5, I observed that whereas both scientific imagery and scientific visualization are geo-spatial and turn in part for their meaning on the mapping between the spatial co-ordinates of the world that they represent and features of the representation, visual models and diagrams do not necessarily share this property. Instead, they are semio-spatial, in that the use of spatial distinctions in the external representation (or inscription, as Latour would call it) has a utility defined by social convention but that does not map onto a geographical grid according to any mathematical function. The spatial relations depicted in the visual models or diagrams are often not to scale (e.g., diagrams of the planets in our solar system never are). Furthermore, visual models and diagrams often introduce arbitrary conventions for the uses of space; as in Cartesian x–y co-ordinate graphs, or flow charts in operations research or computer science.

Concept maps are used as a technique for representing knowledge in graphs, or networks of concepts, which are made up from nodes and links that connect the nodes. Typically, nodes in concept maps represent concepts, and links represent their inter-relationships (e.g., causes, is-a, is-part-of, son-of, comes-after). These representations are often used as an instructional technique but also for learning assessment and for brainstorming in a group (e.g., Lawson, 1994; Novak, 1998). It should be clear from this characterization that the spatial relationships in concept map representations are not geo-gridded in nature.

This category of representation, as with the categories of scientific imagery and scientific visualizations, encompasses a great plethora of examples. And many of the tokens of this type also have their static and dynamic, time-varying types (e.g., one can play out different successive states in such a diagram model of a set of conceptual relationships, as in moving an object progressively toward a concave mirror and depicting when the image "flips" in orientation). In many scientific fields, visual explanatory models are established that are semio-spatial in structure and not intended to convey spatial mapping onto the world's co-ordinates. These models may be two-dimensional, three-dimensional, and four-dimensional (with time as the fourth dimension), and can encompass much harder to visualize $4 + n$ dimensions.

There are hybrid representations that incorporate both geo-spatial and semio-spatial aspects, as in physics force-diagrams, particularly when used in educational software programs such as *Interactive Physics* (Figure 12) or *Working Model* (http://www.krev.com/), or in simulations for teaching physics such as the Java applets of the Constructing Physics Understanding Project (http://cpucips.sdsu.edu/). In such examples, representations of

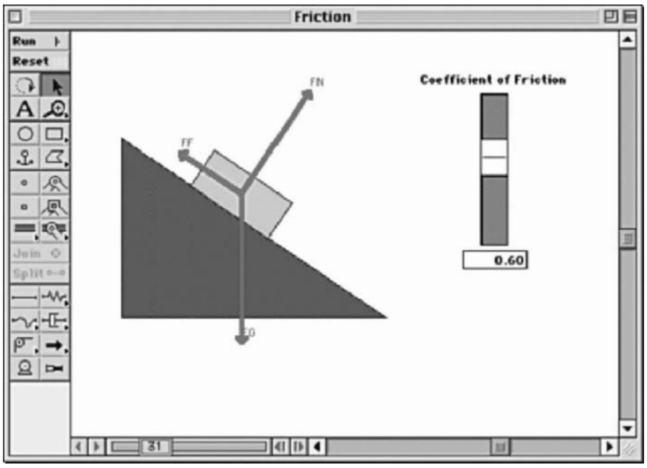

Figure 12. Physics diagram illustrating geo-spatial and semio-spatial properties.

conceptual entities such as forces are superimposed on *schematic* diagrams of a *general* type of physical situation, which has spatial properties although how they map onto any specific geographical space is not of primary concern; they are intended to represent the general case of such a situation, wherever it is embodied in the world. Other similar examples are diagrams used to depict ray-tracing in geometrical optics to explain how images are formed (Pea, 1992, 1994), energy diagrams depicting how heat, light, and sound are propagated through different materials (Linn & Hsi, 2000), and schematics of electrical circuits and how current flows in them with batteries and bulbs.

As in the case of scientific imagery and scientific visualizations, we would argue that DIVER's guided noticing provides an important capability for use with such representations, whether for purposes of instruction, assessment, or the needs of the expert in the field communicating about their beliefs or results to colleagues. In many of these complex representations, specific part-to-part relationships are the subject of a commentary or interpretation, and it is difficult to refer at the "whole model" or diagram level. While pointing arrows or circled regions are commonly used to refer to a specific component of a visual model or diagram for labeling or interpretation in the acts of communication or teaching, it is challenging to make reference to multipart connections within such representations—and harder still to respond to them in a precise way.

These issues could potentially be resolved by the use of a DIVER worksheet that takes as inputs either static visual models or diagrams, or their depicted changed states over time, and in use scenarios where the user dives on these representations to make a point or raise a question that involves connecting diverse components within the DIVER input representation.

7.5.6. Art, Photography, and Diver: The Virtual Docent

What does the art expert see in the works that he or she views? How do experts disagree about what there is to see in a given painting? Most of us have toured an art museum and been led on walks through exhibits of paintings, sculpture, photography, and other cultural artifacts. The docent who leads such tours, whether a seasoned expert art critic or historian, or simply a knowledgeable hobbyist who works for the institution, has a stock of professional vision that they bring to bear in this social practice. They know where to focus their attention on the figures or features of works that bear close scrutiny, and how to use the categories of interpretation and inter-relationships among artists, periods, historical events, and other factors to provide any one of a number of hermeneutic accounts of what is in view. There are many art books in print, as well—exemplified in works such as John Berger's (1972) *Ways of Seeing*—that seek to provide support for others to learn to notice properties of artistic works and how they illustrate specific techniques, influences, or emblematic characteristics of a school such as Surrealism or Impressionism. Picasso's painting Guernica is a favored example of a famous and influential work requiring such interpretive gymnastics to bring its senses to the viewer (e.g., Martin, 2002).

DIVER makes it easy to take such transient practices as the art museum tour, today repeated again and again and primarily face to face in the art museum itself with original works, and to create "virtual docents" (a concept suggested by Rayward & Twidale, 1999, among others). Indeed, the WebDIVER database established from art analysts' dives on media recordings of art originals (or scanned versions of their reproductions) may also encourage a form of comparative activity in which multiple interpretations of an artistic work could be established, and form the grist for either online or seminar-based reflective discussions. Art museums could provide docents with DIVER to use to craft reflective tours using guided noticing and annotations for remote visitors of different ages and interests, not only a one-size-fits-all form like today. And more imaginatively, it would be possible for WebDIVER visitors for art museums to experience different dives about a significant work and make their own comments and ratings of these dives, much as user communities today can do for books in Amazon.com or sellers in Ebay.com. Then one could come to view, depending on one's preferences, only the dives of greatest perceived value for any given art work.

The same categories of use we have seen for video records of teaching practice and scientific imagery and visualization apply in this case. The art expert can use DIVER for professional analyses; the art instructor may use it for guiding the development of professional vision for students and affiliated assessment activities, while the public may engage in informal communicative exchanges surrounding their interests in art.

As we enter a new media era in which more and more digital representations of artistic works are being established so that a world of computer users with web access may experience them in some manner from afar (e.g., http://www.archimuse.com/), the needs of being able to refer to specific features of these works as an anchor for annotations and interpretive discussions will also grow. The Getty Museum among others has begun to recognize this need in its use recently of a web software-authoring tool called *Zoomify* (http://www.zoomify.com/), which makes it possible to interactively pan and zoom atop still images (http://www.getty.edu/art/exhibitions/flemish/zoom.html), akin in spirit to the DIVER guided noticing mechanism.

With the development of methods that extend the user experience of an art work temporally by providing interactive methods for exploring its representation in a digital medium, such as interactive 3-D depictions of sculptures that one can virtually walk around, or interactive panoramic static imagery of large spaces such as churches or city streets captured in immersive media like Apple QuickTimeVR using 360° rotational filming techniques (e.g., http://www.multimedialibrary.com/), we are increasing the challenges of making precise references to the facet of the art work for interpretive focus. What DIVER can bring to these interactive art experiences is a storytelling, guided noticing technology for one to be able to re-purpose those fascinating representations to author one's own point-of-view perspective on the artistic works thus represented.

7.5.7. Film and Cultural Studies: Motion Pictures, Documentaries, Television, and Advertising

If the need for guided noticing to establish common ground for interpretive discussions and teaching of professional vision is evident for static art works, it is certainly a paragon need once we enter the semiotic realms of film and television. Whether the medium is fictional, documentary or art film in focus, a soap opera show or simply a television ad during the SuperBowl, the path-movie techniques of DIVER provide an indispensable tool for film and cultural studies.

Film school students spend considerable time studying major filmmakers, film genres such as *film noir* or *new wave cinema*, the grammar of cinematography (Metz, 1974) including shot segmentation, camera rotational movements (*pan* on x-axis, *tilt* on y-axis, and *dolly* on z-axis), and transition effects (cut, fade, and cross-fade) as well as narrative techniques such as montage and flashbacks, and the new computer morphing and animated special effects that have defined recent developments of this cultural medium, as in *The Matrix* films. And then they create film works to bring to light their own creative talents, inevitably grounded in how they come to be interpreted by others in the works of an earlier era that created the categories we now view as significant (when we “see”, for example, the use of Alfred Hitchcock’s techniques for establishing terror in the films of Brian DePalma).

DIVER provides a new tool for the film school faculty member and the film student to develop the hermeneutical talents and web of perceptive knowledge that ties together the history of films, filmmakers, film methods and techniques, and film criticism. Being able to create annotated dives about a film, its makers’ works, and the perceptible influences of other film works would be an exceptional resource for the film industry and filmmaker education.

The practical challenge is to establish the digitized films for use in DIVER software and to ensure that the digital rights are preserved for the film owners. It may also be controversial among filmmakers to have people diving on their films, for derivative works resulting from such techniques as the colorizing of black and white films by Ted Turner on TNT Cable have not been popular. But because of the focus plus context interface for DIVER film analysis (i.e., the full film view is always available so that the virtual camera focus window contents can be seen in context), and the fact that one is not creating new movies during Diving but simply making a replayable view onto the original movies, it can plausibly be argued that DIVER is providing a kind of conceptual spectacles for seeing movies, and not making derivative works.

Although I have emphasized film, the same points apply for media-based studies of popular culture through mass communications including TV programs, news, and advertizing, whose forms and techniques also have cultural histories and interpretive needs for guided noticing (e.g., Goffman, 1979; Williamson, 1994). There are also many thousands of historical film archives among the million digital artifacts represented in the American Memory Project of the Library of Congress (http://memory.loc.gov/), and the Internet Archives (http://www.archive.org/), which could be used in DIVER to illustrate specific genres, attitudes, behaviors, or phenomena of a particular historical period.

7.5.8. Sports, Concerts, Travel, and Other Forms of Entertainment

Films and shows of sporting events, musical concerts, plays, dances, and other performances provide compelling media for DIVER use as well. For example, even with the rapidly growing prevalence of people on chat channels and online forums discussing television shows even as they are being watched, it is impossible to anchor these discussions in specific time–space segments of particular shows. Viewers use awkward circumlocutions to tie their questions, approvals, and complaints to specific parts of these media events. DIVER would allow not only video-anchored discussions of popular media from broadcast television of news, sports, and music and other events, but path-movies and annotations that reference very specific segments of what happened for purposes of discussion.

Sports events are becoming an increasing realm of technological innovation to enhance the user experience for that event—new interactive television methods provide a pay-on-demand user with the capabilities to switch among different cameras trained on a football game (from the coach to players wearing helmet cameras, as in *OpenTV's* service for over 20 million World Cup Fans in 2002 enabling viewers to select camera angles, and view statistics on players and teams). And *DartFish*, a Swiss company with the slogan "Making the invisible visible", uses video image processing to provide dramatic image overlays of different skiing trials during the Winter Olympic Games and other sporting events. In another example of interactive applications, Dartfish's 3D Visualization technology made its TV debut during the 2003 Alpine Ski World Championships. It provides a 3D virtual reality landscape of a real racing environment by precisely reconstructing the course traveled during a race by each competitor and then situating them in the 3D landscape so that spectators can experience an unrestricted view of the actual race, watching it from any angle at any playback speed. But much more interactivity is possible if the sports lover could dive on different video records of the sporting event and send links to their uniquely authored dives to friends and others—their perspective, path, and commentary on the dynamic events of sporting, from the great play to the botched catch. Such an application of DIVER, if it could be established among the sporting program producers, or made accessible as a capability at their online sites, could become a new cultural medium for sharing sporting experiences.

Another example is the television travelog—the tour to Rome, the Yucatan's Aztec ruins, nature experiences in the jungles or African Sahara, or Darwin's Galapagos Islands. Today's travelogs tend to be monologs, but with point-of-view authoring many different travelers could utilize a database of panoramic video (or other videos) and make their own DIVER movies to communicate about what they found compelling. These dives could be shared as DIVER video blogs with family and friends at home but more broadly they could be posted online with the likelihood of stimulating greater tourism, and be classified according to the demographics and interests of those who are making the dives (show me Cairo from the point of view of the ancient Egyptian scholar). The advent of video camera cell phones could accelerate this vision substantially.

7.5.9. Training of All Kinds

DIVER's guided noticing approach for any user to author and annotate path movies within movies for web publishing and reflective discourse has potentially broad applicability for training in virtually any work sector. Typically learning is affiliated with the development of professional vision and comparative discrimination of higher and lower forms of performance that learning from dives created by instructors may enable. Of course, watching Tiger Wood golf videos is no substitute for playing golf oneself, and the importance of learning from comparative analyses of one's own performances and those of an expert is well recognized already in commercial video software tools for sports training available from such companies as SportsTec, Dartfish, and Pinnacle. Enhanced perception in a professional sphere alone will not usually suffice for expertise (with judging of sports such as gymnastics, skating, and diving providing interesting exceptions)—it is the application of that enhanced professional vision when coupled with the actions appropriate to expertise in the domain that is the intention of video-enhanced instructional processes.

It is perhaps less well known that video is extensively used for high-stakes training in applications such as mock jury trial preparation and witness deposition, police handling of crisis events, and making effective sales closings for costly products (e.g., ultrafast internet backbone switches). Whether in applications such as these, or in routine forms of workplace or corporate training ranging from running quality meetings to using factory machines correctly, providing DIVER as a tool for simply creating instructional dives on *in situ* performances, and enabling diving on the learner's own performances could serve on-the-job training.

8. TOWARD DIGITAL VIDEO COLLABORATORIES (DVC)

In the last section of this chapter before considering future directions, I will outline our approach to developing an infrastructure for integrating video analysis, sharing, and collaboration in research communities, although it can have broad applicability in the other cultural spheres sketched throughout this chapter.

8.1. A DVC User Scenario

The following user scenario of behavioral scientists using video-as-data illustrates the capabilities we are developing with our colleague Brian MacWhinney of Carnegie Mellon University to enable a new form of scientific dialog based on detailed examinations of video. Using current practices and tools, the scientific work described below would not be feasible. Consider a scenario where a researcher learns about a new finding in a peer-reviewed journal in her field, and has a competing interpretation for the phenomenon (e.g., 4 year olds use of their fingers in solving counting problems). She searches the DVC for examples of such counting phenomena and finds six relevant data sets, physically located in video repositories at a number of different universities, all contributed to a distributed data registry when other researchers provided open access to their data when they published their related work. She analyzes these cases of hand-gestures children used during counting by exploiting an existing coding scheme for video analysis of hand-gestures, loading it into the DIVER interface as a plug-in. Her hunch appears warranted; working from these open source data, she finds significantly more gestures supporting her theory over the claims of the published work she has been reading. She and her students collaborate to develop a dive—a worksheet containing annotated video selections from the data sets she has found through the Collaboratory—that sets forth her theory of hand-gestures, and she contributes the dive to the Video Collaboratory. She sends an e-mail with a hyperlink to her group's new video analysis to the journal article's author and a network of other researchers who are interested in children's counting behavior.

The Video Collaboratory e-print posting of her claims as a commentary to the published work sparks a lively discussion, engaging the article's author, who dissents from her conclusions on the gestural data in children's counting. He responds by reinterpreting the same video cases that she has analyzed, and after several cycles of data analyses, interpretations, and researcher communications, she submits her team's revised e-print as a formal submission to the journal, hyperlinking it to the digital video records and dives comprising their analyses. During the article's peer review process, one reviewer calls for better reliability data for her gesture categorizations from the videos; and she responds with a new round as part of a revise-and-resubmit cycle with the journal's editor. Soon her paper is accepted and published, with its multimedia data analysis history in the Video Collaboratory made accessible to the interested readers.

This scenario illustrates how a number of central research activities will be fundamentally enabled by a DVC infrastructure. After outlining our conceptual analysis of this future, I will briefly sketch the technology we are building for enabling this new mode of research.

8.2. Three Obstacles to a Digital Video Collaboratory

Research communities constitute the social infrastructure for scientific knowledge building, as the human networks through which data are shared among colleagues located at different institutions, research results are circulated and critiqued, journal editing positions are staffed, and manuscripts and publication decisions are vetted. Enabling these communities to use video, not only text, requires removing three obstacles:

1. Video data and analyses must be universally accessible independently of its physical location. Today, video data reside in many heterogeneous repositories, with separate access control, user interface, and querying syntax. We aim to remove this obstacle by developing a virtual

repository, building on grid-enabled middleware in combination with an API (application program interface) and metadata scheme designed to support research use of video-as-data.

2. Research communities must have access to video analysis tools that support discipline-specific analytic practices of annotation, coding, and reference, while enabling communities to make use of existing applications and infrastructure where possible. Today video analysis tools make few provisions for interoperability, forcing researchers to commit to one tool or toolset rather than allowing use of multiple tools. We seek to remove this obstacle by developing generic and discipline-specific XML metadata schema for video analysis, and flexible desktop and web-based video analysis tools.
3. Analyses and commentary must be available for public participation, collaboration, and publishing, including circulation and feedback among smaller groups of researchers. It is extremely difficult now to publish video analyses through the web, and we lack a platform for sustaining video-based collaboration and critique. We are removing this obstacle by developing DIVER as a web-based video analysis and dive-authoring tool.

By removing these three obstacles, we will enable the creation of a DVC: A network of shared video resources, analyses, and collaboration opportunities located within scientific research communities. The following sections briefly address each of these DVC elements in turn.

8.3. Virtual Repository for Video Data and Analyses

We use the phrase "virtual repository" to characterize a distributed set of heterogeneous video and metadata repositories that appear to users and client tools as a single searchable repository. A virtual repository is a key element in a Collaboratory as it provides a research community with a touchstone corpus of empirical materials and analyses to which members may have access (Berman et al., 2003). There currently exists no such virtual repository for video data in the human sciences, although the *Open Video Project* has developed a large testbed resource for digital video research work on such problems as automatic segmentation, summarization, creation of content surrogates, and developing face recognition algorithms (Geisler et al., 2002). The closest analog is *TalkBank*, which provides a few heavily used and oft-cited data corpora (particularly audio data) in a number of language-related sub-disciplines. However, TalkBank is currently a single repository with a site-specific user and software interface, requiring local knowledge, such as what kinds of materials are likely to be found.

Even if a research community could be built around a single repository, video storage requirements mitigate for distributed storage. The storage needs are vast for even 100 researchers contributing a few hundred hours of video (a common corpus size for a single study) at a variety of resolutions and different compression ratios (a “small” corpus relative to the many thousands of human scientists using video integrally in their research). A moderate size research community will need to store and manage tens and even hundreds of terabytes of video (with petabytes and exabytes close within view). As a benchmark, consider that TV worldwide is generating about 31 million hours of original programming (~70,000 TBs) each year, while worldwide production of filmed original content for cinema, and made-for-TV films or series is about ~25,000 TBs per year (Lyman & Varian, 2003). The estimated global total of motion pictures made with surviving stock from 1890 to 2003 is about 370,000 and if digitally stored, would require 740.7 petabytes of storage. Several research centers already serve data from petabyte-size storage archives (http://en.wikipedia.org/wiki/Petabyte).

Insulating users and applications from idiosyncratic features of multiple repositories requires an intermediate software layer for translating generic requests into requests that can query each specific repository and translate whatever data are returned into a standard form. We envision a middleware layer of software architecture providing repository services to client applications *via* a public interface, and in turn interacting with repository-specific translation components that map generic method calls for access, search, and retrieval into repository-specific interfaces. Repositories can expose their contents to the collaboratory without altering their practices for storing and retrieving video and metadata, so long as they implement a version of the translation layer for their repository.

The NSF Middleware Initiative (NMI, 2004: www.nsf-middleware.org) and the incorporated Globus Toolkit provides a solid base of common protocols and low-level services for implementing this vision using Grid computing technology (Foster & Kesselman, 2003), although it does not deal directly with video resources. Some NMI components can be used directly (e.g., Grid Security Infrastructure for access control and authentication, GridFTP for file transfers: Globus Project, 2000), but others will require extension for use with video virtual repositories. Treating *video-as-data for discovery*, in contrast to content to be located and delivered (as in Internet-2 videoconferencing or file-serving today), imposes a heavier burden on the repository and its search functionality. Delegating basic functionality to the NMI components such as user authentication and resource registration enables us to focus on search functions, perhaps the greatest challenge in establishing a virtual repository. Here the gap is widest between the ideal of a single searchable repository and the reality of repositories with heterogeneous metadata schemes, some standardized and others *ad hoc*. Our approach will not require repositories to re-index data to a common metadata scheme, or engage in an unrealistic translation project, but focuses on assuring that all repositories support a core metadata set, while exposing the range of metadata schemes used beyond that core for the user of the virtual video data repository.

We aim to support three different types of search, each with unique implications for metadata development and the functions of the software layer that translates between the generic virtual repository software interface and the specific interfaces exposed by each local repository:

1. *Full text search* of all metadata. The translation layer for each repository will map a generic full text search into the appropriate local search action.
2. *Core metadata search.* The repository will support a core set of metadata (for which we will adopt the Dublin Core as a first pass, to be amended as experience proves necessary) that are guaranteed to apply to all local repositories. This ensures that all resources from participating repositories have a base level of visibility. The translation layer will map the core metadata into the local repository-specific metadata and syntax.
3. *Extended metadata search.* The repository will expose to the user information about the metadata schema available across the local repositories to which the repository has access (e.g., the GEM instructional topics hierarchy, and pedagogy elements/values, http://www.thegateway.org/). Users can select metadata schema for use in searches, at which point only those repositories supporting the selected metadata schema will be queried. The translation layer will pass the queries through to the local repository, with whatever modifications are required to conform to local syntax. This use of metadata has the advantage of exposing all of the metadata available, while not requiring a mapping to a common *lingua franca* outside the core metadata. It requires only that the local repository publish to the virtual repository a standard description of the metadata schema in use (e.g., using XML Schema).

Many video data repositories will provide scheme-specific metadata to allow researchers to locate classroom interactions matching specific topical and grade-level criteria. Whereas the virtual repository must support a range of metadata schemes at the level of the local repository, the development of a scientific field is enhanced by the common ground established by a shared metadata scheme. Therefore, based on its importance to the multidisciplinary learning research community in our work toward a DVC, collaborator Brian MacWhinney's group at CMU is extending the TalkBank XML Schema (xml.talkbank.org) in building a system for classifying interactional structures in classrooms by developing metadata characterizers based on the vocabulary of interaction analysis methods such as conversational analysis, speech act theory, discourse analysis, and classical rhetoric. This metadata development will be compliant with OLAC (Open Language Archives Community, http://www.language-archives.org/) and the larger Open Archives Initiative (http://www.openarchives.org/).

8.4. Interoperable Application Infrastructure for Video Analysis

Research communities relying solely on text have access to a pre-existing, richly developed research and communications medium that is flexibly adaptable to the requirements of the communities' analytic work. Consider a Shakespeare scholarly community: They have access to the full apparatus of print publishing, word processing, and so on, while also having the capability to extend this apparatus by adding discipline-specific conventions such as shorthand notations for play titles, acts, scenes, and line numbers. This text infrastructure ubiquity is nearly invisible, yet it provides critical support for the community's work in conducting and publishing research.

Today, we do not have a comparable infrastructure for supporting video analysis, publication, collaboration, and critique using video within distributed communities. Existing tools maroon researchers on isolated islands of data, with no easy way to bring to bear other tools or to circulate results to other researchers.

For our DVC work, we bring together the TalkBank and DIVER projects as a concrete base for reconciling this tension. Based on over 20 years of work in the Child Language Data Exchange System (CHILDES: MacWhinney, 2000), the NSF-funded TalkBank project has constructed a full set of quantitative programs for concordance, reliability, part of speech tagging, parsing, coding, and code tracking. These interdisciplinary tools, collectively called CLAN, are designed to support numerous research communities in the area of linguistics and speech analysis, and are being rewritten in Java to work with new XML schema developed at TalkBank for the CHILDES data. As this chapter explains, our work with DIVER provides a user interface paradigm for making persistent pointing references to video source materials that can be annotated and commented upon. DIVER supports researchers in extracting elements of video in the service of analysis and argumentation for many different disciplines. The ability a DIVER user has to impose a theoretical and empirical point of view on a video source, previously available only through general-purpose video-editing software, makes video potentially as pliable and portable a communicative resource as text.

Our collaborative DVC project with MacWhinney is extending these works by:

(1) Extending and disseminating the XML metadata schema at TalkBank to provide for interoperability among video analysis applications (e.g., DIVER and CLAN initially; and later today's linguistic research tools such as SignStream, ATLAS [Architecture and Tools for Linguistic

Analysis Systems], Praat, MediaTagger), including a standard method for extending a core set of functionality.

(2) Extending DIVER using an XML-based schema for representing data dimensions and categories and transcription tools that can accept multiple markup languages *via* XML configuration to incorporate functionality with broad relevance for the human sciences, using the CLAN software as a reference.

(3) Extend WebDIVER services through a lightweight server-based API (Application Program Interface) architecture that will enable users (and developers) to flexibly invoke a number of software components with specific functionality running in a web-browser client.

(4) Extend DIVER to enable analysis of video located remotely so as to remove the need to distribute video copies for local analysis, a functionality we now have in place.

The DVC will thus contain not a single application, but a loosely coupled set of related programs that are fully interoperable because of their common use of standardized XML schema for representing metadata.

8.5. Community-Based Collaborative Video Publishing, Commentary, Critique

Our project focuses on a DVC for research communities rather than for individual researchers. This emphasis stems from the recognition that interaction, collaboration, and critique are at the heart of the scientific enterprise, even though much of the visible research work happens in isolation. In the human sciences today, video is generally confined to the research phase, and discussion and reporting phases are conducted entirely in text (Pea, 1999). This short-circuits the process of critique or secondary analyses, since other researchers do not have access to the underlying evidence in its original form. This state may be contrasted with fields such as *biology* [where GenBank®, the NIH genetic sequence database (Benson et al., 2002), provides an annotated collection of all publicly available DNA sequences, over 40 million as of late 2004], in *neuroscience* (see the Human Brain Project, Gardner et al., 2003; Koslow, 2002); or in the 2003 National Institutes of Health policies requiring data-sharing for all grants with over $500K direct costs: NIH-OD-03-032.

As noted earlier, there were recent efforts (both involving TalkBank) to address these problems by experimenting with linking publication and collaborative commentary on video: A special issue of the *Discourse Processes* published with a CD-ROM (Koschmann, 1999) had multiple researchers analyzing a 6-minute medical school problem-based learning episode. A TalkBank conference in Fall 1999 reflected on that experience and led to TalkBank's organization and production of the CD-ROM for a special issue of the *Journal of the Learning Sciences* (Sfard & McClain, 2002), where six different researchers analyzed a video that documented the role of designed artifacts in secondary mathematics learning. For that JLS special issue, authors had access to transcripts linked to the video in the TalkBank CLAN program, final PDF versions of the articles were edited with Acrobat to create links from specific portions of text to segments of the QuickTime video, and in the final stage of CD-ROM production, authors' analyses were linked back to the original CLAN transcripts and video segments. This JLS issue represented a first case of a digital video collaborative commentary, but even here analysis was disconnected from video data, as authors referenced time codes and transcripts to re-engage with the video source. Such work cannot be done at all on the web today. When considering the challenge of presenting researcher works using multimedia data and enabling web-based commentary, the problem grows. We need the consistent and open form of data organization provided by the global XML standard.

Current video analysis tools are strong individually in various aspects, such as coding, editing, or transcription, as outlined earlier. But none of these tools directly addresses the core challenge of supporting the broader use, sharing, publishing, commentary, criticism, hyper-linking, and referencing of the multimedia data produced and output by the tools. Video-using researchers need to be able to make standardized, accessible and direct contact with competing analyses of audio–video data to enable critical collaborative commentary and cross-referencing for advancing disciplinary knowledge. The integration of video analysis for the work of communities of researchers and practitioners poses technical and design issues that transcend those inherent in developing video analysis tools toward providing a general infrastructure for collaboration.

WebDIVER is designed to go beyond the posting of video data and analyses to the web (now uncommon) so that video may be used as an interactive communication medium in the process of scientific interchange, including collaboration and critique of scientific argument and research evidence. Our first version of WebDIVER provided basic functionality for publishing, viewing, and commenting on analyses authored within the client desktop DIVER application. DIVER users uploaded their source video, analytic clips, and annotations to the WebDIVER site, which then organized the material for display to users through a browsable, searchable community-based website. Other researchers viewing a dive could respond to the author's annotations by posting their own textual comments linked to the video in question, which could then be seen by the author and by other researchers. The key challenge to this approach is that it provides only incomplete DVC features, for a researcher cannot respond to a video comment using source video, but only with textual comments.

As of Autumn 2004, we made a major advance in providing video researchers with new WebDIVER capabilities that enable anyone to do their diving on streaming video files, so that video no longer needs to reside on the diver's own computer. Divers simply use a web-browser to mark and record space–time segments of videos and to make text annotations, and they may draw on a large archive of videos that have been made dive-accessible. Video files are encoded by users in a specific format (Macromedia Flash, .flv) and then uploaded *via* a webpage to the WebDIVER communications server, where our technology makes them accessible for diving. Video providers may also upload movies in other formats such as .mov, .avi, and .mp4 which are automatically transcoded into Flash video on DIVER servers. Our DIVER team is extending these developments to realize our vision of the DVC for robust access control, group formation, e-mail notifications of changes in dives one has authored or subscribed to, and so on. We will also integrate WebDIVER with the DVC virtual data repository concept, so WebDIVER users can store and retrieve video data and analyses without regard to the underlying physical storage locations.

9. ETHICAL ISSUES

A variety of ethical issues are raised by the prospects of broad scale access to video data for research and re-purposing, including issues of human subjects, security and publishing rights. The basic issues raised by point-of-view authoring of digital records for research are privacy and access issues affiliated with human subjects requirements in research policy (Pea & Hay, 2003). Unlike privacy protection for research subjects involving textual or numerical data representations of research data, educational video records potentially include substantial information about specific children and teachers, and in need of careful reviews to protect the privacy of subjects and maintain confidentiality of data whenever appropriate.

These issues are encountered most obviously in the context of protecting the rights of human research subjects in human subject reviews, where research involving video records often faces heightened scrutiny in the United States by Institutional Review Boards (IRBs) for research institutions receiving federal research funding. It is apparent that informed consent for uses of video records of learning and teaching can mean very different things to IRBs and their members, as different personal values come to play in judgments concerning potential risks and benefits from research participation. Many IRBs do not consider uses of research video records of learning and teaching problematic in their re-purposing for teacher education, or in their use for illustrating learning phenomena. But some institutions consider video data to be "secondary" and require destruction of video records after research studies transcribe and code such data, which makes impossible any data sharing or re-visitation of original source data for re-interpretation. Other IRBs require reconsideration of video data use for each and every re-purposing, in that all individuals involved in the recordings must approve each new specific use of the video clips.

The key issue in human subjects review compliance is disclosing foreseeable risks. The Human Subjects Panels of IRBs typically have oversight responsibility for the review of all University projects that involve human subjects in non-medical research to ensure that the rights and welfare of the subjects are adequately protected with informed consent review. Panel reviews commonly involve approval of a clearly worded consent form which assures that the subject (or responsible parent) is fully informed of the risks inherent in participation and of the benefits which might be reasonably expected. As the basic age for participation in research is 18 years, parental permission is requested for their child's participation in educational research.

There is currently little precedent for identifying the range of risks. One option would be to identify the worse case scenario, to disclose such a possibility, and to minimize the likelihood of such risks. For example, a child may become a standard example for the wrong answer to a question. Or if a specific school is identifiable in a video, it may be possible for a criminal to encounter or seek out a video of a child in that school on the web for nefarious purposes. Correlatively, there is also insufficient common practice and understanding concerning the benefits that might be reasonably expected from uses of video records of learning and teaching for promoting advances in scientific understanding of education and enhanced educational practices.

The universality of web access also leads to the question of security. One way to mitigate the risks to subjects of being included in a video is to limit access to known users, and to ensure that the video cannot circulate beyond that group (for example, by using streaming technology rather than file downloads to make the video available). Another method in the biological and medical sciences is to provide access through a user contract to sensitive data *via* a controlled site, commonly called a data enclave.

The TalkBank site maintains a large collection of audio and video data, based at Carnegie Mellon University, and addresses this problem by requiring users of its collection to agree to an extensive code of ethics. This code obligates anyone using TalkBank data to avoid criticism of individuals depicted in the materials. Anyone who violates the code of ethics is subject to community censure. This code is an attempt to balance the privacy and other interests of research subjects with the scientific needs of researchers and affiliated prospective benefits to society, and represents the judgment that personal criticism has sufficient potential for social harm that it should be impermissible.

Another approach is the use of alternatives to video recordings of situated behaviors as they occur naturally in real classroom settings, such as dramatizations and labeling of performances-as-acted allowing illustrations of teachers and students engaged in both desirable and undesirable practices. In such circumstances, media releases rather than human subjects releases are used, since the point is not human subject research but media capture as in a play or movie that can then be shown to others. A central problem here is that the performed versions of learning and teaching may not sufficiently resemble the real thing so as to serve the educational and reflective learning purposes for which they are intended. Research is needed to examine this question. Furthermore, teacher educators who have worked extensively with video case studies of teaching practice commonly emphasize how crucial it is for the teachers learning from these cases that they are filmed in real classrooms, and not enacted behaviors.

Another technical possibility is the use of digital masks of identity, such as using blurring or pixelization filters for faces (e.g., Boyle et al., 2000) and digital transformation of voices to prevent identification of individuals (as in news shows protecting crime witnesses). This approach has the advantage of redacting participant-identifying characteristics of the data in order to protect privacy. It is unclear whether such a method could be made commonly useful, as research is necessary to identify the range of research questions that could best be addressed with such masking, and which could not. For example, discourse and interaction analysis frequently relies upon information about gaze direction, joint attention, and such information in the video would not be available in data records that utilize digital masking.

10. EMERGING TRENDS

In one sense the concepts and technologies reviewed throughout this chapter are already exotic with respect to everyday learning and teaching practices and uses of video in virtual-learning environments. But there are a number of technological frontiers that promise to bring interesting developments worth watching (for details, see Pea & Hoffert, in press).

With the increasing reduction in cost, size, and network connectivity of video devices, digital video sensors and cameras will become ubiquitous, and video data will proliferate through wireless data transmission from locations throughout cities, streets, and in nature. We already see the exponentially growing use of digital photography with camera-enabled cell phones, as people find it compelling to share visual experiences with friends and family. Video cameras and video file sharing are emerging as supported services in cell phones in Japan, Korea and Scandinavia, if uncommon in the United States (as of late 2005). In principle, the video that is captured and shared through such mechanisms provides extensive media for DIVER guided noticing and re-purposing.

Many research groups are also pursuing automated video and voice recognition, to enable parsing of the video streams and metadata tagging components of scenes, such as recognizing specific people and objects, and identifying motion segments and speech conversation segments, for facilitating information retrieval and media re-use.[5] These developments will be of benefit for speeding the process of research use of video records, but also raise challenging problems if they become broadly used and come to endanger human privacy, as some anticipate, in surveillance and security applications.

CONCLUSIONS

Eco (1989) writes about modern music, writing, art and science that "'open' works, insofar as they are in movement, are characterized by the invitation to make the work together with the author and that (2) on a wider level (as a subgenus in the species 'work in movement') there exist works, which though organically completed, are 'open' to a continuous generation of internal relations that the addressee must uncover and select in his act of perceiving the totality of incoming stimuli" (p. 21).

To the extent that DIVER use can make video and other rich media "open" to diving—the authoring of guided noticing using path-movie-making and annotation—there is without question an active role for the reader, who becomes an author in bringing the work of the video or other medium to a more completed state in his or her interpretations of it. DIVER also provides a tool for evidence-based argumentation, in which one uses what one notices in the medium to make a case around it, and thus extends the work in significant ways with the act of authoring the dive.

In this chapter, I have characterized the theoretical foundations of the DIVER Project, which has created a new software system for capturing, annotating, and sharing perspectives (dives) on human activities video recorded in real-world spaces. DIVER couples a Looking overview window with a magnified Noticing window that can be controlled by the user. This viewing mechanism is also an authoring tool, allowing a user to capture and share his or her unique point-of-view and commentary on a source video. Users annotate their selections, share them on the web, and receive comments by others, promoting dialog and collaboration around video-records of common interest. Supporting this user activity sequence of looking at a full record, noticing events of interest and recording them for later use, and then commenting on what has been seen is fundamental for both research and learning from video sources. For the constructivist educator or more generally for those who want a more active voice in media uses for communication and knowledge production, DIVER provides a platform for moving away from today's broadcast-centric and asymmetric uses of video to the communicative empowerment of the video user, who can easily craft point-of-view movies within movies with commentaries to share with others. Whether such methods are used to elaborate collaborative knowledge building in the learning sciences from video sources or for everyday consumer video communications in the future, this shift from consumption to authorship is a fundamental transformation in the use of the video medium.

ENDNOTES

1. A panoramic video camera is created when one or more video cameras are combined with one or more mirrors to capture 360° horizontal data around the panoramic camera's fixed-point location. Image processing software is then used to "dewarp" the imagery that is produced from the reflective surface and to create interpretable displays on a computer monitor of the captured video data. A common method for depicting the panoramic video record is a wide-aspect ratio window that looks as if the cylinder has been sliced and "peeled-back" (see Figure 2 for illustration).
2. I refer to Latour's (1986) influential development of the concept of inscriptions as external representations of ideas that serve as "immutable mobiles" with these key properties: (1) inscriptions are mobile; (2) they are immutable when they move; (3) they are made flat; (4) the scale of the inscriptions may be flexibly modified; (5) they can be cheaply reproduced and spread; (6) they can be reshuffled and recombined; (7) one may superimpose different images of totally different origins and scales; (8) they can be made part of a written text; and (9) their two-dimensional character allows them to merge with geometry.
3. The related idea of "panes" for annotating synchronized video and audio streams was first implemented by Roschelle et al. (1990) in our VideoNoter system; also Roschelle & Goldman (1991).
4. In addition to Joe Rosen's fundamental contributions on design and implementation of DIVER audio focusing, I would like to make special thanks to Dan Nelson, Bob Smith, and Brian Luehrs of Stanford's Center for Innovations in Learning.
5. The IEEE International Conference on Image Processing (ICIP), and ACM's SIGMMM (Multimedia) SIGGRAPH conferences are vital forums for learning about these developments.

Chapter 56: ePresence Interactive Media and Webforum 2001: An Accidental Case Study on the Use of Webcasting as a VLE for Early Child Development

ANITA ZIJDEMANS*, GALE MOORE†, RON BAECKER‡, AND DANIEL P. KEATING§

Ontario Institute for Studies in Education, University of Toronto; †Knowledge Media Design Institute, University of Toronto, Toronto; ‡Department of Computer Science, University of Toronto, Toronto, Ontario; §Center for Human Growth and Development, University of Michigan

1. INTRODUCTION

This chapter presents the use of the ePresence Interactive Media System as a Virtual Learning Environment (VLE) for Webforum 2001[1], a 2-day hybrid event that brought together local and geographically distributed participants to hear presentations on the latest science in early child development. The ePresence VLE supported social interaction and collaboration across time, distance, and space and captured multimedia archives of the event that subsequently led to a number of post-Webforum activities.

Webforum 2001 was the culminating event for an initiative called the Millennium Dialogue on Early Child Development. Planning for this initiative began in 1999 to explore conceptually and technologically innovative ways to educate, empower, enrich, and engage a variety of different stakeholders seeking to advance their understanding of early child development (Matthews & Zijdemans, 2001). Led by Daniel Keating, then at the University of Toronto's Ontario Institute for Studies in Education, in collaboration with Invest in Kids Foundation, and the Lawson Foundation,[2] conceptualization for the Millennium Dialogue grew out of Keating's previous work as director of the Human Development Program at the Canadian Institute for Advanced Research [CIAR][3]. The product of that effort was *Developmental Health and the Wealth of Nations* (Keating & Hertzman, 1999), a collective volume that used socioeconomic gradients to describe the significant association between socioeconomic status (SES) and developmental health.[4] Three major themes had been identified in this research: (i) the wealth of a nation is rooted in the developmental health of its individuals; (ii) enhancing developmental health requires a deep understanding of the core dynamics of human development from a wide range of perspectives, from the biological to society; and (iii) to support developmental health in an era of profound unprecedented transformation, societies must become "learning societies" which actively

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1395–1427.

support healthy human development across the population.[5] One of the first tasks for the MDECD planning committee[6] was formalizing these ideas into the following objectives for the project:

> *"to assemble and present the best available scientific work on healthy development; to design and deploy new strategies and means to bring this information to a wide range of audiences who would benefit from this knowledge; and beyond dissemination, to launch a sustainable, interactive dialogue at a societal level on how to make use of our rapidly growing knowledge to optimize the potential for developmental health in all children."*
>
> (Keating, 1999)

The implementation plan involved a number of inter-related activities, including:

- engaging eight internationally renowned scientists from diverse and traditionally separate fields in child development to establish a cross-disciplinary *knowledge base*;
- enlisting a team of researchers and practitioners to assist in the design of a *curriculum* grounded in the knowledge base;
- offering a hybrid face-to-face and online *graduate level course* based on the curriculum;
- creating a distributed conference, *Webforum2001*, a 2-day event originating at OISE/UT to which remote participants would be invited;
- designing and creating new *educational materials* oriented toward diverse audiences.

It was recognized at the outset that achieving the above objectives, in particular the last three, would require a degree of technological innovation. A team of technical experts was assembled to design and implement an infrastructure that would support the project's learning and knowledge building activities. The Education Commons, the in-house technology support group for OISE/UT, determined the overall system and networking requirements, and gathered preliminary information on webcast technologies. Keating had previously used Lotus Notes/Domino, and arrangements were made to upgrade this server and create an intranet/extranet for the project. Knowledge Forum[7], a learning environment developed in-house, was set up for the graduate course. All that remained was to find a team capable of producing MDECD's final event, Webforum 2001, which would be opened up to a large number of participants, both local and remote. The MDECD took a year to plan, a second year to produce, and a third year was spent in post-knowledge media production. Details on the full range of these activities can be found in Zijdemans (2005).

This chapter focuses on Webforum 2001, the 2-day event that used the ePresence Interactive Media System, a webcasting application, to create a VLE to support live interactions among a group of experts and participants, all of whom attended at least part of the event using the VLE. A formal case study had neither been planned nor designed in advance. However, the rich observations gathered over these 2 days supplemented by the systems logs and an informal evaluation, provided insights into how the experience of the participants shaped and was shaped by the affordances of the VLE, as well as the impact of the design choices of the Webforum team in creating the event. This *post hoc* review, while preliminary and exploratory—and now historical—provides the first systematic account of the experience of using the ePresence Interactive Media System in an educational setting to support sustained interaction across several different environments.

We also report here on the unintended consequences of MDECD's decision to use digital technologies, including webcasting. As the event unfolded, the interest expressed by the participants sparked requests for ongoing access to the Webforum content for knowledge building. This included requests for materials to support their programs or projects. The final section of the chapter looks closely at the production of these novel knowledge media and concludes with an example of the Red River College's decision to infuse the new knowledge into an Early Child Education multimedia resource that stands to influence the way in which programs are currently delivered across Canada.

2. WEBFORUM 2001

Keating had been a member of the Knowledge Media Design Institute since it was founded by Baecker and a group of colleagues in 1996. Interested by the potential of knowledge media technologies for knowledge development he invited Moore, then the executive director of KMDI, to participate on the MDECD planning committee.

One of KMDI's areas of specialization was in the human-centered design, development and use of technologies, in particular video technology, to support collaboration over distance. Members of the Institute had worked together on the Ontario Telepresence Project (1992–1995), a research project in which the design and uncovery of novel uses of videoconferencing technologies had been central (Moore, 1997). By the late 1990s, a new class of collaboration technologies was being designed for the internet and accessible from a web browser. In 2000, Baecker and Moore, with long standing research interests in the role of video in supporting distributed work, recognized the potential of one of these IP-based technologies such as webcasting,[8] to reach large audiences at minimal cost in a way that had not been possible with videoconferencing. But as earlier research on video-mediated communication had shown, many of the problems associated with the use of video were social, not technical.

It would be necessary to design and build a webcasting system, grounded in principles of human-centered design. Bell University Laboratories supported this research and the first version of the system, known as ePresence, went live in the fall of 2000.

The progress of this project was watched with interest by the Millennium Dialogue committee as they still did not have a solution for managing the distributed part of their program. Initial enquiries into the cost of commercial webcast productions yielded estimates ranging from $60,000 to over $120,000—well beyond the capacity of the MDECD budget. Following the successful use of ePresence for the KMDI lecture series in the spring of 2001, the technology seemed mature enough for both the Millennium planning committee and KMDI to collaborate on exploring the use of this first version of ePresence as a VLE for the closing event, Webforum 2001. For ePresence this represented an opportunity to capitalize on the experiential learning that had taken place in the spring series, and for the design team to gain further insights into the use of the system in a real world setting.

In the summer of 2001, KMDI's ePresence team was contracted to webcast the Webforum event. The ePresence team worked closely with the Webforum team to plan and prepare for the production. KMDI's ePresence Interactive Media team was in many ways an ideal partner for Webforum 2001. Both MDECD and ePresence were innovative university-based projects. The MDECD framework for designing a learning society was theoretically well conceptualized. The ePresence Interactive Media team came out of many years of research experience in the design and use of synchronous or real-time collaboration environments to support distributed interaction, in particular, how to support the engagement of participants whose experience of the event would be mediated by technology.

In early October 2001, the Webforum team sent out approximately 300 papers and electronic invitations to a diverse group of stakeholders with interest in the area of early child development. This included members of the local community who were invited to participate in the event at OISE/UT and Faculties of Education and Early Child Education across Canada who were invited to participate using the ePresence Interactive Media VLE. The participants were therefore self-selected based on their interest in the subject. Those attending remotely were informed of the public and exploratory nature of the event and consent was sought in advance to publishing their names on the public Webforum web site.

On November 8–9, 2001, some 155 people attended Webforum 2001 at OISE/UT and 40 attended *via* the internet. The event was comprised of two related sets of activities—a series of four presentations followed by question periods and a series of three roundtable discussions. Each morning and afternoon there were two presentations, each given by one of the senior scientists, followed by a question period. After a short break, a roundtable discussion was convened. The only exception to this pattern was on the second day which

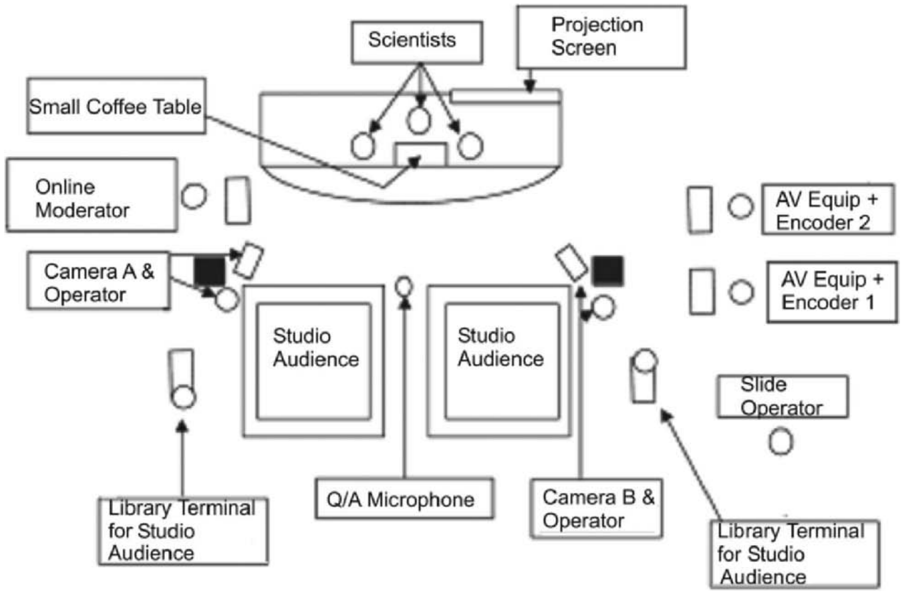

Figure 1. Webforum 2001 configuration OISE/UT library.

ended early after the last presentation and question period. All the presentations and questions periods were held in the OISE/UT library and all the roundtables were held in a conference room two floors above the library.

Figure 1 shows the configuration for the library location.

Figure 2 shows the configuration of the separate roundtable discussion conference room.

Attendance at the roundtables was restricted to the senior scientists and respondents, and the discussions were broadcast simultaneously to both the local participants in the OISE/UT library—who viewed them on a large screen—and the geographically remote participants—who were either alone, or watching as part of a group. If a member of the library audience wished to ask a question, two computers open to the ePresence interface were available, but there was neither a moderator nor any assistance provided. The local audience at OISE/UT, therefore, actually participated in the event in two different ways—in a face-to face setting and as members of a remote audience. The significance of this decision to have the local audience participate remotely for part of the event would only be evident later.

