(iii) *The* $\Sigma^*(M)$ *relations* (also written $\Sigma_1^{(\omega)}(M)$), are those $\Sigma_0^{(n)}(M)$ for some n, and $\boldsymbol{\Sigma}^*(M)$ relations are defined analogously.

A relation more formally speaking is thus a pair: $\langle R, \langle i_1, \ldots, i_k\rangle\rangle$, consisting of the actual graph of the relation as a subset of $H^{i_1} \times \cdots \times H^{i_k}$ together with its type: $\langle i_1, \ldots, i_k\rangle$.

1.3 Definition. A function F is a $\Sigma_k^{(n)}(M)$ *function to* H_M^i *of argument type* $\langle i_1, \ldots, i_k\rangle$ if and only "$y^i = F(x_1^{i_1}, \ldots, x_k^{i_k})$" is a $\Sigma_k^{(n)}(M)$ relation of type $\langle i, i_1, \ldots, i_k\rangle$.

Part of our analysis will show that although, for example, $\Sigma_k^{(n)}(M)$ relations are not just graphs but come with the additional baggage of a type, for most intents and purposes, we shall not have to worry about the type. As the domains $H_M^i \supseteq H_M^j$ for $j \geq i$ are decreasing, replacing a variable in a formula defining a relation, by one of higher type, just reduces the domain specified, and so the resulting relation may be regarded as a *specialisation* of the original: if $\overline{R}(x_1^{j_1}, \ldots, x_k^{j_k}), R(x_1^{i_1}, \ldots, x_k^{i_k})$ are relations on H, then $\overline{R}$ is a *specialisation* of R, if $j_l \geq i_l$ $(0 < l \leq k)$ and $\overline{R} = R \cap H^{j_1} \times \cdots \times H^{j_k}$.

1.4 Lemma. *If* $R(x_1^i, \vec{x}\,)$ *is* $\Sigma_k^{(n)}(M)$*, and* $j \geq i$*, then so is the specialisation* $R(x_1^j, \vec{x}\,)$*.*

1.5 Lemma. *If* $R(x_1^j, \vec{x}\,)$ *is* $\Sigma_k^{(n)}(M)$ *(in* $\vec{q}$*) and* $j \geq i \geq n$*, then* R *is a specialisation of a* $\Sigma_k^{(n)}(M)$ *(in* $\vec{q}$*) relation* $R(x_1^i, \vec{x}\,)$*.*

The proofs of the above are both straightforward inductions on the structure of the defining formula for R. Notice that this implies that any $\Sigma_k^{(n)}(M)$ relation can be considered a specialisation of a $\Sigma_k^{(n)}(M)$ relation whose arguments are all of type less than or equal to n. Note also that trivial operations like permutation of variables, or insertion of dummy ones, in a $\Sigma_k^{(n)}(M)$ relation leave it in the same class of definability.

The next lemma tells how $\Sigma_k^{(n+1)}(M)$ relations R can be expressed as Σ_k relations on a suitably extended $(n+1)$st reduct domain. It is important for the reader to note the uniformities implicit in the statement of the lemma. Firstly note that although the lemma talks about $\Sigma_k^{(n+1)}(M)$ relations, the structure M really does not enter into consideration and the result is independent of it. (The reader should be aware of this kind of ostensible dependence on a structure M, of which it is in reality independent, as this reoccurs in several places in the development below.) The result is really a purely *syntactic* one about the defining formula for R. This is the second uniformity: the relations S^i that appear in the conclusion of the lemma are derived entirely from the matrix of this defining formula, and depend only on it.

1.6 Lemma. *$R(\vec{x}^{\,n+1}, \dots, \vec{x}^{\,0})$ is $\Sigma_k^{(n+1)}(M)$ if and only if there are $\Sigma_1^{(n)}(M)$ relations S^i $(i \le m)$ such that for all $\overrightarrow{x} = \vec{x}^{\,n}, \dots, \vec{x}^{\,0} \in M$:*

$R_{\overrightarrow{x}} =_{\mathrm{df}} \{\langle \vec{x}^{\,n+1}\rangle \mid R(\vec{x}^{\,n+1}, \overrightarrow{x})\}$ is uniformly $\Sigma_k(\langle H_M^{n+1}, \in, Q^0_{\overrightarrow{x}}, \dots, Q^m_{\overrightarrow{x}}\rangle)$,

where each $Q^i_{\overrightarrow{x}}$ (for $i \le m$) has the form

$$Q^i_{\overrightarrow{x}} = \{\langle \vec{y}^{\,n+1}\rangle \mid S^i(\vec{y}^{\,n+1}, \overrightarrow{x})\}.$$

Proof. We should first note that the "uniformly" here (a further uniformity) refers to the fact that the same Σ_k formula ψ of the conclusion works for every choice of $\vec{x}$. Although notationally complicated the lemma is actually rather simple: the relations S^i correspond to the fact that $\Sigma_1^{(n)}$ formulae play a role of atomic formulae in the definition of $\Sigma_0^{(n+1)}$ and are in fact the relations defined by those components. To continue in the proof of $(\Longrightarrow)$, we may write the formula $\varphi(\vec{x}^{\,n+1}, \dots, \vec{x}^{\,0})$ defining R in prenex form:

$$\begin{aligned} &\exists v_1^{n+1} \forall v_2^{n+1} \cdots (\exists w_1^{n+1} \in u_1^{n+1})(\forall w_2^{n+1} \in u_2^{n+1}) \\ &\quad \cdots \psi(\vec{v}^{\,n+1}, \vec{w}^{\,n+1}, \vec{x}^{\,n+1}, \vec{x}\,) \end{aligned} \tag{+}$$

(the bounding variables u_j^{n+1} being amongst the $\vec{v}^{\,n+1}, \vec{x}^{\,n+1}$). As intimated ψ is a propositional combination of $\Sigma_1^{(n)}$ formulae $\varphi_0, \dots, \varphi_m$ which define for us (relabelling the type $n+1$ variables as $\vec{y}^{\,n+1}$) the $S^i(\vec{y}^{\,n+1}, \vec{x}\,)$ $(i \le m)$. Let $Q(\vec{y}^{\,n+1}, \vec{x}\,)$ be the relation corresponding to that propositional combination of the S^i mirroring the structure ψ. Then $R_{\overrightarrow{x}}(\vec{t}\,)$ can be seen to be expressible as:

$$\exists v_1 \forall v_2 \cdots (\exists w_1 \in u_1)(\forall w_2 \in u_2) \cdots Q_{\overrightarrow{x}}(\vec{v}, \vec{w}, \vec{t}\,) \tag{$*$}$$

where now the bounding variables u_j are amongst the $\vec{v}, \vec{t}$.

For the converse, if $R_{\overrightarrow{x}}$ is $\Sigma_k(\langle H_M^{n+1}, \in, Q^0_{\overrightarrow{x}}, \dots, Q^m_{\overrightarrow{x}}\rangle)$, then it has the form of $(*)$. We now just unwind the previous process, thinking of each $Q^j_{\overrightarrow{x}}(\vec{v}, \vec{w}, \vec{t}\,)$ as a propositional combination of $Q^i_{\overrightarrow{x}}$; we now replace $Q^i_{\overrightarrow{x}}$, $\vec{v}$, $\vec{w}$, $\vec{t}$, by $\varphi_i, \vec{v}^{\,n+1}$, $\vec{w}^{n+1}$, $\vec{x}^{\,n+1}$ and obtain the $\Sigma_k^{(n+1)}$ form of $(+)$. $\dashv$

The next lemma relates the last to the reduct structures $M^{n,p(\vec{x})}$.

1.7 Lemma.

(i) *Let* $0 < k$. $R(\vec{x}^{\,n}, \ldots, \vec{x}^{\,0})$ *is* $\Sigma_k^{(n)}(M)$ *if and only if the relation* $R_{\overrightarrow{x}} = \{\langle \vec{x}^{\,n}\rangle \mid R(\vec{x}^{\,n}, \overrightarrow{x})\}$ *of the last lemma is uniformly* $\Sigma_k(M^{n,p(\vec{x})})$, *where* $p(\overrightarrow{x}) =_{\mathrm{df}} \langle\langle \vec{x}^{\,0}\rangle, \ldots, \langle \vec{x}^{\,n-1}\rangle\rangle$.

(ii) *If* $R(\vec{x}^{\,n}, \ldots, \vec{x}^{\,0})$ *is* $\Sigma_0^{(n)}(M)$ *then* $R_{\overrightarrow{x}}$ *is uniformly rudimentary in* $M^{n,p(\vec{x})}$; *conversely if* $R_{\overrightarrow{x}}$ *is* $\Sigma_0(M^{n,p(\vec{x})})$ *then* $R(\vec{x}^{\,n}, \ldots, \vec{x}^{\,0})$ *is* $\Sigma_0^{(n)}(M)$.

Proof. By an induction on n. For $n = 0$ it is trivial. For (i), we suppose this is true for m, and we shall prove it for $n = m + 1$.

For the forward direction, let $R(\vec{x}^{\,n}, \ldots, \vec{x}^{\,0})$ be $\Sigma_k^{(n)}(M)$. By appealing to, and using the notation of, the last lemma, there are $\Sigma_1^{(m)}(M)$ relations $S^0, \ldots, S^t$ so that for $\overrightarrow{x} = \vec{x}^{\,m}, \ldots, \vec{x}^{\,0} \in M$, $R_{\overrightarrow{x}}$ is uniformly $\Sigma_k(\langle H_M^n, \in, Q^0_{\overrightarrow{x}}, \ldots, Q^t_{\overrightarrow{x}}\rangle)$. However each $S^i(\vec{z}^{\,m+1}, \overrightarrow{x})$ can be considered a specialisation of a $\Sigma_1^{(m)}(M)$ relation $\widetilde{S}^i(\vec{z}^{\,m}, \overrightarrow{x})$. We use the notation $\overrightarrow{y} = \vec{x}^{\,m-1}, \ldots, \vec{x}^{\,0}$ and $p(\vec{y}) =_{\mathrm{df}} \langle\langle \vec{x}^{\,0}\rangle, \ldots, \langle \vec{x}^{\,m-1}\rangle\rangle$. Then we can rewrite: $\widetilde{S}^i(\vec{z}^{\,m}, \overrightarrow{x})$ as $\widetilde{S}^i(\vec{z}^{\,m}, \vec{x}^{\,m}, \overrightarrow{y})$. The inductive hypothesis implies that

$$Q^i_{\overrightarrow{y}} =_{\mathrm{df}} \{\langle \vec{z}^{\,m}, \vec{x}^{\,m}\rangle \mid \widetilde{S}^i(\vec{z}^{\,m}, \vec{x}^{\,m}, \overrightarrow{y})\}$$

is uniformly $\Sigma_1(M^{m,p(\vec{y})})$. There is thus a fixed Σ_1-formula $\varphi_{j(i)}$ such that

$$\begin{aligned} \langle \vec{z}^{\,m}, \vec{x}^{\,m}\rangle \in Q^i_{\overrightarrow{y}} \quad &\iff \quad M^{m,p(\vec{y})} \models \varphi_{j(i)}(\vec{z}^{\,m}, \vec{x}^{\,m}) \\ &\iff \quad \langle j(i), \vec{z}^{\,m}\rangle \in A^{\vec{x}^{\,m}}_{M^{m,p(\vec{y})}} \end{aligned}$$

where the latter is of course the standard code predicate occurring in the nth reduct determined by $p(\vec{x})$: $M^{n,p(\vec{x})}$ (cf. [46, 5.1]). However $\langle \vec{z}^{\,m}\rangle \in Q^i_{\overrightarrow{x}} \iff \langle \vec{z}^{\,m}, \vec{x}^{\,m}\rangle \in Q^i_{\overrightarrow{y}}$, so if we replace every occurrence of "$\langle \vec{z}^{\,m}\rangle \in Q^i_{\overrightarrow{x}}$" by "$\langle j(i), \vec{z}^{\,m}\rangle \in A^{\vec{x}^{\,m}}_{M^{m,p(\vec{y})}}$" in the $\Sigma_k(\langle H_M^n, \in, Q^0_{\overrightarrow{x}}, \ldots, Q^t_{\overrightarrow{x}}\rangle)$ definition of $R_{\overrightarrow{x}}$, we obtain a $\Sigma_k(M^{n,p(\vec{x})})$ definition for it. These substitutions and translations did not depend on $\overrightarrow{x}$ or M, but only on the definition of R, and so are themselves uniform and effective.

For the converse, suppose that $R_{\vec{x}}$ is uniformly $\Sigma_k(M^{n,p(\overrightarrow{x})})$-definable by some formula Φ say. This will contain atomic components of the form "$\langle j, \langle \vec{x}^{\,n}, \vec{z}^{\,n}\rangle\rangle \in A^{\vec{x}^{\,m}}_{M^{m,p(\vec{y})}}$" (continuing with the same notation as from the first part). If we can show that these atomic formulae are expressible as $\Sigma_1^{(m)}$ formulae (in variables $j, \vec{z}^{\,n}, \vec{x}^{\,n}, \ldots, \vec{x}^{\,0}$) then we may effectively transform Φ into a $\Sigma_k^{(m)}$ formula by substituting these $\Sigma_1^{(m)}$ formulae for the atomic components. We have however:

$$\langle j, \langle \vec{x}^{\,n}, \vec{z}^{\,n}\rangle\rangle \in A^{\vec{x}^{\,m}}_{M^{m,p(\vec{y})}} \quad \iff \quad M^{m,p(\vec{y})} \models \varphi_j(\langle \vec{x}^{\,n}, \vec{z}^{\,n}\rangle, \vec{x}^{\,m}).$$

We consider the right side here a specialisation of the relation: $M^{m,p(\vec{y})} \models \varphi_j(\langle \vec{w}^{\,m}, \vec{z}^{\,m}\rangle, \vec{x}^{\,m})$ and the latter is (since Σ_1 satisfaction over J-structures is uniformly Σ_1-definable) $\Sigma_1(M^{m,p(\vec{y})})$ in the variables $j, \vec{w}^{\,m}, \vec{z}^{\,m}, \vec{x}^{\,m}$ uniformly for all $\vec{y}$, and by the inductive hypothesis it is $\Sigma_1^{(m)}(M)$. Hence by Lemma 1.4 the atomic component is $\Sigma_1^{(m)}(M)$ also, This suffices for (i).

For (ii), the converse direction works as above, but in the forwards direction, when we perform the replacement "$\langle \vec{z}^{\,m}\rangle \in Q^i_{\overrightarrow{x}}$" by "$\langle j(i), \vec{z}^{\,m}\rangle \in A^{\vec{x}^{\,m}}_{M^{m,p(\vec{y})}}$" as the latter is in general not Σ_0 in the predicate $A^{\vec{x}^{\,m}}_{M^{m,p(\vec{y})}}$ we obtain only that it is rudimentary in $M^{n,p(\vec{x})}$—but that is the only difference. ⊣

We can argue similarly to the above that $(n+1)$st standard codes are themselves uniformly $\Sigma_1^{(n)}$-definable:

1.8 Lemma. *There is an $A^*(\vec{x}^{\,n+1}, \ldots, \vec{x}^{\,0})$ which is $\Sigma_1^{(n)}(M)$ uniformly for all J-structures M such that (again with $p(\vec{x})$ as in the last lemma, and $\overrightarrow{x} = \vec{x}^{\,n}, \ldots, \vec{x}^{\,0}$)*

$$\langle \vec{x}^{\,n+1}\rangle \in A_M^{n+1,p(\vec{x})} \quad \iff \quad A^*(\vec{x}^{\,n+1}, \ldots, \vec{x}^{\,0});$$

i.e. $A_M^{n+1,p(\vec{x})} = A^*_{\vec{x}}$.

In general $\Sigma_1^{(n)}(M)$ relations are not closed under substitution of $\Sigma_1^{(n)}(M)$ functions. We shall need to define a class of functions, the *good functions* which do permit this kind of substitutability. As a preliminary:

1.9 Lemma. *Let $m \le n$, $0 < k$. Let $R(\vec{x}^{\,n}, \ldots, \vec{x}^{\,0})$ be $\Sigma_k^{(n)}(M)$. Let $\vec{F}^{\,n}, \ldots, \vec{F}^{\,0}$ be such that each $F_j^m(\vec{z}^{\,0}, \ldots, \vec{z}^{\,m})$ is a (possibly partial) $\Sigma_1^{(m)}(M)$ function to H_M^m. Then $R(\overrightarrow{F^i(\overrightarrow{z})})$ is uniformly $\Sigma_k^{(n)}(M)$.*

Proof. By induction on n. We assume it holds for $l < n$. For the sake of brevity, we consider just a single $F^m(\vec{z})$ of value type $m \le n$, this illustrates the idea and the reader will see that the rest is merely complication of notation. We can consider $R(F^m(\vec{z}), \vec{x})$ as defined by:

$$M \models \exists x^m (x^m = F^m(\vec{z}) \wedge R(x^m, \vec{x})).$$

If $m = n$ this already shows that $R(F^m(\vec{z}), \vec{x})$ is $\Sigma_k^{(n)}(M)$. So suppose $m < n$ and hence $0 < n$. Write out a prenex form of the definition of $R(x^m, \vec{x})$ with a $\Sigma_0^{(n)}$ matrix φ as:

$$M \models \exists \vec{v}_1^{\,n} \forall \vec{v}_2^{\,n} \cdots Q \vec{v}_k^{\,n} \varphi(\vec{v}, x^m, \vec{x}).$$

The free variable x^m only occurs in the $\Sigma_1^{(n-1)}$ "atomic constituents" of the $\Sigma_0^{(n)}$ formula φ. We shall apply the induction hypotheses to these constituents: they can be effectively listed, and if $\psi(x^m, \vec{y})$ is a typical member of this list, then apply the inductive hypothesis to $\psi(F^m(\vec{z}), \vec{y})$ to yield some $\Sigma_0^{(n)}$ formula. If this is done throughout φ the resultant formula $\widetilde{\varphi}(\vec{v}, \vec{z}, \vec{x})$ is itself now $\Sigma_0^{(n)}$. Hence $R(F^m(\vec{z}), \vec{x})$ is definable over M by

$$\exists \vec{v}_1^n \forall \vec{v}_2^n \cdots Q\vec{v}_k^n (\exists x^m = F^m(\vec{z}) \wedge \widetilde{\varphi}(\vec{v}, \vec{z}, \vec{x})).$$

The process is clearly effective and independent of M. ⊣

1.10 Definition. The *good* $\Sigma_1^{(n)}(M)$ *functions* form the smallest class $\mathfrak{F}$, such that, taking $i, j_1, \ldots, j_k \leq n$,

(i) each partial $\Sigma_1^{(i)}(M)$ function to H_M^i of the form $F(x_k^{j_k}, \ldots, x_1^{j_1}) = x^i \in \mathfrak{F}$;

(ii) if $F(x_k^{j_k}, \ldots, x_1^{j_1}) = x^i \in \mathfrak{F}$ and $G_i(\vec{y}) = z^{j_i} \in \mathfrak{F}$ (and the $\vec{y}$ all have type $\leq n$), then $F(G_k(\vec{y}), \ldots, G_1(\vec{y})) \in \mathfrak{F}$.

The previous lemma together with an induction on the scheme generating the good $\Sigma_1^{(n)}$ functions proves:

1.11 Lemma. *Let $R(x^i, \vec{x})$ be $\Sigma_k^{(n)}(M)$, $k \geq 1$, $n \geq i$. Let $F^i(\vec{y})$ be a good $\Sigma_1^{(n)}(M)$ function of value type i. Then $R(F^i(\vec{y}), \vec{x})$ is uniformly $\Sigma_k^{(n)}(M)$.*

Again we should remark that the $\Sigma_k^{(n)}$ definition of the resultant relation is uniformly obtained from the scheme generating $\Sigma_1^{(n)}$ good functions, and the definition of $R(x^i, \vec{x})$. It has nothing to do with M (or $\vec{x}$). The following corollary then shows that $\Sigma_1^{(n)}$ relations are after all characterisable by their graphs alone.

1.12 Corollary.

(i) *Let $R(x_1^{i_1}, \ldots, x_k^{i_k})$ and $R(y_1^{j_1}, \ldots, y_k^{j_k})$ have the same graph. Then*

$$R(x_1^{i_1}, \ldots, x_k^{i_k}) \in \Sigma_1^{(n)}(M) \iff R(y_1^{j_1}, \ldots, y_k^{j_k}) \in \Sigma_1^{(n)}(M).$$

(ii) *In particular, if $R(x_1^{i_1}, \ldots, x_k^{i_k}) \in \Sigma_1^{(n)}(M)$, then it is a specialisation of $R'(x_1^0, \ldots, x_k^0) \in \Sigma_1^{(n)}(M)$ with the same graph, and all of whose arguments are of value type* 0.

Proof. To see (i) we may substitute into $R(x_1^{i_1}, \ldots, x_k^{i_k})$ the good $\Sigma_1^{(n)}(M)$-projection functions $x_1^{i_1} = y_1^{j_1}, \ldots, x_k^{i_k} = y_1^{j_k}$. (ii) is then a special case of this. ⊣

$\Sigma_k^{(n)}$-Preserving Embeddings

We may define $\Sigma_k^{(n)}$-preserving embeddings in a natural way: Let $\bar{M}, M$ be J-structures, $n, l < \omega$.

(i) $\pi : \bar{M} \longrightarrow_{\Sigma_l^{(n)}} M$ iff $\pi : \bar{M} \longrightarrow M$ and whenever $\varphi(v_1^{j_1}, \ldots, v_m^{j_m}) \in \Sigma_l^{(n)}$, $x_i \in H_{\bar{M}}^{j_i}$ $(1 \leq i \leq m)$ then $\pi(x_i) \in H_M^{j_i}$, and

$$\bar{M} \models \varphi(\vec{x}\,) \quad \Longleftrightarrow \quad M \models \varphi(\overrightarrow{\pi(x)});$$

(ii) $\pi : \bar{M} \longrightarrow_{\Sigma^*} M$ iff $\pi : \bar{M} \longrightarrow_{\Sigma_1^{(n)}} M$ for all $n < \omega$;

(iii) $\pi : \bar{M} \longrightarrow_{\Sigma_0^{(n)}} M$ *cofinally* iff $\pi : \bar{M} \longrightarrow_{\Sigma_0^{(n)}} M$ and $H_M^n = \bigcup \pi``H_{\bar{M}}^n$.

If F is a good $\Sigma_1^{(n)}(\bar{M})$-definable function, then one may show that F has such a definition that is "functionally absolute"; i.e. a definition that defines a function over any acceptable structure N, and thus is robust under $\Sigma_1^{(n)}$-preserving maps. (See [62, 1.8.10].) The key to this is that the canonical Σ_1-Skolem function has such a definition over any acceptable J-structure, in particular for those of the form $M^{n,p}$. Thence the same holds for any other $\Sigma_1^{(n)}(M)$ function to H_M^n also: briefly if $f(\overrightarrow{x})$ where $\overrightarrow{x} = \vec{x}^{\,n}, \ldots, \vec{x}^{\,0}$ is a $\Sigma_1^{(n)}(M)$ function to H_M^n defined by some formula φ, we may define $g_{\overrightarrow{x}}(\vec{x}^{\,n}) \simeq f(\overrightarrow{x})$ and $p(\vec{x}\,) =_{\mathrm{df}} \langle\langle \vec{x}^{\,0} \rangle, \ldots, \langle \vec{x}^{\,n-1} \rangle\rangle$. This makes the definition of $g_{\overrightarrow{x}}(\vec{x}^{\,n})$ $\Sigma_1(M^{n,p(\vec{x}\,)})$. However this depends only on φ and not $\overrightarrow{x}$. Hence there is a single fixed i so that $g_{\overrightarrow{x}}(\vec{x}^{\,n}) \simeq h_{M^{n,p(\vec{x}\,)}}(i, \vec{x}^{\,n})$ and the latter is a uniform functionally absolute definition. In short, concerning embeddings, any $\Sigma_1^{(n)}(\bar{M})$ functionally absolute definition applied over $\bar{M}$ where $\pi : \bar{M} \longrightarrow_{\Sigma_1^{(n)}} M$ also yields a $\Sigma_1^{(n)}$ function over M.

1.13 Lemma. *Let $\bar{M}, M$ be acceptable J-structures. Then: $\pi : \bar{M} \longrightarrow_{\Sigma_k^{(n)}} M$ iff $\pi : \bar{M} \longrightarrow M$ and whenever $\bar{p} \in \Gamma_{\bar{M}}^n$ then $p = \pi(\bar{p}) \in \Gamma_M^n$, and $\pi{\restriction}H_{\bar{M}}^n : \bar{M}^{n,\bar{p}} \longrightarrow_{\Sigma_k} M^{n,p}$.*

Proof. This is a direct consequence of Lemma 1.7. ⊣

The following two lemmata correspond to [46, 5.8, 5.9] expressed in our language.

1.14 Lemma. *Let $\bar{M}$, M be acceptable J-structures. Let $\pi : \bar{M} \longrightarrow M$ be the n-completion of $\pi{\restriction}H_{\bar{M}}^n : \bar{M}^{n,\bar{p}} \longrightarrow_{\Sigma_k} M^{n,p}$ where $\bar{p} \in R_{\bar{M}}^n$ and $p = \pi(\bar{p}) \in \Gamma_M^n$. Then $\pi : \bar{M} \longrightarrow_{\Sigma_k^{(n)}} M$.*

Proof. Let $\bar{q} \in \Gamma_{\bar{M}}^n$ be arbitrary. As $\bar{p} \in R_{\bar{M}}^n$ we have that for any $q = \pi(\bar{q}) \in \Gamma_M^n$ that $A_{\bar{M}}^{n,\bar{q}}$ is rudimentary in $A_{\bar{M}}^{n,\bar{p}}$ in some parameter r say. (See the proof of [46, 5.3(b)].) Then $A_M^{n,q}$ is rudimentary in $A_M^{n,p}$ in $\pi(r) \in H_M^n$ by the same rudimentary definition. So $\pi{\restriction}H_{\bar{M}}^n : \bar{M}^{n,\bar{q}} \longrightarrow_{\Sigma_k} M^{n,q}$. As $\bar{q}$ was arbitrary, the previous lemma shows $\pi : \bar{M} \longrightarrow_{\Sigma_k^{(n)}} M$. ⊣

1.15 Lemma (Downward Extension of Embeddings Lemma). *Let $\bar{M}, M$ be acceptable J-structures. Let $\pi\restriction H^n_{\bar{M}} : \bar{M}^{n,\bar{p}} \longrightarrow_{\Sigma_k} M^{n,p}$ where $\bar{p} \in R^n_{\bar{M}}$. Then there is a unique $\widetilde{\pi} \supseteq \pi$ such that $\widetilde{\pi}(\bar{p}) = p$ and $\widetilde{\pi} : \bar{M} \longrightarrow_{\Sigma^{(n)}_k} M$.*

Some of the fruits of this analysis are seen in the following two lemmas, the first of which is the analogue of Jensen's classical Σ_n-Uniformisation Lemma.

1.16 Lemma ($\Sigma^{(n)}_1$-Uniformisation Theorem). *Let $R(y^n, x_1^{j_1}, \ldots, x_m^{j_m})$ be $\Sigma^{(n)}_1(M)$ with $j_i \leq n$. Then there is a $\Sigma^{(n)}_1(M)$ function F (uniformly definable with respect to any such M) into H^n_M (which is thus good) uniformising R. Namely:*

(a) $\mathrm{dom}(F) = \{\langle x_1^{j_1}, \ldots, x_m^{j_m}\rangle \in M \mid \exists y^n \in M(R(y^n, \vec{x}\,))\}$ *(where $\vec{x} = x_1^{j_1}, \ldots, x_m^{j_m}$);*

(b) $\forall \vec{x} = x_1^{j_1}, \ldots, x_m^{j_m} \exists y^n (R(y^n, \vec{x}\,) \longleftrightarrow R(F(\vec{x}\,), \vec{x}\,))$.

Proof. Writing R in the form $R(y^n, \vec{x}^{\,n}, \ldots, \vec{x}^{\,0})$ and setting again $\overrightarrow{x} = \vec{x}^{\,n-1}, \ldots, \vec{x}^{\,0}$, we have that if $R_{\overrightarrow{x}} =_{\mathrm{df}} \{\langle y^n, \vec{x}^{\,n}\rangle \mid R(y^n, \vec{x}^{\,n}, \overrightarrow{x})\}$, then Lemma 1.7(i) shows that $R_{\overrightarrow{x}}$ is uniformly $\Sigma_1(M^{n,p(\vec{x}\,)})$, where, as before, $p(\vec{x}\,) =_{\mathrm{df}} \langle\langle \vec{x}^{\,0}\rangle, \ldots, \vec{x}^{\,n-1}\rangle\rangle$. If φ_i is a Σ_1 formula yielding this definition, then we may define the partial function

$$F(\vec{x}^{\,n}, \overrightarrow{x}) = F_{\overrightarrow{x}}(\vec{x}^{\,n}) \simeq h_{M^{n,p(\vec{x}\,)}}(i, \langle \vec{x}^{\,n}\rangle).$$

Then $F_{\overrightarrow{x}}$ is a uniformly $\Sigma_1(M^{n,p(\vec{x}\,)})$-definable Skolem function for $R_{\overrightarrow{x}}$, and by Lemma 1.7(i) F is $\Sigma^{(n)}_1$ with value type n, and will do the job. ⊣

1.17 Lemma. *Let $n < \omega$. There is a $\Sigma^{(n)}_1$ formula defining a good $\Sigma^{(n)}_1(M)$ function $F_n(u, v)$ into M (definable uniformly with respect to any J-structure M), so that*

$$\forall p(p \in R^{n+1}_M \longrightarrow |M| = F_n``H^{n+1}_M \times \{p\}).$$

Proof. By induction on n. For $n = 0$, we have that $p(0) \in R_M$ and thus $|M| = h_M``(\omega \times (H^1_M \times \{p(0)\}))$. Thus we can take $F_0(\langle i, v\rangle, w) = h_M(i, \langle v, w\rangle)$. Suppose that the lemma holds for $n-1$ as witnessed by $F_{n-1}(u^{n-1}, w^0)$ and we prove it for n. Let $p \in R^{n+1}_M$. Then $p\restriction n \in R^n_M$. Let $x \in |M|$ be arbitrary; then $x = F_{n-1}(z, p\restriction n)$ for some $z \in H^n_M$; z in turn equals $h_{M^{n,p\restriction n}}(j, \langle y, p(n)\rangle$ for some $y \in H^{n+1}_M$ since $p(n) \in R_{M^{n,p\restriction n}}$ as well. Note that $F_{n-1}(u^n, w^0)$ is also good $\Sigma^{(n-1)}_1(M)$ (as it is obtained from the good $\Sigma^{(n-1)}_1(M)$ function $F_{n-1}(u^{n-1}, w^0)$ by specialising the first variable u^{n-1} to u^n; it is a general fact goodness is preserved by specialisation). Hence we may define

$$F_n(u^n, w^0) \simeq F_{n-1}(h_{M^{n,w^0\restriction n}}((u^n)_0, \langle (u^n)_1, w^0(n)\rangle), w^0\restriction n).$$

As we are substituting good $\Sigma^{(n)}_1(M)$ functions (with value type $\leq n$) into $F_{n-1}(u^n, w^0)$ we end up with a good $\Sigma^{(n)}_1(M)$ function F_n. ⊣

To bring out the nature of the above argument, we may define

$$g_n(\langle j, y^{n+1}\rangle, p) = h_{M^{n,p\restriction n}}(j, \langle y^{n+1}, p(n)\rangle)$$

and more generally

$$g_i(\langle j, y^{i+1}\rangle, p) = h_{M^{i,p\restriction i}}(j, \langle y^{i+1}, p(i)\rangle)$$

and this is uniformly lightface $\Sigma_1^{(i)}(M)$ in the two variables $w^{i+1} = \langle j, y^{i+1}\rangle$ and $x^0 = p$ for $i \leq n$. We may compose these functions and if $p \in R_M^{n+1}$ then any $x \in |M|$ is the value of such an iterated composition. This is expressed below at part (ii) of the next definition and the fact that follows it.

1.18 Definition ($\Sigma_1^{(n)}$-Skolem Functions). Let M be an acceptable J-structure, and let $p \in \Gamma_M^n$.

(i) $h_M^{n,p} = h_{M^{n,p}}$;

(ii) $\widetilde{h}_M^n(w^n, x^0) = g_0(g_1(\cdots g_{n-1}((w^n)_0, \langle (w^n)_1, x^0(n-1)\rangle) \cdots x^0(0)\rangle)$.

Thus $\widetilde{h}_M^n$ is $\Sigma_1^{(n-1)}$ uniformly over all M. The Σ_1 hull of a set $X \subseteq M^{n,p}$ we shall denote by $h_M^{n,p}(X)$ (and is thus the set $\{h_M^{n,p}(i,x)) \mid i \in \omega, x \in X\}$). Note that $\widetilde{h}_M^1(\langle j, y^0\rangle, p(0)) = g_0(j, \langle y, p(0)\rangle) = h_M(j, \langle y, p(0)\rangle)$. If $p \in R_M^n$ then every $x \in M$ is of the form $\widetilde{h}_M^n(z,p)$ for some $z \in H_M^n$. We may similarly form hulls using $\widetilde{h}_M^n$: again if $X \subseteq M^{n,p}$ say, and $q \in M$ then the $\Sigma_1^{(n-1)}$ hull of $X \cup \{q\}$ is the set $\{\widetilde{h}_M^n(x,q)) \mid x \in X\}$). The following states some of these facts and are now easy to establish (see [62, p. 29]):

Fact. Let M be acceptable, and $p \in R_M^n$.

(i) if $\omega\rho_M^n \in M$ and $p \in R_M^n$ then $\widetilde{h}_M^n$ is a good, uniformly defined, $\Sigma_1^{(n-1)}(M)$ function mapping H_M^n onto M: $M = \{\widetilde{h}_M^n(u^n, p) \mid u^n \in H_M^n\}$.

(ii) (a) every $A \subseteq H_M^n$ which is $\mathbf{\Sigma}_1^{(n)}(M)$ is $\mathbf{\Sigma_1}(M^{n,p})$;
(b) $\rho_M^{n+1} = \rho_{M^{n,p}}$.

1.19 Lemma. *Let M be an acceptable J-structure.*

(i) $\mathbf{\Sigma}^*(M) \subseteq \mathbf{\Sigma}_\omega(M)$;

(ii) *If M is sound then* $\mathbf{\Sigma}^*(M) = \mathbf{\Sigma}_{\boldsymbol{\omega}}(M)$.

Proof. For (i) we just have to see that any typed variable v^n can be replaced by $v \in H_M^n$ and the latter is definable (not necessarily at the nth level of the Levy-hierarchy of complexity!). For (ii) we prove ($\supseteq$). Suppose by induction we have shown that for every $\Sigma_m(M)$ formula $\varphi(\vec{y})$ there is a $\mathbf{\Sigma}_1^{(\boldsymbol{m})}(M)$ formula $\widetilde{\varphi}(\vec{y}^0)$ such that $(\forall \vec{x} \in M)((\varphi(\vec{x}))_M \iff (\widetilde{\varphi}(\vec{x}))_M$. Let $n = m+1$

and suppose $p \in R^n_M$ (as M is sound). Let $\widetilde{h}^n_M$ be as at (i) of the last Fact. This is a good $\Sigma_1^{(m)}$ function of value type 0 (and hence good $\Sigma_1^{(n)}$ also) such that

$$\begin{aligned}(\exists x \psi(x, \vec{y}))_M \quad &\Longleftrightarrow \quad (\exists u \in H^n_M)(\psi(\widetilde{h}^n_M(u,p), \vec{y}))_M \\ &\Longleftrightarrow \quad (\exists u \in H^n_M)(\widetilde{\psi}(\widetilde{h}^n_M(u,p), \vec{y}))_M\end{aligned}$$

where $\widetilde{\psi}$ is the $\boldsymbol{\Pi_1^{(m)}}(M)$-formula given by the inductive hypothesis. Thence $(\widetilde{\psi}(\widetilde{h}^n_M(u,p), \vec{y}))_M$ is a $\boldsymbol{\Sigma_1^{(n)}}(M)$ property and $(\exists u^n \widetilde{\psi}(\widetilde{h}^n_M(u,p), \vec{y}))_M$ is a $\boldsymbol{\Sigma_1^{(n)}}(M)$ relation. ⊣

The following is a standard result. For its proof see [62, 1.11.2].

1.20 Lemma. *Suppose $\pi : \bar{M} \longrightarrow_{\Sigma_1^{(n)}} M$ and is such that* (i) $\pi \restriction \omega\rho^{n+1}_{\bar{M}} = \mathrm{id} \restriction \omega\rho^{n+1}_{\bar{M}}$ *and* (ii) $\mathrm{ran}(\pi) \cap P^*_M \neq \varnothing$. *Then π is Σ^*-preserving.*

Solidity Witnesses

Naturally the notion of *solidity witness* (see [46, Sect. 7]) can be defined in this context. We shall not re-enter a discussion of these notions, but simply give the definition.

1.21 Definition. Let M be an acceptable J-structure, $p \subseteq M$ a finite set of ordinals, and $\nu \in M$. The *standard witness for ν with respect to M*, p is the J-structure $W = W^{\nu,p}_M$ where, if n is such that $\omega\rho^{n+1}_M \leq \nu < \omega\rho^n_M$:

$\sigma : W \cong X$ and $X = \widetilde{h}^{n+1}_M(\nu \cup p \backslash (\nu+1))$ and σ is the inverse of the transitive collapse.

The notion of generalised witness has an analogous definition mutatis mutandis. The properties of witnesses, the definitions of n-solidity etc, then all go through. It is easy to check for the L-hierarchy that if $M = J_\beta$, $p = p_M$, the standard parameter, and $\omega\rho^{n+1}_M \leq \nu < \omega\rho^n_M$, then $\nu \in p \Longleftrightarrow W^{\nu,p}_M \in M$. We have for the L-hierarchy a strong form of condensation. We shall use the fact that the L-hierarchy is sound (cf. [46, 9.2]). Note as always for the pure J-hierarchy, the usual condensation property that hulls of a J_β always transitivise to some J_δ for a $\delta \leq \beta$.

1.22 Lemma (Condensation Lemma). *Let $M = J_\beta$, $\pi : J_\delta \longrightarrow_{\Sigma_1^{(n)}} J_\beta$, $\omega\rho^{n+1}_M \leq \alpha < \omega\rho^n_M$, $\pi(\bar{\alpha}) = \alpha$, and $\pi(\bar{p}) = p_{J_\beta} \backslash \alpha$. Then $\bar{p} = p_{J_\delta} \backslash \bar{\alpha}$.*

Proof. As π is $\Sigma_1^{(n)}$-preserving (and $\widetilde{h}^{n+1}_M(u^{n+1} \cup \{p_M\})$ is good $\Sigma_1^{(n)}(M)$) $J_\delta = \widetilde{h}^{n+1}_{J_\delta}(\bar{\alpha} \cup \{\bar{p}\})$. Thence follows that $\omega\rho^{n+1}_{J_\delta} \leq \bar{\alpha}$: for if this failed we should have a $\boldsymbol{\Sigma_1^{(n)}}(J_\delta)$ definable map of $\bar{\alpha} < \omega\rho^{n+1}_{J_\delta}$ onto the whole of J_δ. However this is impossible as the usual simple diagonalisation argument would yield a $\boldsymbol{\Sigma_1^{(n)}}(J_\delta)$-definable subset of $\bar{\alpha}$ which is not in J_δ. This would contradict the definition of $\omega\rho^{n+1}_{J_\delta}$. That $\bar\alpha < \omega\rho^{n}_{J_\delta}$ follows from the $\Sigma_1^{(n)}$ statement "$\exists u^n(u^n = \pi(\bar\alpha))$" and the $\Sigma_1^{(n)}$-preservation property of π.

As $J_\delta = \widetilde{h}^{n+1}_{J_\delta}(\bar\alpha \cup \{\bar p\})$, we have that $\bar p \in R^n_{J_\delta}$; this means that it can be lengthened to a parameter $p' \in P^{n+1}_{J_\delta}$ (cf. [46, 6.4]). By the minimality properties of the standard parameter [46, 6.3] we have then that $p_{J_\delta}\backslash\bar\alpha \leq^* \bar p$. If we had $<^*$ instead of $\leq^*$ then we should have that $\bar p \in \widetilde{h}^{n+1}_{J_\delta}(\bar\alpha \cup \{p_{J_\delta}\backslash\bar\alpha\})$. Applying the $\Sigma_1^{(n)}$-preserving π we'd conclude that $p_M\backslash\alpha \in \widetilde{h}^{n+1}_M(\alpha \cup \{\pi(p_{J_\delta}\backslash\bar\alpha)\})$ with $\pi(p_{J_\delta}\backslash\bar\alpha) = \pi(p_{J_\delta})\backslash\alpha <^* p_M\backslash\alpha$. A contradiction. ⊣

1.1. Variant Fine Structures

Although we may consider the $\Sigma_1^{(n)}$ hierarchy as emerging finally out of the original fine structure of [24], the historical line of development is not so direct. From the time of Jensen's proof of the Covering Lemma for L some attempts at simplifications were made by several people. Silver's development of *Silver machines* built the L-hierarchy in a quite different manner by using a very much slowed down version of construction based on creating hulls and using a different collection of Skolem functions. As opposed to steps in the L-hierarchy, very little happens in the transition from M^δ to $M^{\delta+1}$ in this machine hierarchy. This is expressed by a *finiteness property*: the hull in $M^{\delta+1}$ of a set A can be obtained by taking the hull in M^δ of $A \cap \delta$ together with just finitely many more ordinals less than δ (and lastly adding the point δ). This relatively simple apparatus enjoyed sufficient condensation properties that proofs of $\square$ and Jensen's Covering Lemma for L could be attained (see [8, Chap. IX] for an outline here, and [1] for a machine proof of $\square$). Once the theory of core models came to the fore it was not apparent that this mechanism could be used as a substitute for the fine structure of mice with measures that was then emerging.

The fine structure for mice has also not had a direct development. We mention here some of the history of this fine structure, and the various uses of the word "acceptable" in the literature. The fine structure for the mice of the Dodd-Jensen core model [10] and [9], although used for later core models with sequences of measures [35], and even in manuscript form of Dodd's for models with extenders, would seem to be far from amenable to the type of approximation hierarchy of Silver. The Dodd-Jensen fine structure was based on previous unpublished work of Solovay who had built on Jensen's fine structure for L, to do the same for $L[U]$; the order of set construction was that of relative constructibility in the traditional "macro" sense, and two notions of "acceptability" and "strong acceptability" occurred here. The latter is now closer to the current, and by now standard, use of the word "acceptable". This detailed how sets appeared in such J^U_α hierarchies, and which expressed a strong and uniform version of GCH. However they bore little resemblance to the current ordering of $L[E]$ hierarchies, and were becoming extremely difficult to work with, and, past a strong cardinal, particularly hair-raising.

Various papers from the time were published using this older fine structure, and for very thin core models, that are inner models of K^{DJ}, the vestigial notions of "Q-structure" that were a part of the old theory still play a role (e.g. [58]). However with the very successful reorganising of hierarchies due to Baldwin and Mitchell this form of fine structure became defunct.

Magidor replaced fine structure (in the sense of eliminating the use of projecta and mastercodes) by the use of more general Σ_n hulls and Skolem functions for Σ_n formulae that, albeit not Σ_n-definable, were preserved under condensations in reproving the Covering Lemma for L (this is the proof given in [8]) using the J-hierarchy, and even using the L-hierarchy alone [34].

One of the chief advantages of the Baldwin-Mitchell reorganisation of the hierarchy of construction from sequences of measures or extenders, was that every level of the models to be constructed was sound. Mitchell and Steel published an account [36] of a fine structure together with a model construction, of extenders whose comparison iteration required iteration trees (see the chapter by Steel in this Handbook). This was the first time that an account of fine structure for mice whose comparison required trees of iterations, allied with the Baldwin-Mitchell organisation of hierarchies, was published. The fine structure used there was inspired by the nature of the predicates that were being used. The notion of $r\Sigma_{n+1}$ formula is analogous to $\Sigma_1^{(n)}$ used here (and the notion of $r\Sigma_{n+1}$ embedding between structures with very good parameters is employed in [46] at 5.12). The success of this fine structure, together with the ability to build much larger models, has ensured its widespread use and represented a leap forward in the production of models that could contain many Woodin cardinals (cf. [50]). Jensen in a series of circulated manuscripts developed the theory for similarly large models using the Σ^* language [27, 25]. Another auxiliary variety of acceptability occurs in [14], where Feng and Jensen develop a theory of mice with some overlapping of extenders in the Σ^* language, in order to build a core model without assuming any 'technical hypothesis' in the form of a large cardinal Ω in the universe (see [41, Sect. 1]). In that paper a J-structure $M = \langle J^A_\alpha, \in, A\rangle$ is *strongly acceptable* if $\forall\tau < \alpha\forall\vec{\xi} < \tau\forall\varphi(v_0) \in \Sigma_1$:

$$J^A_{\tau+1} \models \varphi[\vec{\xi}] \wedge J^A_\tau \models \neg\varphi[\vec{\xi}] \Longrightarrow (J^A_{\tau+1} \models \mathrm{Card}(\tau) \leq \max\{\omega, \vec{\xi}\})$$

holds in M. Despite its name the notion is supplemental to acceptability (which it does not in general imply).

We shall lastly mention the *hyperfine structure* of Friedman-Koepke [19]. This is an attractive elongation of the usual L_α-hierarchy by interspersing infinitely many stages between the usual L_α and $L_{\alpha+1}$. A crucial feature, as will be seen below, for many fine-structural arguments is the notion of *singularisation* of an ordinal, the place where an ordinal ν is first seen to definably singularised by some formula. If $\exists x < \alpha\ \varphi(\xi, x, p)$ defines over L_β a cofinal subset of ξ's forming $C \subseteq \nu$ (for some least $\beta = \beta(\nu)$ and according to some $<_{L_\beta}$-least finite parameter sequence of ordinals p) we can think of the triple $(\beta, \varphi, (p^\frown\alpha))$ as a minimal *location* where ν is singularised. If we define $S_\varphi(q, x) =$ the $<_L$-least ξ so that $\varphi(\xi, x, q)$, as being the term for the Skolem function for φ, we have that $C = S_\varphi^{L_\beta}$"$\{(p, x) \mid x < \alpha\}$. We thus focus on structures of the form

$$L_{(\beta,\varphi_n,(p^\frown\alpha))} =_{\mathrm{df}} (L_\beta, \in, <_L, N, I, S, S_{\varphi_0}^{L_\beta}, S_{\varphi_1}^{L_\beta}, \ldots, S_{\varphi_n}^{L_\beta} \restriction \{w <_{\mathrm{lex}} p^\frown\alpha\}, \ldots)$$

(where $\varphi = \varphi_n$, the nth formula in some standard recursive enumeration, with all subformulae of φ_n being some φ_i for an $i \le n$). We can think of this as the singularising structure for ν in this context, as ν is singularised by the last object in this structure: $S_{\varphi_n}^{L_\beta} \restriction \{w <_{\mathrm{lex}} p^\frown\alpha\}$. The functions N, I, S are included, where the first two are functions for naming and interpreting objects respectively, and S is a general Skolem function. Properly construed one may form hulls and, importantly, the finiteness property of Silver's machines is valid here too; one may prove condensation—that hulls inside locations transitively collapse to other locations. Ultimately the theory allows for a particularly elegant and short proof of Global $\square$. This hyperfine structure can be extended to consider premice with a single measure—thus sufficient for forming the Dodd-Jensen K^{DJ}, but like other alternatives to "true" fine structure there seem to be real technical difficulties to going beyond that.

1.2. Σ^* Ultrapowers

We give an account of the formation of a fine-structure preserving ultrapower. [46, 8.4–8.5] gives the definition and construction of the Σ_0 ultrapower. We shall see here how to extend the usual notion of ultrapower that uses functions within the model M, to one using $\Sigma^*(M)$-definable functions f. Such a function f is not in general an element of the domain structure M, but with the correct assumptions, M has enough information about the measure or extender being used to form the ultrapower, that this can be sensibly done. The resulting target ultrapower structure N may contain more objects than the ordinary Σ_0 ultrapower, in particular more ordinals (if we are starting with a set model M). We shall develop this theory for ultrapowers by short extenders that are weakly amenable with respect to the models M concerned. This is more than one needs for dealing with premice with measures of order 0. However, this greater generality will enable us to quickly dispose of "pseudo-ultrapowers" in the next subsection. In any case it is still basically the account of such ultrapowers from [28]. Suppose that $M = \langle J_\alpha^A, A, B\rangle$ is an acceptable J-structure and E is a (κ, ν) extender over M with a single critical point $\mathrm{crit}(E) = \kappa < \mathrm{On} \cap M$ and $E = \langle E_a \mid \alpha \in [\nu]^{<\omega}\rangle$. We shall recall here for later the definition of *weakly amenability* of an extender E with respect to M. This is defined as for any $a \in [\nu]^{<\omega}$, $\langle X_\alpha \mid \alpha < \kappa\rangle \in M$, that $\{\alpha \mid X_\alpha \in E_a\} \in M$. This can be shown equivalent to saying that $\mathcal{P}(\kappa) \cap M = \mathcal{P}(\kappa) \cap \mathrm{Ult}_0(M, E)$ (the latter denoting the usual "ordinary" Σ_0 ultrapower of M by E). At some point we shall additionally assume that E is Σ_1-amenable: this in fact is just clause (1) of [46, 8.9]. Thus such E will be "close to M" in that terminology.

Assuming only that E is an extender, we shall write $\pi_E : M \longrightarrow_E N = \mathrm{Ult}_0(M, E)$ for the ordinary ("coarse") ultrapower embedding. The map π_E is a Σ_0 and cofinal embedding and hence Σ_1-preserving. In general this is as much definable preservation that one could hope for. The notion of Σ^* ultrapower involves using functions that lie outside of M but that are definable classes using formulae of the language $\mathcal{L}^*$. Let M and E be as above.

1.23 Definition. Suppose that E is a (κ, ν) extender over M. The relation $\pi : M \longrightarrow^*_E N$ holds iff the following conditions are met:

(i) Whenever $\rho^k_M > \kappa$, $\pi : M \longrightarrow_{\Sigma_0^{(k)}} N$; where N is transitive.

(ii) Let $\rho^n_M = \min\{\rho^m_M | \rho^m_M > \kappa\}$, and $H = \bigcup_{x \in H^n_M} \pi(x)$. Then $\pi{\restriction}H^n_M : H^n_M \longrightarrow_E H$.

(iii) Whenever $\rho^{k+1}_M > \kappa$, N is the closure of $H \cup \mathrm{ran}(\pi)$ under good $\Sigma_1^{(k)}(N)$ functions.

1.24 Remark. (a) (ii) requires that $\pi{\restriction}H^n_M$ be the usual Σ_0 ultrapower map into H. Thus at this level we have the familiar ultrapower with functions taken from H^n_M. Hence $\mathrm{crit}(\pi) = \mathrm{crit}(E)$.

(b) If $\omega\rho^\omega_M > \kappa$ then $\pi : M \longrightarrow^*_E N$ implies $\pi : M \longrightarrow_{\Sigma^*} N$. If we define a good $\Sigma_1^{(-1)}$ function to be a function in M then clause (iii) makes sense even if $\rho^1._M \leq \kappa$.

In most situations we shall want N to be well-founded (hence the definition), but sometimes it is convenient (although we shall not be concerned with this here) to ask only that the well-founded core of N (which will be assumed transitive) contains ν. The definition straightforwardly implies that if $\omega\rho^1_M < \kappa$ then $\pi : M \longrightarrow_E N$ if $\pi : M \longrightarrow^*_E N$. (We'll see that under this hypothesis the converse is also true.) We shall see that the existence of such a π, and an N with $\pi : M \longrightarrow^*_E N$ satisfying the above, implies that such π and N are unique. Why is this plausible? Suppose such a π and N exist. Suppose $\kappa < \omega\rho^{m+1}_M$ for consideration as in (iii) above. Then for every $z \in N$ there is a good $\Sigma_1^{(m)}(N)$ function F with $z = F(u, \pi(x))$ for some $u \in H$ and $x \in M$ for some m. Let $y \in H^n_M$ be such that $u \in \pi(y)$. Let $\bar{F}$ have the same functionally absolute definition over M as F does over N. Then $\bar{F}$ is a good $\Sigma_1^{(m)}(M)$ function. Let $\varphi(v_0)$ be any Σ_0 formula. Then $M \models \varphi(\bar{F}(u, x))$ is a $\Sigma_1^{(m)}(M)$ property in u, x. Let $w = \{v \in y \mid M \models \varphi(\bar{F}(v, x))\}$. Then, as $w \in H^n_M$ (since $y \in H^n_M$ and we may assume $n > m$):

$$M \models (\forall v^n \in y)(\varphi(\bar{F}(v^n, x)) \longleftrightarrow v^{n+1} \in w).$$

This is $\Pi_0^{(n)}$, and as π is Σ^*-preserving we have:

$$N \models (\forall v^n \in \pi(y))(\varphi(F(v^n, \pi(x))) \longleftrightarrow v^n \in \pi(w));$$

in short, for u as above:

$$N \models \varphi(F(u,\pi(x)) \;\longleftrightarrow\; u \in \pi(w).$$

This is tantamount to saying that Σ_0 facts about $(F(u,\pi(x)))_N$ are determined by checking whether $u \in \pi(w)$ for a $w \in H^n_M$ suitably formed as above. (And similarly for Σ_0 facts such as "$(F(u',\pi(x')) \in F(u,\pi(x)))_N$".) However $\pi\restriction H^n_M : H^n_M \longrightarrow_E H$ is the usual ultrapower of H^n_M by E, and this map is determined by M and by E. And thus so are the Σ_0 facts about N mentioned above. If the $\in$-diagram of N is determined then the whole map $\pi : M \longrightarrow N$ is determined—and thus unique—if it can be shown to exist. To put it another way, the above argument shows that there is an $\in$-isomorphism between any two such ultrapowers N, N'; however if the N, N' are taken as transitive, then this isomorphism is the identity.

We have implicitly in the above assumed that we can map across such good functions in a well-defined way. We justify this more formally in a moment.

We now proceed to describe ultrapowers formed by taking these extra class (over M) functions.

1.25 Definition. $\Gamma = \Gamma(\kappa, M)$ is the set of functions f with $\mathrm{dom}(f) = [\kappa]^k$ (some $k < \omega$) and either $f \in M$ or f is a good $\boldsymbol{\Sigma_1^{(n)}}(M)$ function for some n with $\omega\rho^{n+1}_M \geq \kappa$.

The extension of π to elements of Γ is effected as follows: if $f \in \Gamma$ and $\mathrm{dom}(f) = \kappa$, and f with $\mathrm{dom}(f) = \kappa$ has a functionally absolute $\Sigma_1^{(m)}(M)$ definition in a parameter r, where $\omega\rho^{m+1}_M > \kappa$, then we set $\pi(f)$ to be the function with $\mathrm{dom}(\pi(\kappa))$ defined over N by the same $\Sigma_1^{(m)}$ definition using $\pi(r)$. We need to argue that this is well-defined. Suppose $F^M(v^m, u^0)$ and $G^M(v^m, u^0)$ are two good $\Sigma_1^{(m)}(M)$ definitions in the parameters q, r respectively of the function f. Then $(\forall\xi < \kappa)(F^M(\xi, q) = G^M(\xi, r))$ holds over M. However this can be expressed as $\boldsymbol{\Pi_0^{(m+1)}}(M)$:

$$(\forall x^{m+1} < \kappa)(F^M(x^{m+1}, q) = G^M(x^{m+1}, r)).$$

As π is Π_0^{m+1} preserving, the same statement is true of $\pi(\kappa), \pi(q), \pi(r), F^N$, G^N over N. So $\pi(f)$ is indeed independent of the choice of its functionally absolute definition.

We shall form a suitable domain and a term model more or less exactly following the pattern for Σ_0 ultrapowers as is done in [46, 8.4], although we shall incorporate the functions from $\Gamma_M = \Gamma(\kappa, M)$, and here we only have the single relevant critical point κ (thus we set $\mu_a = \kappa$ for all $a \in \nu$ from their definition). Thus our domain will be:

$$D = \{\langle a, f\rangle \mid f \in \Gamma_M, a \in [\nu]^{<\omega}, f : [\kappa]^{\mathrm{card}(a)} \longrightarrow M\}.$$

The definitions of the $\sim$ and $\dot{\in}$ relations are then unaltered, and we use the same notation "$f^{a,b}$" where $\mathrm{dom}(f) = [\kappa]^n$, $a \subseteq b$, and $a = (u_{i_1}, \ldots, u_{i_n}) \subseteq$

$b = (u_1, \ldots, u_m)$ to denote the function with domain $[\kappa]^m$ given by $f^{a,b}(v) = f(v_{i_1}, \ldots, v_{i_n})$.

$$\begin{aligned}\langle a, f\rangle \sim \langle b, g\rangle &\iff \{u \in [\kappa]^{\mathrm{card}(c)} \mid f^{a,c}(u) = g^{b,c}(u)\} \in E_c \quad \text{for } c = a \cup b,\\ \langle a, f\rangle \mathrel{\dot\in} \langle b, g\rangle &\iff \{u \in [\kappa]^{\mathrm{card}(c)} \mid f^{a,c}(u) \in g^{b,c}(u)\} \in E_c \quad \text{for } c = a \cup b,\\ \dot C(\langle a, f\rangle) &\iff \{u \mid C(f(u)) \mid\in E_a\} \quad (\text{for } C = A, B).\end{aligned}$$

1.26 Definition. The term model $\mathbb{D}$ is defined as: $\mathbb{D} = \langle D, \sim, \dot\in, \dot A, \dot B\rangle$.

We observe:

1.27 Lemma. *Let $\varphi(v_0^{i_0}, \ldots, v_k^{i_k})$ be either a $\Sigma_1^{(n)}$ formula where $\rho_M^{n+1} > \kappa$, or else a $\Sigma_0^{(n)}$ formula where only $\rho_M^n > \kappa$ is assumed. Let $\langle a_0, f_0\rangle, \ldots, \langle a_k, f_k\rangle \in D$, and let $b \in [\nu]^{<\omega}$ be such that $b \supseteq a_0 \cup \cdots \cup a_k$. Assume that for $j \le k$, f_j is a function to $H_M^{i_j}$.*

Then $\{u \mid M \models \varphi(f_0^{a_0 b}(u), \ldots, f_k^{a_k b}(u))\} \in M$.

Proof. Assume first $\rho_M^{n+1} > \kappa$ and that φ is $\Sigma_1^{(n)}$. As we have assumed the value types of the defining formulae of the $f_j \in \Gamma_M$ satisfy $i_j \le n$ for $j \le k$. Then $M \models \varphi(f_0^{a_0 b}(u), \ldots, f_k^{a_k b}(u))$ defines a $\boldsymbol{\Sigma_1^{(n)}}(M)$ relation. Now if φ is $\Sigma_0^{(n)}$ and if $\rho_M^{n+1} > \kappa$ still holds we have nothing to prove. However if $\rho_M^n > \kappa \ge \rho_M^{n+1}$ we have in this case that either the $f_i \in M$ or they are good $\Sigma_1^{(n-1)}$ and the set under consideration is a $\boldsymbol{\Sigma_0^{(n)}}$ subset of κ, and the result is immediate. ⊣

The following lemma is a kind of "uniformisation lemma" that we shall need in order to prove Łoś's theorems.

1.28 Lemma. *Let $R(y^m, x^{i_0}, \ldots, x^{i_k})$ be a $\Sigma_1^{(m)}$ relation with $i_0, \ldots, i_k \le m$. Let $m \le n$ be such that $\rho_M^{n+1} > \kappa$, and let $f_0, \ldots, f_k \in \Gamma$ be good $\boldsymbol{\Sigma_1^{(n)}}(M)$ functions with $f_j : [\kappa]^l \longrightarrow H_M^{i_j}$. Then there is a good $\boldsymbol{\Sigma_1^{(n)}}(M)$ function $g : [\kappa]^l \longrightarrow H_M^m$, $g \in \Gamma$, such that for any $u \in [\kappa]^l$:*

$$M \models \exists y^m R(y^m, f_0(u), \ldots, f_k(u)) \iff M \models R(g(u), f_0(u), \ldots, f_k(u)).$$

Proof. By Lemma 1.16 there is a good $\boldsymbol{\Sigma_1^{(m)}}(M)$ function $F(x^{i_0}, \ldots, x^{i_k}) = y^m$ such that:

$$\begin{aligned}&M \models \exists y^m R(y^m, x^{i_0}, \ldots, x^{i_k})\\ &\quad\iff M \models R(F(x^{i_0}, \ldots, x^{i_k}), x^{i_0}, \ldots, x^{i_k}).\end{aligned}$$

So set $g'(u) \simeq F(f_0(u), \ldots, f_k(u))$. g' is then a good $\boldsymbol{\Sigma_1^{(n)}}(M)$ function. $\mathrm{dom}(g') \subseteq [\kappa]^l$ and by Lemma 1.27, we see that $a =_{\mathrm{df}} \mathrm{dom}(g') \in M$. Now define $G(v^0, w^0)$ by

$$y = G(v^0, w^0) \iff (y = v^0 \wedge w^0 \in a) \vee (y = 0 \wedge w^0 \notin a).$$

Then G is good, $\boldsymbol{\Sigma}_0(M)$, and hence $g(u) =_{\mathrm{df}} G(g'(u), u)$ is good $\boldsymbol{\Sigma_1^{(n)}}(M)$. ⊣

Before proving a Łoś's theorem later for $\Sigma_1^{(n)}$, we state one for Σ_0:

1.29 Lemma. *Let $\varphi(v_0, \ldots, v_k)$ be a Σ_0 formula. Let $\langle a_0, f_0\rangle, \ldots, \langle a_k, f_k\rangle \in D$, and let $b \in [\nu]^{<\omega}$ be such that $b \supseteq a_0 \cup \cdots \cup a_k$. Then*

$$\begin{aligned}&\mathbb{D} \models \varphi(\langle a_0, f_0\rangle, \ldots, \langle a_k, f_k\rangle)\\ &\quad\Longleftrightarrow\quad \{u \mid M \models \varphi(f_0^{a_0 b}(u), \ldots, f_k^{a_k b}(u))\} \in E_b.\end{aligned}$$

This is an induction on the structure of the Σ_0 formula φ using the last two lemmas. We shall give more detail in the $\Sigma_1^{(n)}$ Łoś's theorem which follows.

Using the Σ_0 Łoś's theorem 1.29 one has that if $\pi : M \longrightarrow_E^* N$ then the map from $\mathbb{D}$ to N given by $\langle a, f\rangle \mapsto \pi(f)(a)$ is structure preserving, in particular on $\in$: $\langle a, f\rangle \mathrel{\dot\in} \langle b, g\rangle \Longleftrightarrow \pi(f)(a) \in \pi(g)(b)$. We then have that $\mathbb{D}$ is a model of Extensionality, and $\sim$ is a congruence relation. We thus, as for the Σ_0 ultrapower, form the equivalence classes, written as $[a, f]$, for $\langle a, f\rangle \in \mathbb{D}$. We shall assume from now on that $\dot\in$ is well founded and we thus have an onto factor map $[\,] : \mathbb{D} \longrightarrow \langle N, \in, A', B'\rangle$ satisfying $[x] = / \in [y]$ iff $x \sim / \mathrel{\dot\in} y$ and $\dot C(x) \Longleftrightarrow C'([x])$. Using Lemma 1.29 again we have the map $\pi : M \longrightarrow_{\Sigma_0} N$ is defined by the usual constant functions c_x (with $\mathrm{dom}(c_x) = [\kappa]^0$): $\pi(x) = [0, c_x]$.

It will be useful to have some notation to stratify $\Gamma(\kappa, M)$.

1.30 Definition. Suppose $f \in \Gamma(\kappa, M)$.

$$\Gamma = \Gamma_n(\kappa, M) =_{\mathrm{df}} \begin{cases}\{f \in \Gamma(\kappa, M) \mid \mathrm{ran}(f) \subseteq H_M^n\} & \text{if } \rho_M^{n+1} > \kappa;\\ \{f \in \Gamma(\kappa, M) \mid \mathrm{ran}(f) \in H_M^n\} & \text{if } \omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n.\end{cases}$$

1.31 Lemma. *Suppose n is such that $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$. Set $\overline{H} = H_M^n$, and $H = \bigcup \pi``\overline{H}$ with π as above. Then:*

(i) *$\pi\restriction\overline{H} : \overline{H} \longrightarrow_E H$, i.e. $\pi\restriction\overline{H}$ is the coarse ultrapower map;*

(ii) *$\mathrm{crit}(\pi) = \kappa$, and $[a, f] = \pi(f)(a)$ for $a \in [\nu]^{<\omega}$ and $f \in {}^\kappa\overline{H} \cap \overline{H}$;*

(iii) *$\mathcal{P}(\kappa) \cap \overline{H} = \mathcal{P}(\kappa) \cap H$.*

Proof. (i) Let $x \in H$; then $x = [a, f]$ for some $\langle a, f\rangle \in \mathbb{D}$. Suppose $f \in \Gamma_m(\kappa, M)$. We just need to know that f could have been chosen from $\overline{H}$, i.e. as $\pi\restriction\overline{H}$ is cofinal into H we can find $y \in \overline{H}$ with $x \in \pi(y)$. We can assume that $\mathrm{ran}(f) \subseteq y$, by intersecting f with $\kappa \times y$ if need be, and now the latter is essentially a $\mathbf{\Sigma}_1^{(n-1)}(M)$ bounded subset of ρ_M^n, and thus is in M. By acceptability it must be in $\overline{H}$. (ii) is the usual argument for such ultrapowers. For (iii) ($\subseteq$) is straightforward. For ($\supseteq$) suppose $x \subseteq \kappa, x = [a, f] \in N$. Then $x = \{\xi < \kappa \mid \xi \in \pi(f)(a)\} = \{\xi < \kappa \mid \{u \mid \xi \in f(u)\} \in E_a\}$. Amenability says precisely that then $x \in H$. $\dashv$

We thus have some sort of agreement with the notion of a Σ_0 ultrapower at the "crossing structure" $\overline{H}$ where the projectum crosses over the measurable cardinal. It is more work to establish that we are getting the correct kind of embedding to ensure Σ^*-elementarity.

1.32 Theorem (Fine Structural Ultrapower Theorem).

(i) *N is an acceptable J-structure.*

(ii) (a) $\pi : M \longrightarrow_{\Sigma_0^{(n)}} N$ *if* $\omega\rho_M^n > \kappa$.

(b) $\pi : M \longrightarrow_{\Sigma_2^{(n)}} N$ *if* $\omega\rho_M^{n+1} > \kappa$.

(iii) (*Łoś's Theorem*) *let φ be in $\Sigma_0^{(n)}$ (or in $\Sigma_1^{(n)}$, if $\kappa < \omega\rho_M^{n+1}$) and $b \supseteq \bigcup_i a_i$. Then*

$$N \models \varphi(\pi(f_1)(a_1), \ldots, \pi(f_n)(a_n)) \quad \Longleftrightarrow \quad \{u \mid M \models \varphi(\overrightarrow{f_i^{a_i b}(u)})\} \in E_b.$$

Additionally if we assume E is close to M:

(iv) $\pi : M \longrightarrow_{\Sigma^*} N$,

(v) $\mathcal{P}(\kappa) \cap \mathbf{\Sigma}^*(M) = \mathcal{P}(\kappa) \cap \mathbf{\Sigma}^*(N)$.

Proof. The proof of the theorem is in two stages. The main difficulty is in showing that the maps are between the relevant reducts. What this amounts to is showing that the elements in the natural "strata" that one defines from the functions in Γ are actually those obtained by using the iterated definition of projectum over N. The "strata" referred to arise as the H_n in the following definition: Set $\omega\rho_n = H_n \cap \mathrm{On}$ where:

$$H_n = \begin{cases} \{[a, f] \mid f \in \Gamma_n \wedge \langle a, f\rangle \in D\} & \text{if } \rho_M^n > \kappa, \\ H_M^n & \text{otherwise.} \end{cases}$$

(1) *H_n is transitive.*

Proof of (1). Trivial if $\rho_M^n < \kappa$. Suppose $[b, g] \in [a, f] \in H_n$. If $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$ then transitivity follows in the usual manner for Σ_0 ultrapowers. We may assume then that $g \in \Gamma_m$ for an $m \leq n$ and $\rho_M^{n+1} > \kappa$. Now show there is a $[b', g'] \in H_n$ with $[b', g'] = [b, g]$ by appealing to Lemma 1.28. $\dashv$ (1)

We thus have $N = H_0 \supseteq H_1 \supseteq H_2 \supseteq \cdots$ and that if $x \in H_M^n$, then $\pi(x) \in H_n$; hence if we interpret on the N-side the variables v_j^i as varying over H_i, then π respects types. Thus $\langle N, \in, A', B', H_0, H_1, H_2, \ldots\rangle$ is an $\mathcal{L}^*$-structure, the *pseudo-interpretation* of $\mathcal{L}^*$. Our task is then two-fold: to show that $\pi : M \longrightarrow_{\Sigma^*} N$ in this pseudo-interpretation, and then to show that it is actually the *correct* interpretation, that is, $H_n = H_N^n$ for any n.

(2) (Łoś's Theorem for Pseudo-Interpretations). *Let* $\varphi(v^{i_1}, \ldots, v^{i_k})$ *be a* $\Sigma_1^{(n)}$ *formula, where* $\omega\rho_M^{n+1} > \kappa$, *or a* $\Sigma_0^{(n)}$ *formula if* $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$. *Let* $[a, f_j] \in H_{i_j}$ *with* $f_j \in \Gamma_{i_j}$, *with* $i_j \leq n$ *for* $1 \leq j \leq k$. *Then*

$$N \models \varphi(\overrightarrow{[a, f_j]}) \quad \Longleftrightarrow \quad \{u \mid M \models \varphi(f_1(u), \ldots, f_k(u))\} \in E_a.$$

Proof of (2).

Case 1. $\rho_M^{n+1} > \kappa$.

By induction on the complexity of φ. Note that $\{u \mid M \models \varphi(f_1(u), \ldots, f_k(u))\} \in M$ by Lemma 1.27. We shall only check here the quantifier step $\varphi \equiv \exists v^m\, \psi(v^m, v^{i_1}, \ldots, v^{i_k})$ where $m \leq n$, $\psi \in \Sigma_0^{(m)}$ and (2) is assumed to hold for ψ. The forward direction is quite straightforward: we assume $N \models \varphi(\overrightarrow{[a, f_j]})$; then there is a $[b, f_0] \in H_m$ with $a \subseteq b$, $f_0 \in \Gamma_m$ and $N \models \psi([b, f_0], [b, f_1^{ab}], \ldots, [b, f_k^{ab}])$. By the inductive hypothesis:

$$\{u \mid M \models \psi(f_0^{ab}(u), f_1^{ab}(u), \ldots, f_k^{ab}(u))\} \in E_b.$$

As $\operatorname{ran}(f_0) \subseteq H_M^m$ we have:

$$\{u \mid M \models \exists v^m \psi(v^m, f_1^{ab}(u), \ldots, f_k^{ab}(u))\} \in E_b$$

and so:

$$\{u \mid M \models \exists v^m \psi(v^m, f_1(u), \ldots, f_k(u))\} \in E_a.$$

Conversely, assume that $\{u \mid M \models \exists v^m \psi(v^m, f_1(u), \ldots, f_k(u))\} \in E_a$. By Lemma 1.28 there is a $g \in \Gamma$, $g : [\kappa]^{\operatorname{card}(a)} \longrightarrow H_M^m$ such that:

$$\{u \mid M \models \psi(g(u), f_1(u), \ldots, f_k(u))\} \in E_a.$$

By the inductive hypothesis, $N \models \psi([a, g], \overrightarrow{[a, f_j]})$. As $\omega\rho_M^{m+1} > \kappa$ and $\operatorname{ran}(g) \subseteq H_M^m$ we have an $[a, g] \in H_m$ and hence $N \models \exists v^m \psi(v^m, \overrightarrow{[a, f_j]})$. $\dashv$ *Case 1*

Case 2. $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$.

Note that the only difficulty in *Case 1* was in the converse direction, when we had to appeal to Lemma 1.28. Again we look only at a representative (now bounded) quantifier step: $\varphi \equiv \exists v^n \in u^n \psi(v^n, u^n, v^{i_1}, \ldots, v^{i_k})$ with (2) assumed proven for ψ. The forward direction is just as in the previous case, so we omit it. So suppose for some $f_0 \in \Gamma_n$

$$\{u \mid M \models \exists v^n \in f_0(u) \psi(v^n, f_0(u), f_1(u), \ldots, f_k(u))\} \in E_a.$$

We define a witnessing function g another way, making use of the fact, that by the definition of Γ_n in this case, that $f_0 \in H_M^n$:

$$g(u) = \begin{cases} \text{the } <_M\text{-least } w \in f_0(u) \text{ so that } (\psi(w, f_0(u), f_1(u), \ldots, f_k(u)))_M, \\ 0 \quad \text{if this } w \text{ does not exist.} \end{cases}$$

We may assume $n > 0$ (for otherwise (2) is trivially true in this case). Then, using the fact that the canonical well-order of M is Δ_1^M, we have that g is a $\mathbf{\Sigma}_0^{(n)}(M)$ subset of $\kappa \times \bigcup \mathrm{ran}(f_0) \in H_M^n$, and thus is an element of H_M^n. (This is true even if $n = 0$.) Then for some $X \in H_M^n$ we have $\{u \mid M \models \psi(g(u), f_0(u), f_1(u), \ldots, f_k(u))\} \supseteq X \in E_a$ and we can finish as before. $\dashv$ (2)

(3) (a) *If* $\rho_M^{n+1} > \kappa$ *then* $\pi : M \longrightarrow_{\Sigma_2^{(n)}} N$ *in the pseudo-interpretation.*
(b) *If* $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$ *then* $\pi : M \longrightarrow_{\Sigma_1^{(n)}} N$ *in the pseudo-interpretation.*

Proof of (3). Suppose $\psi \equiv \exists v^n \varphi(v^n, \vec{u}\,)$ where φ is $\Sigma_0^{(n)}$ (or $\Pi_1^{(n)}$ for part (a)). Let $\vec{x} \in M$, and assume that $N \models \exists v^n \varphi(v^n, \pi(\vec{x}\,))$. Let then $[a, f] \in H_n$, $f \in \Gamma_n$ be such that $N \models \varphi([a, f], \vec{x}\,)$. By *Case 1* (or *2* for (b)) above $\{u \mid M \models \varphi(f(u), \vec{x}\,)\} \supseteq X \in E_a$. Hence $M \models \exists v^n \varphi(v^n, \vec{x}\,)$ as $\mathrm{ran}(f) \subseteq H_M^n$. $\dashv$ (3)

We now briefly consider what happens below the critical point κ.

(4) (i) *Let* $\kappa \geq \rho_M^n$. *Then* $\pi : M \longrightarrow_{\Sigma_\omega^{(n)}} N$ *in the pseudo-interpretation.* (ii) $\pi : M \longrightarrow_{\Sigma^*} N$ *in the pseudo-interpretation.*

Proof of (4). (i) This is essentially because we have defined $H_n = H_M^n$ for such n, and $\pi{\restriction}H_M^n = \mathrm{id}{\restriction}H_M^n$ and thus the variables of type n are interpreted in the same domains. Suppose (4) failed for some least such n, as witnessed by some $\Sigma_k^{(n)}$ formula φ of least complexity. Note that φ is not the 'atomic' $\Sigma_1^{(n-1)}$ part of a $\Sigma_0^{(n)}$ formula (by definition of n, or else by (3)(b) if $\omega\rho_M^{n-1} > \kappa$). Elementary considerations show we can assume φ is then not atomic, nor of the form $\neg\psi, (\psi \wedge \chi)$ but is $\varphi \equiv \exists v^n \psi(v^n, \vec{u}\,)$. Suppose $N \models \exists v^n \psi(v^n, \pi(\vec{x}\,))$ for some $\vec{x} \in H_M^n$. Let $y \in H_n = H_M^n$ witness this. $N \models \psi(y, \pi(\vec{x}\,))$. As ψ is a simpler formula, and $\pi(y) = y$, we have $M \models \psi(y, \vec{x}\,)$. (ii) then follows from (i) and (3). $\dashv$ (4)

(5) *N is an acceptable J-structure, π is Q-preserving, and $H_n = J_{\rho_n}^{A'}$ for all $n < \omega$.*

Proof of (5). The property of being an acceptable J-structure is a Q-condition (cf. [46, 1.21]). If $\pi : M \longrightarrow N$ is a standard Σ_0 ultrapower, then in fact π is Σ_0 and cofinal into N and such maps preserve Q properties. However otherwise π is at least $\Sigma_2^{(0)}$ (and *a fortiori* Σ_2)-preserving by (3)(a) which suffices. The same reasoning works level-by-level: if $\rho_M^{n+1} > \kappa$ then $\pi{\restriction}H_M^n : \langle H_m^n, H_m^n \cap A, H_m^n \cap B\rangle \longrightarrow_{\Sigma_2} \langle H_n, A' \cap H_n, B' \cap H_n\rangle$; thus H_n is a J-structure constructed from A'. If $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$ then $\pi{\restriction}H_M^n$: $\langle H_m^n, H_m^n \cap A, H_m^n \cap B\rangle \longrightarrow_{\Sigma_0} \langle H_n, A' \cap H_n, B' \cap H_n\rangle$ which is moreover cofinal, again, as it is a standard Σ_0 ultrapower map (Lemma 1.31), so the same is true at this level. For $\rho_M^n \leq \kappa$ it is trivial. $\dashv$ (5)

If we can now show the pseudo-interpretation is the correct one, we shall have fulfilled all the clauses (i)–(iv) of the theorem. The following computation of the size of the relevant ordinals finishes the task: it only remains to show that the projecta of N correspond to the ordinals ρ_n. We divide into the cases: above and below the measurable κ.

(6) $\rho_m = \rho_N^m$ *if* $\kappa \leq \omega\rho_M^m$.

Proof of (6). By induction on m. This is trivial for $m = 0$.

(6a) $\langle H_m, B\rangle$ *is amenable for* $B \in P(\omega\rho_m) \cap \mathbf{\Sigma}_1^{(m-1)}(N)$. *Hence* $\rho_m \leq \rho_N^m$.

Proof of (6a). Suppose $B \subseteq \omega\rho_m$ and is $\Sigma_1^{(m-1)}(N)$ in the parameter $[a, f]$, say $B(x) \Longleftrightarrow N \models \varphi(x, [a, f])$ with $\varphi \in \Sigma_1^{(m-1)}$. Let $w = [b, g] \in H_m$. (Without loss of generality we shall assume $a = b$ here.) We require $B \cap w \in H_m$. Define h by $h(y^m, v^0) = \{t^m \in y^m \mid M \models \varphi(t^m, v^0)\}$. Thus $h(y^m, v^0)$ is a $\Sigma_0^{(m)}$ function of value type m and thus is good. Hence it is in Γ. h is defined for all y^m, v^0 and $k : [\kappa]^{\mathrm{card}(a)} \longrightarrow H_M^m$ where $k(u) = h(g(u), f(u))$ (note that $\mathrm{ran}(k)$ is indeed contained in H_M^m, as each element of the form $h(y^m, v^0)$ is *bounded* $\Sigma_0^{(m)}$). k is in Γ being a composition of such.

If $\kappa < \omega\rho_M^{m+1}$ we may conclude that $k \in \Gamma_m$ as $\mathrm{ran}(k) \subseteq H_M^m$. If $\omega\rho_M^{m+1} \leq \kappa < \omega\rho_M^m$ we need to see that $k \in H_M^m$ to infer this. Notice that $k(u) \subseteq g(u)$ and thus $K = \{\langle u, z\rangle \mid u \in k(z)\}$ is a $\Sigma_0^{(m)}(M)$ of $\{\langle u, z\rangle \mid u \in g(z)\}$ and the latter is in H_M^n. Hence so is K and we have that k is thus rudimentary over $M^{m,p}$ where p is a suitable choice of parameters including those used to define f, g. Hence $k \in H_M^m$. As

$$[\kappa]^{\mathrm{card}(a)} = \{u \mid M \models \forall t^m \in g(u)[\varphi(t^m, f(u)) \longleftrightarrow t^m \in k(u)]\} \in E_a$$

by Łoś we have $N \models \forall t^m \in [a, g](\varphi(t^m, [a, f]) \longleftrightarrow t^m \in [a, k])$. Hence

$$[a, k] = [a, g] \cap \{t^m \mid N \models \varphi(t^m, [a, f])\} = w \cap A \in H_m. \qquad \dashv \text{(6a)}$$

(6b) *There is an* $A \subseteq \rho_m \cap \mathbf{\Sigma}_1^{(m-1)}(N)$ *such that* $A \notin N$. *Hence* $\rho_m \geq \rho_N^m$.

Proof of (6b).

Case 1. $\kappa < \omega\rho_M^{m+1}$.

Suppose $\bar{A}$ is $\Sigma_1^{(m-1)}(M)$-definable in a parameter $\overline{p}$, but with $\bar{A} \cap \rho_M^m \notin M$, for example we can find such using $\bar{p} \in P_M^m$.

Let A be $\Sigma_1^{(m-1)}(N)$ in $\pi(\bar{p}) = p$ by the same formula φ say. We show that $A \cap \omega\rho_m \notin M$. Suppose otherwise. Let $A \cap \omega\rho_m = [a, f] \in N$. Then $N \models \forall x^m(x^m \in [a, f] \longleftrightarrow \varphi(x^m, p))$.

This is a $\Pi_1^{(m)}$, in p, formula, and by Łoś's Theorem (2):

$$\{u \mid M \models \forall x^n(x^n \in f(u) \longleftrightarrow \varphi(x^n, p))\} \in E_a.$$

So there is a $u \in [\kappa]^{\mathrm{card}(a)}$ with $f(u) \cap \rho_M^n = \overline{A} \cap \rho_M^n$—a contradiction.

Case 2. $\omega\rho_M^{m+1} \leq \kappa < \omega\rho_M^m$.

We alert the reader to this more problematic case. Here we explicitly use the weak amenability property of the extender to ensure that the map is *cofinal* at the level of this crossing projectum structure.

Let $p \in P_M^{m+1}$, and set $\overline{A} = A^{p(m-1)}_{M^{m-1,p\restriction m-1}}$. Then $\bar{A}$ is $\Sigma_1^{(m-1)}(M)$ in p; suppose that it is defined by φ. Let $\widetilde{A}$ be defined over N in the same way using $\pi(p)$. $M^{m,p\restriction m} = \langle H, \overline{A}\rangle$ is amenable and $\pi\restriction H_M^m$ is Σ_0 and cofinal into H_m. As π is $\Sigma_0^{(m)}$-preserving into N, we conclude that for any $x \in H_M^m$ $\pi(x \cap \overline{A}) = \pi(x) \cap \widetilde{A}$. Hence:

(i) $\langle H_m, \widetilde{A}\rangle$ is amenable; (ii) $\pi\restriction H_M^m : M^{m,p\restriction m} \longrightarrow_{\Sigma_0} \langle H_m, \widetilde{A}\rangle$ cofinally, and hence is Σ_1-elementary.

However now we see that ρ_m must equal ρ_N^m; for suppose $\rho_m < \rho_N^m$: then $\widetilde{A} \cap H_m \in N$. As $p \in P_M^{m+1}$ we can pick $B \in \mathcal{P}(\omega\rho_M^{m+1}) \cap \Sigma_1(M^{m,p\restriction m})$ in $p(m)$, with $B \notin M$. As $\pi\restriction\kappa = \mathrm{id}\restriction\kappa$ we have that $B \in \mathcal{P}(\kappa) \cap \boldsymbol{\Sigma}_1(\langle H_m, \widetilde{A}\rangle)$. Since $\langle H_m, \widetilde{A}\rangle \in N$, then so is B. By the amenability of our extender E (and acceptability of our structures) $\mathcal{P}(\kappa) \cap M = \mathcal{P}(\kappa) \cap N$; hence $B \in M$—a contradiction. $\dashv$ (6b)&(6)

In the course of proving (6b) we also showed:

(7) $\pi``P_M^m \subseteq P_N^m$ if $\omega\rho_M^m > \kappa$.

1.33 Remark. The argument of *Case 2*, where $\omega\rho_M^{m+1} \le \kappa < \omega\rho_M^m$, shows that the weak amenability of E implies that $\omega\rho_N^{m+1} \le \rho_{m+1}$. Without the requirement of amenability we should only be able to prove the inequality $\omega\rho_N^m \ge \rho_m$ and not its reverse. (Further only that (7) holds for those m with $\omega\rho_M^{m+1} > \kappa$.) The assumption of amenability then ensures the $\Sigma_0^{(m)}$-*cofinality* of the ultrapower map (and hence that it is in fact $\Sigma_1^{(n)}$-preserving). The assumption of Σ_1-amenability of M will enable us to prove (i) the equality $\omega\rho_N^m = \rho_m$; (ii) as well as that of the projecta below the measurable; (iii) finally, the full Σ^*-elementarity of the map π.

1.34 Remark. Still considering the above *Case 2* where $\omega\rho_M^{m+1} \le \kappa < \omega\rho_M^m$, we can vary assumptions on E, or M and still get that $\pi : M \longrightarrow_{\Sigma_0^{(n)}} N$ cofinally: if we assume E is Σ_1-amenable this suffices (see [62, 3.2.6]); similarly if $R_M^m \neq \varnothing$ then we can get the same conclusion (as well as the bonus that $\pi``R_M^m \subseteq R_N^m$ see [62, 3.2.4]).

First we shall need a preliminary lemma:

1.35 Lemma. *Suppose E is close to M, i.e., E is weakly amenable and Σ_1-amenable over M, and $\omega\rho_M^{n+1} \le \kappa < \omega\rho_M^n$. Let $B \in \boldsymbol{\Sigma}_1^n(N) \cap \mathcal{P}(\kappa)$. Then $B \in \boldsymbol{\Sigma}_1^n(M)$.*

Proof. Suppose for some $\varphi \in \Sigma_0^{(n)}$ and all ξ,

$$\xi \in B \iff \exists v^n \varphi(v^n, \xi, \pi(f)(a)).$$

By weak amenability,

$$\xi \in B \iff \exists u \in H^n_M \ \exists v^n \in \pi(u)\varphi(v^n, \xi, \pi(f)(a)),$$

and by Łoś for $\Sigma_0^{(n)}$,

$$\xi \in B \iff \exists u \in H^n_M(\{w \mid \exists v^n \in u\varphi(v^n, \xi, f(w))\} \in E_a).$$

Notice that the set $X_\xi = \{w \mid \exists v^n \in u\ \varphi(v^n, \xi, f(w))\}$ is a $\Sigma_0^{(n)}$ subset of $\mathrm{dom}(f) \in H^n_M$ (whichever n satisfies $f \in \Gamma_n$) and hence $X_\xi \in H^n_M$. By the Σ_1-amenability assumption, "$X \in E_a$" is $\mathbf{\Sigma}_1(M)$. Thus $B \in \mathbf{\Sigma}_1^{(n)}(M)$. ⊣

(8) *Suppose $\kappa \geq \omega\rho^m_M$. Then* (i) $\rho_m = \rho^m_N$, *and hence $H^m_M = H^m_N$; and* (ii) $\mathbf{\Sigma}_1^{(m)}(M) \cap \mathcal{P}(H^m_M) = \mathbf{\Sigma}_1^{(m)}(N) \cap \mathcal{P}(H^m_N)$.

Proof of (8). Let n be such that $\omega\rho^{n+1}_M \leq \kappa < \omega\rho^n_M$. We prove (8) by induction on $m \geq n+1$. By the last lemma if $m = n+1$, or the inductive hypothesis otherwise:

$$\mathbf{\Sigma}_1^{(m-1)}(M) \cap \mathcal{P}(\omega\rho^m_M) = \mathbf{\Sigma}_1^{(m-1)}(N) \cap \mathcal{P}(\omega\rho^m_M).$$

For (i), that $\rho_m = \rho^m_N$, now follows directly from the fact that (a) $\forall\gamma < \omega\rho^m_M a \in \mathbf{\Sigma}_1^{(m-1)}(N) \cap \mathcal{P}(\gamma)$ then $a \in H^m_M = H^m_N$; and (b) if $A \in \mathbf{\Sigma}_1^{(m-1)}(M) \cap \omega\rho^m_M, A \notin M$ then $A \notin N$.

For (ii), by Lemma 1.6 we have, substituting either M or N for T, that $C \in \mathbf{\Sigma}_1^{(m)}(T) \cap \mathcal{P}(H^m_T)$ if and only if $C \in \mathbf{\Sigma}_1(\langle H^m_T, Q\rangle)$ for some $Q \in \mathbf{\Sigma}_1^{(m-1)}(T) \cap \mathcal{P}(H^m_T)$. By the inductive hypothesis (or again Lemma 1.35 if $m = n+1$), we have such a $Q \in \mathbf{\Sigma}_1^{(m-1)}(M) \cap \mathbf{\Sigma}_1^{(m-1)}(N)$. Since (i) shows $H^m_M = H^m_N$, we have, for $C \subseteq H^m_M$:

$$C \in \mathbf{\Sigma}_1^{(m)}(M) \iff C \in \mathbf{\Sigma}_1(\langle H^m_M, Q\rangle) \iff C \in \mathbf{\Sigma}_1^{(m)}(N).$$

⊣ (6&8)

We can now conclude that the ultrapower embedding is properly Σ^*-preserving.

(9) $\pi : M \longrightarrow_{\Sigma^*} N$ *in the standard interpretation.*

Proof of (9). (4) shows that $\pi : M \longrightarrow_{\Sigma^*} N$ in the pseudo-interpretation. (6) and 8(i) together show that this interpretation is the correct one. ⊣ (9)

1.36 Lemma. π"$P^*_M \subseteq P^*_N$.

Proof. Given (7) it suffices to show π"$P^m_M \subseteq P^m_N$ if $\omega\rho^m_M \leq \kappa$: however if $p \in P^m_M$ is chosen, there is a $C \in \Sigma_1^{(m-1)}(M)$ in p with $C \cap \omega\rho^m_M \notin M$. We have that π is Σ^*-elementary, and $\pi{\restriction}\kappa = \mathrm{id}{\restriction}\kappa$, hence if $\widetilde{C}$ has the same $\Sigma_1^{(m-1)}$ definition over N in $\pi(p)$, we shall have $C \cap \omega\rho^m_M = \widetilde{C} \cap \omega\rho^m_N \notin N$. Hence $\pi(p) \in P^m_N$. ⊣

(10) *For* $\langle a, f\rangle \in D, [a,f] = \pi(f)(a)$.

Proof of (10). All that we have left to show is (iii) in Definition 1.23, that N is the closure of $\mathrm{ran}(\pi) \cup \nu$ under good $\Sigma_1^{(n)}$ functions, for $\omega\rho_M^{n+1} > \kappa$. We've extended π to such functions so it is enough to show $[a,f] = \pi(f)(a)$, for $f \in \Gamma$. If $f \in M$ this would be a standard argument (see, e.g., [46, 8.4, Claim 4]. So suppose $f \in \Gamma_n$, with $\mathrm{dom}(f) = [\kappa]^k$, for some n with $\rho_M^{n+1} > \kappa$, and let G be a functionally absolute $\Sigma_1^{(n)}$ definition of the graph of f in some parameter $p \in M$. Let $\widetilde{G}$ be given by the same definition over N in $\pi(p)$. Then $[\kappa]^k = \{u \mid G(f(u), u, p)\} \in E_a$. Hence $\widetilde{G}([a,f], a, \pi(p))$. Then $\pi(f)(a) = [a,f]$ as $\widetilde{G}$ is the graph of $\pi(f)$. $\dashv$ (10)

We are only left with proving the last clause (v) of the theorem that $\mathcal{P}(\kappa)\cap\boldsymbol{\Sigma}^*(M) = \mathcal{P}(\kappa)\cap\boldsymbol{\Sigma}^*(N)$. That $\subseteq$ holds is given by (9). For $\supseteq$ we argue as follows: if for all n $\rho_M^n > \kappa$ then $\mathcal{P}(\kappa) \cap \boldsymbol{\Sigma}^*(N) \subseteq \mathcal{P}(\kappa) \cap N = \mathcal{P}(\kappa) \cap M$. Otherwise for some n we have $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$. Lemma 1.35 is not quite sufficient, as we need to prove a result for further $m \geq n+1$.

1.37 Lemma. *Let n be such that $\omega\rho_M^{n+1} \leq \kappa < \omega\rho_M^n$. Let $\varphi(v^m, v^{m-1}, \ldots, v^n, v^{n-1}, \ldots, v^0)$ be a $\Sigma_1^{(m)}$ formula for some $m \geq n$. Let $a \in [\nu]^{<\omega}$ and $f^{n-1}, \ldots, f^0$ be such that $f^j \in \Gamma_j, f^j : [\kappa]^{|a|} \longrightarrow H_M^j$ for $j < n$. Then there is a $\Sigma_1^{(m)}$ formula $\varphi'(v^m, v^{m-1}, \ldots, v^n)$ which is effectively obtainable from φ, the $\boldsymbol{\Sigma_1}(M)$ definition of E_a, and the $\boldsymbol{\Sigma_1^{(n-1)}}(M)$ definitions of the f^j, with the property that $(\forall x^m \cdots \forall x^{n+1} \in M)$ $(\forall f \in \Gamma_n$, with $\mathrm{dom}(f) = [\kappa]^{|a|})$*

$$\begin{aligned} &N \models \varphi(x^m, \ldots, x^{n+1}, [a,f], [a, f^{n-1}], \ldots, [a, f^0]) \\ &\iff \quad M \models \varphi'(x^m, \ldots, x^{n+1}, f). \end{aligned}$$

Proof. This is by induction on $m \geq n$. To simplify notation, we shall assume the $\boldsymbol{\Sigma_1^{(n-1)}}(M)$ definitions of the f^j, and the $\boldsymbol{\Sigma_1}(M)$ definition of E_a, are in face lightface, so parameter free. (It is routine to carry these parameters along otherwise.) We first consider the case that $m = n$. (This means that the variables $v^m, \ldots, v^{n+1}$ are absent from φ.) Let $\varphi(v^n, v^{n-1}, \ldots, v^0) \equiv \exists w^n \psi(w^n, v^n, v^{n-1}, \ldots, v^0)$, where $\psi \in \Sigma_0^{(n)}$. Now for the requisite kind of f and f^j:

$$\begin{aligned} &N \models \exists w^n \psi(w^n, [a,f], [a, f^{n-1}], \ldots, [a, f^0]) \\ &\iff \quad (\exists y^n \in H_M^n) N \models \exists w^n \in \pi(y^n) \\ &\qquad\qquad \psi(w^n, [a,f], [a, f^{n-1}], \ldots, [a, f^0]) \end{aligned}$$

(as $\pi{\restriction}H_M^n$ is cofinal into H_n); now by Łoś we have that:

$$\begin{aligned} &(\exists y^n \in H_M^n)\{u \mid M \models \exists w^n \in y^n \psi(w^n, f(u), f^{n-1}(u), \ldots, f^0(u))\} \in E_a \\ &\iff \quad (\exists y^n \in H_M^n)(\exists z^n \in H_M^n)(z^n \in E_a \wedge \\ &\qquad\qquad z^n = \{u \mid M \models \exists w^n \in y^n \psi(w^n, f(u), f^{n-1}(u), \ldots, f^0(u))\}). \end{aligned}$$

This last line can be seen to be a $\Sigma_1^{(n)}$ formula after substituting the $\Sigma_1^{(n-1)}$ definitions of the good $f^j(u)$ for v^j, and is our φ'.

For $m \geq n+1$ the argument is similar, but simpler: let $\varphi \equiv \exists w^m \psi$ with $\psi \in \Sigma_0^{(m)}$. We suppose that we have proven the effectiveness of the translation procedure for $\Sigma_1^{(n-1)}$ and hence for the atomic components of ψ; further that the result works inductively through the connectives, trivially enough. The argument for bounded quantifiers is similar to that for unbounded; we thus concentrate here on this one step, and assume as inductive hypothesis that the result holds for ψ. Now, again assuming we have the requisite functions f and f^j and:

$$\begin{aligned} & N \models \varphi(x^m, \ldots, x^{n+1}, [a,f], [a,f^{n-1}], \ldots, [a,f^0]) \\ \Longleftrightarrow \quad & (\exists w^m \in H_M^m) N \models \psi(w^m, x^m, \ldots, x^{n+1}, [a,f], [a,f^{n-1}], \ldots, [a,f^0]) \\ \Longleftrightarrow \quad & (\exists w^m \in H_M^m) M \models \psi'(w^m, x^m, \ldots, x^{n+1}, f) \\ \Longleftrightarrow \quad & M \models \exists w^m \psi'(w^m, x^m, \ldots, x^{n+1}, f), \end{aligned}$$

using that $H_M^n = H_n$ at the first equivalence, and the inductive hypothesis at the second. $\dashv$

This now can be used to show that $\mathcal{P}(\kappa) \cap \boldsymbol{\Sigma_1^{(m)}}(M) \supseteq \mathcal{P}(\kappa) \cap \boldsymbol{\Sigma_1^{(m)}}(N)$. Hence the last clause (v) is now proven and the proof of the Ultrapower Theorem is complete. $\dashv$ 1.32.

1.3. Pseudo-Ultrapowers

We develop a theory of *pseudo-ultrapowers*. Ordinary ultrapowers (both coarse and fine) can be considered as special types of pseudo-ultrapowers. The latter are used in many combinatorial constructions, and particularly come into their own in the proof of the Covering Lemma for fine structural inner models, or for Global Square, $\square$, or indeed many areas where combinatorial arguments involve fine structure.

One can think of pseudo-ultrapowers as an attempt to develop an answer to the following question. Suppose we have acceptable structures $\overline{Q}$, Q with a map $\sigma : \overline{Q} \longrightarrow_{\Sigma_0} Q$ cofinally between them. Suppose further that $\overline{Q} = J_{\overline{\nu}}^{\overline{A}}$, $Q = J_\nu^A$and moreover that $\overline{Q}$ is extended by an acceptable $\overline{M} = \langle J_{\overline{\beta}}^{\overline{A}}, \overline{B} \rangle$ where either $\overline{\nu} = \overline{\beta}$ or else $\overline{\nu}$ is a cardinal in $\overline{M}$. Can we find a structure M and an extension of σ to a structure preserving map $\widetilde{\sigma} \supseteq \sigma, \widetilde{\sigma} : \overline{M} \longrightarrow M$, where $M = \langle J_\beta^A, B \rangle$? We should hope that the extended map $\widetilde{\sigma}$ would be sufficiently fine-structural. What we should like is that $\widetilde{\sigma}$ should be $\Sigma_1^{(n)}$ for any n with $\omega\rho_{\overline{M}}^n \geq \overline{\nu}$. This may not be always possible for every such n, but with certain conditions on $\overline{M}$ we can achieve this. Weakening these conditions could allow us to weaken the conclusion: for example, we could have this level of elementarity if $\omega\rho_{\overline{M}}^{n+1} \geq \overline{\nu}$.

Requiring additionally that $\overline{\nu}$ be regular in $\overline{M}$ will ensure that the extended map takes $\overline{\nu}$ cofinally into its image. This requirement is a feature of the Global $\square$ proof where we use a pseudo-ultrapower that takes just enough functions to preserve the regularity of $\overline{\nu}$ in the sense of $\overline{M}$ whilst at the same time preserving the fact that it is $\boldsymbol{\Sigma}_1^{(n)}(\overline{M})$ singularised for some $n < \omega$.

1.38 Definition. $\Gamma = \Gamma_{\overline{M},\overline{\nu}} =_{\mathrm{df}}$

$$\begin{aligned}&\{f \mid (\mathrm{dom}(f) \in \overline{Q} \wedge \mathrm{ran}(f) \subseteq \overline{M})\\ &\quad \wedge((f \in \boldsymbol{\Sigma}_1^{(n)}(\overline{M}) \wedge \omega\rho_{\overline{M}}^{n+1} \geq \overline{\nu}) \vee (f \in H_{\overline{M}}^{n} \wedge \omega\rho_{\overline{M}}^{n} \geq \overline{\nu}))\}.\end{aligned}$$

We now define a term model, whose domain is:

$$D = \{\langle a, f\rangle \mid f \in \Gamma_{\overline{M},\overline{\nu}} \wedge a \in \sigma(\mathrm{dom}(f))\}.$$

We define a pseudo-epsilon relation e and a congruence I by:

$$\begin{aligned}\langle a, f\rangle e \langle b, g\rangle &\iff \langle a, b\rangle \in \sigma(\{\langle u, v\rangle \mid f(u) \in g(v)\}),\\ \langle a, f\rangle I \langle b, g\rangle &\iff \langle a, b\rangle \in \sigma(\{\langle u, v\rangle \mid f(u) = g(v)\}),\\ \dot{C}(\langle a, f\rangle) &\iff a \in \sigma(\{u \mid f(u) \in C\}) \text{ for } C = \overline{A}, \overline{B}.\end{aligned}$$

We set $\mathbb{D} = \mathbb{D}_{\bar{Q},\bar{\sigma},\bar{M}} = \langle D, I, e, \dot{A}, \dot{B}\rangle$.

1.39 Lemma. *Let $\varphi(v_0, \ldots, v_k)$ be a Σ_0 formula. Let $\langle a_0, f_0\rangle, \ldots, \langle a_k, f_k\rangle \in D$, and let $b = \langle a_0, \ldots a_k\rangle$. Then*

$$\begin{aligned}&\mathbb{D} \models \varphi(\langle a_0, f_0\rangle, \ldots, \langle a_k, f_k\rangle)\\ &\quad \iff \quad b \in \sigma(\{\langle u_0, \ldots u_k\rangle \mid M \models \varphi(f_0(u_0), \ldots, f_k(u_k))\}).\end{aligned}$$

There is very little difference between the proof of this and the previous Lemma 1.29. By this, we can see that I is an identity for $\mathbb{D}$ and $\mathbb{D}$ models Extensionality. We shall for the purposes of this development assume that e is well-founded. We thus can define a transitivisation map

$$[\,] : D \longrightarrow M;$$

$$[x] = [y] \iff x\, I\, y; \qquad [x] \in [y] \iff x\, e\, y;$$

$$A_M([x]) \iff \dot{A}(x); \qquad B_M([x]) \iff \dot{B}(x).$$

With Σ_0-elementarity guaranteed by the last lemma we define:

1.40 Definition. $\widetilde{\sigma}$, the canonical extension of σ, is defined by: $\widetilde{\sigma}(x) = [\langle 0, \{\langle 0, x\rangle\}\rangle]$; M is the pseudo-ultrapower of $\overline{M}$ by σ.

1.41 Lemma. $\widetilde{\sigma}{\restriction}\overline{Q} = \sigma$.

Proof. Set $\widetilde{Q} = \bigcup \widetilde{\sigma}``\overline{Q}$. Then $\widetilde{Q}$ is transitive. We shall verify: $\widetilde{Q} = \{[\langle a, f\rangle] \mid f \in \overline{Q}\}$. For ($\supseteq$), pick a, f as specified, and set $b = \mathrm{ran}(f)$. As $f \in \overline{Q}$, so is b. Then $[a, f] \in [0, \langle 0, b\rangle]$ as can be directly verified from the Łoś lemma above. For ($\subseteq$), let $x \in \widetilde{\sigma}(y)$ with $y \in \overline{Q}$. If $x = [a, f]$ with $f \in \Gamma$, $a \in \sigma(\mathrm{dom}(f))$, then $a \in \sigma(\{u \in \mathrm{dom}(f) \mid f(u) \in y\})$. However if we set $f' =_{\mathrm{df}} f \cap (\mathrm{dom}(f) \times y)$, (where $\mathrm{dom}(f) \times y$ is a member of $\overline{Q}$) when f itself is not in $\overline{M}$, then this is at most $\boldsymbol{\Sigma}_1^{(n)}(\overline{M})$ where $\omega\rho_{\overline{M}}^{n+1} \geq \bar{\nu}$; it thus lies in $\overline{M}$ and hence by acceptability, in $\overline{Q}$. It is easy to verify by Łoś again that $[a, f] = [a, f']$, and we have thus verified ($\subseteq$).

Define $\sigma' : \widetilde{Q} \longrightarrow Q$ by $\sigma'([a, f]) = \sigma(f)(a)$. We have just shown that $\mathrm{dom}(\sigma') = \widetilde{Q}$. σ' is well-defined:

$$\begin{aligned}
[a, f] = [b, g] \quad &\Longleftrightarrow \quad \langle a, b\rangle \in \sigma(\{\langle u_0, u_1\rangle \mid f(u_0) = g(u_1)\}) \\
&\qquad\quad = \{\langle u_0, u_1\rangle \in \sigma(\mathrm{dom}(f) \times \mathrm{dom}(g)) \mid \sigma(f)(u_0) \\
&\qquad\quad = \sigma(g)(u_1)\} \\
&\Longleftrightarrow \quad \sigma(f)(a) = \sigma(g)(b).
\end{aligned}$$

A similar pair of equivalences show that $[a, f] \in [b, g] \iff \sigma(f)(a) \in \sigma(g)(b)$, and hence σ' is $\in$-preserving.

σ' is onto Q: this is clear, since if $v \in Q$ is arbitrary and $v \in \sigma(x)$ for some $x \in \overline{Q}$ (as σ is cofinal) then let $f \in \overline{Q}$ be the constant function $f : \gamma \longrightarrow x$ with constant value x with $\gamma < \bar{\nu}$; then clearly $v = \sigma(f)(\alpha)$ for some $\alpha < \sigma(\gamma)$. Thus σ' can only be the identity and $\widetilde{\sigma}(x) = [0, \{\langle 0, x\rangle\}] = \sigma(x)$. ⊣

The following theorem gives the basic preservation properties of pseudo-ultrapowers. The reader should compare this with Theorem 1.32.

1.42 Theorem (Pseudo-Ultrapower Theorem). *Let $\widetilde{\sigma} : \bar{M} \longrightarrow_{\Sigma_0} M$ be the canonical extension of $\sigma : \overline{Q} \longrightarrow_{\Sigma_0} Q$. Then*

(i) *$\widetilde{\sigma}$ is Q-preserving, M is an acceptable end extension of Q, and $M = \{\widetilde{\sigma}(f)(u) \mid u \in \sigma(\mathrm{dom}(f)), f \in \Gamma\}$.*

(ii) (a) *$\widetilde{\sigma}$ is $\Sigma_0^{(n)}$-preserving for n with $\omega\rho_{\bar{M}}^{n} \geq \bar{\nu}$;*

(b) *$\widetilde{\sigma}$ is $\Sigma_2^{(n)}$-preserving for n with $\omega\rho_{\bar{M}}^{n+1} \geq \bar{\nu}$.*

Proof. We stratify the functions that will be responsible for the various projectum levels of the target structure M, which we shall name as H_n at first, later demonstrating that they have the correct interpretation. The reader will thus see that the tactic is analogous to that of the previous fine-structural ultrapower result.

Define

$$\begin{aligned}
\Gamma_n &= \begin{cases} \{f \in \Gamma \mid \mathrm{ran}(f) \subseteq H_{\bar{M}}^{n}\} & \text{if } \omega\rho_{\bar{M}}^{n+1} \geq \bar{\nu}, \\ \{f \in \Gamma \mid \mathrm{ran}(f) \in H_{\bar{M}}^{n}\} & \text{if } \omega\rho_{\bar{M}}^{n+1} < \bar{\nu} \leq \omega\rho_{\bar{M}}^{n}, \end{cases} \\
H_n &= \{[\langle a, f\rangle] \mid f \in \Gamma_n \wedge \langle a, f\rangle \in D\} \quad \text{if } \Gamma_n \text{ is defined}, \\
\omega\rho_n &= H_n \cap \mathrm{On}.
\end{aligned}$$

Note (i) If $\omega\rho_{\bar{M}}^{n+1} < \bar{\nu} \leq \omega\rho_{\bar{M}}^{n}$ and $f \in \Gamma_n$ then $f \in \bar{M}$.
Then as for standard ultrapowers:

(1) *H_n is transitive.*

(2) Let $\overrightarrow{\langle\langle a_i, f_i\rangle\rangle} \in {}^m D$, where $f_i \in \Gamma_{j_i}$ and $j_i \leq n$, let $\varphi(v_1^{j_1}, \ldots v_m^{j_m}) \in \Sigma_0^{(n)}$ where $\omega\rho_{\bar{M}}^{n} \geq \bar{\nu}$ (or $\Sigma_1^{(n)}$ if $\omega\rho_{\bar{M}}^{n+1} \geq \bar{\nu}$). Then

$$M \models \varphi[\overrightarrow{[a_i, f_i]}] \iff \vec{a_i} \in \sigma(\{\vec{u} \mid M \models \varphi[\overrightarrow{f_i(\vec{u})}]\}).$$

This directly yields the following as for fine ultrapowers (but only in the pseudo-interpretation):

(3) *$\widetilde{\sigma} : \bar{M} \longrightarrow_{\Sigma_1^{(n)}} M$ for any n with $\omega\rho_{\bar{M}}^{n} \geq \bar{\nu}$, and $\widetilde{\sigma} : \bar{M} \longrightarrow_{\Sigma_2^{(n)}} M$ for any n with $\omega\rho_{\bar{M}}^{n+1} \geq \overline{\nu}$.*

(4) M is acceptable. $\widetilde{\sigma}$ is Q-preserving, and $H_n = |J_{\rho_n}^{A'}|$ where $|M| = |J_{\alpha'}^{A'}|$, for n with $\omega\rho_{\bar{M}}^{n} \geq \bar{\nu}$.

Proof of (4). If $\rho_{\bar{M}}^1 \geq \bar{\nu}$ then by (3) $\widetilde{\sigma}$ is at least Σ_2-preserving; if $\rho_{\bar{M}}^1 < \bar{\nu}$ then $\widetilde{\sigma}$ is actually a cofinal map (it is using only functions f *in*: M see the Note above). In either case Q properties are preserved, and acceptability is such. The last part follows just as in (5) of Theorem 1.32, again noting that $\widetilde{\sigma}$ is cofinal into H_n if $\omega\rho_{\bar{M}}^{n} \geq \overline{\nu} > \omega\rho_{\bar{M}}^{n+1}$, since only functions $f \in \Gamma_n \subseteq |\bar{M}|$ are used. $\dashv$ (4)

(5) $\rho_m = \rho_M^m$ if $\bar{\nu} \leq \omega\rho_{\bar{M}}^{m+1}$; $\rho_m \leq \rho_M^m$ if $\nu \leq \omega\rho_{\bar{M}}^{m}$.

Proof of (5). This is by induction on m; for $m = 0$ it is trivial. We imitate the corresponding proofs of (6) in Theorem 1.32.

(5a) *$\langle H_m, A\rangle$ is amenable for $A \in P(\omega\rho_m) \cap \mathbf{\Sigma}_1^{(m-1)}(M)$. Hence $\rho_m \leq \rho_M^m$.*

Proof of (5a). As before suppose $A \subseteq \omega\rho_m$ and is $\Sigma_1^{(m-1)}(M)$ in the parameter $[a, f]$, say $A(x) \iff N \models \varphi(x, [a, f])$ with $\varphi \in \Sigma_1^{(m-1)}$. Let $w = [b, g] \in H_m$ (again without loss of generality we shall assume $a = b$ here, and similarly by enlarging domains if need be, that $\mathrm{dom}(f) = \mathrm{dom}(g)$ (it suffices given f, g, a, b as here to define functions f', g' with $\mathrm{dom}(f') = \mathrm{dom}(g') = \mathrm{dom}(f) \times \mathrm{dom}(g)$ and further amalgamate to get $c = \langle a, b\rangle$ etc.). We require $A \cap w \in H_m$. This time define

$$h(y^m, v^0) = \{t^m \in y^m \mid \bar{M} \models \varphi(t^m, v^0)\}.$$

Thus $h(y^m, v^0)$ is a $\Sigma_0^{(m)}$ function of value type m and thus is in Γ, being good. We may now define $k : \mathrm{dom}(g) \longrightarrow H_M^m$ where $k(u) = h(g(u), f(u))$.