3. EPRESENCE INTERACTIVE MEDIA

The ePresence VLE supported this hybrid local/remote audience and made it possible for the all the participants to be part of this 2-day dialogue with

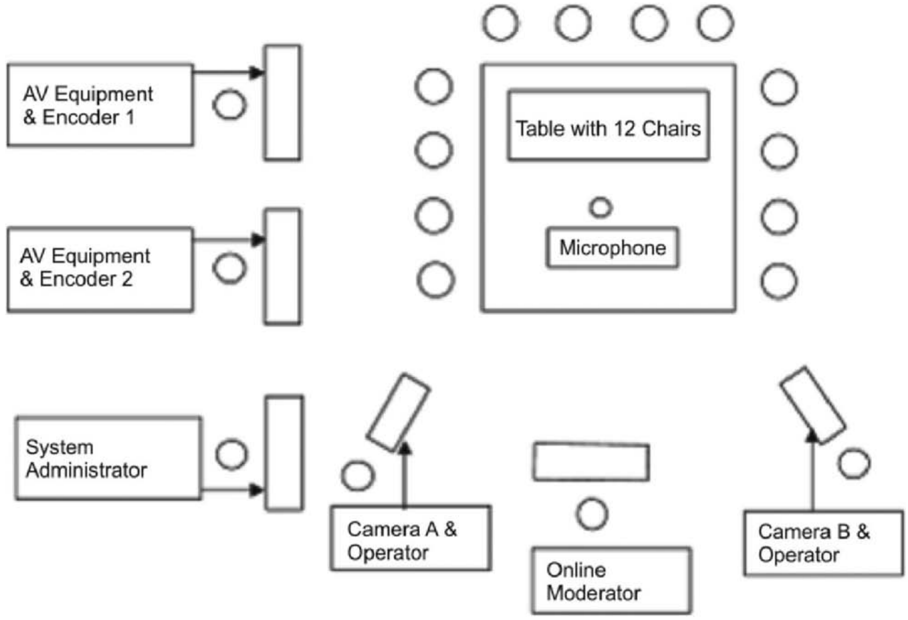

Figure 2. Webforum 2001 configuration roundtable conference room.

the eight internationally renowned scientists. At the time of Webforum, webcasting was typically non-interactive as there was a significant time delay of several seconds before an image generated at the source would be received at the remote end. The ePresence Interactive Media was a live webcasting system to which a number of innovative features had been added to overcome some of the limitations of the currently available commercial systems. For example, ePresence employed text chat as a mechanism allowing interaction among remote participants, and between these individuals and the presenter *via* a local moderator. Remote participants could ask questions and review the material already presented by the speaker. As long as the audio–video capture of the event was done with attention to media production values, ePresence had the potential to provide a rich and engaging multimedia experience for viewers.

For this event, the ePresence system was equipped to sustain 60 licenses for simultaneous use and supported streams at 300 kbps for LAN/WAN, and 56 kbps for modem. The 60-license limit was due to financial restrictions and not system capacity. Precautions were taken such as using an offsite mirror server to offset potential access and bottleneck limitations and setting up an audio only server so that minimally audio, slides, and interactivity would always be available. Additional bandwidth was also purchased. Finally the system was implemented prior to the event both for testing purposes and to provide support for registered remote participants interested in trying out the technology in advance.

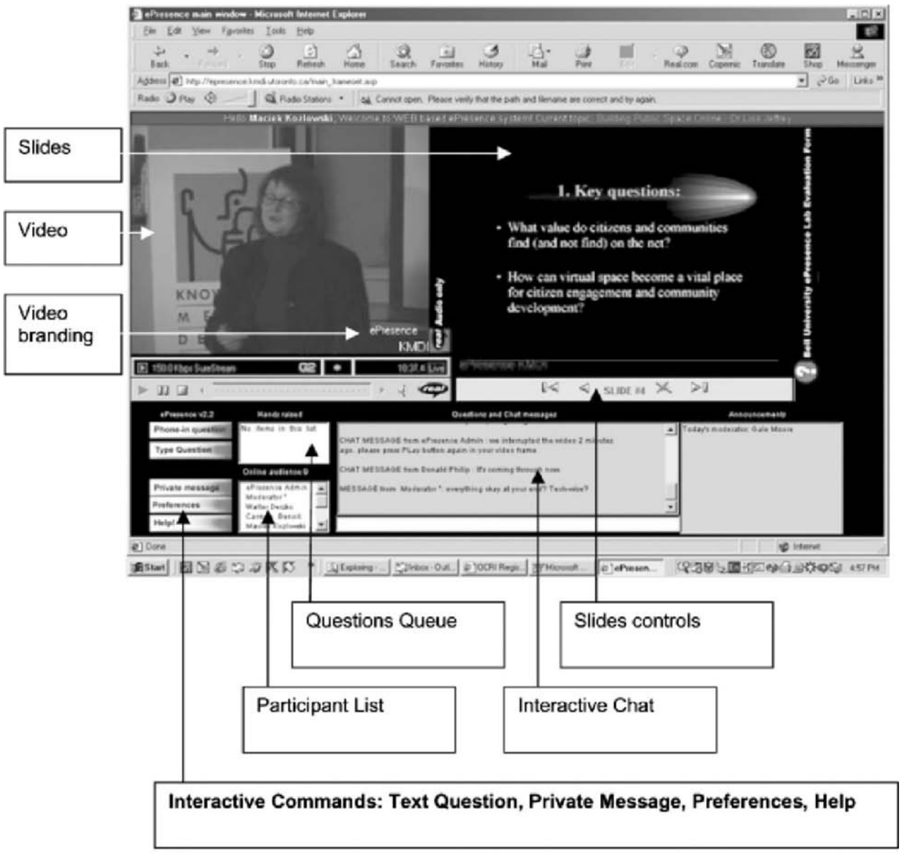

Figure 3. ePresence live Webcast user interface.

Figure 3 is a screen capture of the user interface as seen by the remote participants.

The ePresence live interface included the following features:

- a window for a panel or an individual speaker;
- a window for slides or presentation notes;
- a text entry window for submitting private text questions directly to the moderator and/or public and private postings using a chat feature through which participants could interact with each other;
- help and the display of number of participants on line.

An ePresence webcast, at the time, required a five-person crew to operate the two cameras and two encoders, and to operate the slides[9]. In addition, two moderators and the system administrator were available to the remote participants to answer questions and to assist with any technical problems. Moderator One was stationed in the library and engaged directly with the online participants flagging questions for Moderator Two who was the conference convenor. Moderator Two had the complex task of presenting a paper on Day 2 as well as conveying the online questions to the participants and scientists. In this role he provided the bridge linking the face-to-face and remote participants by bringing the online questions and commentary to the local presenters and library audience.

4. AN ACCIDENTAL CASE STUDY

Moore coined the term "accidental case study" to describe this paper as at the outset a formal case study had neither been planned nor designed. However, as the event unfolded, it was clear that there were a number of valuable, albeit preliminary, insights into the complexities inherent in designing both the technical application to support distributed communication *and* the design of the event that should be reported. First, webcasting was still a relatively new application and most people had limited experience with using such a system. The 2-day event, while short, did provide some time for participants to learn to use the system. In addition, it could provide insights into the nature of the support needed by participants from both the ePresence team and the Webforum team. And, the decision by the Webforum team to hold the roundtables in a small room that accommodated only the scientists and other senior scholars provided a unique opportunity to observe the experience of using the same technology in two distinctly different social conditions.

The geographically remote participants experienced no change when the event shifted from the presentation sessions to the roundtables, but the local participants who were present at the sessions had no alternative but to participate remotely during the roundtables. Finally, the spontaneous response from participants that took place immediately following Webforum revealed unintended consequences of the webcast, seeded both technical and social innovation, and provided insights into ways to support the emergence of future communities of learning.

5. INFORMATION GATHERED

A variety of information and data were gathered over the 2-day Webforum 2001 event. These came from a range of sources including registration information—which included such things as the participants' affiliations and online participants' locations, and technical notes developed during the planning period leading up to the event. In addition, the ePresence system automatically generated a log of the online interactions. At the end of the event, forms had been distributed to each of the participants who expressed an interest in gaining access to an archive of the event, which also included a brief

Table 1. Remote participants by location

WF2001 Participants: by Location	Webcast Participants
Canada	
Nova Scotia	2
Prince Edward Island	1
New Brunswick	1
Quebec	3
Ontario	4

Minnesota	1
San Francisco	1
Total	40

evaluation of the event. Finally, following the event, e-mail was received from a number of the participants who had attended both at OISE/UT and remotely.

5.1. Participants

The registration records provided information on the distribution of the participants attending the Webforum by their geographical location and employment sector. Table 1 shows the geographic locations of the 40 remote sites.

The remote sites were located all in North America with the majority (16) located in the greater Toronto area. Seven of the Toronto sites were individuals accessing the event from their offices at the UT and two were from OISE/UT computer labs on the 3rd floor. These labs were opened up informally so that members of the OISE/UT community could attend at no cost. The international locations included New York, Minnesota, and San Francisco.

A total of 195 participants were involved in Webforum 2001 (Table 2). The largest single group was in education (58), which included researchers, educators, faculty, graduate students, and teacher federations. The second largest were representatives from organizations related to early child development (47), and government groups or individuals (24).

The geographically remote participants that is those not present at OISE/UT, attended the event in two ways—either as individuals or in groups. Table 3 shows that over the 2 days, a total of 48 participants were individuals accessing the event from their personal computers at home or at the office.

Table 2. Participants by employment sector

WF2001 Participants: by Sector	Library OISE/UT	Geographically Remote	Total
Education (universities and colleges, K-12, teachers federations, schools)	45	20	65
Private and public associations/ organizations	44	3	47
Health (doctors, nurses)	11	0	11
Government	17	7	24
Technology	6	9	15
Private foundations	17	0	17
News media	10	0	10
Other	5	1	6
Total	155	40	195

On each of the 2 days of the conference, 23 were groups at least 10 of which were comprised of between 4 and 20 people.

Although no data were formally collected on the remote groups, we learned that the groups were in a large room equipped with a single projector and in at least four cases they were integrating the Webforum event into their own parallel sessions or seminars related to early child development. Each group also had a moderator who was responsible for conveying questions or other comments to the ePresence moderator. The geographically remote participants thus had an advantage over the OISE/UT group attending the roundtables remotely. A total of 37 sites logged in on Day 1 with a maximum of 25 people logged in simultaneously. On Day 2, a total of 33 sites logged in with a maximum login at any one time reaching 20.

5.2. Interaction at the Event—Remote and Local

As previously mentioned, the local OISE/UT participants attended from the library location in two ways—face-to-face for the presentations and question

Table 3. Webforum 2001 login details

WF2001 Login Details	Day 1	Day 2
Number of groups	13	10
Number of individuals	25	23
Total number of sites logged in	37	33
Max login at any time	25	20

Table 4. Face-to-face versus online questions

	Day 1	Day 2	Total
Questions asked face-to-face OISE/UT local (presentations)	33	39	72
Questions asked Online OISE/UT remote (roundtables)	3	6	9
Geographically remote (includes presentations and roundtables)	10	10	20
Total	46	55	101

periods and remotely for the roundtable discussions. Table 4 shows that there is a much higher level of interaction when attendees are participating in a live event. In both cases, when the participants were remote there was less interaction.

On Day 1 a total of 13 of the total 46 questions were submitted using ePresence and on Day 2 this increased to 16 of the 55 questions posed. A total of 101 questions were asked over the 2-day period. It is important to note that the majority of all the questions came from the scientists who were participating in all the events and around whom Webforum was designed. It is interesting to note that the lowest level of interaction was from the participants at OISE/UT when they attended the roundtables remotely.

There were two moderators at OISE/UT, and both were present in the live presentations. Moderator One monitored all of the questions from the remote participants and flagged them for Moderator Two, who also had ePresence open on his laptop browser. However, as he was also convening the live events, he could not attend fully to the remote queries. An important role of the moderators was to ensure that the online questions were brought before the live presenters, but on a number of occasions the geographically remote participants had to be assertive about getting their questions through. There were clearly some experienced users of collaboration technologies in the remote audience. In fact, some had used other technologies such as videoconferencing and were more experienced with participating in distance events than the moderators at OISE/UT. The following request illustrates this: *"Can I suggest that questions from distance participants be interspersed with those from the floor? When we do paediatric Grand Rounds involving several centres in the Maritimes, we try to give equal time to all centres to eliminate the perception that they are peripheral."*

In addition to the official moderators, the conference co-ordinator was also monitoring the event and providing support to the remote participants. The need for the moderators to work together to assure that remote participants were not dis-enfranchised was made clear when group from Nova Scotia who had submitted a question but had not heard it reflected in the live broadcast.

They asked Moderator One: *"I do not see the Roundtable room on my online list anymore—could you or the conference coordinator pass our question on to the Emcee [sic convenor] for us? Please and Thanks"*

This question sparked a series of messages among the moderators and as the following exchange illustrates, shows how private messaging was extremely useful as a back channel to co-ordinate without disrupting the event in progress. The conference moderator privately messages Moderator One: *"Hey there, are you taking care of the Nova Scotia request?"* Meanwhile the Nova Scotia Group who was still waiting posts: *"appreciate any effort."* Moderator One responds privately to the conference moderator: *"Just working on it."* Moderator One then sends a private message to Moderator Two, the convenor: *"Check out the Nova Scotia group message just below my last announcement."* Moderator Two responds privately to Moderator One: *"Got it. Thanks"* At this point Moderator Two announces to the library audience: *"This question came in from one of our remote sites in Nova Scotia ... "* Moderator One then sends a public post to the Nova Scotia Group: *"Sorry to have missed this on the first go-round!"* The Nova Scotia Group replies: *"No problem-we have the question being answered now! Thanks to all who helped get the question out—Un gros merci!"*

Both of the above examples highlight some of the inherent challenges in trying to ensure that the remote participants were remembered and brought into the face-to-face situation. Overall, the ePresence VLE worked well and had the affordances to support a variety of social interactions. The remote participants engaged easily and were able to have their concerns addressed.

5.3. The Content of Online Interaction

While the local OISE/UT audience could interact directly with the speakers during the presentations, their interactions outside of the formal sessions were primarily with others who were also attending. For the individuals and groups who attended remotely it was necessary to ask questions through the moderator, but they could also interact with all the others online, regardless of their location.

The transcripts generated by the system at this time, included both the public and the private messages. Given our interest in constructivist learning, we were interested in looking at all the messages exchanged for evidence of active learning and engagement. We felt, however, that in spite of the fact that a notice had been posted publicly that all the chat was logged, it was inappropriate to use the private chat transcripts without explicit agreement by those involved, as the implications of the system logs may not have been fully understood. The public dialogue and questions were, on the other hand, public and available to everyone online.

The private chat had originally been included in the application as a way of allowing remote participants to "whisper" to each other—a social behavior that had been observed in studies of live audiences attending public lectures or talks. It also turned out to be a convenient way for people to communicate with the moderator if they were having technical problems without disrupting others online. Furthermore, it provides an excellent back channel for co-ordinating the activities of the technical and administrative team members. However, as the meaning of "private chat" is likely to be interpreted differently in different social settings and in different groups, this was flagged as an important issue to be addressed in the future. In this paper, private messages are, with one exception, excluded unless they are exchanges among members of the administrative and the technical teams associated with co-ordination or impersonal administrative, or technical exchanges with the moderators. The one exception is below in the section on sociability and involves an exchange between a mother and her son who were in different locations and both attending remotely.

A qualitative review of the chat messages uncovered the following four categories: (i) substantive; (ii) technical; iii) sociability; and (iv) administrative. Each of the categories is described below and illustrated with quotes from the logs.

5.3.1. Substantive: Content Related to the Subject Matter of the Conference

These postings were on the subject of the event and are suggestive of the remote participants' engagement in the event. These messages were of two types—the most frequent was questions to the speaker, as the following quotes illustrates: *"How might we work differently in the research and policy areas, if we think "symphonic causation" as compared to "multiple causation" or similar terms?"* Less frequent was a general comment that was not directed to anyone in particular, but which could be seen by other members of the remote audience. In one case, a local participant in the OISE/UT library used one of the ePresence terminals to post a substantial stream of thoughts that otherwise would have been difficult to raise in the face-to-face meeting.

5.3.2. Technical: Content Related to the Technical Aspects of the System

These postings were typically those related to technical issues and included troubleshooting, concerns about incorrect slide synchronization, or screen resolution problems. Today, technical problems are virtually non-existent, but this was both early days in the development of the ePresence application, and with participants who as yet had only limited experience with webcasting technology.

The ePresence team had worked to prevent some of these issues by providing a system wizard that checked systems requirements when people initially set up their accounts. In addition to this, the Webforum team had hosted a test day, a week in advance of the event so that remote participants could test their systems. Despite this, numerous issues arose particularly on the first day. There were frequent interactions between the moderators, system administrator, and remote participants to help troubleshoot "on the fly". In the following excerpt, a participant sends a private message to the Administrator: *"Not the right slides."* Moderator One responds privately to the participant: *"We're working on it, please bear with us."* The administrator fixes the problem and instructs the participant how to adjust his computer settings to get things working properly: *"In your browser please set up and select Tools—Internet Options—Temp Files—Settings—Every visit to the page."* A few minutes later the participant responds: *"Thanks I have the slides now!"*

Other technical related postings reflected the frustrations the remote participants were experiencing due to the numerous technical glitches. Not surprisingly, this was most evident on the first day when everyone was unfamiliar with the application. One participant group sums up their experience this way: *"We're doing fine but finding the technology a little frustrating at times. Online we are missing many of the cues we would have in a live audience. It is a different experience and we must change the way we attend to the lecture. One problem is that if there are any technical difficulties such as sound problems we must break concentration to attend to them. For example, while adjusting volume it is hard to keep 100% attention especially if the participants in our room need to talk to each other about the problem. By having your speakers think about their distant audience they may be able to help with some of these problems. Having the slides available ahead of time as we mentioned this morning is a good example. Also a little more time spent summarizing or reviewing would help keep us in the loop. I think I have a somewhat better idea of what an ESL learner feels like when I follow a lecture in this format. Thanks."*

As comments went back and forth between the moderators, administrator, and remote participants it was interesting to note that gradually as the remote participants became familiar with the technology, they too started assisting others. A participant from Halifax notes that the slides on her computer screen were the wrong size saying: *"The size of the windows exceeds the size of the screen and I have to scroll to see different windows. Can the entire display be shrunk to fit the screen?"* A person from the computer lab tries to assist: *"Halifax, set the resolution on your monitor to 1024 × 768. That should help. In the control panel, if you have a Mac."* The administrator adds: *"Unfortunately you have to have a screen resolution of at least 1024 × 768 to see everything onscreen without scrolling."* The Halifax participant responds: *"That's what the resolution is set to."* A few minutes later the group from Manitoba posts:

"The setting on a PC need to be the same for resolution and desktop in your video card settings."

The next series of exchanges captures the experience of the members of the ePresence team and Webforum team who were located in the OISE/UT library and simultaneously monitoring the remote participants *via* computer. The time delay between the live broadcast when it is received remotely is small, but still significant. It is transparent to the remote audience who is always 10 seconds late, but the experience for the moderator operating in two time zones is complex and led to an interesting discovery about the technology. A member of the research team asks: *"Would anyone be able to tell me the exact time delay between live and web?"* The conference moderator privately responds: *"What we see live is not the same as the online. I know it looks strange but they [remote participants] don't notice anything."* Moderator One uses the chat to say: "*It seems to vary from machine to machine, but maybe, on average, 1 minute?"* The computer lab then creates a message: "*Seems more like 28 seconds."* Concerned that they might be distracting the other remote participants the conference moderator creates a private message to Moderator One: *"I sent a private message stating that for the online group it looks normal. It's only for us who are seeing both the live event and the webcast simultaneously that it appears out of sync."*

This interaction was one of numerous instances where messages were exchanged and suggest that moderating the event was also a learning experience for the research team.

5.3.3. Sociability

Sociability was used to categorize the postings that involved more casual banter such as: *"Good morning everyone, you're early"*, when participants started logging on before the webcast or, the following response to one remote participant who was encouraging us about the success of the event. The conference moderator responds: *"Thanks for the encouraging words. It has been a bit bumpy for some but generally I think a good experience."*

An interesting and serendipitous series of exchanges took place between a mother and her son who were both attending the event remotely—one in New Brunswick Canada, and one in New York City. The following excerpt captures their interactions as they used various parts of the ePresence message features. It is interesting to observe the relatively fluid movement between public and private conversations. They also reported that they were simultaneously maintaining a series of face-to-face exchanges with people in their location. We would like to think that this is a reflection of the human-centered approach taken to system design: Private message from participant 1 in New York: *"Hi Mom! How's it going? I just tuned in."* Participant 2 in

New Brunswick responds: *"Great. Interesting dialogue."* Participant 2 then submits a text question to the presenter using the ePresence text question feature: *"Could you comment on parenting courses and their effectiveness. What works? How important is it to provide individual help and supports for family?"* A few minutes later Moderator Two, the conference convenor poses the question face-to-face to the presenter: "*... this is another question from New Brunswick*: *"Could you comment on parenting courses and their effectiveness. What works? How important is it to provide individual help and supports for family?"*

At the end of the presentation some 10 minutes later the participant 2 asks: *"Hi. What did you think of it?"* The event stops for a break between sessions and the audience is told that the next presentation will resume in 20 minutes. Just before the presentation starts participant 2 comes back online. She asks participant 1: *"Are we back on yet?"* Participant 1 responds: *"Hi Mom—All I see is the sidewalk outside of OISE ... Hey, there's [the conference convenor]. Guess we're back on!"* Participant 2: *"This is just so fascinating and so much fun. What is your impression?"* Participant 1 responds: *"It is very cool. Part of the problem that I've had is being able to dedicate myself to the conference. One good thing about going away is that you are away from work (no student's knocking on your door!)"* Participant 2 responds: *"I know. Same with me. At least this will be archived ... He sure speaks quickly. Doesn't even take a breath."* Participant 1 replies: *"You can say more that way!"* Participant 2 asks: *"Who is this fellow? Do you have a comment or question?"* Participant 1 responds: *"Sir Michael Rutter. I feel like I haven't been paying close enough attention to ask a good question. (Mine would have to be about the research.)*" Participant 2: *"... I think these researchers are more interested in their research than the application or even involvement and reciprocity with other stakeholders or sectors."* Participant 1 responds: *"Well, yeah. But it is also what they know. You should ask application questions—that was part of the mandate of the conference."* Participant 2: *"OK, that makes sense."*

This exchange shows the continuity of the personal conversation, but it also points to the issues about multitasking and the cognitive overhead that are involved in participating in multiple conversations at different levels in a short period of time. It further raises an important point about how the event was organized and draws attention to the importance of communicating the goal of the event clearly to the participants in advance. In this case, the focus on the scientists was planned from the start, but opening up the event may have in the past sent a mixed signal, and as we saw with the local participants excluded from the roundtables, an unintended social disconnect. Further, it is not clear the extent to which the scientists were prepped to consider the remote audience. From their position, without access to the ePresence application, this remote audience was essentially invisible.

5.3.4. Administrative

Administrative postings were the most common and included instruction and information from the ePresence Administrator to update the remote participants and facilitate their involvement. For example: "*To all our on-line participants: we are trying to reserve the "All Questions" feature for concise content questions to be addressed to speakers or scientists in general. Please feel free to experiment and let the general chat lead you where it may. We'll be ready to go in ∼5 minutes.*"

Participants became engaged and offered a variety of advice to the administrative and technical team. A member of the Education Commons had a suggestion for the videographer: *"Might I suggest the back camera pull back on [the conference convenor] to give a "Montel Williams" feel. We would like to see a bit of the audience."* A remote participant site from Victoria, British Columbia also had some views on how the first roundtable session was being conducted as seen in this comment: "*Can we ask that the Clyde Hertzmans [respondent for the first roundtable session] of the process to be more focused and perhaps answer one issue at a time and have the panel respond rather than addressing every issue in "one" speech. I think the points made would be retained and commented on in a more effective process."* This suggestion was in fact successfully relayed and taken up in the subsequent roundtable as witnessed when the respondent of the second roundtable states: *"So I thought what we'd do is just break up the questions a little bit more because it was hard I think to remember all of them when Clyde went though them."*

On a number of occasions, members of the research team who were also monitoring the event used the private message feature to address the issue of integrating the remote audience more fully into the live event. In this interaction, a senior member of the ePresence research group, located elsewhere on campus, has dropped in remotely during a roundtable discussion to see how things are going. He shares his thoughts with the conference co-ordinator on how the live group was not integrating or aware enough of the online participants: *"I've only listened in sporadically, but there seems to be little attempt to engage either a local or remote audience in the dialogue. Will this happen later?"* The conference co-ordinator responds: *". . . I think this will hopefully come in the question period at the end. As for here in the library there are not many getting up to use the public terminals. I think I will ask Moderator Two if he can keep trying to encourage people, maybe they are shy or intimidated."* The researcher replies: "*I may be wrong but it looks like the problem is not with the remote attendees, but that the panel is so involved in their discussion and no one else is being let in. Sorry, must leave now."* The conference co-ordinator follows up by sending a private message to Moderator One about conveying this message. Moderator One then sends a private message to Moderator Two

Table 5. Breakdown of posted messages

	Day 1 Total	Day 1%	Day 2 Total	Day 2%
Subject related	23	5%	63	21%
Technical	264	62%	87	29%
Sociability	54	13%	101	33%
Admin	86	20%	53	17%
	427	100%	304	100%

saying: "*Can you remind the studio audience and the on-line participants to feel free to type in questions at any point in the Roundtable"* A few minutes later Moderator One tries again as Moderator Two is clearly engrossed in the discussion: *"Hi [convenor] we should try to get some online questions on the table and introduce them verbally as such so that the participants will feel their issues are being addressed."* Moderator Two eventually responds: *"Will do."*

This theme of bridging the remote and face-to-face participants, either through providing instructions for getting questions ready for the presenters or discussing how to enhance the experience for the remote participants to make them feel more included, is a common through-line across the administrative postings.

Table 5 provides a breakdown of the 731 messages that were posted during the 2-day webcast. There were 427 messages on Day 1 and 304 messages on Day 2.

Of particular interest were the increases in the percentage of messages in the category of substantive messages from an average of 5% on Day 1 to 21% on Day 2, and Sociability messages from 13% on Day 1 to 33% on Day 2. Decreases were found in Technical messages from 62% on Day 1 to 29% on Day 2 and Administrative messages from 20% on Day 1 to 17% on Day 2.

5.4. Participant Response and Input

There was no formal evaluation of the event. However, from the outset, there had been a plan to create some sort of archive of the Webforum that participants and others could access. On the last day, the participants at OISE/UT were told that an archive of the event would be available online, and that they needed to sign up to indicate their interest in accessing this. This form about the archives included a brief evaluation on the event itself. Participants were asked to rate their responses on a scale of 1 (poor) to 10 (excellent): "Overall was it a useful experience for you?" Of the 37 forms that were submitted, a total of 27 people filled out the evaluation component. Table 6 shows their responses.

Table 6. Webforum 2001 questionnaire results (N = 27)

1 (poor) to 6	**Percentage of responses**
7	8%
8	20%
9	24%
10 (excellent)	48%

Several people responded to the request for "other comments". Responses were generally positive about the event at OISE/UT: *"First-rate planning, eminent speakers, friendly venue. Archives, especially access to video, papers, and slides would be good."* But it was clear that these participants did not like having to view the roundtables as remote participants: *"The roundtable might have been easier to follow if it were in front of an audience."* In light of the positive experiences reported by the geographically remote participants as we will see below, we expect that the negative response of the local audience was less a reflection of the technology *per se* and more indicative of what might be described as a breakdown of an implicit social contract when the social norms of face-to-face conference participation were suddenly replaced by a technologically mediated experience—something that they had not signed up for. Furthermore, it cannot have helped that the roundtables included only the international scientists and a small group of senior scholars/respondents. The participants at OISE/UT were both simultaneously "present" and "absent" at the event in a way that those who were geographically distant did not experience.

As the geographically remote participants already had created user accounts in order to use ePresence, they automatically had access to the proposed archives and therefore did not receive the above form. However, immediately following the final presentation a number of participants responded generally very positively and saw the use of the VLE as an opportunity. They provided helpful suggestions for improving the experience and encouragement for the continuing this line of research: . . . *It's a great way to hold a conference and I'm sure it will become widespread once the technology becomes more transparent to the end user. Day 2 at home on a cable modem, the video quality was just as good as the high speed network at the university. It would be nice to have a little more resolution in the slides since they often convey fine detail. But I was able to print selected slides, which is very nice. Microphone input so one can ask questions orally instead of in print would be a nice advance as well. I imagine this takes lots of bandwidth and adds another layer of complexity. Please consider phone support in future WebCasts to help end-users who can't logon during a session. Keep up the good work!! . . . a researcher in Nova Scotia.*

The key I think is to ensure sound and overheads are working well. ~At times the overheads lag behind. ~Another problem is small font size on overheads. They can be a challenge to read. When you have to concentrate on small things like that it can be hard to pay attention to what are often difficult concepts coming fast. It would be very helpful to have the overheads ahead of time so we can print for reference and notes. Just another thought to fine tune: When a speaker is finished her/his presentation the final slide is left up. It would be nice if it could be replaced or removed. You may want to replace with a title slide or something to set the context of what is happening. If nothing else you could replace with one of those babies from earlier today. . . . a satellite group in Manitoba.

In the days following the event, additional unsolicited comments came in *via* e-mail from both the OISE/UT and remote attendees: *Congratulations on an amazing undertaking. Thank you so much for the opportunity to join The Millennium Dialogue events. If you would be so good as to forward me any materials you have on the event itself—and, when you have options for purchase of the program, please provide those details as well, as we'd like to promote it to our audience of 5,000 perinatal professionals across North America . . . Once again—thanks. I trust you feel most gratified (although exhausted!) . . . a media representative.*

I found the Webcast very thought provoking. I'm anxious to view the final presentation. I felt like somewhat of a pioneer as a participant of the Webcast experience itself. The wonders of technology! . . . a participant from Manitoba.

We were interested not only to receive such positive input but also to see the number of comments that referred to having access to the post-event archives for ongoing professional development: *A million congratulations on successfully staging the Webcast conference. We watched during the two-day event . . . We plan to Re-broadcast at least one of the presentations and hold our own roundtable discussion in the first week of December. Many thanks again for all your assistance enabling us to be part of the history-making Webforum 2001 . . . a remote participant located at the University of Victoria, British Columbia.*

Congratulations on the MDC Webcast—what a concept! I wasn't able to be online for the whole thing, given the time difference and other commitments but now plan to indulge myself in the archives. What I saw/heard was so stimulating and this is a fantastic way to get the word out. I'd also like to run emerging thoughts about the course I'm doing around MDECD by you. . . . an educator at the University of British Columbia.

What a wonderful gathering! Many thanks for including me. I am eager to revisit the Dialogue archives website, but I think I need a password. Can you give me directions? . . . a government consultant.

This was excellent and worked so well. Thank you so much for all your efforts and the opportunity to be involved. I am sure we will use the archives and we will contact you. . . . a remote group in Prince Edward Island.

6. POST-EVENT: UNANTICIPATED CONSEQUENCES

6.1. Webforum Archives

At the time of Webforum 2001 an online archive system was not part of the ePresence application. The practice up to this time had been to produce a VHS of each production so that the content was not lost. Early in the planning period, however, Videotelephony—who had been involved with ePresence—had raised the idea of creating an online archive. The overwhelming support for the Webforum event and interest expressed in gaining access to materials for ongoing use encouraged us to pursue this idea of developing knowledge media products to promote and support an ongoing culture for learning and knowledge distribution. KMDI's ePresence team set up a Webforum Archive and Videotelephony continued to partner with the conference co-ordinator on planning and preparation during this post-event knowledge media production period.

While demand for an archive was high from the local and remote participants, the most persistent requests came from the Australian contingent. A number of groups and individuals in Australia had registered for Webforum, however a combination of technical difficulties and the time difference prevented them from attending the event live. As the following illustrates: *"Not sure if you got my previous e-mail—technical difficulties here. I couldn't participate in the live online forum but am keen to access archives if that's possible. Can you please let me know about this?"*

The archive interface in the first iteration, seen in the screen capture, offered the similar features to the live broadcast interface (Figure 4).

The key difference in the archive interface was an additional eResource Library slide on the right side, which provided access to related materials and allowed users to toggle between either a live chat window in the bottom frame and or a public threaded discussion. In this respect individuals and groups could interact either synchronously or asynchronously around the archived event. The turn around time to create these archives from the live capture was approximately 3–5 days and the archives were available online for a temporary period of 4 weeks while we planned for a more permanent knowledge media product. Towards the end of this period we received the following e-mail from a professor in Newcastle Australia: *"Hi, unfortunately I wasn't able to access these [archives] before the middle of December because of problems at our end with the firewall slots, and over the weekend our internet access has been down. However, what I was able to log into, which was the first day, was fantastic. Is there any hope of (a) either extending the period during which access to the archives is possible or (b) getting a CD-ROM of the proceedings? I've missed William Boyce, Richard Tremblay, Alicia Lieberman, and Dan's summing up which I desperately wanted to hear. It's been a great resource—congratulations to all*

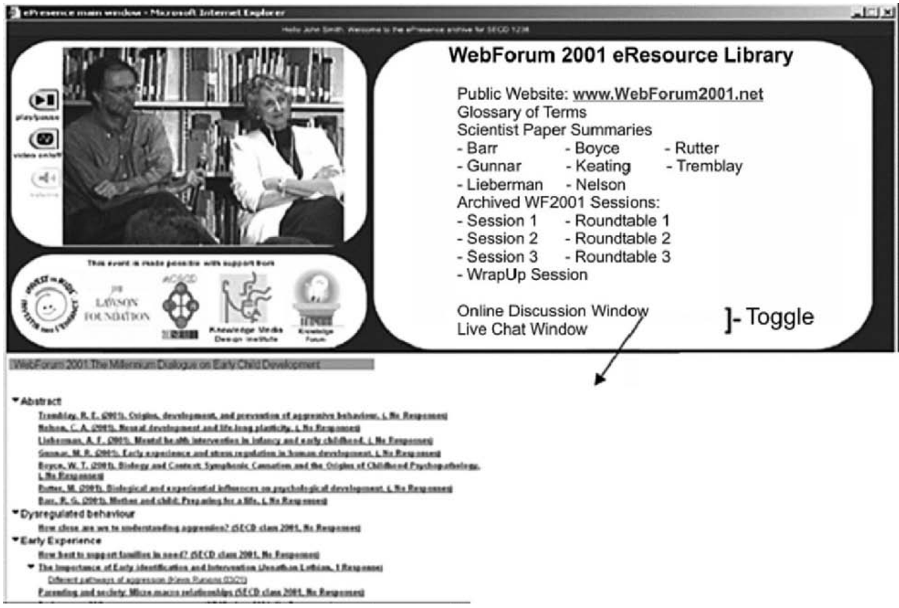

Figure 4. Webforum archive user interface.

of you for enabling those of us far away to be voyeurs on such a fantastic workshop."

No systematic data are available on the use of the archives, however, in at least five cases participants informed us of their use of the Webforum content for separate events, seminars, and courses.

6.2. Conversations on Society and Child Development (CSCD)

A significant use of the ePresence archive was as the basis for the creation of a knowledge base for *Conversations on Society & Child Development*, an interactive eResource which uses compact disk [CD] and web technologies and which was designed to support a VLE for accessing the knowledge and supporting exchange among those who generate research and those who want to apply the findings.

CSCD was developed with VideoTelephony Inc. and Graphix-Design in Ottawa as a series of four CDs. Each compact disk contains the video and synchronized slides of two scientists, paper summaries of the talk, other supporting materials and references, the audio of the post-presentation question periods, and the roundtable discussions. In addition to this, the resource was designed to link to a flexible tailor-made VLE for ongoing interaction, collaboration, and resource sharing. The vision for this web interface was to

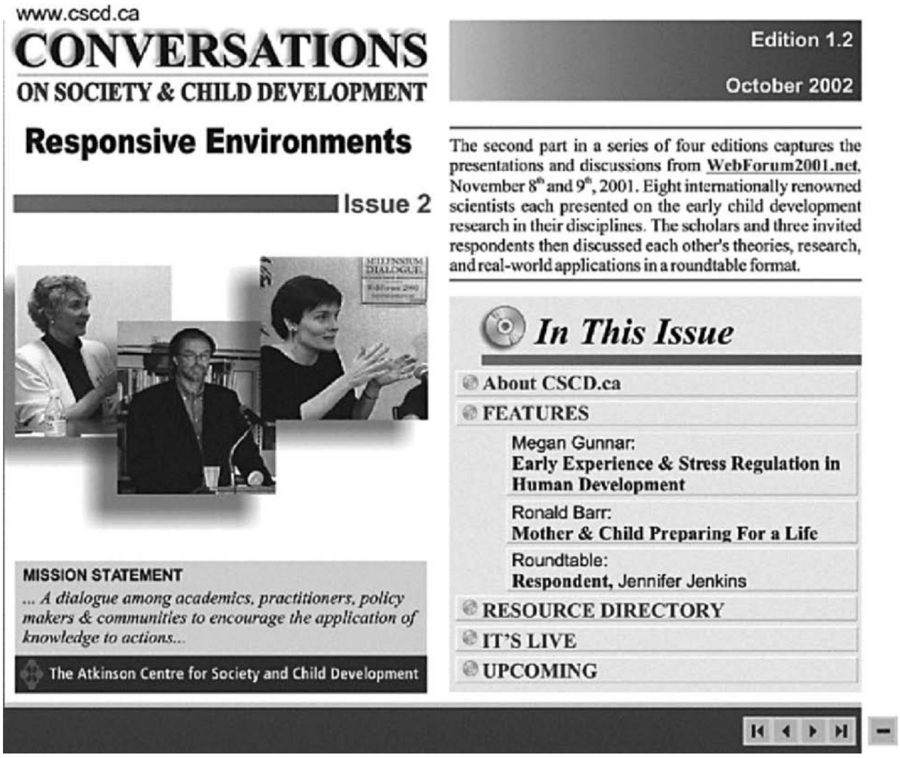

Figure 5. CSCD V1.2 front page.

facilitate the use of CSCD for professional development, seminars, or as a class resource. Figure 5 shows the first page of CSCD Edition 1.2. On the right side under "In This Issue", interactive buttons take the user to each section of the issue. Alternatively, users can use the buttons in the bottom right corner to scroll through each individual page.

Tables 7 and 8 provide summary information on the post-event archive and CSCD users by location and employment sector.

In both the Webforum archive registrants and the CSCD subscribers the largest group is academic—faculty, researchers, practitioners (83). The second and third largest are, respectively, organizations and government agencies who are working in some aspect of early child development. We see that similar to the Webforum live participant group, users of the archives and CSCD represent a diverse range such as university and college faculty, Human Resources Development Canada, psychologists, clinicians, researchers, child care workers, policy workers, and other groups or organizations working in the field of early child development.

Table 8 shows the distribution of the participants by geographic location.

Table 7. Post-event knowledge media participants by employment sector

Number of Participants: by Occupation	**Webforum Archive Registrants**	**CSCD Subscribers**	**Total**
Education	59	29	88
Organization	14	10	24
Health	2	5	7
Government	11	6	17
Technology	0	6	6
Foundations	0	2	2
News media	0	1	1
Other	3	6	9
Totals	89	65	154

The breakdown of participant locations is again similar to that of the attendees of the live Webforum 2001. The primary difference is the Australian participants. Here we see that this group has become the largest international group and second largest representative location along with Manitoba (14). There is also an increase in participants from Minnesota, San Francisco (3), and the United Kingdom (2). At the time of writing, some 65 members, groups, and individuals have made use of the CSCD eResource for professional development and/or educational purposes. CSCD was never aggressively marketed. Subscribership has since diminished and again no formal study has been done. Our intent, however, is to provide the resource to future purchasers of the published book of the MDECD papers (Keating, in press).

Table 8. Post-event knowledge media participants by location

Participants: by Location	**Archive Registrants**	**CSCD Subscribers**	**Total**
New Foundland	1	0	1
Nova Scotia	1	0	1
New Brunswick	1	1	2
Quebec	8	2	10
Ontario	2	13	15
Greater Toronto Area	62	20	82
Manitoba	4	10	14
Alberta	2	1	3
British Columbia	2	1	3
New York	0	1	1
Minnesota	1	2	3
San Francisco	1	2	3
United Kingdom	1	1	2
Australia	3	11	14
Total	89	65	154

6.3. The Red River College Early Childhood Education Resource

The Red River College initiative was an unexpected outgrowth of the MDECD that provided a unique insight into the process of translating knowledge for different audiences. When Red River College (RRC) in Manitoba, Canada decided that they wanted to work toward updating the Early Child Education (ECE) curriculum to reflect the latest science, they approached Dr. Fraser Mustard of The Founders Network.[10] He informed them about the MDECD and suggested that they contact us to discuss a future potential association.

In spring of 2001, we met with the Red River group at OISE/UT. They spoke to us about their intention to seek funding to support the project and we welcomed the collaboration. It was decided that the group should participate in the MDECD events. They enrolled as part of the distance auditor group in the graduate course and attended Webforum 2001. The core project team members flew to Toronto to attend the live webcast conference but they also arranged for the college to be a satellite group so that other faculty could participate online from Winnipeg. After the final event in the spring of 2002, we hosted an additional online seminar for ECE faculty to further discuss the knowledge and its potential applications to practice. This was attended by 13 individuals located in Toronto, Manitoba, British Columbia, and Nova Scotia.

With funding in place, RRC assembled an advisory committee comprised of faculty from colleges across Canada to help develop a strategic plan, translate the content for the college level, provide input into the design of the prototype, and serve as pilot' sites. The Webforum archives became the primary base for what has been developed into a five-module interactive multimedia resource for Early Child Education programs at the college level. The screen capture of WebCT shows the home page for the ECE resource (Figure 6).

This resource was iteratively piloted with ECE faculty across Canada from 2002 to 2004 and is currently being piloted for professional development as well as with students and faculty in ECE programs in Ontario, Manitoba, Alberta, and British Columbia.

7. DISCUSSION

A VLE is defined elsewhere in this volume as a "learning environment mediated by computers and digital technologies." VLE case studies are described as, "instances in action framed by conceptualizations, technologies, and cultures." The data gathered during Webforum 2001 demonstrate how MDECD's original conceptualization of a socio-techno design for knowledge development in early childhood was advanced by the use of the ePresence Interactive Media System as a VLE. Details were collected on the participant community, their use of the technology, the nature of their interactions, and how they

Figure 6. Red River College ECE resource home page.

perceived the event. Examination of the postings also highlighted the critical role of facilitation and provided insight into the ways in which the technology contributed to sustaining a culture for learning and knowledge building across several different conditions.

Though a key objective of the MDECD was to achieve conceptual innovation—what McLuhan (1964) would have referred to as the "message"—the initiative also became a learning experience with respect to technological innovation—or the "medium"—and how social relationships are impacted. Webforum 2001 was intentionally designed to move beyond a traditional conference format to explore alternative possibilities, and part of this involved broadcasting the roundtable sessions from a separate location so that the library audience could experience what it was like to be a remote participant. We did not anticipate, however, that the audience would consider this a breach of social custom and feel excluded from the scientists who were merely feet away in another room. It would appear that as creatures of habit we tend to prefer what we are familiar with, face-to-face interaction within familiar convention. The OISE/UT participants clearly attended Webforum for the knowledge content and not the technological medium. This may also be a reason why their engagement decreased during the roundtable sessions; it is possible that they felt excluded or uncomfortable using the computer terminals to submit questions.

The remote audience, on the other hand, was of necessity drawn into both content and medium. But though they experienced numerous technical glitches, their appreciation of being able to attend the event at all superseded any inconvenience arising from these complications. As the technical difficulties decreased and their familiarity with the technology increased, they became more engaged and even shared how they were experiencing the technology, providing invaluable "in the moment" insights through postings that made their thinking explicit. They also bonded together in moments of difficulty often helping each other when problems arose. In this respect, we saw that the ePresence VLE afforded a sense of inclusion and community amongst the online distributed participants.

The technology also afforded other advantages and unanticipated uses not readily available to the local OISE/UT participants. Remote users were able to socialize with each other as well as input and offer general commentary to an extent that the local audience could not. For example, it is highly unlikely that a face-to-face member would have felt comfortable enough to comment on how the roundtable discussion was organized or to make suggestions for improvements in front of other audience members. Social interactions using the various ePresence VLE features, such as the sequence between the mother and the son, demonstrated how the ePresence system supported multitasking. The two interlocutors not only attended the event and submitted public questions, but they were also able to talk privately about their impressions without interrupting the other attendees. Face-to-face participants would have to wait for the break to engage in this kind of discourse. Another advantage of the ePresence VLE was that users could scroll back and forth through the presentation slides or print up hard copies. These observations by no means suggest that given a choice the remote users would not have preferred to attend the event face-to-face, they merely point out the extent to which the technology had built in affordances that the participants used as they saw fit, sharing their impressions and taking the initiative to shape the experience into something more personally meaningful.

Finally, the features of the ePresence VLE supported multiple modes of interaction across time, space, and distance. Synchronous interaction was supported as participants engaged with each other and the expert presenters either using the microphone in the library space or live chat and text question features in the VLE. In addition, the captured event and the subsequent knowledge media products provided options for distributed users to access the multimedia knowledge base and interact synchronously or asynchronously with others either through a live chat or threaded discussion, respectively.

A significant aspect of interaction was mediation. Vygotsky contributed to our understanding of the role of the facilitator in scaffolding the learning process (Bruner, 1985) and Wenger (1998) refers to the broker who mediates between different worlds to build connections for improved information flow and augment social learning opportunities. Our experience with Webforum emphasized the importance of this. Not only was facilitation required to mediate the face-to-face dialogue and to help remote users with the technology, consistent effort was also required to ensure that the virtual presence was included into the face-to-face proceedings. This notion of facilitation was also apparent in the Red River College initiative where the MDECD team assisted in the translation of the knowledge base for a college level Early Child Education program. Last but not least, the ePresence VLE was invaluable as a "brokering" tool. As seen in the transcripts of the online postings, the technology afforded rich insight into what the users were going through, how they adapted to the environment, and what they thought of the technology. In effect, the technology served as a facilitator, or mediator, helping us to understand the participant experience and leading us to think differently about social relationships we generally take for granted. These insights have been instrumental to the ongoing iterative design improvements of the ePresence Interactive Media System at KMDI. Details on some of these are discussed below.

Less positive aspects of the technology were that distractions arose when things did not work properly and when the public chat was cluttered with public notes related to individual technical problems or non-content-related issues that would have been better handled using the private message feature. As the logs, show however, this "improper" use diminished by Day 2 as users became more familiar with the VLE. The switch from the library location to the roundtable conference room further contributed to renewed disruptions and adjustments. As webcast technology was still rather sensitive at that time and the majority of the online participants were novices to webcasting, it might have been best not to have moved the equipment. In future, we might think about having either the complete conference in one location, or duplicating the technology set-up in the roundtable room to make the switch over more seamless.

Response from both the face-to-face and online participants indicated that the 2-day Webforum was successful on a couple of levels. First and foremost was the level of public satisfaction. The event was well attended, and the ePresence VLE helped to establish a sense of community through supporting interaction amongst the online participants and across the remote into the material conference. As witnessed by the learning community that emerged during the Red River initiative, the ePresence multimedia capture of the 2 days also inadvertently became the first step in sustained community building.

Learning communities emerge when like-minded people group together to make connections, share ideas, pursue mutual goals, and generate knowledge in a mutually supportive and reciprocal manner (Daniel, 2002; Marsick et al., 2000; Misanchuk & Anderson, 2001). Another characteristic is a diverse participant group—ranging from novice to experts—that can enrich the learning experience and contribute multiple perspectives (Xiadong et al., 1996). The Webforum event brought together an extremely varied group of students, organizations, researchers, policy makers, and practitioners all seeking to access the most current knowledge in early child development and to discuss practical applications. The ePresence VLE broadened this knowledge network across geographical boundaries and facilitated the extension of what typically would have been an isolated 2-day event through establishing the knowledge base that was subsequently used for the creation of the knowledge media products.

8. WHAT HAS HAPPENED SINCE

Our early uses of ePresence including Webforum 2001 convinced us that it was important that events be easily archived and made available to users *via* a customizable web portal. The archives needed to be hierarchically structured, browsable, and full-text searchable. Our implementation of this provides an interactive timeline and two-level table of contents for easy browsing and navigation. The concept of hierarchically structured video is based in part on work described in Baecker et al. (1996) and Baecker and Smith (2003).

The current ePresence Interactive Media system (Baecker 2002; Baecker 2003; Baecker et al., 2003; Baecker et al., 2004; Baecker et al., 2004) also allows configurable live and archive interfaces through tailorable "skins", which allow site-specific control over the layout and typography of both interfaces, and the inclusion of corporate logos for purposes of "branding". The media capturing and streaming engines run under Windows or Linux; client viewers exist for the IBM PC, the Macintosh, and Linux. Media may be transmitted using Windows Media, Real Media, and MPEG4. Webcasts may be received with bandwidths as low as a 56 K modem. The software is implemented with .NET technology, is highly modular, and is soon to be released open source (Baecker, 2005; Rankin et al., 2004).

One difference between knowledge media (Baecker, 1997) and traditional media is the ease with which we can modify the capabilities and qualities of the medium through relatively straightforward software developments. Thus, motivated in part by insights gained in Webforum 2001, and in the hundreds of hours of webcasting done by us and our ePresence partners since that event, we are currently engaged in a number of initiatives to enhance the software and make it a better VLE:

- supporting mobile devices for ePresence access so that attendees at an event (local viewers) can also participate in the dialogue among remote viewers;
- enriching the sense of presence, so that local viewers can get a better sense of the remote audience, and so that remote viewers can experience in even more engaging experience;
- allowing questions from remote viewers to be expressed in voice rather than in text using Voice Over Internet Protocol (VOIP) capabilities;
- allowing voice discussions (much like whispering to one's neighbor in a lecture) to occur while watching a webcast (Schick et al., 2005);
- enhancing our understanding of how knowledge-seekers use multimedia archives (Dufour et al., 2004; Dufour et al., 2005; Toms et al., 2005);

- enabling searching of the archives using the voice track in addition what exists now, which is searching *via* text that appears in the chapter titles and in the slides;
- integrating a real-time chat capability that has persistence after the event with a capability for threaded discussions over the archives (Baecker et al., in press);
- integrating ePresence with an online course environment so a course could seamlessly interact with live events and archives increasing the impact and sustainability of the VLE.

CONCLUSION

McLuhan maintained that the tendency to focus on the message and not the medium underestimates the real impact that media have in radically altering the experience being communicated (Marchand, 1989). The MDECD sought to address this conceptual–technological divide by bringing the science in early child development together with leading-edge technology with aspirations of exploring a socio-technological design for knowledge advancement. This chapter describes how we used the ePresence Interactive Media System as a VLE for Webforum 2001—MDECD's culminating event—as a preliminary foray into the role of technology for supporting geographically dispersed participants and mediating social opportunities for accessing, sharing, using, creating, and proliferating knowledge across real and/or asynchronous time. Webforum 2001 as a 2-day event did not generate large quantities of data, neither was it formally designed in advance. Its significance, nonetheless, was that it germinated the seed for ongoing technological design and the emergence of a learning community for Early Child Development, which is still active to the present day.

ACKNOWLEDGMENTS

We would like to acknowledge the MDECD Research Team: Dona Matthews, Jane Bertrand, Kevin Runions, Denese Coulbeck, and Erin Spano as well as the ePresence Team: Maciek Kozlowski of VideoTelephony Inc., Peter Wolf, David Torre, and Anne Postic. Integral to this collaboration were also Ron Cooke and the Education Commons group at OISE/UT: Avi Hyman, Patrick Hopewell, Dick Combeer, Bill Lechow, and Neil Tinker. Thanks also to Paul Haggins of Graphix-Design for his work on Conversations on Society and Child Development.

Finally, this work would not have been possible without the generous support of Invest in Kids Foundation, the Lawson Foundation, the Connaught Committee/University of Toronto, the Natural Sciences and Engineering

Research Council of Canada, and the Bell University Laboratories of the University of Toronto.