If $\bar{\nu} \leq \omega\rho_M^{m+1}$ we may conclude that $k \in \Gamma_m$. If $\omega\rho_M^{m+1} < \bar{\nu} \leq \omega\rho_M^m$ we again have that k is $\Sigma_0^{(m)}$-definable in parameters (note now that $g \in H_M^m$) and we conclude that $k \in H_M^m$ for the same reasons. If

$$\mathrm{dom}(g) = \{u \mid \overline{M} \models \forall t^m \in g(u)[\varphi(t^m, f(u)) \longleftrightarrow t^m \in k(u)]\}$$

and as $a \in \sigma(\mathrm{dom}(g))$, by Łoś's theorem we have:

$$M \models \forall t^m \in [a, g](\varphi(t^m, [a, f]) \longleftrightarrow t^m \in [a, k]).$$

Hence $[a, k] \cap w = [a, g] \cap \{t^m \mid M \models \varphi(t^m, [a, f])\} = A \cap w \in H_m$. $\dashv$ (5a)

(5b) *Assume $\bar{\nu} \leq \omega\rho_{\bar{M}}^{m+1}$. Then there is an $A \subseteq \omega\rho_m \cap \mathbf{\Sigma}_1^{(m-1)}(M)$ such that $A \notin M$. Hence $\rho_m \geq \rho_M^m$.*

Proof of (5b). Suppose $\bar{A}$ is $\Sigma_1^{(m-1)}(\overline{M})$-definable in a parameter $\overline{p}$, but with $\bar{A} \cap \omega\rho_{\overline{M}}^m \notin \overline{M}$, for example we can find such using $\bar{p} \in P_{\overline{M}}^m$. Let A be $\Sigma_1^{(m-1)}(M)$ in $\pi(\bar{p}) = p$ by the same formula φ, say. We show that $A \cap \omega\rho_m \notin M$. Suppose otherwise. Let $A \cap \omega\rho_m = [a, f] \in M$. Then, in the pseudo-interpretation, $M \models \forall x^m(x^m \in [a, f] \longleftrightarrow \varphi(x^m, p))$. By Łoś's theorem $a \in \sigma(w)$ where

$$w = \{u \mid \overline{M} \models \forall x^m(x^m \in f(u) \longleftrightarrow \varphi(x^m, \bar{p}))\}.$$

So $w \neq \varnothing$ so there is a u with $f(u) = \bar{A} \cap \rho_{\overline{M}}^m = A \cap \rho_{\overline{M}}^m$—a contradiction.
$\dashv$ (5)&1.42

It is possible to improve the elementarity of the embedding where $\omega\rho_{\bar{M}}^n \geq \bar{\nu} > \omega\rho_{\bar{M}}^{n+1}$, under certain conditions.

1.43 Lemma. *$\widetilde{\sigma}$ is $\Sigma_0^{(n)}$-preserving and cofinal (hence $\rho_n = \rho_M^n$), and thus $\Sigma_1^{(n)}$-preserving, if* (a) *n satisfies $\omega\rho_{\bar{M}}^n \geq \bar{\nu} > \omega\rho_{\bar{M}}^{n+1}$, and* (b) *$R_{\bar{M}}^n \neq \varnothing$. Further $\widetilde{\sigma}$ "$R_{\bar{M}}^n \subseteq R_M^n$.*

For a proof of this we refer the reader to [62, 3.2.4]. For our purposes in proving Global $\square$, we shall need a refinement of the above construction. We should like the canonical extension map $\widetilde{\sigma}$ to be sufficiently fine structure preserving to ensure that if $\bar{\nu}$ is regular in $\bar{M}$, but $\Sigma_1^{(n)}$ singularised over $\bar{M}$ (by this we mean that for some $\beta < \bar{\nu}$ there is a good $\Sigma_1^{(n)}$ map of a subset of β cofinally into $\bar{\nu}$), then whilst M still thinks that $\nu(= \widetilde{\sigma}(\bar{\nu}))$ is regular, there is nevertheless also a good $\Sigma_1^{(n)}(M)$-singularising map. This may require us to take fewer functions than Definition 1.38 allows.

We now describe the small modification to do this. Assume then that we are in the situation under discussion:

1.44 Definition. Suppose that $\bar{\nu}$ is regular in $\bar{M}$, but is $\Sigma_1^{(k)}$-singularised over $\bar{M}$ for some k: we define $k = k(\bar{M})$ to be least $k < \omega$ for which this is true.

Note that this implies that $\omega\rho_{\bar{M}}^{k+1} \leq \bar{\nu}$. Moreover:

1.45 Lemma.

$$\omega\rho_{\bar{M}}^{k+1} \leq \bar{\nu} \leq \omega\rho_{\bar{M}}^{k}.$$

Proof. By the last remark we have to show that $\bar{\nu} \leq \omega\rho_{\bar{M}}^{k}$. Suppose this failed. Then this would imply that $k = m+1$ for some $m \in \omega$. Let $r \in \bar{M}$ be such that there is a good $\Sigma_1^{(k)}(\bar{M})$ function f singularising $\bar{\nu}$ with domain of f contained in some $\gamma < \bar{\nu}$ and with $\omega\rho_{\bar{M}}^{k} < \gamma$. Let $X = \widetilde{h}_{\bar{M}}^{m+1}(\gamma \cup \{r, p\})$ be the $\Sigma_1^{(m)}(\bar{M})$ hull of the objects displayed where p has been chosen from $P_{\bar{M}}^{*}$. This is of a lower degree of elementarity, and hence $X \cap \bar{\nu}$ is bounded in $\bar{\nu}$. Let $\pi : N \longrightarrow \bar{M}$ be the inverse of the transitive collapse map on X. As $\pi{\restriction}\omega\rho_{\bar{M}}^{k+1} = \mathrm{id}{\restriction}\omega\rho_{\bar{M}}^{k+1}$ and $p \in \mathrm{ran}(\pi) \cap P_{\bar{M}}^{*}$ we map appeal to Lemma 1.20 and see that π is Σ^*-preserving. However the parameter r is in the $\mathrm{ran}(\pi)$ and thus $\mathrm{ran}(f) \subseteq \mathrm{ran}(\pi) = X$. This is absurd. ⊣

We now simply restrict the functions used in forming the canonical extension to those $\Sigma_1^{(n)}(\bar{M})$-definable functions, for an $n < k$.

1.46 Definition. Let $\bar{M}, \bar{\nu}, k = k(\bar{M})$ be as above. Define $\Gamma_{\bar{M},\bar{\nu}}^{k} =_{\mathrm{df}}$:

$$\{f \mid \mathrm{dom}(f) \in \overline{Q} \wedge \mathrm{ran}(f) \subseteq \overline{M}) \wedge (n < k \wedge f \in \mathbf{\Sigma}_1^{(n)}(\overline{M}) \wedge \omega\rho_{\overline{M}}^{n+1} \geq \bar{\nu})\}.$$

1.47 Definition. Suppose we construct the pseudo-ultrapower using functions from $\Gamma_{\bar{M},\bar{\nu}}^{k}$ where $k = k(\bar{M})$. Then the resulting map $\tilde{\sigma}$ is the *canonical k-extension* of σ and M the *canonical k-pseudo-ultrapower.*

1.48 Theorem (k-Pseudo-Ultrapower Theorem). *Let $\bar{M}, \bar{\nu}, k = k(\bar{M})$ be as above. Let $\widetilde{\sigma} : \bar{M} \longrightarrow_{\Sigma_0} M$ be the canonical k-extension of $\sigma : \overline{Q} \longrightarrow_{\Sigma_0} Q$. Then*

(i) *$\widetilde{\sigma}$ is Q-preserving, M is an acceptable end extension of Q, and $M = \{\widetilde{\sigma}(f)(u) \mid u \in \sigma(\mathrm{dom}(f)), f \in \Gamma\}$.*

(ii) (a) *$\widetilde{\sigma}$ is $\Sigma_2^{(n)}$-preserving for $n < k$;*

(b) *$\widetilde{\sigma}$ is $\Sigma_0^{(k)}$-preserving.*

1.49 Lemma. *Suppose $\bar{\nu}$, $\bar{M}$, $n = k(\bar{M})$, $\widetilde{\sigma}$, M are as above. Then*

(i) *$\rho_n = \rho_M^n$, and $\widetilde{\sigma}$ is $\Sigma_0^{(n)}$-preserving and cofinal (thus $\Sigma_1^{(n)}$-preserving);*

(ii) *$\widetilde{\sigma}(\bar{\nu}) = \nu$ and the latter is regular in M;*

(iii) *n is least so that there is a $\mathbf{\Sigma_1^{(n)}}(M)$ map cofinalising ν.*

Note: As in Lemma 1.45 the hypothesis implies here too that $\omega\rho^n_{\bar M} \geq \bar\nu \geq \omega\rho^{n+1}_{\bar M}$.

Proof. From what we have already done, (i) will follow if we can show $\rho_n \geq \rho^n_M$. We first note that $\widetilde\sigma(\bar\nu)$ is regular in M. For $\widetilde\sigma(\bar\nu)$ this is either because $n = 0$ and $\widetilde\sigma$ is then Σ_0 and cofinal—hence Σ_1-preserving, or because $n > 0$ and by the above $\widetilde\sigma$ is Σ_2-preserving. As one would hope $\widetilde\sigma(\bar\nu) = \nu$: suppose $\eta = \widetilde\sigma(f)(a) < \widetilde\sigma(\bar\nu)$ for some $f \in \Gamma^{k(\bar M)}$. Then $f \in \bar M$. Set $\delta = \sup(\mathrm{ran}(f) \cap \bar\nu)$. As $\mathrm{dom}(f) \in \bar M$ and $\bar\nu$ is regular in $\bar M$, $\delta < \bar\nu$. Then $\mathrm{ran}(\widetilde\sigma(f)) \subset \widetilde\sigma(\delta)$. Thus $\eta < \widetilde\sigma(\delta)$. This proves (ii).

By hypothesis there is $\bar f$ a good function $\Sigma^{(n)}_1(\bar M)$ in a parameter $\bar p$ say, that maps a subset of some $\gamma < \bar\nu$ cofinally into $\bar\nu$. (We'll assume $\mathrm{ran}(f) \subseteq \bar\nu$.) Let $p = \widetilde\sigma(\bar p)$. Let $\widetilde A =_{\mathrm{df}} A^{n,p}_M \cap J^{A^{n,p}_M}_{\rho_n}$; $\widetilde M = \langle J^{\widetilde A}_{\rho_n}, \widetilde A\rangle$. Then $\widetilde\sigma{\restriction}\bar M^{n,\bar p} : \bar M^{n,\bar p} \longrightarrow_{\Sigma_0} \widetilde M$ cofinally. $\bar f$ is rudimentary over $\bar M^{n,\bar p}$ and we can let f be rudimentary over $\widetilde M$ by the same definition. Then $\mathrm{dom}(f)$ is bounded in ν. As $\widetilde\sigma{\restriction}\bar\nu$ is cofinal into ν (because σ is) we have $\widetilde\sigma``\mathrm{ran}(\bar f) \subseteq \mathrm{ran}(f)$ and the latter is thus cofinal in ν and hence f singularises ν. However if $\rho_n < \rho^n_M$ we should have $\widetilde M$, and thus f, both members of M. This contradicts the regularity of ν in M which we have just remarked upon above.

Thus $\widetilde\sigma$ is $\Sigma^{(n)}_0$-preserving and cofinal, hence $\Sigma^{(n)}_1$-preserving; $\widetilde\sigma(\bar f)$ is thus well-defined, and is a good $\boldsymbol{\Sigma}^{(n)}_1(M)$ map cofinalising ν. ⊣

1.50 Remark. We can conclude from the above existence of the good cofinalising map that $\omega\rho^n_M \geq \nu \geq \omega\rho^{n+1}_M$ but *not* that $\nu > \omega\rho^{n+1}_M$ even if $\bar\nu > \omega\rho^{n+1}_{\bar M}$.

In the above the $\in$-relation, e, of the term model $\mathbb{D}$ was assumed well-founded. The Interpolation Lemma to follow is again not in the most general form, but will be useful later. The hypotheses imply that $\omega\rho^n_{\bar M} \geq \bar\nu \geq \omega\rho^{n+1}_{\bar M}$ for the named n; we thus may form the term model using the functions in Γ_n. Since $\overline M$ is $\Sigma^{(n)}_0$-embeddable into the well-founded model M by the map g below, we can then embed the term model into M *via* $g'([a,G]) = g(G)(a)$ and g' is then a $\Sigma^{(n)}_0$ map. Hence it is $\in$-preserving on its domain, and so demonstrates that e is well-founded. The structure $\widetilde M$ is that formed by the pseudo-ultrapower construction as the canonical $k(\bar M)$-extension of $\sigma = g{\restriction}J^{\overline A}_{\bar\nu} : J^{\overline A}_{\bar\nu} \longrightarrow J^A_\nu$ from above.

1.51 Lemma (Interpolation Lemma). *Suppose $\overline M = \langle J^{\overline A}_{\bar\beta}, \overline B\rangle$ is a structure such that $\bar\nu$ is regular in $\overline M$, but that $k(\bar M)$ is defined, i.e. for some least $n < \omega$, there is a $\boldsymbol{\Sigma}^{(n)}_1(\overline M)$ function singularising $\bar\nu$. Suppose further that $g : \overline M \longrightarrow_{\Sigma^{(n)}_1} M = \langle J^A_\beta, B\rangle$. Let $\widetilde\nu = \sup g``\bar\nu$. Let $\sigma_1 =_{\mathrm{df}} \mathrm{id}{\restriction}J^{A'}_{\widetilde\nu}$. Then there is a structure $M' = \langle J^{A'}_{\beta'}, B'\rangle$, a map $\widetilde g : \overline M \longrightarrow M'$ with* (a) *$\widetilde g \supseteq g{\restriction}J^{\overline A}_{\bar\nu}$ and* (b) *$\widetilde g$ is $\Sigma^{(n)}_0$ and cofinal at the nth level (and hence $\Sigma^{(n)}_1$-preserving); further there is a unique $g' : M' \longrightarrow_{\Sigma^{(n)}_0} M$, with $g = g' \circ \widetilde g$ and $g'{\restriction}\widetilde\nu = \sigma_1$.*

$$

Figure 10.1: The Interpolation Lemmata

Proof. As intimated, M' and $\widetilde{g}$ come from the construction of this section as the canonical $k(\bar{M})$-extension of the cofinal mapping $g\restriction J^{\overline{A}}_{\overline{\nu}} : J^{\overline{A}}_{\overline{\nu}} \longrightarrow_{\Sigma_0} J^{A}_{\widetilde{\nu}}$ playing the role of $\sigma : \overline{Q} \longrightarrow_{\Sigma_0} Q$. That $\widetilde{g}$ has the requisite properties has been established. g' is defined through: $g'(\widetilde{g}(G)(a)) = g(G)(a)$. Then g' has to be the unique such map with $g = g' \circ \widetilde{g}$ and $g'\restriction\widetilde{\nu} = \mathrm{id}\restriction\widetilde{\nu}$, since $g'(\widetilde{g}(G)(a)) = g' \circ \widetilde{g}(G)(g'(a)) = g(G)(a)$. (Note that trivially $g'\restriction\widetilde{\nu} = \mathrm{id}\restriction\widetilde{\nu} \longleftrightarrow g'\restriction J^{\bar{A}}_{\widetilde{\nu}} = \mathrm{id}\restriction J^{\bar{A}}_{\widetilde{\nu}}$.) ⊣

A slightly more generalised form of the above will be useful. This allows σ_1 to be different from the identity function.

1.52 Lemma (Generalised Interpolation Lemma). *Suppose $\overline{M} = \langle J^{\overline{A}}_{\overline{\beta}}, \overline{B}\rangle$ is a structure such that $\overline{\nu}$ is regular in $\overline{M}$, but that $k(\bar{M})$ is defined, i.e. for some least $n < \omega$, there is a $\boldsymbol{\Sigma_1^{(n)}}(\overline{M})$ function singularising $\overline{\nu}$. Suppose further for $n = k(\bar{M})$ that $g : \overline{M} \longrightarrow_{\Sigma_1^{(n)}} M = \langle J^{A}_{\beta}, B\rangle$ and that $\sigma : J^{\overline{A}}_{\overline{\nu}} \longrightarrow J^{A'}_{\widetilde{\nu}}$, and $\sigma_1 : J^{A'}_{\widetilde{\nu}} : J^{A'}_{\widetilde{\nu}} \longrightarrow J^{A}_{\nu}$ are both Σ_0 with σ cofinal, and finally that $\sigma_1 \circ \sigma = g\restriction J^{\overline{A}}_{\overline{\nu}}$.*

Then there is a structure $M' = \langle J^{A'}_{\beta'}, B'\rangle$, a map $\widetilde{g} : \overline{M} \longrightarrow M'$ with (a) *$\widetilde{g} \supseteq \sigma$ and* (b) *$\widetilde{g}$ is $\Sigma_0^{(n)}$ cofinal at the nth level (and so $\Sigma_1^{(n)}$-preserving); further there is a unique $g' : M' \longrightarrow_{\Sigma_0^{(n)}} M$, with $g = g' \circ \widetilde{g}$ and $g'\restriction\widetilde{\nu} = \sigma_1$.*

Proof. The argument is just as before except now g' is defined through: $g'(\widetilde{g}(G)(a)) = g(G)(\sigma_1(a))$. Again g' has to be the unique such map with $g = g' \circ \widetilde{g}$ and $g'\restriction\widetilde{\nu} = \sigma_1\restriction\widetilde{\nu}$, since $g'(\widetilde{g}(G)(a)) = g' \circ \widetilde{g}(G)(g'(a)) = g(G)(\sigma_1(a))$. ⊣

2. Global □

We derive a global □ sequence in L, the constructible hierarchy. We assume now $V = L$. Our template is basically that of the proof of Jensen [2] here, although we use ideas from [30]. We shall build our C_ν sequence along a closed and unbounded class $S \subseteq \mathrm{Sing}$ of singular ordinals. The definition of the C_ν sets themselves we shall present is extremely uniform, and quite simple. They will be preserved by Σ_0 embeddings between levels of the J-hierarchy of a sufficient ordinal height to see that ν is singular. The choice of the closed and unbounded class S is also rather flexible: we require S again be simply defined so that membership in it is preserved downwards into Σ_1-elementary substructures. To this end we could take S to be the class of all limits of admissible ordinals. (Recall that α is *admissible* if $\langle L_\alpha, \in\rangle$ is a model of Kripke-Platek set theory.) Although this is fine from a technical point of view, it appears to require more closure on the structures J_α than it really needs. For most purposes it will be useful to assume that $\omega\nu = \nu$ as a minimum, (this will have the effect of tying up C_ν with the ordinal height of J_ν), and that $\omega\nu$ is sufficiently closed under some further basic ordinal theoretic operations. We shall accordingly take S to be the class of *primitive recursively (p.r.) closed ordinals.*

2.1 Definition.

(i) The *primitive recursive set functions* are obtained by adding to the rudimentary functions the following schema:

$$f(\vec{x}, y) = g(\vec{x}, y, \langle f(\vec{x}, z) \mid z \in y\rangle).$$

f is *primitive recursive (p.r.) in* $A \subseteq V^n$ iff f is p.r. in χ_A.

(ii) X is *p.r. closed* (*p.r. closed in* A) iff X is closed under the p.r. functions (the p.r. in A functions, respectively).

(iii) α is *p.r. closed* if L_α is p.r. closed.

2.2 Lemma.

(i) *ω is p.r. closed.*

(ii) *Let $\alpha > \omega$. Then α is p.r. closed iff α is closed under the functions f_i $(i < \omega)$ where:*

$$f_0(\nu) = \omega^\nu; \qquad f_{i+1}(\nu) = \text{the } \nu\text{th fixed point of } f_i.$$

If the reader desires then the above can be taken as a definition of a p.r. closed ordinal. It follows relatively easily that:

(1) $\alpha > \omega \wedge \alpha$ p.r. closed $\implies \omega\alpha = \alpha$ and hence $J_\alpha = L_\alpha$.

(2) $\omega\alpha$ p.r. closed $\iff J_\alpha$ p.r. closed.

(3) $\{\alpha \mid \alpha \text{ is p.r. closed}\}$ is closed and unbounded in On.

(4) If α is p.r. closed but not a limit point of the p.r. closed ordinals, then $\alpha = \sup_i\{f_i(\beta) \mid \beta < \alpha\}$ and hence $\mathrm{cf}(\alpha) = \omega$.

Noting that p.r. closure is essentially a Π_2 property of a structure we obtain the relevant property for our subsequent definitions:

2.3 Lemma. *Let $\omega\alpha$ be p.r. closed, and let $f : J_{\overline{\alpha}} \longrightarrow_{\Sigma_1} J_\alpha$. Then $\omega\overline{\alpha}$ is p.r. closed.*

(As we commented above, the property of α being a limit of admissibles, would have satisfied the consequent of the above lemma too.)

2.4 Theorem ($V = L$). *Let $S \subseteq \mathrm{Sing}$ be as above. There is a uniformly definable class $\langle C_\nu \mid \nu \in S \rangle$ so that:*

(i) *$C_\nu \subseteq \nu$ is a set of ordinals unbounded in ν and closed beneath it;*

(ii) *$\mathrm{ot}(C_\nu) < \nu$;*

(iii) *$\overline{\nu} \in (C_\nu)^* \implies \overline{\nu} \in S \wedge C_{\overline{\nu}} = \overline{\nu} \cap C_\nu$;*

(iv) *If $f : \langle J_{\overline{\nu}}, \overline{C} \rangle \longrightarrow_{\Sigma_1} \langle J_\nu, C_\nu \rangle$ then $\overline{\nu} \in S$ and $\overline{C} = C_{\overline{\nu}}$.*

We think of C_ν as a canonical singularising sequence for ν, i.e. it provides a sequence cofinal in ν, and of order type less than ν. It will be defined using the least level of the J-hierarchy, over which we can define a map from a bounded subset of ν cofinally into ν. Our desire for short sequences is expressed by (ii). The important clause is (iii) the *coherence property*: the limit points $\bar{\nu}$ of C_ν, are themselves singular, and the initial segment $C_\nu \cap \bar{\nu}$ gives the canonical singularising sequence for $\bar{\nu}$ itself. (i)–(iii) are often referred to as (one form of) Global $\Box$. Clause (iv) is also a strong one, providing as it does information on condensation-like coherency. We shall first give a construction of a global sequence satisfying most of the above: it simply will not always be unbounded in ν—this may happen when $\mathrm{cf}(\nu) = \omega$. The theorem below contains the heart of the argument. Obtaining the theorem above from it, is relatively speaking, at least over L, a minor adjustment.

2.5 Theorem ($V = L$). *There is a uniformly definable class $\langle C_\nu \mid \nu \in S \rangle$ so that:*

(i) *C_ν is a set of ordinals ν and closed beneath it; if $\mathrm{cf}(\nu) > \omega$ then C_ν is unbounded in ν;*

(ii) *$\mathrm{ot}(C_\nu) < \nu$;*

(iii) *$\overline{\nu} \in (C_\nu) \implies \overline{\nu} \in S \wedge C_{\overline{\nu}} = \overline{\nu} \cap C_\nu$;*

(iv) *If $f : \langle J_{\overline{\nu}}, \overline{C} \rangle \longrightarrow_{\Sigma_1} \langle J_\nu, C_\nu \rangle$ then $\overline{\nu} \in S$ and $\overline{C} = C_{\overline{\nu}}$.*

As indicated if ν is a singular ordinal, then there will be a least level $J_{\beta(\nu)}$ of the J-hierarchy over which ν is *definably singularised*, i.e. there will be a function (possibly partial) that is $\Sigma_\omega(J_{\beta(\nu)})$-definable (possibly in some parameters) mapping (a subset of) some γ cofinally into ν. However any such function is also good $\Sigma_1^{(n)}(J_{\beta(\nu)})$ for some n. This level $J_{\beta(\nu)}$ will be our *singularising structure* M_ν, and n is the level of complexity at which we shall work. We set out a formal definition of our subject matter. Notice, that given $J_{\beta(\nu)}$ all the objects defined below are Σ_0-definable from it.

2.6 Definition. Let $\nu \in S$. Then we associate the following to ν:

(a) $n_\nu =_{\rm df}$ the least $n \in \omega$ so that there is a good $\boldsymbol{\Sigma}_{\mathbf{1}}^{\boldsymbol{(n)}}(M_\nu)$ function singularising ν, where $M_\nu = J_{\beta(\nu)}$.

(b) $M_\nu^k =_{\rm df} M_\nu^{k,p_{M_\nu}\restriction k}$ for $k \leq n_\nu$.

(c) $h_\nu^k =_{\rm df} h_{M_\nu}^{k,p_{M_\nu}\restriction k}$; $h_\nu =_{\rm df} h_\nu^{n_\nu}$; $\widetilde{h}_\nu =_{\rm df} \widetilde{h}_{M_\nu}^{n_\nu+1}$.

(d) (i) $\omega\rho_\nu =_{\rm df} \mathrm{On} \cap M_\nu^{n_\nu}$; (ii) $\kappa_\nu \simeq$ the largest cardinal of J_ν, if such exists.

(e) $p_\nu =_{\rm df} p_{M_\nu} \backslash \nu$ if ν is a limit cardinal of J_ν; $p_\nu =_{\rm df} p_{M_\nu} \backslash \kappa_\nu$ otherwise; $q_\nu =_{\rm df} p_\nu \cap \omega\rho_{M_\nu}^{n_\nu}$.

(f) $\alpha_\nu =_{\rm df} \max\{\alpha < \nu \mid \nu \cap \widetilde{h}_\nu(\alpha \cup \{p_\nu\}) = \alpha\}$, setting $\max \varnothing = 0$.

(g) $\gamma_\nu =_{\rm df} \min\{\gamma < \nu \mid$ there exists a $\Sigma_1^{(n)M_\nu}(\{p_\nu\})$ partial function
$$F : a \longrightarrow \nu, \text{ cofinal, with } a \subseteq \gamma\}.$$

Thus if $\nu = \kappa_\nu^+$, note then we may possibly have κ_ν in p_ν (if κ_ν happens to be in p_ν). We also note that $p_\nu \backslash \nu$ ($= p_\nu$ unless κ_ν is defined) is the least parameter p so that $\widetilde{h}_\nu(\nu \cup p) = J_{\beta(\nu)}$. It is easy to see that α_ν in (f) is always defined, as the set of α's specified is closed; note also that α_ν is perforce strictly less than the first ordinal γ partially mapped by $\widetilde{h}_\nu$(with parameter p_ν) cofinally into ν. We set that first ordinal γ at (g) to be γ_ν. Such a γ_ν exists, since by assumption there is some good $\boldsymbol{\Sigma}_{\mathbf{1}}^{\boldsymbol{(n)}}(M_\nu)$ function singularising ν, using some parameter r. In fact as we are in L we may take $r = p_{M_\nu}$. If $\gamma' = \max(p_{M_\nu} \cap \nu)+1$ ($\max(p_{M_\nu} \cap \kappa_\nu)+1$ if κ_ν is defined), then clearly $\widetilde{h}_\nu(\gamma' \cup p_\nu)$ is cofinal in ν (as we have enough parameters in the domain of this hull to define our cofinalising map); hence $\gamma_\nu \leq \gamma'$ exists.

2.7 Lemma. $\omega\rho_{M_\nu}^{n_\nu} \geq \nu \geq \omega\rho_{M_\nu}^{n_\nu+1}$.

Proof. Let $n = n_\nu$. If the second inequality failed, then the partial function $\boldsymbol{\Sigma}_{\mathbf{1}}^{\boldsymbol{(n)}}(J_{\beta(\nu)})$-singularising ν would be a subset of ν and thus a bounded subset of $\omega\rho_{M_\nu}^{n+1}$ belonging to $J_{\beta(\nu)}$. Suppose the first inequality failed. Then $n > 0$, and $\widetilde{h}_{M_\nu}^n$ maps $H_{M_\nu}^n = J_{\rho_{M_\nu}^n}$ onto $J_{\beta(\nu)} = M_\nu$. However $\widetilde{h}_{M_\nu}^n$ has a $\Sigma_1^{(n-1)}$ definition, which can be easily amended to provide a $\Sigma_1^{(n-1)}$ map from $\omega\rho_{M_\nu}^n$ onto ν—thus contradicting our definition of n. $\dashv$

2.8 Definition. For $\nu, \overline{\nu} \in S$:

(i) We set $f : \bar{\nu} \Longrightarrow \nu$ if $|f| : J_{\overline{\nu}} \longrightarrow_{\Sigma_1} J_\nu$, and $|f|$ is the restriction of $f^* : J_{\beta(\overline{\nu})} \longrightarrow_{\Sigma_1^{(n)}} J_{\beta(\nu)}$ where $n = n_\nu$, $\nu = f^*(\overline{\nu})$ if $\nu < \beta(\nu)$; $\kappa_\nu \in \mathrm{ran}(f)$ (if κ_ν is defined); α_ν, p_ν are both in $\mathrm{ran}(f^*)$.

(ii) $\mathbb{F} =_{\mathrm{df}} \{\langle \bar{\nu}, |f|, \nu \rangle \mid f : \bar{\nu} \Longrightarrow \nu\}$. We sometimes write if $f : \bar{\nu} \Longrightarrow \nu$ that $\bar{\nu} = d(f)$ and $\nu = r(f)$.

(iii) If $\nu < \beta$, we set $p(\nu) =_{\mathrm{df}} p_\nu \cup \{\alpha_\nu, \nu, \kappa_\nu\}$ (the latter if κ_ν is defined); if $\nu = \beta$ then $p(\nu) =_{\mathrm{df}} p_\nu \cup \{\alpha_\nu, \kappa_\nu\}$ (again the latter only if it is defined).

(iv) $f^*_{(\delta,v,\nu)}$ is the inverse of the transitive collapse of the hull $\widetilde{h}_\nu(\delta \cup \{p(\nu), v\})$ in $J_{\beta(\nu)}$.

2.9 Lemma. *If $\exists \bar{\nu}(f : \bar{\nu} \Longrightarrow \nu)$ then $|f|$ and f^* are uniquely determined by* $\mathrm{ran}(|f|) \cap \nu$.

Proof. As $J_{\beta(\nu)}$ is sound, we have by our definitions, and Fact (i) before Lemma 1.19, that $\widetilde{h}_\nu(\omega\nu \cup \{p_\nu\}) = J_{\beta(\nu)}$ (and a similar statement with $\bar{\nu}$ replacing ν throughout). We have a $\Delta_1(J_\nu)$ onto map $g : \omega\nu \twoheadrightarrow J_\nu$. Thus, if $Y = \widetilde{h}_\nu((\omega\nu \cap \mathrm{ran}(|f|)) \cup \{p_\nu\})$, then $Y = \widetilde{h}_\nu(\mathrm{ran}(|f|) \cup \{p_\nu\}) = \mathrm{ran}(f^*)$: if $x \in \mathrm{ran}(f^*)$, then by soundness of $J_{\bar{\beta}}$ above $\bar{\nu}$, $x = f^*(h_{\bar{\nu}}(\bar{\xi}, p_{\bar{\nu}}))$ for some $\bar{\xi} < \omega\bar{\nu}$; thus $x \in Y$. However $f^*(h_{\bar{\nu}}(\bar{\xi}, p_{\bar{\nu}})) = h_\nu(|f|(\bar{\xi}), p_\nu)$ since f^* is $\Sigma_1^{(n)}$-preserving, we have by Lemma 1.22 that $f^*(p_{\bar{\nu}}) = p_\nu$. The converse inclusion is immediate. ⊣

2.10 Remark. The next lemma will show that in clause (iv) there is some μ and a restriction map $|f_{(\delta,q,\nu)}|$ of $f^*_{(\delta,q,\nu)}$ so that $\langle \mu, |f_{(\delta,q,\nu)}|, \nu \rangle \in \mathbb{F}$.

In the sequel we shall not carefully distinguish $|f|$ (or f), from its *canonical extension* f^* (observe Lemma 2.9) and sometimes write $f : J_{\overline{\nu}} \longrightarrow_{\Sigma_1} J_\nu$ where more correctly we should write $f^* \restriction J_{\overline{\nu}}$ or $|f| : J_{\overline{\nu}} \longrightarrow_{\Sigma_1} J_\nu$ (as in the conclusion of the next lemma). Or conversely if $f : \bar{\nu} \Longrightarrow \nu$ then we should properly write "$f^* : J_{\beta(\overline{\nu})} \longrightarrow_{\Sigma_1^{(n)}} J_{\beta(\nu)}$" but sometimes we are slip-shod and again simply substitute f for f^* by virtue of the last lemma.

We shall first prove a pair of lemmata concerning relationships between singularising structures, and associated maps between them. These will then facilitate the definition of our C_ν sequences.

2.11 Lemma. *Let $f : J_{\bar{\beta}} \longrightarrow_{\Sigma_1^{(n)}} J_{\beta(\nu)}$ where $n = n_\nu$; suppose $f(\bar{\alpha}, \bar{p}) = \alpha_\nu, p_\nu$, and (where appropriate) $f(\bar{\kappa}, \bar{\nu}) = \kappa_\nu, \nu$. (The latter if $\nu < \beta(\nu)$; if $\nu = \beta(\nu)$ then we take $\bar{\nu} = \bar{\beta}$.) Then $\bar{\nu} \in S$, $\bar{\beta} = \beta(\bar{\nu})$ (thus $M_{\bar{\nu}} = J_{\bar{\beta}}$), $f : \bar{\nu} \Longrightarrow \nu$; moreover $n, \bar{\alpha}, \bar{p}, \bar{\kappa}$ (the latter when defined) are $n_{\bar{\nu}}, \alpha_{\bar{\nu}}, p_{\bar{\nu}}, \kappa_{\bar{\nu}}$.*

(Remark: we shall drop the qualification "when defined" from now on and will also let the reader include or exclude the ordinal ν as appropriate.)

Proof. We verify that $J_{\bar{\beta}}$ is the singularising structure for $\bar{\nu}$ and the other parameters are as shown, and thus are moved correctly by f. That $\bar{\nu} \in S$ is trivial if $\nu \in \operatorname{ran}(f)$ and follows from Lemma 2.3 otherwise.

(1) $\bar{p} = p_{J_{\bar{\beta}}} \backslash \bar{\nu}$.

Proof of (1). By the Condensation Lemma 1.22. $\dashv$ (1)

Setting $\beta = \beta(\nu)$, we let $\overline{h}$ have the same functionally absolute definition over $J_{\bar{\beta}}$ as $\widetilde{h}_\nu$ does over J_β. $\overline{h}$ is thus $\mathbf{\Sigma_1^{(n)}}(J_{\bar{\beta}})$.

(2) $\overline{\alpha}$ *is defined from* $J_{\bar{\beta}}$ *as* α *was defined from* $J_{\beta(\nu)}$.

Proof of (2). Set

$$\begin{array}{lcl} H(\xi^n, \zeta^n) & \iff & \widetilde{h}_\nu(\omega\xi^n \cup \{p_\nu\}) \cap \nu \subseteq \zeta^n, \\ \overline{H}(\xi^n, \zeta^n) & \iff & \bar{h}(\omega\xi^n \cup \{\bar{p}\}) \cap \bar{\nu} \subseteq \zeta^n. \end{array}$$

The former H is then $\Pi_1^{(n)J_\beta}(\{p_\nu, \nu\})$, ($\nu$ is omitted if $\nu = \omega\rho^n_{J_\beta}$); the latter $\overline{H}$ is $\Pi_1^{(n)J_{\bar{\beta}}}(\{\bar{p}, \bar{\nu}\})$, by the same definition (again, we include $\bar{\nu}$ when $\bar{\nu} < \omega\rho^n_{J_{\bar{\beta}}}$, which occurs by the $\Sigma_1^{(n)}$-elementarity of f^* when $\nu = \omega\rho^n_{J_\beta}$). As $J_\beta \models H(\alpha, \alpha)$ we have $J_{\bar{\beta}} \models \overline{H}(\bar{\alpha}, \bar{\alpha})$. However for any ξ with $\bar{\alpha} < \xi^n < \bar{\nu}$ we must have $J_{\bar{\beta}} \models \neg\overline{H}(\xi^n, \xi^n)$, because $J_\beta \models \neg H(f(\xi^n), f(\xi^n))$ since $\alpha < f(\xi^n) < \nu$. These properties describe α and $\bar{\alpha}$. $\dashv$ (2)

(3) $\exists\overline{\xi}^n < \bar{\nu}(\widetilde{h}_\nu(f(\bar{\xi}^n) \cup \{p_\nu\})$ is unbounded in ν).

If (3) holds for some $\overline{\xi}$ then, in fact $\bar{h}(\xi \cup \{\bar{p}\})$ is cofinal in $\bar{\nu}$, since

$$J_\beta = M_\nu \models (\forall\zeta^n < \nu)(\exists\delta^n < f(\bar{\xi}^n))(\exists i < \omega)(\zeta^n < \widetilde{h}_\nu(i, \langle\delta^n, p_\nu\rangle) < \nu)$$

is a $\Pi_2^{(n)}$ expression and hence goes down to $J_{\bar{\beta}}$ in the objects $\bar{p}, \bar{h}$, $\bar{\xi}$ and $\bar{\nu}$ (the latter if $\nu = f(\bar{\nu}) < \omega\rho^n_{J_\beta}$) It thus witnesses that $\bar{\beta} = \beta(\bar{\nu})$ and $n \geq n_{\bar{\nu}}$. Thus also $\bar{h}$ is a suitable singularising function for $\bar{\nu}$. So suppose (3) fails. Note that then we must have $\tau =_{\mathrm{df}} \sup f``\bar{\nu} \leq \gamma_\nu < \nu$. However, then we have:

(4) $\tau \neq \nu \cap \widetilde{h}_\nu(\tau \cup \{p_\nu\})$.

We cannot have equality here as that would imply that $\tau \leq \alpha_\nu$. However the latter is in $\operatorname{ran}(f{\restriction}\bar{\nu})$!

Hence the following true in J_β:

$$\exists i \in \omega \exists \xi^n < \tau(\nu > \widetilde{h}_\nu(i, \langle \xi^n, p_\nu \rangle) \geq \tau).$$

Let i, ξ^n witness this, and pick $\bar{\delta} < \bar{\nu}$ so that $f(\bar{\delta}) > \xi^n$. Then for any $\bar{\mu} < \bar{\nu}$ as $f(\bar{\mu}) < \tau$:

$$J_\beta \models (\exists \zeta^n < f(\bar{\delta}))(\nu > \widetilde{h}_\nu(i, \langle \zeta^n, p_\nu \rangle) \geq f(\bar{\mu})).$$

This is $\Sigma_1^{(n)}$ and hence, for all $\bar{\mu} < \bar{\nu}$, goes down to $J_{\bar{\beta}}$. Now:

$$J_{\bar{\beta}} \models \forall \bar{\mu} < \bar{\nu} \exists \zeta^n < \bar{\delta}(\bar{\nu} > \bar{h}(i, \langle \zeta^n, \bar{p} \rangle \geq \bar{\mu})).$$

Again, this says that $\bar{h}$ is a suitable singularising function for $\bar{\nu}$. The only possibility left is that (4) could hold. However that would imply that $\tau \leq \alpha_\nu$ which we have already ruled out.

(5) $\bar{\beta} = \beta(\bar{\nu})$ and $n = n_{\bar{\nu}}$.

We have just seen that $\bar{\beta} = \beta(\bar{\nu})$ and $n \geq n_{\bar{\nu}}$. Suppose $m < n$ and that $\bar{g}$ is a $\Sigma_1^{(m)}(J_{\bar{\beta}})$ good function in the parameter $\bar{r}$. Let g be $\Sigma_1^{(m)}(J_\beta)$ using the same functionally absolute definition and the parameter $f(\bar{r})$. Suppose $\bar{\delta} < \bar{\nu}$. By the $\Sigma_1^{(n)}$-elementarity of f we have the following $\Sigma_1^{(n)}$ statement holds in J_β (as $\operatorname{ran}(g \restriction f(\bar{\delta}))$ is bounded in ν):

$$(\exists \xi^n < \nu)(\forall \zeta^m < f(\bar{\delta}))(\forall \eta^m < \nu)(g(\zeta^m) = \eta^m \longrightarrow \eta^m < \xi^n)$$

(assuming $\nu < \beta$; otherwise drop the bound ν). As f is actually $\Sigma_1^{(n)}$-preserving, we have in $J_{\bar{\beta}}$:

$$(\exists \xi^n < \bar{\nu})(\forall \zeta^m < \bar{\delta})(\forall \eta^m < \bar{\nu})(\bar{g}(\zeta^m) = \eta^m \longrightarrow \eta^m < \xi^n).$$

As $\bar{\delta}$ was arbitrary, we conclude that $\operatorname{ran}(\bar{g} \restriction \xi)$ is bounded on any $\xi < \bar{\nu}$. Hence $n \leq n_{\bar{\nu}}$. $\dashv$

2.12 Definition. If $f : \bar{\nu} \implies \nu$, let $\lambda(f) =_{\mathrm{df}} \sup f``\overline{\nu}$; $\rho(f) =_{\mathrm{df}} \sup f``\rho_{\bar{\nu}}$.

2.13 Lemma. *Suppose $f : \bar{\nu} \implies \nu$, and let $\lambda = \lambda(f)$. Then $\lambda \in S$ and there exists a unique $f_0 : \bar{\nu} \implies \lambda$ with $f \restriction \overline{\nu} = f_0 \restriction \overline{\nu}$.*

Proof. With $J_{\beta(\bar{\nu})} = M_{\bar{\nu}}$ and $J_{\beta(\nu)} = M_\nu$ a direct application of the Interpolation Lemma 1.51 with λ as $\widetilde{\nu}$, $M_{\bar{\nu}}$, M_ν as $\overline{M}, M$ respectively, and using $f^* : M_{\overline{\nu}} \longrightarrow_{\Sigma_1^{(n)}} M_\nu$ (where f^* is the canonical extension of f) we have the structure $\widetilde{M} = J_{\widetilde{\beta}}$ and maps $\widetilde{f}$, f' as specified.

(1) $\lambda \in S, n = n_\lambda$.

Proof of (1). As $\widetilde{h}_{\bar{\nu}}(\gamma_{\bar{\nu}} \cup \{p_{M_{\overline{\nu}}}, r\})$ is cofinal in $\overline{\nu}$ for some parameter r then $\lambda \cap \widetilde{h}^{n+1}_{\widetilde{M}}(\widetilde{f}(\gamma_{\bar{\nu}}) \cup \{p', \widetilde{f}(r)\})$ is cofinal in λ (setting $p' = \widetilde{f}(p_{\overline{\nu}}) = f'^{-1}(p_\nu)$).

$$\begin{tikzcd}
\overline{M} = J_{\beta(\bar\nu)} \arrow[r, "\widetilde{f}"'] \arrow[rr, bend left, "f^*"] & \widetilde{M} = J_{\widetilde{\beta}} \arrow[r, "f'"'] & J_{\beta(\nu)} = M \\
J_{\bar\nu} \arrow[u, hook] \arrow[r, "f^* \restriction J_{\bar\nu}"] & J_\lambda \arrow[u, hook] \arrow[r, "f'^* \restriction J_\lambda", "\mathrm{id}"'] & J_\nu \arrow[u, hook]
\end{tikzcd}$$

Figure 10.2: Lemma 2.13

Thus λ is p.r. closed, but not $\Sigma_1^{(n)}$-regular in $J_{\widetilde{\beta}}$. Hence $n \geq n_\lambda$. We need to show that λ is $\Sigma_1^{(n-1)}$-regular in $J_{\widetilde{\beta}}$. Suppose this fails and there is a good $\boldsymbol{\Sigma_1^{(n-1)}}(\widetilde{M})$ function $\widetilde{g}$, mapping a subset of some $\widetilde{\delta} < \lambda$ cofinally into λ. $\widetilde{g}(\xi)$ can be taken to be of the form $\widetilde{G}(\xi, s)$ in some parameter s where the latter is, by the construction of the pseudo-ultrapower, of the form $\widetilde{f}(\overline{g}_0)(\eta)$ for some good $\boldsymbol{\Sigma}_1^{(n-1)}(M_{\overline{\nu}})$ function $\overline{g}_0$ and some $\eta < \lambda$. We now carry back via $\widetilde{f}$ the supposed singularisation of λ to one of $\overline{\nu}$ which is a contradiction. Let $\overline{G}$ be the good $\Sigma_1^{(n-1)}(M_{\overline{\nu}})$ function by the same functionally absolute definition as $\widetilde{G}$. Define a good $\boldsymbol{\Sigma}_1^{(n-1)}(M_{\overline{\nu}})$ partial function by $\overline{g}(\xi) \simeq \overline{G}((\xi)_0, \overline{g}_0((\xi)_1))$. Then $\overline{g}$ will singularise $\overline{\nu}$: pick a $\overline{\tau} < \overline{\nu}$ sufficiently large so that $\widetilde{f}(\overline{\tau}) > \max\{\widetilde{\delta}, \eta\}$; we show that $\bar{g}$ takes a subset of $\bar{\tau}$ cofinally into $\bar{\nu}$. Let $\zeta < \overline{\nu}$ be arbitrary. We find a $\xi < \bar{\tau}$ with $\overline{g}(\xi) > \zeta$, and this will be our contradiction. As $\widetilde{g}$ is assumed cofinalising, there is an $\iota < \widetilde{\delta}$ so that $\widetilde{f}(\zeta) < \widetilde{g}(\iota) = \widetilde{G}(\iota, \widetilde{f}(\bar{g}_0)(\eta)) < \lambda$.

Thus the following is $\Sigma_1^{(n)}$:

$$\exists u^n [u^n < \widetilde{f}(\overline{\tau}) \wedge \widetilde{f}(\zeta) < \widetilde{G}((u^n)_0, \widetilde{f}(\overline{g}_0)((u^n)_1)) < \lambda].$$

Hence in $M_{\overline{\nu}}$ we have as required:

$$\exists u^n [u^n < \overline{\tau} \wedge \zeta < \overline{G}((u^n)_0, \overline{g}_0((u^n)_1)) = \overline{g}(u^n) < \bar{\nu}].$$

$\dashv$ (1)

(2) $p' = p_\lambda$.

Proof of (2). By the pseudo-ultrapower construction we have $\widetilde{M} = \widetilde{h}^{n+1}_{\widetilde{M}}(\lambda \cup \{p'\})$ (and equals $\widetilde{h}^{n+1}_{\widetilde{M}}(\widetilde{\kappa} \cup \{p'\})$ where $\widetilde{\kappa} = \widetilde{f}(\kappa_{\overline{\nu}})$ if $\kappa_{\overline{\nu}}$ is defined). Because of this we have that $p' \in R^n_{\widetilde{M}}$ and can thus be lengthened to a $p'' \in P^{n+1}_{\widetilde{M}} (= R^{n+1}_{\widetilde{M}}$ by the soundness of the L-hierarchy). By the minimality of the standard parameter and the definition of p_λ we thus have $p_\lambda \leq^* p'$. However if $p_\lambda <^* p'$ held, we should have for some $i \in \omega$, $\vec{\xi} < \lambda$ that $p' = \widetilde{h}^{n+1}_{\widetilde{M}}(i, \langle \vec{\xi}, p_\lambda \rangle)$, and thus $p_\nu = \widetilde{h}^{n+1}_\nu(i, \langle f'(\vec{\xi}), f'(p_\lambda)\rangle)$ whence $M_\nu = \widetilde{h}^{n+1}_\nu(\nu \cup f'(p_\lambda))$; this is a contradiction as $f'(p_\lambda) <^* p_\nu$. ⊣ (2)

We may set $f^*_0 = \widetilde{f}$ once we have shown:

(3) *If* $\widetilde{\alpha} =_{\mathrm{df}} \widetilde{f}(\alpha_{\overline{\nu}})$ *then* $\widetilde{\alpha} = \alpha_\lambda$.

We note that $\alpha_\nu = \widetilde{\alpha}$.

That $h_\lambda(\widetilde{\alpha} \cup \{p_\lambda\}) \cap \lambda \subseteq \widetilde{\alpha}$ is proven using:

$$\overline{H}(\xi^n, \zeta^n) \iff h_{\bar{\nu}}(\omega\xi^n \cup \{p_{\bar{\nu}}\}) \cap \bar{\nu} \subseteq \zeta^n.$$

Then $\overline{H}(\alpha_{\bar{\nu}}, \alpha_{\bar{\nu}})$ is a $\Pi^{(n)}_1$ fact about $\alpha_{\bar{\nu}}$ that is preserved up by $\widetilde{f}$ to yield $h_\lambda(\widetilde{\alpha} \cup \{p_\lambda\}) \cap \lambda \subseteq \widetilde{\alpha}$.

This shows that $\widetilde{\alpha}$ is sufficiently closed. To show that no larger ordinal γ with $\widetilde{\alpha} < \gamma < \lambda$ satisfies $h_\lambda(\gamma \cup \{p_\lambda\}) \cap \lambda \subseteq \gamma$; as $\widetilde{f}{\restriction}\bar{\nu}$ is cofinal into λ we may set $\bar{\gamma} = \widetilde{f}^{-1}{}``\gamma$ and then have $\alpha_{\bar{\nu}} < \bar{\gamma}$ and $\widetilde{f}(\bar{\gamma}) \geq \gamma$. So for some $i \in \omega$ and $\bar{\zeta} < \bar{\gamma}$ we have $\bar{\gamma} \leq h_{\bar{\nu}}(i, \langle \bar{\zeta}, p_{\bar{\nu}}\rangle) < \bar{\nu}$. Applying $\widetilde{f}$ we have that $\gamma \leq h_\lambda(i, \langle \widetilde{f}(\bar{\zeta}), p_\lambda\rangle) < \lambda$. As $\widetilde{f}(\bar{\zeta}) < \gamma$ we see that γ is not a closed ordinal. ⊣ (2.13)

2.14 Lemma. *Suppose* $f : \bar{\nu} \implies \nu$. *Then* $\lambda(f) < \nu \longleftrightarrow \rho(f) < \rho_\nu$.

Proof. Let $\lambda = \lambda(f)$. We prove both directions by contraposition. So in the forward direction, suppose $\rho(f) = \rho_\nu$. Then, in the diagram of the previous Lemma the map f' is not only $\Sigma^{(n)}_0$ but is cofinal at the nth level, and thus $\Sigma^{(n)}_1$-preserving. This together with $f'(\lambda, p_\lambda) = \nu, p_\nu$, implies that $\nu \cap f'{}``h_\lambda(\lambda \cup \{p_\lambda\}) \subseteq \nu \cap h_\nu(\lambda \cup \{p_\nu\}) = \lambda$. Were $\lambda < \nu$ this would contradict the fact that $\lambda > \alpha_\nu$ as the latter is in $\mathrm{ran}(f)$.

Conversely, suppose $\lambda = \nu$. Let $\bar{k}$ be the good $\Sigma^{(n)}_1(J_{\beta(\nu)})$ partial function in a parameter $\bar{q}$, cofinalising $\bar{\nu}$. Applying the $\Sigma^{(n)}_1$-preserving f^* we have a good function, k, with the same definition as $\bar{k}$ (in the parameter $f^*(\bar{q})$). Now suppose $\rho' =_{\mathrm{df}} \rho(f) < \rho_\nu$ for a contradiction. Then q would be in $J_{\rho(f)}$, but moreover all the witnesses to the existential quantifiers of type n needed to see that k is cofinal in $\lambda = \nu$ would be in $J_{\rho(f)}$, and those quantifiers could thus be replaced by bounded ones: if, say, $\bar{k}(\xi) = \zeta \leftrightarrow \exists x^n \varphi(x^n, \xi, \zeta, \bar{q})$ with $\varphi \in \Sigma^{(n)}_0$ we then have

$$k(f^*(\xi)) = f^*(\zeta) \iff \exists x^n \in J_{\rho(f)} \varphi(x^n, f^*(\xi), f^*(\zeta), q).$$

Hence over $J_{\beta(\nu)}$ we have a $\boldsymbol{\Sigma^{(n)}_0}$ definition of a singularising function for ν. However as $\nu = \lambda \leq \rho(f) < \rho_\nu$ we have that this function is in $J_{\beta(\nu)}$. This is a contradiction. ⊣

2.1. Defining C_ν

We define outright what the C_ν-sequences will be:

2.15 Definition. Let $\nu \in S$; $C^+_\nu =_{\mathrm{df}} \{\lambda(f) \mid f \Longrightarrow \nu\}$; $C_\nu =_{\mathrm{df}} C^+_\nu \backslash \{\nu\}$.

2.16 Definition. Let $f : \bar{\nu} \Longrightarrow \nu$. Then:

$$\beta(f) =_{\mathrm{df}} \max\{\beta \leq \nu \mid f{\restriction}\beta = \mathrm{id}{\restriction}\beta\}.$$

Simple closure says that $\beta(f)$ is defined. Note that $\beta(f) = \nu$ iff $f = \mathrm{id}_\nu$ iff $f(\beta(f)) \not> \beta(f)$ (if $\nu < \beta(f)$). Further, it is easy to see that $M_{\bar{\nu}} \models$ "$\beta(f)$ is a regular cardinal" (this last is a standard argument: if $\beta(f) < \nu$ were singular in $M_{\bar{\nu}}$ then $\beta(f) > \beta$ and Σ_1-elementarity of f would be a contradiction).

The next lemma lists some properties of $f_{(\gamma,q,\nu)}$ which were defined at Definition 2.8 (and see Remark 2.10). The first of these is a *minimality property* of $f_{(\gamma,q,\nu)}$.

2.17 Lemma.

(i) *If* $\gamma \leq \nu$ *then* $f_{(\gamma,q,\nu)}$ *is the least* $f \Longrightarrow \nu$ *such that* $f{\restriction}\gamma = \mathrm{id}{\restriction}\gamma$ *with* $q, p(\nu) \in \mathrm{ran}(f^*)$, *in that if* g *is any other such with these two properties* (*meaning that if* $g \Longrightarrow \nu$ *with extension* g^* *is so that* $\gamma \cup \{q, p(\nu)\} \subseteq \mathrm{ran}(g^*)$), *then* $g^{-1} f_{(\gamma,q,\nu)} \in \mathbb{F}$.

(ii) $f_{(\gamma,q,\nu)} = f_{(\beta,q,\nu)}$ *where* $\beta = \beta(f_{(\gamma,q,\nu)})$.

(iii) $f_{(\nu,0,\nu)} = \mathrm{id}_\nu$.

(iv) *Let* $f : \bar{\nu} \Longrightarrow \nu$ *with* $\bar{\gamma} \leq \bar{\nu}, f``\bar{\gamma} \subseteq \gamma \leq \nu, \bar{q} \in J_{\bar{\nu}}, f^*(\bar{q}) = q$, *then* $\mathrm{ran}(f^* f^*_{(\bar{\gamma},\bar{q},\bar{\nu})}) \subseteq \mathrm{ran}(f^*_{(\gamma,q,\nu)})$.

With (i) *this implies: if* $\beta(f) \geq \gamma$ *then* $f f_{(\bar{\gamma},\bar{q},\bar{\nu})} = f_{(\gamma,q,\nu)}$.

(v) *Set* $g = f_{(\gamma,q,\nu)}$; $\lambda = \lambda(g)$ *and* $g_0 = \mathrm{red}(g)$. *Then* $q \in J_\lambda$ *and* $g_0 = f_{(\gamma,q,\lambda)}$.

Proof. For (i) note this makes sense since we have specified in effect that $\mathrm{ran}(g^*) \supseteq \mathrm{ran}(f^*_{(\gamma,q,\nu)})$. (i)–(iv) are easy consequences of the definitions. We verify (v). We know that $g_0 \Longrightarrow \lambda$. Set $g'_0 = f_{(\gamma,q,\lambda)}$ and we shall argue that $g_0 = g'_0$. Let $k = g_0^{-1} g'_0$. The argument of Lemma 2.13 shows that $d(g_0) = d(g)$; as $g_0{\restriction}\gamma = \mathrm{id}{\restriction}\gamma$, and $q \in \mathrm{ran}(g_0)$ by (i) the minimality of $g'_0 \Longrightarrow \lambda$ implies we have such a k defined. Thus $k \in \mathbb{F}$. But $k \Longrightarrow d(g_0)$ so we conclude, as $d(g_0) = d(g)$, that $gk \in \mathbb{F}$. But $\mathrm{ran}((gk)^*) \cap \lambda = \mathrm{ran}(g^*) \cap \lambda$. So, using that $gk{\restriction}\gamma = \mathrm{id}{\restriction}\gamma$, and $q, p(\nu) \in \mathrm{ran}(gk)$, and then (i) again, we have $(gk)^{-1} g = k^{-1} \in \mathbb{F}$. Hence $k = \mathrm{id}_{d(g'_0)}$ and thus $g_0 = g'_0$. ⊣

When we have a *cofinal* map f, meaning that $|f|$ is cofinal into $r(f)$, as in the next lemma, then our definitions are preserved through $\Longrightarrow$:

2.18 Lemma. *Let* $f : \bar\nu \Longrightarrow \nu$ *with* $\lambda(f) = \nu$. *Let* $\bar\gamma < \bar\nu$, *and* $\overline{q} \in J_{\bar\nu}$, *with* $\gamma = f(\bar\gamma)$, $f(\bar q) = q$. *Set* $\bar g = f_{(\bar\gamma,\bar q,\bar\nu)}$; $g = f_{(\gamma,q,\nu)}$. *Then*

(i) $\lambda(\bar g) < \bar\nu \Longleftrightarrow \lambda(g) < \nu$;

(ii) *If* $\lambda(\bar g) < \bar\nu$ *then* $f(\lambda(\bar g)) = \lambda(g)$ *and* $f(\beta(\bar g)) = \beta(g)$.

Proof. We first assume $\lambda(\bar g) < \bar\nu$. Set $\lambda' = f(\lambda(\bar g))$. The following is $\Pi_1^{(n)M_{\bar\nu}}(\{\lambda(\bar g), \bar\gamma, p(\bar\nu)\})$:

$$\forall x^n \forall \xi^n < \bar\gamma \forall i < \omega (x^n = \tilde h_{\bar\nu}(i, \langle \xi^n, \overline{q}, p(\bar\nu)\rangle) \wedge x^n < \bar\nu \longrightarrow x^n < \lambda(\bar g)).$$

(if $\bar\nu = \mathrm{On} \cap M_{\bar\nu}$ the conjunct $x^n < \bar\nu$ is omitted). Hence

$$\forall x^n \forall \xi^n < \gamma \forall i < \omega (x^n = \tilde h_{\nu}(i, \langle \xi^n, q, p(\nu)\rangle) \wedge x^n < \nu \longrightarrow x^n < \lambda')$$

as f is $\Pi_1^{(n)}$-preserving. Hence $\lambda' \geq \lambda(g)$.

Claim 1. $\lambda' \leq \lambda(g)$.

As $\lambda(\bar g) < \bar\nu$ we have $\omega\rho(\bar g) < \omega\rho_{\bar\nu}$ by Lemma 2.14. Hence if we set $\bar N = \langle J_{\rho(\bar g)}, A^{n,p_{\bar\nu}\restriction n} \cap J_{\rho(\bar g)}\rangle$ we have that $\overline{N} \in M_{\bar\nu}$ and is an amenable structure, with $\lambda(\bar g) = \sup(\bar\nu \cap h_{\overline{N}}(\bar\gamma \cup \{\bar q, p(\bar\nu) \cap \omega\rho_{\bar\nu}\})$.

Applying f^*, and with $N = f(\overline{N})$, we have (noting that $f(\{\bar q, p(\bar\nu) \cap \omega\rho_{\bar\nu}\}) = \{q, p(\nu) \cap \omega\rho_\nu\})$

$$\lambda' = \sup(\nu \cap h_N(\gamma \cup \{q, p(\nu) \cap \omega\rho_\nu\}).$$

However for amenable structures (including N) we have a uniform definition of the canonical $\Sigma_1(N)$-Skolem function h_N. As $\langle N, A_N\rangle$ is a Σ_0 substructure of $\langle M^n_\nu, A^n_\nu\rangle$, we have that $h_N \subseteq h_\nu$. Hence

$$\lambda' = \sup(\nu \cap h_\nu(\gamma \cup \{q, p(\nu) \cap \omega\rho_\nu\})) = \sup(\nu \cap \tilde h_\nu(\gamma \cup \{q, p(\nu)\})).$$

Thus $\lambda' \leq \lambda(g)$. This finishes *Claim 1*.

Claim 2. $f(\beta(\bar g)) = \beta(g)$.

Let $\beta = f(\beta(\bar g))$. Note that $\bar g = f_{(\beta(\bar g), \bar q, \bar\nu)}$. Consequently $\beta(\bar g) \notin \mathrm{ran}(\bar g)$.

$$\begin{aligned}\beta = f(\beta(\bar g)) &= f(\sup\{\bar\delta < \bar\nu \mid \bar\delta \subseteq \mathrm{ran}(\bar g)\}) \\ &= f(\sup\{\bar\delta < \bar\nu \mid \bar\delta \subseteq h_{\overline{N}}(\bar\gamma \cup \{\bar q, p(\bar\nu) \cap \omega\rho_{\bar\nu}\})\}) \\ &= \sup\{\delta < \nu \mid \delta \subseteq h_{\bar N}(\gamma \cup \{q, p(\nu) \cap \omega\rho_\nu\})\}.\end{aligned}$$

And by the argument above is less than or equal to $\sup\{\delta < \nu \mid \delta \subseteq h_\nu(\delta \cup \{q, p(\nu) \cap \omega\rho_\nu\}) = \beta(g)$. Suppose however $\beta < \beta(g)$. Then in M_ν we have:

$$\exists \xi^n < \gamma \exists i < \omega (\beta = \tilde h_\nu(i, \langle \xi, q, p(\nu)\rangle).$$

However f is $\Sigma_1^{(n)}$-preserving, so this goes down to $M_{\bar\nu}$ as:

$$\exists \bar\xi^n < \bar\gamma \exists i < \omega(\beta(\bar g) = \tilde h_{\bar\nu}(i, \langle \bar\xi^n, \bar q, p(\bar\nu)\rangle).$$

But this implies $\beta(\bar g) \in \mathrm{ran}(\bar g)$ after all which is a contradiction! This finishes *Claim 2* and (ii). Finally, just note for ($\Longleftarrow$) of (i) as $\rho(f) = \rho_\nu$, if $\lambda(g) < \nu$ then by Lemma 2.14 there is an $\eta = f(\bar\eta) < \rho(f)$ with $\tilde h_\nu(\gamma \cup \{q, p(\nu)\}) \cap \omega\rho_\nu \subseteq \eta$. As before this is $\Pi_1^{(n)}$ and goes down to $M_{\bar\nu}$ as $\tilde h_{\bar\nu}(\bar\gamma \cup \{\bar q, p(\bar\nu)\}) \cap \omega\rho_{\bar\nu} \subseteq \bar\eta$. Hence $\lambda(\bar g) < \lambda$. $\dashv$

2.19 Definition. Let $\nu \in S$, $q \in J_\nu$. $B(q,\nu) =_{\mathrm{df}} B^+(q,\nu)\backslash\{\nu\}$ where $B^+(q,\nu) =_{\mathrm{df}} \{\beta(f_{(\gamma,q,\nu)}) \mid \gamma \leq \nu\}$.

Then $B(q,\nu)$ is the set of those $\beta < \nu$ so that $\beta = \beta(f)$ where $f = f_{(\beta,q,\nu)}$. Recall that B^* is always the class of limit points of B for any set $B \subseteq \mathrm{On}$.

2.20 Lemma. *Let $f = f_{(\gamma,q,\nu)}$ where $q \in J_\nu$.*

(i) *Suppose $\gamma \in B(q,\nu)^*$. Then* $\mathrm{ran}(f) = \bigcup_{\beta\in B(q,\nu)\cap\gamma} \mathrm{ran}(f_{(\beta,q,\nu)})$.

(ii) *Let $\gamma \leq \nu$. Suppose $\bar\nu$ is such that $f : \bar\nu \Longrightarrow \nu$ with $f(\bar q) = q$. Then $\gamma \cap B(q,\nu) = B(\bar q, \bar\nu)$.*

(iii) *Let $\lambda = \lambda(f)$; $f_0 = \mathrm{red}(f)$. Then $\gamma \cap B(q,\lambda) = \gamma \cap B(q,\nu)$.*

Proof. (i) is clear; (ii) follows from Lemma 2.17(iv), and (iii) from (ii) and Lemma 2.17(v). $\dashv$

2.21 Definition. Let $\nu \in S$, $q \in J_\nu$.

$$\Lambda^+(q,\nu) =_{\mathrm{df}} \{\lambda(f_{(\gamma,q,\nu)}) \mid \gamma \leq \nu\},$$
$$\Lambda(q,\nu) =_{\mathrm{df}} \Lambda^+(q,\nu)\backslash\{\nu\}.$$

Notice that $\Lambda(q,\nu) \subseteq C_\nu$ and we can think of these as first approximations to C_ν as q varies. We proceed to analyse these sets.

2.22 Lemma. *Let $\nu \in S, q \in J_\nu$.*

(i) *$\Lambda(q,\nu)$ is closed below ν;*

(ii) *$\mathrm{ot}(\Lambda(q,\nu)) \leq \nu$;*

(iii) *if $\lambda \in \Lambda(q,\nu)$ then $q \in J_\lambda$ and $\Lambda(q,\lambda) = \lambda \cap \Lambda(q,\nu)$.*

Proof. Set $\Lambda = \Lambda(q,\nu)$.

(i) Let $\eta \in \Lambda^*$. We are claiming that $\eta \in \Lambda^+(q,\nu)$. For each $\lambda \in \Lambda(q,\nu) \cap \eta$ pick $\beta_\lambda \in B(q,\nu)$ with $\lambda(f_{(\beta,q,\nu)}) = \lambda$. Clearly $\lambda \leq \lambda' \longrightarrow \beta_{\lambda'} \leq \beta_\lambda$. Let γ be the supremum of these β_λ, and then using the closure of $B(q,\nu)$ from (i) of the last lemma, we have $\lambda(f_{(\gamma,q,\nu)}) = \sup_\lambda \lambda(f_{(\beta_\lambda,q,\nu)}) = \eta$.

(ii) Clear.

(iii) Let $\lambda \in \Lambda$, and $g = \lambda(f_{(\beta,q,\nu)})$, where we take $\beta = \beta(g)$. Suppose $g : \bar{\nu} \Longrightarrow \nu$. Let $g(\overline{q}) = q$ and set $g_0 = \mathrm{red}(g)$. Then by Lemma 2.17(v) $g_0 = \lambda(f_{(\beta,q,\nu)})$). If $\gamma \geq \beta$ then $\lambda = \lambda(f_{(\gamma,q,\lambda)}) \leq \lambda(f_{(\gamma,q,\nu)})$. If $\gamma \leq \beta$ then

$$|f_{(\gamma,q,\lambda)})| = |g_0||f_{(\gamma,\bar{q},\bar{\nu})}| = |g||f_{(\gamma,\bar{q},\bar{\nu})}) = |f_{(\gamma,q,\nu)}|$$

where the first equality is justified by Lemma 2.17(v). ⊣

2.23 Lemma. *If $f : \bar{\nu} \Longrightarrow \nu$, $\mu = \lambda(f)$, $\overline{q} \in J_{\overline{\overline{\nu}}}$, $f(\overline{q}) = q$, then:*

(i) $\Lambda(\overline{q}, \bar{\nu}) = \varnothing \Longrightarrow \mu \cap \Lambda(q, \nu) = \varnothing$*;*

(ii) f *"*$\Lambda(\overline{q}, \bar{\nu}) \subseteq \Lambda(q, \mu)$*;*

(iii) *if* $\overline{\lambda} = \max(\Lambda(\overline{q}, \bar{\nu}))$ *and* $\lambda = f(\bar{\lambda})$ *then* $\lambda = \max(\mu \cap \Lambda(q, \nu))$.

Proof. (i) By its definition, if $\Lambda(\overline{q}, \bar{\nu}) = \varnothing$ then $f_{(0,\overline{q},\bar{\nu})}$ is cofinal into $\bar{\nu}$. Hence $\mathrm{ran}(f f_{(0,\overline{q},\bar{\nu})})$ is both cofinal in μ, and contained in $\mathrm{ran}(f_{(0,q,\nu)})$ by Lemma 2.17(iv), thus $\mu \cap \Lambda(q, \nu) = \varnothing$. This finishes (i). Note that by Lemma 2.22(iii) $\Lambda(q, \mu) = \mu \cap \Lambda(q, \nu)$. Let $f_0 = \mathrm{red}(f)$.

(ii) Let $\overline{\lambda} = \lambda(f_{(\bar{\beta},\overline{q},\bar{\nu})}) \in \Lambda(\overline{q}, \bar{\nu})$, and let $f(\overline{\beta}, \overline{\lambda}) = \beta, \lambda = f_0(\overline{\beta}, \overline{\lambda})$. Then $f_0(\lambda(f_{(\bar{\beta},\bar{q},\bar{\nu})})) = \lambda(f_{(\beta,q,\mu)}) \in \Lambda(q, \mu)$.

(iii) Let $\overline{\beta} = \sup\{\gamma \mid \lambda(f_{(\gamma,\bar{q},\bar{\nu})}) \leq \overline{\lambda}\}$. Then $\lambda(f_{(\bar{\beta},\bar{q},\bar{s})}) = \overline{\lambda}$, and by the assumed maximality of $\overline{\beta}$ we have $\lambda(f_{(\bar{\beta}+1,\bar{q},\bar{\nu})})) = \bar{\nu}$. Set $\beta = f(\bar{\beta}) = f_0(\bar{\beta})$, then $\lambda = f_0(\bar{\lambda}) = \lambda(f_{(\beta,q,\mu)})$ using Lemma 2.18 for second equality. However $\lambda(f_{(\beta+1,q,\mu)}) \geq \mu$, since, again by Lemma 2.17(iv), $\mathrm{ran}(f_0 f_{(\bar{\beta}+1,}\bar{q}, \bar{\nu})) \subseteq \mathrm{ran}(f_{(\beta+1,q,\mu)})$. Hence $\lambda = \max(\Lambda(q, \mu)) = \max(\mu \cap \Lambda(q, \nu))$. ⊣

We now note that our definitions of $\lambda(f)$, $B(q, \nu)$, $\Lambda(q, \nu)$, etc. are extremely uniform (and indeed are primitive recursively defined) in the appropriate parameters. In particular if $\mu \in S$, then we can define $F_\mu = \{f_{(\gamma,q,\nu)} \mid \nu \in S \cap \mu, q \in J_\nu, \gamma \leq \nu\}$, $E_\mu = \{\langle \nu, M_\nu, p(\nu), \tilde{h}_\nu \rangle \mid \nu \in S \cap \mu\}$, and $G_\mu = \{\langle \langle \nu, q \rangle, \Lambda(q, \nu) \rangle \mid q \in J_\nu, \nu \in S \cap \mu\}$.

2.24 Remark. E_μ, F_μ, G_μ are uniformly $\Delta_1(J_\mu)$ for $\mu \in S$, with, for $\mu' < \mu, E_{\mu'}, F_{\mu'}, G_{\mu'} \in J_\mu$.

2.25 Lemma. *Let $f : \bar{\nu} \Longrightarrow \nu$ with $\overline{q} \in J_{\overline{\overline{\nu}}}, f(\overline{q}) = q$. Then*

(i) *If $\lambda(f) = \nu$ then $|f| : \langle J_{\bar{\nu}}, \Lambda(\bar{q}, \bar{\nu}) \rangle \longrightarrow_{\Sigma_1} \langle J_\nu, \Lambda(q, \nu) \rangle$;*

(ii) *Otherwise: $|f| : \langle J_{\bar{\nu}}, \Lambda(\bar{q}, \bar{\nu}) \rangle \longrightarrow_{\Sigma_0} \langle J_\nu, \Lambda(q, \nu) \rangle$.*

Proof. (i) It suffices to show that $|f|(\Lambda(\bar{q}, \bar{\nu}) \cap \bar{\tau}) = \Lambda(q, \nu) \cap |f|(\tau)$ for arbitrarily large $\overline{\tau} < \bar{\nu}$. This will follow easily from the last lemma.

If $\bar{\lambda} \in \Lambda(\bar{q}, \bar{\nu})$, then $\Lambda(\bar{q}, \bar{\nu}) \cap \bar{\lambda} = \Lambda(\bar{q}, \bar{\lambda})$ by Lemma 2.22, and by the Remark, if $f(\bar{\lambda}) = \lambda$, we have $f(\Lambda(\bar{q}, \bar{\lambda})) = \Lambda(q, \lambda) = \lambda \cap \Lambda(q, \nu)$ (with the latter equality by Lemma 2.22 again). If $\Lambda(\bar{q}, \bar{\nu})$ is unbounded in $\bar{\nu}$, this suffices; if it is empty or bounded, then the last lemma takes care of these cases.

For non-cofinal maps (ii) we still have, if $\lambda(f) = \mu$, that

$$|f_0| : \langle J_{\bar\nu}, \Lambda(\bar q, \bar\nu)\rangle \longrightarrow_{\Sigma_1} \langle J_\mu, \Lambda(q, \mu)\rangle$$

where $f_0 = \mathrm{red}(f)$. However $\Lambda(q, \mu) = \mu \cap \Lambda(q, \nu)$, and $|f_0| = |f|$. ⊣

We turn to a decomposition of the C_ν sets into a finite sequence of sets of the form $\Lambda(l^i_\nu, \nu)$. This will enable us to extend the results of the last few lemmas from the $\Lambda(q, \nu)$ sets to C_ν sets, whilst at the same time giving us a handle on other data about the C_ν.

2.26 Definition. Let $s \in S$, $\eta \le \nu$. $l^i_{\eta\nu} < \nu$ is defined for $i < m_{\eta\nu} \le \omega$ by induction on i:

$$l^0_{\eta\nu} = 0; \qquad l^{i+1}_{\eta\nu} \simeq \max(\eta \cap \Lambda(l^i_{\eta\nu}, \nu)).$$

We also write l^i for $l^i_{\eta\nu}$ if the context is clear; also we set $l^i_\nu \simeq l^i_{\nu\nu}$; $m_\nu = m_{\nu\nu}$.

We note some easily checked facts about this definition (which we shall use without comment; the last here is by induction on i):

Facts.

- $l^i_{\eta\nu} \le l^{i+1}_{\eta\nu}$ $(i < m_{\eta\nu})$.
- $i > 0$ implies $l^i_{\eta\nu} \in \eta \cap C_\nu$.
- Let $l^i_{\eta\nu}$ be defined, and suppose $l^i_{\eta\nu} < \mu \le \eta$. Then $l^i_{\eta\nu} = l^i_{\mu\nu}$.

2.27 Lemma. *Let $f : \bar\nu \implies \nu$.*

(i) *If $\lambda = \lambda(f)$ then $l^i_{\lambda\nu} \simeq f(l^i_{\bar\nu})$;*

(ii) *let $\overline{\eta} < \bar\nu$, $f(\overline{\eta}) = \eta$; then $l^i_{\eta\nu} \simeq f(l^i_{\overline{\eta}\bar\nu})$.*

Proof. (i) By induction on i. If $i = 0$ this is trivial. Suppose $i = j + 1$. Then, as inductive hypothesis $l^j_{\lambda\nu} = f(l^j_{\bar\nu})$, and thus $|f| : \langle J_{\overline{\nu}}, \Lambda(l^j_{\bar\nu}, \bar\nu)\rangle \longrightarrow_{\Sigma_1} \langle J_\lambda, \Lambda(l^j_{\lambda\nu}, \lambda)\rangle$, by the last lemma, as $|\mathrm{red}(f)| = |f|$. However $\Lambda(l^j_{\lambda\nu}, \lambda) = \lambda \cap \Lambda(l^j_{\lambda\nu}, \nu)$, by Lemma 2.22. Hence, $f(l^i_{\bar\nu}) \simeq f(\max \Lambda(l^j_{\bar\nu}, \bar\nu)) \simeq \max(\lambda \cap \Lambda(l^j_{\lambda\nu}, \nu)) \simeq l^i_{\lambda\nu}$ with the middle equality holding by the inductive hypothesis and Lemma 2.23(iii).

(ii) is proved similarly. ⊣

2.28 Corollary.

(i) *Let $f : \bar\nu \implies \nu$ cofinally. Then $l^i_\nu \simeq f(l^i_{\bar\nu})$.*

(ii) *Let $\lambda \in C_\nu$. Then $l^i_{\lambda\nu} \simeq l^i_\lambda$.*

Proof. (i) is immediate. For (ii) choose $f : \bar\nu \implies \nu$ with $\lambda = \lambda(f)$, and set $f_0 = \mathrm{red}(f)$. Then $l^i_{\lambda\nu} \simeq f(l^i_{\bar\nu}) \simeq f_0(l^i_{\bar\nu}) \simeq l^i_\lambda$ with the last equality holding from (i). $\dashv$

2.29 Lemma. *Let $\eta \le \nu$, $\lambda = \min(C^+_\nu \setminus \eta)$. Then $l^i_\nu \simeq l^i_{\lambda\nu} \simeq l^i_{\eta\nu}$ (for any $i < \omega$ for which any term is defined).*

Proof. Induction on i, again $i = 0$ is trivial. Suppose $l^j_\nu = l^j_{\eta\nu} = l^j_{\lambda\nu}$ and $i = j+1$. Set $l = l^j_{\eta\nu}$; then we have: $\Lambda(l,\nu) \cap \eta = \Lambda(l,\nu) \cap \lambda$, since $\Lambda(l,\nu) \subseteq C_\nu$ and $C_\nu \cap [\eta,\lambda) = \varnothing$. Suppose, without loss of generality that $l^i_{\eta\nu}$ is defined. Then $l^i_{\eta\nu} = \max(\eta \cap \Lambda(l,\nu)) = \max(\lambda \cap \Lambda(l,\nu)) = l^i_{\lambda\nu} = l^i_\lambda$. $\dashv$

2.30 Lemma. *Let $j \le i < m_\nu$. Set $l = l^i_\nu$. Then $l^j_\nu \in \mathrm{ran}(f_{(0,l,\nu)})$.*

Proof. Set $f = f_{(0,l,\nu)}$. Suppose $f : \bar\nu \implies \nu$, and $\lambda = \lambda(f)$. Then $l^j_{\lambda\nu} \simeq f(l^j_{\bar\nu})$ by Lemma 2.27*(i)*. But l^j_ν exists, and $l^j_\nu < \lambda \le \nu$. Hence $l^j_\nu = l^j_{\lambda\nu} = f(l^j_{\bar\nu})$. $\dashv$

We now prove a key lemma showing that the $\langle l^j_{\lambda\nu}\rangle$ sequences are finite.

2.31 Lemma. *Let $\nu \in S$, $\eta \le \nu$. Then $m_{\eta\nu} < \omega$.*

Proof. Suppose this fails. Then for some $\eta \le \nu$ we have that $l^i_{\eta\nu}$ is defined for $i < \omega$. Let $\lambda = \min(C^+_\nu \setminus \eta)$. Then $l^i_{\lambda\nu} = l^i_{\eta\nu}$ by Lemma 2.29. Choose $f : \bar\nu \implies \nu$ with $\lambda = \lambda(f)$. Then $l^i_{\lambda\nu} = l^i_\lambda = f(l^i_{\bar\nu})$ for $i < \omega$ by Corollary 2.28(ii) and Lemma 2.27(i). Hence, taking ν as λ, we may assume, without loss of generality, that l^i_ν is defined for $i < \omega$ for some $\nu \in S$. This will yield a contradiction. We obtain an infinite descending chain of ordinals by showing that as i increases, and thus l^i_ν does so strictly too, the maximal β^i that must be contained in the range of any $f :\implies \nu$ together with l^i_ν in order for $\mathrm{ran}(f)$ to be unbounded in ν strictly *decreases.* This is absurd.

Set $l = l^i_\nu$. Define: $\beta^i = \beta^i_\nu =_{\mathrm{df}} \max\{\beta \mid \lambda(f_{(\beta,l,\nu)}) < \nu\}$. By the definition of l^{i+1}_ν we have that $\lambda(f_{(\beta,l,\nu)}) < \nu_s \longleftrightarrow \lambda(f_{(\beta,l,\nu)}) \le l^{i+1}_\nu$. Furthermore, by the definition of β^i:

(1) $\lambda(f_{\beta^i,l,\nu}) \le l^{i+1}_\nu$;

(2) $\lambda(f_{\beta^i+1,l,\nu}) = \nu$.

Claim. $\beta^{i+1} < \beta^i$ for $i < \omega$.

Proof of Claim. Set $f = f_{(\beta^{i+1},l^{i+1},\nu)}$. Then $\lambda(f) = l^{i+2}$. (We omit the subscript ν from now on.) Let $f : \bar\nu \implies \nu$. Then $l^j_{\bar\nu}$ exists and $f(l^j_{\bar\nu}) = l^j_{l^{i+1},\nu} = l^j_\nu$ for $j < i+1$ since $l^j < l^{i+1} < \nu$. (The first equality comes from Lemma 2.27(i) and (1), the second from Lemma 2.29.) $\dashv$ *Claim*

(3) $\beta^i \geq \beta^{i+1}$.

Proof of (3). Suppose not. Then $(\beta^i + 1) \cup \{l^i\} \subseteq \mathrm{ran}(f)$. Hence we have $\mathrm{ran}(f_{(\beta^i+1,l^i,\nu)}) \subseteq \mathrm{ran}(f)$. Consequently by (2), $\lambda(f) = \nu > l^{i+2}$. Contradiction! $\dashv$ (3)

(4) $\beta^i \neq \beta^{i+1}$.

Proof of (4). Suppose not. As β^{i+1} is the first ordinal moved by f we conclude that $f(\beta^i) > \beta^i$. Set $g = f_{(\beta^i,l,\nu)}, \bar{g} = f_{(\beta^i,\bar{l},\bar{\nu})}$ where $\bar{l} = l^i_{\bar{\nu}}$. Then $g = f\bar{g}$, since $f{\restriction}\beta^i = \mathrm{id}, f(\bar{l}) = l(= l^i_\nu)$. Hence $l^{i+1} = \lambda(g) = \lambda(f\bar{g}) < l^{i+2} = \lambda(f)$. Hence $\lambda(\bar{g}) < \bar{\nu}$. Now we set: $g_0 = f_{(\beta^i,l,l^{i+2})}$. If further $f_0 = \mathrm{red}(f)$, then we have also $g_0 = f_0\bar{g}$ by Lemma 2.17(iv). As $l^{i+1} = \lambda(g) < l^{i+2}$, Lemma 2.18(ii) applies and:

$$f(\beta(\bar{g})) = f_0(\beta(\bar{g})) = \beta(g_0) = \beta(g) = \beta^i.$$

Hence $\beta^i \in \mathrm{ran}(f)$ which is a contradiction. This proves the *Claim* and hence the lemma. $\dashv$

We now set $l_{\eta\nu} = l^{m-1}_{\eta\nu}$, where $m = m_{\eta\nu}$. Again we write l_ν for $l_{\nu\nu}$. We note that then $\Lambda(l_{\eta\nu}, \nu) \cap \eta$ is either unbounded in η or is empty. We analyse the latter case further.

2.32 Lemma. *Suppose* $\Lambda(l_{\eta\nu}, \nu) \cap \eta = \varnothing$. *Set* $l = l_{\eta\nu}$. *Then:*

(i) $l = 0 \Longrightarrow C_\nu \cap \eta = \varnothing$;

(ii) $l > 0 \Longrightarrow l = \max(C_\nu \cap \eta)$;

(iii) $\eta \in C^+_\nu \Longrightarrow \eta = \lambda(f_{(0,l,\nu)})$.

Proof. Set $\rho = \min(C^+_\nu \setminus (l+1)$.

(1) $l = l_{\rho\nu}$.

Proof of (1). Set $n = m_{\eta\nu} - 1$. Then $l = l^n_{\eta\nu} < l+1 < \eta$. Hence (by Fact after Definition 2.1) $l = l^n_{l+1,\nu}$. But $\Lambda(l,\nu) \cap (l+1) = \varnothing$. Hence $l^{n+1}_{l+1,\nu}$ is undefined and $l = l_{l+1,\nu}$. Hence $l = l_{\rho,\nu}$ by Lemma 2.29. $\dashv$ (1)

(2) $\lambda(f_{(0,l,\nu)}) = \rho$.

Proof of (2). Choose $f : \bar{\nu} \implies \nu$, with $\lambda(f) = \rho$ witnessing that $\rho \in C_\nu$. Then, by Lemma 2.27(i), $f(l_{\bar{\nu}}) = l_{\rho\nu} = l$. Set $\bar{l} = l_{\bar{\nu}}$. Now note that we must have that $\lambda(f_{(0,\bar{l},\bar{\nu})}) = \bar{\nu}$. For, if this failed then $f(\lambda(f_{(0,\bar{l},\bar{\nu})})) = \lambda(f_{(0,l,\nu)}) < \rho$ by Lemma 2.18, and so the latter is in $C^+_\nu \cap (l,\rho)$, which is absurd! Then $\lambda(f_{(0,l,\nu)}) = \lambda(ff_{(0,\bar{l},\bar{\nu})}) = \lambda(f) = \rho$. $\dashv$ (2)

From (2) it follows that $\rho \geq \eta$ (for otherwise this contradicts the definition of l as $l_{\eta\nu}$). Hence we have the two alternatives:

If $l = 0$ then (i) holds: $\rho = \min(C^+_\nu \backslash 1) = \min(C^+_\nu) \geq \eta$. If $l > 0$ then $l = \max(C_\nu \cap \eta)$ since $(C_\nu \cap \eta)\backslash(l+1) \subseteq (C_\nu \cap \rho)\backslash(l+1) = \varnothing$ and thus we have (ii).

Finally for (iii) if $\eta \in C^+_\nu$ then $\eta = \max(C^+_\nu \backslash (l+1) = \rho = \lambda(f_{(0,l,\nu)})$. $\dashv$

We now get the closure of the sets C^+_ν as well as a precise characterisation of the points they contain.

2.33 Lemma. *Let λ be an element or a limit point of C^+_ν. Let $l = l_{\lambda\nu}$. Then there is a β such that $\lambda = \lambda(f_{(\beta,l,\nu)})$. Hence C_ν is closed in ν, and*

$$C^+_\nu = \{\lambda(f_{(\beta,l,\nu)}) \mid \beta \leq \nu, l < \nu\}.$$

Proof. The last sentence is immediate from the penultimate one.

Case 1. $\lambda \cap \Lambda(l, \nu) = \varnothing$.

Then $C_\nu \cap \lambda = \varnothing$ or $l = \max(C_\nu \cap \lambda)$ by the last lemma. Hence λ is not a limit point of C^+_ν. Hence $\lambda \in C^+_\nu$, and thus $\lambda = \lambda(f_{(0,l,\nu)})$ by (iii) of that lemma.

Case 2. $\lambda \cap \Lambda(l, \nu)$ is unbounded in λ.

Given $\mu \in \Lambda(l, \nu) \cap \lambda$, let β_μ be such that $\lambda(f_{(\beta_\mu,l,\nu)}) = \mu$. Then $\lambda(f_{(\beta,l,\nu)}) = \lambda$ where $\beta = \sup_\mu \beta_\mu$. $\dashv$

The following is (iii) of Theorem 2.5.

2.34 Lemma. $\lambda \in C_\nu \Longrightarrow \lambda \cap C_\nu = C_\lambda$.

Proof. Assume inductively the lemma proven for all ν' with $\nu' < \nu$, and we prove the result for ν by induction on λ. Let $l = l_{\lambda\nu}$. Hence by Corollary 2.28 $l = l_\lambda$. By Lemma 2.33 $\lambda \in \Lambda(l, \nu)$. Set $\Lambda = \lambda \cap \Lambda(l, \nu)$. Then by Lemma 2.22(ii) $\Lambda = \Lambda(l, \lambda)$.

Case 1. $\Lambda = \varnothing$.

If $l = 0$, then $C_\lambda \subseteq \lambda \cap C_\nu = \varnothing$ (the latter by Lemma 2.32). If $l > 0$, then $l = l_\lambda = \max(C_\lambda \cap \lambda) = \max(C_\lambda) = l_{\lambda\nu} = \max(\lambda \cap C_\nu)$ with the last equality also by the same lemma. As $l < \lambda$, we use the inductive hypothesis on λ: $l \cap C_\nu = C_l$. However, $C_l = l \cap C_\lambda$ by the overall inductive hypothesis taking λ as a $\nu' < \nu$. Hence $C_\lambda = \lambda \cap C_\nu = C_l \cup \{l\}$.

Case 2. Λ is unbounded in λ.

Then $\mu \in \Lambda \longrightarrow \mu \in C_\nu \cap C_\lambda$. Hence by the overall inductive hypothesis $C_\mu = \mu \cap C_\lambda$ and (as $\mu < \lambda$) $C_\mu = \mu \cap C_\nu$. Hence $C_\lambda = \lambda \cap C_\nu = \bigcup_{\mu \in \Lambda} C_\mu$. $\dashv$

The following completes (i) of Theorem 2.5:

2.35 Lemma. $\sup(C_\nu) < \nu \Longrightarrow \mathrm{cf}(\nu) = \omega$.

Proof. Let $l = \sup(C_\nu) = l_\nu$. Then $X = \mathrm{On} \cap \mathrm{ran}(f_{(0,l,\nu)})$ is countable, and cofinal in ν. $\dashv$

We now observe that we readily have (ii) of Theorem 2.5, since $\mathrm{ot}(C_\nu) \leq \sum_{i=0}^{m_\nu - 1} \beta_\nu^i < \nu$ where the β_ν^i are from Lemma 2.31.

2.36 Lemma. *Let $f : \bar\nu \Longrightarrow \nu$. Then $|f| : \langle J_{\bar\nu}, C_{\bar\nu}\rangle \longrightarrow_{\Sigma_0} \langle J_\nu, C_\nu\rangle$.*

Proof. It suffices to show that for arbitrarily large $\tau < \bar\nu$ that $|f|(C_{\bar\nu} \cap \tau) = C_\nu \cap |f|(\tau)$. (As usual we shall write "f" for "$|f|$".)

Case 1. $\Lambda(l_{\bar\nu}, \bar\nu)$ is unbounded in $C_{\bar\nu}$.

If $\bar\lambda \in C_{\bar\nu}$ and $\lambda = f(\bar\lambda)$ then by Lemma 2.23 (and Lemma 2.22) $\lambda \in \Lambda(f(l_{\bar\nu}), \nu) \subseteq C_\nu$. By Remark 2.24 we have $E_{\bar\lambda} \in J_{\bar\nu}$ and $f(E_{\overline\lambda}) = E_\lambda$. By Lemma 2.32 $C_{\bar\lambda} = \{\lambda(f_{(0,l,\nu)}) < \bar\lambda \mid l < \bar\lambda\} \in J_{\bar\nu}$ and is uniformly Σ_0 definable from $E_{\bar\lambda}$ over $J_{\bar\nu}$. Consequently $|f|(C_{\overline\lambda}) = C_\lambda$ by Σ_1-elementarity of $|f|$. But $C_{\overline\lambda} = \overline\lambda \cap C_{\bar\nu}$ and $C_\lambda = \lambda \cap C_\nu$.

Case 2. $\Lambda(l_{\bar\nu}, \bar\nu) = \varnothing$.

Set $l_{\bar\nu} = \bar l$ and let $f(l_{\bar\nu}) = l$. Then $l = l_{\lambda\nu}$ where $\lambda = \lambda(f)$. However $\lambda(f_{0,\bar l,\bar\nu}) = \bar\nu$ by our case hypothesis. Thus $\lambda(f_{(0,l,\nu)}) = \lambda(f f_{(0,\bar l,\bar\nu)}) = \lambda$. Hence $\Lambda(l,\nu) \cap \lambda = \varnothing$. So we have one of the following two cases holding, by Lemma 2.32:

Case 2.1. $\bar l = l = 0$. Then, $C_{\bar\nu} = C_\nu \cap \lambda = \varnothing$, and the result is trivial.

Case 2.2. $\bar l = \max C_{\bar\nu}$. Then $l > 0$ and thus $l = \max(C_\nu \cap \lambda)$. Hence for sufficiently large $\bar\tau > \bar l$:

$$f(\bar\tau \cap C_{\bar\nu}) = f(C_{\bar\nu}) = f(C_{\bar\nu} \cap \bar l \cup \{\bar l\}) = (C_\nu \cap l) \cup \{l\} = C_\nu \cap \lambda = f(\bar\tau) \cap C_\nu.$$

$\dashv$

The following completes (iv) of Theorem 2.4 on the condition that C_ν is cofinal in ν. We shall see afterwards how to tweak a C'_ν to get the result for the non-cofinal C_ν.

2.37 Lemma. *If $f : \langle J_{\overline\nu}, \overline{C}\rangle \longrightarrow_{\Sigma_1} \langle J_\nu, C_\nu\rangle$ and $\sup(C_\nu) = \nu$ then $\overline\nu \in S$ and $\overline{C} = C_{\overline\nu}$.*

Proof. Suppose $f, \overline{C}, \overline\nu$ are as in the antecedent. For $\tau \in C_\nu$, let $f_\tau : \overline\nu_\tau \Longrightarrow \nu$ with $\lambda(f_\tau) = \tau$. By the Interpolation Lemma we have (a) $f_{\overline\nu_\tau \nu_\tau} : M_{\overline\nu_\tau} \longrightarrow_{\Sigma_1^{(n)}} M_\tau$, (b) $\pi_\tau : M_\tau \longrightarrow_{\Sigma_0^{(n)}} M_\nu$; (c) $\pi_\tau \restriction \tau = \mathrm{id} \restriction \tau$, and (d) $\pi_\tau(p_\tau) = p_\nu$. Notice that the map $f_{\overline\nu_\tau \nu_\tau}$ can be defined from $M_{\overline\nu_\tau}$ and M_τ inside J_ν, and both of them in turn are there definable just from τ, since $\beta(\tau) < \nu$.

(1) π_τ, M_τ depend only on τ, and π_τ is the unique $\Sigma_0^{(n)}$-preserving map satisfying (b)–(d).

For such τ let $X = \bigcup_{\tau \in C_\nu} \mathrm{ran}(\pi_\tau)$.

(2) $M_\nu = X$.

Proof of (2). Let $x \in M_\nu$. Clearly X is a $\Sigma_0^{(n)}$ substructure of M_ν. Suppose $x = \widetilde{h}_\nu(i, \xi, p_\nu)$ for a $\xi < \nu$. Suppose we take for "$y = \widetilde{h}_\nu(u, v)$" a functionally absolute $\Sigma_1^{(n)}$ definition of the form $\exists z^n H(z^n, y, u, v)$ with $H \in \Sigma_0^{(n)}$. It will suffice to find $\tau > \xi$ and some $x_\tau \in M_\tau$ with $x_\tau = \widetilde{h}_\tau(i, \xi, p_\tau)$. We then would have $\pi_\tau(x_\tau) = x$. For this we need to be able to find such a suitable witnessing $z^n \in \mathrm{ran}(\pi_\tau)$ for some sufficiently large $\tau \in C_\nu$. For this it will suffice to know:

(3) $\sup_{\tau \in C_\nu}(\mathrm{ran}(\pi_\tau) \cap \omega\rho_\nu) = \omega\rho_\nu$.

Proof of (3). Let $l = l_\nu$. Then $\Lambda(l, \nu)$ is unbounded in ν. Let $\gamma = \sup\{\beta \mid \lambda(f_{(\beta,l,\nu)}) < \nu\}$. Then $\lambda(f_{(\gamma,l,\nu)}) = \nu$ and $\sup(\mathrm{ran}(f_{(\gamma,l,\nu)}) \cap \omega\rho_\nu) = \omega\rho_\nu$ by Lemma 2.14. For $\beta < \gamma$ let $\lambda_\beta = \lambda(f_{(\beta,l,\nu)})$. Then $\sup\{\lambda_\beta \mid \beta < \gamma\} = \nu$. However by considering $k_\beta =_{\mathrm{df}} \mathrm{red}(f_{(\beta,l,\nu)})$ we see that $\mathrm{ran}(k_\beta) \subseteq M_{\lambda_\beta}$ for $\beta < \gamma$. Hence $\mathrm{ran}(f_{(\beta,l,\nu)}) \subseteq \mathrm{ran}(\pi_{\lambda_\beta})$. Thus $\mathrm{ran}(f_{(\beta,l,\nu)}) \subseteq X$ and so $\sup(X \cap \omega\rho_\nu) = \omega\rho_\nu$. ⊣ (3)

If $Y = \mathrm{ran}(f)$ let $\widetilde{Y} = \widetilde{h}_\nu(Y \cup \{p_\nu\})$.

(4) If $y \in \widetilde{Y} \cap J_\nu$ then $\exists \tau \in C_\nu(y \in \widetilde{h}_\tau((Y \cap J_\tau) \cup \{p_\tau\})$, and hence $y \in Y$.

Proof of (4). This is because if "$y = \widetilde{h}_\nu(i, \xi, p_\nu)$" then by (2) this holds relativised to $\mathrm{ran}(\pi_\tau)$ for some $\tau \in C_\nu$. Hence $y = \widetilde{h}_\tau(i, \xi, p_\tau)$. But $M_\tau, p_\tau, \widetilde{h}_\tau$ etc. are Σ_1-definable over J_ν from τ, for any $\tau \in S \cap \nu$; hence "$\exists \tau \in C_\nu(i, \xi, p_\tau \in \mathrm{dom}(\widetilde{h}_\tau))$" is a $\Sigma_1^{\langle J_\nu, C_\nu \rangle}$ statement. Hence there is such a $\tau = f(\overline{\tau})$ in $\mathrm{ran}(f)$. Hence

$$\pi_\tau \widetilde{h}_\tau(i, \xi, p_\tau) = \widetilde{h}_\nu(i, \xi, p_\nu) = y.$$

Thus $y \in Y$. ⊣ (4)

We may now transitivise $\widetilde{Y}$ and obtain $\widetilde{f} \supseteq f$ with $\widetilde{f} : \widetilde{M} \longrightarrow_{\Sigma_1^{(n)}} M_\nu$, and our usual arguments show that $\overline{\nu} \in S$, $\widetilde{M} = M_{\overline{\nu}}$, and $\langle \overline{\nu}, f, \nu \rangle \in \mathbb{F}$, etc. We have yet to argue that $\overline{C} = C_{\overline{\nu}}$. Clearly $\overline{C}$ is unbounded in $\overline{\nu}$. Let $\overline{l} = l_{\overline{\nu}}$. Then $\Lambda(\overline{l}, \overline{\nu})$ is unbounded in $\overline{\nu}$ (otherwise if $l =_{\mathrm{df}} f(\overline{l})$, then $l = l_\nu$ and $\Lambda(l, \nu)$—and C_ν—is bounded in ν).

Claim $\overline{C} \subseteq C_{\overline{\nu}}$.

Proof of Claim. If not let $\overline{\lambda}$ be least in $\overline{C}\backslash C_{\overline{\nu}}$. Suppose (for example) $\overline{\eta}_0 < \overline{\lambda}, \overline{\eta}_0 \in C_{\overline{\nu}}$ and $\overline{\eta} > \overline{\lambda}$ is $\min(\Lambda(\overline{l}, \overline{\nu})\backslash\overline{\lambda})$. As $\overline{\eta} \in \Lambda(\overline{l}, \overline{\nu}), \eta \in \Lambda(l, \nu)$ (where $\eta =_{\mathrm{df}} f(\overline{\eta})$ and as above $l = f(\overline{l}) = l_\nu$). So $\eta \in C_\nu$. Hence as $\overline{\lambda} \in \overline{C}\backslash(\overline{\eta}_0 + 1), f(\overline{\lambda}) \in f(\overline{C} \cap \overline{\eta}) = C_\nu \cap \eta = C_\eta$. However then $\overline{\lambda} \in C_{\overline{\eta}} \subseteq C_{\overline{\nu}}$! ⊣ *Claim*

However now, for $\overline{\lambda} \in \overline{C}$, we have

$$f(\overline{C} \cap \overline{\lambda}) = C_\nu \cap \lambda = C_\lambda = f(C_{\overline{\lambda}}) = f(C_{\overline{\nu}} \cap \overline{\lambda}).$$

So, $\overline{C} \cap \overline{\lambda} = C_{\overline{\nu}} \cap \overline{\lambda}$ for unboundedly many $\overline{\lambda} < \overline{\nu}$, and we are done. ⊣

We now indicate how to modify C_ν in case it is bounded in ν. As we know, if this happens then $\mathrm{cf}(\nu) = \omega$. To deal with this situation we substitute a new C'_ν. (In all other cases we shall alter nothing and set $C'_\nu = C_\nu$.) Clearly, if we set $l = l_\nu$ we have that $\widetilde{h}_\nu$"$\omega \times \{\langle l, p_\nu\rangle\}$ is unbounded in ν, and hence by Lemma 2.14 in $\omega\rho_\nu$.

Let $u_n = \nu \cap \widetilde{h}_\nu$"$n \times \{\langle l, p_\nu\rangle\}$. Then $u_n \in J_\nu$ and is finite, with $\bigcup_n u_n$ cofinal in ν. We take $\xi_{n,\nu} =_{\mathrm{df}} \prec n, l, \alpha_\nu, u_0, \ldots, u_n \succ$ (for some suitable iterate of the Gödel pairing function $\prec - \succ$.) Then $l < \xi_{n,\nu}$ and the latter is monotone as a function of n in ν.

2.38 Lemma. *Let* $\sup(C_\nu) < \nu$. *Let* $f : J_{\nu'} \longrightarrow_{\Sigma_0} J_\nu$ *with* $\xi_{n,\nu} \in \mathrm{ran}(f)$ *for every* $n < \omega$. *Then* (i) $\nu' \in S$; (ii) $\langle \nu', f, \nu\rangle \in \mathbb{F}$; *and* (iii) *if* $f(\xi'_n) = \xi_{n,\nu}$ *then* $\xi'_n = \xi_{n,\nu'}$ *and thus* $C_{\nu'} = \{\xi'_n \mid n < \omega\}$.

Proof. As f is cofinal into ν, it is Σ_1-preserving. (i) is immediate. Let $l = l_\nu$. Let $g = f_{(0,l,\nu)}$. Then $\forall n(\xi_{n,\nu} \in \mathrm{ran}(g))$ and $\lambda(g) = \nu$. Let $g : \overline{\nu} \implies \nu$, and $\widetilde{g} : M_{\overline{\nu}} \longrightarrow_{\Sigma_1^{(n)}} M_\nu$.

Hence by the Generalised Interpolation Lemma 1.52 there is an M' (obtained by taking $f, f^{-1} \circ g, g$ here as σ_1, σ_0, g respectively there) and there is a $\widetilde{g} : M_{\overline{\nu}} \longrightarrow_{\Sigma_1^{(n)}} M'$ and $g_1 : M' \longrightarrow_{\Sigma_1^{(n)}} M_\nu$ (both being cofinal at the nth level). Just as in the proof of Lemma 2.11 $M' = M_{\nu'}$, $n = n(\nu')$ etc. Then as $g_1 \supseteq f$, (ii) follows. If $g(\overline{l}) = l$ then $\overline{l} = l_{\overline{\nu}}$ by Corollary 2.28; taking $l' = f^{-1} \circ g(\overline{l})$ this too shows that $l' = l_{\nu'}$. Then if $f(\xi'_n) = \xi_{n,\nu}$ we have $\xi'_n = \xi_{n,\nu'}$ by the $\Sigma_1^{(n)}$-elementarity of g_1. Hence $C'_{\nu'} = \{\xi_{n,\nu'} \mid n < \omega\}$, and we are done. ⊣

We now mention how a more careful computation of the order types of the C_ν-sequences can be obtained. This is needed for some applications and was done using ordinal addition in [2], but the following is essentially the same calculation and is from [29]. We first generalise the definition of $\beta^i = \beta^i_\nu$.

2.39 Definition. For $\eta \leq \nu$ set : $\beta^i_{\eta\nu} =_{\mathrm{df}} \max\{\beta \mid \lambda(f_{(\beta, l^i_{\eta\nu}, \nu)}) < \eta\}$.

Many of the previous properties of the $\beta^i = \beta^i_\nu$ carry over to these $\beta^i_{\eta\nu}$. Namely:

1. $\lambda(f_{(\beta,l^i_{\eta\nu},\nu)}) < \nu \iff \lambda(f_{(\beta,l^i_{\eta\nu},\nu)}) \leq l^{i+1}_{\eta\nu}$.
2. $\beta^i_{\eta\nu}$ is defined if and only if $l^{i+1}_{\eta\nu}$ is defined, i.e. when $i+1 < m_{\eta\nu}$.
3. $\beta^i_{\eta\nu} \simeq \beta^i_{\lambda\nu}$ if $\lambda = \min(C^+_\nu \backslash \eta)$. (Again as before, $\lambda(f_{(\beta,l^i_{\eta\nu},\nu)}) < \eta \iff \lambda(f_{(\beta,l^i_{\eta\nu},\nu)}) < \lambda$.)
4. $\beta^{i+1}_{\eta\nu} < \beta^i_{\eta\nu}$ when defined. (By the same argument as for $\beta^{i+1} < \beta^i$.)

Now we set $b_\eta = b_{\eta\nu} =_{\mathrm{df}} \{\beta^i_{\eta\nu} \mid i+1 < m_{\eta\nu}\}$. For $\eta \in C_\nu$ we then set $d_\eta = d_{\eta\nu} =_{\mathrm{df}} b_{\eta^+\nu}$ where $\eta^+ = \min(C^+_\nu \backslash (\eta+1))$. (For the rest of the proof we shall drop the subscript ν on ordinals, which remains unaltered throughout.) Then we shall have:

5. Let $\eta \in C_\nu$, with $l^i_{\eta^+} < \eta$. Then $l^i_{\eta^+} = l^i_\eta$ (proof by induction on i). Moreover:
6. Let $\eta \in C_\nu$, with $l^i_{\eta^+} < \eta$ then:

$$l^{i+1}_{\eta^+} = \eta \text{ if } \eta \in \Lambda(l^i_\eta, \nu), \text{ and equals } l^{i+1}_\nu \text{ if not.}$$

Proof of 6: $l^i_{\eta^+} = l^i_\eta$ by 5. If $\eta \in \Lambda(l^i_\eta, \nu)$ then η is maximal in this set below η^+. So the first alternative holds. Note that $i \neq m_{\eta\nu} - 1$ (otherwise by Lemma 2.33 for some β, $\eta = \lambda(f_{(\beta,l^i_{\eta\nu},\nu)}) \in \Lambda(l^i_\eta, \nu)$). Thus l^{i+1}_η is defined and $l^{i+1}_{\eta^+}$ must equal this.

2.40 Lemma. *Let $\eta, \mu \in C_\nu$, with $\eta < \mu$. Then $d_\eta <^* d_\mu$.*

Proof. Let $\eta^+ = \min(C^+_\nu \backslash (\eta+1))$, $\mu^+ = \min(C^+_\nu \backslash (\mu+1))$. Let i be maximal so that $l^i_{\mu^+} = l^i_{\eta^+}$. Then $\beta^j_{\mu^+} = \beta^j_{\eta^+}$ for $j < i$. As $l^i_{\mu^+} \leq \eta < \mu$, we have by 6. above that $l^{i+1}_{\mu^+}$ is defined and $l^{i+1}_{\mu^+} = \mu$ or l^{i+1}_μ. Moreover then $\beta^i_{\mu^+}$ is defined, and by maximality of i, $l^{i+1}_{\eta^+} \neq l^{i+1}_{\mu^+}$.

Claim $l^{i+1}_{\eta^+} < l^{i+1}_{\mu^+}$.

That $l^{i+1}_{\mu^+} < \eta^+$ is ruled out: otherwise $l^{i+1}_{\eta^+} = l^{i+1}_{\mu^+}$ again. So $l^{i+1}_{\eta^+} < \eta^+ \leq l^{i+1}_{\mu^+}$, establishing the Claim.

As $\beta^i_{\mu^+}$ is defined, if $\beta^i_{\eta^+}$is undefined, then we would be finished. Set $l = l^i_{\mu^+} = l^i_{\eta^+}$. Then $\lambda(f_{(\beta^i_{\eta^+},l,\nu)}) = l^{i+1}_{\eta^+}$ and $\lambda(f_{(\beta^i_{\mu^+},l,\nu)}) = l^{i+1}_{\mu^+}$. Hence $\beta^i_{\eta^+} < \beta^i_{\mu^+}$ and thus $d_\eta <^* d_\mu$ as required. ⊣

2.41 Lemma. *Let α be p.r. closed so that for some $\alpha_0 < \alpha$, $\lambda(f_{(\alpha_0,0,\nu)}) = \nu$. Then* $\mathrm{ot}(C_\nu) < \alpha$.

Proof. First note that $\mathrm{ot}(\langle [\alpha]^{<\omega}, <^* \rangle) = \alpha$. Let $\alpha_0 < \alpha$ have the property that $\lambda(f_{(\alpha_0,0,\nu)}) = \nu$. Then $\{\beta^i_{\eta\nu} \mid \eta \leq \nu, i+1 < m_{\eta\nu}\} \subseteq \alpha_0$. Thus $\mathrm{ot}\langle \{d_\eta \mid \eta \in C_\nu\}, <^* \rangle \leq \mathrm{ot}(\langle [\alpha]^{<\omega}, <^* \rangle) < \alpha$. Thus $\mathrm{ot}(C_\nu) < \alpha$. ⊣

We make some remarks on different versions of this proof. We have obtained a rich global $\Box$ sequence by taking as C_ν the set of all possible $\lambda(f)$ where $f \implies \nu$. There are other ways: the C_ν sequences from [18] are defined by a finite recursion piecing together enumerations of initial segments C^i_ν. [30] does not construct the C_ν sets directly, but defines the "smooth category" of functions $f : \bar{\nu} \implies \nu$ and the class of triples $\mathbb{F}$. They establish that $\mathbb{F}$ satisfies a short list of axioms of a smooth category (much as a morass can specified by a list of axioms, as is done below). From the category one can derive Global $\Box$ without any reference to the model whence the category came. The argument is purely combinatorial. This is implicit in [2], and explicit in [29]. These category like objects were used by Jensen to axiomatise various structures such as premorasses, morasses, and the like, and were further used by Stanley [49] to construct morasses *via* forcing. The proof of Global $\Box$ in [19] involves tying the construction to the notion of *semi-singularisation*, and is based on the account in [1] of Silver's proof of $\Box$ using Silver machines.

In larger fine structural models Global $\Box$ can also be proved. The extent of this is discussed below. We sketch here what has to be done (and overcome) in [30] in order to establish the principle in the core model built assuming that it does not have any level M with an ordinal κ with $M \models$ "the Mitchell order of κ, $o(\kappa)$, is κ^{++})". One problem that has to be addressed from the outset is the failure of condensation in the pure form of Lemma 1.22. (Even at the level of a single measurable cardinal this will occur.) A key part of that paper is proving a form of a suitably enhanced Condensation Lemma. In such models there will be many structures that can putatively singularise an ordinal ν. One defines the class S as now a set of pairs $s = \langle \nu_s, M_s \rangle$ where $\nu_s \in \mathrm{Sing}$, and M_s is a mouse $\Sigma^{(n)}_1$ over which (for some n) ν_s is definably singularised. One requires that M_s be a mouse which is *sound above* ν_s. If two mice M_s and M'_s satisfy this, with both hierarchies of M_s and M'_s agreeing up to ν, then in fact a comparison argument shows they are equal. One then defines much as above category maps $f : \bar{s} \implies s$ between $J_{\bar{s}}$ and J_s, where $J_s =_{\mathrm{df}} J^{E^{M_s}}_{\nu_s}$. f now canonically extends to an $f^* : M_{\bar{s}} \longrightarrow M_s$ at the appropriate level of $\Sigma^{(n_s)}_1$-definability. These maps f^* must carry in their range a potentially extended parameter set for the version of the Condensation Lemma to be proven (we discuss these parameters and condensation lemmas a little more below) under the smallness assumption of $\neg\exists\kappa(o(\kappa) = \kappa^{++})$. Having got a smooth category of maps between pairs, we assume a unique choice of mouse M_s and so unique $s = \langle \nu_s, M_s \rangle$, for ν_s is made, in some closed and unbounded class of ordinals D containing all singular cardinals. This should be done in some sensible way so that if $\lambda < \nu_s$ and $\lambda \in D$ then $s{\restriction}\lambda$ can be defined as an ordered pair of λ together with an initial segment of M_s which is a mouse singularising λ, and is also our canonical choice at λ. Then one can get an appropriate form of Global $\Box$.

2.2. Variants and Generalities on $\square$

Variants on $\square$: The Principles $\square_\kappa$

In [24] the principles $\square_\kappa$ for $\kappa > \omega$ a cardinal were first defined.