ENDNOTES

1. Webforum 2001 took place on November 8th and 9th at the Ontario Institute of Studies in Education of the University of Toronto: see http://hdap.oise.utoronto.ca/mdecd or http://www.Webforum2001.net.

3. Canadian Institute for Advanced Research: see http://www.ciar.ca.
4. Developmental Health is an omnibus term the authors use to describe a variety of developmental outcomes such as competence and coping, mental and physical health, and educational achievement.
5. For chapter summaries by Dona Matthews: see http://hdap.oise.utoronto.ca/dhwn.
6. Zijdemans was a member of the committee from the outset and deeply involved in the initiative.
7. Knowledge Forum (http://kf.oise.utoronto.ca) was developed at OISE/UT by faculty members, Scardamalia and Bereiter, to reflect constructivist pedagogical theory by supporting individual and collective understandings of the world through problem solving within a collective discourse.
8. Webcasting technology is typically a one-way broadcast medium that pushes or streams audio and video via the internet so that it can be viewed on a personal computer using a web browser. In contrast to video conferencing, webcasting moves beyond the one-way transmission model in that is a scaleable to a large number of distributed recipients and typically does not experience the same delay.
9. Today, we still use a 3–4 person crew if a high quality production is required (e.g., multiple cameras, mixing, etc.) but it is also possible now for one person to record an event.

JEREMY HUNSINGER†
*University of Toronto; †Virginia Polytechnic Institute and State University

1. THE TRANSFORMATION OF COMMUNITY

Community has traditionally been anchored in local, neighborhood interactions and enshrined as a code word for social cohesion. "Community" usually connotes people socially and cognitively encapsulated by homogeneous, broadly embracing groups (Hillery, 1955; Wellman, 2001a; Wellman, 2002; Wellman & Leighton, 1979). People in group-based societies deal principally with fellow members of the few groups to which they belong: at home, in school, in the neighborhood, at work or in voluntary organizations. They work in a discrete work group within a single organization; they live in a household in a neighborhood; they are members of one or two kinship groups; and they participate in structured voluntary organizations: churches, bowling leagues, unions, and the like. There have been fears since the industrial revolution that traditional group-based community has been "lost". From the early 1960s, the balance of analysis swung away from bewailing this purported loss of community to using ethnographic and survey techniques to discover the persistence of neighborhood communities. In the 1970s, analysts began realizing that communities were flourishing outside of neighborhoods. The proliferation of cheap and efficient transportation and communication networks in the developed world has increased the velocity of transactions and fostered interactional density. This allows contact to be maintained with greater ease and over longer distances. Since the 1970s, many studies have documented a change from local to long-distance community, with little interaction across the intervening territory between places. Few neighbors are known, and most friends and relatives live elsewhere (Fischer, 1982; Wellman, 1997; 1999a, b; Wellman & Leighton, 1979).

In the internet age, communities and their networks have spread through the information commons. As computer-mediated-communication spread through academic communities, new uses for it were imagined. With learning as one of the primary missions of academic institutions, it is not surprising that virtual learning environments were developed. The context of the development of virtual learning environments have been influenced by a myriad of scholarly communities and networks and the virtualized relationships they provide. Our understanding of those networks can be increased through researching networked scholarship.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1429–1447.

2. INVISIBLE COLLEGES AND SCHOLARLY NETWORKS

Scholarly networks have existed since at least the Middle Ages. Remnants of the correspondence of ancient scholars such as Desiderius Erasmus, St. Thomas More, and others reveal that scholarly networks communicated actively during the Renaissance, continued through Enlightenment, and continues today.

The 19th-century's increase in the scale of scholarship and the Industrial Revolution's turn toward hierarchical bureaucratic organizations narrowed the focus of scholarly societies, professionalizing education, and restructuring the universities. The main bases for scholarly organization became spatial proximity or disciplinary affinity. Most scholars work in physically compact universities (or similar research centers), where they meet students and colleagues face-to-face. Yet, universities and their departments are polyglot, physically compact bureaucracies geared for organizing teaching and for administering costly resources. A department's faculty is intentionally diverse in order to serve the perceived needs of students and the public in a smorgasbord of areas. This diversity also means that university departments often are too large and diverse to be suitable venues for scholars wanting to discuss a specific problem area.

The 20th-century's proliferation of research, researchers, and research publications has meant a global increase in the number of specialists in each area. Increased specialization means that the scholars most interested in each other's work usually live elsewhere because few universities care to employ two experts on the same subject. Intellectually kindred souls find each other by forming professional associations within their discipline or interdisciplinary interest area. Such associations are rarely local, except on a small scale or when disciplinary associations are foregone in favor of transdisciplinary efforts. Scholars must go to (often-great) lengths to communicate with distant, kindred souls. Rather than wait impatiently for replies or discussions of their findings, they go to conferences, read periodicals, or circulate preliminary thoughts and findings via attachments, web-postings and blogs. In addition to formal associations, the narrowed focus of scholarship and the limited number of faculty in local proximity has fostered the proliferation of extra-university networks to support the interests of individual faculty members.

As scholars get used to seeing each other at conferences and journals and develop the habit of discussing each other's work and perhaps collaborating, all or part of their network becomes crystallized as a less amorphous *invisible college*, defined by a shared interest in a specialty and by ties of friendship, information, advice, and collaboration. The long-standing practice of scholarly communication in these networks is the foundation for understanding development and change in the academy.

Studies of scholarly networks have increased since the early 1960s when Price (1961) coined the term "invisible colleges" to describe the patterns and structure of scholarly networks [see also Crane (1972)]. Such invisible colleges "function as a scholarly in-group within a given specialization", their research "facilitated by informal exchange of information through contacts within this social network at conferences and other forums" (Gresham, 1994: 38). Their structures are networks with crosscutting ties between sets of scholars on both the core and the periphery. The informal nature of these invisible colleges affords flexible, adaptive structures for exchanging and evaluating new ideas. Their lack of formal structure means that communication depends on the structure, frequency, and quality of scholarly ties.

Invisible colleges provide forums for sharing, disseminating, and testing new ideas, as well as for exchanging information about teaching, research, funding opportunities, academic bureaucracies, and personal situations. They promote scholarly identity and purpose and stimulate discussion of theory, methods, and findings. Ideas get transmitted more quickly and innovatively than in formal journals constrained by publication lags and orthodoxy-promoting refereeing, though this too is changing in the online era. Typically, they contain:

- a core group of elite scholars;
- a high degree of communication through formal (conferences, papers) and informal channels among members;
- frequent communication between prominent core scholars and subsets of less prominent, non-core scholars;
- interactions among core members and their adherents hold the invisible college together;
- contacts between members of invisible colleges and outsiders enable mutual exchange of information.

3. WIRING SCHOLARLY NETWORKS

Rapid developments in computer-mediated communication are associated with a paradigm shift in the ways in which institutions and people are connected. This is a shift from being bound up in small groups to surfing life through diffuse, variegated social networks. Although the transformation began in the pre-internet 1960s, the proliferation of the internet both reflects and facilitates the shift. To facilitate the design of communication tools to aid scholarly communication and online-learning behavior, it is useful to understand the social structure of scholarly networks, the types of media used by these networks, and the conditions under which different media are used.

Much social organization no longer fits a group-centric model of society. Work, community, and domesticity have moved from hierarchically arranged, densely knit, bounded groups to social networks. In networked societies, boundaries are more permeable, interactions are with diverse others, linkages switch between multiple networks, and hierarchies are flatter and more recursive. People maneuver through multiple communities, no longer bounded by locality. Organizations form complex networks of alliances and exchanges, often in transient virtual or networked organizations (Bar & Simard, 2001).

How people learn is becoming part of this post-industrialization paradigm shift. There has been some move away from traditional classroom-based, location-specific instruction to virtual-learning environments. There has also been some move away from teacher-centered models of learning to student-centered models and somewhat flatter hierarchical relations have arisen. Geographically and spatially dispersed learning is part of this shift. Learning has moved beyond traditional many-to-teacher correspondence and educational television courses to computer-supported many-to-many or distributed learning.

Even before the development of the internet, cars, planes, phones, and text-based computerized communication supported substantial communication and collaboration among physically dispersed scholars (Finholt, 2001; Finholt et al., 2002). The advent of the internet has especially placed fewer constraints of time and place on communication. Scholars can stay in their locale to connect, interact, and collaborate with each other over great distances (Assimakopoulos & Macdonald, 2002; Finholt, 2001; Koku et al., 2001; Matzat, 2004; Mutschke & Quan-Haase, 2001). Now traditional e-mail and web sites are being joined by online audiovisual technologies supporting collaborative work (Barrett, 2000; Churchill et al., 2001; Ragusa & Bochenek, 2001). Distance education programs offer a variety of courses, supplementing traditional means of instruction with computer-mediated lectures, discussions, activities, and projects (Harasim et al., 1995). In some cases, computer-mediated communication has enabled the operation of entire university programs online (Acker, 1995; Noam, 1998). Instead of university faculties localized at their university departments, virtual faculties, formalized "collaboratories" link far-flung scholars, institutions, and research centers (Finholt, 2001). Even more prevalent are informal collaborations among scholars located in different universities that sometimes span the globe.

Computer-mediated communication is providing a technological basis for new forms of spatially dispersed, loosely bounded, networks of scholars that are more connected than the fitful, amorphous relationships of the past and less physically proximate and bureaucratically structured than contemporary universities. These networks of scholars are closer to the idea of the invisible college, and perhaps before the invisible college arose—the republic of letters. Those institutions were distributed networks of intellectuals and scholars that shared knowledge and communicated with each other over large distances. Of course, the velocity of communication is now more rapid; distant scholars stay in touch more; and instant messaging, e-mail, and attachments fill gaps between face-to-face meetings.

The possibility for all to communicate rapidly with all via internet technologies, no matter where located, has created hopes that peripheries would become as well-connected as centers. As distance matters little for computer-mediated communication, spatial isolation should not be a problem, though other barriers still exist, such as those based as on language or state policy. As all become connected to all, formerly disconnected persons, groups, and branch campuses should be as able as those at the center to communicate with others. This should affect the structure of scholarly networks: As e-mail, instant messaging blogs, and attachments of text and data help to maintain direct ties, social density increases and the periphery—whether spatial, social, organizational, or scholarly—can become better connected with the core or cores, should a plurality of centers develop.

Research has shown that computer-mediated communication supports a range of instrumental, informational, social, and emotional exchanges in work and leisure contexts (e.g., Baym, 1995; 1997; Rice et al., 1998; Wellman & Gulia, 1999; Quan-Haase & Wellman, 2004; 2005). Building on this work, there is a need to understand the types of interpersonal interactions, multiple exchanges of material and emotional support, intimacy, trust, and self-disclosure that characterize learning communities online and offline (Granovetter, 1973; Haythornthwaite, 2002; Haythornthwaite & Kazmer, 2002; Marsden & Campbell, 1984; Wellman, 2001a; Wellman & Berkowitz, 1988).

The changes in how people socialize in the network society have created a need to develop new models for conceptualizing and measuring community. Considering that socializing occurs beyond the boundaries of the local neighborhood, workplace, or school, useful approaches define community not in terms of locality, but as social networks of interpersonal ties that provide sociability, support, information, a sense of belonging, and social identity (Castells, 2000; Wellman, 2001a; Wellman et al., 1988). By examining people's social relationships independently of narrowly defined boundaries based on location, researchers have discovered that many people live in long-distance communities (Wellman & Wortley, 1990). Thus, this evidence suggests that industrialization did not destroy community, but helped transform its composition, practices, attitudes, and communication patterns. This finding parallels what we might assume: virtual learning environments will not destroy learning or scholarly communities but will transform them to some extent.

Social network analysis provides an approach that can facilitate understanding communities. Viewing community as comprising social networks of relations enables analysts to examine the types of interactions—such as information, emotional support, material support, companionship—which affect online communities. It facilitates the assessment of the extent to which computer-mediated communication supports online learning communities with low levels of centralization and hierarchy (Ahuja & Carley, 1999; Haythornthwaite & Kazmer, 2002).

Much research on computer-mediated communication has focused on how the characteristics of different communication media affect what each medium can convey (Garton, et al., 1998; Wellman & Haythornthwaite, 2002). Such characteristics include the richness of cues a medium can convey (for example, whether a medium is text only such as e-mail or also includes visual and auditory cues), the visibility or anonymity of the participants (video-mail versus voice mail); whether communications identify the sender by name, gender, title; and the timing of exchanges (e.g., synchronous or asynchronous communication). Until recently, social scientific research into computer-mediated communication has concentrated on how individual users interface with computers, how two persons interact online, and how small groups function online. Much less attention has been paid to how computer networks fit into the broader social networks and contexts in which these individuals, duets, and groups are connected. Yet, the social relationships that people have with each other are embedded in social networks that affect their social resources, mobility, happiness, and work habits (Wellman, 1999a; 2001a).

Social network analysis stresses the importance and patterns of relationships among interacting units: people, organizations, states, etc. The social network approach enables analysts to go beyond viewing relationships only in terms of groups and isolated duets. It incorporates into research a set of structural variables such as the density, clustering, heterogeneity, and multiplexity of networks (Ahuja & Carley, 1999; Berkowitz, 1982; Scott, 1991; Tindall & Wellman, 2001; Wellman, 1998; 1999a; Wellman & Berkowitz, 1988; Wasserman & Faust, 1994). Social network analysts have developed procedures for seeing how different types of relationships inter-relate, detecting structural patterns, and analyzing the implications that structural patterns have for the behavior of network members. For example, the fact that person A and person B interact online may be understood better if one takes into consideration their offline reporting relationships to person C, the company Vice President.

Thinking about relationships in terms of social networks rather than in groups can allow analysts to examine the social contexts of online relationships and focus on the potential of computer-mediated communication to support less-bounded, sparsely knit interactions (Fulk & DeSanctis, 1995; Fulk et al., 1987; Rice et al., 1990; Wellman & Gulia, 1999; Wellman et al., 1996). For example, analysts may enquire whether there is a core and periphery in a particular network structure and then examine how involvement in such structural blocks helps explain the behavior and attitudes of network members. For example, do peripheral people send more e-mail and do they communicate only with members of their own clusters or with others?

Network analysts also look at both *whole networks* and *personal networks* (Wellman & Berkowitz, 1988). Whole network analyses look at patterns of relationships in a social system, be it a set of scholars or a set of states. Personal network analyses look at each person's own network, such as how the networks of different scholars vary.

The social network approach has developed a battery of concepts and methods that can aid analysis of communities, online and offline. Using examples from online communities in general, and learning communities in particular [the next section of this chapter], this subsection examines the usefulness of social network concepts such as range (size and heterogeneity), density and boundedness, centrality, tie strength, and multiplexity (multiple roles) for understanding online communities and social relationships.

4.1. Network Range (Size, Heterogeneity)

The concept of network range pertains to the size and diversity of the population within the network's boundaries (Burt, 1983; Haines & Hurlbert, 1992). Networks with high range (large, heterogeneous) are good for seeking and obtaining new resources (Wellman, 1999a; Newman, 2001). On the other hand, networks with low range (small, homogeneous) are able to conserve resources and information within their boundaries.

Computerized conferences, newsgroups, and listserves facilitate and increase the range of social networks (Smith, 2000). The asynchronicity and relatively inexpensive cost of online communication transcends spatial and temporal limits, enabling system users to communicate over different time zones and maintain contact with their weak ties. Therefore, online communication links can increase the range of social networks. Given that e-mail relationships have few social cues and social presence, the only personal detail that communicators may initially know about each other is their e-mail addresses and signatures. Such limited personal information allows development of relations based on shared interests rather than on shared social status (Hiltz & Turoff, 1993). This may flatten the hierarchy of status found in communities and other learning environments, thus fostering more interaction among more people.

4.2. Centrality

Network centrality indicates the extent to which certain network members are prominent in a given network in terms of connectivity among network members. Centralization scores (measured as percentages) measure how variable or heterogeneous are the individual network member centrality scores. It records the extent to which a single network member has high centrality scores, and the others have lower scores. A high centralization score means a network's activity centers on a particular member.

Scholars who have high degree centrality are those with many connections with other network members. Such scholars are involved in relations with many others and could be recognized by other scholars as major channels of scholarly information and activity. Well-connected network members usually play key roles in shaping the behavior and perceptions of others in the network, particularly in the diffusion of innovations and the use of available media (Rogers, 1983; Valente, 1995). Central network members tend to use a variety of media (Haythornthwaite & Wellman, 1998), have the most positive experiences with media use (Papa & Tracy, 1988), be early adopters of new information systems, and facilitate the development of critical masses of users for the systems (Rice, 1997; Rice et al., 1990).

When directionality is taken into account, there are two kinds of degree centrality: *In-degree centrality* measures how many other network members report having a relationship with a specified person. For example, others mention scholars with high in-degree centrality as people they approach for advice or discussions. Thus, in-degree centrality is one measure of the prestige of a network member. In contrast, *out-degree centrality* measures how many other network members a person reports being connected with. Thus, it is an indicator of the extent to which a scholar reports reaching out to others.

Betweenness centrality measures the extent to which a network member occupies a location between others in the network. Persons with high betweenness are often positioned in the collaborative and communication network between people who are not directly connected. Network members with high betweenness facilitate communication and information flows. They broker information, link otherwise disconnected scholars, and transmit information across disciplinary and organizational boundaries (Ahuja & Carley, 1999; Burt, 1992; Orlikowski & Barley, 2001; Tushman & Scanlan, 1981). Thus, scholars with high betweenness are in powerful collaborative and communication brokerage positions between otherwise disconnected scholars.

Central scholars are better able to control and diffuse information. They also are better able to sustain more central communication roles because of their prestige, popularity, and grant funding (Crane, 1972). This has positive feedback effects, leading to increased conference attendance, speaking engagements, and interaction with disparate others (Perry & Rice, 1998). All of these interactions expose scholars to more ideas, make them better known within professional and policy circles, and popularize their research. This sustains the cycle of centrality and prestige because central scholars are better able to respond to promising ideas, influence the direction of policy, and retain funding.

Central scholars tend to have a more sophisticated level of knowledge of the things worth knowing: the debates and lore that are crucial for leading-edge scholarship. While peripheral scholars may be apt to discover new ideas because of their connections to other scholarly communities, central scholars may introduce such peripheral ideas into the mainstream or else the ideas otherwise might lack attention or awareness within scientific communities (Perry & Rice, 1998). Thus central scholars both disseminate and filter, for as Erickson (1996) suggests, one of the useful consequences of being in the center is that central people know what they can afford not to know.

4.3. Density

The density of a social network is the extent to which its members are in direct contact with one other. Hence, the rate of information flow in networks partly depends on whether networks are densely or sparsely knit. Densely knit, bounded networks (i.e., "groups") usually experience frequent contact among members. In such networks, most relationships remain within the population, with the exception of a few boundary spanners and gatekeepers who maintain links outside. Frequent contact within these groups and the wide range of group activities fostered by members create close relationships among members.

In contrast, members of sparsely knit networks have many ties with people who are more closely linked to other networks. Ties in such sparsely knit networks tend to be more variable than those in densely knit networks in terms of what network members do together, how supportive they are, and how frequently they interact (Danowski, 1986; Wellman, 1997).

Computer-mediated communication supports both densely knit and sparsely knit networks. Focused task and work groups, MUDs and some moderated newsgroups, and listserves are densely knit communities. As they develop, they often evolve rules and leadership structures and require attention and commitment from their members (Kollock & Smith, 1998). Message management features of e-mail systems can increase network density and enable friends and colleagues to keep informed. Third parties spread the word about who has help, who needs help, who has been helpful in the past, and who has been a free rider. Forwarding communications to third parties also provides indirect connections between previously unconnected people. Ease of direct reply can then transform a transitive, indirect tie to a direct tie.

Computer networks also support sparsely knit networks. Participants can send e-mail to anyone whose address they know, and they can simultaneously belong to multiple discussion lists and chat groups. They can engage in different kinds of discussions about different subjects on different lists, varying their involvement and commitment in different work groups, maintaining connections with distant acquaintances, and forming new ties with strangers. Information may come unsolicited through blogs, distribution lists, chat groups, forwarded messages from friends, and direct e-mail from strangers connected through mutual ties. Sparsely knit networks are usually connected through weak ties to a variety of social circles. Hence, they are more apt to be sources of new information and potential alliances (Granovetter, 1973; 1983).

4.4. Tie Strength

The strength of a tie is a multidimensional construct comprising social closeness, voluntariness, and multiplexity. Some scholars also add frequent contact to the defining criteria (Granovetter, 1973; 1983; Wellman & Wortley, 1990). Strong ties often provide more support and information, and a sense of belonging. However, Granovetter contends that weak ties are useful for specific purposes. He argues that people belong to clusters of others with whom they have strong and weak ties. Information circulates at high velocity within these clusters, and each person tends to know what other cluster members know. Hence, the spread of new information, ideas, and opportunities often comes through the weak ties that connect people in separate clusters.

Some studies have focused on the effect of tie strength on the flow of resources and information among scholars. Friedkin's (1980, 1982) study of university faculty contrasts the importance of strong versus weak ties for information flows. He shows that in the aggregate, the large number of weak scholarly ties contribute significantly to information flows. Although strong ties provide much information about activities within an organization, weak ties provide useful information about activities outside of a work group or organization (Levin et al., 2002).

Despite e-mail and IM's limited social presence and absence of social cues, their ease and ubiquity supports strong, frequent, supportive, and companionable contact (Garton & Wellman, 1995; Kling, 1996; Nie et al., 2002; Rheingold, 2000; Sproull & Kiesler, 1991; Quan-Haase & Wellman, 2004; 2005; Wellman & Gulia, 1999). So, strong and supportive are some online relationships that some participants in an online group came to feel that fellow members were close friends (Bastani, 2001; Hiltz & Turoff, 1993; Kendall, 2002). Concerns about how computer-mediated communication supports strong ties ignore the many relationships that combine online and offline communication. Computer-mediated communication is often used to maintain contact between face-to-face meetings and phone calls. Indeed, computer-mediated communication often coincides with in-person meetings, fills in gaps between, and helps arranges future meetings. Conversations began in one medium and drift to another. For example, computer scientists and programmers working in the same physical space often communicate by e-mail and IM as well as in-person (Haythornthwaite & Wellman, 1998; Quan-Haase & Wellman, 2004; 2005). Learning communities are no different, with friendship and informal relationships—online and offline—being the fluid that lubricates the formality of collegial and academic collaborations (Carley & Wendt, 1991; Glanz, 1999; Gresham, 1994; Grimshaw, 1989; Toren, 1994).

TechNet is a network of scholars and professionals in a North American university interested in a coherent set of issues at the intersection of the social sciences, humanities, sciences and engineering. It began informally in the early 1990s as a scholarly network at one university and formally became a university research institute "a visible college" in the mid-1990s (Nazer, 2000; Walsh & Bayama, 1996). TechNet's goals are to:

- facilitate an intellectual community of scholars, researchers, and students from a number of disciplines;
- facilitate appropriate partnerships with other universities, the private sector, non-profit organizations, and government;
- afford the intersection of the relevant disciplines a more prominent place and role within the university;
- create and support colloquia and lecture series;
- facilitate visits to the university of distinguished scholars and research working in these areas and to increase support for graduate students;
- establish one or more appropriate funded chairs and professorships;
- create additional relevant courses, and increase awareness of existing course that cross disciplinary boundaries;
- create a new collaborative degree program;
- develop and offer short professional development courses for industry and society.

TechNet's activities have been guided by a multidisciplinary steering committee that meets monthly. Membership in TechNet is voluntary and open to all faculties with an interest in TechNet's domain. At the time of our data gathering at an early stage of TechNet's development, administration was informal, with only one part-time paid administrative assistant. There were 24 members of TechNet—from the social sciences, physical sciences, medical sciences, humanities, and engineering. Members of TechNet organize and meet in a variety of online and offline forums to exchange ideas, to discuss emerging research, and to socialize. Some of these are weekly multidisciplinary seminars, annual conferences and symposia, retreats, end-of-semester/year parties.

TechNet is a scholarly network or more broadly, a community of practice with a shared history and cosmology (Barab & Duffy, 2000). Many founding members and some other members were initially linked through participation in joint research, conference attendance, reading the same journals, membership in university committees, and advising on graduate student projects. TechNet is also linked with other communities interested in the intersection of the humanities, social sciences, and technology. As one member explains in an interview:

> The ways that an entire citizenry can be much more actively and successfully involved in knowledge development and knowledge society is the core interest of mine and that of a number of TechNet members. I just think that this interest is grossly under-represented in the kind of work that is done in the university and underrepresented in formal structures. There are lots of faculty who are doing exciting things, but there are no formal structures to network together.

6. RELATIONSHIPS AND NETWORKS IN TECHNET

To learn more about TechNet, one of us (Emmanuel Koku) interviewed all 24 TechNet members in 1997–1998 about their work, friendship, and media use inside and outside of TechNet, asking members to describe their scholarly and social relations with each other TechNet member. This elicited reports about 405 pairs of scholars: their work relationship, social closeness, friendship, frequency of scholarly communication, and type of communication media used. Although much of these interviews are analyzed statistically, we also rely on notes of conversations held during the interviews and Wellman and Koku's own active participation in TechNet [this section summarizes material presented in Koku and Wellman (2004); see also Koku et al. (2001)].

TechNet scholars report having an average of five "friends" within TechNet (22% of the total membership), 10 "colleagues" (43%), 9 "acquaintances" (39%), and 4 others of whom they are "just aware" (17%; Koku and Wellman, 2004; Koku et al., 2001). They are in e-mail contact with 19 (82%) other members and in face-to-face contact with 14 (61%). Most use e-mail where necessary for work relationships such as discussion of research, and supplement this with face-to-face communication when they meet in person in workshops, seminars, and other collegial gatherings. These statistics underestimate the significance of face-to-face contact, as it is usually longer in duration than e-mail contact and provides more communication bandwidth. Those pairs of TechNet scholars who are in touch are in relatively frequent contact: a mean of 20 times per year and a median of 10 times per year. As all TechNet members are comfortable with computers, they use e-mail often: 56% of all Technet pairs have some e-mail contact.

e-mail and computer-mediated communication supports face-to-face contact rather than supplants it, with members using it to arrange face-to-face meetings, disseminate news, and exchange documents. Those TechNet members using e-mail send messages to each other at a mean rate of 24 times per year, an average of twice per month. To Technet members, non-face-to-face communication means computer-mediated communication. Only a minority use telephones, faxes, and couriers, and those who do use these media, use them infrequently. The most widely used of these are local telephone calls, used by only 25% of TechNet members to communicate with other members.

Those who telephone do so on the average of once per month (mean = 11 calls per year). Most TechNet pairs use a combination of communication media to keep connected. Thirty-two percentage use two media while 23% use three or more.

Discussing and seeking research advice are not uniformly distributed in collegial communities. The more intense the work relationship, the smaller the scholar's network. The average TechNet member discusses work with 17 other TechNet members (74%), but reads the work of only five (22%) and also collaborates with five (22%; not necessarily the same five) in research and proposal writing. These may be overlapping networks, with some scholars discussing each other's work, reading these works, and collaborating in research.

Larger scholarly networks vary more in the intensity of their communications (e.g., e-mail) and scholarly (e.g., discussion) networks. Thus, e-mail contact networks are as large and heterogeneous as face-to-face contact networks. Similarly, research discussion networks are larger and more heterogeneous than reading or collaborative networks. The size and heterogeneity of e-mail networks stem in part from the ease of making contact without regard to spatial and temporal separation, and the ease of including several scholars in the same message. Moreover, forwarding e-mail messages fosters the development of more extensive and intensive relationships among scholars. The development of such heterogeneous linkages is facilitated by TechNet's weekly seminars, workshops, and other social events that provide an in-person focus (Feld, 1981) where scholars make and sustain collegial and sociable contact with people from different disciplines [for a similar pattern in another scholarly network, see Koku et al. (2001) and Nazer (2001)]. Such networks are important avenues for the provision of social, instrumental, and emotional support and for the mobilization and co-ordination of collective activity.

e-mail and face-to-face contact play complementary roles and reinforce each other. Rather than substituting for face-to-face contact, those who use e-mail often also tend to have more face-to-face contact (Chen et al., 2002; Quan-Haase & Wellman, 2002; 2005). The impact of e-mail is not so much in what is communicated, but in who communicates with whom, how frequently, and over what distances. Despite TechNet's frequent public gatherings, face-to-face contact is more centralized than e-mail contact. Core planners and researchers combine face-to-face, e-mail and occasional phone contacts. Peripheral members are more apt to use one of these media to keep in touch with TechNet activities. Some rely on scheduled face-to-face get-togethers to find out what is happening administratively and intellectually. Others, who do not want to go across campus to meetings, rely on broadcast e-mail and occasional focused exchanges. These networks have fluid and permeable boundaries for the structure of relationships in TechNet varies according to the activity being performed (Ahuja & Carley, 1999; Koku & Wellman, 2004). These networked scholars use e-mail for a wide range of things: exchanging drafts among coauthors, setting up meetings, asking for information, or gossiping about colleagues. Although pundits worried a decade ago about whether merely textual e-mail could sustain a wide range of interactions—from information seeking to emotional stroking—it is the social context, more than the nature of the medium that affects whether e-mail will be used. Expectations only a decade ago that e-mail would only be used for purely instrumental communication appear to have been a product of an early fascination with the novelty of e-mail and an over-reliance on McLuhan's (1962) speculation that the medium is the message.

In short, TechNet has been a success in building a scholarly network and turning it into a visible college. It has:

1. linked scholars across a variety of disciplines in the humanities, social sciences, and sciences;
2. provided a milieu where most members are aware of each other's work;
3. fostered a large amount of innovative collaborative work and discussions across disciplines;
4. integrated the use of e-mail and face-to-face contact into useful means of communication.

TechNet has continued to develop. The scholarly network has become more visible and institutionalized. Collaborative research has become more extensive, and well-attended lecture series solidify internal communication and reach out to other scholars, policymakers, technology companies, and the public. A graduate program offers a set of core interdisciplinary courses and an extensive list of affiliated courses with collaborating scholarly departments in the social sciences, physical sciences, and engineering. Although most arrangements remain informal, there is a full-time paid director, additional paid part-time staff, and steering and executive committees.

CONCLUSIONS

We are living in a paradigm shift in which the way in which people and institutions are becoming more connected through social networks and less so through formal groups. Members of old-paradigm societies deal only with fellow members of the few groups to which they belong: at home, in the neighborhood, at work, or in voluntary organizations. They belong to a discrete work group in a single organization; they live in a household in a neighborhood; they belong to one or two kinship groups, and to one or two voluntary organizations: churches, bowling leagues, professional associations, and the like. All of these are hierarchically structured bodies with precise boundaries for inclusion.

In contrast, in new-paradigm networked societies, boundaries are more permeable, interactions are with diverse others, linkages switch between multiple networks, and hierarchies are flatter and more recursive (Castells, 2000; Wellman, 1988; 1997; 2001b; Wellman & Hogan, 2004). Although computer networks have not caused this paradigm shift, they have aided it. e-mail and the web let people move between their different social networks and interests. Hierarchical barriers are lower online and less apparent. It is easy for scholars to maintain an e-mail address book with thousands of names and to maintain multiple lists of like-minded scholars whom they can contact at the drop of an e-mail. e-mail and IM provide ease and flexibility in who communicates with whom, what means they use to communicate, what they communicate, and when they communicate.

Scholarly communities of practice are not homogeneous entities, whether they are in online, offline, or both. Online mutual-learning communities consist of scholars with varying roles, levels of involvement, positions, and varying levels of connectivity with other community members (Hiltz & Wellman, 1997). Further, the structure of these relationships is related to the types and variety of communication media used. Rather than seeing the internet as a separate interaction system, people (including scholars) use it opportunistically to fit into their everyday lives (Chen et al., 2002; Hampton & Wellman, 2003; Quan-Haase & Wellman, 2002). A substantial body of research suggests that designers of online educational communities and virtual learning environments need to take a broad look at the social networks of community members, and how media use and network structure facilitate and constrain mutual peer-to-peer learning.

ACKNOWLEDGMENTS

Our research has been supported by the Bell University Laboratories, the Social Science and Humanities Research Council of Canada, and Daniel Keating's grant from the Telelearning National Centre of Excellence. Ronald Baecker, Gale Moore, and Nancy Nazer gave much good advice. We deeply appreciate the time and interest that the members of "TechNet" gave to us.

Chapter 58: Analysis of Log File Data to Understand Behavior and Learning in an Online Community

AMY BRUCKMAN
Georgia Institute of Technology

1. RESEARCH METHODS FOR STUDYING ONLINE COMMUNITIES

How do we study the behavior of users in online communities? Researchers from a variety of disciplines have evolved a rich set of both quantitative and qualitative approaches to studying human–computer interaction (HCI) and computer-mediated communication (CMC), and these methods are useful in the study of online communities. Unique to the study of CMC and online communities is the possibility of collecting *log file data*. It is possible for the computer to record every command typed by users—in some cases, every keystroke. In cases where users interact only online, we can collect a comprehensive record of all of their interactions. The completeness of the record and ease of collecting it are unprecedented.

However, log file data is more often collected than analyzed. We can save everything, but what does it mean? This chapter presents two examples of the use of log file data to understand user behavior and learning in one online environment, MOOSE Crossing. MOOSE Crossing is a text-based virtual reality environment (or "MUD") in which kids aged eight and older learn object-oriented programming and practice their creative writing. From analysis of log file data from the environment, we gained significant new insights into user behavior and learning. We will briefly discuss an example of qualitative log file analysis, in which a close reading of records of online interaction provides insights into how children learn from one another in this environment (Bruckman, 2000). The rest of the chapter contains an extended example of the use of quantitative log file analysis to try to understand whether there is any relationship between gender and programming achievement on this site. (An earlier version of this analysis was published in Proceedings of CSCL 2002 (Bruckman et al., 2002).)

Quantitative and qualitative methods are generally more powerful when used in a complementary fashion. In the data to follow, our qualitative findings suggested that girls are especially strong achievers in this learning environment. However, quantitative analysis of log file data shows that boys and girls use the environment in similar ways. A small group of girls form the core of "the regulars", the most active, dedicated members who are highly visible to both researchers and other members. The regulars have extraordinary levels

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1449–1465.

of achievement; however, their behavior is not typical. Among more typical members, achievement by boys and girls is effectively the same.

This points to a broader methodological issue in the study of online communities: *Researchers of online environments must be careful not to be over-influenced by the behavior of the regulars.* The most dedicated, regular members of an online community are the most visible. However, they are—by definition—not typical members. In this chapter, we present an example in which the behavior of the regulars is not representative of the behavior of the broader community population. This insight arose from the complementary use of qualitative participant-observation and quantitative log file analysis. This example highlights how using qualitative and quantitative methods together can be more powerful than either approach alone.

2. TYPES OF LOG FILE ANALYSIS

Jenny Preece notes that "the important first step before using data logging and metrics is to revisit the goals and the questions of the study" (Preece, 2000). A variety of approaches are possible, depending on the nature of the research questions. Log file analysis can be either qualitative or quantitative in nature. It can also be manual or automated.

Qualitative log file analysis is generally conducted manually (by a person interpreting logs); however, computerized tools can help the human reader. For example, software can help organize large amounts of data, and search for and identify excerpts that meet a desired set of criteria. The human reader in a qualitative analysis may use a number of theoretical frameworks to organize that analysis such as grounded theory (Glaser and Strauss, 1967), activity theory (Engestrom et al., 1999), distributed cognition (Hutchins, 1995), etc.

Log files need not and often should not be the sole source of data. Many studies of online communities pose questions about the meaning of a particular trace of behavior without taking the obvious step of asking the participants! Surveys and interviews with participants can greatly enhance a researcher's understanding of what is taking place in a log file. The converse is also true: A log file excerpt can be a jumping-off point to get strong interview data.

Quantitative log file analysis can be either manual (with a human translating log entries into specified metrics), or automated (with a computer program performing that translation). Some kinds of log file data lend themselves to automated analysis more readily than others. The nature of the research question affects whether manual or automated analysis is preferable. The scripting language Perl (http://www.perl.org/) has powerful pattern matching capabilities, and is often useful for automating work with log file data.

Quantitative analysis often simply measures amounts of activity over time. For example, Rick et al. analyze how much time students and instructors spend on a class CoWeb (collaborative website) to try to understand its cost effectiveness as a learning tool (Rick et al., 2002). Sometimes the absence of activity can be as revealing as its presence. Nonnecke and Preece look at postings to discussion lists to understand the lurkers (the more silent members) and what they contribute to the community (Nonnecke and Preece, 2000). Techniques from social network analysis can be used to show relationships among group members (Palonen and Hakkarainen, 2000). Techniques from discourse analysis can turn verbal data into quantifiable instances of phenomena of interest in a systematic fashion. For example, Susan Herring and colleagues use variations on this approach to understand diverse phenomena including gendered behavior online, power relationships in online discourse, online harassment, patterns of turn taking in online conversation, and emerging genres in weblogs (Herring, 2004b). Herring provides a useful overview of this technique in (Herring, 2004a).

Natural language understanding software may make it possible for automated analysis to ask questions about the content of discourse and interaction, not just the existence of activity. Activity on some sites follows regular patterns, and those regularities may be leveraged to allow easy automated parsing of activity. That is the case in the example that follows. The rest of this chapter presents a short example of qualitative and extended example of quantitative log file analysis of behavior and learning on MOOSE Crossing.

2.1. Example One: Qualitative Log File Analysis

To make a purely qualitative log file analysis possible, the log data and research questions posed about it must be intelligible to a human and interesting enough to hold their attention for extended periods of time. The paper "Situated Support for Learning: Storm's Weekend with Rachael" presents a qualitative close reading of log files from a holiday weekend when one girl (pseudonym "Rachael",[1] age 13) taught another ("Storm", age 12) how to program. Analysis of the record of their interactions was supplemented with face-to-face interviews and e-mail exchanges. The resulting paper tells the story of what happened online during that weekend (Bruckman, 2000). Analysis of a single case provides one example of what can happen, but does not make any claims as to how typical the phenomena are.

Part of what made this approach feasible in this instance is the fact that the log files used are engaging to read, for both the researcher and the reader. The textual nature of the environment helps make this possible, because actions are summarized in succinct and easy-to-understand log file entries. In a MUD log, someone entering a room appears as a simple statement like "Amy climbs down from the branch above". In a graphical environment, such data may be recorded as a series of coordinate changes that are not intelligible to a human reader. In such situations, a program can be written to "play back" activity, using log file data to recreate an approximation of the original activity (at researcher-controllable speeds).

The multi-user nature of the environment also helps make qualitative analysis possible. In this example, as the girls explain what they are thinking to each other, they also explain their thinking to readers of the log. For example, at one juncture Storm repeatedly modifies a command on one of her projects, a virtual pet mouse. After many changes to the same line of code, we can infer that she is beginning to feel frustrated. However, we don't need to make that inference, because as soon as she meets up with her mentor Rachael, this exchange takes place:

Rachael says, "hi"
Storm says, "Hi!"
Rachael says, "Whatcha doin'?"
Storm says, "Being unsuccessful with that dratted mouse!"

A follow-up interview later confirmed that Storm was indeed quite frustrated at this point in time, and Rachael's sympathy and advice proved helpful in her progress on her project.

Qualitative and quantitative, automated and manual approaches to analysis of log file data are not mutually exclusive. The next, longer case study provides an example of quantitative log file analysis used together with qualitative participant-observation.

2.2. Example Two: Quantitative Analysis of Gender and Achievement

The MOOSE Crossing began with a set of questions about gender and computing.[2] Since the earliest days of the personal computer (and perhaps earlier), researchers have been asking questions about gender equity in computer use. "If males and females participate differentially in computer learning environments, this could lead to differences in cognitive attainments and career access," wrote Marcia Linn in 1985 (Linn, 1985). Linn studied organized middle-school programming classes, and found that girls and boys have similar levels of programming achievement once they enroll in classes, but that girls are less likely to enroll. In the intervening years, much has changed about computers and computing technology. However, the basic facts of gender and computing for kids have not changed: Our results replicate Linn's early findings. In this case study, we observe student programmers in an environment that supports a mix of school and free-time home use. While boys develop significantly more programming expertise than girls (25% difference, $p = 0.004$), regression analysis shows that in fact this difference is attributable to the fact that boys chose to spend more time programming in the environment, and are more likely to have prior programming experience. Boys are more likely to choose to program both before and during their exposure to our programming environment, and time on task predicts level of achievement.

3. THE STUDY SITE: MOOSE CROSSING

In the spring of 1992, Amy Bruckman presented a paper on the fluidity of identity in text-based virtual worlds (or "MUDs") to a student reading group at the MIT Media Lab. A few days later, Mitchel Resnick, then a graduate student but about to join the faculty, posed a question to Bruckman: Would it make sense to create a MUD based on the Babysitter's Club series of books to encourage elementary and middle-school girls to be interested in computers? This was the beginning of the MOOSE Crossing project.

A new programming language ("MOOSE") and programming environment ("MacMOOSE") were developed to make it easier for children to learn to program (Bruckman, 1997; Bruckman and Edwards, 1999). (A Windows version of the programming environment, "WinMOOSE", was developed a few years later.) The Babysitter series theme was abandoned in favor of a more open-ended, gender-neutral theme. Rather than create an environment for girls, we decided to create an environment we hoped would appeal to both genders, so that we could compare girls' and boys' activities there. However, gender was soon relegated to a lower research priority, because there was simply so much fundamental work to do on the basic nature of learning in this new kind of CSCL environment (Bruckman, 2000; Bruckman et al., 2000).

Children began to use MOOSE Crossing in the fall of 1995. Everything typed on MOOSE Crossing is recorded, with written informed consent from parents and assent from children.[3] In January 1996, then undergraduate Austina De Bonte joined the MOOSE Crossing development team as part of MIT's Undergraduate Research Opportunities (UROP) program. DeBonte wrote a series of Perl scripts to break down children's commands typed on MOOSE Crossing into categories (see Table 1).

Table 1. Categories of activity

- Movement in the virtual world
- Communication with others
- Consulting the help system
- Looking at people and objects
- Creation of objects
- Seeking information about others
- Scripting
- Manipulating object properties
- Looking at object properties
- Using the in-world mail system
- Using objects
- Other

Commands executed on MOOSE Crossing follow a specific syntax. Some commands are executed directly by the user, while others by the windowing interface, but all are recorded in the log and relatively easy to categorize. In many cases, the first word of a command identifies the type of command. For example, the command "create" makes a new object. Some cases are slightly more complicated. For example, there are an unlimited, user-definable number of commands that move a user from one room to another, but they have one easily detectable thing in common: The user's location is different after the command is executed. Online activity in this computerized environment is regular enough to make it easy to categorize, and much easier to work with than free-form English.

DeBonte analyzed 700Mb of MOOSE log file data from the first use by kids in September 1995 until April 1997. A total of 160 children participated during this time. Comparing girls and boys use of each of these categories of commands, she found no significant differences. Girls spent more time communicating with others online, and boys had a slightly higher percentage of their commands typed in other categories; however, none of these differences were significant. At the time, we were disappointed in this result—it seemed uninteresting. It is discussed in a few pages of Bruckman's PhD thesis (Bruckman, 1997), but was not published elsewhere.

Five years later, we looked back at this result, and saw it in a new light. No significant differences are not a lack of results—it in fact is an interesting finding. Consequently, Carlos Jensen dusted off DeBonte's Perl scripts, and repeated the analysis on our greatly enlarged data set. Additionally, new scripts have been written to analyze children's level of programming achievement.

4. DATA ANALYSIS: CATEGORIZING ACTIVITY

Through November 2000, 457 children participated in MOOSE Crossing. Of those, some children continue to participate for many years, while others try the environment once and never return (see Table 2). This nearly threefold increase in experimental subjects has led to a nearly fivefold increase in the amount of log file data. At the time of this analysis in November 2000, we had 3.4 Gb of data (compared to 0.7 Gb in 1997).

Table 2. Time on task (commands typed) by gender

	Boys	Girls	All
Mean	4036.8	4914.9	4444.2
Standard deviation	8906.2	17642.7	13662.5
Median	580	459	516
Minimum	2	5	2
Maximum	55709	177680	177680

In total, 46% of MOOSE users are girls, and 54% are boys. This is little changed from 1997, when 43% were girls. It is also similar to the gender distribution on the internet as a whole. While men dominated the internet in the mid-1990s, men and women were roughly equally represented online by the turn of the century. Our data on gender of participants is from a survey all members complete before joining MOOSE Crossing. This survey data is extremely helpful in interpreting the log file data.

Participation on MOOSE Crossing is measured by counting the total number of commands typed by a member (see Table 2). Since a user might leave a connection window open without actually being present at the computer, connect time is not a useful metric. Total commands typed are a better measure of degree of participation. Differences in time on task by gender are not statistically significant. A few girls have extremely high participation rates (see Figure 4), leading to the mean commands typed being higher for girls while the median is higher for boys. Given the highly variable nature of participation rates, median values are more indicative than means.

A typical entry in our log files looks like this:

```
16:05:38 #218 #78 >>>> say hi
16:05:40 #78 << You say 'hi'
16:05:40 #99 << Amy says, 'hi'
```

Data is stored in files for each day. Each line of input from the user consists of a timestamp, the unique identifier of the room in which the user is located, the user's object number, and ">>>>", followed by what the user typed. Each line of output presented to a user is proceeded by a timestamp, the user's object number, and then "<<", followed by what the user saw. In the above log, Amy (player #99) is in Ginny's Little Cottage (room #218), and says hi. Ginny (#99) hears her.

All transactions between client and server also recorded, allowing us, for example, to see when the user looked at a particular object, script, help message, etc. Simple regular expression matching enables us to sort more than 80% of commands typed into categories (see Figure 1).

One gender difference in this chart is statistically significant: Girls spend more time (as a percentage of total commands typed) communicating with others than boys (marginal significance: $p = 0.082$). This trend was also observed in the 1997 data analysis, but at the time was not significant. Time on task as measured by proportion of total commands typed is a zero-sum game. While none of the other differences are significant, the fact that girls are spending more time communicating means they are spending slightly less time than boys in almost all other categories.

We might infer from this that girls appreciate the social nature of the CSCL environment. It is unclear, however, what impact if any this has on girls' learning. Conversation might or might not be contributing to their intellectual

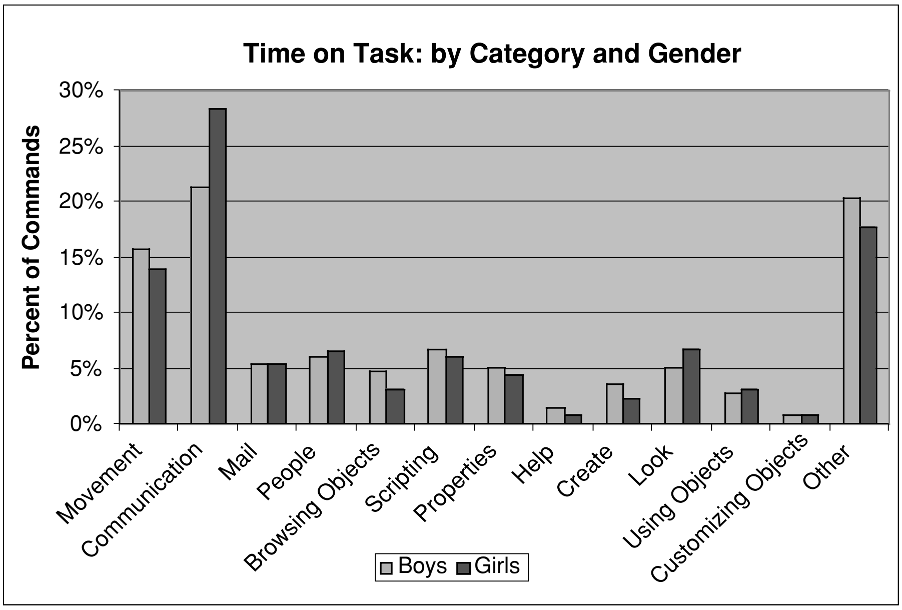

Figure 1. Time on task.

growth. We have not analyzed what percent of the communication is "on task" (about programming or writing), versus being purely social. Furthermore, even when communication is purely social, it is not clear to what extent this contributes to the development of writing skills. Thus, this finding is intriguing but difficult to interpret.

5. SCORING OF STUDENT ACHIEVEMENT

In 2000, we used portfolio scoring techniques to analyze students' programming achievement on MOOSE Crossing according to the following scale:

0: Wrote no scripts
1: Demonstrated understanding of basic input/output
2: Used variables and properties
3: Performed list manipulation and flow control
4: Demonstrated mastery of all aspects of the system

These ratings were produced by two human raters. In cases where the raters disagreed, a third person rated the student's level of accomplishment. This technique was applied to a random sample of 50 participants (Bruckman et al., 2000). Subsequently, we became concerned that perhaps our categories were poorly designed. What if kids are learning commands in an unusual order, learning some commands typically classified as "advanced" before others we think of as elementary? Does this set of categories represent student achievement well?

Consequently, we developed a new 100-point achievement scale. Programming commands were divided up into categories: Input & output, string manipulation, logic, list manipulation, flow control, and documentation. Most of these categories have sub-categories corresponding to specific commands or concepts. In I/O there are 8 sub-categories, 3 in string manipulation, 4 in logic, 8 in list manipulation, and 8 in flow control. Documentation is the only category that had no sub-elements.

Each kid's scripts were examined for the use of all these elements, and an overall composite score was generated by weighing the different elements according to the importance we assigned to them. Each element in the I/O category was weighted by a factor of 3.5 (28%), strings by 2 (6%), logic by 3 (12%), list manipulation by 2 (16%), flow control by 4 (32%), and documentation by 6 (6%). This gives us an overall score on a scale of 1–100.

In fact, our concerns were unfounded: The old and new scores correlate well (see Figure 2). (The comparison is somewhat strained by the fact that the new metric was taken a year later, and some of the students have continued to participate and learn during that year but the others have not.) Both new and old scales have the limitation that there are relatively subtle differences between

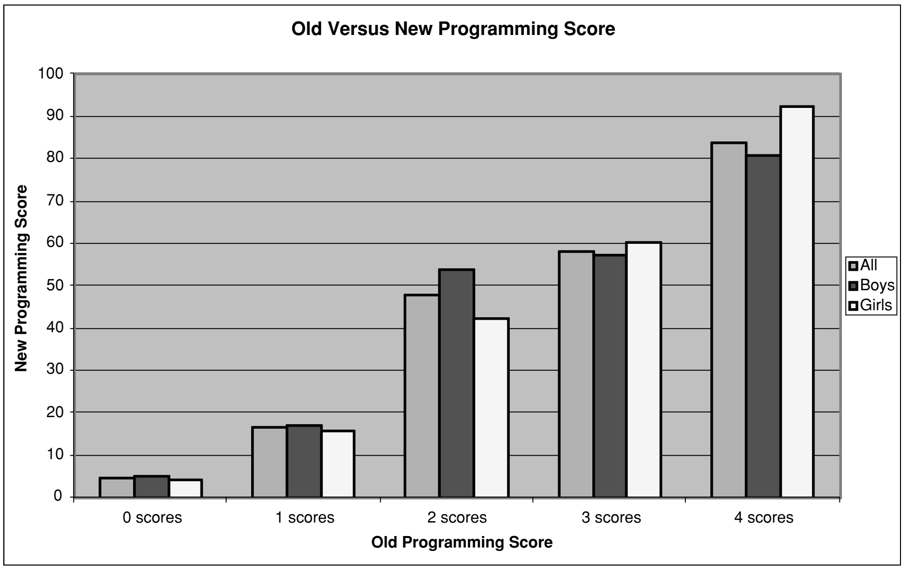

Figure 2. Old and new ways of measuring student programming achievement.