2.42 Definition. Let $\kappa > \omega$ be a cardinal. The principle $\square_\kappa$ asserts the existence of a sequence $\langle C_\alpha \mid \alpha \in \mathrm{Sing} \cap \kappa^+\rangle$ so that:

(i) C_α is closed unbounded in α;

(ii) $\mathrm{cf}(\alpha) < \kappa \implies |C_\alpha| < \kappa$;

(iii) $\beta \in (C_\alpha)^* \implies \beta \cap C_\alpha = C_\beta$.

Note that this implies that if $\mathrm{cf}(\alpha) = \kappa$ then $\mathrm{ot}(C_\alpha) = \kappa$. An equivalent variant on this is that with (ii) replaced by the apparently weaker:

(ii)$'$ $\mathrm{ot}(C_\alpha) \leq \kappa$.

Note first that this is immediate for regular κ. Otherwise to see this fix $D \subseteq \kappa+1$ closed and unbounded with $\mathrm{ot}(D) = \mathrm{cf}(\kappa)+1$, $0 \in D$, and $\max(D) = \kappa$. Assuming we have a sequence of C'_α's satisfying (i), (iii), and the new clause (ii)$'$ then, if $\mathrm{ot}(C'_\alpha) \in (D)^*$, replace C'_α with $C_\alpha = \{\beta \in C'_\alpha \mid \mathrm{ot}(C'_\alpha \cap \beta) \in D\}$; otherwise there is a maximal $\delta \in D$ with $\delta < \mathrm{ot}(C'_\alpha)$; in this case set $C_\alpha = \{\beta \in C'_\alpha \mid \mathrm{ot}(C_\alpha \cap \beta) \geq \delta\}$.

A further equivalent variant adds to (ii)$'$ a strengthened

(iii)$'$ $\beta \in C_\alpha \Longrightarrow \beta \cap C_\alpha = C_\beta$,

but accordingly a weakened

(i)$'$ C_α is closed below $\alpha \wedge (\mathrm{cf}(\alpha) > \omega \implies C_\alpha$ is unbounded in $\alpha)$.

It is plausible from the definition of $\square$ that it implies $\forall \kappa > \omega(\kappa \in \mathrm{Card} \longrightarrow \square_\kappa)$. The proof of this is a combinatorial argument (see [8, VI 6.2]) which is not fine-structural, so we do not give it. In fact Jensen showed:

2.43 Theorem (Jensen [24]). *Assume $V = L$; then for any infinite cardinal κ, $\square_\kappa$ holds with the addition that there is a stationary $E \subseteq \kappa^+$ so that for any α, $\beta \in (C_\alpha)^* \longrightarrow \beta \notin E$.*

In the proof of the latter theorem a particular $E \subseteq \mathrm{Cof}(\omega) =_{\mathrm{df}} \{\beta \in \mathrm{On} \mid \mathrm{cf}(\beta) = \omega\}$ was designated. In fact $\square_\kappa$ implies that for any stationary $S \subseteq \kappa^+$ there is some stationary $T \subseteq S$ which does not reflect in this sense: for any $\alpha < \kappa^+$(with $\mathrm{cf}(\alpha) > \omega$ of course) $T \cap \alpha$ is not stationary. (Given any such S, by Fodor's Lemma, find $T \subseteq S$ with $\alpha \in T \longrightarrow \mathrm{ot}(C_\alpha) = \delta$ for some fixed δ. Now if $\mathrm{cf}(\beta) > \omega$, $|(C_\beta)^* \cap T| \leq 1$ and thus $T \cap \beta$ cannot be stationary.)

It is consistent relative to the existence of a Mahlo cardinal that $\square_\kappa$ fails at a regular cardinal by a result of Solovay. On the other hand:

2.44 Theorem (Jensen [24]). *Assume $V = L[A]$ where $A \subseteq \kappa^+$ and that for any ν less than κ^+, we have: $L[A \cap \nu] \models$"ν is singular". Then $\Box_\kappa$ holds.*

In L the existence of $\Box_\kappa$-sequences can be proved by localised methods similar to that of Global $\Box$. For the $L[A]$ result above one defines singularising structures of the form $J^a_{\beta(\nu)} \models$"$a \subseteq \nu$" for the relativised J^a-hierarchies in general. The assumption on the $A \cap \nu$ is to ensure that sufficiently often there are such singularising structures for $a = A \cap \nu$ in $L[A]$. One can prove the local $\Box_\kappa$ by reworking the local proof of $\Box_\kappa$; in [2] this is done in a global fashion for all possible singularising structures for arbitrary a (see Theorem 6.21 op. cit.) and then specialised results such as $\Box_\kappa$, or combinatorial principles necessary for the Coding Theorem, are obtained. Thus Solovay's result is exact: if κ^+ is not Mahlo in L we may take A as a closed and unbounded set in κ^+ of L-singular cardinals and construct a $\Box_\kappa(A)$ sequence which implies the existence of $\Box_\kappa$ (see the next definition and discussion below).

2.45 Definition. Let $S \subseteq$ Sing be a class. Then denote by $\Box(S)$ the assertion that there exists a $\Box$-sequence $\langle C_\alpha \mid \alpha \in S\rangle$, satisfying:

(i) C_ν is a closed subset of $\nu \cap S$; if $\mathrm{cf}(\nu) > \omega$ then it is unbounded in ν;

(ii) $\mathrm{ot}(C_\nu) < \nu$;

(iii) $\bar{\nu} \in (C_\nu)* \implies C_{\bar{\nu}} = \bar{\nu} \cap C_\nu$.

Let $T \subseteq \kappa^+ \cap \mathrm{Sing}$ be closed and unbounded. $\Box_\kappa(T)$ is the assertion that there exists a $\Box$-sequence $\langle C_\alpha \mid \alpha \in T\rangle$, satisfying:

(i) C_ν is a closed subset of $\nu \cap T$; if $\mathrm{cf}(\nu) > \omega$ then it is unbounded in ν;

(ii) $\mathrm{ot}(C_\nu) \leq \kappa$;

(iii) $\bar{\nu} \in (C_\nu)^* \implies C_{\bar{\nu}} = \bar{\nu} \cap C_\nu$.

It is a straightforward combinatorial argument in ZFC once one has a $\Box_\kappa(T)$ sequence for a T closed and unbounded in κ^+ to fill in the gaps between successive members of T with suitable C_β's to enlarge the $\Box_\kappa(T)$ to a $\Box_\kappa(\kappa^+) = \Box_\kappa$ sequence. For S equal to all of SingCard $=_{\mathrm{df}}$ Sing $\cap$ Card, if we have $\Box(S)$ and $\forall\kappa(\Box_\kappa)$ then we have Global $\Box$ (and conversely (Jensen)). Thus if $S \supseteq$ SingCard and moreover for all $\kappa > \omega$ $S \cap (\kappa, \kappa^+)$ is unbounded, then $\Box(S) \Longrightarrow \Box$ again by the "filling in of gaps" just referred to.

Variants on $\Box$: Weakenings and Extensions, $\Box$ with Scales

2.46 Definition. Let $0 < \lambda \leq \kappa$ be cardinals, with κ uncountable. The principle $\Box_\kappa^{<\lambda}$ asserts the existence of a sequence $\langle \mathcal{F}_\alpha \mid \mathrm{Lim}(\alpha), \alpha \in (\kappa, \kappa^+)\rangle$ with, for every limit α, $0 < |\mathcal{F}_\alpha| < \lambda$, and further so that $C \in \mathcal{F}_\alpha$ implies

(i) C is closed unbounded in α;

(ii) $\mathrm{ot}(C) \leq \kappa$;

(iii) $\beta \in C^* \implies \beta \cap C \in \mathcal{F}_\beta$.

$\Box_\kappa^{<\lambda^+}$ is abbreviated as $\Box_\kappa^\lambda$.

In [24] $\Box_\kappa^\kappa$ was formulated in an equivalent formulation called $\Box_\kappa^*$, and clearly $\Box_\kappa^1$ is $\Box_\kappa$. These intermediate so-called *weak square principles* were introduced by Schimmerling in [42]. We defer discussion of these principles until later, but Jensen had already remarked in [24] that if $2^\kappa = \kappa^+$ then $\Box_\kappa^*$ is equivalent to the existence of a special Aronszajn tree on κ^+ (also due to him is the straight equivalence of these two principles, without the assumption that $2^\kappa = \kappa^+$); in fact if $\kappa^{<\kappa} = \kappa$ then one can construct a $\Box_\kappa^*$ sequence; hence that if κ is regular $\Box_\kappa^*$ follows from ZFC + GCH; further notice that the case of κ singular is of particular interest for the question of the existence of $\Box_\kappa^*$ sequences. Whereas from $\Box_\kappa$ we can construct non-reflecting stationary subsets of κ^+ as above, this cannot be done from $\Box_\kappa^*$ alone (although $\Box_\kappa^{<\omega}$ does suffice; see [6]). Mitchell has shown that $\mathrm{Con}(\mathrm{ZFC} + \exists\kappa(\kappa$ is a Mahlo cardinal$)) \implies \mathrm{Con}(\mathrm{ZFC} + \neg\Box_{\omega_1}^*)$ by a suitable forcing collapsing κ to $\aleph_2$.

Improved-$\Box_\kappa^{<\lambda}$ sequences add a requirement (iv) to the above definition by insisting that at least one element $C \in \mathcal{F}_\alpha$ has $\mathrm{ot}(C) = \mathrm{cf}(\alpha)$. In general $\Box_\kappa$ does not imply Improved-$\Box_\kappa^{<\lambda}$: in the Mitchell model mentioned above, if one effects a further forcing to add back a $\Box_{\omega_2}$-sequence without adding any ω_2-sequences, one ends up with a model where Improved- $\Box_{\omega_2}^{<\omega_2}$ still fails (see [6, Sect. 5]). However [6, Theorem 10] Global $\Box$ implies Improved-$\Box_\kappa^{<\omega}$ for every uncountable cardinal κ.

Enhancements of $\Box$ have been developed. We detail just one here. The following is a natural property allying $\Box_{\aleph_n}$-sequences for $n < \omega$ with a scale on $\aleph_\omega$. It was defined in [7] at 3.1. Let $I_n = \mathrm{Lim} \cap (\omega_n, \omega_{n+1})$ for $n \leq \omega$. CS below will essentially be asserting the existence of $\Box_{\aleph_n}$-sequences, albeit with domains I_n rather than all of $\mathrm{Sing} \cap \omega_{n+1}$, plus a scale for $\aleph_\omega$.

2.47 Definition. CS asserts the existence of $\langle C_\alpha^n \mid 0 < n \leq \omega, \alpha \in I_n\rangle$ and $\langle f_\alpha \,|\, \alpha \in I_\omega\rangle$ so that:

(1) $\forall n \forall \alpha \in I_n$

(a) $C_\alpha^n \subset \alpha \cap I_n$ and is closed and unbounded in α;

(b) $\mathrm{cf}(\alpha) < \omega_n \implies \mathrm{ot}(C_\alpha^n) < \omega_n$.

(2) $\forall\alpha \in I_\omega$ f_α is a function so that:

  (a) $\mathrm{dom}(f_\alpha) = (k, \omega]$ for some $k < \omega$ such that $\mathrm{ot}(C^\omega_\alpha) < \omega_k$;

  (b) $\forall n \in \mathrm{dom}(f_\alpha)$, $f_\alpha(n) \in I_n$;

  (c) $\beta \in (C^\omega_\alpha)^* \Longrightarrow \mathrm{dom}(f_\alpha) \subseteq \mathrm{dom}(f_\beta)$;

  (d) $\forall n \in \mathrm{dom}(f_\alpha)$, $(C^n_{f_\alpha(n)})^* = \{f_\beta(n) \mid \beta \in (C^\omega_\alpha)^*\}$.

(3) $\langle f_\alpha \mid \alpha \in I_\omega\rangle$ forms a scale in $\Pi_n \aleph_{n+1}$; *i.e.* it is increasing and cofinal in the eventual domination ordering.

In [7] the consistency of CS is established by forcing. (With some work the methods here of the proof of Global square restricted to $\aleph_{\omega+1}$ together with a few "premorass-like" considerations from the next section, establish the existence of the scale sequence $\langle f_\alpha \mid \alpha \in I_\omega\rangle$ and hence that CS holds in L.) They use CS to demonstrate the existence of a mutually stationary sequence on $\aleph_\omega$ that is not tightly stationary. CS is a special case of the *condensation coherent* global $\Box$-sequences of Donder et al. [13], also shown to hold in L, and can be derived from them. The authors used condensation coherent sequences to demonstrate the existence of *squared scales* of Abraham and Shelah. Donder et al. [13] derive their principle again from a "category" like object. A similar structure is the *Fine Scale Principle* of Friedman [17] used in his proof of the Coding Theorem.

Applications

We discuss only very briefly some positive applications of $\Box$-sequences. The reader should see the chapter by Todorčević in this Handbook. We do not intend here to go extensively into applications of $\Box$ and weak $\Box^\lambda_\kappa$-sequences to *stationary reflection* properties but refer the reader to the extensive [6] for many results in this area, and to the chapter by Eisworth in this Handbook.

In [24, Sect. 6] $\Box$ arguments were originally used to prove two characterisations of weakly compact cardinals in L:

2.48 Theorem (Jensen [24]). *Assume $V = L$; let $\kappa \in \mathrm{Reg}$ but not weakly compact. Then there is a κ-Suslin tree.*

The proof proceeds by establishing:

2.49 Theorem (Jensen [24]). *Assume $V = L$; then for any non-weakly compact $\kappa \in \mathrm{Reg}$, there is a stationary $E \subseteq \kappa$ and a sequence $\langle C_\alpha \mid \alpha \in \mathrm{Lim} \cap \kappa\rangle$ such that* (i) *C_α is closed and unbounded in α, and* (ii) *$\alpha, \beta \in (C_\alpha)^* \Longrightarrow (\beta \notin E \wedge \beta \cap C_\alpha = C_\beta)$.*

From this, one characterisation of weakly compact cardinals in L already follows. Stationary reflection is a consequence of Π^1_1-indescribability: if $E \subseteq \kappa$

is stationary, then for some $\beta < \kappa$ we have that $E \cap \beta$ is stationary. The theorem above thus shows that in L, for non-weakly compact κ this must fail. The use of the $\langle C_\alpha \mid \alpha \in \mathrm{Lim} \cap \kappa \rangle$ sequences from the above facilitates the inductive construction of a κ-Suslin tree. Even outside of L we may obtain (see [8]):

- CH $+ \Box_{\omega_1} \implies$ there exists an ω_2-Suslin tree (Gregory [22]);
- GCH $+ \Box_\kappa \implies$ there exists a κ^+-Suslin tree.

The role of the C_α-sequences in all these (and other) proofs is typically to ensure that the inductive definition of the required structure can be continued at limit stages of uncountable cofinality.

A final result from Jensen's paper is a cardinal transfer theorem due to Silver (see Definition 3.8 for this notation).

2.50 Theorem (Silver [24]). *If* GCH *holds, κ is a singular cardinal, and $\Box_\kappa$ holds, then* $(\omega_1, \omega) \longrightarrow (\kappa^+, \kappa)$.

One of the major applications of $\Box$ and $\Box$-like principles is in *class forcing*: the construction of many coding conditions and coding-style conditions for forcing over L or other models, involves an extensive use of $\Box$-like (and morass-like) machinery. Jensen's original Coding Theorem (see [2]) heavily exploited such principles, especially when formulating conditions for coding information down past singular cardinals. Work of Sy Friedman has transformed notions of class forcing for a variety of constructions over L that similarly involve fine-structural arguments for defining conditions (see [18] and the chapter by Friedman in this Handbook). Just as an example, his Fine Scale Principle alluded to above is employed in his proof of coding.

A recent use of the (proof of) Global $\Box$ in $L[E]$ models is that of Koepke-Welch [33] deriving large cardinal strength from the assumptions of a mutual stationarity principle of Foreman-Magidor (see again [7]). Fine structural methods are also employed by Ishiu [23] to demonstrate the existence of *strong club guessing sequences* in L. Let $S \subseteq \mu$ be stationary with $\mu \in \mathrm{Reg}$. An S-strong club guessing sequence $\langle C_\alpha \mid, \alpha \in S \rangle$ is a sequence where each $C_\alpha \subseteq \alpha$ is closed and unbounded, and so that for any closed and unbounded $D \subseteq \mu$, there is a further closed and unbounded $E \subseteq \mu$ so that $\beta \in E \cap S \implies \exists \delta (C_\beta \backslash \delta \subseteq D)$. Ishiu shows that in L the existence of a μ-strong club guessing sequence is equivalent to the non-ineffability of μ. The heart of the proof is to show that there is a $\mathrm{Sing} \cap \mu$-strong club guessing sequence. He directly constructs the C_α's using fine structural arguments reminiscent partly of $\diamondsuit^*$, and partly of $\Box$ methods, by looking at singularising structures. As he does not require coherence of the guessing sequence this is simpler than proving the existence of Global $\Box$ up to μ.

The Failure of $\Box_\kappa$

It was an early (1974) result of Solovay that showed that the κ^+-supercompactness of a cardinal λ implied the failure of $\Box_\kappa$ [47] (this was later reduced to κ^+-compactness by Gregory; see also [48] for a discussion of this). With the advent of Jensen's Covering Lemma for L it was clear that if any cardinal κ satisfied $\kappa^+ = (\kappa^+)^L$ then the absolute nature of the defining clauses of $\Box_\kappa$ implied that a $\Box_\kappa$ sequence in L is a $\Box_\kappa$ sequence in V. As the Covering Lemma (under the assumption of $\neg 0^\#$) implied that $\kappa^+ = (\kappa^+)^L$ for any singular, or weakly compact cardinal κ, this means that then V would have such $\Box_\kappa$-sequences. In larger extender models K the Weak Covering Lemma (and thus the correct computation of cardinal successors of singulars) can be achieved for K up to a strong cardinal [27] and up to a Woodin cardinal [37]. Hence the failure of, say, $\Box_{\aleph_\omega}$ expressed directly the failure of the Covering Lemma over an inner model (or at least the correct cardinal successor computation) at the cardinal $\aleph_\omega$. Indeed this failure came to be seen as a test question concerning inner models, and implies (at least if $\aleph_\omega$ is a strong limit cardinal) the existence of $\mathrm{AD}^{L[\mathbb{R}]}$; see Theorem 2.59 below.

The principle $\Box_\kappa$ was seen to hold at other classes of cardinals, assuming the rigidity of a suitable canonical inner model. For Jensen's Core Model K^{MOZ} built with measures of order zero, Vickers and Welch [55] showed that successors of Jónsson cardinals were correctly computed in K^{MOZ}, hence $\Box_\kappa$ held at Jónsson κ (the point here is that regular Jónsson cardinals, although weakly inaccessible need not be weakly compact, nevertheless we may show correct cardinal successor computation at κ). Welch [59] showed the same conclusion for the core model K^{Steel}, assuming no inner model with a Woodin cardinal below the measurable cardinal Ω needed for K^{Steel}'s construction. (That $\kappa^+ = (\kappa^+)^{K^{\mathrm{Steel}}}$ under these assumptions, and hence that $\Box_\kappa$ holds, for κ weakly compact is due to Schimmerling-Steel [43].) The Jónsson property in fact yields some strong reflection properties on $\Box$ sequences, assuming the Weak Covering Lemma over the inner model: if there is no inner model with a Woodin cardinal, if Ω is measurable, $\kappa < \Omega$ any regular Jónsson, then the set of regular cardinals $\mu < \kappa$ such that $\Box_\mu$ holds in V, is stationary below κ ([59]). Chang's Conjecture implies the failure of $\Box_{\omega_1}$ as shown by Todorčević.

There are extensive results in the area of forcing and $\Box$ which we shall only lightly touch on here, but we do mention that the proper forcing axiom PFA causes a dramatic failure of square: Todorčević proved [52] that $\mathrm{ZFC} + \mathrm{PFA} \vdash \forall\kappa\neg\Box_\kappa$. Hence PFA implies the existence of an inner model with a measurable cardinal, for example. Magidor noted that Todorčević's proof actually shows that $\mathrm{ZFC} + \mathrm{PFA} \vdash \forall\kappa\neg\Box_\kappa^{\aleph_1}$; however this can be contrasted with his further result that showed (unpublished 1995) that $\mathrm{Con}(\mathrm{ZFC} + \exists\kappa(\kappa \text{ a supercompact cardinal})) \implies \mathrm{Con}(\mathrm{ZFC} + \mathrm{PFA} + \forall\kappa\Box_\kappa^{\aleph_2})$. Hence the possibility arises to use the various weak square principles as a means of calibrating consistency strength. The impact of Martin's Maximum (MM) is stronger than that of PFA: Foreman and Magidor formulated a "very weak square" principle [15] VWS_κ, weaker than $\square^*_\kappa$, and the latter showed that MM implies $\neg\,\mathrm{VWS}_\kappa$ for κ with $\mathrm{cf}(\kappa) = \omega$. By Solovay's result mentioned above, a supercompact destroys the possibility of any $\square_\lambda$ holding for any $\lambda > \kappa$; Shelah showed from the same assumption that any $\square^*_\lambda$ will also fail for any singular λ satisfying $\mathrm{cf}(\lambda) < \kappa < \lambda$ (see [15]). However it is consistent with a supercompact κ that for a cardinal λ satisfying: $\kappa \leq \mathrm{cf}(\lambda) < \lambda$ that $\square_\lambda^{\mathrm{cf}(\lambda)}$ holds [6, Theorem 17]. This complements the observation of Burke and Kanamori that Solovay's methods can show that if κ is λ^+ strongly compact, and $\mathrm{cf}(\lambda) < \kappa$ then $\square_\lambda^{<\mathrm{cf}(\lambda)}$ fails.

If $\mathbb{P}$ is Prikry forcing at a measurable cardinal, then it was shown in [3] that $\square^*_\kappa$ holds in $V^{\mathbb{P}}$. This was improved in [5] to that of $\square^\omega_\kappa$ holding; results of [6] however show that if κ is supercompact then in $V^{\mathbb{P}}$ one has the failure of $\square^{<\omega}_\kappa$.

Jensen [29] showed that for regular κ the principles $\square^\lambda_\kappa$ decreased in strength as λ increases from 1 to κ. In [6] it is shown how this can be done for singulars: from a supercompact a forcing extension can be constructed in which some previously chosen cardinals $0 < \nu < \mu$ (which can be finite) satisfy $\square^\mu_{\aleph_\omega}$ but $\neg\square^\nu_{\aleph_\omega}$.

2.3. $\square$ in Fine-Structural Inner Models

We come now to the interesting question of the status of $\square$-principles in canonical inner models. As for L, Global $\square$, and for all κ, $\square_\kappa$ were shown by Welch [57] to hold in the first such model to go beyond L : the Dodd-Jensen Core Model K^{DJ} built assuming the non-existence of an inner model with a measurable cardinal. Wylie [60] proved the same for Jensen's Core Model for measures of order zero. Whereas [57] had used the older fine structure that was available at that time, Wylie's thesis used the modern arrangement of the hierarchies and the corresponding fine structure.

Several issues surface at this point: Firstly, the *indexing* of extenders plays an important role. Secondly, it was also apparent that *extender fragments* which had been introduced by Mitchell and Steel in their fine structure for $L[E]$ models [36] arise also naturally when considering proofs of $\square$ for models with many measures. Thirdly, additional further condensation results would be needed to be proven both for them, and in general. Concerning this third issue: for example, whereas Skolem hulls of an initial segment of the L-hierarchy collapse to levels of L, for $L[E]$ hierarchies (even with E coding only sequences of measures) certain hulls may collapse not to an initial segment of the J^E_α hierarchy in which they were taken, but to initial segments of an ultrapower of this J^E_α hierarchy, thus leading to multi-claused condensation lemmas. (This has already been mentioned above for Jensen-Zeman [30] and is a substantial mathematical preface to their proof of Global $\square$ in the model below $o(\kappa) = \kappa^{++}$.) Wylie's thesis contains the first kind of condensation results of a type needed to prove $\square$ in the modern setting.

Concerning the first two issues, the indexing of extenders: several possibilities arise for how one might build extender E-hierarchies. Mitchell and Steel built in [36] an extender model $L[\vec{E}\,]$ with a Woodin cardinal using an indexing rule for building E-sequences which indexed with ordinal α an extender E if, when taking the ultrapower $j : M \longrightarrow N = \mathrm{Ult}(M, E)$ then $\alpha = (\nu(E)^+)^N$ where ν was the supremum of the *generators* of the extender E (or simply $(\mathrm{crit}(E)^+)^N$ if $\mathrm{crit}(E)$ was the sole generator). (This ordinal ν can be characterised as the least ordinal $\nu' \geq (\mathrm{crit}(E)^+)^N$ so that the extender of length α derived from j gives rise to the same ultrapower as E.) The *fragments* of the extender E_α which are of the form $E_\alpha \cap ([\eta]^{<\omega} \times J^{\vec{E}}_\xi\,)$ (where $\xi < (\kappa^+)^{J^{\vec{E}}_\alpha}$) are members of $J^{\vec{E}}_\alpha$ (see the discussion at [50, 2.9]). Moreover the fragments just defined appear cofinally in α as ξ rises to $(\kappa^+)^{J^{\vec{E}}_\alpha}$. The extender E_α may now be coded as an *amenable* predicate which is essential for fine structure to work.

Alternative indexing schemes have been proposed. Notably, S. Friedman realised that reindexing could affect proofs of fine-structural principles and suggested the scheme whereby an index α for an extender would be $(j(\kappa))^{+N}$, with j and N as above. This suggestion has been fully worked out by Jensen in [25], and shows *inter alia* how the results of Mitchell and Steel can be performed using this indexing. Each scheme has its advantages, but for the proofs of combinatorial principles such as $\Box_\kappa$ the Friedman-Jensen scheme allows certain difficulties to be postponed to later in the large cardinal hierarchy, beyond superstrong cardinals as we shall see later.

The analysis of fragments and condensation principles for the proof of $\Box$ there, at that time by Wylie and S. Friedman, would be continued independently by Friedman, Jensen, Schimmerling, and Zeman.

Notwithstanding the above analyses, in $L[E]$ models beyond measures the question of $\Box_\kappa$ became increasingly complex. Schimmerling [42] proved that in the Steel Core model built below a Woodin cardinal that (a) $\forall\kappa\, \Box^{<\kappa}_\kappa$ held; (b) that in the core model below n strong cardinals $\Box^{n+1}_\kappa$ held for all κ. Below one strong cardinal Schimmerling divided a certain $S \subseteq \kappa^+$ into two parts $S = S^0 \cup S^1$ and defined a $\Box_\kappa$-sequence $\langle C^i_\alpha \mid \alpha \in S^i \rangle$ for $i < 2$. However this was not a disjoint partition; hence setting $\mathcal{F}_\alpha = \{C^i_\alpha \mid \alpha \in S^i, i < 2\}$ yielded only a $\Box^2_\kappa$ sequence. A modification of the latter proof by Jensen in [29] showed that $\forall\kappa\, \Box_\kappa$ holds in the core model below 1 strong cardinal. Zeman [61] showed Global $\Box$ in the same model.

Jensen and Zeman's paper [30] proves Global $\Box$ in an $L[E]$ model built using Jensen's fine structure and utilising the indexing of extenders of [27]. The model is relatively small, as the assumption is that there are no inner models with a cardinal κ with Mitchell order $o(\kappa) = \kappa^{++}$. The proof establishes the existence of a "smooth category" like formulation of a set of axioms, that in turn automatically, in an entirely separate and purely combinatorial argument, can be shown to yield up Global $\Box$. The proof reveals some of the difficulties of extending condensation arguments to larger models. They are able to prove the necessary sequence of lemmata by adding to the requirements on the range of the maps $f : \bar{\nu} \implies \nu$ that we specified above, that it contained certain further parameters. In short if certain canonical witness maps σ sending W_M^{ν,p_M} into M were not cofinal at the nth stage where $\omega\rho_M^n > \nu \geq \omega\rho_M^{n+1}$ (where $\nu \in p_M$), then it is necessary to require the maps f to contain the ordinal $\sup(\mathrm{ran}(\sigma)) \cap \omega\rho_M^n$ witnessing that non-cofinality. (As there are only finitely many $\nu \in p_M$) this could be at most finitely many requirements.) With this strengthening a form of the Condensation Lemma (under the no $o(\kappa) = \kappa^{++}$ assumption) is provable and the proof can proceed. For larger models it is not clear how one can in general preserve standard parameters: one could put the witnesses themselves into the ranges of the maps, and thus preserve the standard parameters "downwards" into suitable substructures. However the smooth category approach also requires sufficient preservation in an upward direction, so it is unclear whether it is possible to perform this in a larger model context (and is one reason we did not demonstrate this approach in our account here).

There are serious difficulties in generalising the $\square_\kappa$ arguments to larger $L[E]$ models. The problems have to do with condensation and dealing with the extenders fragments that Schimmerling had already encountered, and which had been already seen earlier as a hurdle as described above. This was definitively solved in the last few years by work of Jensen on the former properties of condensation, and of Schimmerling and Zeman on the analysis of extender fragments. We now have a complete picture of how $\square_\kappa$ can be proven in Jensen style $L[E]$ models and at precisely which place this first breaks down, which we now describe.

Firstly a theorem due to Burke [4].

2.51 Theorem. *If* $\{a \subseteq \kappa^+ \mid \mathrm{ot}(a) \in \mathrm{Card}\}$ *is stationary then* $\square_\kappa$ *fails.*

Secondly, we make the following definition due to (but not christened by) Jensen. It was obtained by extracting the kernel of Solovay's proof of the failure of $\square_\kappa$ from a strongly compact.

2.52 Definition. A cardinal κ is *subcompact* iff for every $B \subseteq \kappa^+$, there are $\mu < \kappa$, $A \subseteq \mu^+$, and an elementary embedding $j : \langle H(\mu^+), \in, A\rangle \longrightarrow \langle H(\kappa^+), \in, B\rangle$ with $\mathrm{crit}(j) = \mu$.

It is easy to check here that μ's implicit weak inaccessibility implies the regularity of κ as $j(\mu) = \kappa$. The following is easily derived from Theorem 2.51; the argument is very similar to Solovay's, and seems to have been rediscovered by Jensen. As it is direct we give it:

2.53 Theorem (Jensen). *If* κ *is subcompact, then* $\square_\kappa$ *fails.*

Proof. Suppose, for a contradiction, that $B \subseteq \kappa^+$ codes up a $\square_\kappa$-sequence $\langle D_\alpha \mid \alpha < \kappa^+\rangle$. Let μ, A, j be suitable witnesses to the definition of subcompactness of κ for this B. By elementarity we have $\langle C_\alpha \mid \alpha < \mu^+\rangle$, a $\square_\mu$ sequence, coded by A. Let $S = \{\nu < \mu^+ \mid \mathrm{cf}(\nu) < \mu\}$. Then easily $j``S$ is $<\mu$-closed; set $\gamma = \sup(j``\mu^+)$. Then $(D_\gamma)^* \cap j``S$ is unbounded in γ and $<\mu$-closed. Let $T = \{\nu < \mu^+ \mid j(\nu) \in (D_\gamma)^*\}$. Then T is unbounded in μ^+. Finally let $E = \bigcup\{C_\nu \mid \nu \in T\}$; then E is a union of cohering sets and hence is closed and unbounded in μ^+ and $E \cap \nu = C_\nu$ for all $\nu \in T$. However this would imply that for all sufficiently large $\nu \in T$, $\text{ot}(C_\nu) > \mu$ which contradicts the definition of $\Box_\mu$ sequence. ⊣

A modification of the argument above yields also Burke's theorem 2.51. Schimmerling and Zeman's main theorem is:

2.54 Theorem (Schimmerling and Zeman [45]). *In any Jensen-style $L[E]$ model the following are equivalent:*

(i) $\Box_\kappa$;

(ii) $\Box_\kappa^{<\kappa}$;

(iii) κ *is not subcompact;*

(iv) $\{\nu < \kappa^+ \mid E_\nu \neq \varnothing\}$ *is not stationary in* κ^+.

(Here (i) implies (iii) is the Burke/Jensen result mentioned above, and (ii) implies (iii) is an easy modification of that; Schimmerling and Zeman proved the main result here that (iv) implies (i), and Jensen proved (i) implies (iv) around the time that the notion of Definition 2.52 was formulated. Later Zeman noticed that this argument can be modified to obtain that (iii) implies (iv).)

Thus in such $L[E]$ models $\Box_\kappa$ holds wherever $\Box_\kappa^{<\kappa}$ does. Recall that in this style of $L[E]$ model, if $J_\nu^E \models$ "κ is the largest cardinal", then if $\lambda = \text{crit}(E_\nu)$, then $E_\nu(\lambda) = \kappa$.

As $D =_{\text{df}} \{\nu \,|\, J_\nu^E \models$ "κ is the largest cardinal"$\}$ is closed and unbounded in κ^+, we have, if (iv) fails, that for stationarily many ν that $\nu \in D \wedge E_\nu \neq \varnothing$. Then for some cardinal $\lambda < \kappa$ there are unboundedly many (in fact stationary many) $\nu < \kappa^+$ with $E_\nu \neq \varnothing \wedge \text{crit}(E_\nu) = \lambda \wedge j_{E_\nu}(\lambda) = \kappa$. Thus λ is superstrong in $L[E]$, as κ is a cardinal of $L[E]$ and $V_\kappa^{L[E]} \subseteq \text{Ult}(L[E], E_\nu)$.

The proof of $\Box_\kappa$ for a non-subcompact κ involves splitting κ^+ into *disjoint* pieces S^0, S^1. On one of these the E-sequence is relatively benign and an L-like construction of a $\Box_\kappa$-sequence is possible. The harder, and new, part is on the set S^1 where the work is dealing with extender fragments rather than levels of $L[E]$, and in both cases it has to be shown that there is no conflict between the sequences of the two sides, e.g. that $\alpha \in S^i \Longrightarrow C_\alpha \subseteq S^i$. However the important feature remains that in either case the sequence C_ν is first order definable over the least level $J_{\beta(\nu)}^E$ of the $L[E]$ hierarchy where ν becomes singular. Finally:

2.55 Theorem (Zeman). *In any Jensen style $L[E]$ model,* $\Box(\text{SingCard})$ *holds.*

The use of methods from Woodin's core model induction enabled strong conclusions to be obtained from the failure of, first $\Box_\kappa^{<\omega}$ and now with the above results, that of $\Box_\kappa$. We give some samples of the applications of Schimmerling and Zeman's theorem 2.54, but refer the reader to their [44] for a full survey.

2.56 Theorem. *Let κ be a singular cardinal satisfying $\mu^{\aleph_0} < \mu$ for all $\mu < \kappa$. Then if $\square_\kappa$ fails Projective Determinacy holds.*

2.57 Theorem. *Let κ be a weakly compact cardinal and suppose $\square_\kappa$ fails; then every set of reals in $L(\mathbb{R})$ is determined.*

The last two were first proven by Schimmerling and Steel essentially in [43] assuming the failure of $\square_\kappa^{<\omega}$. The latter theorem concluded with PD, but was then improved by Woodin using the full Core Model Induction to get the result quoted, still from the failure of $\square_\kappa^{<\omega}$.

2.58 Theorem. *Let κ be a measurable cardinal and suppose $\square_\kappa$ fails; then there is a transitive proper class model of* $\mathrm{ZF} + \mathrm{AD}_\mathbb{R}$.

We lastly remark that:

2.59 Theorem (Steel [51]). *If κ is a singular strong limit cardinal and $\square_\kappa$ fails then every set in $L(\mathbb{R})$ is determined.*

It is an open question whether the requirement on being a strong limit can be lifted here, for example at $\aleph_\omega$, or whether the result can be proven from the failure of $\square_\kappa$ at a Jónsson cardinal κ. In these last four theorems the use of the failure of $\square_\kappa$ is not as a simple quotation of the failure of correct cardinal successor computation in an inner model: there may be no canonical inner model at hand. In essence fine structural segments are pieced together to approximate some form of a hierarchy coded by subsets $A_\alpha \subseteq \kappa$ for $\alpha < \kappa^+$. Typically some first subset A_0 codes V_κ and then the construction puts together mouse-like segments over A_α's. In these segments parts of a $\square_\kappa$ sequence are pieced together (or of $\square_\kappa^{<\omega}$ in fine structural hierarchies using the earlier work of Schimmerling). The definitions of the various $\langle C_\nu \mid \nu < \lambda_\alpha \rangle$'s are purely local (for λ_α increasing unboundedly below κ^+; as we remarked just before Theorem 2.55, the sequence C_ν is definable in some sort of similar fashion to our proof above in L: it is first-order definable over $J^E_{\beta(\nu)}$ where $\beta(\nu)$ names the first place in the $L[E]$-hierarchy where ν is definably singularised). Hence the result can be derived without knowing that there is some inner model (which might have required some further assumption concerning a larger measurable cardinal, for example) over which the Covering Lemma held.

The reader should consult [41, Sect. 5] for further applications in this area.

3. Morasses

The notion of morass is a somewhat complex one. In many ways morasses seem to encapsulate the totality of the fine structure available in a model, although the $\square$ concept has been more influential. The notion can be motivated through its original application to the Gap-2 Cardinal Transfer Theorems of Jensen (cf. Theorem 3.9 below). However they can be construed as pictures of the extremely regular behaviour of, e.g. the inner model L, in that one sees how structures, or levels of the L_α-hierarchy, say L_{κ^+}, can be approximated by directed systems of levels L_β for β of smaller cardinality then κ. A morass at a cardinal κ is characterised by a gap parameter. A morass at κ of gap 1 (a "$(\kappa, 1)$ morass") then is a system approximating the levels L_α for $\alpha \in (\kappa, \kappa^+]$ by means of levels L_β for $\beta < \kappa$ and maps between them: $f_{\beta\beta'}$. A gap-2 morass at κ is a "higher gap morass", and approximates $L_{\kappa^{++}}$ by means again of structures L_β for $\beta < \kappa$ and a more complex system of maps, which can be construed as a "morass of morasses" building up a double gap approximating process through systems of maps. There is no need to restrict to gaps of length two, and indeed for regular κ one can define (κ, γ) morasses for any $\gamma < \kappa$, once one has seen how to do it for 2.

We shall first give a definition of a gap-1 morass at κ in a manner somewhat reminiscent of a category. This is a formal definition of maps and structures which encapsulate the notion. The notation is intentionally similar to what we have done for Global $\square$: this will bring out the similarities, and also make plausible the existence of such a structure in L.

3.1 Definition. Let $\kappa > \omega$ be regular. A *gap-1 morass at* κ is a pentuple $\langle S, S^1, \prec, \langle \mathfrak{A}_\nu \mid \nu \in S^1\rangle, \langle \widehat{f}_{\bar\nu\nu} \mid \bar\nu \prec \nu\rangle\rangle$ satisfying the following:

M0(i) S is a set of p.r. closed pairs of ordinals $\langle \alpha, \nu\rangle$ with $\alpha < \nu < \kappa^+$ such that: $\langle \alpha, \nu\rangle, \langle \alpha', \nu'\rangle \in S \wedge \alpha' < \alpha \longrightarrow \nu' < \alpha$.

M0(ii) $S^1 =_{\rm df} \{\nu \mid \exists\alpha\langle\alpha, \nu\rangle \in S\}$; for $\nu \in S^1$ we let α_ν denote the unique α such that $\langle \alpha, \nu\rangle \in S$; $S^0 =_{\rm df} \{\alpha_\nu \mid \nu \in S^1\}$; $S_\alpha =_{\rm df} \{\nu \mid \alpha_\nu = \alpha\}$. Then: For $\alpha \in S^0$, S_α is closed in $\sup(S_\alpha)$; $\kappa = \sup(S^0 \cap \kappa) = \max(S^0)$; S_κ is unbounded in κ^+.

M0(iii) $\prec$ is a tree on S^1; $\bar\nu \prec \nu \longrightarrow \alpha_{\bar\nu} < \alpha_\nu$.

M0(iv) (a) For $\nu \in S^1$, $\mathfrak{A}_\nu$ is a transitive amenable structure, $J_\nu \subseteq |\mathfrak{A}_\nu|$; if $\tau \in S_{\alpha_\nu} \cap \nu$ then $|\mathfrak{A}_\tau| \subseteq |\mathfrak{A}_\nu|$.

(b) If h is a Σ_1-Skolem function for $\mathfrak{A}_\nu$ then $|\mathfrak{A}_\nu| = h``(\omega \times J^{<\omega}_{\alpha_\nu})$.

M0(v) $\langle \widehat{f}_{\bar\nu\nu} \mid \bar\nu \prec \nu\rangle$ is a commuting system of maps; $\widehat{f}_{\bar\nu\nu} : \mathfrak{A}_{\bar\nu} \longrightarrow_{\Sigma_1} \mathfrak{A}_\nu$; $\widehat{f}_{\bar\nu\nu}{\restriction}J_{\bar\nu} : \langle J_{\bar\nu}, S_{\alpha_{\bar\nu}} \cap \bar\nu\rangle \longrightarrow_Q \langle J_\nu, S_{\alpha_\nu} \cap \nu\rangle$; $\widehat{f}_{\bar\nu\nu}(\alpha_{\bar\nu}) = \alpha_\nu$; $\widehat{f}_{\bar\nu\nu}{\restriction}\alpha_{\bar\nu} = \mathrm{id}{\restriction}\alpha_{\bar\nu}$.

CP1 If $B_\nu =_{\rm df} \{\alpha_{\bar\nu} \mid \bar\nu \prec \nu\}$ and $B^+_\nu =_{\rm df} B_\nu \cup \{\alpha_\nu\}$ then B^+_ν is closed.

M1 If $\tau \in S_{\alpha_\nu} \cap \nu$ then B_τ is unbounded in α_ν.

M2 If $\bar\nu \prec \nu$, $\bar\tau \in S_{\alpha_{\bar\nu}} \cap \bar\nu$ and $\tau = \widehat{f}_{\bar\nu\nu}(\bar\tau)$, then $\bar\tau \prec \tau \wedge \widehat{f}_{\bar\tau\tau}{\restriction}J_{\bar\tau} = \widehat{f}_{\bar\nu\nu}{\restriction}J_{\bar\tau}$.

M3 B_ν unbounded in α_ν implies $|\mathfrak{A}_\nu| = \bigcup_{\bar\nu \prec \nu} \mathrm{ran}(\widehat{f}_{\bar\nu\nu})$.

CP2 If $\bar\nu \in (S_{\alpha_{\bar\nu}})^*$ then:

(a) $\bar\nu \prec \nu \wedge \sup(\widehat{f}_{\bar\nu\nu}``\bar\nu) = \lambda < \nu \longrightarrow \bar\nu \prec \lambda \wedge \widehat{f}_{\bar\nu\lambda}{\restriction}J_{\bar\nu} = \widehat{f}_{\bar\nu\nu}{\restriction}J_{\bar\nu}$;

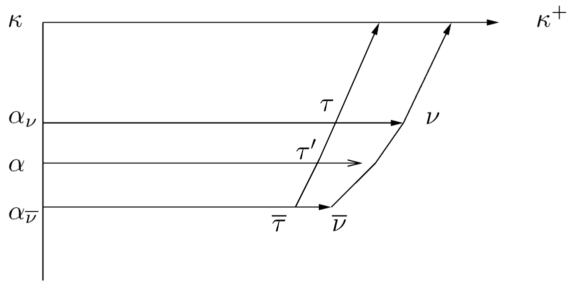

Figure 10.3: Continuity property CP2b

(b) $\bar{\nu} \prec \nu \wedge \sup(\widehat{f}_{\bar{\nu}\nu}``\bar{\nu}) = \nu \wedge \alpha > \alpha_{\bar{\nu}} \longrightarrow [(\forall \tau \in S_{\alpha_\nu} \cap \mathrm{ran}(\widehat{f}_{\bar{\nu}\nu})\ \alpha \in B_\tau) \longrightarrow \alpha \in B_\nu]$.

A morass is *universal* if $H(\kappa^+) = \bigcup_{\nu \in S^1} |\mathfrak{A}_\nu|$.

Note (i). Other forms of closure property can be used in M0(i) for example that of being a limit of admissibles. By M0(i) the definition of α_ν (in M0(ii)) makes sense. In M0(v) recall [46, 1.18] the definition of *Q-embedding*: A *Q-formula* is one of the form $\forall u \exists v \supseteq \varphi(v)$, where φ is Σ_1 and must not contain u. Notice that this can suitably express the notion of cofinality. Then $\pi : M \longrightarrow_Q N$ if π preserves all Q-formulae.

Note (ii). If we are not interested in universality, then it is possible to give a similar "axiomatic" treatment of a gap-1 morass which does not mention L or J structures, but simple ordinal structures $\langle \nu, \in \rangle$: one omits the references to structures, thus M3 becomes "B_ν is unbounded α_ν implies $\nu + 1 = \bigcup_{\bar{\nu} \prec \nu} \mathrm{ran}(f_{\bar{\nu}\nu})$" where now we only consider maps$f_{\bar{\nu}\nu} : \bar{\nu} + 1 \longrightarrow \nu + 1$. M0(v) now must be formulated in a way that expresses the similarity of the structure $\langle \bar{\nu} + 1, S_{\alpha_{\bar{\nu}}} \cap \bar{\nu} \rangle$ to that of $\langle \nu + 1, S_{\alpha_\nu} \cap \nu \rangle$ (see, for example, [8] for details). M0–M3 are known as the *morass axioms* and CP1, CP2 as the first and second *continuity properties* respectively. It is in particular the latter that gives the morass its strength. CP2(b) can be equivalently stated as:

CP2(b)$'$
$$[\bar{\nu} \prec \nu \wedge \sup(\hat{f}_{\bar{\nu}\nu}``\bar{\nu}) = \nu \wedge \alpha \in \bigcap_{\overline{\tau} \in S_{\alpha_{\overline{\nu}}} \cap \overline{\nu}} \{\alpha_{\tau'} \mid \overline{\tau} \prec \tau' \prec \widehat{f}_{\bar{\nu}\nu}(\overline{\tau})\}]$$
$$\longrightarrow (\exists \nu' \prec \nu)(\alpha_{\nu'} = \alpha).$$

3.1. Construction of Gap-1 Morasses in L

Let κ be a regular cardinal. We give the construction of a universal $(\kappa, 1)$-morass in the constructible universe. We assume then $V = L$. In this we can make use of some of the notions and lemmata of the section on Global $\Box$.

Let $S = \{\langle \alpha, \nu \rangle \mid \alpha < \nu,\ \nu$ is a limit of admissibles, $\nu \in \mathrm{Sing} \cap \kappa^+$, $J_\nu \models$ "α is regular and is the largest cardinal"$\}$.

Note that for $\langle\alpha,\nu\rangle\in S$, as α is a cardinal in the sense of J_ν then it is *a fortiori* a limit of admissibles. We remark that our taking of ν as a limit of admissibles is overkill: much less would suffice: we just need to be able to take the transitivisation of certain simply defined hulls of smaller J_η inside J_ν. (As, for example, the intersection of On with such a hull has order type less than or equal to η, very mild recursions of length at most η can define the transitive collapse maps.) Using the p.r. closed ordinals here would be possible. M0(i) is then clear (by appealing to the acceptability of the J-hierarchy!). Likewise M0(ii) is true of the sets S^0, S^1, S_α defined there. As $\nu\in\mathrm{Sing}$ the concepts of the least level $\beta(\nu)$ at which ν is singularised, by some $\boldsymbol{\Sigma_1^{(n)}}(J_{\beta(\nu)})$ function etc., as used in the proof of Global $\Box$ make sense, and we adopt them here too.

3.2 Definition. Let $\nu\in S^1$. Then we associate the following objects to ν:

(a) The same n_ν, M^k_ν, h^k_ν, h_ν, $\widetilde{h}_\nu$, ρ_ν from Definition 2.6;

(b) $\alpha_\nu =_{\mathrm{df}}$ the largest cardinal of J_ν;

(c) $p_\nu =_{\mathrm{df}} p_{M_\nu}\backslash\alpha_\nu$; $q_\nu =_{\mathrm{df}} p_\nu\cap\omega\rho^{n_\nu}_{M_\nu}$.

Note that p_ν is thus the $<^*$-least parameter so that $\widetilde{h}_\nu(\alpha_\nu\cup\{p_\nu\}) = J_{\beta(\nu)}$. It is really also the same p_ν from before; it is only that we have renamed κ_ν there as α_ν. It has become customary to use α_ν for the largest cardinal in the sense of J_ν. Although "κ_ν" would have been more consistent with the Global $\Box$ proof, this is only apparent: even for the $\Box$-proof, it is the ordinal α_ν that is important, rather than the κ_ν; here the important ordinal is again this α_ν. q_ν also has the same definition.

We set $\mathfrak{A}_\nu = M^{n_\nu}_\nu = \langle J_{\rho_\nu}, A^{n_\nu}_{\beta(\nu)}\rangle$. M0(iv) is then immediate, as h_ν is indeed a suitable Σ_1-Skolem function.

3.3 Definition. For $\nu,\overline{\nu}\in S^1$:

(i) We set $f:\overline{\nu}\implies\nu$ if $f: J_{\overline{\nu}}\longrightarrow_{\Sigma_1} J_\nu$, and f is the restriction of $f^*: J_{\beta(\overline{\nu})}\longrightarrow_{\Sigma_1^{(n)}} J_{\beta(\nu)}$ where $n=n_\nu, \nu=f^*(\overline{\nu})$ if $\nu<\beta(\nu); \alpha_\nu\in\mathrm{ran}(f)$; $p_\nu\in\mathrm{ran}(f^*)$.

(ii) $\mathbb{F}=\{\langle\overline{\nu},f,\nu\rangle \mid f:\overline{\nu}\implies\nu\}$.

(iii) If $\nu<\beta$, we set $p(\nu)=_{\mathrm{df}} p_\nu\cup\{\alpha_\nu,\nu\}$; otherwise $p(\nu)=_{\mathrm{df}} p_\nu\cup\{\alpha_\nu\}$.

(iv) $f^*_{(\delta,q,\nu)}$ is the inverse of the transitive collapse of the hull $\widetilde{h}_\nu(\delta,\{p(\nu)\cup q\})$ in $J_{\beta(\nu)}$.

Now we have a new version of Lemma 2.9:

3.4 Lemma. *If* $\exists\bar{\nu}(f:\overline{\nu}\implies\nu)$ *then* f *and* f^* *are uniquely determined by* $\mathrm{ran}(f)\cap\alpha_\nu$.

This justifies the following definition:

3.5 Definition. If $f : \bar{\nu} \implies \nu$ then we set:

(i) $f^*_{\bar{\nu}\nu}$ to be that unique extension f^* given by the last lemma;

(ii) $\widehat{f}_{\bar{\nu}\nu} = f^*_{\bar{\nu}\nu} \restriction \mathfrak{A}_{\bar{\nu}} \longrightarrow \mathfrak{A}_\nu$.

Lemma 2.11 still applies in this context, where now we amend the notation to read "$\nu \in S^1$" or "$\bar{\nu} \in S^1$" rather than just plain "S", and drop all references to κ. If $f : \bar{\nu} \implies \nu$ we see that $f(\alpha_{\bar{\nu}}) = \alpha_\nu$. This is clear if $\nu < \beta(\nu)$ (or equivalently $\bar{\nu} < \beta(\bar{\nu})$) since then $f : J_{\bar{\nu}} \longrightarrow J_\nu$ is in fact elementary. However even if $\beta(\nu) = \nu$, $\alpha_\nu \in \mathrm{ran}(f)$, hence $J_\nu \models$ "$f(\alpha_{\bar{\nu}})$ is a cardinal"; but clearly $f(\alpha_{\bar{\nu}})$ cannot be strictly greater than α_ν (as such are not J_ν-cardinals) nor strictly less (since $f^{-1}(\alpha_\nu)$ is a $J_{\bar{\nu}}$-cardinal $\geq \alpha_{\bar{\nu}}$).

3.6 Definition.

(i) For $f = \langle \bar{\nu}, f, \nu \rangle \in \mathbb{F}$ we call f^* *good* if

$$f^* \restriction J_{\bar{\nu}} : \langle J_{\bar{\nu}}, S_{\alpha_{\bar{\nu}}} \cap \bar{\nu} \rangle \longrightarrow_Q \langle J_\nu, S_{\alpha_\nu} \cap \nu \rangle.$$

(ii) $\bar{\nu} \prec \nu$ iff there is an $f = \langle \bar{\nu}, f, \nu \rangle \in \mathbb{F}$ with f^* good, and $f^* \restriction \alpha_{\bar{\nu}} = \mathrm{id} \restriction \alpha_{\bar{\nu}}$. We shall write in this case $f : \bar{\nu} \prec \nu$. We set $\bar{\nu} \preccurlyeq \nu \longleftrightarrow \bar{\nu} \prec \nu \vee \bar{\nu} = \nu$.

One should bear in mind that again, just as for similar remarks about E_ν in the proof of Global $\Box$, "$y = S_\gamma \cap \eta$" for $\eta < \nu$ is a simple $\Sigma_0^{J_\nu}$ relation of y, γ and J_η. Thus, in particular, if $f = \langle \bar{\nu}, f, \nu \rangle \in \mathbb{F}$, then $f(S_{\alpha_{\bar{\nu}}} \cap \eta) = S_{f(\alpha_{\bar{\nu}})} \cap f(\eta) = S_{\alpha_\nu} \cap f(\eta)$. What is the Q-preservation property for? For the simple reason that if $f = \langle \bar{\nu}, f, \nu \rangle \in \mathbb{F}$, then without Q-preservation of $f^* \restriction J_{\bar{\nu}}$ we may have $S_{\alpha_{\bar{\nu}}} \cap \bar{\nu}$ unbounded in $\bar{\nu}$ (a Q-property) whilst $S_{\alpha_\nu} \cap \nu$ is bounded in ν. If we insist on Q-preservation then we shall have, if $f : \bar{\nu} \implies \nu$:

- $S_{\alpha_{\bar{\nu}}} \cap \bar{\nu}$ unbounded in $\bar{\nu}$ iff $S_{\alpha_\nu} \cap \nu$ is unbounded in ν.

The next three properties are Σ_1:

- $\eta = \min(S_{\alpha_{\bar{\nu}}} \cap \bar{\nu}) \longrightarrow f(\eta) = \min(S_{\alpha_\nu} \cap \nu)$;
- η the successor element in $S_{\alpha_{\bar{\nu}}} \cap \bar{\nu}$ of η' implies $f(\eta)$ is the successor element of $f(\eta')$ in $S_{\alpha_\nu} \cap \nu$;
- $\eta \in (S_{\alpha_{\bar{\nu}}} \cap \bar{\nu})^* \longrightarrow f(\eta) \in (S_{\alpha_\nu} \cap \nu)^*$.

The above can be easily checked. If we simply define gap-1 morasses without "structural properties" i.e. simply as maps between ordinals, one specifies these last three bullet points as an axiom on the S_α's (see [8, p. 341]).

For almost all triples $f = \langle \bar{\nu}, f, \nu \rangle \in \mathbb{F}$ the Q-preservation property holds anyway. Just as remarked before this definition, this is clear if $\nu < \beta(\nu)$ since then $f : J_{\bar{\nu}} \longrightarrow J_\nu$ is even elementary. It is still clear if $n_\nu > 1$ since then $f : J_{\bar{\nu}} \longrightarrow J_\nu$ is Σ_2-preserving. It is only if $n_\nu = 1$ and $\beta(\nu) = \nu$ that we may not get Q-preservation automatically.

It is now reasonably clear that $\prec$ will be a tree: this is because if $f : \bar{\nu} \prec \nu$ and $g : \nu' \prec \nu$ then, if $\alpha_{\bar{\nu}} < \alpha_{\nu'}$ we shall have $\mathrm{ran}(f^*) \subsetneq \mathrm{ran}(g^*)$ and hence $\langle \bar{\nu}, g^{-1} \circ f, \nu' \rangle \in \mathbb{F}$. It is also easy to check that the composed map $g^{-1} \circ f : J_{\bar{\nu}} \longrightarrow J_{\nu'}$ is Q-preserving, and this map witnesses that $\bar{\nu} \prec \nu'$. Equally clearly if $\alpha_{\bar{\nu}} = \alpha_{\nu'}$, then we must have $\bar{\nu} = \nu'$. Thus we have $\prec$ is a tree, and the second part of M0(iii) follows too.

The only remaining part of M0 is part (v). That the system of maps commutes follows from the same for the system for $\Longrightarrow$. The Q-preservation property of $f : J_{\bar{\nu}} \longrightarrow_Q J_\nu$ has been built into the definition of $\prec$.

For the first continuity property CP1, if $D \subseteq B^+_\nu$ then for each $\alpha_{\bar{\nu}} \in D$ we may consider the hull sets $H_{\bar{\nu}} =_{\mathrm{df}} \mathrm{ran}(f^*_{\bar{\nu}\nu})$ in $J_{\beta(\nu)}$. Let $Y = \bigcup_{\alpha_{\bar{\nu}} \in D} H_{\bar{\nu}}$, and then $\alpha =_{\mathrm{df}} \sup(D) \subseteq Y$. Then one may check that if the inverse of the transitive collapse of Y is $g^* : J_{\bar{\beta}} \longrightarrow_{\Sigma_1^{(n)}} J_\beta$ where $\mathrm{ran}(g^*) = Y$, then setting $g = g^* \restriction J_\tau$, $g^*(\tau) = \nu$ (if $\nu < \beta(\nu)$) and $\alpha_\tau = \alpha$, we have by Lemma 2.11 $\bar{\beta} = \beta(\tau)$, and $\langle \tau, g, \nu \rangle \in \mathbb{F}$. That g is a Q-preserving embedding between J_τ and J_ν is also easily checked: as before this only comes into question if $n = 1$ and $\nu = \beta(\nu)$. But here we can see that a union of "Q-hulls" of the form $H_{\bar{\nu}}$ forms a Q-elementary hull Y. Thus $g = g^* \restriction \tau$ is Q-preserving. Thus $\tau \preccurlyeq \nu$ and $\alpha_\tau \in B^+_\nu$.

For M1: let $\tau \in S_{\alpha_\nu} \cap \nu$. As $J_\nu \models$ "α_ν is the largest cardinal" we must have that $\beta(\tau) < \nu$. Now by recursion form a chain of $\Sigma_1^{(n_\tau)}$ hulls $H_\gamma = \widetilde{h}_\tau(\gamma \cup \{p(\tau)\})$ for $\gamma < \alpha_\nu$. This recursion can be effected inside J_ν as the latter is an admissible set (or is the union of such); moreover we can (i) pick out a closed and unbounded $D \subseteq \alpha_\nu$ where $\gamma \in D \longrightarrow H_\gamma \cap \alpha_\nu = \gamma$; and (ii) form the transitive collapses of such H_γ. This is because α_ν is a regular cardinal of J_ν. Then $\gamma \in D \longrightarrow \gamma = \alpha_{\bar{\tau}}$ for some $\alpha_{\bar{\tau}} \in B_\tau$.

Note that we have just shown for such τ that B_τ is unbounded in τ; but we have also shown that $B_\tau \in J_\nu$. In fact the relation "$\alpha_{\bar{\tau}} \in B_\tau$" is a uniform $\Sigma_0^{J_\nu}$ relation of $\bar{\tau}, \tau$ and $\beta(\tau)$. Consequently J_ν knows all about the morass relations for $\langle \alpha, \tau \rangle \in S$ with $\langle \alpha, \tau \rangle <_{\mathrm{lex}} \langle \alpha_\nu, \nu \rangle$.

For M2: note that, with the notation of the hypothesis, $f^*_{\bar{\nu}\nu}(J_{\beta(\bar{\tau})}) = J_{\beta(\tau)}$ and thus $f^*_{\bar{\nu}\nu} \restriction J_{\beta(\bar{\tau})} : J_{\beta(\bar{\tau})} \longrightarrow_{\Sigma_\omega} J_{\beta(\tau)}$. However $\mathrm{ran}(f^*_{\bar{\tau}\tau})$ is determined by $\mathrm{ran}(f^*_{\bar{\tau}\tau}) \cap \alpha_\nu = \alpha_{\bar{\tau}} = \alpha_{\bar{\nu}} = \mathrm{ran}(f^*_{\bar{\nu}\nu}) \cap \alpha_\nu$. Hence $f^*_{\bar{\nu}\nu} \restriction J_{\bar{\tau}} = \widehat{f}_{\bar{\nu}\nu} \restriction J_{\bar{\tau}} = \widehat{f}_{\bar{\tau}\tau} \restriction J_{\bar{\tau}}$. As $f^*_{\bar{\nu}\nu}(J_{\bar{\tau}}) = J_\tau$ we certainly have $\widehat{f}_{\bar{\nu}\nu} \restriction J_{\bar{\tau}} : \langle J_{\bar{\tau}}, S_{\alpha_{\bar{\tau}}} \cap \bar{\tau} \rangle \longrightarrow_Q \langle J_\tau, S_{\alpha_\tau} \cap \tau \rangle$. Hence we have all the conditions for $\bar{\tau} \prec \tau$.

For M3: Suppose $x \in \mathfrak{A}_\nu = M_\nu^{n_\nu} = \langle J_{\rho_\nu}, A^{n_\nu}_{\beta(\nu)} \rangle$. Let $h = h_{\mathfrak{A}_\nu} = h_\nu$. Then $x = h_\nu(i, \vec{\alpha}, \alpha_\nu, q_\nu \backslash \alpha_\nu)$ for some $\vec{\alpha} \in [\alpha_\nu]^{<\omega}$. As B_ν is unbounded in α_ν find $\alpha' > \max(\vec{\alpha})$, with $\alpha' = \alpha_\tau \in B_\nu$. Then $x = \widehat{f}_{\tau\nu}(h_\tau(i, \vec{\alpha}, \alpha_\tau, q_\tau \backslash \alpha_\tau))$.

Now for the distinguishing axioms of the morass: CP2. For (a) we use the Interpolation Lemma in the form of a direct application of Lemma 2.13 to get that there is an $f_0 : \bar{\nu} \Longrightarrow \lambda$ with $f \restriction \overline{\nu} = f_0 \restriction \overline{\nu}$ (where $f = f^*_{\bar{\nu}\nu}$). However f_0 is nothing other than the required map $f^*_{\bar{\nu}\lambda}$. (That $f^*_{\bar{\nu}\lambda} \restriction J_{\bar{\nu}}$ is a Q-embedding is also immediate, as by assumption it is cofinal into λ!.) Hence $\bar{\nu} \prec \lambda \wedge f^*_{\bar{\nu}\lambda} \restriction J_{\bar{\nu}} = f^*_{\bar{\nu}\nu} \restriction J_{\bar{\nu}}$.

For CP2(b): We work in the terms of the equivalent statement CP2(b)$'$.

Given the hypotheses there, let $\tau = \widehat{f}_{\bar{\nu}\nu}(\bar{\tau})$ for $\bar{\tau} \in S_{\alpha_{\bar{\nu}}} \cap \bar{\nu}$. Let $X = \bigcup_{\bar{\tau} \in S_{\alpha_{\bar{\nu}}} \cap \bar{\nu}} X_{\bar{\tau}}$ where $X_{\bar{\tau}} = \mathrm{ran}(\widehat{f}_{\tau'\tau} \restriction J_{\tau'})$ and τ' is that unique η satisfying $\bar{\tau} \prec \eta \prec \tau$ and with $\alpha_\eta = \alpha$. Note that $X_{\bar{\tau}} \cap \alpha_\nu = \alpha$ and so $X \cap \alpha_\nu = \alpha$. $X \prec_{\Sigma_0} J_\nu$. Let the transitive collapse map be $g_1^{-1} : J_\nu \restriction X \cong J_{\nu'}$. Define $g_0 = g_1^{-1} \circ (\widehat{f}_{\bar{\nu}\nu} \restriction J_{\bar{\nu}})$. Note moreover, that as $\bar{\nu} \in (S_{\alpha_{\bar{\nu}}})^*$:

$$w \in J_{\bar{\nu}} \quad \Longrightarrow \quad \exists \bar{\tau} \in S_{\alpha_{\bar{\nu}}}[w \in J_{\bar{\tau}} \wedge \widehat{f}_{\bar{\tau}\tau}(w) = \widehat{f}_{\tau'\tau}(\widehat{f}_{\bar{\tau}\tau'}(w)) = \widehat{f}_{\bar{\nu}\nu}(w)]$$

by M2. Thus g_0 is total on $J_{\overline{\nu}}$. By assumption $f^*_{\bar{\nu}\nu}$ is cofinal into ν. We then have that both g_0 and g_1 are cofinal. Now we may apply the Generalised Interpolation Lemma, setting g, σ and σ_1 there as $f^*_{\bar{\nu}\nu}$, g_0, g_1 here respectively. We obtain $\widetilde{g} : M_{\overline{\nu}} \longrightarrow_{\Sigma_1^{(n)}} J_{\beta'}$ and $g' : J_{\beta'} \longrightarrow_{\Sigma_0^{(n)}} M_\nu$ with $\widetilde{g} \restriction J_{\overline{\nu}} = g_0$, $g' \restriction J_{\nu'} = g_1$. However g_1 is cofinal into ν and $f^*_{\bar{\nu}\nu}$ is cofinal at the $n$level (as $f_{\bar{\nu}\nu} : \bar{\nu} \Longrightarrow \nu$ cofinally, we can obtain this latter fact from Lemma 2.14); the proof of the Generalised Interpolation Lemma shows that in this case g' is cofinal at the nth level, and so is in fact also $\Sigma_1^{(n)}$-preserving. As $g_1(\alpha) = \alpha_\nu$ and $p_\nu \backslash \alpha_\nu \in \mathrm{ran}(f^*_{\overline{\nu}\nu})$ then $p_\nu \backslash \alpha_\nu \in \mathrm{ran}(g')$. We have, setting $g'(p') = p_\nu \backslash \alpha_\nu$, by an application of Lemma 2.11, that $p' = p_{\nu'} \backslash \alpha$, $M_{\nu'} = J_{\beta'}$ and $g' = f^*_{\nu'\nu}$, whence $\langle \nu', g_1, \nu \rangle \in \mathbb{F}$. However then we have that $\langle \overline{\nu}, g_0, \nu' \rangle \in \mathbb{F}$ with $\widetilde{g}_0 = f^*_{\overline{\nu},\nu'}$ by the same Lemma again.

The Σ_0-preserving yet cofinality of the maps g_0 and g_1 guarantees that they are Q-preserving (note that $S_{\alpha_{\overline{\nu}}} \cap \overline{\nu}, S_{\alpha_{\nu'}} \cap \nu', S_{\alpha_\nu} \cap \nu$ are all cofinal in their respective ordinals). Thus $f^*_{\overline{\nu}\nu'}$, and $f' = f^*_{\nu'\nu}$ are good (in the sense of Definition 3.6), and $\overline{\nu} \prec \nu' \prec \nu$ with $\alpha_{\nu'} = \alpha \in B_\nu$ as required. ⊣

3.2. Variants

Higher Gap Morasses

In the construction of the gap-1 morass at ω_1 say, we could have defined S^1 as the class of pseudo-successor cardinals, ordinals ν so that there exists $\alpha = \alpha_\nu < \nu$ so that $J_\nu \models$ "$\alpha = \omega_1$ and is the largest cardinal". A gap-n morass at ω_1 ($n < \omega$) would ask for classes S^i ($1 \leq i \leq n$) with $\nu \in S^i \longrightarrow \exists \alpha < \nu J_\nu \models$ "$\alpha = \omega_1 \wedge \mathrm{ot}\{\gamma > \omega \mid \gamma \in \mathrm{Card}\} = i$". Here we are allowing any $\nu < \omega_{n+1}$. In the gap-2 case, we would think of a system that approximates to ω_3 via a system of maps built out of countable objects approximating objects of size ω_1 reaching up to ω_2 much as a gap-1 morass does, but then additional maps piece these together in turn to obtain objects of size ω_2 that will reach up to ω_3. An enhanced set of axioms extending those of Definition 3.1 regulate this overall structure. Additional axioms (the "logical axioms") are also needed to control continuity properties and ensure that maps correctly transfer pieces of the morass from one structure to another. These higher gap morasses were introduced by Jensen [26].

There is no particular need to consider only finite gaps: countable length gaps (for morasses at ω_1); and generally gap-η morasses at κ can be constructed in L for $\eta < \kappa$, $\kappa \in \mathrm{Reg}$. Venturing beyond that, Irrgang has proposed definitions for gap-β morasses at ω_1 for $\beta > \omega_1$ and demonstrated their construction.

Hyperfine structural constructions exist of gap-1 morasses (Friedman et al. [21]), and for the gap-2 case (Friedman and Piwinger [20]); the latter is ostensibly different from the Jensen morass as they come with enhanced preservation properties. This "perfect preservation" comes about from the extremely fine gradations of locations, that enables even more stages in the hierarchy than for the J-hierarchy—thus developing a structure not *prima facie* available for the usual J-hierarchy.

Coarse Morasses

On occasions the full structure of the morass is simply not used and a coarse morass suffices. As its name implies, it is obtained by dropping some clauses from that of a full morass: namely those of the second continuity property CP2 and M0(v). As we don't need such fine elementarity between the structures we can simplify M0(iv) as well. (Indeed as we shall see, this principle requires no fine structure for its construction at all.)

3.7 Definition. Let $\kappa > \omega$ be regular. A *coarse gap-1 morass* at κ is a quadruple $\langle S, S^1, \prec, \langle \widehat{f}_{\bar\nu\nu} \mid \bar\nu \prec \nu\rangle\rangle$ satisfying M0(i)–(iii), M0(iv)(a), CP1, M1-3 of Definition 3.1, together with

M0(v)$'$ $\langle \widehat{f}_{\bar\nu\nu} \mid \bar\nu \prec \nu\rangle$ is a commuting system of maps; $\widehat{f}_{\bar\nu\nu} : \mathfrak{A}_{\bar\nu} \longrightarrow_{\Sigma_\omega} \mathfrak{A}_\nu$;
$\widehat{f}_{\bar\nu\nu}(\alpha_{\bar\nu}) = \alpha_\nu; \widehat{f}_{\bar\nu\nu}\restriction\alpha_{\bar\nu} = \mathrm{id}\restriction\alpha_{\bar\nu}$.

In L coarse morasses are easily constructed: take the class S of pairs $\langle\alpha,\nu\rangle$ such that:

- Both J_α, J_ν are limits of ZF^- models, and $J_\nu \models$ "$\alpha = \alpha_\nu$ is the largest cardinal".

If $\langle\alpha,\nu\rangle \in S$ set $\mathfrak{A}_\nu =_{\mathrm{df}} J_\nu$. We define ν^* to be the least $\nu' \geq \nu$ so that (i) $J_{\nu'} \models \mathrm{ZF}^-$; (ii) for some $p \in J_{\nu'}$, every $x \in J_{\nu'}$ is $J_{\nu'}$-definable from parameters in $\alpha_\nu \cup \{p\}$. An elementary argument shows that such a ν^* must exist, and we set p_ν to be the $<_L$-least p satisfying (ii). Then set $q_\nu = p_\nu$ if $\nu^* = \nu$, or to equal $\langle p_\nu, \nu\rangle$ otherwise. The standard kinds of argument we have been using show quickly that if $f^* : J_{\nu'} \longrightarrow_{\Sigma_\omega} J_{\nu^*}$ with $q_\nu \in \mathrm{ran}(f^*)$, then $f^*(\bar\nu) = \nu$ implies $\nu' = \bar\nu^*$; we may define $\bar\nu \prec \nu$ if there exists an $f^* : J_{\bar\nu^*} \longrightarrow_{\Sigma_\omega} J_{\nu^*}$ such that $f^*\restriction\alpha_{\bar\nu} = \mathrm{id}\restriction\alpha_{\bar\nu}$, $f^*(\alpha_{\bar\nu}) > \alpha_{\bar\nu}$ and $q_\nu \in \mathrm{ran}(f^*)$. We set $\widehat{f}_{\bar\nu\nu} =_{\mathrm{df}} f^*\restriction J_{\bar\nu}$. It can be verified without much new work that if we now fix a regular cardinal κ and restrict our pairs $\langle\alpha,\nu\rangle$ so that $\nu < \kappa^+$ with $J_\nu \models$ "$\alpha_\nu \in \mathrm{Reg}$", then (setting S^1 to be the obvious class of such ν) our relation $\prec\restriction\kappa^+ \times \kappa^+$, together with all possible maps $\widehat{f}_{\bar\nu\nu}$, satisfies the coarse morass definitions. For more detail the reader may consult [11], where it is further shown how to extend the gap-1 coarse notion easily to a generalised gap *global coarse morass* of arbitrarily large gaps.

Morasses with Extra Structure

Various extra structure has been imposed on the morass concept in order to get strengthened results. This has occasioned the so-called *morasses with linear limits* [12], *morasses with built-in* $\diamondsuit$, and *morasses with built-in* $\square$ of Friedman [17].

Simplified Morasses

A substantial simplification of the morass notion is that of the *simplified morass* of Velleman [53]. Working to try and obtain a Martin's axiom-like postulate equivalent to the existence of gap-1 morasses, he derived a very simple and short list of axioms concerning sets of maps between ordinals. He showed that given a morass one could show (by forcing) the existence of a structure satisfying this axiom list: the simplified morass. This work derived from earlier work of Shelah and Stanley who were trying also to obtain similar forcing axioms. The advantage here is indeed that of simplicity: it delivers an easily comprehended structure ready for possible application.

Velleman left open the question of whether such morasses could be constructed directly in L. He later went on to develop higher gap simplified morasses [54] and morasses with linear limits. That simplified morasses existed in L was proven first by Donder [12] in the gap-1 case, and by Jensen (unpublished), building on Donder's work, for the higher gaps. For a construction of gap-1 and -2 morasses from simplified morasses see [38]. A Silver machine construction of a gap-1 morass was given in [40].

Applications

Jensen's original applications were to cardinal transfer theorems.

3.8 Definition. $(\kappa, \lambda) \longrightarrow (\theta, \eta)$ holds if for every structure whose universe has size κ with a distinguished unary predicate with extension in the structure of size λ, also has a model of size θ whose predicate has size η.

3.9 Theorem (Jensen) (The Gap-$n+1$ Cardinal Transfer Theorem). *If there is a gap-n morass at ω_1 then $(\kappa^{+(n+1)}, \kappa) \longrightarrow (\omega_{n+1}, \omega)$.*

Jensen also derived the following form of *Prikry's principle* from gap-1 morasses, symbolically this is:

$$\begin{pmatrix} \omega_2 \\ \omega_1 \end{pmatrix} \not\longrightarrow \begin{bmatrix} \aleph_0 \\ \aleph_1 \end{bmatrix}_{\aleph_1}.$$

Interpreted this says that there is a partition of $\omega_2 \times \omega_1$ into $\aleph_1$ many sets $\{I_\gamma \mid \gamma < \omega_1\}$ such that $\forall A \subseteq [\omega_2]^{\aleph_0} \forall B \subseteq [\omega_1]^{\aleph_1} \forall \gamma < \omega_1 (A \times B) \cap I_\gamma \neq \varnothing$. (See [39] for more on this and some further generalisations.)

We state as a further example here, versions of the non-existence of free subsets from gap-2 morasses. The notion of "free" here is as a kind of maximal independent set. We typically ask that for every means of associating ordinals with tuples we can find some large set which is free of associations. Let $\mathrm{Fr}(\omega_3, 4, \omega_1)$ denote: "For every $F : [\omega_3]^4 \longrightarrow \omega_3$ such that for every quadruple a from ω_3 satisfies $F(a) \notin a$, there exists X a subset of ω_3 of cardinality ω_1 with $X \cap F``[X]^4 = \varnothing$".

3.10 Theorem (Jensen, unpublished). *Suppose* CH + *"there exists a gap-2 morass". Then* $\neg\,\mathrm{Fr}(\omega_3, 4, \omega_1)$.

Set-theoretical applications of morasses are not legion. The reader may consult [39] and [31] as a survey of early principles derivable from gap-1 morasses. A Morass with built in $\square$ forms a building block of the Strong Coding forcing constructed in [16]. For applications of gap-1 and global coarse morasses to derive in L one and two cardinal versions of $\diamond$ sequences, Kurepa trees without Aronszajn subtrees, and some negative partition relations, see Donder [11].

11. Elementary Embeddings and Algebra

Patrick Dehornoy

Contents

M. Foreman, A. Kanamori (eds.), *Handbook of Set Theory*,
DOI 10.1007/978-1-4020-5764-9_12,

It has been observed for many years that computations with elementary embeddings entail some purely algebraic features—as opposed to the logical nature of the embeddings themselves. The key point is that the operation of applying an embedding to another satisfies, when defined, the self-distributivity law $x(yz) = (xy)(xz)$. Using specific properties of the elementary embeddings and their critical ordinals, hence assuming some large cardinal hypotheses, Richard Laver established two purely algebraic results about sets equipped with a self-distributive operation (LD-systems), namely the decidability of the associated word problem in 1989, and the unboundedness of the periods in some finite LD-systems in 1993. The large cardinal assumption was eliminated from the first result by the author in 1992 using an argument that led to unexpected results about Artin braid groups; as for the second of Laver's results, no proof in ZF has been discovered so far, and the only result known to date is that it cannot be proved in Primitive Recursive Arithmetic.

1. Iterations of an Elementary Embedding

Our aim is to study the algebraic operation obtained by *applying* an elementary embedding to another one. For $j, k : V \prec M$, we can apply j to any set-restriction of k, and, in good cases, the images of these restrictions cohere so as to form a new elementary embedding that we shall denote by $j[k]$. It is then easy to see that the application operation so defined satisfies various algebraic laws.

Convention: All elementary embeddings we consider here are supposed to be distinct from the identity. An easy rank argument shows that every such embedding moves some ordinal; in particular, the least ordinal moved by j is called the *critical ordinal* of j, and denoted $\mathrm{crit}(j)$.

1.1. Kunen's Bound and Axiom (I3)

If j is an elementary embedding of V into a proper subclass M, then $j[j]$, whenever it is defined, is an elementary embedding of M into a proper subclass M' of M, and it is not clear that $j[j]$ can in turn be applied to j, whose set-restrictions need not belong to M in general. So, if we wish the application operation on elementary embeddings to be everywhere defined, we should consider embeddings where the source and the target models coincide. Here comes an obstruction.

1.1 Proposition (AC; Kunen [15]). *There is no $j : V \prec V$.*

Proof. Assume $j : V \prec V$. Let $\kappa_0 = \mathrm{crit}(j)$, and, recursively, $\kappa_{n+1} = j(\kappa_n)$. Let $\lambda = \sup_n \kappa_n$. By standard arguments, each κ_n is an inaccessible cardinal, so λ is a strong limit cardinal. Fix an injection i_n of $\mathcal{P}(\kappa_n)$ into λ. Then the mapping $X \mapsto (i_n(X \cap \kappa_n))_{n\in\omega}$ defines an injection of $\mathcal{P}(\lambda)$ into λ^ω. Using

AC, we fix an enumeration $(\gamma_\xi, X_\xi)_{\xi<\nu}$ of $\lambda \times [\lambda]^\lambda$, and then recursively construct an injective sequence $(s_\xi)_{\xi<\nu}$ in λ^ω such that s_ξ belongs to $[X_\xi]^\omega$: this is possible because the cardinality of $\lambda \times [\lambda]^\lambda$ equals that of λ^ω. Let $f : \lambda^\omega \to \lambda$ be defined by $f(s) = \gamma_\xi$ for $s = s_\xi$, and $f(s) = 0$ for s not of the form s_ξ. Let $X \in [\lambda]^\lambda$. Then, for each $\gamma < \lambda$, there exists a $\xi < \nu$ satisfying $(\gamma, X) = (\gamma_\xi, X_\xi)$. For this ξ, we have $s_\xi \in [X]^\omega$ by hypothesis, and $f(s_\xi) = \gamma_\xi$. Hence the function f, which lies in $V_{\lambda+2}$, has the property that the range of $f{\restriction}X^\omega$ is λ for every X in $[\lambda]^\lambda$.

Let us consider $j(f)$. We have $j(\lambda) = \sup_n \kappa_{n+1} = \lambda$, hence $j(f)$ is a function of λ into itself, and, as j is elementary, $j(f)$ has the property that, for every X in $[\lambda]^\lambda$, the range of $j(f){\restriction}X^\omega$ is λ. Now, let X be the set $\{\theta < \lambda \mid \theta \in \mathrm{ran}(j)\}$. For every s in X^ω, we have $s(n) \in \mathrm{ran}(j)$ for every n, hence $s = j(s')$ for some s', and $j(f)(s) = j(f)(j(s')) = j(f(s')) \in X$. As X is a proper subset of λ, the range of $j(f){\restriction}X^\omega$ is not λ, and we have got a contradiction. ⊣

We are thus led to considering weaker assumptions, involving embeddings that are defined on ranks rather than on the whole universe.

1.2 Definition (Gaifman, Solovay-Reinhardt-Kanamori [21]).

$$\text{Axiom (I3): For some } \delta\text{, there exists a } j : V_\delta \prec V_\delta.$$

Assume $j : V_\delta \prec V_\delta$. Let $\kappa_0 = \mathrm{crit}(j)$, and $\kappa_n = j^n(\kappa_0)$. The proof of Proposition 1.1 shows that, letting $\lambda = \sup_n \kappa_n$, it is impossible (assuming AC) that the function called f there belongs to the target model of j. The function f belongs to $V_{\lambda+2}$, so $\delta \geqslant \lambda+2$ is impossible, and the only remaining possibilities for Axiom (I3) are $\delta = \lambda$, and $\delta = \lambda + 1$. The second possibility subsumes the first:

1.3 Lemma. *Assume $j : V_{\delta+1} \prec V_{\delta+1}$. Then we have $j{\restriction}V_\delta : V_\delta \prec V_\delta$.*

Proof. First, $j(\delta) < \delta$ is impossible, so we necessarily have $j(\delta) = \delta$, and, therefore, $j{\restriction}V_\delta$ maps V_δ to itself. As for elementarity, an easy induction shows that, for $\vec{a}$ in V_δ and Φ a first-order formula, $V_\delta \models \Phi(\vec{a})$ is equivalent to $V_{\delta+1} \models \Phi^{V_\delta}(\vec{a})$, and, therefore, $V_\delta \models \Phi(\vec{a})$ is equivalent to $V_{\delta+1} \models \Phi^{V_\delta}(\vec{a})$, hence to $V_{\delta+1} \models \Phi^{V_{j(\delta)}}(j(\vec{a}))$, and finally to $V_\delta \models \Phi(j(\vec{a}))$. ⊣

Thus, without loss of generality, we can restrict to the case $j : V_\lambda \prec V_\lambda$ in the sequel, i.e., when using Axiom (I3), we can add the assumption that δ is the supremum of the cardinals $j^n(\mathrm{crit}(j))$.

Before turning to the core of our study, let us observe that Axiom (I3) lies very high in the hierarchy of large cardinals.

1.4 Proposition. *Assume $j : V_\delta \prec V_\delta$, with $\kappa = \mathrm{crit}(j)$. Then there exists a normal ultrafilter on κ concentrating on cardinals that are n-huge for every n.*

Proof. As above, let $\kappa_n = j^n(\kappa)$. Let $U_n = \{X \subseteq \mathcal{P}(\kappa_n) \mid j``\kappa_n \in j(X)\}$. Then U_n is a κ-complete ultrafilter U_n on $\mathcal{P}(\kappa_n)$, and, for every $i < n$, the set $\{x \in \mathcal{P}(\kappa_n) \mid \mathrm{ot}(x \cap \kappa_{i+1}) = \kappa_i\}$ belongs to U_n, since its image under j is $\{x \in \mathcal{P}(\kappa_{n+1}) \mid \mathrm{ot}(x \cap \kappa_{i+2}) = \kappa_{i+1}\}$, which contains $j``\kappa_n$ as we have $j``\kappa_n \cap \kappa_{i+2} = j``\kappa_{i+1}$. By [14, 24.8], this means that κ is n-huge.

Then we use a classical reflection argument, especially easy here. Let $U = \{X \subseteq \kappa \mid \kappa \in j(X)\}$. Then U is a normal ultrafilter over κ. Let X_0 be the set of all cardinals below κ that are n-huge for every n. Then $j(X_0)$ is the set of all cardinals below $j(\kappa)$ that are n-huge for every n, which contains κ as was seen above. So X_0 belongs to U. ⊣

1.2. Operations on Elementary Embeddings

For λ a limit ordinal, we denote by $\mathcal{E}_\lambda$ the family of all $j : V_\lambda \prec V_\lambda$. In most cases $\mathcal{E}_\lambda$ is empty, and Axiom (I3) asserts that at least one $\mathcal{E}_\lambda$ is nonempty.

No function $f : V_\lambda \to V_\lambda$ is an element of V_λ. However, we can approximate f by its restrictions $f{\restriction}V_\gamma$ with $\gamma < \lambda$, each of which belongs to V_λ. If g is (another) function defined on V_λ, then g can be applied to each restriction $f{\restriction}V_\gamma$. If g happens to be an elementary embedding, the images $g(f{\restriction}V_\gamma)$ form a coherent system, and, in this way, we can *apply* g to f.

1.5 Definition. For $j, k : V_\lambda \to V_\lambda$, the *application of* j *to* k is defined by

$$j[k] = \textstyle\bigcup_{\gamma<\lambda} j(k{\restriction}V_\gamma).$$

This definition makes sense, as, by construction, $k{\restriction}V_\gamma$ belongs to $V_{k(\gamma)+3}$, and therefore to V_λ.

1.6 Lemma. *Assume* $j, k \in \mathcal{E}_\lambda$. *Then* $j[k]$ *belongs to* $\mathcal{E}_\lambda$, *and we have* $\mathrm{crit}(j[k]) = j(\mathrm{crit}(k))$.

Proof. When γ ranges over λ, the various mappings $k{\restriction}V_\gamma$ are compatible. As j is elementary, $j(k{\restriction}V_\gamma)$ is a partial mapping defined on $V_{j(\gamma)}$, and the partial mappings $j(k{\restriction}V_\gamma)$ and $j(k{\restriction}V_{\gamma'})$ associated with different ordinals γ, γ' agree on $V_{j(\gamma)} \cap V_{j(\gamma')}$. Hence $j[k]$ is a mapping of V_λ into itself.

Let $\Phi(\vec{x})$ be a first-order formula. For each γ in λ, we have

$$\forall \vec{x} \in V_\gamma (\Phi(\vec{x}) \iff \Phi((k{\restriction}V_\gamma)(\vec{x}))),$$

hence, applying j,

$$\forall \vec{x} \in V_{j(\gamma)} (\Phi(\vec{x}) \iff \Phi(j(k{\restriction}V_\gamma)(\vec{x}))),$$

so $j[k]$ is an elementary embedding of V_λ into itself.

The equality $\mathrm{crit}(j[k]) = j(\mathrm{crit}(k))$ follows from the fact that $k(\mathrm{crit}(k)) > \mathrm{crit}(k)$ implies $j[k](j(\mathrm{crit}(k)) > j(\mathrm{crit}(k))$, while $\forall \gamma < \mathrm{crit}(k)\, (k(\gamma) = \gamma)$ implies $\forall \gamma < j(\mathrm{crit}(k))\, (j[k](\gamma) = \gamma)$. ⊣

Note that, for j, k in $\mathcal{E}_\lambda$ and $\gamma < \lambda$, the equality

$$j[k]\restriction V_{j(\gamma)} = j(k\restriction V_\gamma) \tag{11.1}$$

is true by construction, as well as the formula

$$j[k](x) = jkj^{-1}(x) \tag{11.2}$$

whenever x belongs to the image of j.

Besides the application operation, composition is another binary operation on $\mathcal{E}_\lambda$. We insist that application is *not* composition. As (11.2) shows, application is a sort of conjugation with respect to composition.

Let us turn to the algebraic study of the application and composition operations. The former is neither commutative nor associative, but the following algebraic relations are satisfied. As usual, id_X denotes the identity map on set X.

1.7 Lemma (Folklore). *For $j, k, \ell \in \mathcal{E}_\lambda \cup \{\mathrm{id}_{V_\lambda}\}$, we have*

$$j[k[\ell]] = j[k][j[\ell]],\ j{\circ}k = j[k]{\circ}j,\ (j{\circ}k)[\ell] = j[k[\ell]],\ j[k{\circ}\ell] = j[k]{\circ}j[\ell]. \tag{11.3}$$

Proof. Let $\gamma < \lambda$. Then $\ell\restriction V_\gamma$ belongs to V_β for some $\beta < \lambda$. From the definition, we have $k[\ell]\restriction V_{k(\gamma)} = (k\restriction V_\beta)(\ell\restriction V_\gamma)$. Applying j we get

$$j(k[\ell]\restriction V_{k(\gamma)}) = j(k\restriction V_\beta)[j(\ell\restriction V_\gamma)].$$

By (11.1), the left factor is $j[k[\ell]]\restriction V_{j(k(\gamma))}$, and $j(k(\gamma)) = j[k](j(\gamma))$ implies that the right factor is $j[k][j[\ell]]\restriction V_{j(k(\gamma))}$. As γ is arbitrary, we deduce $j[k[\ell]] = j[k][j[\ell]]$.

Let $x \in V_\lambda$. For γ sufficiently large, we have $x \in \mathrm{dom}(k\restriction V_\gamma)$, hence

$$j(k(x)) = j((k\restriction V_\gamma)(x)) \ = j(k\restriction V_\gamma)(j(x)) = j[k](j(x)),$$

which establishes the equality $j{\circ}k = j[k]{\circ}j$. Applying the latter to $x = \ell\restriction V_\gamma$, one easily deduces $(j{\circ}k)[\ell] = j[k[\ell]]$.

Finally, using the fact that j preserves composition, we obtain

$$\begin{aligned} j[k{\circ}\ell]\restriction V_{j(\gamma)} &= j((k{\circ}\ell)\restriction V_\gamma) = j((k\restriction V_{\ell(\gamma)}){\circ}(\ell\restriction V_\gamma)) \\ &= (j[k]\restriction V_{j\ell(\gamma)}){\circ}(j[\ell]\restriction V_{j(\gamma)}) = (j[k]{\circ}j[\ell])\restriction V_{j(\gamma)}, \end{aligned}$$

for every γ, and hence $j[k{\circ}\ell] = j[k]{\circ}j[\ell]$. ⊣

Also $j[\mathrm{id}_{V_\lambda}] = \mathrm{id}_{V_\lambda}$ and $\mathrm{id}_{V_\lambda}[j] = j$ hold for every j in $\mathcal{E}_\lambda \cup \{\mathrm{id}_{V_\lambda}\}$. In order to fix the vocabulary for the sequel, we put the following definitions:

1.8 Definition.

(i) $(S, *)$ is a *left self-distributive system*, or LD-*system*, if $*$ is a binary operation on S satisfying

$$x * (y * z) = (x * y) * (x * z). \tag{LD}$$

(ii) $(M, *, \cdot, 1)$ is a *left self-distributive monoid*, or LD-*monoid*, if $(M, \cdot, 1)$ is a monoid and $*$ is a binary operation on M satisfying

$$x \cdot y = (x * y) \cdot x, \qquad (x \cdot y) * z = x * (y * z),$$
$$x * (y \cdot z) = (x * y) \cdot (x * z), \qquad x * 1 = 1. \tag{11.4}$$

Observe that an LD-monoid is an LD-system and $1 * x = x$ always holds, as (11.4) implies $x * (y * z) = (x \cdot y) * z = ((x * y) \cdot x) * z = (x * y) * (x * z)$, and, similarly, $1 * x = (1 * x) \cdot 1 = 1 \cdot x = x$. With these definitions (various other names have been used in literature), we can restate Lemma 1.7 as

1.9 Proposition. *Let λ be a limit ordinal. Then $\mathcal{E}_\lambda$ equipped with application is an* LD-*system, and $\mathcal{E}_\lambda \cup \{\mathrm{id}_{V_\lambda}\}$ equipped with application and composition is an* LD-*monoid.*

Before developing our study further, we conclude this section with an independent result which we shall see in Sect. 3 leads to interesting consequences.

1.10 Proposition. *Assume $j : V_\lambda \prec V_\lambda$. Then we have $j[j](\alpha) \leqslant j(\alpha)$ for every ordinal $\alpha < \lambda$.*

Proof. Let β satisfy $j(\beta) > \alpha$ and $\forall \xi < \beta\, (j(\xi) \leqslant \alpha)$. As j is elementary, we deduce $j[j](j(\beta)) > j(\alpha)$ and $\forall \xi < j(\beta)\, (j[j](\xi) \leqslant j(\alpha))$—we can make things rigorous by replacing the parameter j with some approximation of the form $j \restriction V_\gamma$ with γ sufficiently large. As $\alpha < j(\beta)$ holds, we can take $\xi = \alpha$ in the second formula, which gives $j[j](\alpha) \leqslant j(\alpha)$. $\dashv$

1.3. Iterations of an Elementary Embedding

We now turn to the specific study of the iterations of a fixed elementary embedding $j : V_\lambda \prec V_\lambda$, as developed by Laver. So we concentrate on the countable subfamily of $\mathcal{E}_\lambda$ consisting of those embeddings that can be obtained from j using application (or both application and composition).

1.11 Definition. For $j \in \mathcal{E}_\lambda$, we denote by $\mathrm{Iter}(j)$ the sub-LD-system of $\mathcal{E}_\lambda$ generated by j, and by $\mathrm{Iter}^*(j)$ the sub-LD-monoid of $\mathcal{E}_\lambda \cup \{\mathrm{id}_{V_\lambda}\}$ generated by j. The elements of $\mathrm{Iter}^*(j)$ are called the *iterates* of j, while the elements of $\mathrm{Iter}(j)$ are called the *pure iterates* of j.

By definition, the pure iterates of j are those elementary embeddings that can be obtained from j using the application operation repeatedly, so they comprise $j, j[j], j[j[j]], j[j][j]$, etc. As application is a non-associative operation, the iterates of j do not reduce to powers of j; however, even the notion of a power has to be made precise. We shall use the following notation:

1.12 Definition. For j in $\mathcal{E}_\lambda$—or, more generally, in any binary system—we recursively define the nth *right power* $j^{[n]}$ of j and the nth *left power* $j_{[n]}$ of j by $j^{[1]} = j_{[1]} = j$, $j^{[n+1]} = j[j^{[n]}]$, and $j_{[n+1]} = j_{[n]}[j]$.

For future use, let us mention some relations between the powers in an arbitrary LD-system:

1.13 Lemma. *The following relations are satisfied in every* LD-*system:*

$$x^{[p+1]} = x^{[q]}[x^{[p]}] \quad \text{for } 1 \leqslant q \leqslant p, \qquad (x^{[p]})^{[q]} = x^{[p+q-1]} \quad \text{for } 1 \leqslant p, q. \tag{11.5}$$

In the sequel, we investigate the possible quotients of the algebraic structures $\mathrm{Iter}(j)$ and $\mathrm{Iter}^*(j)$, i.e., we look for equivalence relations that are compatible with the involved algebraic operation(s). A simple idea would be to concentrate on critical ordinals, or, more generally, on the values at particular fixed ordinals, but this naïve approach is not relevant beyond the first levels. Another idea would be to consider the restrictions of the embeddings to a fixed rank, i.e., to consider equivalence relations of the form $j{\restriction}V_\gamma = j'{\restriction}V_\gamma$. However, such relations are not compatible with the application operation in general, and we are led to slightly different relations.

1.14 Definition (Laver). Assume j, $j' \in \mathcal{E}_\lambda \cup \{\mathrm{id}_{V_\lambda}\}$. For γ a limit below λ, we say that j and j' are *γ-equivalent*, denoted $j \stackrel{\gamma}{\equiv} j'$, if, for every x in V_γ, we have $j(x) \cap V_\gamma = j'(x) \cap V_\gamma$.

By definition, $\stackrel{\gamma}{\equiv}$ is an equivalence relation on $\mathcal{E}_\lambda \cup \{\mathrm{id}_{V_\lambda}\}$. Note that $j \stackrel{\gamma}{\equiv} j'$ implies $j(x) \cap V_\gamma = j'(x) \cap V_\gamma$ for every x in V_λ—not only in V_γ—since, for $y \in V_\beta$ with $\beta < \gamma$, the relation $y \in j(x) \cap V_\gamma$ is equivalent to $y \in j(x \cap V_\beta) \cap V_\gamma$, and $x \cap V_\beta$ belongs to $V_{\beta+1}$, hence to V_γ since γ is limit.

We begin with easy observations.

1.15 Lemma. *Assume $j \stackrel{\gamma}{\equiv} j'$ and $\alpha < \gamma$. Then we have either $j(\alpha) < \gamma$, whence $j'(\alpha) = j(\alpha)$, or $j(\alpha) \geqslant \gamma$, whence $j'(\alpha) \geqslant \gamma$. So, in particular, we have either* $\mathrm{crit}(j) = \mathrm{crit}(j') < \gamma$, *or both* $\mathrm{crit}(j) \geqslant \gamma$ *and* $\mathrm{crit}(j') \geqslant \gamma$.

Proof. Assume $j' \stackrel{\gamma}{\equiv} j$ and $\alpha, \beta < \gamma$. Then, by definition, $j(\alpha) > \beta$ is equivalent to $j'(\alpha) > \beta$. ⊣

1.16 Lemma. *Assume $j, k \in \mathcal{E}_\lambda$. Then $j[k]$ and k are* $\mathrm{crit}(j)$*-equivalent.*

Proof. Let $\gamma = \mathrm{crit}(j)$. An induction on rank shows that $j{\restriction}V_\gamma$ is the identity mapping. Then $y \in k(x)$ is equivalent to $j(y) \in j[k](j(x))$, hence to $y \in j[k](x)$ for x, y in V_γ. ⊣

1.17 Proposition. *For limit $\gamma < \lambda$, γ-equivalence is compatible with composition.*

Proof. Assume $j \stackrel{\gamma}{\equiv} j'$ and $k \stackrel{\gamma}{\equiv} k'$. Let $x, y \in V_\gamma$, and $y \in j(k(x))$. As γ is limit, we have $x, y \in V_\beta$ for some $\beta < \gamma$, so $y \in j(k(x))$ implies $y \in j(k(x) \cap V_\beta) \cap V_\gamma$. By hypothesis, we have $k(x) \cap V_\beta = k'(x) \cap V_\beta \in V_{\beta+1} \subseteq V_\gamma$, hence

$$j'(k'(x) \cap V_\beta) \cap V_\gamma = j(k'(x) \cap V_\beta) \cap V_\gamma = j(k(x) \cap V_\beta) \cap V_\gamma.$$

We deduce $y \in j'(k'(x))$, hence $j(k(x)) \cap V_\gamma \subseteq j'(k'(x)) \cap V_\gamma$. By symmetry, we obtain $j(k(x)) \cap V_\gamma = j'(k'(x)) \cap V_\gamma$, so $j \circ k$ and $j' \circ k'$ are γ-equivalent. $\dashv$

1.18 Lemma. *Let $j : V_\lambda \prec V_\lambda$. Then, for each γ satisfying $\mathrm{crit}(j) < \gamma < \lambda$, there exists a δ satisfying $\delta < \gamma \leqslant j(\delta) < j(\gamma)$.*

Proof. Let $\kappa = \mathrm{crit}(j)$. Let δ be the least ordinal satisfying $\gamma \leqslant j(\delta)$: since $\gamma \leqslant j(\gamma)$ is always true, δ exists, and we have $\delta \leqslant \gamma$. Assume $\delta = \gamma$. This means that $\xi < \gamma$ implies $j(\xi) < \gamma$, hence $j^n(\xi) < \gamma$ for each n. This contradicts $\gamma < \lambda$ and (by the remark after Lemma 1.3) $\lambda = \sup_n j^n(\kappa)$. $\dashv$

1.19 Proposition. *Assume $j \overset{\gamma}{\equiv} j'$ and $k \overset{\delta}{\equiv} k'$ with $j(\delta) \geqslant \gamma$. Then we have $j[k] \overset{\gamma}{\equiv} j'[k']$.*

Proof. Assume first $\mathrm{crit}(j) \geqslant \gamma$. By Lemma 1.15, we also have $\mathrm{crit}(j') \geqslant \gamma$. Moreover, $\delta \geqslant \gamma$ holds, for $\delta < \gamma$ would imply $j(\delta) = \delta < \gamma$. Hence, $k \overset{\delta}{\equiv} k'$ implies $k \overset{\gamma}{\equiv} k'$. Then, by Lemma 1.16, we find $j[k] \overset{\gamma}{\equiv} k \overset{\gamma}{\equiv} k' \overset{\gamma}{\equiv} j'[k']$.

Assume now $\mathrm{crit}(j) < \gamma$, and, therefore, $\mathrm{crit}(j') = \mathrm{crit}(j)$. Since $k \overset{\delta}{\equiv} k'$ implies $k \overset{\delta'}{\equiv} k'$ for $\delta' \leqslant \delta$, we may assume without loss of generality that δ is minimal satisfying $j(\delta) \geqslant \gamma$, which, by Lemma 1.18, implies $\gamma > \delta$. Let $j \overset{*}{\cap} V_\alpha$ denote the set $\{(x, y) \in V_\alpha^2 \mid y \in j(x)\}$. By definition, $j \overset{\alpha}{\equiv} j'$ is equivalent to $j \overset{*}{\cap} V_\alpha = j' \overset{*}{\cap} V_\alpha$. We have

$$j[k] \overset{*}{\cap} V_\gamma = (j[k] \overset{*}{\cap} V_{j(\delta)}) \cap V_\gamma^2 = j(k \overset{*}{\cap} V_\delta) \cap V_\gamma^2.$$

By construction, $k \overset{*}{\cap} V_\delta$ is a set of ordered pairs of elements of V_δ, hence an element of V_γ. The hypotheses $k \overset{*}{\cap} V_\delta = k' \overset{*}{\cap} V_\delta$ and $j(x) \cap V_\gamma = j'(x) \cap V_\gamma$ for $x \in V_\gamma$ imply

$$j[k] \overset{*}{\cap} V_\gamma = j(k \overset{*}{\cap} V_\delta) \cap V_\gamma = j'(k \overset{*}{\cap} V_\delta) \cap V_\gamma = j'(k' \overset{*}{\cap} V_\delta) \cap V_\gamma = j'[k'] \overset{*}{\cap} V_\gamma,$$

so $j[k]$ and $j'[k']$ are γ-equivalent. $\dashv$

Let $j, k, \ell \in \mathcal{E}_\lambda$. Left self-distributivity gives $j[k[\ell]] = j[k][j[\ell]]$, but these embeddings need not be equal to $j[k][\ell]$, unless $j[\ell] = \ell$ holds. Now, by Lemma 1.16, $j[\ell]$ and ℓ are $\mathrm{crit}(j)$-equivalent, which implies that $j[k[\ell]]$ and $j[k][\ell]$ are $j[k](\mathrm{crit}(j))$-equivalent. Generalizing the argument, we obtain the following technical lemma. The convention is that $j[k][\ldots]$ means $(j[k])[\ldots]$.

1.20 Lemma. *Assume $j, j_1, \ldots, j_p \in \mathcal{E}_\lambda$, and let $\gamma = \mathrm{crit}(j)$.*

(i) *Assume $j[j_1[j_2]\ldots[j_\ell]](\gamma) \geqslant \gamma'$ for $1 \leqslant \ell \leqslant p-1$. Then we have*

$$j[j_1][j_2]\ldots[j_p] \overset{\gamma'}{\equiv} j[j_1[j_2]\ldots[j_p]]. \tag{11.6}$$

(ii) *Assume* $\mathrm{crit}(j_1[j_2]\ldots[j_\ell]) < \gamma$ *for* $1 \leqslant \ell \leqslant p-1$ *and* $\mathrm{crit}(j_1[j_2]\ldots[j_p]) \leqslant \gamma$. *Then we have*

$$\mathrm{crit}(j[j_1][j_2]\ldots[j_p]) = j(\mathrm{crit}(j_1[j_2]\ldots[j_p])). \tag{11.7}$$

Proof. (i) Use induction on p. For $p=1$, (11.6) is an equality. Otherwise, we have, by induction hypothesis, $j[j_1][j_2]\ldots[j_{p-1}] \overset{\gamma'}{\equiv} j[j_1[j_2]\ldots[j_{p-1}]]$, and, therefore,

$$j[j_1][j_2]\ldots[j_{p-1}][j_p] \overset{\gamma'}{\equiv} j[j_1[j_2]\ldots[j_{p-1}]][j_p]. \tag{11.8}$$

Lemma 1.16 gives $j_p \overset{\gamma}{\equiv} j[j_p]$, which implies

$$j[j_1[j_2]\ldots[j_{p-1}]][j_p] \overset{\gamma'}{\equiv} j[j_1[j_2]\ldots[j_{p-1}]][j[j_p]], \tag{11.9}$$

since $j[j_1[j_2]\ldots[j_{p-1}]](\gamma) \geqslant \gamma'$ holds by hypothesis. The right factor of (11.9) is also $j[j_1[j_2]\ldots[j_p]]$ by left self-distributivity, and combining (11.8) and (11.9) gives (11.6).

(ii) The case $p=1$ is trivial. Assume $p \geqslant 2$, and let γ' be the smallest of $j[j_1](\gamma)$, $j[j_1[j_2]](\gamma)$, $\ldots$, $j[j_1[j_2]\ldots[j_{p-1}]](\gamma)$. Applying (i), we find

$$j[j_1][j_2]\ldots[j_p] \overset{\gamma'}{\equiv} j[j_1[j_2]\ldots[j_p]]. \tag{11.10}$$

Let q be minimal satisfying $\gamma' = j[j_1[j_2]\ldots[j_q]](\gamma)$, and $j' = j_1[j_2]\ldots[j_q]$. Then we have $\gamma' = j[j'](\gamma)$. By hypothesis, we have $\mathrm{crit}(j') < \gamma$, so there exists a δ satisfying $\delta < \gamma \leqslant j'(\delta)$. From (11.10) we deduce

$$j(\gamma) \leqslant j(j'(\delta)) = j[j'](j(\delta)) = j[j'](\delta) < j[j'](\gamma) = \gamma'.$$

Hence $\mathrm{crit}(j_1[j_2]\ldots[j_p]) \leqslant \gamma$ implies $\mathrm{crit}(j[j_1[j_2]\ldots[j_p]]) \leqslant j(\gamma) < \gamma'$. Therefore the right embedding in (11.10) has its critical ordinal below γ', and, by Lemma 1.15, so has the left-hand embedding, and the two critical ordinals are equal. ⊣

1.4. Finite Quotients

By Proposition 1.19, γ-equivalence is compatible with the application operation, so that taking quotients under $\overset{\gamma}{\equiv}$ leads to a well-defined LD-system. We shall describe this quotient LD-system completely when γ happens to be the critical ordinal of some iteration of the investigated embedding.

By construction, for $j : V_\lambda \prec V_\lambda$, the sets $\mathrm{Iter}(j)$ and $\mathrm{Iter}^*(j)$ consist of countably many elementary embeddings, each of which except the identity has a critical ordinal. So, we can associate with j the countable family of all critical ordinals of iterates of j.

1.21 Definition. The ordinal $\mathrm{crit}_n(j)$ is defined to be the $(n+1)$th element in the increasing enumeration of the critical ordinals of iterations of j.

The formulas $\mathrm{crit}(j[k]) = j(\mathrm{crit}(k))$, $\mathrm{crit}(j\circ k) = \inf(\mathrm{crit}(j), \mathrm{crit}(k))$ and an obvious induction show that $\mathrm{crit}(i) \geqslant \mathrm{crit}(j)$ holds for every iterate i of j. Hence $\mathrm{crit}_0(j)$ is always $\mathrm{crit}(j)$. We shall prove below the values $\mathrm{crit}_1(j) = j(\mathrm{crit}(j))$ and $\mathrm{crit}_2(j) = j^2(\mathrm{crit}(j))$. Things become complicated subsequently. At this point, we do not know (yet) that the sequence of the ordinals $\mathrm{crit}_n(j)$ exhaust all critical ordinals in $\mathrm{Iter}^*(j)$: it could happen that some nontrivial iterate i of j has its critical ordinal beyond all $\mathrm{crit}_n(j)$'s.

1.22 Theorem (Laver). *Assume $j : V_\lambda \prec V_\lambda$. Then $\mathrm{crit}_n(j)$-equivalence is a congruence on the* LD*-monoid* $\mathrm{Iter}^*(j)$*, and the quotient* LD*-monoid has 2^n elements, namely the classes of j, $j_{[2]}$, ..., $j_{[2^n]}$, the latter also being the class of the identity.*

The proof requires several preliminary results.

1.23 Lemma. *Assume that i_1, i_2, ..., i_{2^n} are iterates of j. Then we have $\mathrm{crit}(i_1[i_2]\dots[i_p]) \geqslant \mathrm{crit}_n(j)$ for some p with $p \leqslant 2^n$.*

Proof. We use induction on n. For $n = 0$, the result is the inequality $\mathrm{crit}(i_1) \geqslant \mathrm{crit}(j)$, which we have seen holds for every iterate i_1 of j. Otherwise, we apply the induction hypothesis twice. First, we find $q \leqslant 2^{n-1}$ satisfying

$$\mathrm{crit}(i_1[i_2]\dots[i_q]) \geqslant \mathrm{crit}_{n-1}(j). \tag{11.11}$$

If the inequality is strict, we have $\mathrm{crit}(i_1[i_2]\dots[i_q]) \geqslant \mathrm{crit}_n(j)$, and we are done. So, we can assume from now on that (11.11) is an equality. By applying the induction hypothesis again, we find $r \leqslant 2^{n-1}$ satisfying

$$\mathrm{crit}(i_{q+1}[i_{q+2}]\dots[i_{q+r}]) \geqslant \mathrm{crit}_{n-1}(j).$$

If r is taken to be minimal, we can apply Lemma 1.20(i) with $p = r$, $j = i_1[i_2]\dots[i_q]$, $j_1 = i_{q+1}, \dots, j_p = i_{q+r}$, $\gamma = \mathrm{crit}_{n-1}(j)$, and $\gamma' = \mathrm{crit}_n(j)$. Indeed, with these notations, we have $\mathrm{crit}(j_1[j_2]\dots[j_s]) < \gamma$ for $s < r$, hence

$$\mathrm{crit}(j[j_1[j_2]\dots[j_s]]) = j(\mathrm{crit}(j_1[j_2]\dots[j_s])) = \mathrm{crit}(j_1[j_2]\dots[j_s]) < \gamma,$$

and, therefore, $j[j_1[j_2]\dots[j_s]](\gamma) > \gamma$, which gives $j[j_1[j_2]\dots[j_s]](\gamma) \geqslant \gamma'$ by definition. So we have

$$j[j_1][j_2]\dots[j_p] \overset{\gamma'}{\equiv} j[j_1[j_2]\dots[j_p]].$$

We have $\mathrm{crit}(j[j_1[j_2]\dots[j_p]]) \geqslant j(\gamma) \geqslant \gamma' = \mathrm{crit}_n(j)$, so, by Lemma 1.15, we deduce

$$\mathrm{crit}(j[j_1][j_2]\dots[j_p]) \geqslant \mathrm{crit}_n(j)$$

i.e., $\mathrm{crit}(i_1[i_2]\dots[i_q]\dots[i_{q+r}]) \geqslant \mathrm{crit}_n(j)$, as was expected. ⊣

The main task is now to show that all the iterates of j can be approximated by left powers of j up to $\mathrm{crit}_n(j)$-equivalence. Firstly, we approximate arbitrary iterates by pure iterates.

1.24 Lemma. *Assume that n is a fixed integer, and i is an iterate of j. Then there exists a pure iterate i' of j that is* $\mathrm{crit}_n(j)$*-equivalent to i.*

Proof. Let $\gamma = \mathrm{crit}_n(j)$, and let A be the set of those iterates of j that are γ-equivalent to some pure iterate of j. The set A contains j, and it is obviously closed under application. So, in order to show that A is all of $\mathrm{Iter}^*(j)$, it suffices to show that A is closed under composition, and, because γ-equivalence is compatible with composition, it suffices to show that, if i_1, i_2 are pure iterates of j, then some pure iterate of j is γ-equivalent to $i_2{\circ}i_1$. To this end, we define recursively a sequence of pure iterates of j, say i_3, i_4, ... by the clause $i_{p+2} = i_{p+1}[i_p]$. Then we have

$$i_3{\circ}i_2 = i_2[i_1]{\circ}i_2 = i_2{\circ}i_1,$$

and, recursively, $i_{p+1}{\circ}i_p = i_2{\circ}i_1$ for every p. We claim that $\mathrm{crit}(i_p) \geqslant \gamma$ holds for at least one of the values $p = 2n$ or $p = 2n+1$. If this is known, we find $i_2{\circ}i_1 = i_p{\circ}i_{p-1} = i_p[i_{p-1}]{\circ}i_p \overset{\gamma}{\equiv} i_{p-1}$, and we are done.