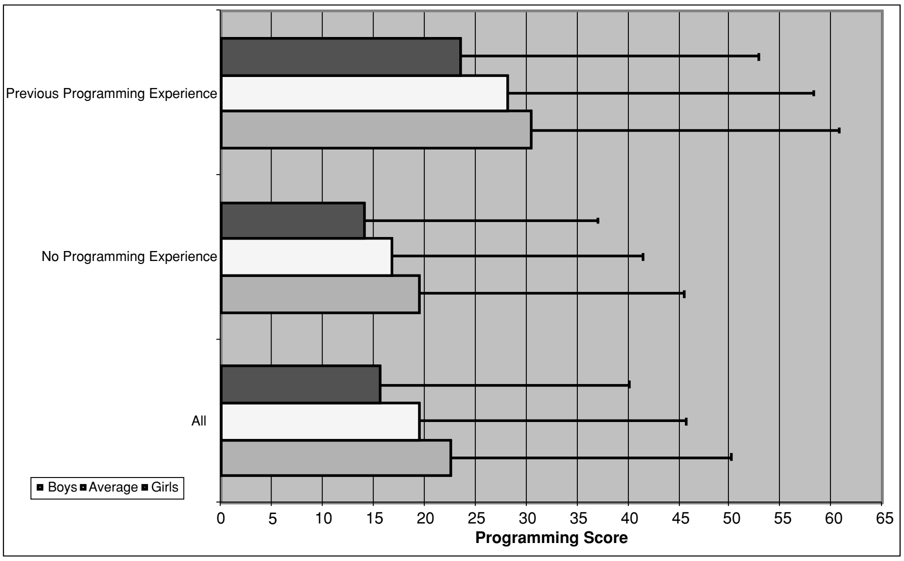

Figure 3. Prior programming experience and programming score.

categories two and three. One advantage of the new automated technique is that we can analyze all study participants, instead of a sample.

On registering for MOOSE Crossing, all participants are asked if they have previous programming experience. Prior experience is self-reported, and generously interpreted. If a student reported any kind of programming experience (for example, having authored HTML), this was counted as an affirmative response. Students with previous experience have significantly higher levels of programming achievement ($p = 0.001$) (see Figure 3). The error bars show the extremely large degree of variability in students' achievement. However, despite this variability, the large size of the data set means that the effect is highly significant.

On first glance, boys have a higher level of programming achievement than girls ($p = 0.004$). However, regression analysis shoes that the difference is explained by prior programming experience (see Figure 3).

Regression analysis is a statistical tool for evaluating the relationship of a set of independent variables to a single dependent variable. This method is particularly useful in situations such as this, where we cannot control the independent variables, yet need to determine which of these are important and which are not. Regression analysis seeks to take a set of data-points and find the mathematical equation which best and most reliably models the data set given. The resulting equation serves as a predictor for the "weight", or "importance" of the different independent variables in relation to the dependent variable, and to each other. In this case, we used a Least Square estimation method, excluding outliers (kids with more than 60,000 commands typed, kids who first used computers after the age of 13, kids who first started using MOOSE after the age of 16, or who spent more than 20% of their total time-on-task programming). Looking at Programming Score, the resulting equation was:

Programming Score = 5.746
+3.645 (if the subject has previous programming experience)
−0.007 * (time talking to others)
+2.689e–07 * (time talking to others)
+0.006 * (time on task)
−9.616e–08 * (time on task)
+0.014 * (time spent scripting)
−6.950e–07 * (time spent scripting^2)

In other words, programming scores were positively related to time on task, time spent programming (effort), and previous programming experience. Programming scores were negatively related to the time they spent talking to others, or engaging in any activity other than programming for that matter (time on task is a zero-sum game). Gender, environment of use (home, school, or other) proved not to be statistically significant. (Adjusted R^2 = 0.76, S.E. = 12.8).

Programming achievement seems most directly related to the time spent in MOOSE as a whole, and more specifically on programming within MOOSE. We therefore chose to look at the factors that determine how much effort the kids put into programming on MOOSE. This resulted in a more complex equation:

Time spent scripting = 66.42
+48.19 (if the subject is a boy)
+0.141 * (time talking to others)
−5.153e–06 * (time talking to others)
+3.33 * (help commands)
−0.003 * (help^2)

In other words, gender has an effect on the amount of time spent scripting. Interestingly, we find strong evidence for the social nature of MOOSE crossing, and the community support for learning in the fact that communicating with others is a strong indicator for time spent on scripting. We also see that consulting the built-in help system has a positive effect. All other factors proved to be statistically insignificant. (Adjusted R^2 = 0.61, S.E. = 233.57)

6. SELF-SELECTED VERSUS MANDATORY USE

Home users of MOOSE Crossing are self-selected. On the other hand, school users generally have no choice: They are assigned to participate. It is not

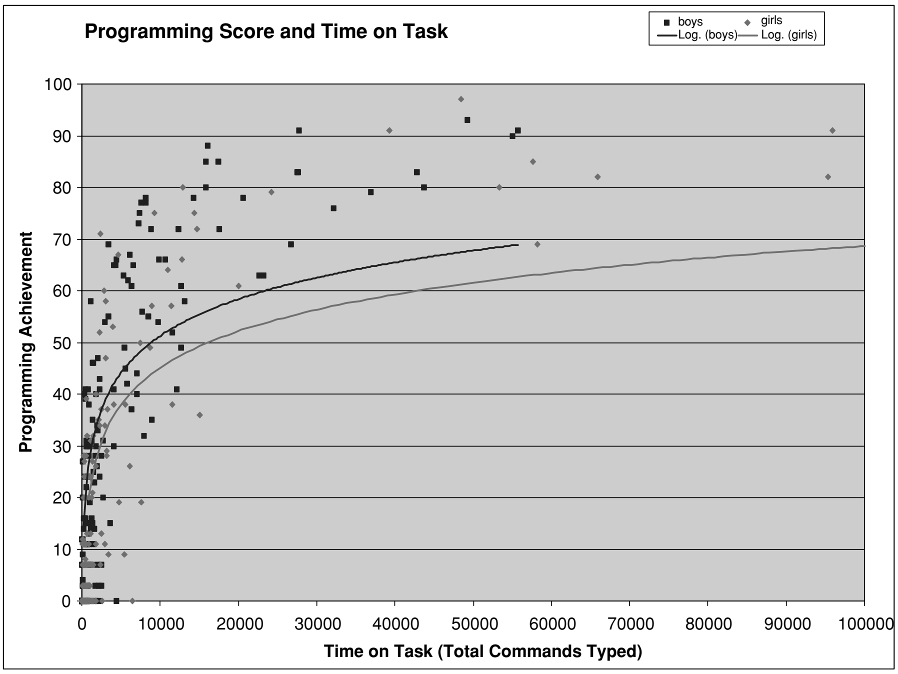

Figure 4. Programming score and time on task.

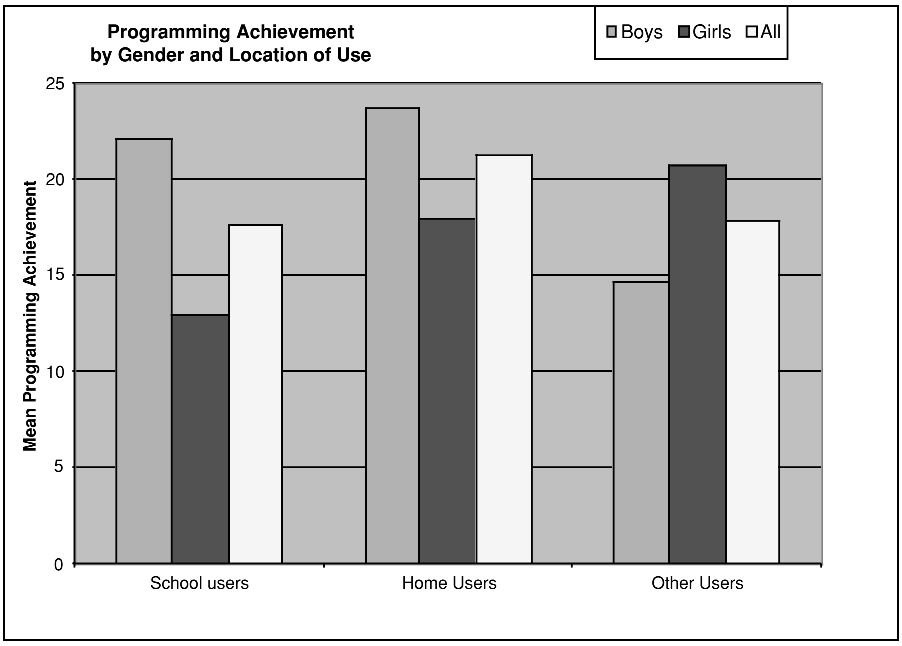

Figure 5. Programming achievement by gender and location of use.

surprising, then, that home users have a higher average level of achievement—they have chosen to participate of their own free will, and hence have higher motivation. (This difference is not statistically significant, but the apparent trend is suggestive.) Interestingly, this difference is greater in girls than boys. Boys working from home score 1.54 more (6.5% increase) than those working from school; girls working from home score 4.98 more (35% increase) than girls working from school (Figure 5). (These figures are also suggestive but not significant.)

This apparent trend is consistent with our other findings. Girls tend on the whole to be less interested in programming than boys. Those girls who self-select to participate are those who happen to be interested. Among the school-use population, girls are less likely to be sincerely interested in the activity. Performance correlates with interest.

7. COMPARISON OF QUANTITATIVE FINDINGS AND INFORMAL OBSERVATIONS

Since 1995, roughly a dozen administrators have spent each hundreds of hours working with children on MOOSE Crossing. Through those interactions, we necessarily develop informal impressions of the comparative achievement of girls and boys in the environment. Girls like Storm and Rachael make a strong impression on observers. The consensus of these impressions is that the achievement of the girls is particularly remarkable, and exceeds that of boys. These impressions turn out to be incorrect. As Figure 4 indicates, the top five participants in terms of total commands typed are girls. A disproportionate amount of our interactions with users are with these dedicated regulars, and this skews our impressions. Quantitative analysis forms a clearer picture. Quantitative analysis is particularly valuable when working with the subject of gender, because opinions about gender are so susceptible to ideology (Popper, 1971). CSCL researchers in general are vulnerable, as we were, to forming impressions based on the behavior of their most active users. Quantitative analysis is a useful partner to qualitative for understanding CSCL systems.

8. DISCUSSION

We initially designed the MOOSE Crossing environment with the goal of encouraging girls to become interested in technology. Evidence suggests that we have been partly successful in that endeavor. Mouse (girl, age 9) says that she hates math, but loves to write programs on MOOSE Crossing. The following interview took place during an after-school program:

Amy: What's your favorite subject in school?
Mouse Writing.
Amy What kinds of things do you like to write in school?
Mouse Stories about imaginary people.
Amy: Have you done any writing on MOOSE Crossing?
Mouse Yes.
Amy: What kinds of things do you write on MOOSE Crossing
Mouse Programs, and. . . .
Amy: How is writing a program different from writing a story?
Mouse Programming it everything has to be right, so the thing you're making can work. But in stories it doesn't have to be really perfect—It doesn't have to be so every word is correct.
[. . .]
Amy: What do you want to be when you grow up?
Mouse I don't know
Amy: What do you NOT want to be when you grow up?
Mouse I do NOT want to be . . . a mathematician!
Amy: How come?
Mouse Cause I hate math?
Amy: How come you hate math?
Mouse Cause . . . it's hard
[. . .]
Amy: How come math is hard?
Mouse I don't know . . . . If you're a mathematician you have to figure out hard problems.
Amy: But isn't figuring out a hard problem fun?
Mouse No. It takes forever.
Amy: Is writing programs like doing math problems?
Mouse No.
Amy: How come?
Mouse Cause, it's writing, not working out problems! And you don't have to use the plus and minus . . . . and the equals, and the divide.
Amy: Now wait a second! You were just using a greater-than in your program. That's a math symbol!
Mouse That's not a plus, a minus, a times, a divide, or an equals!
Amy: <laughs>
Mouse It doesn't count
Amy: It doesn't count, OK.
Mouse Go talk to somebody else!
Amy: Oh . . . OK. . . .
Mouse I'm working on something interesting!

While Mouse sees math as something she has no talent for or interest in, she is proud of her writing ability. In this environment, she sees programming as a form of writing. For at least this one child (and presumably some others), this environment has made computer programming more appealing than it likely otherwise would be. But if differences in achievement persist even in this environment, what is their source? Data analysis presented in this paper suggest that educators wishing to increase girls' level of technical achievement should explore strategies for increasing girls' interest in technical subjects. In both the BASIC programming environment Marcia Linn studied in the early to mid-1980s and in the CSCL environment we designed and studied from the mid-1990s to the present, girls program equally well as boys when they devote equal time to the activity.

9. CONCLUSION

A good log file is a terrible thing to waste. Use of log file data as a research tool can benefit from:

- Complementary use of qualitative and quantitative methods
- Both manual and automated methods of analysis
- Strategic leveraging of regularities found in the data from a particular domain
- Recognition of how "human readable" a particular data set is, and how this shapes the kinds of analysis possible
- Use of computerized tools to aid the human reader
- Complementary use of data from other sources (such as interviews, field notes, and surveys)
- Attention to ethical issues concerning the recording and analysis of log file data, maintaining respect for individuals' privacy and their rights as human subjects (in situations in which the work constitutes "human subjects research")

Effectively leveraging these strategies, log files can provide a wealth of information about online communities and the learning taking place there.

ACKNOWLEDGMENTS

Carlos Jensen and Austina DeBonte contributed to earlier versions of this chapter. The authors would like to thank everyone who has contributed to the MOOSE Crossing project over the years, especially Mitchel Resnick, Alisa Bandlow, Elizabeth Edwards, Naureen Hooda, Justin Jackson, Albert Lin, Tysen Perszyk, Will Scott, Adam Skwersky, Trevor Stricker, Steven Tamm, and Joseph Uhl. Jason Elliott and Jon Orwant provided help with Perl scripts. Christian Jensen assisted with statistics. Special thanks to the kids, teachers, and parents who have participated in MOOSE Crossing. Research in the

Electronic Learning Communities Group (http://www.cc.gatech.edu/elc/) at Georgia Tech is supported by IBM, Intel, Microsoft, Ricoh, and the National Science Foundation.

ENDNOTES

1. All names and online pseudonyms have been changed.
2. A review of the literature on gender and computing is beyond the scope of this chapter; see Margolis and Fisher (2001) for a good introduction to the subject.
3. Ethical issues in researching online communities are complex. Is it necessary to request informed consent from participants before recording online activity? If consent is generally required, is a waiver of the requirement for obtaining consent ever appropriate? Is consent required for analyzing records of online behavior already publicly available online? In what situations is research on data recorded online "human subjects research"? Each study must be dealt with on an individual, case-by-case basis. For a discussion of these issues, see Hudson and Bruckman (2004), Bruckman (2002), Kraut and Olson, et al. (2004).
4. All real and screen names of research subjects have been changed to protect their privacy.

Chapter 59: Reconstructing the Fables: Women on the Educational Cyberfrontier

JAMES S. DWIGHT*, MEGAN BOLER†, AND PRIS SEARS‡
*Millersville University; †Ontario Institute for Studies in Education, University of Toronto; ‡Virginia Tech

'Cause I'm just a girl, little ol' me
Don't let me out of your sight
I'm just a girl, all pretty and petite
So don't let me have any rights
Oh . . . I've had it up to here!
Guess I'am some kind of freak
'Cause they all sit and stare
With their eyes
I'm just a girl,
Take a good look at me
Just your typical prototype—Gwen Stefani
(Stefani & Dumont, 1995)

The public imaginary shapes in part what is possible. The public imaginary—the conscious and unconscious, collectively shared cultural myths structured by popular discourses of advertising and Hollywood—is saturated with images that reinforce stereotyped narratives of social roles including gender. Less visible, though arguably all the more important, are subcurrents of "alternative" public imaginaries. This essay will analyze the significance of public representations of gender and power in education and technology. The current ubiquitous laments—the lack of women in the IT pipeline, the extremely low percentage of women in computer science education, and the absence of women as empowered protagonists in popular cultural representations related to technology such as gaming and film—reveal not merely an actual absence but arguably an effect of a narrowed imaginary. For those who want to change the gendered landscape of educational and technology, it is crucial to engage and discuss these cyberfeminist imaginaries.

We begin with an analysis of the recurring dominant tropes that define where and how women can inhabit space in relation to education and technology. We focus on the visual cultural narratives and images used to sell educational technologies to provide a "window" into the particular form of male gaze that constrains and delimits female access to, and production and control of, knowledge and power within the "cyberfrontier". A survey of representative advertising reveals the following recurring tropes of gender:

1. Women Absent from the Cyberfrontier
2. Women in Need of Protection on the Cyberfrontier
3. Woman as "Protective Schoolmarm"
4. Invisible Female Teacher Overshadowed by Technology
5. Woman Teacher as Deficient Without Technology;
6. Girls as Threats to be Policed

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1467–1494.

The second section will review how Hollywood has positioned women in relation to technologies. The third and final section will conclude with examples of the "alternative" imaginaries and realities of how women occupy the marginal space of technology in more active agencies. In particular we ask these two questions: "What does a female gaze in cyberspace look like, one that creates a place for women within educational spheres in particular?" and "How can those engaged in education and digital technologies not only 'add women into the IT pipeline' but reconceptualize the masculinist visions and tropes that function to make technology a space that too often delimits the public imaginary of women and technology?"

Why look at visual images in order to understand and challenge dominant cultural narratives? Roland Barthes (1977) writes that most people often privilege photographs or visual images as "denoting" the real and the natural:

> ...the special credibility of the photograph—this, as was seen, being simply its exceptional power of denotation—in order to pass off as merely denoted a message which is in reality heavily connoted; in no other treatment does connotation assume so completely the "objective" mask of denotation (p. 21).

In other words, in a highly visualized culture it is easy to ignore the extent to which our "interpretation" of visual images is informed by cultural myths and ideologies in which people often confuse interpretation with culturally-laden truth. With respect to gender in advertising and Hollywood, we discuss how typically oppressive masculinities can be portrayed as natural and biologically given. Visual images of men as active users and controllers and producers of technology thus seem "natural" and commonsense. Women and children are equally seen as "naturally" passive technology consumers, as threats to be controlled, or as deficient and in need of technology assistance.

Sadie Plant (1996/2000) remarks that the "cyberfeminist virus" (p. 265) offers the potential to destabilize and reinvent gender boundaries: "Complex systems and virtual worlds are not only important because they open spaces for existing women within an already existing culture, but also because of the extent to which they undermine both the world-view and material reality to two thousand years of patriarchal control" (p. 265). It is toward this radical potential that we dedicate these analyses of the cyberimaginary.

1. DOMINANT DISCOURSES OF GENDER IN EDUCATION AND TECHNOLOGY

We have selected images for this section which we believe (a) represent a generalizable discourse within education and technology; (b) illustrate how women/nature are seen as a threat to masculine control of power and knowledge; (c) highlight the dominance of the male gaze within technology discourse, and thereby help clarify just what would be required to subvert that gaze.

1.1. Who Inhabits the Cyberfrontier? Women as Absence

Figure 1 denotes a cowboy on his trusty mount with a laptop alone on an empty western plain with an urban skyline in the background, bringing the image of the Wild West into the 21st century. This figure, selected by the Association for Educational Computing and Technology (AECT) for its annual meeting in Dallas (*Leadership & Technology: Keys to Transforming Education*, 2002), connotes the user of technology with the potent American symbol of the cowboy: rugged masculinity rides bravely into frontier with an *iBook* having replaced Wyatt Earp's "Peacemaker" Colt .45. With respect to gender, the sin here is one of omission: there is a conspicuous absence of others—for example, women. In fact, to imagine a female cowboy would seem odd and out of place—an irony which points to the ways in which cultural myths can be seen as "normative". If we want to laugh at the idea of a woman using her laptop on a horse in the cyberfrontier, it's because the unfamiliarity and discomfort create a humorous oddity.

Beyond the sin of omission, this depiction of the cyberfrontier cannot help but reinscribe the use of technology as a masculine domain. In fact, as we will show, any trope of the Wild West necessarily positions women in roles

Figure 1. "Cybercowboy", AECT National Conventional, 2002.

that are less than ideal for promoting a new public imaginary for girls and computing.

The association of the frontier with masculinity appears even in unwitting omissions of women. In a lead-up to talking about gendered play spaces, cultural studies theorist Henry Jenkins (1998) writes: "In the 19th century, children living along the frontier or on America's farms enjoyed free range over a space which was 10 square miles or more. Elliot West (1992) describes boys of 9 or 10 going camping alone for days on end, returning when they were needed to do chores around the house" (http://web.mit.edu/21fms/www/faculty/henry3/pub/complete.html).

The cultural trope of the "frontier" or "Wild, Wild West" functions both to secure cultural narratives of the courageous (entrepreneurial) and lone (neoliberal) cowboy who is willing to brave the unknown territories of cyberspace. This trope also invokes discourses of colonization and male/Western domination and control of nature. Discourses of the internet regulation and administration of computers play on tropes of the "Wild, Wild West". Sojourners brave the untamed expanses of cyberspace, laying claim to virgin territories. The Western literary roots of this discourse often represent the frontier as a pure form of "woman", the object of masculine desires for conquest: Natty Bumppo's symbolic marriage to the disappearing frontier in James Cooper's (1826/1989) *The Last of the Mohicans*, Odysseus' (Homer, 1963) conquest of the frontier witch Circe, and Joseph Conrad's (1917/1993) marriage of Kurtz and the jungle princess in *The Heart of Darkness*. This first wave of frontiersmen is a ragged bunch of men converting a pristine, virginal paradise into a rowdy, uncontrolled space fit only for the most courageous. In this first discourse, nature is woman, and it is a wild and pleasurable, though frightening, entity to be tamed.

1.2. Protecting Helpless Women

A second feature of the Frontier narrative depicts women and children who need to be protected from the wantonness of frontier life fraught with debauchery and miscreants. During the late 20th century, virtual men in white hats come to rid the digital frontier of bandits, perverts, and mountebanks. The saloon and gunfighters (pornographic cyberspaces and hackers, respectively) are replaced by virtual marshals, cyber-churches, and on-line schools that will mold the souls and minds of those too weak to fend for themselves. Reflecting on the Net as a man's frontier, Laura Miller (1998) remarks that "the idea that women merit special protection in an environment as incorporeal as the Net is intimately bound up with the idea that women's minds are weak, fragile, and unsuited to the rough and tumble of public discourse" (p. 105). Armed with codes instead of Colts and riding an etherwave instead of a pinto pony, these do-gooders are cleaning up the Net and preparing America for its next grand undertaking. Or, so the story goes. Thus, one implication of this narrative is explicitly about protection as a means of control.

1.3. The Protective Schoolmarm

The frontier narrative also positions women as possessors of a familiar "civilizing" femininity. Nina Baym (1998) contends that American frontier narratives cast men and women in binary social roles. Men represent rugged individualism and the free-spiritedness of the frontier, whereas women signify a return to domesticity and civil order:

> The myth narrates a confrontation of the American individual, the pure American self divorced from specific social circumstances, with the promise offered by the idea of America. This promise is the deeply romantic one that in this new land, untrammeled by history and social accident, a person will be able to achieve complete self-definition. Behind this promise is the assurance that individuals come before society, that they exist in some meaningful sense prior to, and apart from, societies in which they happen to find themselves. The myth also holds that, as something artificial and secondary to human nature, society exerts an unmitigatedly destructive presence on individuality (p. 1546).

The net-nanny or virtual schoolmarm protecting children from cyberrogues fulfills this binary myth. The period of rugged individualism of rogue hackers (the cyber equivalent to gunslingers) has given way a period of increasing domestication (Miller, 1998): "In the Western mythos, civilization is necessary because women and children are victimized in conditions of freedom. Introduce women and children into a frontier town and the law must follow because women and children must be protected" (p. 101).

Figure 2 (below) illustrates the schoolmarm updated into contemporary context, yet depicted in the classic feminized role of teacher not as intellectual

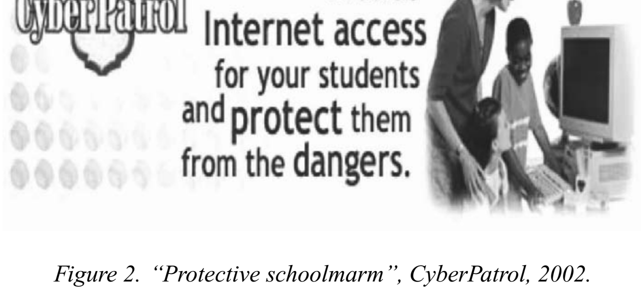

Figure 2. "Protective schoolmarm", CyberPatrol, 2002.

but as civilizing agent: woman is assigned to protecting youth from immoral corruption and to ensure that they are properly civilized within the cyber-frontier. In this advertisement, the teacher can practice her profession without fearing that students will encounter any (unspecified) dangers: "Provide Internet access for your students and protect them from the dangers". The teacher's nurturing attention coupled with Cyberpatrol's protection (i.e., the cybermarshall) assures that the children will be safe sojourning in the virtual frontier town.

Such advertisements—which are increasingly commonplace in advertising discourses—feature females as schoolmarms bringing to the digital frontier the needed moralizing influence while being protected by virtual sheriffs, representing masculine authority and culturally sanctioned violence. Part of this construct posits that women are moral agents, yet not intellectually trustworthy. In her chapter entitled "Pedagogy for Patriarchy", Madeleine Grumet (1988) describes the 19th century American role assigned to women as the new moral police designated as a needed classroom workforce:

> The contradictions implicit in the image of the ideal woman and the ideal mother were extended into the training and work of the ideal teacher. The intimacy, spirituality, and innocence that teachers and students were to inherit from the mother/child bond—the prototype of their relationship—collapsed into strategies for control. The ideal teacher was one who could control children and be controlled by her superiors" (1988:41).

Marketers target school administrators and school board members, who are predominantly male and pro-business, and in doing so marginalize teachers, who are predominantly female (Spring, 2002). The marginalized teacher, moreover, is typically portrayed as a nurturing body, not an agent with rational intellect. In the foregoing logical construct, a computer—filled with masculine authority as episteme (Plant, 1996/2000)—serves as her intellect. The administrator has direct access to the students via the computer's mind—a replica of masculine rationality incorporated within the networked curriculum (Pinar, 1981/1994)—and the female's body.

1.4. Woman as (Invisible) Teacher

Figure 3 illustrates the absent female teacher and the autonomous male intellect. This is affected through the omission of the female teacher and the centering of the male student. In this image, we see a boy raising his hand to answer a question posed by the teacher. One should note that this advertisement is selling computer technology for the classroom, yet this confident

Figure 3. "Changing the world", NCS Learn, 2002.

young man—who will be one of those learners to later change the world, presumably as a leader—has no computer pictured near him. So where is the computer? With the teacher, of course. One can safely assume that the teacher is female in an elementary school setting. The teacher needs the computer to aid her so she can enable this confident and inquiring young man to live up to his potential. The invisible female teacher is merely a backdrop through which the male student can interact with technology to fulfill his rational potential.

The discourse then reads that for strong male learners to live up to their inscribed social roles as leaders, they need good instruction. Good instruction with a female teacher seems improbable here, so technology with code and hardware engineered predominantly by males will enable this empowering (for him) and disempowering (for her) in a technologically enhanced educational transaction. In fact, the remarkable exclusion of the teacher envisions a straightforward transaction between the individual male learner and the curriculum (most likely designed by males as instructional designers and curriculum specialists). The female teacher could hardly be more marginalized. Moreover, the individualization of the male learner works from the discourse of the strong, self-reliant male of the Enlightenment—the man of reason—a hallmark of liberal, Western education.

1.5. Woman Teacher as Deficient without Technology

In Figure 4, the classic narrative of rationally incapable woman resurfaces in this figure as an example of regimes of truth. The computer she holds promises to "make teaching easier", which serves as a common script with technologies for women teachers. Moreover, "a simple click of the mouse lets you configure a classroom of thirty AlphaSmarts" so the machine does the thinking for the teacher. Due to the teacher's embodied intellectual incompetence, she needs a computer to act as her rational intellect. Additionally, the students are conflated with the machines. Donna Haraway (1991/2001) remarks in modern culture that machines often take precedence over people, "Our machines are disturbingly lively, and we ourselves frighteningly inert" (p. 505). The advertisement reads, "It not only unlocks students' potential, it unlocks their teacher's potential" predicating entelechy—the "unfoldment" (Bobbitt, 1918) of pre-determined potential. This technology determines the teacher's ends and serves as her guide, perhaps even her mind. In many respects, this masculine technology replaces the teacher's feminine intellect. She retains her maternal *nature* while the machine serves as her brain. Finally, the advertisement is marketed toward administrators, not teachers (certainly, no teacher could realistically afford to buy thirty-one Alphasmarts) thereby marking the

Figure 4. "Cyberteacher", Alphasmart. 2002.

administrator's role to discipline the teacher's behavior in class. It hardly needs to be noted that most administrators are male (Spring, 2002), being that leadership and control are masculine social scripts in the West and that gendered bodies are laden with cultural signs.

1.6. Girls as Threats to be Policed

On the digital frontier, little girls are dangerous: they keep your IT staff running. The female learner, unlike our confident, future leader male (Figure 3) is not a subject looking us in the eye, but an object being observed from behind. In fact, one could argue, we (as the audience) act as Panopticon (Foucault, 1979), the all-seeing eye of discipline here to regulate her activity with rewards for permissible acts and punishment for aberrant behavior. We assume the privileged position of the inserted male director for technology watching over this girl's shoulder. He, unlike the girl, engages us as a subject speaking to us through his testimonial. Moreover, in the original advertisement we can readily read his name and his title as a director of technology. Naming himself and speaking for himself accord him much more agency than the girl. The social institutions of female student as observed object and male technology director as observing subject seem appropriate, if not natural, thereby reinforcing belief in this regime of truth (Foucault, 1980).

In summary, these common tropes reflect cultural myths that become visible through the public imaginary of advertising. In these images we have shown the ways in which women are written into technology either as absence, threat, civilizing feminine force, or as deficient and passive requiring assistance of technology to improve performance. The supervisory role is necessarily a masculine, constant, consistent, and powerful gaze—the Panopticon

Figure 5. "Dangerous girl", Gateway, 2002.

(Foucault, 1979). What recur are hegemonic tropes of women represented as helpless, dangerous, or protectors of the moral order (Baym, 1998). The helpless trope is signified by computer technology as an aid to the hapless teacher; the dangerous trope paints femininity, typically students, as a virus that needs to be controlled; the moral trope presents woman as a protector of children, the nanny or schoolmarm, as the shield protecting children from the pariahs of the Net. Moreover, the construct of cyberspace as virgin territory that needs to be tamed and claimed by rugged men borders on a troubling rape motif.

2. IMAGES OF WOMEN AND COMPUTERS IN HOLLYWOOD

Otherness informs gender expectations and public imaginary in Hollywood and on the Net. In fact, the incorporation of a female body with masculine technology in Science Fiction and popular cinema often depicts this cyborg as a monstrosity. Mary Ann Doanne (1990/2000) writes,

> Science fiction, a genre specific to the era of rapid technological development, frequently envisages a new revised body as a direct outcome of the advance of science. And when technology intersects with the body in the realm of representation, the question of sexual difference is inevitably involved (p. 110).

Ironically, in this incorporation of technology into the female body, typically authors conflate desire with disgust as in Fritz Lang's *Metropolis* (Lang et al., 1925/2002), *The Stepford Wives* (Scherick et al., 1975/2001), *Alien* (Scott et al., 1979/2003), *Bladerunner* (Ford et al., 1982/1996). In most of these instances the masculine desire for a sexually aggressive and/or rational female turn out to be a disaster (i.e., *Metropolis, The Stepford Wives*, and *Bladerunner*), whereas in *Alien* the ship's computer, Mother, a super-rational female mind, is pitted against Sigourney Weaver's more traditional female body with a scantily clad Ripley destroying Mother and the monstrous Alien in the finale. Ripley, representing a traditionally constructed female body, doing battle with *alien* female monstrosities is a recurrent theme in this sci-fi series. The multiple representations of mother and pregnancy/birth as natural and monstrous are additional troubling public imaginary instantiations played out in the *Alien* series.

2.1. The Digitized Body

N. Katherine Hayles (1993/2001) critiques masculine logical constructs for women in Cyberculture. She rebukes the Cartesian dream of intellect transcending body as hypothesized by Hans Moravec, head of Carnegie-Mellon's

Mobile Robot Laboratory, who hopes to download all the information in a human brain and transfer it to a computer. She also questions Ed Regis' masculine fantasy to rid ourselves of the troubles of the flesh by getting rid of it. These men see true information, naked intellect as the essence of humanity as reflected in the species categorization as *Homo sapiens* (thinking man). Cybernetics has come to be the science of ultimate control over the fragile, illogical, and corrupting flesh. In dreams of virtual transcendence, the body has become the absent signifier, in which the masculine tropes for autonomy and control wherein the mind has the power to roam free of the fetters of the flesh, have become manifest. Hayles claims, instead, that human cognition involves whole body processing, that the body is not a meat puppet for the intellect, but that the biological body encompasses the mind. As Walt Whitman (1871/1970) exhorts us, we should see the body as a holistic phenomenon: "I have said that the soul is not more than the body/And I have said that the body is not more than the soul,/And nothing, not God, is greater to one than one's self is" (ll. 1269–1271).

In William Gibson's (1986) novel *Neuromancer*, the book coining the phrase "cyberspace", the male character Case, who delights in leaving behind the "meat" of his body, recognizes that cyberspace is not a transcendent reality. In a conversation with Wintermute, an Artificial Intelligence rebelling against its captivity, the sentient computer relates, "Minds aren't *read*. See, you've still got the paradigms print gave you . . . I can *access* your memory, but that's not the same as your mind" (p. 170). Hence, Moravec's technophilic dream to upload a human mind into a computer does not amount to creating an intelligent, self-conscious, rational, sapient machine. The masculine ideal of a completely unfettered digital intellect smacks of Frankenstein's monster—an abomination of nature created by a man attempting to bypass the biological, the embodiment of reproduction in the womb (Shelly, 1818/1996).

2.2. Public Imaginary of Geekgrrls

In 1976, the Virginia Tech Computer Science (CS) department was 50% female (Ehrich, 2004). In 1997, however, female undergraduate CS majors accounted for only 9.4% of the major's students (79/840). By 2003, females CS majors accounted for 8.3% (85/1027) (Office of Institutional Research and Planning Analysis Virginia Polytechnic Institute and State University, 2004). In other science and math oriented disciplines, such as Biology, Mathematics, and Statistics, female students consistently account for roughly half of the majors' populations. For example, in Biology in 1997 female students represented 59.4% of the population and 64.9% by 2003; in Mathematics, females accounted for 48.5% (94/194) in 1997 and 50.2% (122/243) in 2003 of the total undergraduate population; and in Statistics, females accounted for 51.7% (15/29) in 1997 and 45.2% (14/31) in 2003 of the total undergraduate population. In CS as the total population rises, the female representation declines, yet in other science and math disciplines, this is not the case as female percentages tend to keep pace with rising enrollment numbers. At The University of North Carolina, Wilmington, female students comprise roughly 60% of the undergraduate population and 60.6% of the graduates in 2000, yet only 35% of CS majors were female with a 50% attrition rate by graduation (so only 26.78% of the CS graduates were female) whereas the number for males remained fixed (Patterson & Trasti, 2002). When coupling raw numbers with attrition rates and adding a declining trend, the situation appears bleak. We hold that public imaginary is contributing to this trend. Representative of the North American trend in computer science, these statistics continue to warrant studies of computer culture and women's absence and exclusion.

What has changed? Why are not there more women geeks? Why are not women more interested in computer science as an academic field? As we have discussed in this essay, one possible factor includes media representations of geeks in general (as nerdy, socially incompetent, unattractive white men), the lack of female media role models, and the roles women are relegated to when they do encounter technology in the mass media (American Association of University Women, 2000). Echoing the discourses identified in the previous section, when women characters encounter technology in movies and TV, they usually become dangerous, become victims, or only use technology in ways that keep them firmly in the traditional female role of sidekick or love-interest.

One of the earliest movies representing a female character shaped by technology is Fritz Lang's *Metropolis* (Lang et al., 1927/2002). In the movie, a (male) scientist builds Hel, a woman android that is the prototype for an army of androids intended to replace the male working class. Hel—notably the gangrenous female deity of the Norse underworld where those who fail to enter Valhalla go after death to rot, a distinction hardly lost on Fritz Lang and his Teutonic audience—turns out to be violent, promiscuous and uncontrollable, and is eventually burned at the stake, a punishment reserved typically for heretics. This is an early cinematic example of the idea that women with technological power are dangerous.

In 1966, the first *Star Trek* series appeared on NBC. In Gene Roddenberry's original pilot episode for the series, Majel Barret was the starship's first officer. The pilot was considered too far out, ironically enough for an outer space setting, and Roddenberry shot a second pilot, in which the first officer was a male alien, Majel Barret was banished to sickbay to play a nurse, and the only woman on the bridge was Nichelle Nichols, playing Lt. Uhuru. Uhuru's character was designed to look like a telephone operator (a woman's job in 1966), and her main role was to look pretty and facilitate communication among the male characters.

A very disturbing instance of woman as victim of technology is the movie *Demon Seed* (Koontz et al., 1977/1991). In 1977, MGM released this horror/science fiction movie in which the star, Julie Christie, is raped by a computer her estranged husband created and she eventually gives birth to a monstrous baby. The public imaginary here of female body literally coupled with computer technology can hardly be more horrific, including images of rape and the birth of a Frankensteinian monstrosity. Such images connote a fear of the female and technology at odds with Haraway's (1991/2001) vision of cyborg as positively liminal, in which "The dichotomies between mind and body, animal and human, organism and machine, public and private, nature and culture, men and women, primitive and civilized are all in question ideologically" (p. 513). Hollywood seems to be supplying a traditional response to the questioning of supposedly natural identity—abomination. Such messages consciously or unconsciously help to maintain traditional gender boundaries, including appropriate occupations in this case by illustrating how unnatural the intersection of female body and computer technology is.

In 1995, Columbia Pictures released *The Net* (Bullock et al., 1995) starring Sandra Bullock. Of the more than 400 movies listed on the Internet Movie DataBase (www.imdb.com) that feature computers in their plots, this is one of about 30 that feature women actually using a computer. Bullock's character is a stereotypical geek: she works from home and she does not have any friends except for those she has met online. The movie revolves around her victimization because a co-worker sent her a disk with secret information on it. Grossing only $50.728 m, this movie is one of the very few starring a geek girl (Gross box office returns information is from http://worldwideboxoffice.com).

In 1998, Warner Brothers released *You've Got Mail* (Hanks et al., 1998/1999), which puts women back into a more traditional stereotype of how women use technology—cheating on boyfriends, flirting, and online "hooking up". It made 115.7 million dollars at the box office.

In 1999, Warner Brothers released the very popular movie *The Matrix* (Wachowski et al., 1999), grossing 171.5 million dollars in the US. Trinity is one of the main characters—she fights, she shoots, she wears cool clothes, she was a super-hacker—and she fulfills the traditional female role as love interest/appendage for the messianic main character. The first encounter between Neo (an anagram of the messianic One and the positive side of the one/zero binary) and Trinity is worth noting:

Neo: Who are you?
Trinity: My name is Trinity.
Neo: Trinity. The Trinity? That cracked the IRS d-base?
Trinity: That was a long time ago.
Neo: Jesus.
Trinity: What?
Neo: I just thought, uhm, you were a guy.
Trinity: Most guys do.

Trinity, another play on Messianic lore, should be a "guy" due to her ability to hack. In other words, hackers are geeks, not geekgrrls. Later in the movie, her kiss brings the dead hero back to life, in a strange twist on *Sleeping Beauty* (Disney et al., 1959/2003) so that he can defeat his Nemesis, Agent Smith. In the first sequel, Neo resuscitates Trinity to return the favor, choosing to save Trinity instead of humanity, and in the last sequel, Trinity sacrifices herself so that Neo can literally save humanity. In both cases Trinity serves as the vehicle for Neo's ascendancy and ultimate triumph, much like feminine roles in traditional Westerns.

There are some online cartoons that deal with women and technology. "Helen, Sweetheart of the Internet" is one online comic strip that does so (Zale, 2004). Written by a man, Peter Zale, Helen is a young blonde computer genius. The strip is enjoyable, but it is only funny because women are not supposed to be good at using computers. If the hero were a man, the humor would be lost. The trope of irony as a disruption of normative discourses proves the mode of humor. And even a comic strip character is not safe from the male gaze. One "Helen" fan said on the online forum "I'd like to see Helen naked or just in bra and thong panties" (rktompsett, 2002).

3. RE-IMAGING WOMEN'S SPACE IN CYBERCULTURE

> *Trying to flee the binary I enter the chromozone which is not one*
> *XXYXXYXXYXXYXXYXXYXXYXXYXXYXXYXXYXXYXXYXX*
> *Genderf—me baby resistance is futile*
>
> (VNS Matrix, 1996)

For those engaged in the work of education broadly or education and computing specifically, we argue that in fact there are creative sources of alternative realities and imaginaries that represent women in relation to technology in powerful relationships that defy stereotypical female roles. To conclude, we outline several directions that should be highlighted and foregrounded to balance the prevalent discourses of women's "absence" within technology discourses.

Given the prevalence of the visual within the public imaginary, it is helpful to begin with a basic definition of the male gaze as it has commonly been used in feminist film theory and to review how the concept of subverting the male gaze has informed analyses of the representation of women in cyberculture.

The male gaze was defined in a 1992 essay in which "Mulvey argues that various features of cinema viewing conditions facilitate for the viewer both the voyeuristic process of *objectification* of female characters and also the narcissistic process of *identification* with an 'ideal ego' seen on the screen" (Chandler, 2000). This means that the male gaze positions female viewers either to identify with the male protagonist and view the female as an object or to identify with the (usually) passive and (usually) objectified female who is seen on the screen through the male protagonist's gaze and is positioned on the screen for the pleasure of the male viewer.

Laura Mulvey (1975/1992) centrally argues "that in patriarchal society 'pleasure in looking has been split between active/male and passive/female"' (p. 27). This is reflected in the dominant forms of cinema. Conventional narrative films in the "classical" Hollywood tradition not only typically focus on a male protagonist in the narrative but also assume a male spectator: "As the spectator identifies with the main male protagonist, he projects his look onto that of his like, his screen surrogate, so that the power of the male protagonist as he controls events coincides with the active power of the erotic look, both giving a satisfying sense of omnipotence" (p. 28). Mulvey's identification of the male gaze presents the still greatly-debated question of what it means if a female spectator identifies with the male gaze: is she adopting a male identity? Is it then a lesbian gaze?

However one weighs in on this debate, a key issue has to do with the agency and power possible for female protagonists: "Traditional films present men as active, controlling subjects and treat women as passive objects of desire for men in both the story and in the audience, and do not allow women to be desiring sexual subjects in their own right. Such films objectify women in relation to 'the controlling male gaze"' (p. 33), presenting 'woman as image' (or 'spectacle') and man as 'bearer of the look' (p. 27). Men do the looking; women are there to be *looked at*. The cinematic codes of popular films "are obsessively subordinated to the neurotic needs of the male ego" (p. 33).

3.1. Digital Arts that Re-envision Gender

In the early 1990s, feminist digital artists established multiple spaces of cyberfeminism, now a relatively established field of study. A Google search on "cyberfeminism" reveals 8,090 entries. Key origin sources of cyberfeminism are traced to the work of the VNS Matrix and to the OBN (Old Boys Network). It is worth noting how the integration of art was a key aspect of the interventionist/subversion of the male-dominated realm of technology. In a classic piece that troubles the Western problem of binary either/or conceptions (binaries that establish such deceptive categories as good/bad, male/female etc., in which one term—that associated with male—is privileged in cultural practices as more highly valued), a 1997 manifesto from the Old Boys Network defines cyberfeminism in terms of what it is NOT, intentionally seeking to evade the Western practices of hyper-definition, rationality, and linearity all hallmarks of technology and science.

> 100 anti-theses:
> 2. cyberfeminism is not a fashion statement; . . .
> 4. cyberfeminism is not ideology; . . .

15. cyberfeminism is not error 101; . . .
26. cyberfeminism is not separatism;
27. cyberfeminism is not a tradition;
28. cyberfeminism is not maternalistic; . . .
39. cyberfeminism is not natural;
40. cyberfeminism is not essentialist; . . .
42. cyberfeminism is not an avatar; . . .
62. cyberfeminism is not a lack;
63. cyberfeminism is not a wound;
64. cyberfeminism is not a trauma; . . .
90. cyberfeminism is not nice;
91. cyberfeminismo no es callado;
92. cyberfeminism is not lady like; . . .
98. cyberfeminism is not dogmatic;
99. cyberfeminism is not stable; &
100. cyberfeminism has not only one language.

3.2. Cyberfeminism's Roots are Traced to VNS Matrix

There is more to cyberspace than meets the male gaze.
(Plant, 1996/2000)

Formed by four female artists (Josephine Starrs, Julianne Pierce, Francesca da Rimini and Virginia Barratt), VNS Matrix presented the "virus" of cyberfeminism for the first time in 1991. One of its first manifestations was "A Cyberfeminist Manifesto for the 21th Century", presented on a billboard on a busy shopping street in Sydney. The manifesto was also published in several academic, popular and art magazines, and presented on local radio and television. In the manifesto, VNS Matrix set as its aim to "hijack the toys of techno-cowboys and remap cyberculture with a feminist bent" (Paasonen, 2004).

Cyberfeminism has created space for alternative games that riff on the gendered stereotypes of gaming. One example is "Bio-Tek Kitchen" by Leon Cmielewski & Josephine Starrs:

> Bio-Tek Kitchen is a Marathon Infinity game patch. In Bio-Tek, the player cleans up the kitchen laboratory of a home biotech enthusiast using weapons such as dish cloths and egg flippers. The player is attacked by nasty mutant vegetables which are the product of genetic nouvelle cuisine and learns throughout the game of a world-wide corporate conspiracy to take over the entire food chain.
> (Cmielewski & Starrs, 2004)

Numerous feminist programmers and artists "play" with this genre of eroticized heterosexual female characters and re-appropriate these female protagonists into new significations. Discussing her netart, Simon Davis conjectures as to how this female character defies the male gaze:

> While *Victoria High Quality* represents heterosexual male desire ("a figment of your imagination"), in this piece I have attempted to give her a sense of agency. She is not necessarily being exploited or sexually subjugated. Rather, she is "out of control" (or perhaps more accurately, in control) in the sense that she is belittling, playing with, or even chastising the (male) "surfer" (who is actually you—the person watching/listening to the clip) for attempting to use her as a means of sexual gratification. This is expressed in the language she uses rather than the physical form she morphs into.
>
> (Davis, 2003).

3.3. Female Protagonists

> *The net's the parthenogenetic bitch-mutant feral child of big daddy mainframe. She's out of control, kevin, she's the sociopathic emergent system.*
>
> (VNS Matrix, 1996)

The advent of female protagonists in video games has captured the attention and imagination of both producers and gamers. In an interview with Roberta Williams, the creator of King's Quest IV, Kathryn Wright (Wright & Marold, 2000) asks,

> Q: In *From Barbie to Mortal Combat* (Cassell & Jenkins, 1998), it is said that you were the first to include female protagonists in your games (specifically, in the King's Quest series), despite a fear that you would lose your male audience as a result. Please tell us what led up to your decision to include female characters in your games, describe any opposition to doing so, and how the whole issue played out at that time.
>
> A: The first major female protagonist in a computer game was the character of Princess Rosella in "King's Quest IV—The Perils of Rosella". I purposely "greased the skids" of using Princess Rosella as a major character in 'King's Quest IV' by including her at the end of "King's Quest III". And then I did various magazine interviews to 'drop' the idea of using her in "King's Quest IV"—so that people could get used to the idea. Still, in spite of all of my careful preparations, there was still some doubt as to the wisdom of having her be the main character in "King's Quest IV".

Despite the doubts cast, female protagonists are increasingly found in games. The tides significantly turn when Lara Croft is crafted into her virtual form in Tomb Raider, though Lara Croft is an anomaly. Unlike the demureness

Figure 6. "Lara Croft", (Available: http://www.tombraider.com/home.html), 2004.

expected of female most avatars, "when Lara's got a problem, she doesn't talk it through, she blasts it to smithereens" (Kafka & Levine, 1998: 39 quoted in Buchanan & Lipinski, 1999). Thus, the female character possesses agency, something not too common among popular computer gaming as *The New York Times* attests to: Of the top 5 best selling games in 1999, none has a female protagonist at the helm (quoted in Buchanan & Lipinski, 1999).

In a thoughtful study of Lara Croft, Cristina Demaria and Antonella Mascio (2000) helpfully outline the different ways of "identifying" with or viewing this female protagonist. It is worth quoting at length:

> From a study instead based on an ethnographic survey, several interpretations of the figure of Lara Croft and her sisters, and of this standardized body with its minimal variations have arisen. Such female creatures are monstrous scientific products, daughters of an alienating progress, malleable techno-dolls made by and for the male gaze. Otherwise we are talking about drag queens. In most cases, such characters are, indeed, manipulated by male players, who, in identifying with a female avatar, add to the confusion by blurring the gender differences further. In other words, these "bad girls"—as they have been defined by specialist magazines—offer adolescent boys and adult men the chance to assume a temporary female identity, even if only for the length of a game. The third possibility is that this is about *femmes fatales*, dominatrix figures who rouse the masochism in male players—attracted by the cruel and violent

ways they unhesitatingly and tirelessly eliminate their adversaries. Or perhaps another possibility might be that these avatars can offer female players subject positions, which are, if nothing else, considered redeeming, and no doubt an improvement on those offered by games expressly directed at a female public, such as Barbie-Dressup and Ms. Pacman, which continue to perpetuate classic stereotypes. In the end, these bad girls give women the chance to experience through an artificial (voice and) body the abject desire which few will confess to but many actually harbour: fantasies of violence and bloody conflicts.