In order to prove the claim, we separate the cases $\mathrm{crit}(i_2) > \mathrm{crit}(i_1)$ and $\mathrm{crit}(i_2) \leqslant \mathrm{crit}(i_1)$. In this first case, we have

$$\mathrm{crit}(i_3) = i_2(\mathrm{crit}(i_1)) = \mathrm{crit}(i_1) \quad \text{and} \quad \mathrm{crit}(i_4) = i_3(\mathrm{crit}(i_2)) > \mathrm{crit}(i_2).$$

An immediate induction gives

$$\mathrm{crit}(i_1) = \mathrm{crit}(i_3) = \mathrm{crit}(i_5) = \cdots, \qquad \mathrm{crit}(i_2) < \mathrm{crit}(i_4) < \mathrm{crit}(i_6) < \cdots.$$

By definition, we have $\mathrm{crit}(i_1) \geqslant \mathrm{crit}_0(j)$, and, therefore, $\mathrm{crit}(i_2) \geqslant \mathrm{crit}_1(j)$, and, inductively, $\mathrm{crit}(i_{2n}) \geqslant \gamma$, as was claimed.

Assume now $\mathrm{crit}(i_2) \leqslant \mathrm{crit}(i_1)$. Similar computations give

$$\mathrm{crit}(i_1) < \mathrm{crit}(i_3) < \mathrm{crit}(i_5) < \cdots, \qquad \mathrm{crit}(i_2) = \mathrm{crit}(i_4) = \mathrm{crit}(i_6) = \cdots,$$

and we find now $\mathrm{crit}(i_{2n+1}) \geqslant \gamma$. So the claim is established, and the proof is complete. ⊣

Let us e.g. consider $i = j{\circ}j$. We are in the case "$\mathrm{crit}(i_2) \leqslant \mathrm{crit}(i_1)$", and we know that the pure iterate i_{2n+1} as above is a $\mathrm{crit}_n(j)$-approximation of i. For instance, we find $i_3 = j_{[2]}$, $i_4 = j_{[3]}$, $i_5 = j_{[3]}[j_{[2]}] = {j_{[4]}}^{[2]}$, so $j{\circ}j$ and $(j_{[4]})^{[2]}$ are $\mathrm{crit}_2(j)$-equivalent. It can be seen that the critical ordinal of $(j_{[4]})^{[2]}$, i.e., $j_{[4]}(\mathrm{crit}(j_{[4]}))$, is larger than $\mathrm{crit}_2(j)$, namely it is $\mathrm{crit}_3(j)$, so the previous equivalence is actually a $\mathrm{crit}_3(j)$-equivalence.

1.25 Proposition. *Assume $j : V_\lambda \prec V_\lambda$, $i \in \mathrm{Iter}^*(j)$, and $n \geqslant 0$. Then i is* $\mathrm{crit}_n(j)$*-equivalent to $j_{[p]}$ for some p with $p \leqslant 2^n$.*

Proof. By Lemma 1.24, we may assume that i is a pure iterate of j. The idea is to iteratively divide by j on the right, i.e., we construct pure iterates of j, say $i_0, i_1, \ldots$ such that i_0 is i, and i_p is $\mathrm{crit}_n(j)$-equivalent to $i_{p+1}[j]$

for every p. So, i is $\mathrm{crit}_n(j)$-equivalent to $i_p[j]\dots[j]$ (p times j) for every p. We stop the process when we have either $i_p = j$, in which case i is $\mathrm{crit}_n(j)$-equivalent to $j_{[p+1]}$, or $p = 2^n$: in this case, we have obtained a sequence of 2^n iterates of j, and Lemma 1.23 completes the proof.

Let us go into detail. In order to see that the construction is possible, let us assume that i_p has been obtained. If $i_p = j$ holds, we are done. Otherwise, i_p has the form $i'_1[i'_2[\dots[i'_r[j]]\dots]]$, where $i'_1, \dots, i'_r$ are some uniquely defined pure iterates of j. Applying the identity $j[k[\ell]] = (j{\circ}k)[\ell]$ $r-2$ times, we find $i_p = (i'_1{\circ}\cdots{\circ}i'_r)[j]$, and we define i_{p+1} to be a pure iterate of j that is $\mathrm{crit}_n(j)$-equivalent to $i'_1{\circ}\cdots{\circ}i'_r$.

Assume that the construction continues for at least 2^n steps, and let us consider the 2^n embeddings $i_{2^n}[j]$, $i_{2^n}[j][j], \dots, i_{2^n}[j][j]\dots[j]$ (2^n times j). By 1.23, there must be a $p \leqslant 2^n$ so that the critical ordinal of $i_{2^n}[j][j]\dots[j]$ (p times j) is at least $\mathrm{crit}_n(j)$. Let i' be the latter elementary embedding. Then i is $\mathrm{crit}_n(j)$-equivalent to $i_{2^n}[j][j]\dots[j]$ (2^n times j), which is also $i'[j][j]\dots[j]$ ($2^n - p$ times j), and, therefore, i is $\mathrm{crit}_n(j)$-equivalent to $\mathrm{id}[j][j]\dots[j]$ ($2^n - p$ times j), i.e., to $j_{[2^n-p]}$, and we are done as well. ⊣

The previous argument is effective. Starting with an arbitrary iteration i of j and a fixed level of approximation $\mathrm{crit}_n(j)$, we can find some left power of j that is $\mathrm{crit}_n[j]$-equivalent to i in a finite number of steps. However, the computation becomes quickly intricate, and there is no uniform way to predict how many steps are needed. For instance, let $i = j^{[3]}$, the simplest iterate of j that is not a left power. We write $i = (j{\circ}j)[j]$, and have to find an approximation of $j{\circ}j$. Now, $j{\circ}j$ is $\mathrm{crit}_3(j)$-equivalent to $j_{[3]}$, and, in this particular case, we obtain directly that $j^{[3]}$ is $\mathrm{crit}_3(j)$-equivalent to $j_{[3]}[j]$, i.e., to $j_{[4]}$. If we look for $\mathrm{crit}_4(j)$-equivalence, the computation is much more complicated. The results below will show that, if i is $\mathrm{crit}_3(j)$-equivalent to $j_{[4]}$, then it is $\mathrm{crit}_4(j)$-equivalent either to $j_{[4]}$ or to $j_{[12]}$. By determining the critical ordinal of $i[j][j][j][j]$, we could finally prove that $j^{[3]}$ is $\mathrm{crit}_4(j)$-equivalent to $j_{[12]}$. We shall see an easier alternative way for proving such statements in Sect. 3.2 below.

1.26 Proposition. *Assume $j : V_\lambda \prec V_\lambda$. Then, for every p, we have $\mathrm{crit}(j_{[p]}) = \mathrm{crit}_m(j)$, where m is the largest integer such that 2^m divides p.*

Proof. Let $\mathcal{H}_n$ be the conjunction of the following relations:

(i) $\mathrm{crit}(j_{[2^n]}) \geqslant \mathrm{crit}_n(j)$,

(ii) $p < 2^n$ implies $\mathrm{crit}(j_{[p]}) = \mathrm{crit}(j_{[2^m]})$ with m maximal such that 2^m divides p,

(iii) $m < n$ implies $\mathrm{crit}(j_{[2^m]}) < \mathrm{crit}(j_{[2^n]})$.

We prove $\mathcal{H}_n$ using induction on n. First, $\mathcal{H}_0$ reduces to $\mathrm{crit}(j) = \mathrm{crit}_0(j)$. Then, assume $\mathcal{H}_n$ and consider the embeddings $j_{[2^n+p]}$ for $1 \leqslant p \leqslant 2^n$. By definition, we have $j_{[2^n+p]} = j_{[2^n]}[j]\ldots[j]$ (p times j). Then $\mathcal{H}_n$(ii) and (iii) imply $\mathrm{crit}(j_{[s]}) < \mathrm{crit}(j_{[2^n]})$ for $s < 2^n$, while $\mathcal{H}_n$(i) implies $\mathrm{crit}(j_{[2^n]}) \geqslant \mathrm{crit}_n(j)$. By Lemma 1.20(ii) applied with $j = j_{[2^n]}$ and $j_1 = \cdots = j_p = j$, we have

$$\mathrm{crit}(j_{[2^n+p]}) = j_{[2^n]}(\mathrm{crit}(j_{[p]})).$$

For $p < 2^n$, we deduce $\mathrm{crit}(j_{[2^n+p]}) = \mathrm{crit}(j_{[p]}) = \mathrm{crit}_m(j)$ where m is the largest integer such that 2^m divides p, which is also the largest integer such that 2^m divides $2^n + p$, which is (ii) of $\mathcal{H}_{n+1}$. For $p = 2^n$, we obtain

$$\mathrm{crit}(j_{[2^{n+1}]}) = j_{[2^n]}(\mathrm{crit}(j_{[2^n]}) > \mathrm{crit}(j_{[2^n]}) = \mathrm{crit}_n(j),$$

and we deduce $\mathrm{crit}(j_{[2^{n+1}]}) \geqslant \mathrm{crit}_{n+1}(j)$, which is (i) of $\mathcal{H}_{n+1}$, and $\mathrm{crit}(j_{[2^{n+1}]}) > \mathrm{crit}(j_{[2^n]})$, which is (iii) of $\mathcal{H}_{n+1}$. Hence $\mathcal{H}_n$ is satisfied for each n.

Now, it follows from Proposition 1.25 that the critical ordinal of any iterate of j is either equal to the critical ordinal of some left power of j, or is larger than all ordinals $\mathrm{crit}_m(j)$. Since the sequence of all ordinals $\mathrm{crit}(j_{[2^n]})$ is increasing, the only possibility is $\mathrm{crit}(j_{[2^n]}) = \mathrm{crit}_n(j)$. ⊣

1.27 Lemma. *The left powers $j_{[p]}$ and $j_{[p']}$ are $\mathrm{crit}_n(j)$-equivalent if and only if $p = p' \bmod 2^n$ holds.*

Proof. We have $\mathrm{crit}(j_{[2^n]}) = \mathrm{crit}_n(j)$, so $j_{[2^n]}$ is $\mathrm{crit}_n(j)$-equivalent to the identity mapping, which by Proposition 1.19 inductively implies that $j_{[p]}$ and $j_{[2^n+p]}$ are $\mathrm{crit}_n(j)$-equivalent for every p. Hence the condition of the lemma is sufficient. On the other hand, we prove using induction on $n \geqslant 0$ that $1 \leqslant p < p' \leqslant 2^n$ implies that $j_{[p]}$ and $j_{[p']}$ are not $\mathrm{crit}_n(j)$-equivalent. The result is vacuously true for $n = 0$. Otherwise, for $p' \neq 2^{n-1} + p$, the induction hypothesis implies that $j_{[p]}$ and $j_{[p']}$ are not $\mathrm{crit}_{n-1}(j)$-equivalent, and *a fortiori* they are not $\mathrm{crit}_n(j)$-equivalent. Now, assume $p' = 2^{n-1} + p$ and $j_{[p]}$ and $j_{[p']}$ are $\mathrm{crit}_n(j)$-equivalent. By applying Proposition 1.19 $2^{n-1}-p$ times, we deduce that $j_{[2^{n-1}]}$ and $j_{[2^n]}$ are $\mathrm{crit}_n(j)$-equivalent, which is impossible as we have $\mathrm{crit}(j_{[2^{n-1}]}) < \mathrm{crit}_n(j)$ and $\mathrm{crit}(j_{[2^n]}) \geqslant \mathrm{crit}_n(j)$. ⊣

We are now ready to complete the proof of Theorem 1.22.

Proof. The result is clear from Proposition 1.25 and Lemma 1.27. That $j_{[2^n]}$ and the identity mapping are $\mathrm{crit}_n(j)$-equivalent follows from $\mathrm{crit}_n(j)$ being the critical ordinal of $j_{[2^n]}$. ⊣

1.5. The Laver-Steel Theorem

Assume $j : V_\lambda \prec V_\lambda$. By Lemma 1.6, $j^n(\mathrm{crit}(j))$ is the critical ordinal of $j^{[n+1]}$, which is also, by Lemma 1.13, $j^{[n]}[j^{[n]}]$: so, in the sequence of right powers $j, j^{[2]}, j^{[3]}, \ldots$, every term is a left divisor of the next one. Kunen's bound asserts that the supremum of the critical ordinals in the previous sequence is λ. Actually, this property has nothing to do with the particular choice of the embeddings $j^{[n]}$, and it is an instance of a much stronger statement, called the Laver-Steel theorem in the sequel, which is itself a special case of a general result of John Steel [22] about the Mitchell ordering:

1.28 Theorem (Steel). *Assume that $j_1, j_2, \ldots$ is a sequence in $\mathcal{E}_\lambda$ that is increasing with respect to divisibility,* i.e., *for every n, we have $j_{n+1} = j_n[k_n]$ for some k_n in $\mathcal{E}_\lambda$. Then we have $\sup_n \mathrm{crit}(j_n) = \lambda$.*

Here we shall give a simple proof of this result due to Randall Dougherty.

1.29 Definition. Assume $j \in \mathcal{E}_\lambda$, and $\gamma < \lambda$. We say that the ordinal α is *γ-representable by j* if it can be expressed as $j(f)(x)$ where f and x belong to V_γ and f is a mapping with ordinal values. The set of all ordinals that are γ-representable by j is denoted $S_\gamma(j)$.

1.30 Lemma. *Assume $j' = j[k]$ in $\mathcal{E}_\lambda$, and let γ be an inaccessible cardinal satisfying $\mathrm{crit}(j) < \gamma < \lambda$. Then the order type of $S_\gamma(j)$ is larger than the order type of $S_\gamma(j')$.*

Proof. The point is to construct an increasing mapping of $S_\gamma(j')$ into some proper initial segment of $S_\gamma(j)$. The idea is that $S_\gamma(j')$ is (more or less) the image under j of some set $S_\delta(k)$ with $\delta < \gamma$, which we can expect to be smaller than $S_\gamma(j)$ because $\delta < \gamma$ holds and γ is inaccessible.

By Lemma 1.18, there exists an ordinal δ satisfying $\delta < \gamma \leqslant j(\delta)$. Let G be the function that maps every pair (f, x) in V_δ^2 such that f is a function with ordinal values and x lies in the domain of $k(f)$ to $k(f)(x)$. By construction, the image of G is the set $S_\delta(k)$. The cardinality of this set is at most that of V_δ^2, hence it is strictly less than γ since γ is inaccessible. So the order type of the set $S_\delta(k)$ is less than γ, and, by ordinal recursion, we construct an order-preserving mapping H of $S_\delta(k)$ onto some ordinal β below γ. Let us apply now j: the mapping $j(H)$ is also order-preserving, and it maps $j(S_\delta(k))$, which is $S_{j(\delta)}(j')$, onto $j(\beta)$. By hypothesis, $j(\delta) \geqslant \gamma$ holds, so $S_{j(\delta)}(j')$ includes $S_\gamma(j')$. Let α be an ordinal in the latter set: by definition, there exist f and x in V_γ with f a mapping with ordinal values and x an element in the domain of $j'(f)$ satisfying $\alpha = j'(f)(x)$, and we have

$$j(H)(\alpha) = j(H)(j'(f)(x)) = j(H)(j(G)((f,x))) = j(H{\circ}G)((f,x)). \quad (11.12)$$

Now both $H{\circ}G$ and (f, x) are elements of V_γ. Thus (11.12) shows that the ordinal $j(H)(\alpha)$ is γ-representable by j, and the mapping $j(H)$ is an order-preserving mapping of $S_\gamma(j')$ into $S_\gamma(j)$. Moreover, the image of the mapping H is, by definition, the ordinal β, so the image of $j(H)$ is the ordinal $j(\beta)$, and, therefore, $j(H)$ is an order-preserving mapping of $S_\gamma(j')$ into $\{\xi \in S_\gamma(j) \mid \xi < j(\beta)\}$. Now we have $j(\beta) = j(f)(0)$, where f is the mapping $\{(0, \beta)\}$. Since $\beta < \gamma$ holds, we deduce that $j(\beta)$ is itself γ-representable by j, and that the above set $\{\xi \in S_\gamma(j) \mid \xi < j(\beta)\}$ is a proper subset of $S_\gamma(j)$. So the order type of $S_\gamma(j')$, which is that of $\{\xi \in S_\gamma(j) \mid \xi < j(\beta)\}$, is strictly smaller than the order type of $S_\gamma(j)$. $\dashv$

We can now prove the Laver-Steel theorem easily.

Proof. Assume for a contradiction that there exists an ordinal γ satisfying $\gamma < \lambda$ and $\gamma > \mathrm{crit}(j_n)$ for every n. We may assume that γ is an inaccessible cardinal: indeed, by Kunen's bound, there exists an integer m such that $j_1^m(\mathrm{crit}(j_1)) \geqslant \gamma$ holds, and we know that $j_1^m(\mathrm{crit}(j_1))$ is inaccessible. Now Lemma 1.30 applies to each pair (j_n, j_{n+1}), showing that the order types of the sets $S_\gamma(j_n)$ make a decreasing sequence, which is impossible. ⊣

1.31 Theorem (Laver). *Assume $j : V_\lambda \prec V_\lambda$.*

(i) *The ordinals* $\mathrm{crit}_n(j)$ *are cofinal in* λ, i.e., *there exists no θ with $\theta < \lambda$ such that* $\mathrm{crit}_n(j) < \theta$ *holds for every n.*

(ii) *For every iterate i of j, we have* $\mathrm{crit}(i) = \mathrm{crit}_m(j)$ *for some integer m, and, therefore, i is* $\mathrm{crit}_m(j)$*-equivalent to the identity.*

Proof. (i) By definition, every entry in the sequence j, $j_{[2]}$, $j_{[3]}$, $\ldots$ is a left divisor of the next one; hence Theorem 1.28 implies that the critical ordinals of j, $j_{[2]}$, $\ldots$ are cofinal in λ. By definition, these critical ordinals are exactly the ordinals $\mathrm{crit}_n(j)$.

(ii) Proposition 1.25 implies that either $\mathrm{crit}(i) > \mathrm{crit}_m(j)$ holds for every m, or there exists m satisfying $\mathrm{crit}(i) = \mathrm{crit}_m(j)$. By (i), the first case is impossible. ⊣

Observe that the point in the previous argument is really the Laver-Steel theorem, because Proposition 1.25 or Lemma 1.23 alone do not preclude the critical ordinal of some iterate i lying above all $\mathrm{crit}_m(j)$'s.

It follows from the previous result that, for every m, the image under j of the critical ordinal $\mathrm{crit}_m(j)$ is again an ordinal of the form $\mathrm{crit}_n(j)$. Indeed, $\mathrm{crit}_m(j)$ is the critical ordinal of $j_{[2^m]}$, and, therefore, $j(\mathrm{crit}_m(j))$ is the critical ordinal of $j[j_{[2^m]}]$, hence the critical ordinal of some iterate of j and, therefore, an ordinal of the form $\mathrm{crit}_n(j)$ for some finite n.

1.6. Counting the Critical Ordinals

As we already observed, the definition of an elementary embedding implies that the critical ordinal of $j[k]$ is the image under j of the critical ordinal of k. Hence every embedding in $\mathcal{E}_\lambda$ induces an increasing injection on the critical ordinals of $\mathcal{E}_\lambda$. In particular, every iterate of an embedding j acts on the critical ordinals of the iterates of j, which we have seen in the previous section consists of an ω-indexed sequence $(\mathrm{crit}_n(j))_{n<\omega}$. Let us introduce, for $j : V_\lambda \prec V_\lambda$, two mappings $\hat{j}, \tilde{j} : \omega \to \omega$ by

$$\hat{j}(m) = p \quad \text{if and only if} \quad j(\mathrm{crit}_m(j)) = \mathrm{crit}_p(j),$$

and $\tilde{j}(n) = \hat{j}^n(0)$. By definition, $\mathrm{crit}_{\tilde{j}(n)}$ is $j^n(\mathrm{crit}_0(j))$, so, if we use κ for $\mathrm{crit}(j)$ and κ_n for $j^n(\kappa)$, we simply have $\mathrm{crit}_{\tilde{j}(n)} = \kappa_n$: thus $\tilde{j}(n)$ is the number of critical ordinals of iterates of j below κ_n.

The aim of this section is to prove the following result:

1.32 Theorem (Dougherty [7]). *For $j : V_\lambda \prec V_\lambda$, the function $\tilde{\jmath}$ grows faster than any primitive recursive function.*

For the rest of the section, we fix $j : V_\lambda \prec V_\lambda$, and write γ_m for $\mathrm{crit}_m(j)$. Thus $\hat{\jmath}$ is determined by $\gamma_{\hat{\jmath}(m)} = j(\gamma_m)$ and $\tilde{\jmath}$ by $\gamma_{\tilde{\jmath}(n)} = j^n(\gamma_0)$. We are going to establish lower bounds for the values of the function $\tilde{\jmath}$. The first values of the function $\tilde{\jmath}$ can be computed exactly by determining sequences of iterated values for $j_{[p]}$. We use the notation

$$i : \Vdash\!\!\!\rightarrow \theta_0 \mapsto \theta_1 \mapsto \cdots$$

to mean that we have $\theta_0 = \mathrm{crit}(i)$, $\theta_1 = i(\theta_0)$ $(= \mathrm{crit}(i^{[2]}))$, etc. For instance, by definition of $\tilde{\jmath}$, we have

$$j : \gamma_0 \mapsto \gamma_{\tilde{\jmath}(1)} \mapsto \gamma_{\tilde{\jmath}(2)} \mapsto \gamma_{\tilde{\jmath}(3)} \mapsto \cdots .$$

Now, for each sequence of the form

$$i : \Vdash\!\!\!\rightarrow \theta_0 \mapsto \theta_1 \mapsto \theta_2 \mapsto \cdots ,$$

we deduce for each elementary embedding j_0 a new sequence

$$j_0[i] : \Vdash\!\!\!\rightarrow j_0(\theta_0) \mapsto j_0(\theta_1) \mapsto j_0(\theta_2) \mapsto \cdots .$$

Applying the previous principle to the above sequence with $j_0 = j$, and using $\tilde{\jmath}(1) = 1$, we obtain the sequence

$$j_{[2]} : \Vdash\!\!\!\rightarrow \gamma_1 \mapsto \gamma_{\tilde{\jmath}(2)} \mapsto \gamma_{\tilde{\jmath}(3)} \mapsto \cdots .$$

Applying the same principle with $j_0 = j_{[2]}$, we obtain

$$j_{[3]} : \Vdash\!\!\!\rightarrow \gamma_0 \mapsto \gamma_{\tilde{\jmath}(2)} \mapsto \gamma_{\tilde{\jmath}(3)} \mapsto \cdots .$$

Then $\gamma_2 = \mathrm{crit}(j_{[4]})$ implies $\gamma_2 = j_{[3]}(\gamma_0)$, so the previous sequence shows that the latter ordinal is $\gamma_{\tilde{\jmath}(2)}$, i.e., we have proved $\gamma_{\tilde{\jmath}(2)} = \gamma_2$, and, therefore we have $\hat{\jmath}(1) = 2$. Similar (but more tricky) arguments give $\hat{\jmath}(2) = 4$. Equivalently, we have $\tilde{\jmath}(1) = 1$, $\tilde{\jmath}(2) = 2$, $\tilde{\jmath}(3) = 4$, which means that the critical ordinals of the right powers j, $j^{[2]}$, and $j^{[3]}$ are γ_1, γ_2, and γ_4 respectively.

We turn now to the proof of Theorem 1.32. The basic argument is the following simple observation.

1.33 Lemma. *Assume that some iterate i of j satisfies $i : \gamma_p \mapsto \gamma_q \mapsto \gamma_r$. Then we have $r - q \geqslant q - p$.*

Proof. As the restriction of i to ordinals is increasing, $\gamma_p < \alpha < \alpha' < \gamma_q$ implies $\gamma_q < i(\alpha) < i(\alpha') < \gamma_r$. Moreover, if α is the critical ordinal of i_1, $i(\alpha)$ is that of $i[i_1]$, and, if i_1 is an iterate of j, so is $i[i_1]$. Hence the number of critical ordinals of iterates of j between γ_q and γ_r, which is $r - q - 1$, is at least the number of critical ordinals of iterates of j between γ_p and γ_q, which is $q - p - 1$. $\dashv$

1.34 Definition. A sequence of ordinals $(\alpha_0, \ldots, \alpha_p)$ is said to be *realizable* (with respect to j) if we have $i : \Vdash\!\!\to \alpha_0 \mapsto \cdots \mapsto \alpha_p$ for some iterate i of j. We say that the sequence $(\alpha_0, \ldots, \alpha_p)$ is a *base* for the sequence $\vec{\theta} = (\theta_0, \ldots, \theta_n)$ if, for each $m < n$, the sequence $(\alpha_0, \ldots, \alpha_p, \theta_m, \theta_{m+1})$ is realizable.

Observe that the existence of a base for a sequence $\vec{\theta}$ implies that $\vec{\theta}$ is increasing, and that, if $(a_0, \ldots, a_p)$ is a base for $\vec{\theta}$, so is every final subsequence of the form $(a_m, \ldots, \alpha_p)$: if i admits the critical sequence $\Vdash\!\!\to \alpha_0 \mapsto \cdots \mapsto \theta_m \mapsto \theta_{m+1}$, then $i^{[2]}$ admits the critical sequence $\Vdash\!\!\to \alpha_1 \mapsto \cdots \mapsto \theta_m \mapsto \theta_{m+1}$.

1.35 Lemma. *Assume that the sequence* $(\theta_0, \theta_1, \ldots)$ *admits a base. Then* $\theta_n \geqslant \gamma_{2^n}$ *holds for every* n.

Proof. Assume that (γ_p) is a base for $(\theta_0, \theta_1, \ldots)$. Define f by $\theta_n = \gamma_{f(n)}$. Lemma 1.33 gives $f(n+1) - f(n) \geqslant f(n) - p$ for every n. As $f(0) > p$ holds by definition, we deduce $f(n) \geqslant 2^n + p$ inductively. $\dashv$

For instance, the embedding $j_{[2]}$ leaves γ_0 fixed maps $\gamma_{\tilde{\jmath}(r)}$ to $\gamma_{\tilde{\jmath}(r+1)}$ for $r \geqslant 1$. So its $(r-1)$-th power with respect to composition satisfies

$$(j_{[2]})^{r-1} : \Vdash\!\!\to \gamma_1 \mapsto \gamma_{\tilde{\jmath}(r)}, \qquad \gamma_2 \mapsto \gamma_{\tilde{\jmath}(r+1)}.$$

Applying these values to the critical sequence of j, we obtain

$$(j_{[2]})^{r-1}[j] : \Vdash\!\!\to \gamma_0 \mapsto \gamma_{\tilde{\jmath}(r)} \mapsto \gamma_{\tilde{\jmath}(r+1)}.$$

Hence (γ_0) is a base for the sequence $(\gamma_{\tilde{\jmath}(1)}, \gamma_{\tilde{\jmath}(2)}, \ldots)$. Lemma 1.35 gives $\tilde{\jmath}(n) \geqslant 2^{n-1}$. In particular, we find $\tilde{\jmath}(4) \geqslant 8$. This bound destroys any hope of computing an exact value by applying the scheme used for the first values: indeed this would entail computing values until at least $j_{[255]}$. We shall see below that the value of $\tilde{\jmath}(4)$ is actually much larger than 8.

In order to improve the previous results, we use the following trick to expand the sequences admitting a base by inserting many intermediate new critical ordinals.

1.36 Lemma. *Assume* $(\alpha_0, \ldots, \alpha_p, \beta, \gamma)$ *is realizable,* $\vec{\theta}$ *is based on* (β) *and it goes from* γ *to* δ *in* n *steps. Then there exists a sequence based on* $(\alpha_0, \ldots, \alpha_p)$ *that goes from* β *to* δ *in* 2^n *steps.*

Proof. We use induction on $n \geqslant 0$. For $n = 0$, the sequence (β, γ) works, since $(\alpha_0, \ldots, \alpha_p, \beta, \gamma)$ being realizable means that (β, γ) is based on $(\alpha_0, \ldots, \alpha_p)$. For $n > 0$, let δ' be the next to last term of $\vec{\theta}$. The induction hypothesis gives a sequence $\vec{\tau}\,'$ based on $(\alpha_0, \ldots, \alpha_p)$ that goes from γ to δ' in 2^{n-1} steps. As (δ', δ) is based on (β), there exists an embedding i satisfying

$$i : \Vdash\!\!\to \beta \mapsto \delta' \mapsto \delta.$$

We define the sequence $\vec{\tau}$ by extending $\vec{\tau}\,'$ with 2^{n-1} additional terms

$$\tau_{2^{n-1}+m} = i(\tau'_m) \quad \text{for } 1 \leqslant m \leqslant 2^{n-1}.$$

By hypothesis, we have $\tau'_{2^{n-1}} = \delta'$, hence $\tau_{2^n} = i(\delta') = \delta$. So $\vec{\tau}$ goes from β to δ in 2^n steps. Moreover, $(\alpha_0, \dots, \alpha_p)$ is a base for $\vec{\tau}\,'$, so, for $0 \leqslant m < 2^{n-1}$, there exists an i'_m satisfying

$$i'_m : \Vdash\!\!\rightarrow \alpha_0 \mapsto \cdots \mapsto \alpha_p \mapsto \tau'_m \mapsto \tau'_{m+1}.$$

As β is the critical ordinal of i and $\alpha_p < \beta$ holds, this implies

$$i[i'_m] : \Vdash\!\!\rightarrow \alpha_0 \mapsto \cdots \mapsto \alpha_p \mapsto i(\tau'_m) \mapsto i(\tau'_{m+1}),$$

which shows that $(\alpha_0, \dots, \alpha_p)$ is a base for $\vec{\tau}$. Note that the case $m = 0$ works because $\tau'_0 = \beta$ implies $i(\tau'_0) = i(\beta) = \delta' = \tau_{2^{n-1}}$, as is needed. ⊣

By playing with the above construction one more time, we can obtain still longer sequences. In order to specify them, we use an *ad hoc* iteration of the exponential function, namely g_p recursively defined by $g_0(n) = n$, $g_{p+1}(0) = 0$, and $g_{p+1}(n) = g_{p+1}(n-1) + g_p(2^{g_{p+1}(n-1)})$. Thus, g_1 is an iterated exponential. Observe that $g_p(1) = 1$ holds for every p.

1.37 Lemma. *Assume $(\beta_0, \dots, \beta_{p+1}, \gamma)$ is realizable, $\vec{\theta}$ is based on (β_p, β_{p+1}) and it goes from γ to δ in n steps. Then there exists a sequence based on (β_{p+1}) that goes from γ to δ in $g_{p+1}(n)$ steps.*

Proof. We use induction on $p \geqslant 0$, and, for each p, on $n \geqslant 1$. For $n = 1$, the sequence (γ, δ) works, since, if i satisfies $\Vdash\!\!\rightarrow \beta_p \mapsto \beta_{p+1} \mapsto \gamma \mapsto \delta$, then $i^{[2]}$ satisfies $\Vdash\!\!\rightarrow \beta_{p+1} \mapsto \gamma \mapsto \delta$. Assume $n \geqslant 2$. Let δ' be the next to last term of $\vec{\theta}$. By induction hypothesis, there exists a sequence $\vec{\tau}\,'$ based on (β_{p+1}) that goes from γ to δ' in $g_{p+1}(n-1)$ steps. As in Lemma 1.36, we complete the sequence by appending new terms, but, before translating it, we still fatten it one or two more times. First, we apply Lemma 1.36 to construct a new sequence $\vec{\tau}\,''$ based on (β_p, β_{p+1}) that goes from β_{p+1} to δ' in $2^{g_{p+1}(n-1)}$ steps and is based on (β_{p-1}, β_p) for $p \neq 0$ (resp. on (β_p) for $p = 0$). For $p \neq 0$, we are in position for applying the current lemma with $p-1$ to the sequence of $\vec{\tau}\,''$. So we obtain a new sequence $\vec{\tau}\,'''$ based on (α_p), and going from β_{p+1} to δ' in $g_p(2^{g_{p+1}(n-1)})$ steps. For $p = 0$, we simply take $\vec{\tau}\,''' = \vec{\tau}\,''$: as $g_0(N) = N$ holds, this remains consistent with our notations. Now we make the translated copy: we choose i satisfying $\Vdash\!\!\rightarrow \beta_p \mapsto \beta_{p+1} \mapsto \delta' \mapsto \delta$, and complete $\vec{\tau}\,'$ with the new terms

$$\tau_{g_{p+1}(n-1)+m} = i(\tau'''_m) \quad \text{for } 0 < m \leqslant g_p(2^{g_{p+1}(n-1)}).$$

The sequence $\vec{\tau}$ has length $g_{p+1}(n-1) + g_p(2^{g_{p+1}(n-1)}) = g_{p+1}(n)$, and it goes from γ to $i(\delta')$, which is δ. It remains to verify the base condition for the new terms. Now assume that i'''_m satisfies $\Vdash\!\!\rightarrow \beta_p \mapsto \tau'''_m \mapsto \tau'''_{m+1}$. As in the proof of Lemma 1.36, we see that $i[i'''_m]$ satisfies $\Vdash\!\!\rightarrow \beta_{p+1} \mapsto i(\tau'''_m) \mapsto i(\tau'''_{m+1})$, which completes the proof, as $i(\tau'''_0) = \delta'$ guarantees continuity. ⊣

By combining Lemmas 1.36 and 1.37, we obtain:

1.38 Lemma. *Assume $(\beta_0, \dots, \beta_{p+1}, \gamma)$ is realizable, $\vec{\theta}$ is based on (β_p, β_{p+1}) and it goes from γ to δ in n steps. Then there exists a sequence based on (β_0) that goes from β_1 to δ in $h_1(h_2(\dots(h_{p+1}(n))\dots))$ steps, where $h_q(m)$ is defined to be $2^{g_q(m)}$.*

Proof. We use induction on $p \geqslant 0$. In every case, Lemma 1.37 constructs from $\vec{\theta}$ a new sequence $\vec{\theta}'$ based on (β_{p+1}) going from β_{p+1} to δ in $g_{p+1}(n)+1$ steps. Then, Lemma 1.36 constructs from $\vec{\theta}'$ a new sequence $\vec{\theta}''$ that goes from (β_{p+1}) to δ in $2^{g_{p+1}(n)}+1 = h_{p+1}(n)+1$ steps, a sequence based on (α_{p-1}, α_p) for $p \neq 0$, and on (α_p) for $p = 0$. For $p = 0$, the sequence $\vec{\theta}''$ works. Otherwise, we are in position for applying the induction hypothesis to $\vec{\theta}''$. ⊣

We deduce the following lower bound for the function $\tilde{\jmath}$.

1.39 Proposition. *Assume $j : V_\lambda \prec V_\lambda$. Then, for $n \geqslant 3$, we have*

$$\tilde{\jmath}(r) \geqslant 2^{h_1(h_2(\dots(h_{n-2}(1))\dots))}. \tag{11.13}$$

Proof. By definition, $(\gamma_{\tilde{\jmath}(n-1)}, \gamma_{\tilde{\jmath}(n)})$ is based on $(\gamma_{\tilde{\jmath}(n-3)}, \gamma_{\tilde{\jmath}(n-2)})$, and the auxiliary sequence $(\gamma_0, \dots, \gamma_{\tilde{\jmath}(n-2)})$ is realizable. Indeed, j satisfies

$$j : \Vdash\!\!\!\rightarrow \gamma_{\tilde{\jmath}(0)} \mapsto \gamma_{\tilde{\jmath}(1)} \mapsto \gamma_{\tilde{\jmath}(2)} \mapsto \gamma_{\tilde{\jmath}(3)},$$

and, therefore, we have

$$j^{[n+1]} : \Vdash\!\!\!\rightarrow \gamma_{\tilde{\jmath}(n)} \mapsto \gamma_{\tilde{\jmath}(n+1)} \mapsto \gamma_{\tilde{\jmath}(n+2)} \mapsto \gamma_{\tilde{\jmath}(n+3)}$$

for every n. By applying Lemma 1.38, we find a new sequence based on (γ_0) that goes from γ_1 to $\gamma_{\tilde{\jmath}(n)}$ in $h_1(h_2(\dots(h_{n-2}(1))\dots))$ steps. We conclude using Lemma 1.38. ⊣

We thus proved $\tilde{\jmath}(4) \geqslant 2^8 = 256$, and $\tilde{\jmath}(5) \geqslant 2^{h_1(h_2(h_3(1)))} = 2^{2^{g_1(16)}}$. It follows that $\tilde{\jmath}(5)$ is more than a tower of base 2 exponentials of height 17.

Let us recall that the Ackermann function f_p^{Ack} is defined recursively by $f_0^{\mathrm{Ack}}(n) = n+1$, $f_{p+1}^{\mathrm{Ack}}(0) = f_p^{\mathrm{Ack}}(1)$, and $f_{p+1}^{\mathrm{Ack}}(n+1) = f_p^{\mathrm{Ack}}(f_{p+1}^{\mathrm{Ack}}(n))$. We put $f_\omega^{\mathrm{Ack}}(n) = f_n^{\mathrm{Ack}}(n)$. Using the similarity between the definitions of f_p^{Ack} and g_p, it is easy to complete the proof of Theorem 1.32.

Proof. The function f_ω^{Ack} is known to grow faster than every primitive recursive function, so it is enough to show $2^{h_1(h_2(\dots(h_{n-2}(1))\dots))} \geqslant f_\omega^{\mathrm{Ack}}(n-1)$ for $n \geqslant 5$. First, we have $g_p(n+3) > f_p^{\mathrm{Ack}}(n)$ for all p, n. This is obvious for $p = 0$. Otherwise, for $n = 0$, using $g_p(2) \geqslant 3$, we find

$$g_p(3) > g_{p-1}(2^{g_p(2)}) > f_{p-1}^{\mathrm{Ack}}(6) > f_{p-1}^{\mathrm{Ack}}(1) = f_p^{\mathrm{Ack}}(0).$$

Then, for $n > 0$, we obtain

$$g_p(n+3) > g_{p-1}(2^{g_p(n+2)}) > g_{p-1}(f_p^{\mathrm{Ack}}(n-1)+3) > f_{p-1}^{\mathrm{Ack}}(f_p^{\mathrm{Ack}}(n-1)) = f_p^{\mathrm{Ack}}(n).$$

Finally, we have $g_2(n) = n+2$ for every n, and therefore

$$2^{h_1(h_2(\ldots(h_{n+2}(1))\ldots))} = 2^{h_1(h_2(\ldots(h_{n+1}(2))\ldots))} = 2^{h_1(h_2(\ldots(h_n(2^{n+3}))\ldots))} > g_n(2^{n+3})) \geqslant g_n(n+3) > f_n^{\mathrm{Ack}}(n),$$

hence $2^{h_1(h_2(\ldots(h_{n+2}(1))\ldots))} \geqslant f_\omega^{\mathrm{Ack}}(n-1)$. ⊣

Let us finally mention without proof the following strengthening of the lower bound for $\tilde{\jmath}(4)$:

1.40 Proposition (Dougherty). *For $j : V_\lambda \prec V_\lambda$, we have*

$$\tilde{\jmath}(4) \geqslant f_9^{\mathrm{Ack}}(f_8^{\mathrm{Ack}}(f_8^{\mathrm{Ack}}(254))).$$

In other words, there are at least the above huge number of critical ordinals below κ_4 in $\mathrm{Iter}(j)$.

2. The Word Problem for Self-Distributivity

The previous results about iterations of elementary embeddings have led to several applications outside set theory. The first application deals with free LD-systems and the word problem for the self-distributivity law (LD): $x(yz) = (xy)(xz)$. In 1989, Laver deduced from Lemma 1.20 that the LD-system $\mathrm{Iter}(j)$ has a specific algebraic property, namely that left division has no cycle in this LD-system, and he derived a solution for the word problem for (LD). Here we shall describe these results, following the independent and technically more simple approach of [4].

2.1. Iterated Left Division in LD-systems

For $(S, *)$ a (non-associative) algebraic system, and x, y in S, we say that x is a *left divisor* of y if $y = x * z$ holds for some z in S; we say that x is an *iterated left divisor* of y, and stipulate $x \sqsubset y$ if, for some positive k, there exist $z_1, \ldots, z_k$ satisfying $y = (\ldots((x * z_1) * z_2)\ldots) * z_k$. So $\sqsubset$ is the transitive closure of left divisibility. In the sequel, we shall be interested in LD-systems where left division (or, equivalently, iterated left division) has no cycle.

We let T_n be the set of all terms constructed using the variables $x_1, \ldots, x_n$ and a binary operator $*$, and T_∞ for the union of all T_n's. We denote by $=_{LD}$ the congruence on T_∞ generated by all pairs of the form $(t_1 * (t_2 * t_3)), (t_1 * t_2) * (t_1 * t_3))$. Then, by standard arguments, $T_n/{=_{LD}}$ is a free LD-system with n generators, which we shall denote by F_n. The word problem for (LD) is the question of algorithmically deciding the relation $=_{LD}$.

2.1 Theorem (Dehornoy [4]; also Laver [18] for an independent approach). *Assume that there exists at least one* LD*-system where left division has no cycle.*

(i) *Iterated left division in a free* LD*-system with one generator is a linear ordering.*

(ii) *The word problem for* (LD) *is decidable.*

The rest of this subsection is an outline of the proof of this statement, which can be skipped by a reader exclusively interested in set theory.

2.2 Definition. For t, t' terms in T_∞, we say that t' is an LD-*expansion* of t if we can go from t to t' by applying finitely many transformations consisting of replacing a subterm of the form $t_1 * (t_2 * t_3)$ with the corresponding term $(t_1 * t_2) * (t_1 * t_3)$.

By definition, t' being LD-equivalent to t means that we can transform t to t' by applying the law (LD) in either direction, i.e., from $x * (y * z)$ to $(x * y) * (x * z)$ or *vice versa*, while t' being an LD-expansion of t means that we transform t to t' by applying (LD), but only in the expanding direction, i.e., from $x * (y * z)$ to $(x * y) * (x * z)$, but not in the converse, contracting direction.

2.3 Definition. For t a term and k small enough, we denote by $\mathrm{left}^k(t)$ the kth iterated left subterm of t: we have $\mathrm{left}^0(t) = t$ for every t, and $\mathrm{left}^k(t) = \mathrm{left}^{k-1}(t_1)$ for $t = t_1 * t_2$ and $k \geqslant 1$. For t_1, t_2 in T_∞, we say that $t_1 \sqsubset_{LD} t_2$ is true if we have $t'_1 = \mathrm{left}^k(t'_2)$ for some k, t'_1, t'_2 satisfying $k \geqslant 1$, $t'_1 =_{LD} t_1$, and $t'_2 =_{LD} t_2$.

By construction, saying that $t_1 \sqsubset_{LD} t_2$ is true in T_1 is equivalent to saying that the class of t_1 in the free LD-system F_1 is an iterated left divisor of the class of t_2. The core of the argument is:

2.4 Proposition. *Let t_1, t_2 be one-variable terms in T_1. Then at least one of $t_1 \sqsubset_{LD} t_2$, $t_1 =_{LD} t_2$, $t_2 \sqsubset_{LD} t_1$ holds.*

2.5 Corollary. *If $(S, *)$ is an* LD*-system with one generator, then any two elements of S are comparable with respect to iterated left division.*

Proving Proposition 2.4 relies on three specific properties of left self-distributivity. As in Sect. 1, we use the notation $x^{[n]}$ for the nth right power of x.

2.6 Lemma.

(i) *For every term t in T_1, we have $x^{[n+1]} =_{LD} t * x^{[n]}$ for n sufficiently large.*

(ii) *Assume that $\mathrm{left}^n(t)$ is defined, and t' is an* LD*-expansion of t. Then $\mathrm{left}^{n'}(t')$ is an* LD*-expansion of $\mathrm{left}^n(t)$ for some $n' \geqslant n$.*

(iii) *Any two* LD-*equivalent terms admit a common* LD-*expansion.*

We skip the purely algebraic proofs of these properties, and just explain how to derive Proposition 2.4.

Proof. Let t_1, t_2 be arbitrary terms in T_1. By Lemma 2.6(i), we have $t_1 * x^{[n]} =_{LD} x^{[n+1]} =_{LD} t_2 * x^{[n]}$ for n sufficiently large. Fix such a n. By Lemma 2.6(iii), the terms $t_1 * x^{[n]}$ and $t_2 * x^{[n]}$ admit a common LD-expansion, say t. By Lemma 2.6(ii), there exist nonnegative integers n_1, n_2 such that, for $i = 1, 2$, the term $\mathrm{left}^{n_i}(t)$ is an LD-expansion of $\mathrm{left}(t_i * x^{[n]})$, i.e., of t_i. Thus we have $t_1 =_{LD} \mathrm{left}^{n_1}(t)$, and $t_2 =_{LD} \mathrm{left}^{n_2}(t)$. Three cases may occur: for $n_1 > n_2$, $\mathrm{left}^{n_1}(t)$ is an iterated left subterm of $\mathrm{left}^{n_2}(t)$, and, therefore, $t_1 \sqsubset_{LD} t_2$ holds; for $n_1 = n_2$, t_1 and t_2 both are LD-equivalent to $\mathrm{left}^{n_1}(t)$, and $t_1 =_{LD} t_2$ is true; finally, for $n_1 < n_2$, $\mathrm{left}^{n_2}(t)$ is an iterated left subterm of $\mathrm{left}^{n_1}(t)$, and, therefore, $t_2 \sqsubset_{LD} t_1$ holds. ⊣

Finally, we can complete the proof of Theorem 2.1.

Proof. (i) Proposition 2.4 tells us that any two elements of the free LD-system F_1 are comparable with respect to the iterated left divisibility relation. Assume that S is any LD-system. The universal property of free LD-systems gives a homomorphism π of F_1 into S. If $(a_1, \ldots, a_n)$ is a cycle for left division in F_1, then $(\pi(a_1), \ldots, \pi(a_n))$ is a cycle for left division in S. So, if there exists at least one LD-system S where left division has no cycle, the same is true for F_1, i.e., the iterated left divisibility relation of F_1 is irreflexive. As it is always transitive, it is a (strict) linear ordering.

(ii) Let us consider the case of one variable terms first. For t_1, t_2 in T_1, we can decide whether $t_1 =_{LD} t_2$ is true as follows: we systematically enumerate all pairs (t_1', t_2') such that t_1' is LD-equivalent to t_1 and t_2' is LD-equivalent to t_2. By Proposition 2.4, there will eventually appear some pair (t_1', t_2') such that either t_1' and t_2' are equal, or t_1' is a proper iterated left subterm of t_2', or t_2' is a proper iterated left subterm of t_1'. In the first case, we conclude that $t_1 =_{LD} t_2$ is true, in the other cases, we can conclude that $t_1 =_{LD} t_2$ is false whenever we know that $t \sqsubset_{LD} t'$ excludes $t =_{LD} t'$, i.e., whenever we know that left division has no cycle in F_1.

The case of terms with several variables is not more difficult. For t in T_∞, let $t^\dagger$ denote the term obtained from t by replacing all variables with x_1. For t_1, t_2 in T_n, we can decide whether $t_1 =_{LD} t_2$ is true as follows. First we compare $t_1^\dagger$ and $t_2^\dagger$ as above. If the latter terms are not LD-equivalent, then t_1 and t_2 are not LD-equivalent either. Otherwise, we can find a common LD-expansion t of $t_1^\dagger$ and $t_2^\dagger$. Then we consider the LD-expansion t_1' of t_1 obtained in the same way as t is obtained from $t_1^\dagger$, i.e., by applying (LD) at the same successive positions, and, similarly, we consider t_2' obtained from t_2 as t is obtained from $t_2^\dagger$. Then, either t_1' and t_2' are equal, in which case we conclude that $t_1 =_{LD} t_2$ is true, or t_1' and t_2' have some variable clash, in which case, using the techniques of Lemma 2.6(iii), we can conclude that $t_1 =_{LD} t_2$ is false. ⊣

2.2. Using Elementary Embeddings

In the mid-1980's, Laver showed the following:

2.7 Proposition (Laver). *Left division in the* LD*-system* $\mathcal{E}_\lambda$ *has no cycle.*

Proof. Assume that $j_1, \dots, j_n$ is a cycle for left division in $\mathcal{E}_\lambda$. Consider the infinite periodic sequence $j_1, \dots, j_n, j_1, \dots, j_n, j_1, \dots$. Theorem 1.28 applies, and it asserts that the supremum of the critical ordinals in this sequence is λ. But, on the other hand, there are only n different embeddings in the sequence, and the supremum of finitely many ordinals below λ cannot be λ, a contradiction. ⊣

The original proof of the previous result in [18] did not use the Laver-Steel theorem, but instead a direct computation based on Lemma 1.20.

Using the results of Sect. 2.1, we immediately deduce:

2.8 Theorem (Laver, 1989). *Assume Axiom* (I3). *Then:*

(i) *Iterated left division in a free* LD*-system with one generator is a linear ordering.*

(ii) *The word problem for* (LD) *is decidable.*

Another application of Proposition 2.7 is a complete algebraic characterization of the LD-system made by the iterations of an elementary embedding.

2.9 Lemma ("Laver's criterion"). *A sufficient condition for an* LD*-system* S *with one generator to be free is that left division in* S *has no cycle.*

Proof. Assume that left division in S has no cycle. Let π be a surjective homomorphism of F_1 onto S, which exists by the universal property of F_1. Let x, y be distinct elements of F_1. By Corollary 2.5, at least one of $x \sqsubset y$, $y \sqsubset x$ is true in F_1, which implies that at least one of $\pi(x) \sqsubset \pi(y)$, $\pi(y) \sqsubset \pi(x)$ is true in S. The hypothesis that left division has no cycle in S implies that, in S, the relation $a \sqsubset b$ excludes $a = b$. So, here, we deduce that $\pi(x) \neq \pi(y)$ is true in every case, which means that π is injective, and, therefore, it is an isomorphism, i.e., S is free. ⊣

We deduce the first part of the following result

2.10 Theorem (Laver). *Assume* $j : V_\lambda \prec V_\lambda$. *Then* $\mathrm{Iter}(j)$ *equipped with the application operation is a free* LD*-system, and* $\mathrm{Iter}^*(j)$ *equipped with application and composition is a free* LD*-monoid.*

We skip the details for the LD-monoid structure, which are easy. The general philosophy is that, in an LD-monoid, most of the nontrivial information is concentrated in the self-distributive operation. In particular, if X is any set and F_X is the free LD-system based on X, then the free LD-monoid based on X is the free monoid generated by F_X, quotiented under the congruence generated by the pairs $(x \cdot y, (x * y) \cdot x)$. It easily follows that there exists a realization of the free monoid based on X inside the free LD-system based on X. So, in particular, every solution for the word problem for (LD) gives a solution for the word problem of the laws that define LD-monoids.

2.3. Avoiding Elementary Embeddings

The situation created by Theorem 2.8 was strange, as one would expect no link between large cardinals and such a simple combinatorial property as the word problem for (LD). Therefore, finding an alternative proof not relying on a large cardinal axiom—or proving that some set-theoretic axiom is needed here—was a natural challenge.

2.11 Theorem (Dehornoy [5]). *That left division in the free* LD*-system with one generator has no cycle is a theorem of* ZFC*.*

Outline of Proof. The argument of [5] consists in studying the law (LD) by introducing a certain monoid $\mathcal{G}_{LD}$ that captures its specific geometry. Viewing terms as binary trees, one considers, for each possible address α of a subterm, the partial operator Ω_α on terms corresponding to applying (LD) at position α in the expanding direction, i.e., expanding the subterm rooted at the vertex specified by α. If $\mathcal{G}_{LD}$ is the monoid generated by all operators $\Omega_\alpha^{\pm 1}$ using composition, then two terms t, t' are LD-equivalent if and only if some element of $\mathcal{G}_{LD}$ maps t to t'. Because the operators Ω_α are partial in an essential way, the monoid $\mathcal{G}_{LD}$ is not a group. However, one can guess a presentation of $\mathcal{G}_{LD}$ and work with the group G_{LD} admitting that presentation. Then the key step is to construct a realization of the free LD-system with one generator in some quotient of G_{LD}, a construction that is reminiscent of Henkin's proof of the completeness theorem. The problem is to associate with each term t in T_1 a distinguished operator in $\mathcal{G}_{LD}$ (or its copy in the group G_{LD}) in such a way that the obstruction to satisfying (LD) can be controlled. The solution is given by Lemma 2.6(i): the latter asserts that, for each term t, the term $x^{[n+1]}$ is LD-equivalent to $t * x^{[n]}$ for n sufficiently large, so some operator χ_t in $\mathcal{G}_{LD}$ must map $x^{[n+1]}$ to $t * x^{[n]}$, i.e., in some sense, construct the term t. Moreover Lemma 2.6(i) gives an explicit recursive definition of χ_t in terms of χ_{t_1} and χ_{t_2} when t is $t_1 * t_2$. Translating this definition into G_{LD} yields a self-distributive operation on some quotient of G_{LD}, and proving that left division has no cycle in the LD-system so obtained is then easy—but requires a number of verifications. $\dashv$

2.12 Remark. A relevant geometry group can be constructed for every algebraic law (or family of algebraic laws). When the self-distributivity law is replaced with the associativity law, the corresponding group is Richard Thompson's group F [2]. So G_{LD} is an analog of F.

Theorem 2.11 allows one to eliminate any set-theoretic assumption from the statements of Theorem 2.8. Actually, it gives more. Indeed, the quotient of G_{LD} appearing in the above proof turns out to be Artin's braid group B_∞, and the results about G_{LD} led to unexpected braid applications.

Artin's braid group B_n admits many equivalent definitions. Usually, B_n is introduced for $2 \leqslant n \leqslant \infty$ as the group generated by elements σ_i, $1 \leqslant i < n$, subject to the relations

$$\sigma_i\sigma_j = \sigma_j\sigma_i \quad \text{for } |i-j| \geqslant 2, \qquad \sigma_i\sigma_j\sigma_i = \sigma_j\sigma_i\sigma_j \quad \text{for } |i-j| = 1. \tag{11.14}$$

The connection with braid diagrams comes when σ_i is associated with an n-strand diagram where the $(i+1)$st strand crosses over the ith strand; then the relations in (11.14) correspond to ambient isotopy.

2.13 Theorem (Dehornoy [5]). *For x, y in B_∞, say that $x < y$ holds if, among all possible expressions of $x^{-1}y$ in terms of the $\sigma_i^{\pm 1}$, there is at least one where the generator σ_i of minimal index i occurs only positively (i.e., no σ_i^{-1}). Then the relation $<$ is a left-invariant linear ordering on B_∞.*

The result is a consequence of Theorem 2.11. Indeed, there exists a (partial) action of the group B_n on the nth power of every left cancellative LD-system, and one obtains a linear ordering on B_n by defining, for x, y in B_n and $\vec{a}$ in F_1^n, the relation $x <_{\vec{a}} y$ to mean that $\vec{a} \cdot x$ is lexicographically smaller than $\vec{a} \cdot y$. One then checks that $<_{\vec{a}}$ does not depend on the choice of $\vec{a}$ and it coincides with the relation $<$ of Theorem 2.13. In this way, one obtains the previously unknown result that braid groups are orderable. A number of alternative definitions of the braid order have been found subsequently, in particular in terms of homeomorphisms of a punctured disk, and of hyperbolic geometry [6]. Various results have been derived, in particular new efficient solutions for the word problem of B_n with possible cryptographic applications.

The following result, first discovered by Laver (well-foundedness), was then made more explicit by Serge Burckel (computation of the order type):

2.14 Theorem (Laver [20], Burckel [1]). *For each n, the restriction of the braid ordering to the braids that can be expressed without any σ_i^{-1} is a well-ordering of type $\omega^{\omega^{n-2}}$.*

Returning to self-distributivity, we can mention as a last application a simple solution to the word problem for (LD) involving the braid group B_∞. Indeed, translating the inductive proof of Lemma 2.6(i) to B_∞ leads to the explicit operation

$$x * y = x\,\mathrm{sh}(y)\sigma_1\mathrm{sh}(x)^{-1}, \tag{11.15}$$

where sh is the endomorphism that maps σ_i to σ_{i+1} for every i. Laver's criterion Lemma 2.9 implies that every sub-LD-system of $(B_\infty, *)$ with one generator is free, i.e., that $(B_\infty, *)$ is a torsion-free LD-system. Then, in order to decide whether two terms on one variable are LD-equivalent, it suffices to compare their evaluations in B_∞ when x is mapped to 1 and (11.15) is used. Note that, once (11.15) has been guessed, checking that it defines a self-distributive operation on B_∞ is easy, and, therefore, any argument proving that left division in $(B_\infty, *)$ has no cycle is sufficient for fulfilling the assumptions of Theorem 2.1 without resorting to the rather convoluted construction of G_{LD}. Several such arguments have been given, in particular by David Larue using automorphisms of a free group [16] and by Ivan Dynnikov using laminations [6].