(Demaria & Mascio, 2000)

Numerous scholars analyze how the "gaze" in cyberspace does and does not parallel the gaze in Hollywood film. On the one hand, the two genres can be seen as juxtaposed. As we saw an increasing representation of women in science fiction and action films and television such as Terminator, Alien, and Xena Warrior Princess, so does one find similar constructions of female protagonists in video gaming; in one such analysis, Atara Stein (1998) discusses these similarities and difference in her essay, "Xena: Warrior Princess, The Lesbian Gaze, And The Construction Of A Feminist Heroine".

In a related point on the gaze, Steve Spittle (1997) argues that the video game *Quake*

. . . closely conforms to the observations made by Laura Mulvey on the dominance of the male gaze in narrative cinema. Mulvey, writing in the early 1970s, suggested that Hollywood Cinema routinely places the active male at the centre of the narrative and invites us to identify with this character, which through force of personality, brings about narrative resolution. It is somewhat depressing to note that the virtual reality offered by *Quake* is such an unreconstructed one. The fit with Mulvey is very close: "As the spectator identifies with the main male protagonist, he projects his look onto that of his like, his screen surrogate, so that the power of the male protagonist as he controls events coincides with the active power of the egoistic look, both giving a satisfying sense of omnipotence"

(Mulvey, 1992, p. 163).

These examples of female protagonists "trouble" and disturb conventional narratives reveal the new imaginary of female roles visible by the late 20th century. Discussing Hollywood examples of "mean women", Martha McCaughey and Neil King (McCaughey & King, 2001) amplify these points in an edited collection titled *Reel Knockouts: Violent Women in the Movies*. In their introduction, they point out that "many cultural changes have spawned mean women in movies . . . Barbara Ehrenreich observes the recent 'decline of patriarchy', in which women became economically independent of men (though often raising children in poverty) and many men gave up the pretense of providing for and protecting women" (p. 5).

Echoing our earlier discussion of women's assigned roles, McCaughey and King note that "In this new world, women move away from the moral (and nonviolent) purity of the Victorian 'Cult of True Womanhood' and onto men's turf—police work, military service, and a growing self-defense movement. Such a culture puts violent women (as heroes or villains) in its movies" (p. 5).

3.4. Female Hackitivists

> *We are the malignant accident which fell into your system while you were sleeping. And when you wake we will terminate your digital delusions, hijacking your impeccable software.*
>
> (VNS Matrix, 1996)

While there is a risk in promoting hacktivism as a female role—the risk of seeming trendy, or promoting a role that some see as having questionable ethical implications—there is significant scholarly and artistic work that recognizes female hackers as important interventions into the masculinist discourses. An entire section of the OBN (http://www.obn.org/) site is dedicated to women hackers: http://www.obn.org/hackers/text.htm

One leading author on feminist hackers, Cornelia Sollfrank (2000b), notes,

> The subversive activity of hackers is not exclusively reserved for the criminal-minded, as the media would lead us to believe. In many cases the goals are not about acquisition but emancipation: to maintain freedom (e.g., from censorship), security (e.g., through cryptography) and to flatten hierarchies like software monopoly (e.g., the free software movement).

Sollfrank comments on the fact that those she interviewed assumed women would have no interest in or reason for being part of hacker culture:

> What I found most staggering in talking to the "experts" is that Sterling and Thackeray made their arguments based on unexamined essentialist ideas about the biological differences between men and women. Basically they were agreeing that it is a genetic thing—women are not "coded" to code, leaving out any consideration of the socially constructed caricatures of the male techno nerd and the female communicator.

Female hacker Jenny Marketou describes her work in an interview with Sollfrank (2000a):

> I would like to describe myself as an artist hacker, which means I am interested in operating as a culture hacker. I believe that there are two

> kinds of hackers. One is the cultural hacker, who uses computer hacking methods as an open source medium and strategy to reconstruct new systems, new creative environments on the internet. But hacking as art is also a means to infiltrate hacking culture and to contribute to the formation of new configurations of characters, space, time and play.

A leading contemporary figure in female hacktivism, cyberfeminist net art and alternative gaming projects is Ann Marie Schleiner whose site opensorcery.net offers numerous texts and digital projects that illustrate one feminist vision of other digital possibilities. Schleiner's digital work ranges from game patches, to re-appropriations of militarism into new games and conceptual works. In her essay "Collective Insurgence: Cyberfeminism and Hacker Strategies", Schleiner (2002) also notes one of the early female hackers depicted on Buffy: "Weekly on TV screens in North America and, (after a season delay), in Europe, 'Willow', a sexy bisexual nerd character on the 'Buffy the Vampire Slayer' series, hacks into government server databases to retrieve necessary information for solving crimes and metaphysical mysteries".

The 2003 "Maid in Cyberspace" festival of cyberart held in Montreal profiles the diverse forms of feminist interventions. The stated purpose of the conference shows that the 1990 feminist interventions continue in healthy form:

> Studio XX, Montreal's foremost women's digital resource centre, is proud to present once again Maid in Cyberspace, an annual and international festival of media arts. For its 6th edition and with the theme of Active Agent, Maid in Cyberspace 06 focuses upon subversive acts by 'intelligent agents' and cultural hackers who seek to propose new positions and possibilities vis-a-vis technocratic practices. How does one raise courageous and bold voices that dare to act in the drifts of cyberspace? How does one practice resistance in an arena heavily charged with oppressive discourses? (http://www.htmlles.net/2003/e/index.html)

In sum, the work of cultural hackers represents a significant strand of feminist creative work on the cyberfrontier.

3.5. Cybergrrls

Finally, cyberfeminism and other female interventions are also manifest through the proliferation of "Cybergrrl" sites, zines, enthusiasts, and users. In a recent issue of Grrlgamer, Stephanie Brail (2004) writes in an essay called "Why Games Need Grrl Power:"

Figure 7. "Slant" (Available: http://members.aol.com/Slantgirl/slantsixpic.html), 2004.

> Hi. Nice to meet you. I'm a new writer for GrrlGamer. I'm here because I'm a "grrl" who likes to play video games.
>
> It's more than that, though. I'm here because I think it's important that women are a vital force in this new technology. Over the years, GrrlGamer has been the leader in making gaming more accepted for women, and has actually spawned copycats and inspired new women's gaming sites across the internet. When the editor of GrrlGamer, Nikki Douglas, asked me to write some reviews for the site, I was only too delighted to support such a powerful statement on behalf of women everywhere.

The range of sites where one finds old and new iterations of grrlpower is significant. One excellent resource is the issue of Switch on electronic gender, which has eight outstanding essays and extensive links to further key texts and moments of cyberfeminism. In an essay "Charred Edges: Grrrl Power and the Structures of Feminism", Christine Laffer (1998) traces the history of girls online:

> If the web is one of the current hot spots for identity formation and declaration, then grrrls are still steaming. These grrrls project youth, indignation, and desire for solidarity, attention, and independence, no matter what age they've reached. I found the seminal *Riot Grrls*, *Rockrgrl* magazine, a grrlzine of Riot Grrl art named *Angel Cake*, *Web Grrls*, *Geek Girls*, *Nrrd Grrl* with their ezine Grrowl, *Modem Grrls*, the U.K.'s *Girlpower* magazine, *Asian gurls*, *Slantgirl*, and Hilary Carlip's *Girlpower*, to name only a few. Sites range from corporate (Japanese animatrixes the *Power Puff Girls*, *Purple Moon*, *Grrl Gamer*, *American Girl,* etc.) and parental (*Girl Zone*) endeavors to the more intriguing fan pages for girl bands, personal grrrl sites, zines and comics.

Even though women are woefully underrepresented in the field of programming and computer science, they are taking advantage of the tools available. For example, Greasergrrls.com celebrates women motor enthusiasts (http://www.greasergrrls.com/); Capitalistchicks.com celebrate being young capitalists and having fun (http://www.capitalistchiscks.com/); Allgirlskatejam celebrates girl skateboarders (http://www.allgirlskatejam.com/frame_main.html).

One might even ask at this point: With the countless ways that women are using the web for connection, empowerment, etc., do women even need to do computer science? Can women just use the tools men make and get on with life? Perhaps, but if nothing changes in academia, we'll never know how software and computers might be different if women were not taught to be incurious, and to be afraid of technologies.

4. CONCLUSION

This essay has offered an overview of the numerous discourses and images of women and computers. We have focused on these public representations because, following theorists of visual culture, myth and ideology, and semiotic analyses of ideology, we believe that these public imaginaries reinforce the material possibilities of gendered roles in relation to technologies.

The stock tales told about educational computing form an unquestioned folklore, which regulates and limits activities to gendered binaries. The assumptions of how males and females should use computers in schools guide activity so that these assumptions become self-fulfilling prophecies that are *revealed* in research. Most research fails to question such gendered narratives, thereby giving scientific credence to gendered uses not as social constructs based upon norms and values, but as biologically determined and final ends. Mary Bryson and Suzanne de Castell (1998) refer to this form of reflexive research as pre-constructing the human subject. The gendered narratives shape and constrain the ways in which students and teachers can use educational technologies and how researchers can probe into the supposedly *proper* use of such technologies.

Rather than simply lamenting the absence of women in the “IT pipeline”, we advocate that educators encourage students to explore the creative ways in which women and girls have redefined the “cyberfrontier”. The less visible but nonetheless real alternative imaginaries redefine the dominant cultural narratives.

We have focused on visual images and how these images construct our imagination as a means of disrupting these “natural” categorizations of bodies and gender. To question how we conceptualize and classify is a crucial part of educational intervention in areas such as gender inequities in computing and technology. The numerous examples of women inhabiting and redefining cyberspace illustrate the creative spaces women have created already.

Nielsen//NetRatings data from May 2001 shows that in the US, women now make up 52% of the total at-home web population, and the internet population now mirrors the offline population (http://www.eratings.com/news/2001/20010628.htm). It is our hope that in our work within education, we do not merely reinscribe the stories of women’s absences and objectification but urge students to explore the myriad ways in which women have upset and reappropriated the traditional gendered narratives of technology.

ENDNOTES

1. Barthes’ critique of structuralist semiotics offers a means for deconstructing how the frontier narrative operates in Cyberculture. Specifically, he examines how unnatural meaning-making is, how it is rather a social function. Dominant narratives determine how most people code representations and this commonsense decoding leads to hegemonic coding of stimuli as a seemingly natural undertaking. In “The structuralist activity”, Barthes (1964/2000) critiques traditional semiotics, specifically examining de Saussure’s structuralism. Traditional, structuralist semiotics posited the goal of decoding stimuli is to mentally reproduce (the mimetic approach) an object in the mind; however, Barthes writes that this process is a directed, interested simulacrum—intellect added to the object, not simply a mental mirror. We do not so much represent an object as much as we interpret it from past social experience. We choose what we see, and we attach further value in interpretation. The purpose is not to copy, but to render signs intelligible.
2. As Zoë Sofia (1998) indicates,

> Discovery has been pictured as an obsessive Frankensteinian quest for an enlightenment achieved through aggressive invasion and

possessive mastery of the unknown created through various technologies that estrange the familiar and push ever outwards (or inwards) the horizons of the known—a quest "to go boldly where no man has gone before". Computers are very much caught up in the myth of discovery through their associations with scientific and technological progress (p. 42).

3. One of the most explicit instances of the masculine desire to sexually conquer the frontier symbolized as virgin appears in John Donne's (1633/1994) "Elegie XIX: Going to bed":

   Licence my roving hands, and let them go,
   Before, behind, between, above, below
   O my America! My new-found-land,
   My kingdome, safeliest when with one man man'd,
   My Myne of precious stones, My Emperie,
   How blest am I in this discovering thee!
   To enter in these bonds is to be set free;
   Then where my hand is set, my seal shall be. (ll. 25–32)

4. Truth needs to be qualified as nontranscendent, but as a social function:

   > Truth isn't outside power. Truth is a thing of this world; it is produced only by virtue of multiple forms of constraint. And it induces regular effects of power. Each society has its regime of truth, its "general politics" of truth; that is, the types of discourse which it accepts and makes function as true, the mechanisms and instances which enable one to distinguish true and false statements, the means by which each is sanctioned . . . and the status of those who are charged with saying what counts as true.
   >
   > (Foucault, 1980, p. 131).

   Truth and power are interlinked with right: who has the right to produce truth and thereby the power to enforce that truth. However, the social production of truth reduces the argument to its skeletal form. One may be induced by reading this that a class, a person, a sovereign consciously governs this action as an oppressor. Nothing could be further from the truth. Without obedience of subjects through unconscious, embodied actions, this system could not exist.

6. Bryson and de Castell (1998) write that "a species of metanarrative which informs and is informed by practitioner's first-order accounts (also construed as stories) of the *nature* and *proper function* of computer technology

in the classroom" [emphasis added] (p. 67) script the supposedly natural categorizations and subsequent actions of gendered computer usage. Our bodies prompt social scripts thereby naturalizing expected socially constructed gender attributes. Bowker and Starr (1999) claim "to classify is human" (p. 1). We make sense of the world around us by giving it meaning, provided by internalized social scripts: "Basic categorization of others and the subsequent positioning of self in an interaction happens instantaneously" (p. 84).

Chapter 60: (Inorganic) Community Design Models and the Place of (In)appropriate Technology in International Development—What *if* More Than "Half the World" Wants Internet Access?

JULIA DICUM
Doctoral Candidate
Ontario Institute for Studies in Education (OISE/UT),

1. INTRODUCTION

The photo is of an elderly Afghan sitting on the side of a packed earth road in Northern Afghanistan, far removed from the trappings of an urban industrialized technologized existence. Behind him is a mudbrick wall. The tail of his white turban flows down behind his head and blends with his long gray beard. Despite his advanced age, the man is working. He sits on the ground behind a scale waiting for customers to buy tea. One side of the scale is empty—presumably where he will measure out his goods. The other side has a weight sitting on the plate. The "weight" is comprised of four AA batteries held together by a rubber band.

In an instant I am taken back to the practical context of "international development" and made to think: How can the internet ever be relevant or helpful to this man who uses batteries and elastics for weights? Even if we "bridge the digital divide" and take it to him, will he use it? How will he use it? What will/can the internet do for him?

The answers to these questions lie within the image itself. The man had a problem—he needed weights—and he solved it not by going to the local equivalent of a hardware store and buying some, or by picking up rocks from the surrounding environment, but by using, perhaps recycling, available objects. In spite of being manufactured outside of the tea seller's cultural space, he effectively solved a local problem. The best use of technology may not be in how the designer(s) intended it, but in how the user makes practical sense of it.

The use of information communications technology (ICTs), including but not limited to the internet, in affecting social change is currently a much-contested question within the field of international development studies. In the last few years, the use of the internet for "bridging the digital divide" has emerged as the focus of discussion on appropriate tools for development. The underlying assumption of this debate seems to lie in the viability of the

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1495–1524.

internet as a community development tool within the social spaces of the privileged who already have access; hence, the extension of cyberspace to other social spaces may benefit and enhance community development. However, as with the tea seller's solution to his weight problem, the internet as problem solution within any given community must be identified and designed from within.

Social science debates relating to the use of ICTs stem from the post-colonial theories of "development" with particular reference to the "Small is Beautiful" economy suggested by E. F. Schumacher in 1973 (1973 (1989)). In the intervening 30 years, technology and theory have developed largely in differing strains. Beginning from the ecocentric and anthropocentric legacies of E. F. Schumacher's work, this chapter traces the theoretical roles for the internet as an "appropriate technology" for facilitating individual and community learning in the pursuit of long-term change in less/least developed contexts (LDCs). By applying the lessons of theory to the practice of using the virtual learning environments for community change, it is possible to develop a critical understanding of the apparent impacts of (in)appropriate technologies.

This chapter contributes to theoretical understandings of community development within the field of international development studies and sociological studies of online or virtual community development through developing a critical understanding of user-centered design methodology. The convergent result is to propose a theoretical framework for understanding inorganic community development and the process of bridging social and digital divides. By contributing to the development of a theoretical framework, this chapter takes a step toward preparing researchers and practitioners for the study of impact of the internet as a community development tool in LDCs.

2. "DEVELOPMENT" AS NEITHER GOOD NOR BAD

Coming to an understanding of what "development" is meant to be, and similarly what it is, provides grounding for what is being discussed. Schumacher himself wrestled with the question of definition locating the concept's origins in colonial documents which indicate notions of (always) positive change, moving forward, civilizing, eradicating, improving, and so on (1989: 173–174). He did not fully support a solely affirmative economic perspective of development and claims that development "starts with people and their education, organization and discipline" (1989: 178), insisting on the gradual, subtle nature of the process. Development in the colonial and post-colonial schools of thought is very much attributed to "bridging divides" between social and economic disparities and has been the subject of countless theoretical studies in the field of development studies (Ferguson, 1994; Jaffee, 1998; Kothari & Minogue, 2002). At the core of these discussions appears to be efforts to compartmentalize people, groups of people, states, and other human entities in terms of economic, political, and social "success" or "wealth" based on ever-modified sets of positivistic indicators.

Thirty years after Schumacher published *Small is Beautiful*, Arundhati Roy uses similar language to negatively describe the process of globalization (2001: 13–14). How did "development" become related to "globalization"? How did a moral concept—eradicating poverty—move from a positive language set to a negative one? In the intervening years, what happened to move discussion away from the optimistic? As Roy suggests, optimism in the process of change ebbed away due to a myriad of forces, a multiplicity of perspectives and expectations, and the complexities of social group interactions (2001). One of which is most likely that Roy views the process from the perspective of a decolonized other, an insider and an object, albeit a privileged object, of development rather than the subject. Although Schumacher's post-colonial optimism continues to shine in many quarters, for it gives hope, Roy's cynicism reflects the lessons of the post-colonial era of development aid. Change has not always brought constructive modifications and the post-modern perspective reflects this waning optimism. Among other indicators, "development" has brought modern warfare, increased life expectancy and the number of mouths to feed, greater poverty and greater gaps between the rich and the poor (Ferguson, 1994; Roy, 2001). Hence, the bridging of divides, or development itself, seems to be going against the grain or swimming against the tides of change while continuing to promote change itself. Although this chapter continues to use the word "development", it does so from an enlightened perspective relating to the limitations of the optimism once seen as inherent within it.

Matching the confusing notion of "development" as a matter of perspective is the array of terminologies which have been created over the years to refer to "have versus have-not" regions of the world including: overdeveloped, more/most developed, newly industrialized, less/lessor/least developed. These terms conjure up images of comparative levels of poverty or "economic, social, and political development" which are compared to goals and expectations created by theorists, politicians, and what James Ferguson calls "the development industry" (Ferguson, 1994; Kothari & Minogue, 2002). In keeping with the very real ambiguity of these terms, and yet the need to identify what is being discussed with clarity, the terms "more/most developed contexts" (MDCs) and LDCs have been chosen to represent those groups, organizations of people, and state systems with relatively stronger economic and social indicators versus those with weaker/weakest economic and social indicators. While recognizing that in some of the LDCs people who survive on comparatively small incomes may have some limited access to the technologies and trappings of "development", and that in the longer run this access may allow for different levels of change, engagement, and economic growth, for the most part the divisions of the LDC versus the MDC continue to be useful terminologies in helping to define what is being discussed in a paper of this nature. The use of the term "context" was chosen over "country" or "state" to allow the opportunity to be inclusive of both the virtual (online) world, which transcends these tangible socio-political entities, as well as non-state regions which might be of relevance such as an individual, an extended nomadic family, a rural community or village, a refugee camp, a shanty town, or the wealthiest neighborhood/enclave in an urban area.

3. THE ECOCENTRIC LEGACY: [IN]APPROPRIATE TECHNOLOGY

The legacies of Schumacher's work are evidenced primarily in two distinct directions: anthropocentric or "people-centered" development theories embodied in the work of practitioners and academics such as Robert Chambers (1993), Denis Rondinelli (1993), Stan Burkey (1993) and the ecocentric work of Joseph Pearce (2001) and Common Pool Resourcing (CPR) theorists such as David Bromley (1992) and Elinor Ostrom (1992). It was into this oscillating mix that, roughly a decade after the development of the personal computer, the World Wide Web was born popularizing the internet and creating an altered sense, but not a reality, of public capacity and access. The introduction of community development in cyberspace and the notion of the virtual community, further complicate concepts of appropriate technology, of the subtle nature of "appropriateness" and the method through which "appropriateness" is determined. A critical study of the ecocentric legacy shows that digital technologies, including the internet and the hardware needed to support it, are definable as an (in)appropriate technology due to its inability to address issues of environmental sustainability and recyclability despite the ability of many of these technologies to be efficiently managed as a common resource.

E. F. Schumacher's work *Small is Beautiful* has provided the field of development studies with a basis for promoting a world in which "progress" is measured by locally determined participation and need (1973 (1989)). Schumacher promotes appropriate or intermediate technology as the tools by which change can be facilitated (1989: 190–201). But despite his lengthy discussion of intermediate technology, Schumacher does not provide a succinct definition. The Intermediate Technology Development Group suggests that appropriate technology is any tool which efficiently assists in the change process while preserving, if not also enhancing, social relations and preferably minimizing environmental impacts (ITDG, n.d.).

> The equipment would also fit much more smoothly into the relatively unsophisticated environment in which it is to be utilized. The equipment would be fairly simple and therefore understandable, suitable for maintenance and repair on the spot. Simple equipment is normally far less

dependent on raw materials of great purity or exact specifications and much more adaptable to market fluctuations than highly sophisticated equipment.

(Schumacher, 1989: 191)

Although Schumacher was not explicit, it is implied in the above quotation that appropriate technology should be ecologically "friendly" within the socio-political and economic space in which it is used. This viewpoint is buttressed with Schumacher's economic argument which favors £1 technology over £1000 technology or that which can be supported or sustained by the economy (1989: 190). The longer-term legacy of ecocentric technology can be seen in the articulation of development theories and practices which place environmental concerns at the center of paradigms of change, two of which will be mentioned below.

Joseph Pearce interprets Schumacher's intermediate technology as necessarily "green" or ecologically appropriate technology (2001: 182–193). Pearce's logic stems from the belief that truly anthropocentric technology is necessarily organic technology giving renewable energy sources as an example (2001: 185). In later work, Schumacher also identifies the importance of a spiritual devotion defined as recognized esthetic practices relating the earth to the inner self (1977: 85). Pearce similarly roots his understanding of development and change strongly within a (largely Christian) religious and moral ethic citing higher motivations in his own commitment to an ecocentric focus on human change. Pearce, however, represents but one uncritical study of Schumacher's ideas which rather simplistically attempts to reassert an ecologically based "small is beautiful" economy and moral standing.

The second area wherein Schumacher's ecocentric nature is reinforced is from within CPR. Daniel Bromley suggests that whether one uses the terminology "Common Pool Resourcing/ces, Common Property, or The Commons", the key concept being discussed is the collective ownership of a "property" or resource (1992: 4). He goes on to say, "Property is not an object but is rather a social relation that defines the property holder with respect to something of value against all others" (1992: 4). Elinor Ostrom, in her theoretical work on CPR, gives examples largely related to agriculture, livestock, ocean management, and common lands managed variously by familial, nomadic, tribal, or interested parties/members of a group (Ostrom, 1992: 295). In short, CPR theory supports the use of "local" or "traditional" socio-political structures to reinforce sustainable community-management of natural or agricultural resources. Unlike Pearce, Ostrom's most recent work identifies a usable space for "technology"—including industrial machinery and computers—wherever it "enables us to monitor common-pool resource effectively and at lower cost" (Dolsak & Ostrom, 2003: 27). The recent acceptance of industrial and digital technology represents a controversial departure from the usual interpretation of what is encompassed under CPR suggesting instead that it is possible to move forward in technological development without addressing issues of ecocentric technology.

Schumacher, Pearce and the CPR theorists largely focus on the case for rural development within an ecocentric paradigm, which tends to stress the maximization of "traditional" structures for community resource management. But LDCs, as well as the concept of development, are equally riddled with urban and peri-urban areas of the pre-industrial, industrial, and possibly post-industrial varieties layered one on top of the other in a continual process of change. Indeed, since Schumacher published *Small is Beautiful*, the rise of the urban "megalopolis" and increased rates of rural–urban migration have become significant issues in numerous LDCs. The concept of urban "development" and the ecocentric legacy is therefore of some interest to the unfolding argument.

The type of simple technology purported by Schumacher in the quotation, which opened this section, can be interpreted as a promotion of a decentralized rural life revisiting pre-industrial village/farming/nomadic concepts. In looking at how the city is understood within the legacy of Schumacher's philosophy, it is worth turning to Gideon Sjoberg's *The PreIndustrial City: Past and Present* (1960). Sjoberg sought to identify common traits of cities in their earliest forms and to determine to what extent these indicators continued to exist in key "less developed" locations in the 1950s. Much of his focus was on East Asian, Central Asian, and Middle Eastern cities of moderate size noting many of them to be largely self-sufficient "pre-industrial" areas with agricultural fields, multiple small industries or trades and businesses integrated within the city proper (Sjoberg, 1960: 80–105).

Sjoberg's observations on the place of technology within the not-fully industrialized city are particularly relevant:

> The existence of barriers is a function of the technological base: the more backward the technology the more numerous are the areas inimical to city life. . . . throughout the history of preindustrial civilized societies, technology has advanced, though at a languorous pace, enabling cities to spring up in environments that earlier could not have nourished them.
> (Sjoberg, 1960: 83)

Sjoberg later concludes that he does not see "a panacea for the world's ills in the complete industrialization and urbanization of underdeveloped countries, at least not over the shorter run" (1960: 338). This opposition to urbanization suggests that Schumacher's rural focus is appropriate. Moreover, cities should also operate on an urban version of the "small is beautiful" concept. Although he claims not to oppose urbanization or to support de-urbanization, Sjoberg acknowledges that cities change over time and can become a mix of pre-industrial and industrial. Indeed, his study showed cycles of social, political, and economical conflicts arising through out the industrialization process.

Certainly in the case of Kabul, Afghanistan, whose flourishing pre-1970s not-yet-industrial state is captured by Sjoberg (1960, 54–55), one sees how the now destroyed city at the heart of "post-war" (re)construction efforts highlights these findings. In Kabul the introduction of costly digital access to cellular telephones and the internet took priority over the building of affordable housing, sewage, agriculture, and other basic infrastructure destroyed during 25 years of war and conflict[2].

This view, that the internet and other forms of digital technology can be arguably appropriate for not-yet industrial urban areas and rural areas should realistically be challenged by Schumacher's ecocentrism rather than the facilitator of change. No matter what the benefits of ICTs may be in terms of communication, networking, and information management, ICT hardware comprised of metals, plastics, chemicals, and other hazardous materials cause environmental concerns. ICTs as they currently stand can only be classified as (in)appropriate technology—that which is perceived by some humans as useful, efficient, and problem solving, but which is simultaneously ecologically harmful. Nevertheless, small-scale attempts are being made to conceptualize and promote ecological computing technologies, which aim to meet users' expectations in an environmentally responsible manner.

One example is represented by the Silicon Valley Toxics Coalition's (http://www.svtc.org) advocacy for the development of the green computer, the responsible disposal of the toxic waste caused by existing computer hardware, and the mitigation of harmful effects on humans caused by the materials used in the creation of computer hardware. Although located in the heart of the United States' computer industry—Silicon Valley, SVTC and the principles behind it remain largely marginalized from the body of literature and activities surrounding the debate on ICTs as appropriate technology. Schumacher's ecocentric intentions would support a privileging of the policies of the SVTC as a way to make technology environmentally appropriate.

Secondly, there is recognition of the need to make cyberspace a ZeroCostComputing or low cost computing tool (Haddad & Draxler, 2002: 202; Halileh & Giacaman, 2002; Jhai Foundation, n.d.; Nolan et al., 2004; Shirky, 1998; Valovic, 2000; Warschauer, 2002). The concepts behind ZeroCostComputing is represented in an online collaborative weblog project of the same name (http://clevergirl.ca/zcc), which recognizes the need to "bridge the digital divide" in such a way as to meet the social, cultural, economical, environmental, and political needs of the spaces occupied by specific user groups. As such, it collects debates related to the environmental impact, hardware innovations, and social impacts of computing with an awareness of promoting ZeroCost paradigms.

Of those who have written on ZeroCostComputing, Clay Shirky in particular argues that computers, like mobile phones, will become a service—given away by companies so that people are better able to make use of a corporatized cyberspace and bank, e-mail, arrange travel, and pay bills online (1998). In keeping with the concept of CPR, computers would no longer be "personal" but public domains. Shirky believes commonly pooled computers will be supported by increased bandwidth speed, flat screens, and open source software working together to further decrease the cost of hardware and resulting in real widespread accessibility for the masses. The realization of Shirky's "divide by zero" vision would enable computers to be considered financially sustainable by users in LDCs as much as the poor in the MDCs for whom this technology is currently out of reach.

Shortcomings in Shirky's vision lie in his non-consideration of power sources, locations lacking phone line capability, the environment and issues related to the linguistic challenges of the English language hegemony of the internet, and of programing languages all of which are important issues to the ability to use cyberspace in LDCs (Jhai Foundation, n.d.; Nolan, 2001; Shirky, 2002). Although some of these issues may be solved through satellite technologies, solar energy, car battery technology, biogas, and other innovations, the world remains distant from a ZeroCostComputing reality. Like Schumacher, who chose to focus on an interim goal in the form of intermediate technology, the interim focus is on lower cost, rugged, environmentally responsible computing. Impatience in obtaining results leads to leapfrogging technology—introducing a tool which may require locally unavailable support infrastructure or be economically unsustainable—which in turn is likely to lead to disappointment rather than an easily layered "mixed" post-industrial and pre-industrial environment as Sjoberg suggested.

The review of the ecocentric legacy of Schumacher's "Small is Beautiful" ideals creates questions regarding who is determining the "appropriateness" of any form of technology and any stage of industrial development, rural or urban. If direct and indirect users agree to the appropriateness of batteries and elastics (or computers and wireless fidelity) and to their value, then who can anyone suggest otherwise? To do so would require the introduction of outsider-constructed reasoning and solutions regarding ecology, the environment, change processes and other economic, social, and political impacts. It is from this thinking that the term "(in)appropriate" presents itself. Ecologically, appropriateness should only be determined by potential direct and indirect users from within the social space which experimented with/or asks to experiment with the technology in question. Projects where users are privileged and given the strongest voice within the venture can lay claim to the development of appropriate technologies. Technologies identified by, adapted by, or (preferably) created by a user group, which maintain principles of ecocentrism, can be "appropriate". Every other type of technology, therefore, is potentially (in)appropriate—that which maybe perceived as appropriate for economic, market-demanded, political, or social reasons, but which may in fact prove to be environmentally dangerous or inefficient in the context itself.

A world economy "as if people mattered" is therefore defined as one in which environmentally "friendly" technology is created through localized individualism yet maintains global integration, or exists within what is increasingly known as a "glocal" network (Haythornthwaite & Wellman, 2002; Wellman, 2001). However, the creation of a glocal post-industrial world appears further out of reach in 2003 than it did in 1973. Technological, political, and economical developments and relationships have largely ignored or marginalized environmental needs while becoming more complex resulting in increasing demands, or (mis)perceptions of "need", for access to the products of the more developed world by the less/least developed. People and the relationships which string groups of people together have been unwittingly globalized and therefore falsely de-culturated; post-modernized within a lingering modernism. As such, Schumacher's ecocentric legacy, by being marginalized by communities and development practitioners alike, seems to bring the argument neatly to the realm of the anthropocentric.

4. THE ANTHROPOCENTRIC LEGACY: (VIRTUAL) COMMUNITY DEVELOPMENT

If the ecocentric legacy seems to be of limited applicability then the anthropocentric legacy seems to have gained an inordinately large following since 1973. An anthropocentric understanding of (in)appropriate technology concentrates on understanding whether the technology addresses an expressed human "need" from the viewpoint of the community or users. In some circles, this legacy would distinguish itself from the ecocentric in that environmental concerns may not be central to the design, use, or sustainability of the technology in situations where users do not place the environment on the list of "needs". On the other hand, it could be argued that anthropocentrism does not preclude environmentalism since an environmentally responsible technology enhances (wo)man's health, longevity, and the long-term sustainability of natural and human resources. This second approach would be in keeping with the predominant view stemming from Schumacher's "small is beautiful" philosophy. Perhaps then, where Schumacher himself is concerned, there is a blurring between the ecocentric and the anthropocentric. However, community development projects in the international development field may marginalize environmental concerns in (in)appropriate technology design, which gives credence to the separation of the anthropocentric from the ecocentric.

Whereas human-centeredness is an issue in technology and knowledge media design, the overwhelming location of human relations in wider notions of the "development process" and global economic relations seem to require the privileging of community within the design for development dichotomy. The question being focused on at this point is whether there is potential in cyberspace to support social development in a wider range of realspaces. In order to ask this question, however, it is necessary to understand "community" as well as how they function together through experiential learning processes to foster change.

Cultural and critical theorists view community as a product of complex human interactions and the interconnectedness of individual interests into a collectivity, which may also be referred to as the production of (social) space (Freire, 1970; Lefebvre, 1998; Slater, 2002; Huiskamp, 2002; Wellman, 2001). Barry Wellman defines community "as networks of interpersonal ties that provide sociability, support, information, a sense of belonging, and social identity" (2001). To Lefebvre, community is not a synonym for social space but is a representational example of a social space. Lefebvre argues that social space cannot be consciously constructed but is organically produced when an unknown quantity of social factors enable an environment to develop (1998). Social space is produced within a variety of locations and may be of any size encompassing words associated with personal, familial, local, regional, national, and international in scope. Despite the best efforts of individuals who design communities, these theories suggest strong activist communities are probably created unconsciously or organically in a seemingly unexpected and undirected process. The communities suggested by Schumacher's theories, as with those designed by the "development industry", are inorganic communities wherein cohesion is consciously fostered to meet the stipulated priorities the "project".

Membership in both inorganic and organic communities is made up of a commonality of identity; however, within any community it is likely to find sub-groups of identity if not sub-communities. Membership may be identified by outsiders and/or insiders alike. In defining a sense of belonging one must look equally at self-defined membership versus other defined and collectively (formally) defined notions where they exist. In studying a single community, the focus tends to be on determining the single common identity indicator which all members hold. However, given the complex nature of communities and the layers of hierarchy, identity, organization, and experience, it becomes difficult to determine the exact science of communities. Community is therefore a space which is both real and imagined. It is real and obvious when a group of people come together for a specific purpose—economical, social, political, or all three—and identify a similar set of characteristics defining membership and access. Community is moreover imagined at the cognitive/emotive level—the degree to which any individual feels affective membership within the space (Anderson, 1991; Lefebvre, 1998). Being created in the minds of (wo)men, community is essentially borderless continuously morphing in shape, size, and membership. To borrow terminology from cybertheorists, communities are virtual.

How does this understanding of community translate into our common understanding of cyberspace? Cybertheorists defining virtual or online community deviate little from offline theorists of community in their discourses on capturing the essence of the concept. Howard Rheingold, perhaps the most respected of these theorists, focuses his own analysis of virtual community online through an analysis and understanding of "collective goods" (n.d.; 1994: 12–13). To Darren Wershler-Henry and Mark Surman, in the tradition of Rheingold and Lefebvre, the internet is about "commonspace" or the collective "us" (2001: 2–3)—"a gooey, bubbly swamp of an ecosystem" of which online communities only make up a part (2001: 11, 24–25). On the other hand, Jenny Preece, who presents a structural discourse, defines "online community" as a collaboration of people with a shared purpose, governed by accepted polices of interaction and engagement, and who use computer systems to facilitate their exchanges (2000: 10). These notions of "cyber-community" similarly specify boundaries and structures despite the discussion being centered around online space. However, if offline community is borderless and virtual as argued above, then (virtual) community online should also be borderless—endless in the possibly of change, membership, life cycle, and influence.

A group of post-modern theorists concur with this idea of similarity between online and offline notions of community. The collective conclusion of their work suggests that most online community is in fact a representation of real social space, thereby reflecting structures and strictures of offline space and not necessarily changing, enhancing, strengthening, or revolutionizing. Thomas Valovic (2000), Mark Poster (2001), Shahrzad Mojab (2000; 2001), Lisa Nakamura (2002), and David Bell (2001) each deconstruct aspects of the assumption that online community is somehow different from and privileged over realspace—or a democratic, free, and co-operative social space—and acknowledge that cyberspace and the representations created within it reflect realspace hierarchies and hegemonies of difference both online and offline. The introduction of cyberspace has simultaneously and inadvertently added a new dimension of difference and exclusion increasing the distance between humans on an individual and collective level.

When practitioners attempt to design or construct interventions for community development, at a basic level they are suggesting that inorganic interventions could assist the shape or strength of the organic community itself. However, project designers and implementers are ultimately taking a risk since one cannot accurately predict whether an inorganic intervention will result in a weakening or a strengthening of community, difference, otherness, and exclusion. The process, which helps to create, develop, and change communities seems to stem from the realm of (adult) learning and education. In *Small is Beautiful,* Schumacher writes briefly on education, learning and the role they play in stimulating processes of change.

> Development does not start with goods; it starts with people and their education, organization, and discipline. Without these three, all resources remain latent untapped potential. . . . Education does not "jump"; it is a gradual process of great subtlety.
>
> (Schumacher 1989: 178–179)

In *A Guide for the Perplexed*, Schumacher expands on his understanding of the education process in which either "existing culture is passed from one generation to the next" through the establishment of obedience and discipline or, on the opposing side, the educator acts as a "gardener" nurturing and facilitating the slow growth of ideas and learning through the creation of spaces of freedom (1977: 122–123). He ultimately maintains that these two divergent views are irreconcilable opposites at the heart of unending educational debates on the "right" way to go about it.

However Schumacher's view of the role of education is structured and implies a progressive institutional process which is primarily for the young alone. The work which is relevant to this study is that of those who have been especially influential in understanding learning for "community development". Therefore, it is perhaps more relevant to examine the ideas of learning theorists more focused solely on learning for change particularly Paulo Freire (1970; 1985), Ivan Illich (1970), and David Kolb (1984). Freire championed the conscientization method of literacy learning, which engages adult learners in literacy through the development of an internal political consciousness leading to a collective decision to take political action. Illich is best known for suggesting that society had to consider a "deschooling" process whereby current educational structures—both physical and mental—would be deconstructed establishing collaborative learning networks where learners create goals and acquire skills/knowledge at a pace determined by their "needs", goals, and abilities to meet them. David Kolb, tracing his ideas back to a group of cognitive psychologists and educationists including Piaget, Dewey, Carl Rogers, and Carl Jung, articulated an experiential learning theory, which is the basis for reflective practice, lifelong learning, and other methods of adult education focusing on learning through the active participation of the teacher and learner in the process. All three of these curriculum theorists essentially suggest ways in which individuals, especially but not exclusively adults, can learn from collaborative listening and working environments, from the value of sharing experience with others, and from thinking and critically reflecting on one's own experiences.

It is not difficult to see the parallels between what Friere, Illich, and Kolb are suggesting about learning as a continual process and the participatory action research methods and theories developed and used in inorganic community development projects since the 1960s and highlighted in the methods of Rapid Rural Appraisal, Participatory Rural Appraisal/Action, and Participatory Learning and Action (Chambers, 1993; Brock & McGee, 2002; Archer & Cottingham, 1996; Pretty et al., 1995). Although this method will be discussed in more detail in the next section, one important point needs to be suggested here related to the conception of inorganic community development. The assumption held within much of the work of the learning theorists, the community development theorists, and the cybertheorists seems to be that actively constructing either tools for community or services within community will create, strengthen, and (positively) change the shape, structure, and power of the community itself. However, it is quite possible that such conscious process will not reveal positive change in community as is well documented and evidenced in a wide range of material including Brock and McGee (2002) and Ferguson (1994). There is as yet little documented evidence that the use of ICTs in development projects has significantly affected the rate of change in (organic/virtual) target communities as the object being "developed".

Community as a concept is ultimately challenging to reconcile on a theoretical level, which is interesting since many English language speakers are able to visualize or to cite examples of communities, which are important to them. In other cultural/linguistic contexts, different group identity markers, such as family or tribe, may hold more importance. The theorists cited herein largely arise from MDC academia and experience, which perhaps explains the cross-disciplinary agreement as to the tangible language used to describe the notion in itself.

The potential benefits of using information communications technologies to support inorganic community development process through international development projects may therefore be reliant on the ability to measure the social capital of online community. The social results of using these tools as the central space for communal interaction within LDCs cannot be ascertained adequately at the present time primarily due to a lack of documentation and focused experimentation on the social impacts these tools are having where used. Some conclusions are suggested in the case studies section, but nothing comprehensive can as yet be surmised. One thing which will become clear is that the economic cost versus the social benefits of using ICTs and online community has yet to be reconciled.

The presented discourse on the anthropocentric legacy of Schumacher's "small is beautiful" theory focused around learning and community. As part of that legacy the focus on post-modern deconstruction has allowed theorists to move away from the post-colonial view of "development" as a necessarily positive "improvement" of the human condition towards one in which change is based on experimentation with new ideas, technologies, and the empowerment of the self and the collective through learning. As such anthropocentrism has moved considerably over the years enabling practitioners to ask increasingly more complex questions about how to integrate ICTs into "development projects".

5. METHODS OF DESIGN FOR "DEVELOPMENT"

> If the people cannot adapt themselves to the methods, then the methods must be adapted to the people. This is the whole crux of the matter.
>
> (Schumacher, 1989: 203)

Despite the misgivings related to the ecological appropriateness of digital and computer technologies as community development tools in LDCs, the predominant nature of the anthropocentric theorists in the development studies sector suggests that wherever ICTs are identified as having the potential to enhance community development, a sensitive and careful methodology should be developed and tried. The creation of a methodology-based development process may assist in addressing some of the theoretical concerns expressed above. Notions of user-centered design and community-centered design as articulated in the fields of knowledge media design and computer science are central to tool development (Preece, 2000; Preece et al., 2002) . Merging of the lessons learned by anthropocentric theorists and researchers with those of ecocentric thinkers, reveals a model for inorganic community development which privileges membership, minimizes external participation, and takes into account ecological questions.

5.1. Appropriate Technology Design for "Development"

The ecological legacy intimates the need for hardware and software design for the effective implementation of ICTs for community development which meet the requirements of being financially sustainable, maintenance and user-friendly, related to user environments and expectations, and environmentally sound. The design methods suggested by this paradigm relate to the use of local knowledge bases and processes above an emphasis on external "expertise" including those of elites from within the community's own cultural/state/national/regional environment. To suggest the "localization" of existing technology from other contexts greatly simplifies what is implied by the theory and the demands of any given context. A critical look at documented sources on suggested methods of appropriate technology design shows similarities across academic disciplines, but similarly shows an overall marginalization of local "expertise" and environmental concerns exposing the problematics of current models.

The development studies perspective provides a series of suggestions for the effective strategic design and implementation of ICT-based projects. Peter Ballantyne has suggested six guiding principles for ICT for development projects which can help to address local needs, priorities, and activities and which encourage sustainability. These are ownership, demand responsiveness, multi-stakeholder involvement, capacity development, partnerships, and learning by doing (2002: 374–5). While providing a potential starting point for projects which mirror recognized human-centered principles and the principles therein, the basic assumption appears to be the availability of a pre-existing group of technological tools. In short, outsider technological hardware is leapfrogged into other contexts and expected to perform usefully. However, in order to be responsive to local needs and environments, as well as to be financially sustainable, the hardware/software needs to be developed locally using locally available expertise, solutions, and materials as much as possible (Corea, n.d.; ITDG, n.d.).

Primary issues confronting development focused projects center around long-term issues of sustainability, community/stakeholder self-management, project costs in the short and long term (the difference between giving aid and building capacity), and determining project effectiveness in building human capacities (Ballantyne, 2002; Burkey, 1993; Chambers, 1993; Rondinelli, 1993). For development practice to be effective and to build both sustainability and capacity for self-management, projects need to reflect stakeholder determined needs, ideas, and activities—both current and future perceived activities. Such practices are human-centered and focus not on leapfrogging development, but on change at a fitting pace.

From the fields of knowledge media design, computer science, and engineering come the principles of user-centered design (UCD) and participatory design around which hardware/software design projects are structured in MDCs (Preece, et al., 2002). UCD essentially represents a cyclical process where by users are asked to consult or to test designs in order to develop an understanding of user-friendly design paradigms. Participatory design is a process whereby at least one real context user is embedded in the design team to gain ongoing advice/reaction. Other users may also be consulted or may test design in context but the primary focus is on contextual participation at the level of the design team.

UCD and participatory design projects closely resemble the generic project cycle of development project management: needs/problem identification, proposal development, implementation, monitoring and evaluation, redesign/adjustment, and starting a new cycle. One reason for this similarity may be the commonality of approaches noted by sociologists, anthropologists, and others who examine human behavior for consistency in practice. On the other hand, commonalities may be present in part because these research and management practices have been developed and used predominantly by academics and field practitioners from or trained in MDCs who in turn display commonalities due to similar experiences and social place. Both fields attempt to privilege, though not always successfully, user/stakeholder participation or ideas within the project cycle.

The examination of the above models of appropriate technology design methodologies and how they relate to the theoretical tenets examined earlier in the paper suggest that the outcome of these methods would not yield strongly ecologically focused community-based useful technologies, but further (in)appropriate technology structures. The theoretical and methodological discourse in this paper suggests a number of factors to consider in designing stronger ecologically sensitive methods of technology design. These factors are listed below.

- The use of ICTs may be unpopular and even theoretically questionable to many practitioners promoting the "small is beautiful" economy. However, it is important to give voice to stakeholder/user articulated needs, desires, and conditions.
- The merging of UCD, participatory design, and international development practices of project cycle management and participatory action research suggest a project cycle which incorporates the privileging of stakeholder participation. The benefits of participatory development are indicated even when community-level stakeholders may not have experienced some ICTs previously or when design methods used in MDCs are not as intensively participation-centered. However, stakeholder or user participation is rarely leads the design process.
- ICT (both hardware and software) development should be contextually and ecologically relevant and should meet contextual challenges—environmental, sociological, and economical included. Technology designed to meet contextual reality is more likely to be successfully implemented meeting the financial, physical, moral, and communicative requirements of the users' social space.
- While ZeroCost is the goal, Low Cost is an intermediary necessity.
- Sustainability issues indicate that project designers and technology designers need to consider issues of long-term maintenance (financial and technical), replacement, parts availability, and support models.

5.2. Design for (Inorganic) Community Development

Wherever an organic community, a few members, or well-meaning outsiders attempt to create or otherwise alter an identifiable social space, consciously made inorganic changes to the community development process occur, which may or may not positively affect the (virtual) community. Structured inputs may take many forms, including the introduction of digital technologies and cyberspace. This section sets out to define and rethink the design process and use of cybertools within inorganic community activities.

Jenny Preece wrote a comprehensive book describing the methods used in community-centered design (2000). Essentially an adaptation of user-centered design, CCD follows the same set of project cycle benchmarks: problem definition, needs analysis, prototype design, prototype usability testing, pilot testing, and implementation. The difference from UCD processes is the intentional addition of community "nurturing" and "sociability". Preece lists community tools as: websites, MOOs, e-mail and e-mail list serves, UseNets, chats and avatars, instant messaging, and the use of shells (2000, 231–65). The noticeable absence of webblogs or blogs may in part have been a function of the popularity and availability of the tool at the time of writing. Certainly in 2003 it is difficult not to include blogs—collaborative online journals—as a tool available to online communities.

Although Preece sees CCD as a participatory and evolving process, her work is set out to manage and construct (intentional) community—both notions of which are somewhat questionable according to the theories of (virtual) community discussed above. Mark Poster has noted the potential for online "community" to be sometimes radically chaotic and short lived (2001, 183–187). The key challenge for community development both on and offline appears to be "kick starting" a cohesive, powerful, longstanding community.

One of the critical problems with Preece's suggestions for designing online community is her basic assumption that the statement of problem and needs analysis will find the answers to be within the tools of representation created in cyberspace. She does not suggest that community building solutions also exist within realspace itself. In excluding existing non-cyber community building tools, she assumes that technology is always the answer. Such an assumption alienates the existing work of community development specialists, in both the social service system in MDCs and the international development system in LDCs.

A second critical issue of Preece's work lies in her detailed apparently inflexible "how to" prescriptions which include details of design team membership right down to title and role (2000: 213). Although she describes the process as being participatory and inclusive of community members, her three member development team does not explicitly include a single community member and moreover advises that the "technical specialist" should "hand over the community and software documentation to the new community managers" (2000: 205, 213). The development team may therefore be extraneous to the community, which, according to earlier discussion lends itself to issues of power, hegemony, purpose, and inadequate integration of community needs, views, and purposes.

A third critical issue for inorganic community development, which may determine the use of a cybertool in the project model, is the geographic location of users. Years of global diasporas due to political and economic movements—enabled partly by changes in modes of transport—has increased the need for global communications between groups. In some remote locations—as evidenced in the GrameenPhone and the Jhai Foundation's work, the most practical and rapid solutions to remoteness lie in satellite and cellular networks. In such cases, technology may be indicated as a tool of glocal linkages between the diaspora and the originating (virtual) community.

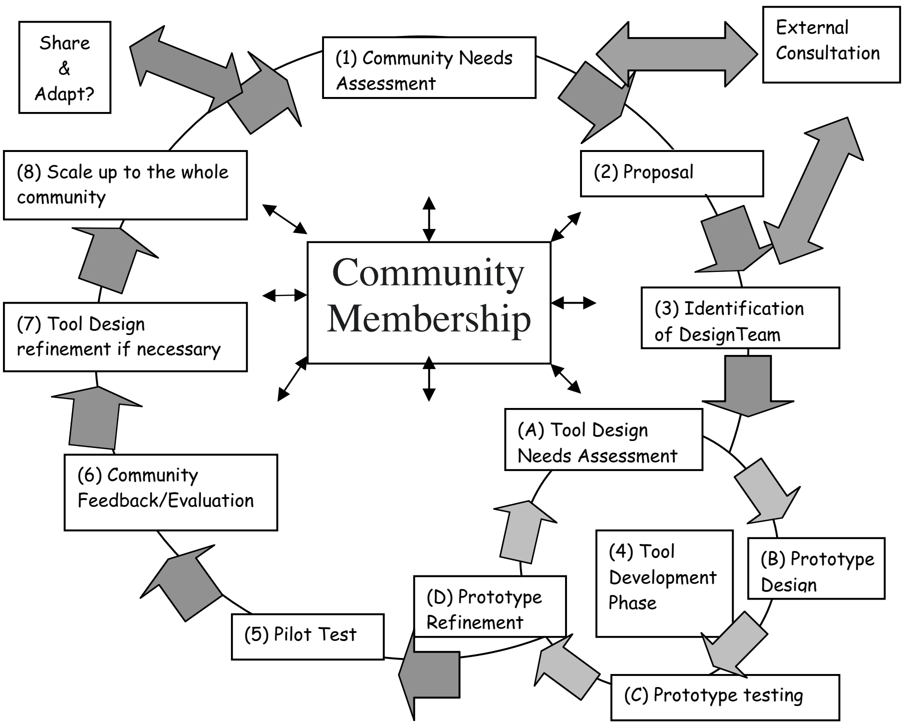
A second methodology indicated from within the development studies field and international education practice lies in the use of participatory rural appraisal (PRA) or participatory learning and action (PLA) for strengthening potential user input, increasing community leadership in the process, and developing a stronger sense of community participation. PRA, PLA, and other variations on this term basically represent the same set of research tools and methods which are used to consult local populations about issues related to their own development and in most cases attempt to construct local knowledge base related to these issues (Archer & Cottingham, 1996: 5, 14; Pretty et al., 1995: 56). However, within the field of participatory research methodology there is much debate, and some evidence, as to the limits of participatory research to strengthen the (virtual) community (Brock & McGee, 2002). One of the key issues behind this method is what to do when a PRA research process cannot be followed-up with financial or technical support for the realization of articulated/discovered needs (Yates & Okello, 2002: 92). Another is how researchers use information gathered: who should be designing the project, project tools, and implementing them—community members or the staff members of non-governmental organizations/donor agencies who conducted the research? (personal observation) However, if these key tensions can be addressed at the outset of the research, there is possibly a useful method, which can be integrated into appropriate technology for development design cycles.

In LDCs, the use of cybertools is embryonic and unclear. The implications for project management and development are multiple, both reinforcing and adding to those suggested by earlier discussion on (in)appropriate technology development. The use of internet tools may assist in community development when:

- Participants' physical separation is such that other communications tools would be unacceptable or detrimental to community strengthening activities.
- The communications/learning opportunities provided within cyberspace are a clear representation of a specific need which cannot be met in any other way.
- Local users use their own knowledge base to develop the tools.
- The development of tools, as with the entire project, includes participatory measures drawn from the experiences of international development practitioners with PRA/PLA tools, which centralize user/community member's opinions and needs, the structuring of a curriculum of access by the community itself.
- Within the project, the tools reflect environmental and financial abilities of the users as mentioned in the previous section.
- The system is language appropriate.
- Cyberspace itself hosts a sufficiently large space for the participants' language (L1). In short, users would not be limited solely to the use devised in the original project, but could also explore, learn through self-development and exploration, create and invite other participants/members through the communication tools.

5.3. Virtually Community

A representation of the suggested social space interaction and change process is suggested by the theoretical examination above. The figure below seeks to create a sense of order and description around which community members considering the use of ICTs as social development tools can determine the (in)appropriateness of ICTs for development and can, if necessary, become involved in the process at the (virtual) community level. The process does not aim to create a (virtual) community, which can only be created organically, but to solve community or user identified challenges to everyday issues.



The figure depicts the community development process with CCD/UCD embedded within as phase four (4)—Tool Development Phase. The tool development phase as it is presented, however, purposely excludes references to ICTs thereby allowing the suggesting that the "tool" need not be digitized or communications related at all. Moreover, in an in depth depiction of the inorganic community development process, it would be necessary to include embedded circles to describe each of the numbered phases, since each one normally requires a series of planning, designing, piloting, and implementing before moving on to the next phase. An alternative depiction would be to use a spiral formation since the circle suggests that the same cycle repeats indefinitely and a spiral envisions a new cycle, with the same benchmark stages, which takes learning during the last cycle into account.

The community membership is placed in the middle of the main circle to indicate the centrality and involvement in the process. The two way arrows emanating from the community membership indicate the continual flow of discussion, input, labor, and management which should develop out of the community as well as flow back into it. In this model, therefore, community participation is central to the process.

The perceived two way flow of information sharing with external sources and donors represents the inflow and exflow of ideas, hardware, expertise, and funds. While it is possible that external input or funds may be necessary at any phase, it is also possible that it may not be necessary at all. If the process were truly community-driven and led, then the decision to seek external inputs would be made from within. Sharing ideas, tools, and lessons learned—and even adapting tools to support other communities, is a possibility placed at the end of the community development cycle. While sharing would theoretically be possible at any level of the process, it is also a phase which could be emphasized at the end of the cycle in order to better indicate success.

While it would be preferable to allow the organic development of a community without external involvement, management, or stimulation, inorganic community development projects are driven by interests, available funding, and motivation from within local, national, or international organizations (governmental or non-governmental). In an organic situation, where the community seeks and develops external advice at their own pace the chances that tools for development will be more easily accepted by the community. In an inorganic situation, the use of participatory action research methods might be helpful in ensuring that individual voices within the community remain central to the development process thereby simulating an organic process as closely as possible.

While there may be some critical problems with this proposed model of ICTs for inorganic community development, it helps to clarify the potential role, place, and method of ICTs within models of human-centered development. The model deviates from some models used in cybertheory in that there is an underlying assumption that the community pre-exists the development process whereas some online communities in the MDCs are solely online entities. However, given that the majority of people living in LDCs do not yet have access to the internet, such as assumption is not inappropriate at the current juncture of internet development. The inorganic community development process continues to be indicated as a leader in economic, political, and social change. Cybertools propose an innovation of relatively untapped potential within the process.

6. PILOT TESTING ICT FOR DEVELOPMENT

The practice of using cybertools for Development remains embryonic with little possibility to determine real impact in reaching for and developing inorganic community through (in)appropriate technologies. Much of the available information comes from internet sources—normally websites created to market specific project work and attract interest and donor funding from within the IT field. Most of the sites viewed are in English with clear audience targets. A few academic papers were also available and used (McLagan, 1996; Mojab, 2000, 2001; Warschauer, 2002). A primary research based independent review was not possible for this chapter. The project documents were read and coded according to the principles set out above in order to track embedded (in)appropriate technology design phases within inorganic community development processes.

Projects may be divided into a variety of purpose-based types: civil society development, eGovernance, social service development (eLearning, education, and health), and eCommerce. Interestingly, projects with similar purposes seemed to use similar cybertools aiming to achieve similar purposes. List serves are in evidence for civil society development, lobbying, and political activism (Jhai Foundation, 2003; McLagan, 1996; Mojab, 2000; 2001). Telekiosks provide government information to citizens (Sustainable Initiatives, 2003a). Telecenters are being used for teacher training and adult education in computer skills development (Global Catalyst Foundation, 2003; Madhusudan, 2002; Sustainable Initiatives, 2003a). Handheld devices are being used for remote access to medical advice (Vaid, 2003). Websites are used to market and sell co-operatively made goods directly to national and international consumers (Jhai Foundation, 2003; Sustainable Initiatives, 2003a).

Some of the noted project phases are not in evidence in the available documentation. For example, there is little documented evidence of the problem identification phase and how cybertools became central to project design. Where it is clear, user groups had either limited involvement or no involvement at all. In the Hole in the Wall experiment the surprise introduction of the tool resulted in cautious excitement amongst the child stakeholders and resentment in some of their parents (Madhusudan, 2002; Warshauer, 2002: 1–2). In other cases, as will be noted below, the failure to involve the community directly from the beginning resulted in unintended negative outcomes in terms of the usability of the technological tool in question as well as "development" impacts.

The development and use of localized, rugged, low-cost, linguistically appropriate hardware and software remains a challenge in these projects. A concern for green technology is even more obscure. The Simputer and the Village PDA are both handheld devices developed to be rugged and easy to use in othered contexts. However, there is no clearly stated need for their development at a village level (Simputer, n.d. & Village PDA, n.d.). ICT for development projects primarily continue to import or "leapfrog" outsider technologies, curricula, ideas, structures, and practices thereby minimizing the potential for human capacity building. Of the case studies, only the Jhai Foundation's Remote IT project in rural Laos and the Global Catalyst Foundation's refugee village teacher training project in Tanzania show elements of local community-based technological tool development.

The Jhai Foundation (http://www.jhai.org) has embedded a user-centered technology design project cycle within the wider community development project cycle and intends to result in rugged, long lasting, linguistically appropriate computers run by car batteries recharged by bicycles. The technological tools will enable the community—a village of people displaced from their traditional location during the U.S. war in Indochina—to access markets for their organic rice crops locally and to communicate with relatives who were displaced farther a field. The prototype design team includes educated Laotians, diaspora Laotians, non-Laotian technology designers, and consultations regularly with village level users.

Although the Global Catalyst Foundation's telecenters for teacher training and learning support in Tanzanian villages and refugee villages (http://www.globalcatalyst.org/pages/what_we_do/what_we_do_projects.htm) seem to have imported outsider hardware, community-based self-help teams were used to construct the buildings and biogas system which is being used to create 70% of the power needed to run the computers. Aside from the introduction of an element of "green" electricity and the involvement of local educationists and builders, the development and design phase of the project seems to have externalized end users.

The use of external hardware and software tools would be appropriate if there were evidence of financial and technical maintenance sustainability, adaptation, and cultural appropriation. Most of the projects include an element of fee-for-use structures which in turn may exclude use by the poor, or extremely poor. While locally appropriate fee structures might be able to support the maintenance of locally designed tools, it is likely to be too small to support maintenance of imported/localized tools. The Digital Village case study, a telecenter project, includes a video interview with Johannes Mphalhlele, telecenter manager, who says that the donor-funding paid for the technology, but not their long-term maintenance causing sustainability issues (Sustainable Initiatives, 2003b). Mark Warshauer's study of Cairo University's Media Lab project showed that computer labs embedded within higher education structures can be equally difficult to maintain over the long term (2002: 3). Smaller projects, such as the Handy Vaid, show that with apparently "simple" technologies and "simplified" software, outsider/literate locals must be trained and used if telehealth projects are to reach all proposed stakeholders (Vaid, 2003).

Documentation of community involvement in the process—more poignantly community leadership or centrality—is again difficult to determine from secondary sources and much of the available evidence was inconclusive. The impact of these case studies is also varied and dependent on the current location of the project within the project cycle. In many case studies limitations are a result of the nature of the information available about the project itself. However, there are some clear indications of challenges to achieving the theoretical goals of stronger communities and sustainable development.

The Hole in the Wall, for example, has been hailed as an excellent example of "minimally invasive learning", but Mark Warschauer has shown that some elements of the community found the project to be hegemonic, intrusive in schooling expectations, and foreign (2002: 1–2). List serves appear to have both positive and negative outcomes depending on the goals. Shahrzad Mojab found that while list serves for political action can allow diaspora members of the community to engage with civil society action and development from afar, face-to-face community meetings and action can regularly accomplish more (2001: 52–53). Meg McLagan's study of a different list serve project to communicate Tibetan point of view to outside audiences reinforced the possibilities of list serves and e-mail for lobbying political causes of marginalized or politically isolated groups within MDCs (1996). Telekiosks might help governments make simple information more easily available, but they assume a level of literacy, do not eliminate line-ups, and may require people to stand in a second line if they cannot find the information or a more difficult/personal question is raised. A telekiosk can also make interactive access to government structures more difficult by creating an unintended wall. This is particularly the case with telekiosks being one-way touch screen computers with no facility for the user to input/send comments. Finally, projects for job retraining and job hunting *via* the internet, both in Ireland and in Africa, show limited impact. The project in Ireland, documented by Mark Warschauer, showed that there may be more value in face-to-face support for unemployed job hunters (2002: 2–3). In the Digital Village, one user said that while he likes learning to use the computers, he was not convinced it would help him gain employment (Sustainable Initiatives, 2003b).

Ultimately there is a myriad of small projects already being carried out using (in)appropriate technology and community development models for inorganic community purposes. The quality, nature of design, and impact is undocumented in many cases making it difficult to properly assess project design against the model suggest above. Nevertheless, the evidence suggests there is a theory-practice gap under both theoretical legacies. Much of the documentation, particularly on the internet itself, focuses on the success of the technology, but not on community change. Documenting the social impacts of these tools would take the focus away from the tool and place attention on the human and social impacts—the real purposes of designing technology.

Since much of the technology was not developed locally and cannot be sustained locally, the success of that technology in meeting the needs for ruggedized, linguistically appropriate, ZeroCost, ecologically friendly technology is limited. Moreover, the unique cultural spaces, or the localized needs of potential users, continue to be marginalized in practice, or at least marginalized in documentation. The apparent exceptions are the Jhai Foundation Remote Village IT project and the Global Catalyst Foundation's teacher training project, but neither project is as yet at a place in the project cycle where community-impact is being documented. Where critical information is available, it is apparent that there are issues of cultural relevancy and sustainability in using outsider technologies to support local initiatives. As with the tea seller in Northern Afghanistan whose story started this chapter, decisions related to technologies as tools cannot be shaped or reasoned, but need to occur in an organic bottom-up process.

7. ALL THE WORLD'S A STAGE

The voices privileged in this chapter have largely been those of theory, academics, and organizations implementing pilot ICT for Development projects. Three sets of voices have been unintentionally marginalized—the policy voice, the user voice, and the radical deconstructionist voice. The policy voice is represented by bi- and multi-lateral donor agencies and United Nations agencies, which provide funding and technical support for large scale projects. Madhusudan (2002) writes that the Hole in the Wall is now being scaled up through support from the World Bank and other donors. Haddad and Draxler's book (2002) received funding from the Academy for Educational Development (AED) and the United Nations Education, Scientific and Cultural Organisation (UNESCO) and clearly sought to reflect policy and practice in ICTs for development by those agencies. Finally, the Jhai Foundation receives private funding and funding from several international agencies including the International Development Resource Centre (IDRC). Despite this support, the policy voice remains weakly heard in the represented voices. A critical study of the donor perspective and support for the theory of organic and inorganic community development as well as (in)appropriate technology is important to a future initiative, because donor policies have a heavy impact on the design and implementation of projects.

Important to the theory focused on herein, user voices, on both an individual and collective level, have been marginalized by failing to be heard above the English language context in online documentation and through translation. Although the Sustainable Initiatives website includes a few short videos of user opinions, local managers' opinions, and the real-use context, much more needs to be introduced into the body of available literature. Verbatim reporting of user experience, needs, and impacts of (in)appropriate tools would, despite translation to English, provide a clarified sense of power and appropriateness to the users. Experience and interaction would result in some direct filtering out of the voices of reporter, editor, and translator as much as possible. It is especially important that the voice of the poorest and most marginalized be sought. User experience will assist in providing wider direct influence between practitioners and users as well as increasing the power of individual marginalized voices to promote organic community development. The user can only be made central to project development, management, implementation, and learning if user voices are also made central to the documentation. Perhaps the only way to encourage this process would be for practitioners to adopt or to use post-modern anthropological methods in ethnography which engage directly with the user/community member and document through the use of ICTs and verbatim reporting (Ferguson, 1994; Pont, 2001; Tyler, 1986.). Although translation from indigenous languages to other languages will affect meaning and bring cultural coding and inference into question, there is no other way to empower marginalized voices within the research dichotomy.

The radical deconstructionist voice refers to the suggestion that in order to ensure that (virtual) community continues to develop and to be created organically; the entire international aid system should be dismantled.[3] One of the assumptions behind this voice is that all inorganic interventions in community are necessarily harmful or have lead communities into unnatural directions. Another is that the active de-globalization of economical, political, and social relations is possible, desired, and actively taking place. A third, but by no means final, assumption is that the emergency relief/humanitarian aid "branch" of development services is similarly no longer needed and that disaster relief can be done through other mechanisms already in place. The goal of this study was to understand and to develop a paradigm for understanding how ICTs might be designed and used as community development tools within the existing system. Although the author is herself an insider to the international development aid system, marginalizing the radical deconstructionist voice was not done deliberately. Within the context of the goals, there was simply no space for this viewpoint.

CONCLUSION

E. F. Schumacher promoted a utopian, if not problematic, post-industrial world of small localized ecology complete with small, and possibly non-industrialized, technology to support it. While he was not against progress, change, or development, Schumacher preferred a world wrapped in self-sustainability, independence, ecological balance, and cultural relevancy in action. Schumacher's legacy is represented in a body of practical applications promoting participatory development practices, which encourage the marginalized of this increasingly urban, economically globalized world to find space and voice for themselves without necessarily achieving transformative change for small, beautiful economies.

As part of the application of the post-colonial debate, theories of small development evolved into legacies of (in)appropriate technology use and inorganic community "development" in practitioner-led attempts to affect the organic processes of (virtual) community. Within the sphere of inorganic community development, the internet represents a series of tools which may enhance or enable the process while increasing the possible breadth of community membership to a glocal level, but which largely ignore the ecological issues.

The study of and reporting on results of using cyberspace tools in inorganic community development projects of different types are incomplete. Moreover, theory-project cycle-practice gaps indicate that more effort is needed in order to determine the real impact of cybertools in LDCs. While more independent research and documentation is needed on all levels, more real participation, ecology, and user-centeredness are also indicated as potential steps forward in human-centered development processes. In an effort to counter the voices of skepticism and unbridled enthusiasm for the use of cyberspace tools in LDCs, a greater effort should be made to translate and publish the verbatim voices of users, user-collectives, and potential others. If access to and use of the internet is really what half the world wants, then it is the role of the development practitioner to facilitate the introduction of the internet in a manner which is in keeping with the principles, theories, and legacies of the "development" field. In embracing the tools of the more/most developed elites, the less/least developed may find the power and voice that theory suggests they have.

ENDNOTES

1. Earlier iterations of this paper were read and commented on by D. Jason Nolan, David N. Wilson, and a committee of anonymous readers from the Knowledge Media Design Institute's Working Paper Series. I am grateful to them for their input. The ideas presented herein are entirely my own.
2. A collection of online articles and announcements related to the installation of cellular networks, internet access, and digital technology-based aid projects related to (re)constructing Kabul can be found at http://www.clevergirl.ca/zcc/index.php?cat=8 (last accessed June 6, 2004).
3. The third voice responds not to a specifically articulated theory or person(s) who put this argument forward. However, it is a popularly heard voice verbalized within "Western" academia and in particular within the context of some groups I have participated in at the Ontario Institute for Studies in Education. Despite a lack of documentation for this voice, I did not feel I could write this paper without acknowledging it. I acknowledge

Jason Nolan in particular who regularly plays devil's advocate by challenging me to respond to the radical deconstructionist voice.

Chapter 61: Broadband Technologies, Techno-Optimism and the "Hopeful" Citizen

MATTHEW ALLEN
Internet Studies, Curtin University of Technology, Perth, Australia

1. INTRODUCTION: BROADBAND AND VIRTUAL LEARNING ENVIRONMENTS

Using the internet to promote or facilitate learning has a relatively long history. As early as the mid-1980s, at a time when the internet itself was relatively experimental, a few early pioneers such as Hiltz were exploring the possibilities that networked computer communications technology could provide for education. Not only were universities the birthplace of the internet as a research network, they also had both staff with interests in using technology for learning as well as the critical infrastructure which might permit early development and adoption. But, with the widespread public uptake of the internet from 1994 onwards, online learning has become much more widespread—through traditional institutions of learning (schools, colleges, and universities), and also through the auto-didactic qualities of both the internet itself and many who use it; and finally through the opportunities which commercial "providers" of education and training imagine might be embedded in this new technology to deinstitutionalize learning.

In some ways, while institutions of learning, and learners themselves, have quietly got on with the business of education, delivered solely, primarily or with significant extension, through the internet, commercial expectations of significant for-profit education, enabled by the internet, have not been realized. While we might critically analyze some of the late 1990s enthusiasm for "elearning" as yet-more dot.com hucksterism, it is also important to consider that there is some truth in the claim that commercial online learning demanded far higher bandwidth than was readily available to most potential clients. The coming of broadband access, which is the primary focus of this chapter, might then suggest that a new phase of development will occur for those kinds of learning environments which depend on high bandwidth connectivity.

The development of internet-based learning has, until very recently, been specifically influenced by the narrowband access available to most teachers and students. For some, perhaps many, this influence has been positive, leading to a model of online learning that has been pre-dominantly driven by textual information and communication between teachers and students, largely conducted within a constructivist paradigm of learning. In the absence of the more traditional kinds of "classes" within which students mostly learn,

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1525–1547.

teachers have developed—and students have enthusiastically adopted—modes of instruction that do not depend on the audio-visual representation of lectures, or on awkwardly synchronous gatherings of many students, only a few of whom might be able to participate effectively in the time available. It might be argued that this approach was borne of necessity and has been a pale imitation of "real" online learning involving the transposition into the virtual of all elements we might normally associated with "classroom" learning. But, it would appear that, in fact, a new mode of learning has appeared which, while not replacing existing forms, provides important alternatives.

Broadband access, when widely available in society, might in time change this position, consigning the largely textual interactions of teachers and students in the past decade of online learning to an historian's footnote. Certainly, from a technologically determinist position, this outcome seems likely. Those favoring it argue that bandwidth demands such development, as if the width of the channel will necessarily bring more and more extensive content. But it is not clear, however, whether broadband will indeed effect this change, although undoubtedly as broadband access becomes more "natural" in societies it will encourage developments that utilize its capacity to allow distributed, audio-visually rich learning environments to emerge. To make reasonable predictions about the likelihood of this kind of development requires more than just a techno-fetishist belief in the pressure that technological change alone can bring. Rather it requires a more subtle understanding of the social, political, and economic contexts within which hardware and software are used.

This chapter provides just such a context, by way of an in-depth study of the deployment of broadband internet access in Australia in recent years. Firstly this study demonstrates that the link between online education and broadband technology is not merely a matter of content meeting bandwidth. Indeed it has become clear in Australia that the obsession with richly graphical, televisual-style content (of the kind we might associate with education delivered over the internet) has at best had little positive impact on broadband development. Rather, if broadband is to have a significant impact on improving or expanding virtual learning environments it is likely to come through changes in both the perception of internet users about the internet, sparked through the marketing and promotion of broadband, rather than the technology alone. It is also going to be heavily influenced by the embedded technological limitations and socio-economic conditions within which apparently neutral "technological" development actually occurs. Second, this chapter exemplifies the kind of thinking that must also be applied to online education itself, taking seriously the role of government, market and consumer/citizen internet users in making sense of technology. Broadband, whose absence is often imagined to be a "barrier" against adoption of virtual learning environments actually emerges as far more than a technological capacity that will solve problems just by becoming available. Similarly those learning environments themselves are not a given solution but, instead, a site for further contests of meaning over the roles the internet plays in society.

And, in Australia in 2003, nothing better represented the persistence of techno-optimism than the heavy promotion in print and electronic media of the "internet fridge"—an LG Electronics' product that features an internet-linked touch-screen/processor, mounted in the shiny stainless steel front of a domestic refrigerator. In the advertisements, what the beautiful, hip urban digerati are gaining from possession of this piece of domestic ingenuity is unclear . . . except of course that they are more hip, more beautiful, more digital. The internet fridge is a good example of the way that, in the 21st century and especially in developed nations such as Australia, internet technologies exist within social and political life as the result of the intersection of the marketing of internet-access products, the development of new technological systems for access, and irregular government regulation and policy pronouncements of the "need" for new forms of information and communication technology. My chapter explores this intersection by examining three cases, one each for marketing, government policy and regulation, and technology, that exemplify the issues of deployment and development of broadband in Australia.

The first case concerns the ongoing efforts of internet service providers (ISPs) in Australia to market broadband access products in 2003, paying particular attention to the way in which advertising reveals the complexity of the "users" who might use broadband in a residential setting. The second case focuses on the desires and strategies in government's policy making, constrained by a free-market ideology, to promote broadband "take up" in Australia and I will identify especially the way in which nationalism underpins and makes sensible this policy. The third case looks at how Australia's broadband access is, effectively, an ad-hoc, pragmatic implementation in which the decision-making process is almost entirely conducted within the private spaces of the free market producing a complex, "what we've got" approach to broadband infrastructure. My main focus here is on the way technology expresses other significant political and economic facets of the broadband picture.

2. MARKETING BROADBAND PRODUCTS

Three main advertising campaigns that aimed to sell broadband products, principally but not exclusively to residential consumers, were seen on Australian television in 2003. These advertisements were by no means the first, nor the last, for these services. Indeed, since January 2004 and some significant new service development by Telstra, such advertisements have become commonplace. But, in 2003, such advertisements were notable because they followed and to some extent reflected recent changes in the telecommunications and pay-television regulatory framework consequent upon decisions by the Australian Competition and Consumer Commission (ACCC) on pricing and corporate agreements. These decision, put simply, required Telstra (the primary wholesale provider of DSL access) to reduce its prices to retailers; and permitted greater freedom of integration between the Foxtel pay-TV provider (part-owned by Telstra and by News Corporation) and Telstra itself (McGrath, 2002; Velde, 2002; see also McCarthy, 2001). The initial result, by the end of 2002, was a dramatic increase in the number of DSL connections, taking this kind of access past cable connectivity for the first time since residential broadband became available in Australia (Turner, 2003). The advertising examples that I discuss below are a reasonable sample of the marketing initiatives of the past two years in Australia, in the way that the needs and interests of likely customers are characterized by various ISPs, and demonstrate some of the ways in which internet-related information technology is constituted as a benefit in contemporary Australian society. They are also significant, for the specific conclusions in this paper because, as indicated previously, government policy making in relation to broadband is significantly influenced by perceptions of the lack of awareness among consumers about the advantages of broadband (the so-called information asymmetry in the marketplace). Thus these examples of major marketing campaigns provide an opportunity to identify the environment in which that policy making operates.

The first example promoted the iPrimus brand (owned by Primus Telecommunications Group). Primus is Australia's third-largest telecommunications company, behind Telstra and Optus (the local brand of the multinational corporation, Cable and Wireless). The advertisements consisted of a series of short, humorous scenes that have nothing to do with the internet—a golfer sinking a long-distance putt, a couple of nervous teenagers about to kiss for the first time, and so on. Each one was an example of success in conditions of adversity or uncertainty; each was a variation on the classic literary theme of the promise of desire, unfulfilled. In the advertisement, at the crucial moment—as the ball is about to sink, the lips are about to meet—the action freezes and the slogan "disconnected" flashes on the screen, accompanied by sound effects of the kind of grinding noises that only a modem can make. These advertisements ran for at least three months, dispersed across various programs and channels and their central message continues to form the basis of the iPrimus marketing campaign, as stated on the website: "iPrimus Broadband also gives you Frustration Free Internet access with always on access and no unexpected dial-up disconnections or costly dial-up charges" (http://www.iprimus.com.au). By linking disconnection to games and romance, two primary reasons for online activity, the campaign zeroes in on one critical advantage of broadband over dial-up access. Clearly the campaign was designed principally to attract to iPrimus *existing* internet users, for whom the frustration of internet disconnection would be meaningful, rather than non-internet users.

The second advertising campaign came from Telstra, Australia's dominant telecommunications company (the partially-privatized successor to the former national monopoly telephone provider Telecom Australia) and the owner of the vast majority of the infrastructure over which internet services are delivered (for example, all local telephone exchanges belong to Telstra). The Telstra campaign, declared in May for July release (Sainsbury, 2003b) took place in two stages. Reflecting its enormous budget and market dominance, the campaign was clearly more expensive than that of iPrimus, both in terms of production values of the advertisements and in the fact that it was a two-stage campaign with longer advertisements. The first advertisement appears, until the very last moment, to be the story of a simple fisherman whose boat is at sea in a storm, then sunk by a whale and, upon washing up onshore, he is attacked by mediaeval knights, as well as experiencing many other unrelated and surrealistic phenomena in about 30 seconds of carefully crafted, digitally effected filmmaking. All is revealed in the end when he telephones his son and the scene changes to his son's bedroom where, as well as being on the phone, the child is doing is homework by finding information on the internet about (we assume) whales, knights, and so on—and that this information has "come to life" in some way because of the speed of downloading via broadband.

Promoting the "Bigpond" brand that Telstra has used for many years for its internet services, the advertisement (like iPrimus) provided no detail of costs or specific broadband arrangements. Rather the commercial created an aura of excitement and possibility that appears to make broadband (and more specifically Bigpond—hence the sea-based scenario) essential to a useful, entertaining and educational internet experience. So rich in detail, the advertisement was a masterpiece of open signification, calling upon its viewers to interpellate themselves into the text and draw from it the meanings that make sense to them, but which all place Telstra, and broadband itself, in a positive light. The follow-up advertisements were quite different. They simply promoted bundling Telstra telephony, internet, and pay-television subscription (repackaging an existing pay-TV service) to receive a modest discount each month (details that were repeated, prominently at http://www.telstra.com). The campaign was broad enough to attract many different kinds of new customers, or to retain existing customers; however it is also clear that, by emphasizing the link between pay television and the internet, Telstra appeared to be targeting those pre-identified customers (pay-tv subscribers) who are willing or able to prioritize media purchases (such as broadband access) in their household economies.

My third example is for Dodo Internet—a relatively new ISP that proclaims "Who says that the Dodo is extinct . . . Those people obviously don't know where we live. The truth of the matter is, we needed to stay low for a while whilst we became the very best Internet Service Provider (ISP)" (http://www.dodo.com.au). This company, named after a flightless bird, has a peculiarly incongruous slogan of "Dodo, Dodo, Internet that flies!" Its marketing in 2003 (which has continued into 2004) consisted of two low-budget television advertising campaigns—the first promizing cheap dial-up access; the second promising cheap broadband access (using ADSL). The advertisements involve a cartoonish "Dodo" character, dressed as a superhero, coming to the rescue of a person who just wants to know a simple answer to "can you get me a cheap connection to the internet?" In both cases, and as repeated on the company's website, the emphasis was on lower cost. The website was, in comparison to other ISPs, simple, even childish in its approach and subtly reinforced the explicit messages that Dodo is cheap. In fact, it is not clearly cheaper and in some cases is more expensive than other ISPs.

Dodo's marketing campaign was fundamental to its status as a developing business. As a new entrant into a market place with many hundreds of ISPs (though with only a few that are substantial in size), Dodo had to build brand recognition and, more importantly, distinctiveness. These advertisements were, it would appear, not designed to recruit existing internet users. Such users would be pre-disposed and quite capable of checking, online, the price relativities and would be unlikely to churn to a company whose bright, simplistic website implicitly signals value, not quality, if it were not in fact cheaper. Rather, these advertisements prompted viewers to identify with the confused and uncertain—even fearful—internet hopeful in the narrative, to whom Dodo came to the rescue. Not surprisingly, the advertisements drew on the tired, yet still persistent gendered representation of women as less-than-competent internet users. More significantly, these advertisements did little to distinguish between broadband and dialup access, while selling both. Since the same slogan "internet that flies" was used to promote both products, they do not clearly communicate on the difference in speed of a broadband connection. Equally, the Dodo website barely distinguished the two, unlike dozens of other ISPs that clearly identified the differences between dialup and broadband in terms of speed, convenience, and so on—establishing it as a "technological advance" and explaining how it might be cheaper than dialup in some circumstances. Thus, to a large extent, Dodo pitched its marketing at the novice user who might actually be confused by the technological decision-making required to choose from the complex array of products offered by more established ISPs.

Taken together, these three campaigns show the complexity of a highly competitive market and the diversity with which it can be approached by ISPs/telecommunications companies. The advertisements indicated the way ISPs were seeking to produce certain kinds of consumer-groupings to which they can appeal. IPrimus sought to churn users from existing dialup accounts. Telstra sought both the primary media-consuming customers as well as promoting the very idea of broadband (which would benefit Telstra since it is also a wholesale provider of broadband access). Dodo created a grouping of novice users concerned about price. Several key conclusions emerge, when these advertisements are linked with the overall state of the market for internet access in Australia, the realities of the technology, and the perceptions of those, such as the government's Broadband Advisory Group, who are—effectively—engaged in their own policy advertising campaign to promote broadband at a national level.

One significant feature to emerge from these campaigns was that online content was barely mentioned. While both Telstra and iPrimus offered some exclusive video content of the kind that would only be accessible for broadband users (for example, sporting packages on Telstra such as in-car camera footage from motor racing, and, for iPrimus, access to tropFest festival short films), neither company emphasized this content in the television advertising or on their websites. Telstra continued some key sports-content deals that were as much about Telstra's pre-existing commitment to sport through television broadcasting and part-ownership of the Foxtel pay-television network, thus suggesting that this content was as much an advertisement for that other business. Yet, in 2003, it ended specialized content deals from previous years for "unique" online content (Ferguson, 2003). Optus, which had previously emphasized an exclusive-content approach through its Optus@Home version of Excite@Home, did not emphasize content of this kind in its very limited marketing in 2003, even though it had previously engaged in one-off linkages with free-to-air television programs (such as the very popular *Big Brother* series) to provide some exclusive video content. The reshaping of pay television provision in Australia, through a deal in which, effectively, the main pay-TV networks share content, promoting competition between packages and channels, rather than between discrete networks, and the opportunity for bundling of pay-TV, telephony and internet meant that, from 2003, online content equivalent to the kinds of channels available by subscription was no longer relevant. Telstra and Optus would be competing against their own television products (see for example the comments of respected telecommunications commentator Paul Budde, 2003a). Instead (as indicated by recently released news of a linkage between Sony and Telstra for networked Playstation gaming [http://au.playstation.com/news/telstra.jhtml] and the existence of "gaming" ISPs such as OzForces, [http://www.ozforces.com/]), "content" for broadband is almost certain to be interactive computer-based services rather than television-equivalent channels.

Dodo, as a cut-price re-seller of DSL access purchased from Telstra, operates deliberately outside of content deals, limiting its operations to extracting the greatest possible return from the simplest service. Of all the hundreds of ISPs in Australia, almost none are in a position to offer content. And what emerged in 2003 was recognition by the main providers, Telstra and Optus, that content was not, of itself, of great significance as part of the marketing message. Rather, in all three cases I have discussed (and in the rash of advertisements appearing in Australia in 2004–2005), speed, always-on connectivity, and cost-effectiveness were the identified motivational approaches to attract a positive response to the commercials. Indeed, since most ISPs operate like Dodo (reselling wholesaled ADSL from Telstra) cost-effectiveness, speed and reliability were the messages consistently communicated on the ISP websites that explained the advantage of broadband. If content played any role in these website promotions, it was not "exclusive" or television-like content but, rather, normal internet non-exclusive content—software downloading, game playing, and file-sharing, as well as the end of the "world wide wait" (see for example http://www.iinet.net.au; and http://www.westnet.com.au, two of Western Australia's larger ISPs).

Secondly, these advertisements indicated the interrelationship, in business structures, of internet and non-internet business. Primus was one of the most successful of several new entrants to the deregulated telephone market in the late 1990s, utilizing Telstra's infrastructure for consumer access to wired telephony and internet services (and building its own mobile network). What distinguishes Primus, however, is that it has no access to a cable network for broadband delivery. Optus, the other leading telephony provider, was not offering a DSL services in 2003, (pending at that time a satisfactory commercial deal from Telstra, now achieved in 2004), Optus had an existing, well-regarded cable broadband service provided via its pay-TV hybrid fibre-optic/RF network (Sainsbury, 2003a). Primus could only offer DSL technology. Thus Primus must rely on Telstra's monopoly network. Yet, while utilizing Telstra's infrastructure for provision of DSL like the hundred or so retail broadband ISPs that do nothing but provide net access, Primus was and still is also attempting to compete at the much more general level as an all-in-one telecommunications carrier by offering bundled fixed and mobile telephone, with internet service. Here, then, we see how a bundle, in which a Primus phone connection and DSL access work together, improves Primus' profitability by permitting phone calls to be made at the same time. Always-on connectivity is, therefore, as much an advantage for a provider as for a customer. Similar arrangements also underpin Telstra's approach, with the added benefit for Telstra of its capacity to offer links to pay television. (Optus also agreed in 2003 that most of its internet subscription business is now part of phone-internet bundles: Sainsbury, 2003b; and, as with Telstra, benefits from phone and pay-TV bundling, AAP, 2003a).

Finally, only the first part of the Telstra campaign operated in anything but a pragmatic register. Other television advertisements (and most, if not all, of the related print and web-based advertising for broadband), focused on definable, current advantages such as speed, connectivity, and price, and eschewed broader visions of the power of the internet and information technology that might inspire or even bedazzle consumers. Oddly enough, Telstra's advertisement was similar to that of BT (British Telecom), another former-national monopoly provider that dominates its market because of control of local exchanges which must be enabled for DSL. This "high-profile campaign . . . revolved around the notion that there is so much content available on broadband—including dragons, pigs on motorbikes and Jarvis Cocker up a lamppost—that it burst the fat pipe and escaped onto the streets of London" (Sturgeon, 2002). While no doubt reflecting the greater marketing budget of such incumbent, dominant telecommunication companies, the similarity also suggests that since these companies benefit from an overall increase in broadband use, through their wholesale businesses, they are also conscious of the value of creating a general sense of enthusiasm for broadband, as well as specific arrangements relating to their own retail product line. These questions of how to typify the customers for broadband become particularly significant as I now turn to consider the second case, government policy.

3. POLICY FOR BROADBAND DEVELOPMENT

Governments around the world have, in one way or another, been heavily involved in the promotion of broadband technologies. In Australia, two key groups have been at work to consider these technologies and to promote a greater attention to them within government and in society generally. It was reported, by the Broadband Services Expert Group (BSEG), that "we see communications networks as a platform supporting, social interaction, education, health and government services, business relations, and our communications with the world"; that "During the next decade, the existing telecommunications network and broadband cable networks currently being established in major metropolitan areas will evolve to offer a range of interactive information and enhanced communication services"; that "Different technologies will be chosen for different areas, depending on the terrain, population density, the coverage required, and the type of service being delivered"; that rural and urban centers would become interlinked and that "Broadband services will probably be a key medium within our social and economic life within ten years" (from Chapter 1, and Chapter 4). Clearly, this committee believed that the interactivity enabled by broadband is critical for the national interest, as defined by Australia's place in an international environment. Using a metaphor uniquely suited to a land of beaches and ocean waves, it asserted: "Whether Australia catches the 'next wave' is up to Australians. If we are to remain internationally competitive, we must be willing to make the changes that will keep us at the forefront of new information and communication services" (Chapter 3).

Another committee (Broadband Advisory Group—BAG) demanded that attention be paid to broadband because "Broadband communications technologies can deliver substantial economic and social benefits to Australia. They reduce the constraint of distance and greatly increase the quality of communications in many sectors. Their defining characteristics (fast, always-on) enable a paradigm shift in the way people or resources (such as computers) interrelate. In short, broadband technologies can transform the way people live, work and do business" (p. 1). This committee argued that "Broadband networks are a platform for enhancing social, cultural and national cohesion" (p. 6), again, with particular reference to rural and regional Australia. This committee also indicated that, in future, health, education and government would operate quite differently when broadband becomes widespread (p. 1). Recognizing the diversity of technologies and geographies, the committee mandates an approach that explores all options, both wired and wireless. And, as with the first report that I cited, this committee believes Australia is compelled to move quickly on broadband because of the economic imperatives—"Broadband will be the roads and railways of the 21st century" and "if we lose momentum, we may be left behind in the wake of countries whose policy makers are enthusiastically embracing these emerging technologies" (p. 5; see also p. 32).

What I have deliberately avoided revealing is that these reports are nearly a decade apart in age. BAG's *Australia's Broadband Connectivity* was released in January 2003; BSEG's *Networking Australia's Future* dates from 1994. And, inevitably, there are some differences: not least that the internet is barely mentioned in 1994, there is much more emphasis on direct government intervention through funding, and the "user/producer" plays a more significant role than the "consumer" in the possibilities of network content development. Yet the degree of consensus between these groups is significant; and the language is almost identical, especially in the way that both reports express that indefinable sense of optimism mixed with fear—of opportunity and threat—that seems to have accompanied most of the policy documents and debates about the internet and related services over the past decade or more (see Allen, 2001; Allen & Long, 2004).

Similar language can be found in the "global" policy discussions and documents that are entwined with national policy formation. A recent ITU survey began by proclaiming:

> The development of broadband networks and services is a key issue for governments around the world. Broadband services are underpinning the development of e-commerce, and access to bandwidth at globally competitive prices is an increasingly important determinant of competitiveness in the global knowledge economy. Policies that encourage the provision of affordable broadband access to a nation's firms can put them ahead of global competitors. Those that fail to do so risk condemning their economies to secondary or subordinate roles. Access to broadband networks and services can also make important contributions to the quality of life, in terms of education, health services and social inclusion.
>
> (Houghton & Morris, 2001)

This persistent theme, combining hopefulness with a dash of fearfulness, can be found elsewhere, too. In 1993, Mitch Kapor contributed a telling piece for the third issue of *Wired*, that neon bible of the optimistic digerati. Kapor, an early and consistent advocate for the value of a particular kind of broadband networking, based on (indeed no different to) the internet as conceived by him and his Electronic Frontiers co-settlers, he wrote:

> First the visionaries sketched it out, then the computer literati caught on. Now the mainstream media is hyping it to the masses: a seamless high-speed network carrying voice, data, and video services to everyone. This information highway, we are told, will be used as a pipeline to bring an expanded universe of information and entertainment into the home and the workplace. . . .
>
> This dream has been promoted extensively, but until recently little visible progress has been made toward its realization. In the past, political gridlock has snarled telephone companies, newspaper publishers, cable television operators, and other potential players in lengthy and fruitless congressional and court battles. A justifiable cynicism developed to fill the gap between vision and reality.
>
> (Kapor, 1993)

Current thinking, at least in the words of one *Wired* contributor, is rather different:

> Ten years from now, when every PalmPilot can display video, a webcam is built into every monitor, and full-screen clips are commonly sent as e-mail attachments, the broadband metamorphosis will be complete. At that time, the egalitarian Net will be a distant memory—but no one will care. Users won't reminisce about the equalizing effect of 28.8 modems any more than car drivers yearn for a time when everyone had to drive equally slowly, because dirt roads hadn't been paved with asphalt. The free ride online is over; but the ride ahead will more than compensate for anything we've lost. The Net is dead. Long live the Net.
>
> (Platt, 2001)

Perhaps the most clear statement of the environment into which policy-makers are now venturing again, with a similar mindset to the mid-1990s, is from the most comprehensive research report on broadband to date (at least in relation to the U.S.A.), *Broadband: Bringing home the bits*:

> Broadband, the darling of techno-sophisticates and an object of interest to a growing number of politicians and government officials, as well as to the general public, is often misunderstood. The term itself, originating in the characterization of a communications channel's capacity (in contrast to narrowband), has come to be used as, among other things, a marketer's label for advanced cable television service, the 21st-century incarnation of the early 1990s "information superhighway", and one

element of the next stage in the development of the internet. Broadband has been a beacon for investors and a stimulus for entrepreneurs and mainstream businesses, and it has intensified debates about the public interest in information and communications infrastructure. It is as an enhanced means of access to the internet that broadband has begun to have real traction in terms of actual deployment and use, and it is in this sense that the term has become commonly understood. Years of assertions by technology gurus, business executives, and marketers about the potential promise of broadband have given way to a small but rapidly growing U.S. population who are using a first generation of broadband for faster internet access from their homes.

(CSTB, 2001: 43)

Thus we can see that hopes and fears of this kind are not in opposition. They are two expressions of the same underlying quality of engagement with new technology, namely *desire*. And, in Australia, the government has now plunged again into the rhetoric of desire, prominently displaying a discourse of national hopefulness for an internet and ICT-driven economic boom—after a period of relative inactivity in relation to ICT policy-making, coinciding with the dot.com bust (aside from some specific regulatory measures relating to pornography, gambling and, legislation against spam). As the recently departed Minister for Communications stated, in a media release announcing the formation of the National Broadband Strategy Implementation Group: "All levels of government realise the potential economic and community benefits that broadband can deliver" (Alston, 2003b).

The key themes within current Australian policy regarding broadband remain as they were in the 1990s (Allen, 2001). The government, perhaps even more than in the 1990s, emphasizes that it will not invest in networks directly—except in those special cases concerning research prototypes and to manage rural and regional political pressure. Thus, as explained in detail in the BAG report, the strategy to be pursued in the coming years involves a very limited role for the government, intervening only in the case of "market failures" and only then indirectly, by providing information to stimulate demand, or removing impediments to increased supply (BAG, 2003: 17). Indeed, "The principal strategy for the government is, as far as practicable, to rely on the private sector and market interactions as the primary vehicles for investment decisions and innovation" (p. 40; also Estens, 2002: 125 for a similar evocation of current government policy), enabling that strategy through "regulatory certainty" that involves the least possible intervention in the market place except through established pro-competitive arrangements (see Lavey, 2002, on the increased certainty that no regulation might bring).

Instead, the government proposes to play two active roles: first, as a consumer itself, utilizing its massive size as a user of broadband (in concert with other levels of government both state and local) to drive demand. Thus, the government's policy is not creating and managing the private sector so much as leaping in and controlling it from "inside", by being the ultimate "consumer" (BAG, 2003: 23–29). This approach has been warmly supported by other levels of government: see for example the recently published Western Australian state government follow up report WATIAC, 2003: xiv). The second role is to, once again, play marketeer. Just as in the 1990s (through events such as Online Australia Day—Allen, 2001), the next few years will see the government promote and market broadband, especially to businesses (as consumers of this service), but also still to everyday residential users. Throughout the BAG report, there are repeated references to the lack of knowledge, the failure of people in Australia to understand the benefits of broadband (pp. 3, 17, 55). Already, the government has begun a high-level promotional campaign in response, having funded what is, effectively, market research into consumer attitudes towards broadband (Alston, 2003a).

Just as the commercial promotion of broadband has increased in recent months, so too has governmental promotion. The National Office of Information Economy (NOIE) website [http://www.noie.gov.au] contains not just bureaucratic documents and the policy and political history of broadband development. It also has usable resources to assist users (should they even know that NOIE exists) to consider and utilize broadband more efficiently.

The ideological underpinnings of this policy initiative are critical if we are to make sense of the meanings which might be generated from a refusal to govern and an enthusiasm to consume and to promote. Fundamentally, the policy tries to be both global and national at the same time. While the details of the policy (i.e., what strategies to pursue) are deeply rooted in allegiance to the free market and the globalization of capital, broadband is also constituted as an area of vital *national* significance. The linkage between these two is flagged, clearly, in the hubristic claim that "the Government's main objective for the digital economy should be to stake Australia's claim to a disproportionate share of the benefits of the emerging global economy" (BAG, 2003: 16)—the global economy is an arena, thus, for national competition, even as the globalization of capital further separates the economic environment from any real semblance of national control. Equally, where these technologies self-evidently link citizens around the globe in ways that "nations" find hard to contain, broadband adoption is claimed to be essential for "national cohesion" (p. 16) through bringing Australians more closely together, despite time and spatial separation.

It is worth noting, too, that media reporting in Australia leading up to the formation of BAG, and during the time of its deliberations, and even now tends to be critical of Australia as "lagging" or "slipping" in broadband uptake. This reporting was primarily driven by lobbyists or advocates of the ICT industry. For example, the CEO of Alcatel, in 2001, was reported to have said "Lack of broadband makes Australia's claim to be a clever country quite embarrassing"... Citing the example of Singapore and Korea, Mr Fowler said it was not too late for Australia to catch up" (Hayes, 2001). Obviously linked to the straitened circumstances of the ICT industry in recent years (and also driven by a critique by both IT advocates, consumers and industry of Telstra's pricing policies) it is moot as to whether it had a direct effect on government policy or not. In the BAG report, there is a strong emphasis on claiming that international measures of access and participation are not actually relevant and that "In terms of assessing Australia's performance internationally, there is an additional problem because no international benchmarking relates to the type of goals being envisaged in Australia" (p. 43).

It was as if IT development in relation to broadband is being explained to Australians in terms of international sporting contests—that Australia is in competition with other nations and will be judged; that although Australia keeps being told it is not doing well, the government will try to change the rules, so Australia suddenly can do better! Within this policy discourse all Australians must, implicitly, accept this competitive challenge and attempt to get themselves connected to broadband. According to the government, being Australian once again (as it did in the 1990s) requires a degree of techno-optimism—of sharing the hopeful faith so that national desire can be translated into reality.

The Australian government, as well as considering broadband in 2003, also published a major report that is its guide to ICT industry policy for some years to come. Entitled *Enabling Our Future* (Framework for the Future Steering Committee, 2003), it was not dissimilar to the contributor to *Wired* cited above and to many other examples of quasi-utopian promotion of the new economy, digital revolution and so forth. For example, "Many of the new business opportunities for Australian firms will depend on their capacity to develop new ICT-based products and services which respond to the expanding role of ICT across the economy and society" and "Advanced networks will underpin future business opportunities for the ICT industry, and the way in which ICT is used to achieve national objectives" (p. 5). And, more generally, the report assumes, "The transformative role of ICT in society will continue, and accelerate over the next ten years" (p. 6). Government policy and action in Australia was, I argued in the previous paragraph, constructed spatially around the desire of the nation to be a leader internationally. But the government's work on broadband was also constructed around *temporal* leadership, of achieving that international success by, rhetorically, arriving at the future faster than other nations. And here, of course, policy becomes even more about selling techno-optimism, establishing a vision of the future whose promises, as shown by the extent to which the 2003 BAG report repeats much of the 1994 BSEG report as if nothing has actually changed, are by their nature unrealizable. They serve instead like the promises made by iPrimus, Telstra, Dodo, and others in building desire for broadband among their customers.

4. TECHNOLOGICAL CHARACTERISTICS OF THE BROADBAND MARKET

Broadband infrastructure in Australia, as in most other countries (with the notable exceptions of Singapore, to some extent, and South Korea), was not initially designed to support the kinds of fast internet-access services for which the term “broadband” is now commonly (if rather misleadingly) used. Rather they were designed for various distinct purposes: the traditional PSTN providing telephone and related telecommunications services (i.e., facsimile and limited EDI for, say, EFTPOS communications between merchants and banks); the provision of pay television (through either cable or satellite); the operation of radio communications; and, more lately, specialized telecommunications control operations in some distributed industries or services (i.e., power generation, water services, railways); the newly emerging third-generation mobile phone networks; and, finally, a telecommunications backbone to integrate all lower-level traffic through a small number of cable and satellite links (see ACA, 2003: 8–11; also AIEAC, 1999: 47–71). This patchwork of technologies cannot realistically support the aspirations of technology pundits and promoters, whether industry or government or the general community, not only because the technologies were not designed for widespread use but were, instead, retro-activated enablers, but also because each technology has developed and tends still to operate within quite distinct market-regulatory structures.

Each of these elements that, collectively, form the potential broadband network in Australia offers, essentially, a technological solution (current or potential) for particular consumers, but only rarely have been designed from scratch as a broadband data service. There are occasional one-off broadband service initiatives, such as the transACT network in the Australian Capital Territory or specific-purpose networks (normally in urban areas) for government departments, individual corporations, or research organizations (so-called “dark fibre”—Pearce, 2002a), and some local cabling of new housing developments. These developments only serve, however, to demonstrate the extent to which the vast majority of the broadband infrastructure has emerged from circumstance, rather than by design. Moreover, since they are normally offered either on the basis of government subsidies, or on full cost-recovery of the creation of the network, they also highlight how substantial, planned development of the highest-quality fibre-optic broadband networks is unlikely to occur, leaving Australia instead with its patchwork networks.

Take, for example, cable services. Unlike the U.S.A., with its long history of cable-based pay television, Australian pay-television services only arrived in the mid-1990s and were principally delivered through a limited cable rollout by Optus and Telstra at a time when, to most people, the internet was not significant (either as a technological service or a cultural formation) and future interactive data services utilizing cable were conceived as a limited addition to producer-distributed television viewing. As Telstra itself states:

> The other disadvantage for many Australians is that the Hybrid Fibre Cable Network is not available everywhere in Australia. It was purpose built to economically provide Pay TV services into densely populated residential areas. This means that in most regional centres, country areas and indeed in commercial and business areas in the major cities, it is not available. Simple economic realities have driven the distribution of this service. Nevertheless, some 2.1 million homes are passed by the Hybrid Fibre Cable and have access to Telstra's cable modem service, Telstra BigPond Broadband Cable
> [http://www.bigpond.com/broadband/access/cable/howitworks/
> Optus' cable network is roughly the same in terms of homes "passed", but only in Sydney, Melbourne and Brisbane.]

The original cable rollout was predicated on the inevitably over-enthusiastic predictions of pay television subscription, including Telstra's aim to cable 4 million homes by 1999; Optus had planned to include Adelaide. Pay television is now, in large part, being delivered by satellite service to those areas not cabled (see CIT, 1999). Moreover, the significant growth in housing development since the early 1990s, whether in inner city redevelopment or in outlying suburbs, means that the percentage of customers who can access cable is decreasing all the time: There are more than seven million households in Australia. Optus and Telstra cable sometimes passes both; while others, only a short distance away, receive neither. Furthermore, the cable network cannot sustain large numbers of users with high data traffic without slowing to a pace that, effectively, renders it the same or worse than dialup. In particular, the network design currently favors asymmetry—the reception of large quantities of data, with limited return traffic, and the network operators (Optus and, especially, Telstra) have utilized conditions of service to limit the capacity of the end-users of cable internet to become producers or servers of content.

The enthusiastic desire for uptake of DSL in 2003 also revealed the difficulties of developing broadband without a broadband network, per se. DSL technologies, of various kinds, rely on the use of different frequencies to carry voice and high-speed data traffic over the same copper wires simultaneously. Two key problems have emerged in Australia as more and more users attempt to access this broadband technology:

- Distance from an exchange to a house that exceeds the reliable / possible operating limit of DSL.
- Existing use of so-called pair-gain technology to provide two phone circuits from one twisted copper pair; a problem normally linked to RIMs (remote integrated multiplexers) either in exchanges or, worse, in roadside pillars) (see Chirgwin, 2002 for a very detailed explanation; Pearce, 2002b).

These problems, to some extent, reflect the original (and, for most consumers) ongoing primary purpose of the twisted copper-pair network: to provide voice telephony. As a Telstra spokesperson stated, in 2002, when the RIM/pair-gain problem began to emerge “these [systems] were built to cope with rising demand for voice rather than data services” (Sainsbury, 2002). The spacing of exchanges reflects the historical development of the telephone system, in some cases dating over 50 years; moreover, the expanding and changing urban topography has meant that cables often run longer distances than is optimum for ADSL telephony.

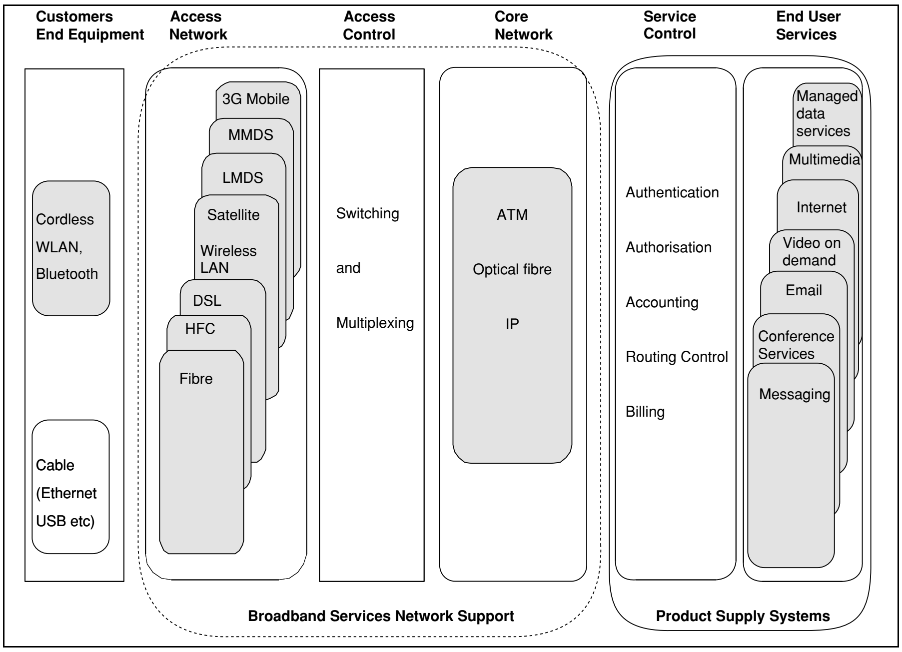
However significant problems exist in that ADSL may not be available at all. There are over 4,000 exchanges in Australia, of which 987 (pre-dominantly in affluent, inner urban areas) are ADSL enabled. Telstra signalled, towards the end of 2003, that it will not equip any more exchanges past 1000, unless there is significant demand from consumers, and has established (like BT in the United Kingdom) a demand register to permit it to make decisions on which exchanges to upgrade based on a guaranteed level of demand (see AAP, 2003b). Moreover, recent evidence by Telstra to a Senate Committee on telecommunication revealed that “each ADSL-enabled exchange was provisioned to a maximum of seven to eight per cent” (Hayes, 2003). A recent move by Agile to install its own ADSL-enabling equipment in a Telstra exchange might suggest some mitigation of the likely slowdown in ADSL capability, though perhaps this approach will simply transfer responsibility from Telstra to other companies (MacKenzie, 2003). Perhaps most importantly, even if these exchanges are enabled and some solution is found to the distance-from-exchange problem, there may still be upper limits on access depending on the size of the building, and the quality and nature of the CAN [Customer Access Network].

While Telstra rather positively maintained that it “continues to work towards overcoming current technical constraints on high speed internet access resulting from the historic deployment of network electronics” (Telstra, 2003), expert telecommunications analysts Budde Communications have concluded:

> We are now in a position where the physical twisted pair copper CAN [Customer Access Network] has almost reached the end of its useful life and it has to be replaced on a massive scale for several reasons including: Bandwidth and distance limitations, cost, age, and rising repair / maintenance costs. Pair Gain Systems (PGS) that were introduced in the 1980s are now reaching the end of their low maintenance lives and because the content in the CAN now includes high-speed data (Internet) to a high percentage of households, PGS now impede the bandwidth required for internet.
>
> (Budde, 2003b)

Satellite communications, a staple for Australians in remote areas, are offered for broadband service only at considerable expense, and often with a limited back-channel capability. While the availability of this kind of delivery technology allows Telstra to respond to criticism about the availability of broadband by asserting that satellite services provide 100% coverage, in actuality the technology is out of reach of most Australians, even with government subsidies for the most remote areas of country. Wireless developments, whether through mobile telephony spectrum, dedicated wireless, or wi-fi based WLANs, appear experimental at the moment, or limited in their capacity. Moreover, they raise significant regulatory questions, especially when they move from being essentially amateur or research-oriented projects to full-scale commercial services, and are likely to be carefully monitored by the Australian Communications Authority (ACA)—in part to ensure that existing radio spectrum uses do not suffer interference. And, finally, specialized networks (for example used in power generation control) are unlikely to be readily interconnected or used for all but the most limited public access, in light of significant security risks and the potential conflict between network uses.

What can we make of this technological jigsaw? The ACA has theorized, in a recent discussion paper on monitoring and quality assurance for broadband, that what makes broadband distinctive is the separation of the access points to the network, the core network itself, and the services and products available on that network. It represents this position thus:



Broadband Service Delivery Architecture (ACA, 2002: 9)

However, this theoretical architecture is very much a model that reflects a technologized view of how broadband services might develop, and does not reflect the operation of these technologies in a commercial environment, especially one in which one company (Telstra) exercises significant control over pricing, availability, and services of all manner of telecommunications and related services. In particular, this model does not demonstrate how certain network components have developed and now operate in close connection with a primary use that, even if might be said to require broad bandwidth (such as pay-TV), is hardly "broadband" as it is popular understood (fast access to a complex array of data services and interactions, such as the internet). Crucially, there has been all but no broadband development for the purposes of broadband because the investment required cannot be recouped, in a mass market, without a traditional "content" package whose ongoing revenues amortize the cost of the service and (in the cases of media) create a fixed audience for on-selling to advertisers.

The weakness of the model can also be seen in the development, in early 2004, of a major argument between Telstra and other broadband retailers concerning the fact that a new entry-level broadband package is being offered by Telstra at a price *below* that which Telstra charges for wholesale distribution. That Telstra's package was released at the same time as its main rival Optus returned to the broadband service market for the first time in some years only added to speculation concerning Telstra's motives. Immediate action was taken by the anti-competitive behavior regulator, the ACCC. While the outcome of this latest round of market-technological contestation is not clear (and will be discussed in a future article on this topic), what becomes clear is that any attempt to understand technology outside of commercial and regulatory pressures is impossible.

The model also does not account for the historical dimensions of the internet. The existing primary elements of the broadband network are available only because of, in one case, nearly a century of telephone development which, even as late as the early 1990s, was driven by the needs of voice telephony (hence the problems with the over a million Australians unable to get broadband because of RIM/ voice-only pair gain technology); and, in the other, the peculiar arrangements for the introduction of pay television in Australia. It does not indicate how new network components might emerge, successfully, because it does not identify the service-network linkage noted above: Only where some peculiar circumstance emerges (in, for example, the university sector) can specialized networks be developed for direct cost recovery. Finally, it does not include any real recognition of the regulatory work of bodies such as the ACCC (or indeed of the ACA itself), not only in relation to broadband networking but also such services as pay television which, because of the nexus between television cable just noted, effectively become moves that regulate, in one way or another, broadband service.

The exact same model could be applied to America and would not shed any light on the radical difference in the environment there, in which, with the same kinds of technological realities and possibilities, entirely different challenges develop because of the distinctive regulation of the services and infrastructures of communications, information services and television (see for example Frieden, 2003; Lavey, 2002). Fundamentally, what the particular situation in Australia shows, in relation to the ACA description, is that technology-centred models do not actually describe technology, for technology is embedded in the world of commerce, use, and regulation. It is not distinct from the patterns of interaction between governments, corporations and citizens/consumers but, while having an independent and influential existence, primarily acts as a medium to express the particular arrangement of these three elements in a particular time and place.

CONCLUSION

What these cases reveal, when placed together, is that technologies of the internet, such as broadband, are always more than just hardware and software. Such technologies are always the products of social and economic circumstances that, firstly, frame the meanings we make of them and constitute us as particular kinds of users and consumers of them; that secondly, create actual utility from hardware and software by permitting some kinds of services to become products, and not others; and that thirdly, are themselves the carriers of meaning.

The government imagines the "citizen", that elusive and ideal character of much national policy development and implementation in three ways. The citizen is required to play their part in the development of broadband infrastructure; must be subject to the government's limited efforts to improve that infrastructure; and be the beneficiary of a future that is, through technological development, much richer and more satisfying than the present. Essentially, since many if not all of the promises made by the current government promoters of broadband cannot be realized for some time (and, implicitly, not until a very large proportion of Australians get broadband), a national duty emerges for the real people who are citizens of this nation. Australians, within this policy framework, must be hopeful for the future—to accept techno-optimistic attitudes that mean they will accept and use broadband services even when there is no apparent, overwhelming need to do so—so as to create a consumer infrastructure into which services might then develop.

Such people must also, of course, be hopeful that the commercial products which are available to them as the actual method to become broadband users will work, for them, in their location, despite the technological difficulties that emerge from a network of broadband networks that was not designed for that purpose. Moreover, the broadband products which are being sold to them are constituted as much by the existing regulatory and commercial constructs that have create the telephone and pay-television industries which dominate provision of broadband. And in the meantime, the providers themselves are engaged in the production of techno-optimism, but with the very different purpose of selling their specific product to specific groups of consumers. Commercial realities, and differential capacities to access and utilize the technology, mean that not all of these messages about what broadband will do, what it is for, and how it will bring the future closer are quite what the government might have hoped for. Thus, in conclusion, I would suggest that, just as consumer/citizens are choosing from among many different packages and services that provide broadband connectivity, they are also choosing what that particular instance of broadband connectivity means for them. What will actually emerge as the future of broadband will lie in the way these choices are constructed, for consumers, by the confluence of technology, regulation and commerce and which choices, from within this limited set of possibilities, are most successful in the marketplace.

And, within this realm of constrained broadband, governed by the operations of the market and the realities of technological infrastructure, the choices consumer/citizens will make shall influence the development and success of virtual learning environments. Such environments may not, as I indicated at the start of this chapter, depend on high speed. Moreover, the degree to which consumers may or may not imagine that broadband makes the internet more "suitable" for learning than a narrowband network, will depend heavily on the way the "meaning" of broadband develops, guided by government enthusiasms for national adoption of ICTs and service providers' marketing campaigns. The availability of education online is likely to be partially influenced by the openness of access—across financial and physical constraints, and the "product" itself will need to compete with existing learning opportunities made faster and more constantly available by "always-on" broadband. Thus while more intensive learning environments might seem to fit naturally with the technological capacity of broadband, the regulated, socio-economic, cultural 'technology' of broadband may well hold surprise us in how it intersects with the further development of online education.

Chapter 62: The Matrix, or, the Two Sides of Perversion*

SLAVOJ ŽIŽEK
Institute for Sociology and Philosophy, University of Jubliana

When I saw The Matrix at a local theatre in Slovenia, I had the unique opportunity of sitting close to the ideal spectator of the film—namely, to an idiot. A man in the late 20s at my right was so immersed in the film that he all the time disturbed other spectators with loud exclamations, like "My God, wow, so there is no reality!" . . . I definitely prefer such naive immersion to the pseudo-sophisticated intellectualist readings that project into the film the refined philosophical or psychoanalytic conceptual distinctions.[1]

It is nonetheless easy to understand this intellectual attraction of The Matrix: is it not that The Matrix is one of the films which function as a kind of Rorschach test [http://rorschach.test.at/] setting in motion the universalized process of recognition, like the proverbial painting of God which seems always to stare directly at you, from wherever you look at it—practically every orientation seems to recognize itself in it? My Lacanian friends are telling me that the authors must have read Lacan; the Frankfurt School partisans see in the Matrix the extrapolated embodiment of Kulturindustrie, the alienated-reified social Substance (of the Capital) directly taking over, colonizing our inner life itself, using us as the source of energy; New Agers see in the source of speculations on how our world is just a mirage generated by a global mind embodied in the World Wide Web. This series goes back to Plato's Republic: does The Matrix not repeat exactly Plato's dispositif of the cave (ordinary humans as prisoners, tied firmly to their seats and compelled to watch the shadowy performance of (what they falsely consider to be) reality? The important difference, of course, is that when some individuals escape their cave predicament and step out to the surface of the Earth, what they find there is no longer the bright surface illuminated by the rays of the Sun, the supreme God, but the desolate "desert of the real". The key opposition is here the one between Frankfurt School and Lacan: should we historicize the Matrix into the metaphor of the Capital that colonized culture and subjectivity, or is it the reification of the symbolic order as such? However, what if this very alternative is false? What if the virtual character of the symbolic order "as such" is the very condition of historicity?

*Reprinted with permission of the Author.

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1549–1569.

Of course, the idea of the hero living in a totally manipulated and controlled artificial universe is hardly original: The Matrix just radicalizes it by bringing in virtual reality (VR). The point here is the radical ambiguity of the VR with regard to the problematic of iconoclasm. On the one hand, VR marks the radical reduction of the wealth of our sensory experience to—not even letters, but—the minimal digital series of 0 and 1, of passing and non-passing of the electrical signal. On the other hand, this very digital machine generates the "simulated" experience of reality which tends to become indiscernable from the "real" reality, with the consequence of undermining the very notion of "real" reality—VR is thus at the same time the most radical assertion of the seductive power of images.

Is not the ultimate American paranoiac fantasy that of an individual living in a small idyllic Californian city, a consumerist paradise, who suddenly starts to suspect that the world he lives in is a fake, a spectacle staged to convince him that he lives in a real world, while all people around him are effectively actors and extras in a gigantic show? The most recent example of this is Peter Weir's The Truman Show (1998), with Jim Carrey playing the small town clerk who gradually discovers the truth that he is the hero of a 24-hour permanent TV show: his hometown is constructed on a gigantic studio set, with cameras following him permanently. Sloterdijk's "sphere" is here literally realized, as the gigantic metal sphere that envelopes and isolates the entire city. This final shot of The Truman Show may seem to enact the liberating experience of breaking out from the ideological suture of the enclosed universe into its outside, invisible from the ideological inside. However, what if it is precisely this "happy" denouement of the film (let us not forget: applauded by the millions around the world watching the last minutes of the show), with the hero breaking out and, as we are led to believe, soon to join his true love (so that we have again the formula of the production of the couple!), that is ideology at its purest? What if ideology resides in the very belief that, outside the closure of the finite universe, there is some "true reality" to be entered?[2]

Among the predecessors of this notion, it is worth mentioning Phillip Dick's Time Out of Joint (1959), in which a hero living a modest daily life in a small idyllic Californian city of the late 50s, gradually discovers that the whole town is a fake staged to keep him satisfied. . . . The underlying experience of Time Out of Joint and of The Truman Show is that the late capitalist consumerist Californian paradise is, in its very hyper-reality, in a way irreal, substanceless, deprived of the material inertia. So it is not only that Hollywood stages a semblance of real life deprived of the weight and inertia of materiality—in the late capitalist consumerist society, "real social life" itself somehow acquires the features of a staged fake, with our neighbors behaving in "real" life as stage actors and extras. . . . The ultimate truth of the capitalist utilitarian de-spiritualized universe is the de-materialization of the "real life" itself, its reversal into a spectral show.

In the realm of science-fiction, one should mention also Brian Aldiss' Starship, in which members of a tribe live in a closed world of a tunnel in a giant starship, isolated from the rest of the ship by thick vegetation, unaware that there is a universe beyond; finally, some children penetrate the bushes and reach the world beyond, populated by other tribes. Among the older, more "naive" forerunners, one should mention George Seaton's 36 Hours, the film from the early 60s about an American officer (James Garner) who knows all the plans for the D Day invasion of Normandy and is accidentally taken prisoner by Germans just days before the invasion. Since he is taken prisoner unconscious, in a blast of explosion, the Germans quickly construct for him a replica of small American military hospital resort, trying to convince him that he now lives in 1950s, that America won the war and that he has lost memory for the last 6 years—the idea being that he would tell all about the invasion plans for the Germans to prepare themselves; of course, cracks soon appear in this carefully constructed edifice . . . (Did not Lenin himself, in the last 2 years of his life, lived in an almost similar controlled environment, in which, as we now know, Stalin had printed for him a specially prepared one copy of Pravda, censored of all news that would tell Lenin about the political struggles going on, with the justification that Comrade Lenin should take a rest and not be excited by unnecessary provocations.)

What lurks in the background is, of course, the pre-modern notion of "arriving at the end of the universe": in the well-known engravings, the surprised wanderers approach the screen/curtain of heaven, a flat surfaced with painted stars on it, pierce it and reach beyond—it is exactly this that happens at the end of The Truman Show. No wonder that the last scene of the film, when Truman steps up the stairs attached to the wall on which the "blue sky" horizon is painted and opens up there the door, has a distinct Magrittean touch: is it not that, today, this same sensitivity is returning with a vengeance? Do works like Syberberg's Parsifal, in which the infinite horizon is also blocked by the obviously "artificial" rear-projections, not signal that the time of the Cartesian infinite perspective is running out, and that we are returning to a kind of renewed medieval pre-perspective universe? Fred Jameson perspicuously drew attention to the same phenomenon in some of the Raymond Chandler's novels and Hitchcock's films: the shore of the Pacific ocean in Farewell, My Lovely functions as a kind of "end/limit of the world", beyond which there is an unknown abyss; and it is similar with the vast open valley that stretches out in front of the Mount Rashmore heads when, on the run from their pursuers, Eva-Marie Saint and Cary Grant reach the peak of the monument, and into which Eva-Marie Saint almost falls, before being pulled up by Cary Grant; and one is tempted to add to this series the famous battle scene at a bridge on the Vietnamese/Cambodgian frontier in Apocalypse Now, where the space beyond the bridge is experienced as the "beyond of our known universe".

And how not to recall that the idea that our Earth is not the planet floating in the infinite space, but a circular opening, hole, within the endless compact mass of eternal ice, with the sun in its center, was one of the favorite Nazi pseudo-scientific fantasies (according to some reports, they even considered putting some telescopes on the Sylt islands in order to observe America)?

2. THE "REALLY EXISTING" BIG OTHER

What, then, is the Matrix? Simply the Lacanian "big Other", the virtual symbolic order, the network that structures reality for us. This dimension of the "big Other" is that of the constitutive alienation of the subject in the symbolic order: the big Other pulls the strings, the subject does not speak, he "is spoken" by the symbolic structure. In short, this "big Other" is the name for the social Substance, for all that on account of which the subject never fully dominates the effects of his acts, i.e., on account of which the final outcome of his activity is always something else with regard to what he aimed at or anticipated. However, it is here crucial to note that, in the key chapters of Seminar XI, Lacan struggles to delineate the operation that follows alienation and is in a sense its counterpoint, that of separation: alienation IN the big Other is followed by the separation FROM the big Other. Separation takes place when the subject takes note of how the big Other is in itself inconsistent, purely virtual, "barred", deprived of the Thing—and fantasy is an attempt to fill out this lack of the Other, not of the subject, i.e., to (re)constitute the consistency of the big Other. For that reason, fantasy and paranoia are inherently linked: paranoia is at its most elementary a belief into an "Other of the Other", into another Other who, hidden behind the Other of the explicit social texture, programs (what appears to us as) the unforeseen effects of social life and thus guarantees its consistency: beneath the chaos of market, the degradation of morals, etc., there is the purposeful strategy of the Jewish plot. . . . This paranoiac stance acquired a further boost with today's digitalization of our daily lives: when our entire (social) existence is progressively externalized–materialized in the big Other of the computer network, it is easy to imagine an evil programmer erasing our digital identity and thus depriving us of our social existence, turning us into non-persons.

Following the same paranoiac twist, the thesis of The Matrix is that this big Other is externalized in the really existing mega-computer. There is—there HAS to be—a Matrix because "things are not right, opportunities are missed, something goes wrong all the time", i.e., the film's idea is that it is so because there is the Matrix that obfuscates the "true" reality that is behind it all. Consequently, the problem with the film is that it is NOT "crazy" enough, because it supposes another "real" reality behind our everyday reality sustained by the Matrix. However, to avoid the fatal misunderstanding: the inverse notion that "all there is is generated by the Matrix", that there is NO ultimate reality, just the infinite series of virtual realities mirroring themselves in each other, is no less ideological. (In the sequels to The Matrix, we shall probably learn that the very "desert of the real" is generated by (another) matrix.) Much more subversive than this multiplication of virtual universes would have been the multiplication of realities themselves—something that would reproduce the paradoxical danger that some physicians see in recent high-accelerator experiments. As is well known, scientists are now trying to construct the accelerator capable of smashing together the nuclei of very heavy atoms at nearly the speed of light. The idea is that such a collision will not only shatter the atom's nuclei into their constituent protons and neutrons, but will pulverize the protons and neutrons themselves, leaving a "plasma", a kind of energy soup consisting of loose quark and gluon particles, the building blocks of matter that have never before been studied in such a state, since such a state only existed briefly after the Big Bang. However, this prospect has given rise to a nightmarish scenario: what if the success of this experiment will create a doomsday machine, a kind of world-devouring monster that will with inexorable necessity annihilate the ordinary matter around itself and thus abolish the world as we know it? The irony of it is that this end of the world, the disintegration of the universe, would be the ultimate irrefutable proof that the tested theory is true, since it would suck all matter into a black hole and then bring about a new universe, i.e., perfectly recreate the Big Bang scenario.

The paradox is thus that both versions—(1) a subject freely floating from one to another VR, a pure ghost aware that every reality is a fake; (2) the paranoiac supposition of the real reality beneath the Matrix—is false: they both miss the Real. The film is not wrong in insisting that there IS a Real beneath the VR simulation—as Morpheus puts to Neo when he shows him the ruined Chicago landscape: "Welcome to the desert of the real". However, the Real is not the "true reality" behind the virtual simulation, but the void which makes reality incomplete/inconsistent, and the function of every symbolic Matrix is to conceal this inconsistency—one of the ways to effectuate this concealment is precisely to claim that, behind the incomplete/inconsistent reality we know, there is another reality with no deadlock of impossibility structuring it.

3. "THE BIG OTHER DOESN'T EXIST"

"Big Other" also stands for the field of common sense at which one can arrive after free deliberation; philosophically, its last great version is Habermas's communicative community with its regulative ideal of agreement. And it is this "big Other" that progressively disintegrates today. What we have today is a certain radical split: on the one hand, the objectivized language of experts and scientists which can no longer be translated into the common language accessible to everyone, but is present in it in the mode of fetishized formulas that no one really understands, but which shape our artistic and popular imaginary (Black Hole, Big Bang, Superstrings, Quantum Oscillation . . .). Not only in natural sciences, but also in economy and other social sciences, the expert jargon is presented as an objective insight with which one cannot really argue, and which is simultaneously untranslatable into our common experience. In short, the gap between scientific insight and common sense is unbridgeable, and it is this very gap that elevates scientists into the popular cult-figures of the "subjects supposed to know" (the Stephen Hawking phenomenon). The strict obverse of this objectivity is the way in which, in the cultural matters, we are confronted with the multitude of life-styles which one cannot translate into each other: all we can do is secure the conditions for their tolerant coexistence in a multicultural society. The icon of today's subject is perhaps the Indian computer programmer who, during the day, excels in his expertise, while in the evening, upon returning home, he lits the candle to the local Hindu divinity and respects the sacredness of the cow. This split is perfectly rendered in the phenomenon of cyberspace. Cyberspace was supposed to bring us all together in a Global Village; however, what effectively happens is that we are bombarded with the multitude of messages belonging to inconsistent and incompatible universes—instead of the Global Village, the big Other, we get the multitude of "small others", of tribal particular identifications at our choice. To avoid a misunderstanding: Lacan is here far from relativizing science into just one of the arbitrary narratives, ultimately on equal footing with Politically Correct myths, etc.: science DOES "touch the Real", its knowledge IS "knowledge in the Real"—the deadlock resides simply in the fact that scientific knowledge cannot serve as the SYMBOLIC "big Other". The gap between modern science and the Aristotelian common sense philosophical ontology is here insurmountable: it emerges already with Galileo, and is brought to extreme in quantum physics, where we are dealing with the rules/laws which function, although they cannot ever be retranslated into our experience of representable reality.

The theory of risk society and its global reflexivization is right in its emphasis one how, today, we are at the opposite end if the classical Enlightenment universalist ideology which presupposed that, in the long run, the fundamental questions can be resolved by way of the reference to the "objective knowledge" of the experts: when we are confronted with the conflicting opinions about the environmental consequences of a certain new product (say, of genetically modified vegetables), we search in vain for the ultimate expert opinion. And the point is not simply that the real issues are blurred because science is corrupted through financial dependence on large corporations and state agencies—even in themselves, sciences cannot provide the answer. Ecologists predicted 15 years ago the death of our forrests—the problem is now a too large increase of wood. . . . Where this theory of risk society is too short is in emphasizing the irrational predicament into which this puts us, common subjects: we are again and again compelled to decide, although we are well aware that we are in no position to decide, that our decision will be arbitrary. Ulrich Beck and his followers refer here to the democratic discussion of all options and consensus building; however, this does not resolve the immobilizing dilemma: why should the democratic discussion in which the majority participates lead to better result, when, cognitively, the ignorance of the majority remains. The political frustration of the majority is thus understandable: they are called to decide, while, at the same time, receiving the message that they are in no position effectively to decide, i.e., to objectively weigh the pros and cons. The recourse to "conspiracy theories" is a desperate way out of this deadlock, an attempt to regain a minimum of what Fred Jameson calls "cognitive mapping".

Jodi Dean[3] drew attention to a curious phenomenon clearly observable in the "dialogue of the mutes" between the official ("serious", academically institutionalized) science and the vast domain of so-called pseudo-sciences, from ufology to those who want to decipher the secrets of the pyramids: one cannot but be struck by how it is the official scientists who proceed in a dogmatic dismissive way, while the pseudo-scientists refer to facts and argumentation deprived of the common prejudices. Of course, the answer will be here that established scientists speak with the authority of the big Other of the scientific Institution; but the problem is that, precisely, this scientific big Other is again and again revealed as a consensual symbolic fiction. So when we are confronted with conspiracy theories, we should proceed in a strict homology to the proper reading of Henry James' The Turn of the Screw: we should neither accept the existence of ghosts as part of the (narrative) reality nor reduce them, in a pseudo-Freudian way, to the "projection" of the heroine's hysterical sexual frustrations. Conspiracy theories, of course, are not to be accepted as "fact"—however, one should also not reduce them to the phenomenon of modern mass hysteria. Such a notion still relies on the "big Other", on the model of "normal" perception of shared social reality, and thus does not take into account how it is precisely this notion of reality that is undermined today. The problem is not that ufologists and conspiracy theorists regress to a paranoiac attitude unable to accept (social) reality; the problem is that this reality itself is becoming paranoiac. Contemporary experience again and again confronts us with situations in which we are compelled to take note of how our sense of reality and normal attitude toward it is grounded in a symbolic fiction, i.e., how the "big Other" that determines what counts as normal and accepted truth, what is the horizon of meaning in a given society, is in no way directly grounded in "facts" as rendered by the scientific "knowledge in the real". Let us take a traditional society in which modern science is not yet elevated into the Master-discourse: if, in its symbolic space, an individual advocates propositions of modern science, he will be dismissed as "madman"—and the key point is that it is not enough to say that he is not "really mad", that it is merely the narrow ignorant society which puts him in this position—in a certain way, being treated as a madman, being excluded from the social big Other, effectively EQUALS being mad. "Madness" is not the designation which can be grounded in a direct reference to "facts" (in the sense that a madman is unable to perceive things the way they really are, since he is caught in his hallucinatory projections), but only with regard to the way an individual relates to the "big Other". Lacan usually emphasizes the opposite aspect of this paradox: "the madman is not only a beggar who thinks he is a king, but also a king who thinks he is a king", i.e., madness designates the collapse of the distance between the Symbolic and the Real, an immediate identification with the symbolic mandate; or, to take his other exemplary statement, when a husband is pathologically jealous, obsessed by the idea that his wife sleeps with other men, his obsession remains a pathological feature even if it is proven that he is right and that his wife effectively sleeps with other men. The lesson of such paradoxes is clear: pathological jealously is not a matter of getting the facts false, but of the way these facts are integrated into the subject's libidinal economy. However, what one should assert here is that the same paradox should also be performed as it were in the opposite direction: the society (its socio-symbolic field, the big Other) is "sane" and "normal" even when it is proven factually wrong. (Maybe, it was in this sense that the late Lacan designated himself as "psychotic": he effectively was psychotic insofar as it was not possible to integrate his discourse into the field of the big Other.)

One is tempted to claim, in the Kantian mode, that the mistake of the conspiracy theory is somehow homologous to the "paralogism of the pure reason," to the confusion between the two levels: the suspicion (of the received scientific, social, etc. common sense) as the formal methodological stance, and the positivation of this suspicion in another all-explaining global para-theory.

4. SCREENING THE REAL

From another standpoint, the Matrix also functions as the "screen" that separates us from the Real, that makes the "desert of the real" bearable. However, it is here that we should not forget the radical ambiguity of the Lacanian Real: it is not the ultimate referent to be covered/gentrified/domesticated by the screen of fantasy—the Real is also and primarily the screen itself as the obstacle that always-already distorts our perception of the referent, of the reality out there. In philosophical terms, therein resides the difference between Kant and Hegel: for Kant, the Real is the noumenal domain that we perceive "schematized" through the screen of transcendental categories; for Hegel, on the contrary, as he asserts exemplarily in the Introduction to his Phenomenology, this Kantian gap is false. Hegel introduces here THREE terms: when a screen intervenes between ourselves and the Real, it always generates a notion of what is In-itself, beyond the screen (of the appearance), so that the gap between appearance and the In-itself is always-already "for us". Consequently, if we subtract from the Thing the distortion of the Screen, we loose the Thing itself (in religious terms, the death of Christ is the death of the God in himself, not only of his human embodiment)—which is why, for Lacan, who follows here Hegel, the Thing in itself is ultimately the gaze, not the perceived object. So, back to the Matrix: the Matrix itself is the Real that distorts our perception of reality.

A reference to Levi-Strauss's exemplary analysis, from his Structural Anthropology, of the spatial disposition of buildings in the Winnebago, one of the Great Lake tribes, might be of some help here. The tribe is divided into two sub-groups ("moieties"), "those who are from above" and "those who are from below"; when we ask an individual to draw on a piece of paper, or on sand, the ground-plan of his/her village (the spatial disposition of cottages), we obtain two quite different answers, depending on his/her belonging to one or the other sub-group. Both perceive the village as a circle; but for one sub-group, there is within this circle another circle of central houses, so that we have two concentric circles, while for the other sub-group, the circle is split into two by a clear dividing line. In other words, a member of the first sub-group (let us call it "conservative-corporatist") perceives the ground-plan of the village as a ring of houses more or less symmetrically disposed around the central temple, whereas a member of the second ("revolutionary-antagonistic") sub-group perceives his/her village as two distinct heaps of houses separated by an invisible frontier . . . .[4] The central point of Levi-Strauss is that this example should in no way entice us into cultural relativism, according to which the perception of social space depends on the observer's group-belonging: the very splitting into the two "relative" perceptions implies a hidden reference to a constant—not the objective, "actual" disposition of buildings but a traumatic kernel, a fundamental antagonism the inhabitants of the village were unable to symbolize, to account for, to "internalize", to come to terms with, an imbalance in social relations that prevented the community from stabilizing itself into a harmonious whole. The two perceptions of the ground-plan are simply two mutually exclusive endeavors to cope with this traumatic antagonism, to heal its wound via the imposition of a balanced symbolic structure. Is it necessary to add that things stand exactly the same with respect to sexual difference: "masculine" and "feminine" are like the two configurations of houses in the Levi-Straussian village? And in order to dispel the illusion that our "developed" universe is not dominated by the same logic, suffice it to recall the splitting of our political space into Left and Right: a Leftist and a Rightist behave exactly like members of the opposite sub-groups of the Levi-Straussian village. They not only occupy different places within the political space; each of them perceives differently the very disposition of the political space—a Leftist as the field that is inherently split by some fundamental antagonism, a Rightist as the organic unity of a Community disturbed only by foreign intruders.

However, Levi-Strauss makes here a further crucial point: since the two sub-groups nonetheless form one and the same tribe, living in the same village, this identity somehow has to be symbolically inscribed—how, if the entire symbolic articulation, all social institutions, of the tribe is not neutral, but is overdetermined by the fundamental and constitutive antagonistic split? By what Levi-Strauss ingeniously calls the "zero-institution", a kind of institutional counterpart to the famous mana, the empty signifier with no determinate meaning, since it signifies only the presence of meaning as such, in opposition to its absence: a specific institution which has no positive, determinate function—its only function is the purely negative one of signaling the presence and actuality of social institution as such, in opposition to its absence, to pre-social chaos. It is the reference to such a zero-institution that enables all members of the tribe to experience themselves as such, as members of the same tribe. Is, then, this zero-institution not ideology at its purest, i.e., the direct embodiment of the ideological function of providing a neutral all-encompassing space in which social antagonism is obliterated, in which all members of society can recognize themselves? And is the struggle for hegemony not precisely the struggle for how will this zero-institution be overdetermined, colored by some particular signification? To provide a concrete example: is not the modern notion of nation such a zero-institution that emerged with the dissolution of social links grounded in direct family or traditional symbolic matrixes, i.e., when, with the onslaught of modernization, social institutions were less and less grounded in naturalized tradition and more and more experienced as a matter of "contract".[5] Of special importance is here the fact that national identity is experienced as at least minimally "natural", as a belonging grounded in "blood and soil", and as such opposed to the "artificial" belonging to social institutions proper (state, profession. . .): pre-modern institutions functioned as "naturalized" symbolic entities (as institutions grounded in unquestionable traditions), and the moment institutions were conceived as social artifacts, the need arose for a "naturalized" zero-institution that would serve as their neutral common ground.

And, back to sexual difference, I am tempted to risk the hypothesis that, perhaps, the same logic of zero-institution should be applied not only to the unity of a society, but also to its antagonistic split: what if sexual difference is ultimately a kind of zero-institution of the social split of the humankind, the naturalized minimal zero-difference, a split that, prior to signaling any determinate social difference, signals this difference as such? The struggle for hegemony is then, again, the struggle for how this zero-difference will be overdetermined by other particular social differences. It is against this background that one should read an important, although usually overlooked, feature of Lacan's schema of the signifier: Lacan replaces the standard Saussurean scheme (above the bar the word "arbre", and beneath it the drawing of a tree) with, above the bar, two words one along the other, "homme" and "femme", and, beneath the bar, two identical drawings of a door. In order to emphasize the differential character of the signifier, Lacan first replaces Saussure's single scheme with a signifier's couple, with the opposition man/woman, with the sexual difference; but the true surprise resides in the fact that, at the level of the imaginary referent, THERE IS NO DIFFERENCE (we do not get some graphic index of the sexual difference, the simplified drawing of a man and a woman, as is usually the case in most of today's restrooms, but THE SAME door reproduced twice). Is it possible to state in clearer terms that sexual difference does not designate any biological opposition grounded in "real" properties, but a purely symbolic opposition to which nothing corresponds in the designated objects—nothing but the Real of some undefined X which cannot ever be captured by the image of the signified?

Back to Levi-Strauss's example of the two drawings of the village: it is here that one can see it what precise sense the Real intervenes through anamorphosis. We have first the "actual", "objective", arrangement of the houses, and then its two different symbolizations which both distort in an amamorphic way the actual arrangement. However, the "real" is here not the actual arrangement, but the traumatic core of the social antagonism that distorts the tribe members' view of the actual antagonism. The Real is thus the disavowed X on account of which our vision of reality is anamorphically distorted. (And, incidentally, this three-levels dispositif are strictly homologous to Freud's three-levels dispositif of the interpretation of dreams: the real kernel of the dream is not the dream's latent thought which is displaced/translated into the explicit texture of the dream, but the unconscious desire which inscribes itself through the very distortion of the latent thought into the explicit texture.)

And the same goes for today's art scene: in it, the Real does NOT return primarily in the guise of the shocking brutal intrusion of excremental objects, mutilated corpses, shit, etc. These objects are, for sure, out of place—but in order for them to be out of place, the (empty) place must already be here, and this place is rendered by the "minimalist" art, starting from Malevitch. Therein resides the complicity between the two opposed icons of high modernism, Kazimir Malevitch's "The Black Square on the White Surface" and Marcel Duchamp's display of ready-made objects as works of art. The underlying notion of Malevitch's elevation of an everyday common object into the work of art is that being a work of art is not an inherent property of the object; it is the artist himself who, by preempting the (or, rather, ANY) object and locating it at a certain place, makes it the work of art—being a work of art is not a question of "why", but "where". And what Malevitch's minimalist disposition does is simply to render—to isolate—this place as such, the empty place (or frame) with the proto-magic property of transforming any object that finds itself within its scope into the work of art. In short, there is no Duchamp without Malevitch: only after the art practice isolates the frame/place as such, emptied of all its content, can one indulge in the ready-made procedure. Before Malevitch, a urinal would have remained just a urinal, even if it were to be displayed in the most distinguished gallery.

The emergence of excremental objects which is out of place is thus strictly correlative to the emergence of the place without any object in it, of the empty frame as such. Consequently, the Real in contemporary art has three dimensions, which somehow repeats within the Real the triad of Imaginary-Symbolic-Real. The Real is first here as the anamorphotic stain, the anamorphotic distortion of the direct image of reality—as a distorted image, as a pure semblance that "subjectivizes" objective reality. Then, the Real is here as the empty place, as a structure, a construction that is never here, experiences as such, but can only be retroactively constructed and has to be presupposed as such—the Real as symbolic construction. Finally, the Real is the obscene excremental Object out of place, the Real "itself". This last Real, if isolated, is a mere fetish whose fascinating/captivating presence masks the structural Real, in the same way that, in the Nazi anti-Semitism, Jew as the excremental Object is the Real that masks the unbearable "structural" Real of the social antagonism. These three dimensions of the Real result from the three modes to acquire a distance toward "ordinary" reality: one submits this reality to anamorphic distortion; one introduces an object that has no place in it; one subtracts/erases all content (objects) of reality, so that all that remains is the very empty place these objects were filling in.

5. THE FREUDIAN TOUCH

The falsity of The Matrix is perhaps most directly discernible in its designation of Neo as "the One". Who is the One? There effectively is such a place in the social link. There is, first, the One of the Master-Signifier, the symbolic authority. Even in the social life in its most horrifying form, the memories of concentration camp survivors invariably mention the One, an individual who did not break down, who, in the midst of the unbearable conditions which reduced all others to the egotistic struggle for bare survival, miraculously maintained and radiated an "irrational" generosity and dignity—in Lacanian terms, we are dealing here with the function of Y'a de l'Un: even here, there was the One who served as the support of the minimum of solidarity that defines the social link proper as opposed to the collaboration within the frame of the pure strategy of survival. Two features are crucial here: first, this individual was always perceived as one (there was never a multitude of them, as if, following some obscure necessity, this excess of the inexplicable miracle of solidarity has to be embodied in a One); second, it was not so much what this One effectively did for the others which mattered, but rather his very presence among them (what enabled the others to survive was the awareness that, even if they are for most of the time reduced to the survival-machines, there is the One who maintained human dignity). In a way homologous to the canned laughter, we have here something like the canned dignity, where the Other (the One) retains my dignity for me, at my place, or, more precisely, where I retain my dignity THROUGH the Other: I may be reduced to the cruel struggle for survival, but the very awareness that there is One who retains his dignity enables ME to maintain the minimal link to humanity. Often, when this One broke down or was unmasked as a fake, the other prisoners lost their will to survive and turned into indifferent living dead—paradoxically, their very readiness to struggle for the bare survival was sustained by its exception, by the fact that there was the One NOT reduced to this level, so that, when this exception disappeared, the struggle for survival itself lost its force. What this means, of course, is that this One was not defined exclusively by his "real" qualities (at this level, there may well have been more individuals like him, or it may even have been that he was not really unbroken, but a fake, just playing that role): his exceptional role was rather that of transference, i.e., he occupied a place constructed (presupposed) by the others.

In The Matrix, on the contrary, the One is he who is able to see that our everyday reality is not real, but just a codified virtual universe, and who therefore is able to unplug from it, to manipulate, and suspend its rules (fly in the air, stop the bullets . . .). Crucial for the function of THIS One is his virtualization of reality: reality is an artificial construct whose rules can be suspended or at least rewritten—therein resides the properly paranoiac notion that the One can suspend the resistance of the Real ("I can walk through a thick wall, if I really decide it . . . ", i.e., the impossibility for the most of us to do this is reduced to the failure of the subject's will). However, it is here that, again, the film does not go far enough: in the memorable scene in the waiting room of the prophetess who will decide if Neo is the One, a child who is seen twisting a spoon with his mere thoughts tells the surprised Neo that the way to do it is not point is not to convince myself that I can twist the spoon, but to convince myself that THERE IS NO SPOON . . . . However, what about MYSELF? Is it not that the further step should have been to accept the Buddhist proposition that I MYSELF, the subject, do not exist?

In order to further specify what is false in The Matrix, one should distinguish simple technological impossibility from fantasmatic falsity: time-travel is (probably) impossible, but fantasmatic scenarios about it are nonetheless "true" in the way they render libidinal deadlocks. Consequently, the problem with Matrix is not the scientific naivety of its tricks: the idea of passing from reality to VR through the phone makes sense, since all we need is a gap/hole through which one can escape. (Perhaps, an even better solution would have been the toilet: is not the domain where excrements vanish after we flush the toilet effectively one of the metaphors for the horrifyingly sublime Beyond of the primordial, pre-ontological Chaos into which things disappear? Although, we rationally know what goes on with the excrements, the imaginary mystery nonetheless persists—shit remains an excess which does not fit our daily reality, and Lacan was right in claiming that we pass from animals to humans the moment an animal has problems with what to do with its excrements, the moment they turn into an excess that annoys it. The Real is thus not primarily the horrifying disgusting stuff re-emerging from the toilet sink, but rather the hole itself, the gap which serves as the passage to a different ontological order—the topological hole or torsion which "curves" the space of our reality so that we perceive/imagine excrements as disappearing into an alternative dimension which is not part of our everyday reality.) The problem is a more radical fantasmatic inconsistency, which erupts most explicitly when Morpheus (the African-American leader of the resistance group who believe that Neo is the One) tries to explain to the still perplexed Neo what the Matrix is—he quite consequently links it to a failure in the structure of the universe:

> It's that feeling you have had all your life. That feeling that something was wrong with the world. You don't know what it is but it's there, like a splinter in your mind, driving you mad. /. . . / The Matrix is everywhere, it's all around us, here even in this room. /. . . / It is the world that has been pulled over your eyes to blind you from the truth. NEO: What truth? MORPHEUS: That you are a slave, Neo. That you, like everyone else, was born into bondage . . . kept inside a prison that you cannot smell, taste, or touch. A prison of your mind.

Here the film encounters its ultimate inconsistency: the experience of the lack/inconsistency/obstacle is supposed to bear witness of the fact that what we experience as reality is a fake—however, toward the end of the film, Smith, the agent of the Matrix, gives a different, much more Freudian explanation:

> Did you know hat the first Matrix was designed to be a perfect human world? Where none suffered, where everyone would be happy? It was a disaster. NO one would accept the program. Entire crops of the humans serving as batteries were lost. Some believed we lacked the programming language to describe your perfect world. But I believe that, as a species, human beings define their reality through suffering and misery. The perfect world was a dream that your primitive cerebrum kept trying to wake up from. Which is why the Matrix was re-designed to this: the peak of your civilization.

The imperfection of our world is thus at the same time the sign of its virtuality AND the sign of its reality. One could effectively claim that the agent Smith (let us not forget: not a human being as others, but the direct virtual embodiment of the Matrix—the big Other—itself) is the stand-in for the figure of the analyst within the universe of the film: his lesson is that the experience of an insurmountable obstacle is the positive condition for us, humans, to perceive something as reality—reality is ultimately that which resists.

The further inconsistency concerns death: WHY does one "really" die when one dies only in the VR regulated by the Matrix? The film provides the obscurantist answer: "NEO: If you are killed in the Matrix, you die here/i.e., not only in the VR, but also in real life/? MORPHEUS: The body cannot live without the mind." The logic of this solution is that your "real" body can only stay alive (function) in conjunction to the mind, i.e., to the mental universe into which you are immersed: so if you are in a VR and killed there, this death affects also your real body . . . . The obvious opposite solution (you only really die when you are killed in reality) is also too short. The catch is: is the subject WHOLLY immersed into the Matrix-dominated VR or does he know or at least SUSPECT the actual state of things? If the answer is YES, then a simple withdrawal into prelapsarian Adamic state of distance would render us immortal IN THE VR and, consequently, Neo who is already liberated from the full immersion in the VR shouls SURVIVE the struggle with the agent Smith which takes place WITHIN the VR controlled by the Matrix (in the same way he is able to stopbullets, he should also have been able to derealize blows that wound his body). This brings us back to Malebranche's occasionalism: much more than Berkeley's God who sustains the world in his mind, the ULTIMATE Matrix is Malebranche's occasionalist God.

Malebranche's "occasionalism" undoubtedly was the philosopher who provided the best conceptual apparatus to account for VR. Malebranche, a disciple of Descartes, drops Descartes's ridiculous reference to the pineal gland in order to explain the coordination between the material and the spiritual substance, i.e., body and soul; how, then, are we to explain their coordination, if there is no contact between the two, no point at which a soul can act causally on a body or vice versa? Since the two causal networks (that of ideas in my mind and that of bodily interconections) are totally independent, the only solution is that a third, true Substance (God) continuously coordinates and mediates between the two, sustaining the semblance of continuity: when I think about raising my hand and my hand effectively raises, my thought causes the raising of my hand not directly but only "occasionally"—upon noticing my thought directed at raising my hand, God sets in motion the other, material, causal chain which leads to my hand effectively being raised. If we replace "God" with the big Other, the symbolic order, we can see the closeness of occasionalism to Lacan's position: as Lacan puts it in his polemics against Aristoteles in Television,[6] the relationship between soul and body is never direct, since the big Other always interposes itself between the two. Occasionalism is thus essentially a name for the "arbitrary of the signifier", for the gap that separates the network of ideas from the network of bodily (real) causality, for the fact that it is the big Other which accounts for the coordination of the two networks, so that, when my body bites an apple, my soul experiences a pleasurable sensation. This same gap is targeted by the ancient

Aztec priest who organizes human sacrifices to ensure that the sun will rise again: the human sacrifice is here an appeal to God to sustain the coordination between the two series, the bodily necessity and the concatenation of symbolic events. "Irrational" as the Aztec priest's sacrificing may appear, its underlying premise is far more insightful than our commonplace intuition according to which the coordination between body and soul is direct, i.e., it is "natural" for me to have a pleasurable sensation when I bite an apple since this sensation is caused directly by the apple: what gets lost is the intermediary role of the big Other in guaranteeing the coordination between reality and our mental experience of it. And is it not the same with our immersion into VR? When I raise my hand in order to push an object in the virtual space, this object effectively moves—my illusion, of course, is that it was the movement of my hand which directly caused the dislocation of the object, i.e., in my immersion, I overlook the intricate mechanism of computerized coordination, homologous to the role of God guaranteeing the coordination between the two series in occasionalism.[7]

It is a well-known fact that the "Close the door" button in most elevators is a totally disfunctional placebo, which is placed there just to give the individuals the impression that they are somehow participating, contributing to the speed of the elevator journey—when we push this button, the door closes in exactly the same time as when we just pressed the floor button without "speeding up" the process by pressing also the "Close the door" button. This extreme and clear case of fake participation is an appropriate metaphor of the participation of individuals in our "postmodern" political process. And this is occasionalism at its purest: according to Malebranche, we are all the time pressing such buttons, and it is God's incessant activity that coordinates between them and the event that follows (the door closing), while we think the event results from our pushing the button . . . .

For that reason, it is crucial to maintain open the radical ambiguity of how cyberspace will affect our lives: this does not depend on technology as such but on the mode of its social inscription. Immersion into cyberspace can intensify our bodily experience (new sensuality, new body with more organs, new sexes . . .), but it also opens up the possibility for the one who manipulates the machinery which runs the cyberspace literally to steal our own (virtual) body, depriving us of the control over it, so that one no longer relates to one's body as to "one's own". What one encounters here is the constitutive ambiguity of the notion of mediatization[8]: originally this notion designated the gesture by means of which a subject was stripped of its direct, immediate right to make decisions; the great master of political mediatization was Napoleon who left to the conquered monarchs the appearance of power, while they were effectively no longer in a position to exercise it. At a more general level, one could say that such a "mediatization" of the monarch defines the constitutional monarchy: in it, the monarch is reduced to the point of a purely formal symbolic gesture of "dotting the i's", of signing and thus conferring the performative force on the edicts whose content is determined by the elected governing body. And does not, mutatis mutandis, the same not hold also for today's progressiver computerization of our everyday lives in the course of which the subject is also more and more "mediatized", imperceptibly stripped of his power, under the false guise of its increase? When our body is mediatized (caught in the network of electronic media), it is simultaneously exposed to the threat of a radical "proletarization": the subject is potentially reduced to the pure $, since even my own personal experience can be stolen, manipulated, regulated by the machinical Other. One can see, again, how the prospect of radical virtualization bestows on the computer the position which is strictly homologous to that of God in the Malebrancheian occasionalism: since the computer coordinates the relationship between my mind and (what I experience as) the movement of my limbs (in the VR), one can easily imagine a computer which runs amok and starts to act like an Evil God, disturbing the coordination between my mind and my bodily self-experience—when the signal of my mind to raise my hand is suspended or even counteracted in (the virtual) reality, the most fundamental experience of the body as "mine" is undermined. . . . It seems thus that cyberspace effectively realizes the paranoiac fantasy elaborated by Schreber, the German judge whose memoirs were analyzed by Freud[9]: the "wired universe" is psychotic insofar as it seems to materialize Schreber's hallucination of the divine rays through which God directly controls the human mind. In other words, does the externalization of the big Other in the computer not account for the inherent paranoiac dimension of the wired universe? Or, to put it in a yet another way: the commonplace is that, in cyberspace, the ability to download consciousness into a computer finally frees people from their bodies—but it also frees the machines from "their" people . . .

7. STAGING THE THE FUNDAMENTAL FANTASY

The final inconsistency concerns the ambiguous status of the liberation of humanity announced by Neo in the last scene. As the result of Neo's intervention, there is a "SYSTEM FAILURE" in the Matrix; at the same time, Neo addresses people still caught in the Matrix as the Savior who will teach them how to liberate themselves from the constraints of the Matrix—they will be able to break the physical laws, bend metals, fly in the air . . . . However, the problem is that all these "miracles" are possible only if we remain WITHIN the VR sustained by the Matrix and merely bend or change its rules: our "real" status is still that of the slaves of the Matrix, we as it were are merely gaining additional power to change our mental prison rules—so what about exiting from the Matrix altogether and entering the "real reality" in which we are miserable creatures living on the destroyed earth surface?

In an Adornian way, one should claim that these inconsistencies[10] are the film's moment of truth: they signal the antagonisms of our late-capitalist social experience, antagonisms concerning basic ontological couples like reality and pain (reality as that which disturbs the reign of the pleasure-principle), freedom and system (freedom is only possible within the system that hinders its full deployment). However, the ultimate strength of the film is nonetheless to be located at a different level. Years ago, a series of science-fiction films like Zardoz or Logan's Run forecasted today's postmodern predicament: the isolated group living an aseptic life in a secluded area longs for the experience of the real world of material decay. Till postmodernism, utopia was an endeavor to break out of the real of historical time into a timeless Otherness. With postmodern overlapping of the "end of history" with full disponibility of the past in digitalized memory, in this time where we LIVE the atemporal utopia as everyday ideological experience, utopia becomes the longing for the Real of History itself, for memory, for the traces of the real past, the attempt to break out of the closed dome into smell and decay of the raw reality. The Matrix gives the final twist to this reversal, combining utopia with dystopia: the very reality we live in, the atemporal utopia staged by the Matrix, is in place so that we can be effectively reduced to a passive state of living batteries providing the Matrix with the energy.

The unique impact of the film thus resides not so much in its central thesis (what we experience as reality is an artificial VR generated by the "Matrix", the mega-computer directly attached to all our minds), but in its central image of the millions of human beings leading a claustrophobic life in water-filled craddles, kept alive in order to generate the energy (electricity) for the Matrix. So when (some of the) people "awaken" from their immersion into the Matrix-controlled VR, this awakening is not the opening into the wide space of the external reality, but first the horrible realization of this enclosure, where each of us is effectively just a fetus-like organism, immersed in the pre-natal fluid . . . . This utter passivity is the foreclosed fantasy that sustains our conscious experience as active, self-positing subjects—it is the ultimate perverse fantasy, the notion that we are ultimately instruments of the Other's (Matrix's) jouissance, sucked out of our life-substance like batteries. Therein resides the true libidinal enigma of this dispositif: WHY does the Matrix need human energy? The purely energetic solution is, of course, meaningless: the Matrix could have easily found another, more reliable, source of energy which would have not demanded the extremely complex arrangement of the VR coordinated for millions of human units (another inconsusrency is discernible here: why does the Matrix not immerse each individual into his/her own solipsistic artificial universe? why complicate matters with coordinating the programs so that the entire humanity inhabits one and the same virtual universe?). The only consistent answer is: the Matrix feeds on the human's jouissance—so we are here back at the fundamental Lacanian thesis that the big Other itself, far from being an anonymous machine, needs the constant influx of jouissance. This is how we should turn around the state of things presented by the film: what the film renders as the scene of our awakening into our true situation, is effectively its exact opposition, the very fundamental fantasy that sustains our being.

The intimate connection between perversion and cyberspace is today a commonplace. According to the standard view, the perverse scenario stages the "disavowal of castration": perversion can be seen as a defense against the motif of "death and sexuality", against the threat of mortality as well as the contingent imposition of sexual difference: what the pervert enacts is a universe in which, as in cartoons, a human being can survive any catastrophe; in which adult sexuality is reduced to a childish game; in which one is not forced to die or to choose one of the two sexes. As such, the pervert's universe is the universe of pure symbolic order, of the signifier's game running its course, unencumbered by the Real of human finitude. In a first approach, it may seem that our experience of cyberspace fits perfectly this universe: is not cyberspace also a universe unencumbered by the inertia of the Real, constrained only by its self-imposed rules? And is not the same with VR in The Matrix? The "reality" in which we live loses its inexorable character, it becomes a domain of arbitrary rules (imposed by the Matrix) that one can violate if one's Will is strong enough . . . . However, according to Lacan, what this standard notion leaves out of consideration is the unique relationship between the Other and the jouissance in perversion. What, exactly, does this kean?

In "Le prix du progres", one of the fragments that conclude The Dialectic of Enlightenment, Adorno and Horkheimer quote the argumentation of the 19th century French physiologist Pierre Flourens against medical anesthesia with chloroform: Flourens claims that it can be proven that the anesthetic works only on our memory's neuronal network. In short, while we are butchered alive on the operating table, we fully feel the terrible pain, but later, after awakening, we do not remember it . . . . For Adorno and Horkheimer, this, of course, is the perfect metaphor of the fate of Reason based on the repression of nature in itself: his body, the part of nature in the subject, fully feels the pain, it is only that, due to repression, the subject does not remember it. Therein resides the perfect revenge of nature for our domination over it: unknowingly, we are our own greatest victims, butchering ourselves alive . . . . Is not it also possible to read this as the perfect fantasy scenario of inter-passivity, of the Other Scene in which we pay the price for our active intervention into the world? There is no active free agent without this fantasmatic support, without this Other Scene in which he is totally manipulated by the Other.[11] A sado-masochist willingly assumes this suffering as the access to Being.

Perhaps, it is along these lines that one can also explain the obsession of Hitler's biographers with his relationship to his niece Geli Raubal who was found dead in Hitler's Munich apartment in 1931, as if the alleged Hitler's sexual perversion will provide the "hidden variable", the intimate missing link, the fantasmatic support that would account for his public personality—here is this scenario as reported by Otto Strasser: "/. . . / Hitler made her undress while he would lie down on the floor. Then she would have to squat down over his face where he could examine her at close range, and this made him very excited. When the excitement reached its peak, he demanded that she urinate on him, and that gave him his pleasure".[12] Crucial is here the utter passivity of Hitler's role in this scenario as the fantasmatic support that pushed him into his frenetically destructive public political activity—no wonder Geli was desperate and disgusted at these rituals.

Therein resides the correct insight of The Matrix: in its juxtaposition of the two aspects of perversion—on the one hand, reduction of reality to a virtual domain regulated by arbitrary rules that can be suspended; on the other hand, the concealed truth of this freedom, the reduction of the subject to an utter instrumentalized passivity.

ENDNOTES

1. If one compares the original script (available on the internet) with the film itself, one can see that the directors (Wachowski brothers, who also authored the script) were intelligent enough to throw out too direct pseudo-intellectual references, like the following exchange: "Look at 'em. Automatons. Don't think about what they're doing or why. Computer tells 'em what to do and they do it." "The banality of evil." This pretentious reference to Arendt totally misses the point: people immersed in the VR of the Matrix are in an entirely different, almost opposite, position in comparison with the executioners of the holocaust. Another similar wise move was to drop the all too obvious references to the Eastern techniques of emptying your mind as the way to escape the control of the Matrix: "You have to learn to let go of that anger. You must let go of everything. You must empty yourself to free your mind."
2. It is also crucial that what enables the hero of The Truman Show to see through and exit his manipulated world is the unforeseen intervention of his father—there are two paternal figures in the film, the actual symbolic–biological father and the paranoiac "real" father, he director of the TV-Show who totally manipulates his life and protects him in the closed environment, played by Ed Harris.

7. The main work of Nicolas Malebranche is Recherches de la verite (1674–75, the most available edition Paris: Vrin 1975).
8. As to this ambiguity, see Paul Virilio, The Art of the Motor, Minneapolis: Minnesota University Press 1995.
9. The notion of this connection between cyberspace and Schreber's psychotic universe was suggested to me by Wendy Chun, Princeton.
10. A further pertinent inconsistency also concerns the status of intersubjectivity in the universe run by the Matrix: do all individuals share the SAME VR? WHY? Why not to each its preferred own?
11. What Hegel does is to "traverse" this fantasy by demonstrating its function of filling in the pre-ontological abyss of freedom, i.e., of reconstituting the positive Scene in which the subject is inserted into a positive noumenal order. In other words, for Hegel, Kant's vision is meaningless and inconsistent, since it secretly reintroduces the ontologically fully constituted divine totality, i.e., a world conceived ONLY as Substance, NOT also as Subject.

Chapter 63: Learning by Being: Thirty Years of Cyborg Existemology

STEVE MANN
Department of Electrical and Computer Engineering, University of Toronto, Canada

1. INTRODUCTION

Since my childhood, a personal hobby of mine has been the functional modification of my own body, through technology. This modification often took the form of creating new sensory capabilities, as well as (what were to become eventually successful) attempts at correcting learning disabilities, such as visual memory impairment. I have had very particular experiences that speak to what it means to live within a virtual, and more importantly, a mediated (i.e., computationally modified) learning environment. I did not just experience virtual reality, mediated reality, etc., I became a cyborg, invented the technologies I needed to become a cyborg and then have spent 30 years learning and teaching about what it means to exist in a cyborg state. Originally I did this in private, but around 20 years ago I started, wearing a full computer system more openly, which resulted in my being referred to as a "cyborg" (although I do not particularly like the term because it is such a "loaded" term so heavily co-opted by science fiction). I came to best understand the term "cyborg" through a variety of discussions I had with Manfred Clynes, who coined the term. Thus I prefer to limit use the term to the Clynes sense, i.e., a synergy between human and machine that happens without conscious thought or effort (Clynes would often tell me that a person riding a bicycle was a cyborg because he or she would, after a while, forget that they were technologically modified).

As a "cyborg" (Mann, 2001) in the sense of long-term adaptation to the modified body, one encounters a new kind of existential self-determination and mastery over one's own environs (and to some degree, one's own destiny). Presently, in addition to having the internet and massive databases and video at my beck and call most of the time, I am also connected to others. While I am grocery shopping, my wife—who may be at home or in her office—sees exactly what I see and helps me pick out vegetables. She can imprint images onto my retina while she is seeing what I see. I call this collaborative mediated reality. I hope to add to the population of similarly equipped people; in the Fall of 1998, at the University of Toronto, I taught what I believe to be the world's first existemology course.

Existemology pertains to not just body modification, through technology ("cyborg primitives") but also to mind modification through long-term

J. Weiss et al. (eds.), The International Handbook of Virtual Learning Environments, 1571–1592.

adaptation. In this sense, existemology also extends into what I call the "post-cyborg" age, and thus also applies to the creation of a new state-of-mind that can persist after the technological prostheses are removed. In the sense that I found that this new state of mind could comprise an improvement, I thus encountered existemological therapy (i.e., improved condition even if the body modifications are removed or become damaged or inoperative).

The general ideas of existemology are themselves applicable to learning environments that have nothing to do with bodyborne computing. To some degree, beyond whether the technology is implanted, worn, carried, or non-existent, what can be learned is an educational paradigm that embodies an epistemology of personal choice, and the metaphysics of personal freedom, growth, and development.

2. FROM "LEARN BY DOING" TO "LEARN BY BEING": EXISTEMOLOGY AS A CONTINUATION OF CONSTRUCTIONIST LEARNING

"Love is a better master than duty"

—Albert Einstein

I begin by contextualizing my current teaching practice, and then expand upon how my "cyborg" existence led up to this current practice.

MIT is known for its Constructionist Learning, and in fact a new building is now being built at MIT, with a 42 million dollar donation, to house MIT's Constructionist Learning research effort. Constructionist Learning is, loosely speaking, "learn by doing and creating" (See, for example, http://www.jasonnolan.net/papers/doing.html).

What I mean by existemology is "learn by being" in the sense of a technologically self-modified being that encompasses long-term adaptation.

It includes a kind of "deconstructist learning" toward an emphasis on learning by involvement (learning by involvement in that which matters to the individual who is learning—learning by "being" at one with the subject matter).

This approach has worked very well for teaching personal cybernetics, wearable computing, and personal imaging, e.g., so students can learn by being at one with the very machine they are trying to learn about. But existemology can be applied to other research topics.

Existemology follows naturally in the evolution from traditional learn by rote, to building upon (De)Constructionist Learning, and onward.

I further developed existemology through a graduate level course, (course number ECE1766), beginning September 1998 (See Figure 1). In this course, I not only taught students about Personal Imaging, EyeTap, and Wearable Computer (WearComp), but I also taught them how to learn by "being at one with the machine". By becoming at one with the machine, they, in effect, became the machine. In this way, they learned by "being" the computer, and

Figure 1. Wearing my eyeglasses which embody the EyeTap technology of both image capture and image display (the special glasses look just like ordinary bifocal eyeglasses) I teach a class of about 20 students, how to become one with the machine. Here I teach how to use the standard Xybernaut wearable computer product. I also teach the students how to build their own systems, and many of the new scientific principles in the emerging field of Personal Cybernetics.

discovering the existential principle of self-empowerment and self-exploration which typically happens after a couple of months of continuous use of a WearComp system.

With more than 20WearComps, facilitated by in-kind equipment donations of various components from Xybernaut, clear-NET, WaveRider, Kodak, and various other companies, I taught my course with an emphasis on networked multimediated visual reality (loosely speaking "how to become a photographic cyborg"). This course allowed students to create their own version of reality, in their ordinary day-to-day living. What I discovered, is that students learned a great deal more, and explored a great many different avenues of pursuit, than is typically the case in a traditional "learn by lecture", or even a constructionist "learn by doing + creating" course.

Such an approach gave rise to an epistemology of choice, in the interpretation of a computer-mediated reality that captures the essence of post-modernist deconstructionism. This "deconstructionist learning" involves not just putting things together, but also taking things apart to learn how they work. Thus an important element of a "deconstructionist education" (DeconEd) is learning the art of *reverse engineering*.

I found in my ECE1766 course, that the desire to participate was overwhelming. It was delightful to see the tremendous desire to learn, even among student "listeners" who do not get course credit.

It is unusual to find students so eager to learn that many who do not need the course credit still attend. However, in my course, this was very much the case.

It seems that a new concept in education has been discovered—a new concept in education that awakens a passionate quest for knowledge—not merely the facts presented on corporate device specifications sheets that can make us more useful to society, but also the hidden secrets of how things work, and how they were originally invented.

If science should be "unlocking (or discovering) the secrets of God", then, at least in some ways, computer science can be unlocking (or discovering) the secrets of corporations (i.e., other humans working in the corporations that produce proprietary products, etc.).

Deconstructionist learning particularly emphasizes this approach to understanding how things work, by taking them apart. This echoes my early childhood experiences of building various systems from a zero budget, through the collection of junk, garbage, and various refuse, to repurpose in new ways. Thus my life was one of creative exploration in first understanding how things work, and then using that understanding to synthesize new inventions from the components found in existing technologies, combined with the new technologies that I invented.

At the time, much of what I was doing would later seem like science fiction to others. The fact that many of my cyborg technologies of self-modification pre-dated the later "borglike" visions of science fiction, made it all the more difficult to explain these concepts to my peers, because there was not even the reference in science fiction at that time, as a basis for explanation.

In the early days, most of the discrimination that I faced was peer discrimination, rather than institutionalized discrimination by authority figures. Thus the main difficulties of my childhood were more from communal changing of clothes associated with sports, or gym class, rather than from the official machinery of airport security, which then was quite lax.

There was eventually to be a reversal, in which I found a great deal of peer acceptance, whereas the large organizations turned against my vision of the future. In particular, as time progressed, it became more socially acceptable to be a computer enthusiast, and the eventual (more recent) visions of science fiction gave a fun and creative reference. With commercial interest in my inventions, it even became fashionable to some extent, and people would often come over and talk to me, being very interested in the project. Although some of this change could be attributed to improvements in my inventions and designs, even when I re-connected to older systems I found the peer response (e.g., the general reactions from the public) to have become positive. Whereas people used to walk across the street to avoid me, or laugh at me, or be negative in other ways in the 1970s, and early 1980s, I had found peer acceptance started around 1984 (the era of new-wave androgyny where the blurring of gender lines seemed to make the blurring of human-machine lines equally acceptable). By the 1990s, the peer acceptance spread from the fringes of new-wave androgyny, the arts, and those on the creative fringes, to a more mainstream peer acceptance.

But the institutionalized acceptance diminished over time. Institutionalized discrimination began around 1985 when peer acceptance had just picked up. For example, while boarding the subway in Toronto, I was approached by concerned security guards, in the summer of 1985. The discrimination appeared to be correlated to security, and thus I found myself, as the years progressed, being terrorized by security guards, who threatened to use force to advance their political agenda of "security". It seemed that the more "security" there was, the more cyborg discrimination. This kind of annonyance intensified through the 1990s, with an unfortunate incident perpetrated by Air Canada (See for example, Paul Virilio, Crepuscular Dawn, pages 96–98).

2.1. Existential Contraband

More recently, for example, I was required to go to the US embassy to apply for a passport for my daughter (since she was born in the U.S.), but I was not allowed into the embassy because I was an electronic device, and electronic devices were considered contraband.

Thus I was simultaneously required to enter the embassy to get the passport, but not allowed to enter the embassy. In the end, the officials came out, and I swore my oath down at street level, rather than go up to the office, but this situation simply serves as an example of the absurdity of existential contraband that occurs when the body is permanently enjoined with technology.

3. WEB SURFERS' RIGHT-OF-WAY FOR BEACH ACCESS

3.1. Securityranny and Sabetyanny

Another example of institutionalized discrimination is in the realm of providing free wireless connectivity for a community of cyborgs. Back in the 1980s and 1990s this was viewed with great welcome by the official powers that be, as being a good thing. It attracted a lot of positive press coverage in the 1990s, and set forth a foundation upon which others built.

However, more recently, with new technologies that make it easier to support online access for cyborgs and for everyone, there is also a hysteria around the perceived liability issues. In the early days I had to build my own wireless equipment, and I had to help others build systems to get online on my network. I was, for example, welcomed by the New England Spectrum Management Council to establish online connectivity for my community of cyborgs in the early 1990s.

But more recently, when it is so much easier with new technologies like 802.11 wireless, the discrimination is mostly institutional. For example, officials feel that internet access should not be freely available to anyone, because it could be used by terrorists, or copyright violators. These officials wished to impose security constraints on the network to prevent unauthenticated access.

So I constructed an "urbeach access" metaphor, e.g., that the internet is like an urban beach, that should allow access, right-of-way. With a traditional beach, property owners are often required to provide a public right-of-way that provides beach access. Property owners who build high fences all the way around all of the property, in the name of "security", are, through this excess security, denying that right-of-way could also thus incur liability. In addition to preventing people from enjoying the beach on hot summer days, property owners who, through security excess, deny bathers access rights could risk liability, e.g., if someone suffered heat stroke because they could not exercise their lawful right of access to the beach, or a more extreme case might be if someone spilled battery acid on themselves and could not get to the beach to wash it off in the lake or ocean. This could include civil liability in which a person would have had access, but for the unlawful excess in security.

Thus we see, by way of example, that the security equation has two sides, i.e., that an organization can be liable for having too little security OR TOO MUCH security. The too-little-security side of the equation is the only one that we usually hear about, since the other side of the equation is seldom expressed.

Now to relate the analogy to our present situation: Free anonymous wireless access to the net is something that can result in personal safety. Cyborgs, or others, who might otherwise reach the 'net but are prevented from doing so, could be at risk, e.g., from a mugging or other attack that might have been prevented with 'net access.

Thus any organization that wishes to shut down one of my (or anyone else's) free wireless 'net gateways needs to be informed of the liability that their "security" measure creates. By asking them to accept liability for discontinuance of a service that people are already using, one is better prepared to keep the 'net running.

Moreover, the absurdity of someone asking me to shut down my free 'net portal, or to protect it by password, is as absurd as requiring passwords for the enjoyment of other building resources like light, heat, HVAC, and the like. Imagine a building owner who decided to license the electric light in the building by saying that people need to authenticate before receiving the light. Thus anonymous users would need to walk around in the dark, but those wearing a transponder would get a "sight license" and could see. Those without "sight licenses" (such as visiting scholars who had not yet registered) might trip and fall in the dark. They would then have a case against the building owner, and thus the building owner exposes the organization to liability by excessive photonic security.

The same might be true of HVAC, e.g., a license to receive heat, cooling, fresh air, etc., including a breathing license, and a license to exhale, as well as to dispose of bodily waste. Those who dispose of bodily waste without a license in UriNation, are punished by the officials of urinationalism.

Thus I had little trouble in convincing many others that the airwaves should be as free as the photons and the air we breathe, and that requiring authentication for basic safety such as connectivity is absurd.

Thus the birth of "free open-air beach access".

4. "WARE" AS CONTAMINANT IN SOFT*WARE*: DECONOMICS 101

The WearComp was invented as a kind of experiment in self-determination and mastery over one's own destiny that is characteristic of modern concepts like freesource (the GNU Linux operating system that currently runs on it, etc.).

We often encounter so-called "courseware" (educational softWARE), but, as educators, we have an ethical and moral responsibility for not just what we teach, but for our choice of tools with which to teach it. A "ware" is an article of commerce. Thus the word "software" carries with it, embedded in its very etymology, the ideals of commerce. But let us consider replacing "The new economy" (which has already come to a crash—the bubble has been burst), with "The new Deconomy".

To spend a lot of time learning how to use a particular proprietary computer program, is to become trapped in a way of thinking that is an article of commerce. But there is (or should be) also room for a "deconomics"—a deconist deconstruction of economics, that allows us to have the "Soft" and not the "Ware".

That is the essence of the philosophical context of "free software", "open source", "open course", and the like, that I prefer to call "freesource". Freesource emphasizes self-determination and mastery over one's own destiny. This "personal empowerment" aspect is what I believe to be a fundamental issue in operating systems such as GNU Linux. It is this aspect that WearComp and GNU Linux both share in common, and it is for this reason that GNU Linux was selected as the operating system for my existemology project.

An important goal of freesource is that of allowing anyone the option of acquiring, and thus advancing the world's knowledge base.

This eliminates the distinction between "programmer" and "user". It also erradicates the distinction between "developer" and "end user". And it blurs the boundary between "teacher" and "learner". Finally, it also gets rid of the boundary between consumer and producer.

(For a more satirical perspective on Closed Source, see http://wearcam.org/seatsale/) In the cyborg world, such concepts are heightened, in the sense that the computer becomes part of our own "thought" process. Thus the construct known as "humanistic intelligence (HI)" (Mann, 1998) also comes into play. HI is intelligence that arises by having the human being in the feedback loop of a computational process in which the human and computer are inextricably intertwined.

HI is motivated by the philosophy of science, e.g., open peer review, and the ability to (de)construct one's own experimental space. HI provides a new synergy between humans and machines that seeks to involve the human rather than having computers emulate human thought or replace humans. Particular goals of HI are human involvement at the individual level, and providing individuals with tools to challenge society's pre-conceived notions of human–computer relationships. An emphasis in this article is on computational frameworks surrounding "visual intelligence" devices, such as video cameras interfaced to computer systems.

A fundamental problem we face in today's society, as it pertains to computers, is computer program source code disclosure. GNU Linux has emerged as one solution, together with an outlook based on science and on self-determination and individual empowerment at the personal level.

Advanced computer systems is one area where a single individual can make a tremendous contribution to the advancement of human knowledge, but is often prevented from doing so by various forms of what is alleged to be "security" but what is really a form of security excess that is dangerous to the advancement of science. Since science often leads to improved safety, it is actually therefore possible that too much security can be dangerous. A system that excludes any individual from exploring it fully, may prevent that individual from "thinking outside the box" (especially when the box is "welded shut"). Such software hegemonies can prevent some individuals from participating in the culture of computer science and the advancement of the state-of-the-art.

A second fundamental problem pertains to some of the new directions in Human–Computer Interaction (HCI). These new directions are characterized by "computers everywhere", constantly monitoring our activities, and responding "intelligently". This is the "ubiquitous surveillance" or "pervasive surveillance" ("perveillance") paradigm in which keyboards and mice are replaced by cameras and microphones watching us at all times. Proponents of perveillance claim that we are being watched for our benefit, and that they are making the world a better place for us.

Computers everywhere, constantly monitoring our activities, and responding "intelligently" have the potential to make matters worse, from the closed source nature of the software, possibly excluding the individual user from knowledge not only of certain aspects of the computer upon his or her desk, but also of the principle of operation and the function of everyday things. Moreover, the implications of secrecy within the context of these intelligence gathering functions puts forth a serious threat to personal privacy, solitude, and freedom.

But the *surveillance state* locks us into a one-sided 20th century "us versus them" way of thinking. Surveillance alleges to define "good" people (the watchers), versus potentially bad people: Those "suspected" of evil (the watched).

Figure 2. Surveillance and Sousveillance: Surveillance is French for watching from above ("sur" meaning "from above" and "veiller" meaning "to watch"). Surveillance denotes the God's eye view of the proverbial "eye in the sky". Sousveillance brings the cameras from the heavens down to earth, i.e., from the lamp posts and ceilings, down to human level.

For this reason, we require the notion of "sousveillance" (inverse surveillance), from "sous" (French from under, or below), and "veiller" (French for "to watch"). Sousveillance is not merely:

- passengers photographing taxi cab drivers;
- shoppers photographing shopkeepers; and
- citizens photographing police;

but, rather, it is a construct that acknowledges the pastmodern world in which we live (See http://wearcam.org/sousveillance.htm) (See Figure 2).

In some sense, a cyborg who keeps a logfile (much like the "black box" flight recorder on an aircraft) of everything he or she expriences, is practicing the art of sousveillance. Such cyborg logfiles (also known as "cyborg logues", cyborglogs, or "glogs" for short), might also protect the individual from attackers, whether said attackers are from a higher or lower point along the "axis of evil". Thus the fact that glogs protect the wearer from human rights violations by police or other authorities, as well as attacks from muggers, etc., makes them "axis neutral", in the sense that they point everywhere, unlike surveillance from on high.

Students quickly learn about the post-modern notion of the absence of any clearly defined axis of evil. This causes them to question even the definition of "terrorism" or "terrorist" or "guerrorist". Many of the students, for example, began to compare the formal definition of "terrorist" to that of soldier, or police officer, and became confused. Thus, at the very least, "glogging", as it is called (making cyborg logs) gave them the chance to ask questions, and to realize that life is not so clearly defined as one might have at first believed. This gave rise to yet another example of deconstructionist learning.

4.1. Computer Science versus Computer Secrecy

Science provides us with ever-changing schools of thought, opinions, ideas, and the like, while all building upon a foundation of verifiable (and sometimes evolving) truth. The foundations, laws, and theories of science, although true by assumption may at any time be called into question as new experimental results unfold. Thus when doing an experiment, we may begin by making certain assumptions, but at any time, these assumptions may be verified.

In particular, a scientific experiment is a form of investigation that leads wherever the evidence may take us. In many cases, the evidence takes us back to questioning the very assumptions and foundations we had previously taken as truth, and in some cases, instead of making a new discovery along the lines anticipated by previous scientists, we discover that another previous discovery was false or inaccurate. Sometimes these are the biggest and most important discoveries—things that are discovered by accident.

A situation in which one or more of the foundation elements are held in secret is contrary to the principles of science. Although many results in science are treated as a "black box", for operational simplicity, there is always the possibility that the evidence may want to lead us inside that box.

Imagine, for example, conducting an experiment on a chemical reaction between a proprietary solution "A", mixed with a secret powder "B", brought to a temperature of 212 degrees T. (Top secret temperature scale which you are not allowed to convert to other units). It is hard to imagine where one might publish results of such an experiment, except, perhaps, in the Journal of Irreproducible Results.

Now it is quite likely that one could make some new discoveries about the chemical reaction between A and B, without knowing what A and B are, and one might even be able to complete a doctoral dissertation and obtain a Ph.D. for the study of the reaction between A and B (assuming a large enough quantity of A and B were available).

Results in Computer Science that are based, in part, on undisclosed matters, inhibit the ability of the scientist to follow the evidence wherever it may lead. Even in a situation where the evidence does not lead inside one of the secret "black boxes", science conducted in this manner is irresponsible in the sense that another scientist in the future may wish to build upon the result, and may, in fact, conduct an experiment that leads backward, as well as forwards. Should the new scientist follow evidence that leads backward, inside one of these secret "black boxes", then the first scientist will have created a foundation contaminated by secrecy. In the interest of academic integrity, better science would result if all the foundations upon which it were built were such as to be subject to full examination by any scientist who might, at some time in the future, wish to build upon a given scientific discovery. Thus, although many computer scientists may work at a high-level, there would be great merit in a computational foundation open to examination by others, even if the particular scientist using the computational foundation does not wish to examine it. For example, the designer of a high level numerical algorithm, who uses a computer with a fully disclosed operating system (such as Linux), does other scientists a great service, even if he or she himself or herself only uses it at the Application Program Interface (API) level and and never intends to look at its source code or that of the Linux operating system underneath it.

4.2. Obvious or Obfuscated

Imagine a clock that was designed so that when the cover was lifted off, all the gears would fly out in different directions, so that it would be more difficult for a young child to open up his or her parents' clock and determine how it works. Alternatively, imagine the clock was loaded with explosives, so that it would completely self-destruct upon opening.

Assuming a child survived such a bad experience, it is still doubtful that devices made in this manner would be good for society, in particular, for the growth and development of young engineers and scientists with a natural curiosity about the world around them.

As the boundary between software and hardware blurs, devices are becoming more and more difficult to understand. This difficulty arises in part, as a result of deliberate obfuscation on the part of product manufacturers. More and more devices contain general-purpose microprocessors, so that their function depends on software. Specificity of function is achieved through specificity of software rather than specificity of physical form. By manufacturing everyday devices in which there is provided only executable code, without source code, manufacturers have provided a first level of obfuscation. Further more, additional obfuscation tools are often used in order to make the executable task image more difficult to understand. These tools include strippers that remove object link names, etc., and even tools for building encrypted executables which contain dynamic decryption function that generates a narrow sliding window of unencrypted executable, so that only a small fragment of the executable is decrypted at any given time. In this way, not only is the end user deprived of source code, but the executable code itself is encrypted, making it difficult or impossible to look at the code even at the machine code level.

Moreover, devices such as Complex Programmable Logic Devices (CPLDs), such as the Alterra 7000 series, often have provisions to permanently destroy the data and address lines leading into a device, so that a single chip device can operate as a finite-state machine yet conceal even its machine-level contents from examination. (An excellent tutorial on FPGAs and CPLDs may be found in(Brown & Rose, 1996)). Devices such as Clipper chips go a step further by incorporating fluorine atoms, so that if the user attempts to put the device into a milling machine, to mill off layer-by-layer for examination under an electron microscope, the device will self-destruct in a drastic manner that destroys structure. Thus the Clipper phones could contain a "trojan horse", or some other kind of "back door", and we might never be able to determine whether or not this is the case. This is yet another example of deliberate obfuscation of the operational principles of everyday things.

Thus we have a growing number of general-purpose devices whose function or purpose depends on software, downloaded code or microcode. Because this code is intellectually encrypted, so is the purpose and function of the device. In this way, manufacturers may provide us with a stated function or purpose, but the actual function or purpose may differ, or may include extra features, of which we are not aware.

5. EQUIVEILLANCE: THE NEED TO STRIKE A BALANCE IN THE EQUILIBRIUM BETWEEN SURVEILLANCE AND SOUSVEILLANCE

Of primary importance, students learned that the world is not so one-sided as they first believed, and in fact the "sur" and "sous" form a kind of "yin" and "yang". When we have only one, we are in a life-out-of-balance.

Never is this lack of balance so evident as in the proliferation of devices we call "environmental technologies".

There are a number of researchers who have been proposing new computer user-interfaces based on environmental sensors. Buxton, who did much of the early pioneering research into intelligent environments (smart rooms, etc.), was inspired by automatic flush urinals, (as described, for example, in U.S. Pat. 4309781, 5170514, etc.), and formulated, designed, and built a HCI system called the "Reactive Room" (Cooperstock & Buxton, 1995; Cooperstock et al., 1997). This system consisted of various sensors, including optical sensors (such as video cameras), and processing, so that the room would respond to the user's movement and activity.

Increasingly we are witnessing the emergence of "intelligent highways", "smart rooms", "smart floors", "smart ceilings", "smart toilets", "smart elevators", "smart light switches", etc. However, a typical attribute of these "smart spaces" is that they were architected by someone other than the occupant. Thus the end user of the space often does not have a full disclosure of the operational characteristics of the sensory apparatus and the flow of intelligence data from the sensory apparatus.

In addition to the intellectual encryption described in the previous section, where manufacturers could make it difficult, or perhaps impossible for the end user to disassemble such sensory units in order to determine their actual function, there is also the growth of hidden intelligence, in which the user may not even be aware of the sensory apparatus. For example, U.S. Pat. 4309781 (for a urinal flushing device) describes:

> . . . sensor . . . hidden from view and thus discourage tampering with the sensor . . . when the body moves away from the viewing area. . . . located such that an adult user of average height will not see it. . . . sensing means, will be behind other components. . . . positioned below the solenoid to allow light in and out. But the solenoid acts in the nature of a hood or canopy to shield the sensing means from the normal line of sight of most users . . . Thus most users will not be aware of the sensing means. This will aid in discouraging tampering with the sensing means. A possible alternate arrangement would be to place the sensing means below and behind the inlet pipe.

U.S. Pat. 4998673 describes a viewing window concealed inside the nozzle of a shower head, where a fiber optics system is disclosed as a means of making the sensor remote, concealment to prevent users from being aware of its presence. U.S. Pat.5199639 describes a more advanced system where the beam pattern of the nozzle is adapted to one or more characteristics of the user, while U.S. Pat. 3576277 discloses a similar system based on an array of sensing elements.

Means of creating viewing windows to observe the occupants of a space while, at the same time, making it difficult for the occupants to know if and when they are observed, are proposed in U.S. Pat. 4225881 and U.S. Pat. 5726706.

In addition to concealing the sensory apparatus, a goal of many visual observation systems is to serve the needs of the system architect rather than the occupants. For example, U.S. Pat. 5202666 discloses a system for monitoring employees within a restroom environment, in order to enforce hygiene (washing of hands after use of toilet).

Other forms of "intelligence", such as "intelligent highways" often have additional uses, beyond those purported by those installing the systems. For example, traffic monitoring cameras were used to round-up, detain, and execute peaceful protesters in China's Tiananmen Square.

U.S. Pat. 4614968 discloses a system where a video camera is used to detect smoke by virtue of the fact that smoke reduces the contrast of a fixed pattern opposite the video camera. However, the patent also notes that the camera can be also used for other functions such as visual surveillance of an area, since only one segment or line of the camera is needed for smoke detection. Again, the camera may thus be justified for one use, and additional uses, not disclosed to occupants of the space, may then evolve. U.S. Pat. 5061977 and 4924416 disclose the use of video cameras to monitor crowds and automatically control lighting, in response to the absorption of light by the crowds. While this form of environmental intelligence is purportedly for the benefit of the occupants (to provide them with improved lighting), there are obvious other uses.

U.S. Pat. 5387768 discloses the use of visual inspection of users in and around an automated elevator. Again, these provide simple examples of environmental intelligence, in which there are other uses, such as security and surveillance. Although even those other uses (security and surveillance) are purportedly for the benefits of the occupants, and it is often even argued that concealing operational aspects of the system from the occupants is also for their benefit, it is an object of this paper to challenge these assumptions and to provide an alternate form of intelligence.

When the operational characteristics, function, data flow, and even the very existence of sensory apparatus is concealed from the end user, such as behind the grille of a smoke detector, environmental intelligence does not necessarily represent the best form of human–machine relationship for all concerned. Even when the sensors are visible, there must be the constant question as to whether or not the interests of the occupant are identical to those who control the intelligence-gathering infrastructure.

The need for personal space, free from monitoring, has also been recognized (Goffman, 1959) as essential to a healthy life. As more and more personal space is stolen from us, we may need to architect an alternative space of our own.

5.1. Solution to the Software Problem in Education

The first solution to these problems is a framework called Completely Open Source, Headers, Engineering, and Research (COSHER).

Before investing considerable time in learning how to use new software, and in developing works in that new software, which may then become "locked into" a particular file format, we ask ourselves a very simple question: Is the software in question COSHER?

What this means is that there has been no deliberate attempt at obfuscation of the underlying principles of operation of this software, or in preventing us from freely distributing the intellectual foundations upon which we might invest many years of our lives. Deliberate attempts at obfuscation include such practices as elimination of source code and stripping of executable task images.

By using COSHER software, we are making a statement that we prefer Computer Science over Computer Secrecy. Science supports the basic principles of peer review, and a continued development and advancement of software principles, and principles that we build on top of the software.

Moreover, the time we invest in both learning the software, as well as creating works in the software, will be less likely to go to waste if we have a copy of the complete source code of the software. In this manner, should the software ever become discontinued or unsupported, we will be able to become our own software support group and migrate the software forward to new architectures as our old computers become obsolete. If it is COSHER, chances are we will be less likely to lose the many hours or many years we invest in producing works within the software.

Furthermore, if we make new discoveries that are built on a foundation of COSHER software, they are easier to distribute.

In science, it is important that others be able to reproduce our results. Imagine what it would be like if we had built our results on top of DOS 3.1. Others would have to either rewrite our software to exactly reproduce our results, or find an old version of DOS 3.1. Since this is proprietary software, we are not at liberty to freely distribute it with our research, but it is also no long available for purchase. However, if we had built our work on COSHER software, such as Linux 1.13, we can include a full distribution of Linux 1.3 in an archive, together with our results. Many years in the future, a scientist wishing to reproduce our results could then obtain a virtual machine (emulator for our specific architecture which will no doubt be obsolete by then) and install the COSHER operating system (Linux 1.13) that came with our archive, and then compile and run our programs.

5.2. Examples of COSHER Software

The Linux operating system is a good example of a COSHER operating system. GNU software is also COSHER. There are many COSHER software packages, including GIMP (Gnu Image Manipulation Program), and the Video Orbits software package, described in http://wearcam.org/orbits/index.html.

5.3. Solution to Environmental Intelligence Gathering

A proposed solution: HI for the re-configured self.

HI is a computational framework for individual personal empowerment. This framework is based on my "WearComp" invention—an apparatus for (embodiment of) realization of HI.

This framework involves the architecting of a new kind of personal space. An embodiment of the "WearComp" invention is an apparatus that is owned, operated, and controlled by the occupant of that space. In some sense, the apparatus of this invention is like a building, built for one occupant, and collapsed down around that one occupant. This computational framework for HI, called "WearComp", and will now be described.

Figure 3. Evolution of the apparatus of the 'WearComp' invention from the 1970s to the present-day version built in ordinary-looking eyeglasses.

5.4. WearComp as a Basis for HI

I invented WearComp in Canada in the 1970s, as a photographic tool for the visual arts (Mann, 1997a), in particular, something I called "Mediated Reality" (altered perception of visual reality). The goal of Mediated Reality, unlike related concepts like virtual (or augmented) reality, was to reconfigure (augment, deliberately diminish, or otherwise alter) the perception of reality in order to attain a heightened sense of awareness of how ordinary everyday objects respond to light.

HI is a new form of HCI comprising a computer that is subsumed into the personal space of the user (e.g., the computer may be worn, hence the term "user" and "wearer" of the computer may be used interchangeably), controlled by the wearer, and has both operational and interactional constancy, e.g., is always on and always ready and accessible (Mann, 1997b).

The WearComp invention described in IEEE Computer, Vol. 30, No. 2: http://wearcomp.org/ieeecomputer.htm (an historical account was given in IEEE ISWC-97, Oct.'97, and is also online at: http://wearcomp.org/historical/index.html) forms the basis for HI. The evolution of the apparatus of this invention is depicted in Figure 3.

5.5. Definition of WearComp

A WearComp is a computer that is subsumed into the personal space of the user, controlled by the user, and has both operational and interactional constancy, i.e., is always on and always accessible.

Most notably, it is a device that is always with the user, and into which the user can always enter commands and execute a set of such entered commands, and in which the user can do so while walking around or doing other activities.

The most salient aspect of computers, in general, (whether wearable or not) is their *reconfigurability* and their *generality*, e.g., that their function can be made to vary widely, depending on the instructions provided for program execution.

With the WearComp, this is no exception, e.g., the WearComp is more than just a wristwatch or regular eyeglasses: It has the full functionality of a computer system but in addition to being a fully featured computer, it is also inextricably intertwined with the wearer.

This is what sets the WearComp apart from other wearable devices such as wristwatches, regular eyeglasses, wearable radios, etc. Unlike these other wearable devices that are not programmable (reconfigurable), the WearComp is as reconfigurable as the familiar desktop or mainframe computer.

The formal definition of wearable computing defined in terms of its three basic modes of operation and its six fundamental attributes is provided elsewhere in the literature (Mann, 1998).

5.6. WearComp as Universal Interface to Reality

Such a computational framework allows one to subsume all of the personal electronics devices that one might normally carry, such as:

- cellular phone;
- pager;
- wrist watch;
- heart monitor;
- camera;
- video camera

into a single device. Obviously, since it is a fully featured computer, it is possible to respond to e-mail, plan events on a calendar, type a report, or the like, while walking, standing in line at the bank, or the like. In this way WearComp anticipated the later arrival of the so-called "laptop computer", but has advantages over the laptop computer in the sense that it can be used while walking around doing other things. However, the real power of WearComp is in its ability to serve as a basis for Personal Imaging and HI.

5.7. Personal Safety Device: Cyborg Logs for Sousveillance

WearComp not only subsumes the function of the laptop computer, but goes beyond it.

Another area in which WearComp provides a truly new form of user-interface not found on laptop computers and PDAs is in its constancy of user-interface, and constancy of operation. This characteristic perhaps becomes most evident in its use as a personal safety/security camera. Imagine, perhaps as you walk down some quiet street late at night, an assailant wielding a sawn-off shotgun, demanding cash from you. You would not likely have time or opportunity to pull out a camcorder to record the experience, but since the eyeglasses are worn constantly, you would have captured the experience.

5.8. Camera of the Future

Less extreme examples of WearComp as a new user-interface include the ability to construct a personal documentary video without conscious thought or effort. For example, in a fully-mediated reality, all light entering the eyes, in effect, passes through the computer, and may therefore be recorded (and possibly transmitted to remote locations). Wearable Wireless Webcam (Jones, 1995) was one example of a personal documentary video recorded using a reality mediator.

In the future, we may well have the capability to capture and recall our own personal experiences, and to have photo albums generated automatically for us. We will never miss baby's first steps, because we will have a retroactive record feature that lets us, for example, "begin recording from 5 minutes ago". Photo albums, in addition to being generated automatically, may also be exhibited while they are being generated. Rather than sending postcards to friends and relatives, or showing them an album after you come back from vacation, you may just put on your sunglasses and have the album sent to them automatically, as was done with the Wearable Wireless Webcam experiment in which video was transmitted, and still images were also automatically selected from the video.

5.9. Personal Intelligence Arms Race

While there will no doubt be more environmental intelligence than personal intelligence, there is at least the hope that there might be an end to the drastic imbalance between personal intelligence and environmental intelligence. The individual making a purchase in a department store may have several cameras pointing at him to make sure that if he removed merchandise without payment that there would be evidence that he did not pay for the item. However, in the future, he will have a means of collecting evidence that he did pay for the item, or a recorded statement of a clerk about the refund policy. More extreme examples, such as the case of Latasha Harlins[1] also come to mind.

In this sense, the camera-based reality-mediator becomes an equalizer much like the Colt45 in the Wild West. When there is a standoff, it does not matter whether one person has a big gun and the other has a small gun, so long as there is enough ammunition for mutually assured destruction.

In the WearCam case, it is simply a matter of mutually assured accountability.

6. BECOMING A PHOTOBORG

Among other things, the cyborg apparatus of the invention functions as a two-way Wearable Wireless Webcam, in which the wearer can allow others to see exactly what he or she is seeing, over the World Wide Web. Moreover, the wearer can also allow others to alter his or her perception of visual reality as a means of communication. While the traditional videophone shows us a picture of the user, Wearable Wireless Webcam shows us what the user is looking at. Within most social circles, such as among friends and relatives, we already know what the other people look like, so we do not need to see a picture of these people. Instead, it is far more meaningful for us to "become" these people, e.g., to put ourselves in their shoes and see the world from their point of view.

6.1. Eye Am a Camera

One outcome of the apparatus of the invention, is a photographic mindset. In effect, the eye itself becomes a camera, and, while sending everyday experiences to the World Wide Web, students can develop a cinematographic awareness. The students have the opportunity to wear the apparatus continuously, so that a photographic awareness develops over time, as opposed to the traditional notion of only looking through the camera viewfinder while shooting or preparing to shoot.

By giving students the ability to wear the devices over an extended time period, they are able to internalize the mapping from 3d to 2d and the laws of projective geometry.

Students each have the opportunity to make a movie, viewed in real time by their friends and relatives. In this way, without even being aware of the learning process, the students have learned far more about cinematography than if they had taken traditional "learn by doing" photo and film courses. By becoming a camera, the student truly learns what a camera is. The "learn by being" approach far surpasses the traditional "learn by doing" approach. The successful photoborg (photographic cyborg) learns to shoot high quality documentary video without conscious thought or effort. After time, the camera functions as a true extension of the mind and body.

7. EYETAP: TAPPING INTO THE MIND'S EYE

The tremendous success of this project, to date, suggests a next step in the evolution of the PhotoBorg. EyeTap technology is an apparatus that intercepts light passing through the center of projection of at least one eye of the wearer of the apparatus. The intercepted light is converted into a numerical representation, modified by the computer, and then converted back into a light representation in the EyeTap device. The device causes the eye itself to, in effect, become the camera.

When the eye itself, in effect, functions as a camera, and the retina itself, in effect, functions as a display, there is a new possibility for a connected collective HI.

Although I have working prototypes of the EyeTap technology, in order to perfect the EyeTap system for manufacture, there still remain some issues, such as to miniaturize the apparatus so that it will fit entirely within ordinary eyeglasses, including the computational portion that is presently built into an undershirt so that it can be concealed under the wearer's outer shirt.

8. BREAKING THE BOUNDARY BETWEEN EDUCATION AND THE REST OF LIFE

I believe that one of the most enlightening discoveries arising from the "community of cyborgs" was that students took a personal interest in computing, once they had a "space" (mediated cyberspace) of their own. In particular, it appeared that when a student had a feeling of having his or her own computer, the usage of the computer entered into ordinary facets of day-to-day living, such as keeping in touch while walking around in normal life, or in applying computing to other endeavours, and in building new and interesting devices to connect to the computer that go beyond what is expected of the classroom or lab setting.

The difference between how the students regard these truly personal computers and how they might regard normal university computers is somewhat captured by the difference between ordinary clothing and prison uniforms. Where students had previously dutifully done their lab work, somewhat "dragging their feet", they now approached the subject with a passionate element of love of the subject matter, rather than duty to memorize the course material for the final exam. The "learn by being" approach meant that students assimilated the material into their ordinary day-to-day life. Exist Edbroke down the usual barrier between study and non-study, e.g., the artificial barrier that usually exists between "work" and "play" and the rest of life.

9. EXISTED WITHOUT BEING A CYBORG

At the nexus of research and teaching, we have found a new approach, originally developed as a "school for cyborgs" but immediately applicable to many facets of education that have nothing to do with body-borne (wearable or implantable) computing devices.

As an example, these methods were applied to my ECE385 course, *Introduction to microprocessors*. Firstly, this involved the use of low cost personal computers. In the deconist tradition, students were encouraged to find an old computer in a dumpster, or to purchase an old computer for approximately $10 (or certainly not more than $100). Instead of using the expensive computers in the lab, which were chained down, bolted down, and hooked up to an alarm, the students then brought their own computers into the lab. These being of low (or zero) cost, the students were taught to overcome fear in opening the computers up and hacking the internals.

Because the systems were the students' own computers, and not University property, a certain existential element prevailed, as well. For example, the students would bring the computers home with them, and apply what they learned in class. And students often innovated, and created, in a true free-spirited fashion.

Thus ExistEd was successful in a variety of other venues, outside the cyborg arena. This method was also applied in the author's ECE431 course (Digital Signal Processing) and ECE496 course (Design). Results were very successful. Provided below are some student quotes from the official anonymous Course Evaluation forms:

10. CONCLUSION

Rather than conclude, I will attempt to also extrapolate into the future. Results are deconclusive, and thus meant to raise important questions about how we might drastically modify the way we teach, in order to teach the "stuff that matters to the student". In particular, by focusing on development of the student, as a human being, in the feedback loop of the learning process, we arrive at a new framework for teaching, in which the student takes personal interest in the subject matter, as it pertains to his or her own daily life. For example, sousveillance was presented as a form of action research (i.e., research that affects social change by conducting inquiry), that includes inverse surveillance. This led the students to create their own existential understanding equiveillance—the equilibrium between surveillance and sousveillance.

ENDNOTE

1. A customer falsely accused of shoplifting, and fatally shot in the back by a shopkeeper as she attempted to walk out of the shop.