The developments sketched above have no connection with set theory. As large cardinal axioms turned out to be unnecessary, one could argue that set theory is not involved here, and deny that any of these developments can be called an application of set theory. The author disagrees with such an opinion. Had not set theory given the first hint that the algebraic properties of LD-systems are a deep subject [17, 3], then it is not clear that anyone would have tried to really understand the law (LD). The production of an LD-system with acyclic division using large cardinals gave evidence that some other example might be found in ZFC, and hastened its discovery. Without set theory, it is likely that the braid order would not have been discovered, at least as soon:[1] could not this be accepted as a definition for an application of set theory? It is tempting to compare the role of set theory here with the role of physics when it gives evidence for some formulas that remain then to be proved in a standard mathematical framework.

3. Periods in the Laver Tables

Here we describe another combinatorial application of the set theoretic results of Sect. 1. This application involves some finite LD-systems discovered by Laver in his study of iterations of elementary embeddings [19]. In contrast to the results mentioned in Sect. 2, these results have not yet received any ZF proof.

3.1. Finite LD-Systems

The results of Sect. 1.4 give, for each $j : V_\lambda \prec V_\lambda$, an infinite family of finite quotients of $\mathrm{Iter}(j)$, namely one with 2^n elements for each n. The finite LD-systems so obtained will be called the Laver tables. In this section, we show how to construct the Laver tables directly, and list some of their properties.

Let us address the question of constructing a finite LD-system with one generator. We start with an incomplete table on the elements $1, \dots, N$, and try to complete it by using the self-distributivity law. Here, we consider the case when the first column is assumed to be cyclic, i.e., we have

$$a * 1 = a + 1, \quad \text{for } a = 1, \dots, N-1, \; N * 1 = 1. \tag{11.16}$$

[1] *A posteriori*, it became clear that the orderability of braid groups could have been deduced from old work by Nielsen, but this was not noted until recently.

3.1 Lemma.

(i) *For every N, there exists a unique operation $*$ on $\{1, \ldots, N\}$ satisfying* (11.16) *and, for all a, b,*

$$a * (b * 1) = (a * b) * (a * 1).$$

(ii) *The following relations hold in the resulting system:*

$$a * b \begin{cases} = b & \textit{for } a = N, \\ = a + 1 & \textit{for } b = 1, \textit{ and for } a * (b-1) = N, \\ > a * (b-1) & \textit{otherwise.} \end{cases}$$

For $a < N$, there exists $p \leqslant N - a$ and $c_1 = a + 1 < c_2 < \cdots < c_p = N$ such that, for every b, we have $a * b = c_i$ with $i = b \pmod p$, hence, in particular, $a * b > a$.

We denote by S_N the system given by Lemma 3.1. At this point, the question is whether S_N is actually an LD-system: by construction, certain occurrences of (LD) hold in the table, but this does not guarantee that the law holds for all triples. Actually, it need not: for instance, the reader can check that, in S_5, one has $2 * (2 * 2) = 3 \neq (2 * 2) * (2 * 2) = 5$.

3.2 Proposition.

(i) *If N is not a power of 2, there exists no* LD-*system satisfying* (11.16).

(ii) *For each n, there exists a unique* LD-*system with domain $\{1, \ldots, 2^n\}$ that satisfies* (11.16)*, namely the system S_{2^n} of Lemma 3.1.*

The combinatorial proof relies on an intermediate result, namely that S_N is an LD-system if and only if the equality $a * N = N$ is true for every a. It is not hard to see that this is impossible when N is not a power of 2. On the other hand, the verification of the property when N is a power of 2 relies on the following connection between S_N and $S_{N'}$ when N' is a multiple of N:

3.3 Lemma.

(i) *Assume that S is an* LD-*system and $g_{[N'+1]} = g$ holds in S. Then mapping a to $g_{[a]}$ defines a homomorphism of $S_{N'}$ into S.*

(ii) *In particular, if S_N is an* LD-*system and N divides N', then mapping a to $a \bmod N$ defines a homomorphism of $S_{N'}$ onto S_N.*

(Here $a \bmod N$ denotes the unique integer equal to a *modulo* N lying in the interval $\{1, \ldots, N\}$.)

3.4 Definition. For $n \geqslant 0$, the nth Laver table, denoted A_n, is defined to be the LD-system S_{2^n}, i.e., the unique LD-system with domain $\{1, 2, \ldots, 2^n\}$ that satisfies (11.16).

The first Laver tables are

A_0	1
1	1

A_1	1	2
1	2	2
2	1	2

A_2	1	2	3	4
1	2	4	2	4
2	3	4	3	4
3	4	4	4	4
4	1	2	3	4

A_3	1	2	3	4	5	6	7	8
1	2	4	6	8	2	4	6	8
2	3	4	7	8	3	4	7	8
3	4	8	4	8	4	8	4	8
4	5	6	7	8	5	6	7	8
5	6	8	6	8	6	8	6	8
6	7	8	7	8	7	8	7	8
7	8	8	8	8	8	8	8	8
8	1	2	3	4	5	6	7	8

The reader can compute that the first row of A_4 is $2, 12, 14, 16, 2, \ldots$, while that of A_5 is $2, 12, 14, 16, 28, 30, 32, 2, \ldots$.

By Lemma 3.1, every row in A_n is periodic and it comes in the proof of Proposition 3.2 that the corresponding period is a power of 2. In the sequel, we write $o_n(a)$ for the number such that $2^{o_n(a)}$ is the period of a in A_n, i.e., the number of distinct values in the row of a. The examples above show that the periods of 1 in $A_0, \ldots, A_5$ are $1, 1, 2, 4, 4$, and 8 respectively, corresponding to the equalities $o_0(1) = 0$, $o_1(1) = 0$, $o_2(1) = 1$, $o_3(1) = 2$, $o_4(1) = 2$, $o_5(1) = 3$. Observe that the above values are non-decreasing.

It is not hard to prove that, for each n, the unique generator of A_n is 1, its unique idempotent is 2^n, and we have $2^n *_n a = a$ and $a *_n 2^n = 2^n$ for every a.

An important point is the existence of a close connection between the tables A_n and A_{n+1} for every n (we write $*_n$ for the multiplication in A_n):

3.5 Lemma.

(i) *For each n, the mapping $a \mapsto a \bmod 2^n$ is a surjective morphism of A_{n+1} onto A_n.*

(ii) *For every n, and every a with $1 \leqslant a \leqslant 2^n$, there exists a number $\theta_{n+1}(a)$ with $0 \leqslant \theta_{n+1}(a) \leqslant 2^{o_n(a)}$ and $\theta_{n+1}(2^n) = 0$ such that, for every b with $1 \leqslant b \leqslant 2^n$, we have*

$$a *_{n+1} b = a *_{n+1} (2^n + b) = \begin{cases} a *_n b & \text{for } b \leqslant \theta_{n+1}(a), \\ a *_n b + 2^n & \text{for } b > \theta_{n+1}(a), \end{cases}$$

$$(2^n + a) *_{n+1} b = (2^n + a) *_{n+1} (2^n + b) = a *_n b + 2^n.$$

For instance, the values of the mapping θ_4 are

a	1	2	3	4	5	6	7	8
$\theta_4(a)$	1	1	2	4	2	2	1	0

We obtain in this way a short description of A_n: the above 8 values contain all information needed for constructing the table of A_4 (16×16 elements) from that of A_3.

The LD-systems A_n play a fundamental role among finite LD-systems. In particular, it is shown in [12] how every LD-system with one generator can be obtained by various explicit operations (analogous to products) from a well-defined unique table A_n. Let us mention that as an LD-system A_n admits the presentation $\langle g \mid g_{[m+1]} = g\rangle$ for every number m of the form $2^n(2p+1)$, and that the structure $(A_n, *)$ can be enriched with a second binary operation so as to become an LD-monoid:

3.6 Proposition. *There exists a unique associative product on A_n that turns $(A_n, *, \cdot)$ into an* LD*-monoid, namely the operation defined by*

$$a \cdot b = (a * (b+1)) - 1 \quad \text{for } b < 2^n, \qquad a \cdot b = a \quad \text{for } b = 2^n. \tag{11.17}$$

3.2. Using Elementary Embeddings

In order to establish a connection between the tables A_n of the previous section and the finite quotients of $\mathrm{Iter}(j)$ described in Sect. 1.4, we shall use the following characterization:

3.7 Lemma. *Assume that S is an* LD*-system admitting a single generator g satisfying $g_{[2^n+1]} = g$ and $g_{[a]} \neq g$ for $a \leqslant 2^n$. Then S is isomorphic to A_n.*

Proof. Assume that S is an LD-system generated by an element g satisfying the above conditions. A double induction gives, for $a, b \leqslant 2^n$, the equality $g_{[a]} * g_{[b]} = g_{[a*b]}$, where $a * b$ refers to the product in A_n. So the set of all left powers of g is closed under product, and S, which has exactly 2^n elements, is isomorphic to A_n. ⊣

We immediately deduce from Theorem 1.22:

3.8 Proposition (Laver [19]). *For $j : V_\lambda \prec V_\lambda$, the quotient of* $\mathrm{Iter}(j)$ *under* $\mathrm{crit}_n(j)$*-equivalence is isomorphic to A_n.*

Under the previous isomorphism, the element a of A_n is the image of the class of the embedding $j_{[a]}$, and, in particular, 2^n is the image of the class of $j_{[2^n]}$, which is also the class of the identity map.

By construction, if S is an LD-system, and a is an element of S, there exists a well-defined evaluation for every term t in T_1 when the variable x is given the value a. We shall use $t(1)^{A_n}$, or simply $t(1)$, for the evaluation in A_n of a term $t(x)$ of T_1 at $x = 1$, and $t(j)$ for the evaluation of $t(x)$ in $\mathrm{Iter}(j)$ at $x = j$. With this notation, it should be clear that, for every term $t(x)$, the image of the $\mathrm{crit}_n(j)$-equivalence class of $t(j)$ in A_n under the isomorphism of Proposition 3.8 is $t(1)^{A_n}$.

The previous isomorphism can be used to obtain results about the iterations of an elementary embedding. For instance, let us consider the question of determining which left powers of j are $\mathrm{crit}_4(j)$-approximations of $j \circ j$ and of $j^{[3]}$. By looking at the table of the LD-monoid A_4, we obtain

$A_4 \models 1 \circ 1 = 11$, and $A_4 \models 1^{[3]} = 12$. We deduce that $j \circ j$ is $\mathrm{crit}_4(j)$-equivalent to $j_{[11]}$ and $j^{[3]}$ is $\mathrm{crit}_4(j)$-equivalent to $j_{[12]}$.

The key to further results is the possibility of translating into the language of the finite tables A_n the values of the critical ordinals associated with the iterations of an elementary embedding.

3.9 Proposition. *Assume $j : V_\lambda \prec V_\lambda$. Then, for every term t and for $n \geqslant m \geqslant 0$ and $n \geqslant a \geqslant 1$,*

(i) $\mathrm{crit}(t(j)) \geqslant \mathrm{crit}_n(j)$ *is equivalent to* $A_n \models t(1) = 2^n$.

(ii) $\mathrm{crit}(t(j)) = \mathrm{crit}_n(j)$ *is equivalent to* $A_{n+1} \models t(1) = 2^n$.

(iii) $t(j)(\mathrm{crit}_m(j)) = \mathrm{crit}_n(j)$ *is equivalent to* $A_{n+1} \models t(1) * 2^m = 2^n$.

(iv) $j_{[a]}(\mathrm{crit}_m(j)) = \mathrm{crit}_n(j)$ *is equivalent having the period of a jump from* 2^m *to* 2^{m+1} *between* A_n *and* A_{n+1}.

Proof. (i) By definition, $\mathrm{crit}(t(j)) \geqslant \mathrm{crit}_n(j)$ is equivalent to $t(j)$ being $\mathrm{crit}_n(j)$-equivalent to the identity mapping, hence to the image of $t(j)$ in A_n being the image of the identity, which is 2^n.

(ii) Assume $\mathrm{crit}(t(j)) = \mathrm{crit}_n(j)$. Then we have $\mathrm{crit}(t(j)) \geqslant \mathrm{crit}_n(j)$ and $\mathrm{crit}(t(j)) \not\geqslant \mathrm{crit}_{n+1}(j)$, so, by (i), $A_n \models t(1) = 2^n$ and $A_{n+1} \not\models t(1) = 2^{n+1}$. Now $A_n \models t(1) = 2^n$ implies $A_{n+1} \models t(1) = 2^n$ or 2^{n+1}, so 2^n is the only possible value here. Conversely, $A_{n+1} \models t(1) = 2^n$ implies $A_n \models t(1) = 2^n$ and $A_{n+1} \not\models t(1) = 2^{n+1}$, so, by (i), $\mathrm{crit}(t(j)) \geqslant \mathrm{crit}_n(j)$ and $\mathrm{crit}(t(j)) \not\geqslant \mathrm{crit}_{n+1}(j)$, hence $\mathrm{crit}(t(j)) = \mathrm{crit}_n(j)$.

(iii) As $\mathrm{crit}_m(j)$ is the critical ordinal of $j_{[2^m]}$, we have $t(j)(\mathrm{crit}_m(j)) = \mathrm{crit}(t(j)[j_{[2^m]}])$. By (ii), $\mathrm{crit}(t(j)[j_{[2^m]}]) = \mathrm{crit}_n(j)$ is equivalent to $A_{n+1} \models t(1) * 1_{[2^m]} = 2^n$. Now we have $A_{n+1} \models 1_{[2^m]} = 2^m$ for $n \geqslant m$.

(iv) The image of $j_{[a]}$ is a both in A_n and A_{n+1}, hence (iii) tells us that $j_{[a]}(\mathrm{crit}_m(j)) = \mathrm{crit}_n(j)$ is equivalent to $A_{n+1} \models a * 2^m = 2^n$. If the latter holds, the period p of a in A_{n+1} is 2^{m+1}: indeed, $A_{n+1} \models a * 2^m < 2^{n+1}$ implies $p > 2^m$, while $2 \times 2^n = 2^{n+1}$ implies $p \leqslant 2 \times 2^m$. Conversely, assume that the period of a is 2^m in A_n and 2^{m+1} in A_{n+1}. We deduce $A_n \models a * 2^m = 2^n$ and $A_{n+1} \not\models a * 2^m = 2^{n+1}$, so the only possibility is $A_{n+1} \models a * 2^m = 2^n$. ⊣

For instance, we can check $A_3 \models 1^{[3]} = 4$, and $A_5 \models 1^{[4]} = 16$. Using the dictionary, we deduce that the critical ordinal of $j^{[3]}$ is $\mathrm{crit}_2(j)$, while the critical ordinal of $j^{[4]}$ is $\mathrm{crit}_4(j)$. Also, we find $A_4 \models 4 * 4 = 8$, which implies that $j_{[4]}$ maps $\mathrm{crit}_2(j)$ to $\mathrm{crit}_3(j)$—as can be established directly. Similarly, we have $A_5 \models 1 * 4 = 16$, corresponding to $j(\mathrm{crit}_2(j)) = \mathrm{crit}_4(j)$. As for (iv), we see that the period of 1 jumps from 1 to 2 between A_1 and A_2, that it jumps from 2 to 4 between A_2 and A_3, and that it jumps from 4 to 8 between A_4 and A_5. We deduce that, if j is an elementary embedding of V_λ into itself, then j maps $\mathrm{crit}_0(j)$ to $\mathrm{crit}_1(j)$, $\mathrm{crit}_1(j)$ to $\mathrm{crit}_2(j)$, and $\mathrm{crit}_2(j)$ to $\mathrm{crit}_4(j)$, i.e., we have $\kappa_2 = \gamma_4$ with the notations of Sect. 1.6. Similarly, the period of 3 jumps from 8 to 16 between A_5 and A_6: we deduce that $j_{[3]}$ maps $\mathrm{crit}_3(j)$ to $\mathrm{crit}_5(j)$.

By Proposition 3.9(iii): $\hat{\jmath}(m) = n$ is equivalent to $A_{n+1} \models 1 * 2^m = 2^n$. As the latter condition does not involve j, we deduce

3.10 Corollary. *For $j : V_\lambda \prec V_\lambda$, the mappings $\hat{\jmath}$ and $\tilde{\jmath}$ do not depend on j.*

In the previous examples, we used the connection between the iterates of an elementary embedding and the tables A_n to deduce information about elementary embeddings from explicit values in A_n. We can also use the correspondence in the other direction, and deduce results about the tables A_n from properties of the elementary embeddings.

Now, the existence of the function $\hat{\jmath}$ and, therefore, of its iterate $\tilde{\jmath}$, which we have seen is a direct consequence of the Laver-Steel theorem, translates into the following asymptotic result about the periods in the tables A_n. We recall that $o_n(a)$ denotes the integer such that the period of a in A_n is $2^{o_n(a)}$.

3.11 Proposition (Laver). *Assume Axiom* (I3). *Then, for every a, the period of a in A_n tends to infinity with n. More precisely, for $j : V_\lambda \prec V_\lambda$,*

$$o_n(a) \leqslant \tilde{\jmath}(r) \quad \textit{if and only if} \quad n \leqslant \tilde{\jmath}(r+1) \tag{11.18}$$

holds for $r \geqslant a$. In particular, (11.18) *holds for every r in the case $a = 1$.*

Proof. Assume first $a = 1$. Then j maps $\mathrm{crit}_{\tilde{\jmath}(r)}(j)$ to $\mathrm{crit}_{\tilde{\jmath}(r+1)}(j)$ for every r. Hence, by Proposition 3.9(iv), the period of 1 doubles from $2^{\tilde{\jmath}(r)}$ to $2^{\tilde{\jmath}(r)+1}$ between $A_{\tilde{\jmath}(r+1)}$ and $A_{\tilde{\jmath}(r+1)+1}$. So we have

$$o_{\tilde{\jmath}(r+1)}(1) = \tilde{\jmath}(r) \quad \text{and} \quad o_{\tilde{\jmath}(r+1)+1}(1) = \tilde{\jmath}(r) + 1,$$

which gives (11.18). Assume now $a \geqslant 2$. By Lemma 1.13, we have $(j_{[a]})^{[r]} = j^{[r+1]}$ for $r \geqslant a$, so the critical ordinal of $(j_{[a]})^{[r]}$ is $\mathrm{crit}_{\tilde{\jmath}(r)}(j)$. Hence, for $r \geqslant a$, the embedding $j_{[a]}$ maps $\mathrm{crit}_{\tilde{\jmath}(r)}(j)$ to $\mathrm{crit}_{\tilde{\jmath}(r+1)}(j)$, and the argument is as for $a = 1$. ⊣

We conclude with another result about the periods in the tables A_n.

3.12 Proposition (Laver). *Assume Axiom* (I3). *Then, for every n, the period of* 2 *in A_n is at least the period of* 1.

Proof. Assume that the period of 1 in A_n is 2^m. Let n' be the largest integer such that the period of 1 in $A_{n'}$ is 2^{m-1}. By construction, the period of 1 jumps from 2^{m-1} to 2^m between $A_{n'}$ and $A_{n'+1}$. Assume that j is a nontrivial elementary embedding of a rank into itself. By Proposition 3.9(iv), j maps $\mathrm{crit}_m(j)$ to $\mathrm{crit}_{n'}(j)$. Now, by Proposition 1.10, $j[j]$ maps $\mathrm{crit}_m(j)$ to some ordinal of the form $\mathrm{crit}_{n''}(j)$ with $n'' \leqslant n'$. This implies that the period of 2 jumps from 2^{m-1} to 2^m between $A_{n''}$ and $A_{n''+1}$. By construction, we have $n'' \leqslant n' < n$, hence the period of 2 in A_n is at least 2^m. ⊣

3.3. Avoiding Elementary Embeddings

Once again, the situation of Propositions 3.11 and 3.12 is strange, as it is not clear why any large cardinal hypothesis should be involved in the asymptotic behavior of the periods in the finite LD-systems A_n. So we would either get rid of the large cardinal hypothesis, or prove that it is necessary.

We shall mention partial results in both directions. In the direction of eliminating the large cardinal assumption, i.e., of getting arithmetic proofs, Dougherty and Aleš Drápal have proposed a scheme that essentially consists in computing the rows of (sufficiently many) elements $2^p - a$ in A_n using induction on a, which amounts to constructing convenient families of homomorphisms between the A_n's. Here we shall mention statements corresponding to the first two levels of the induction:

3.13 Theorem (Drápal [11]).

(i) *For every d, and for $0 \leqslant m \leqslant 2^d + 1$, $b \mapsto 2^{2^d} b$ defines an injective homomorphism of A_m into A_{m+2^d}; it follows that, for $2^d \leqslant n \leqslant 2^{d+1} + 1$, the row of $2^{2^d} - 1$ in A_n is given by*

$$(2^{2^d} - 1) *_n b = 2^{2^d} b.$$

(ii) *For every d, and for $0 \leqslant m \leqslant 2^{2^{d+1}}$, the mapping f_d defined by $f_d : 2^i \mapsto 2^{(i+1)2^d} - 2^{i2^d}$ and $f_d(\sum b_i 2^i) = \sum b_i f_d(2^i)$ defines an injective homomorphism of A_m into A_{m2^d}; it follows that, for $0 \leqslant n \leqslant 2^{2^{d+1}+d}$ such that 2^d divides n, the row of $2^{2^d} - 2$ in A_n is given by*

$$(2^{2^d} - 2) *_n b = f_d(b).$$

So far, the steps $a \leqslant 4$ have been completed, but the complexity quickly increases, and whether the full proof can be completed remains open.

3.4. Not Avoiding Elementary Embeddings?

We conclude with a result in the opposite direction:

3.14 Theorem (Dougherty-Jech [9]). *It cannot proved in* PRA *(Primitive Recursive Arithmetic) that the period of* 1 *in the table A_n goes to infinity with n.*

The idea is that enough of the computations of Sect. 1.6 can be performed in PRA to guarantee that, if the period of 1 in A_n tends to infinity with n, then some function growing faster than the Ackermann function provably exists.

Assume $j : V_\lambda \prec V_\lambda$. For every term t in T_1, the elementary embedding $t(j)$ acts on the family $\{\mathrm{crit}_n(j) \mid n \in \omega\}$, and, as was done for j, we can associate with $t(j)$ an increasing injection $\widetilde{t(j)} : \omega \to \omega$ by

$$\widetilde{t(j)}(m) = n \quad \text{if and only if} \quad t(j)(\mathrm{crit}_m(j)) = \mathrm{crit}_n(j).$$

If t and t' are LD-equivalent terms, we have $t(j) = t'(j)$, hence $\widetilde{t(j)} = \widetilde{t'(j)}$, so, for a in the free LD-system F_1, we can define f^j_a to be the common value of $\widetilde{t(j)}$ for t representing a. We obtain in this way an F_1-indexed family of increasing injections of ω to itself, distinct from identity, and, by construction, the equality

$$\mathrm{crit}(f^j_{a*b}) = f^j_a(\mathrm{crit}(f^j_b)) \tag{11.19}$$

is satisfied for all a, b in F_1, where we define $\mathrm{crit}(f)$ to be the least m satisfying $f(m) > m$. The sequence $(f^j_a \mid a \in F_1)$ is the trace of the action of j on critical ordinals, and we shall see it captures enough of the combinatorics of elementary embeddings to deduce the results of Sect. 1.6.

Let us try to construct directly, without elementary embedding, some similar family of injections on ω satisfying (11.19). To this end, we can resort to the Laver tables. Indeed, by Proposition 3.9, the condition $t(j)(\mathrm{crit}_m(j)) = \mathrm{crit}_n(j)$ in the definition of $\widetilde{t(j)}$ is equivalent to $A_{n+1} \models t(1) * 2^m = 2^n$. So we are led to

3.15 Definition (PRA). For a in F_1, we define f_a to be the partial mapping on ω such that $f_a(m) = n$ holds if, for some term t representing a, we have $A_{n+1} \models t(1) * 2^m = 2^n$.

As A_{n+1} is an LD-system, the value of $t(1)*2^m$ computed in A_{n+1} depends on the LD-class of t only, so the previous definition is non-ambiguous. If there exists a $j : V_\lambda \prec V_\lambda$, then, for each a in F_1, the mapping f_a coincides with f^j_a, and, therefore, each f_a is a total increasing injection of ω to ω, distinct from identity, and the f_a's satisfy the counterpart of (11.19). In particular, we can state

3.16 Proposition (ZFC + I3). *For each a in F_1, the function f_a is total.*

Some of the previous results about the f_a's can be proved directly. Let us define a *partial increasing injection* on ω to be an increasing function of ω into itself whose domain is either ω, or a finite initial segment of ω. We shall say that a partial increasing injection f is *nontrivial* if $f(m) > m$ holds for at least one m, and that m is the *critical integer* of f, denoted $m = \mathrm{crit}(f)$, if we have $f(n) = n$ for $n < m$, and $f(m) \neq m$, i.e., either $f(m) > m$ holds or $f(m)$ is not defined.

For f a partial increasing injection on ω, and m, n in ω, we write $f(m) \tilde{\geqslant} n$ if either $f(m)$ is defined and $f(m) \geqslant n$ holds, or $f(m)$ is not defined; we write $\mathrm{crit}(f) \tilde{\geqslant} m$ for $\forall n < m\,(f(n) = n)$. Then $f(m) = n$ is equivalent to the conjunction of $f(m) \tilde{\geqslant} n$ and $f(m) \tilde{\ngeqslant} n+1$, and $\mathrm{crit}(f) = m$ is equivalent to the conjunction of $\mathrm{crit}(f) \tilde{\geqslant} m$ and $\mathrm{crit}(f) \tilde{\ngeqslant} m+1$.

3.17 Lemma (PRA).

(i) *For every p, we have* $\mathrm{crit}(f_{x_{[2^p]}}) = p$.

(ii) *For t representing a, and for $n \geqslant m$, $f_a(m) \tilde{\geqslant} n$ is equivalent to $A_n \models t(1) * 2^m = 2^n$.*

(iii) *The mapping* f_a *is a partial increasing injection.*

(iv) *The relation* $\mathrm{crit}(f_a) \tilde{\geqslant} n$ *is equivalent to* $A_n \models t(1) = 2^n$*.*

(v) *If* $\mathrm{crit}(f_b)$ *and* $f_a(\mathrm{crit}(f_b))$ *are defined, so is* $\mathrm{crit}(f_{a*b})$ *and we have* $\mathrm{crit}(f_{a*b}) = f_a(\mathrm{crit}(f_b))$*.*

Proof. (i) First, $f_{x_{[2^p]}}(m) = m$ is equivalent to $A_{m+1} \models 1_{[2^p]} * 2^m = 2^m$ by definition. This holds for $m < p$, as we have $A_{m+1} \models 1_{[2^p]} = 2^{m+1}$, and $A_{m+1} \models 2^{m+1} * x = x$ for every x. On the other hand, $A_{m+1} \models 1_{[2^p]} = 2^m$ holds, hence so does $A_{m+1} \models 1_{[2^p]} * 2^m = 2^{m+1} \neq 2^m$. So $\mathrm{crit}(f_{x_{[2^p]}})$ exists, and it is p.

(ii) If $f_a(m) = p$ holds for some $p \geqslant n$, $A_{p+1} \models t(1) * 2^m = 2^{p+1}$, hence $A_n \models t(1) * 2^m = 2^n$ by projecting. And $f_a(m)$ not being defined means that there exists no p satisfying $A_{p+1} \models t(1) * 2^m < 2^{p+1}$: in other words $A_{p+1} \models t(1) * 2^m = 2^{p+1}$ for $p+1 \geqslant m$, and, in particular, for $p+1 = n$.

(iii) Assume $f_a(m+1) = n+1$. Then $A_{n+2} \models t(1)*2^{m+1} = 2^{n+1}$ holds, i.e., $t(1)$ has period 2^{m+2} at least in A_{n+2}. By projecting from A_{n+2} to A_{n+1}, we deduce that $t(1)$ has period 2^{m+1} at least in A_{n+1}, hence $A_{n+1} \models t(1)*2^m \leqslant 2^n$. If the latter relation is an equality, we deduce $f_a(m) = n$. Otherwise, by projecting, we find some integer $p < n$ for which $A_{p+1} \models t(1) * 2^m = 2^p$, and we deduce $f_a(m) = p$. In both cases, $f_a(m)$ exists, and its value is at most n. This shows that the domain of f_a is an initial segment of ω, and that f_a is increasing.

(iv) Assume $\mathrm{crit}(f_a) \tilde{\geqslant} n$, i.e., $f_a(m) = m$ holds for $m < n$. We have $f_a(n-1) \tilde{\ngeqslant} n$, hence $A_n \models t(1) * 2^{n-1} \leqslant 2^{n-1}$, whence $A_n \models t(1) = 2^n$, as $A_n \models a * 2^{n-1} = 2^n$ holds for $a < 2^n$. Conversely, assume $A_n \models t(1) = 2^n$, and $m < n$. By projecting from A_n to A_{m+1}, we obtain $A_{m+1} \models t(1) = 2^{m+1}$, hence $A_{m+1} \models t(1) * 2^m = 2^m < 2^{m+1}$, which gives $f_a(m) \tilde{\ngeqslant} m+1$ by (ii). As $f_a(m) \tilde{\geqslant} m$ holds by (ii), we deduce $f_a(m) = m$.

(v) Let $a, b \in F_1$ be represented by t_1 and t_2 respectively. Assume first $f_a(p) \tilde{\geqslant} n$ and $\mathrm{crit}(f_b) \tilde{\geqslant} p$. By (iv), the hypotheses are $A_n \models t_1(1)*2^p = 2^n$, and $A_p \models t_2(1) = 2^p$. By projecting from A_n to A_p, we deduce that $t_2(1)^{A_n}$ is a multiple of 2^p. Hence, the hypothesis $A_n \models t_1(1) * 2^p = 2^n$ implies $A_n \models (t_1 * t_2)(1) = t_1(1) * t_2(1) = 2^n$, hence, by (iv), $\mathrm{crit}(f_{a*n}) \tilde{\geqslant} n$.

Assume now $f_a(p) \tilde{\ngeqslant} n+1$ and $\mathrm{crit}(f_b) \tilde{\ngeqslant} p+1$. The hypotheses are $A_{n+1} \models t_1(1) * 2^p \neq 2^{n+1}$, i.e., the period of $t_1(1)$ in A_{n+1} is 2^{p+1} at least, and $A_{p+1} \models t_2(1) \neq 2^{p+1}$, hence $A_{p+1} \models t_2(1) \leqslant 2^p$. We cannot have $A_{n+1} \models t_2(1) \geqslant 2^{p+1}$ because, by projecting from A_{n+1} to A_{p+1}, we would deduce $A_{p+1} \models t_2(1) = 2^{p+1}$, contradicting our hypothesis. Hence we have $A_{n+1} \models t_2(1) \leqslant 2^p$, and the hypothesis that the period of $t_1(1)$ in A_{n+1} is 2^{p+1} at least implies $A_{n+1} \models t_1(1) * t_2(1) \leqslant 2^n$, hence $\mathrm{crit}(f_{a*b}) \tilde{\ngeqslant} n+1$. So the conjunction of $f_a(p) = n$ and $\mathrm{crit}(f_b) = p$ implies $\mathrm{crit}(f_{a*b}) = n$. ⊣

The only point we have not proved so far is that the function f_a be total. Before going further, let us observe that the latter property is connected with the asymptotic behavior of the periods in the tables A_n, as well as with several equivalent statements:

3.18 Proposition (PRA). *The following statements are equivalent:*

(i) *For each a in F_1, the function f_a is total.*

(ii) *For every term t, the period of $t(1)$ in A_n goes to infinity with n—so, in particular, the period of every fixed a in A_n goes to infinity with n.*

(iii) *The period of 1 in A_n goes to infinity with n.*

(iv) *For every r, there exists an n satisfying $A_n \models 1^{[r]} < 2^n$.*

(v) *The subsystem of the inverse limit of all A_n's generated by $(1, 1, \ldots)$ is free.*

Proof. Let t be an arbitrary term in T_1, and a be its class in F_1. Saying that the period of $t(1)$ in A_n goes to ∞ with n means that, for every m, there exists n with $A_n \models t(1) * 2^m < 2^n$, i.e., $f_a(m) \tilde{\ngeqslant} n$. If the function f_a is total, such an n certainly exists, so (i) implies (ii). Conversely, if (ii) is satisfied, the existence of n satisfying $f_a(m) \tilde{\ngeqslant} n$ implies that $f_a(m)$ is defined, so (i) and (ii) are equivalent, and they imply (iii), which is the special case $t = x$ of (ii).

Assume now (iii). By the previous argument, the mapping f_x is total. If f_a and f_b are total, then, by Lemma 3.17(v), $\mathrm{crit}(f_{b^{[n]}})$ exists for every n, and so does $f_a(\mathrm{crit}(f_{b^{[n]}}))$, which is $\mathrm{crit}(f_{(a*b)^{[n]}})$. This proves that $f_{a*b}(m)$ exists for arbitrary large values of m, and this is enough to conclude that f_{a*b} is total. So, inductively, we deduce that f_a is total for every a, which is (i).

Then, we prove that (ii) implies (iv) using induction on $r \geqslant 1$. The result is obvious for $r = 1$. Let p be maximal satisfying $A_p \models 1^{[r-1]} = 2^p$, which exists by induction hypothesis. By (ii), we have $A_n \models 1 * 2^p < 2^n$ for some $n > p$, so the period of 1 in A_n is a multiple of 2^{p+1}. By hypothesis, we have $A_{p+1} \models 1^{[r-1]} = 2^p$, hence $A_n \models 1^{[r-1]} = 2^p \bmod 2^{p+1}$, so 2^p is the largest power of 2 that divides $1^{[r-1]}$ computed in A_n. As the period of 1 in A_n is a multiple of 2^{p+1}, we obtain $A_n \not\models 1 * 1^{[r-1]} = 2^n$, so $A_n \models 1^{[r]} = 1 * 1^{[r-1]} < 2^n$.

Assume now (iv), and let t be an arbitrary term. By Lemma 2.6(i), there exist q, r satisfying $t^{[r]} =_{LD} x^{[q]}$. By (iv), $A_n \models 1^{[q]} = t(1)^{[r]} < 2^n$ for some n, hence $A_n \models t(1) < 2^n$, since every right power of 2^n in A_n is 2^n. Hence (iv) implies (iii).

Assume (i), and let $t, t_1, \ldots, t_p$ be arbitrary terms. By (ii), we can find n such that none of the terms $t, t*t_1, (t*t_1)*t_2, \ldots, (\ldots(t*t_1)\ldots)*t_p$ evaluated at 1 in A_n is 2^n: this is possible since $A_n \models t(1) \neq 2^n$ implies $A_m \models t(1) \neq 2^m$ for $m \geqslant n$. So we have

$$A_n \models t(1) < (t * t_1)(1) < ((t * t_1) * t_2)(1) < \cdots$$

and, in particular, $A_n \models t(1) \neq (\cdots(t * t_1)*) \cdots * t_p)(1)$. This implies that left division in the sub-LD-system of the inverse limit of all A_n's generated by $(1, 1, \ldots)$ has no cycle, and, therefore, by Laver's criterion, this LD-system is free. Conversely, assume that (i) fails, i.e., there exists a $p \geqslant 1$ such that $A_n \models 1 * 2^p = 2^n$ for every n. Let α denote the sequence $(1, 1, \ldots)$ in the inverse limit. Then we have $\alpha_{[2^p]} = (1, 2, \ldots, 2^p, 2^p, \ldots)$ and

$$\alpha * \alpha_{[2^p+1]} = (\alpha * \alpha_{[2^p]}) * (\alpha * \alpha) = \alpha * \alpha.$$

The sub-LD-system generated by α cannot be free, since $g * g = g * g_{[2^p+1]}$ does not hold in the free LD-system generated by g. So (v) is equivalent to (i)–(iv). ⊣

The status of the equivalent statements of Proposition 3.18 remains currently open. However, the results of Sect. 1.6 enable us to say more. We have seen that the function $\tilde{\jmath}$ associated with an elementary embedding j grows faster than any primitive recursive function. In terms of the functions f_a^j, we have $\tilde{\jmath}(n) = (f_x^j)^n(0)$. As the functions f_a^j and f_a coincide when the former exist, it is natural to look at the values $f_x^n(0)$. The point is that we can obtain for this function the same lower bound as for its counterpart f_x^j without using any set theoretic hypothesis:

3.19 Proposition (PA). *Assume that, for each a, the function f_a is total. Then the function $n \mapsto f_a^n(0)$ grows faster than any primitive recursive function.*

Proof. We consider the proof of Proposition 1.32, and try to mimic it using f_a and critical integers instead of f_a^j and critical ordinals. This is possible, because the only properties used in Sect. 1.6 are the left self-distributivity law and Relation (11.19) about critical ordinals. First, the counterpart of Lemma 1.33 is true since every value of f_a is an increasing injection and its domain is an initial interval of ω. Then the definitions of a base and of a realizable sequence can be translated without any change. Let us consider Lemma 1.36. With our current notation, the point is to be able to deduce from the hypothesis

$$f_b : \Vdash\!\!\!\to m_0 \mapsto m_1 \mapsto \cdots \mapsto m_p \tag{11.20}$$

the conclusion

$$f_{a*b} : \Vdash\!\!\!\to f_a(m_0) \mapsto f_a(m_1) \mapsto \cdots \mapsto f_a(m_p). \tag{11.21}$$

An easy induction on r gives the equality $(f_a)^n(\mathrm{crit}(f_a)) = \mathrm{crit}(f_{a^{[n+1]}})$. Now (11.20) can be restated as

$$\mathrm{crit}(f_b) = m_0, \quad \mathrm{crit}(f_{b^{[2]}}) = m_1, \quad \ldots, \quad \mathrm{crit}(f_{b^{[n+1]}}) = m_n.$$

By applying f_a and using Lemma 3.17(v), we obtain

$$\mathrm{crit}(f_{a*b}) = f_a(m_0), \quad \ldots, \quad \mathrm{crit}(f_{a*b^{[n+1]}}) = f_a(m_n).$$

By (LD), we have $f_{a*b^{[n]}} = f_{(a*b)^{[n]}}$, and therefore (11.20) implies (11.21).

So the proof of Lemma 1.36 goes through in the framework of the f_a's, and so do those of the other results of Sect. 1.6. We deduce that, for $n > 3$, there are at least $2^{h_1(h_2(\dots(h_{n-2}(1))\dots))}$ critical integers below the number $f_x^n(0)$, where h_p are the fast growing function of Sect. 1.6, and, finally, we conclude that the function $n \mapsto f_x^n(0)$ grows at least as fast as the Ackermann function. $\dashv$

It is then easy to complete the proof of Theorem 3.14:

Proof. By Proposition 3.18, proving that the period of 1 in A_n goes to infinity with n is equivalent (in PRA) to proving that the functions f_a are total. By Proposition 3.19, such a proof would also give a proof of the existence of a function growing faster than the Ackermann function. The latter function is not primitive recursive, and, therefore, such a proof cannot exist in PRA. $\dashv$

As the gap between PRA and Axiom (I3) is large, there remains space for many developments here.

To conclude, let us observe that, in the proof of Proposition 3.19, the hypothesis that the injections are total is not really used. Indeed, we establish lower bounds for the values, and the precise result is an alternative: for each r, either the value of $f_x^n(0)$ is not defined, or this value is at least some explicit value. In particular, the result is local, and the lower bounds remain valid for small values of r even if $f_x^n(0)$ is not defined for some large n. So, for instance, we have seen in Sect. 1.6 that, for $j : V_\lambda \prec V_\lambda$, we have $\tilde{\jmath}(4) \geqslant 256$, which, when translated into the language of A_n, means that the period of 1 in A_n is 16 for every n between 9 and 256 at least. The above argument shows that this lower bound remains valid even if Axiom (I3) is not assumed. The same result is true with the stronger inequality of Proposition 1.40, so we obtain

3.20 Theorem (Dougherty). *If it exists, the first integer n such that the period of 1 in A_n reaches 32 is at least $f_9^{\mathrm{Ack}}(f_8^{\mathrm{Ack}}(f_8^{\mathrm{Ack}}(254)))$.*

We refer to [8, 10, 13] (and to unpublished work by Laver) for many more computations about the critical ordinals of iterated elementary embeddings.

1. Introduction

In this chapter we present a survey of the area of set theory in which iterated forcing interacts with elementary embeddings. The original plan was to concentrate on forcing constructions which preserve large cardinal axioms, particularly *reverse Easton* iterations. However this plan proved rather restrictive, so we have also treated constructions such as Baumgartner's consistency proof for the Proper Forcing Axiom. The common theme of the constructions which we present is that they involve extending elementary embeddings. We have not treated the preservation of large cardinal axioms by "Prikry-type" forcing, for example by Radin forcing or iterated Prikry forcing. For this we refer the reader to Gitik's chapter in this Handbook.

After some preliminaries, the bulk of this chapter consists of fairly short sections, in each of which we introduce one or two technical ideas and give one or more examples of the ideas in action. The constructions are generally of increasing complexity as we proceed and have more techniques at our disposal. Especially at the beginning, we have adopted a fairly leisurely and discursive approach to the material. The impatient reader is encouraged to jump ahead and refer back as necessary. At the end of this introduction there is a brief description of the contents of each section.

Here is a brief review of our notation and conventions. We defer the discussion of forcing to Sect. 5.

- $P(X)$ is the power set of X. If X is a subset of a well-ordered set then $\mathrm{ot}(X)$ is the order-type of X. V_α is the set of sets with rank less than α. $\mathrm{tc}(X)$ is the transitive closure of X. H_θ is the set of x such that $\mathrm{tc}(\{x\})$ has cardinality less than θ.

- For τ a term and M a model, τ_M or τ^M denotes the result of interpreting the set-theoretic term τ in the model M, for example V_α^M or 2^ω_M. When $\tau_M = \tau \cap M$ we sometimes write "$\tau \cap M$" instead of "τ_M", especially when τ is a term of the form "$P(X)$" or "V_α".

- f is a *partial function f from X to Y* ($f : X \rightsquigarrow Y$) if and only if $f \subseteq X \times Y$ and for every $a \in X$ there is at most one $b \in Y$ with $(a, b) \in f$. f is a *total function from X to Y* ($f : X \to Y$) if and only if for every $a \in X$ there is exactly one $b \in Y$ with $(a, b) \in f$. As usual we write "$f(a) = b$" for "$(a, b) \in f$". id_X is the identity function on X.

- We use On for the class of ordinals, Card for the class of cardinals, Lim for the class of limit ordinals, Reg for the class of regular cardinals and Sing for the class of singular ordinals.

- If α is a limit ordinal then $\mathrm{cf}(\alpha)$ is the cofinality of α. If δ is a regular cardinal then $\mathrm{Cof}(\delta)$ is the class of limit ordinals α such that $\mathrm{cf}(\alpha) = \delta$. Expressions like "$\mathrm{Cof}(<\kappa)$" have the expected meaning.

- $|X|$ is the cardinality of X.

- ${}^X Y$ is the set of all functions from X to Y. If κ and λ are cardinals then $\kappa^\lambda = |{}^\lambda \kappa|$.

- We will make the following abuse of notation. When M and N are transitive models with $M \subseteq N$ we will write "$N \models {}^\beta M \subseteq M$" to mean that every β-sequence from M which lies in N actually lies in M, even in situations where possibly M is not definable in N. A similar convention applies when we write "$N \models {}^\beta \mathrm{On} \subseteq M$".

- $[X]^\lambda$ is the set of subsets of X of cardinality λ. Expressions like $[X]^{\leq\lambda}$ have the obvious meaning. If κ is regular and $\kappa \leq \lambda$ then $P_\kappa \lambda = \{a \in [\lambda]^{<\kappa} : a \cap \kappa \in \kappa\}$; this is a departure from the more standard notation in which the terms "$P_\kappa \lambda$" and "$[\lambda]^{<\kappa}$" are synonymous.

- A *tree* is a structure $(T, <_T)$ where $<_T$ is a well-founded strict ordering on T, and each element of T has a linearly ordered set of predecessors. T_α is the set of elements of height α, $T \restriction \alpha$ is the set of elements of height less than α.

- A tree is *normal* if and only if it is nonempty, has a unique minimal element, and has the properties that every element has two immediate successors and that every element of limit height is determined uniquely by the set of its predecessors in the tree. For κ regular a *κ-tree* is a normal tree of height κ, in which every level has size less than κ.

- ω_α is the αth infinite cardinal.

- Throughout we use "inaccessible" to mean "strongly inaccessible" and "Mahlo" to mean "strongly Mahlo".

- An *ideal on X* is a non-empty family of subsets of X which is downwards closed and closed under finite unions; a *filter on X* is a non-empty family of subsets of X which is upwards closed and closed under finite intersections. An ideal I is *proper* if $X \notin I$, and a filter F is *proper* if $\emptyset \notin F$; most of the ideals and filters appearing in this chapter will be proper. If I is an ideal on X then $\{X \setminus A : A \in I\}$ is a filter on X, which is called the *dual filter* and will often be denoted by I^*; similarly if F is a filter then $F^* = \{X \setminus A : A \in F\}$ is an ideal.

Ideals often arise in measure theory, where the class of measure zero sets for a (complete) measure on X is an ideal. If I is an ideal on X then we say that $A \subseteq X$ is *positive for I* or *I-positive* iff $A \notin I$, and we often write I^+ for the class of positive sets; we also sometimes say that A is *measure one for I* if $A \in I^*$. Similarly if F is a filter we say A is *F-positive* iff $A \notin F^*$, and is *F-measure one* iff $A \in F$.

- An *ultrafilter* on X is a maximal proper filter on X, or equivalently a filter U such that for all $A \subseteq X$ exactly one of the sets $A, X \setminus A$ is in U. An ultrafilter is *principal* if and only if it is of the form $\{A \subseteq X : a \in A\}$ for some $a \in X$.

- If I is an ideal and λ is a cardinal, then I is *λ-complete* if and only if I is closed under unions of length less than λ; similarly a filter F is *λ-complete* if and only if F is closed under intersections of length less than λ.

  If κ is a regular cardinal then a *measure on κ* is a κ-complete non-principal ultrafilter on κ. The measure U is *normal* if and only if it is closed under *diagonal intersections*, that is for every sequence $\langle X_i : i < \kappa \rangle$ with $X_i \in U$ for all $i < \kappa$, the *diagonal intersection* $\{\beta : \forall \alpha < \beta \; \beta \in X_\alpha\}$ of the sequence lies in U.

The prerequisites for reading this chapter are some familiarity with iterated forcing and the formulation of large cardinal axioms in terms of elementary embeddings. Knowledge of the material in Baumgartner's survey paper on iterated forcing [6, Sects. 0, 1, 2 and 5] and Kanamori's book on large cardinals [43, Sects. 5, 22, 23, 24 and 26] should be more than sufficient.

I learned much of what I know about elementary embeddings and forcing from Hugh Woodin, and would like to thank him for many patient explanations. I have also profited greatly from conversations with Uri Abraham, Arthur Apter, Jim Baumgartner, Matt Foreman, Sy Friedman, Moti Gitik, Aki Kanamori, Menachem Magidor, Adrian Mathias and Saharon Shelah.

Several people have been kind enough to read drafts of this chapter and give me their comments. Thanks in particular to Arthur Apter, Matt Foreman, Sy Friedman, Radek Honzik, Aki Kanamori, John Krueger, Peter Lumsdaine and Ernest Schimmerling; apologies to anyone whom I have omitted from this list.

We conclude this introduction with the promised road map of the chapter.

- Section 2 discusses basic facts about elementary embeddings.

- Section 3 describes how we approximate elementary embeddings by ultrapowers and more generally by *extenders*, a special kind of limit ultrapower.

- Section 4 reviews some basic large cardinal axioms and their formulation in terms of elementary embeddings.

- Section 5 contains a discussion of the basics of forcing. Our convention (following Kunen [46]) is that a *notion of forcing* is a preordering with a designated largest element; we discuss the relationship with the other standard approaches to forcing. We review the basic closure, distributivity and chain condition properties and introduce some variants (the Knaster property and strategic closure) which are important later. We also introduce some basic forcing posets, Cohen forcing and the standard cardinal collapsing posets.

- Section 6 defines four forcing posets which enable us to distinguish different closure properties and will all play various roles later in the chapter. These are the posets to add a Kurepa tree, a non-reflecting stationary set, a square sequence and finally a club set disjoint from a prescribed co-stationary set in ω_1.

- Section 7 reviews iterated forcing, essentially following the approach of Baumgartner's survey [6]. We discuss the preservation of various closure and chain conditions and the idea of a factor iteration.

- Section 8 describes how to build generic objects over sufficiently closed inner models for sufficiently closed forcing posets. We apply this to construct a variant form of Prikry forcing first isolated by Foreman and Woodin in their work on the global failure of GCH [20].

- Section 9 proves a key lemma of Silver's on lifting elementary embeddings to generic extensions, discusses the properties of the lifted embeddings and gives some easy applications.

- Section 10 discusses the key idea of a *generic elementary embedding*, constructs some examples and applies them to a discussion of stationary reflection at small cardinals.

- Section 11 describes Silver's idea of iterating forcing with Easton supports. As a first application we sketch a simpler proof of a theorem by Kunen and Paris [47], that under GCH a measurable cardinal κ may carry κ^{++} normal measures.

- Section 12 introduces another key idea of Silver's, that of a *master condition*. As a first example of a master condition argument we give something close to Silver's original consistency proof for the failure of GCH at a measurable cardinal, starting from the hypothesis that there is a model of GCH in which some κ is κ^{++}-supercompact.

- Section 13 describes a technique, which is due to Magidor, for doing without a master condition under some circumstances. As an example we redo the failure of GCH at a measurable cardinal from the hypothesis that there is a model of GCH in which some κ is κ^+-supercompact.

- Section 14 describes how we may absorb κ-closed forcing posets into a large enough κ-closed collapsing poset, so that the quotient is also κ-closed. We then apply this to prove a theorem of Kunen [45] about saturated ideals, a theorem of the author from joint work with Džamonja and Shelah [13] about *strong non-reflection*, and Magidor's theorem [55] that consistently every stationary set in $\omega_{\omega+1}$ reflects.

- Section 15 discusses how to transfer generic filters between models of set theory, and sketches an application to constructing generalized versions of Prikry forcing.

- Section 16 shows that we may apply the ideas in this chapter in the context of weak large cardinal axioms such as weak compactness, and sketches a proof that GCH may first fail at a weakly compact cardinal.

- Section 17 proves two theorems of Jech, Magidor, Mitchell and Prikry [41]. The first result is that ω_1 may carry a precipitous ideal, the second is that in fact the non-stationary ideal on ω_1 may be precipitous. The argument for the second result uses the absorption idea from Sect. 14, and also involves iterating a natural forcing for *shooting club sets* through stationary sets.

- Section 18 sketches the proof of Gitik's result [23] that the precipitousness of NS_{ω_2} is equi-consistent with a cardinal of Mitchell order two.

- Section 19 gives two more applications of iterated club shooting, Jech and Woodin's result [40] that $\mathrm{NS}_\kappa \restriction \mathrm{Reg}$ can be κ^+-saturated for a Mahlo cardinal κ and Magidor's result [55] that consistently every stationary set of cofinality ω ordinals in ω_2 may reflect at almost all points of cofinality ω_1.

- Section 20 discusses some variant collapsing posets which are often useful, Kunen's *universal collapse* [45] and the *Silver collapse*. We sketch Kunen's proof [45] that ω_1 can carry an ω_2-saturated ideal, starting from the hypothesis that there is a huge cardinal.

- Section 21 sketches some results primarily due to Hamkins which put limits on what we can achieve by reverse Easton forcing. As a sample application we sketch an easy case of Hamkins' *superdestructibility theorem* [32].

- Section 22 describes an idea of Laver's for introducing a kind of universal generic object by forcing with a poset of terms. As an application we sketch an unpublished proof by Magidor [51] of his celebrated theorem [52] that the least measurable cardinal can be strongly compact.

- Section 23 introduces the idea of analyzing iterations by term forcing. As an example we introduce yet another collapsing poset and give a version of Mitchell's proof [57] that ω_2 may have the tree property.

- Section 24 discusses how to build universal iterations using prediction principles. We prove Laver's theorem that supercompact cardinals carry *Laver diamonds*, and use this to give Baumgartner's proof for the consistency of the Proper Forcing Axiom [15] and Laver's proof that a supercompact cardinal κ can be made indestructible under κ-directed closed forcing [49].

- Section 25 introduces an idea due to Woodin for altering generic objects, and then applies this to give Woodin's consistency proof for the failure of GCH at a measurable from an optimal assumption.

2. Elementary Embeddings

We will be concerned with elementary embeddings $k : M \longrightarrow N$ where M and N are transitive models of ZFC and k, M, and N are all classes of some universe of set theory. It will not in general be the case that k or N are classes of M or that $N \subseteq M$. In particular we will be interested in the situation of a "generic embedding" where $j : V \longrightarrow M \subseteq V[G]$ for $V[G]$ a generic extension of V, and j, M are defined in $V[G]$.

This notion is straightforward if M and N are sets but one needs to be a little careful when M and N are proper classes. We refer the reader to Kanamori's book [43, Sects. 5 and 19] for a careful discussion of the metamathematical issues. From now on we will freely treat elementary embeddings between proper classes as if those classes were sets, a procedure which can be justified by the methods of [43]. We reserve the term "inner model" for a transitive class model of ZFC which contains all the ordinals.

We start by recalling a few basic facts about elementary embeddings.

2.1 Proposition. *Let M and N be transitive models of* ZFC *and let the map $k : M \longrightarrow N$ be elementary. Then*

1. *The pointwise image $k``M$ is an elementary substructure of $N$, the Mostowski collapse of the structure $(k``M, \in)$ is M, and k is the inverse of the collapsing isomorphism from $k``M$ to M.*

2. *$k(\alpha) \geq \alpha$ for all $\alpha \in M \cap \mathrm{On}$.*

3. *If $k\restriction(\beta + 1) = \mathrm{id}_{\beta+1}$ and $A \in M$ with $A \subseteq \beta$, then $k(A) = A$.*

Proof. Easy. $\dashv$

2.2 Proposition. *Let M be a transitive model of* ZFC*, let $x \in M$ and let $M \models$ "$x \in H_{\lambda^+}$" where λ is an infinite M-cardinal. Then there is a set $A \subseteq \lambda$ such that $A \in M$ and for any transitive model N of* ZF*, $A \in N$ implies that $x \in N$.*

Proof. Let $f \in M$ be an injection from $\mathrm{tc}(\{x\})$ to λ, let G be Gödel's pairing function and let

$$A = \{G(f(a), f(b)) : a, b \in \mathrm{tc}(\{x\}) \text{ and } a \in b\}.$$

If $A \in N$ then N can compute x by forming the Mostowski collapse of the well-founded extensional relation $\{(\alpha, \beta) : G(\alpha, \beta) \in A\}$, and then finding the element of maximal rank in this set. $\dashv$

We abbreviate the rather cumbersome assertion "A is a set of ordinals such that $\{(\gamma, \delta) : G(\gamma, \delta) \in A\}$ is a well-founded relation whose transitive collapse is $\mathrm{tc}(\{x\})$" by "A codes x". The assertions "A codes x" and "A codes something" are both Δ_1^{ZFC} and are thus absolute between transitive models of ZFC.

2.3 Proposition. *Let M and N be transitive models of* ZFC *and let the map $k : M \longrightarrow N$ be elementary. If $k``(M \cap \mathrm{On})$ is cofinal in $N \cap \mathrm{On}$ then exactly one of the following is true:*

1. *$k = \mathrm{id}_M$ and $M = N$.*
2. *There exists a $\delta \in M \cap \mathrm{On}$ such that $k(\delta) > \delta$.*

Proof. Suppose the second alternative fails, so that $k \restriction (M \cap \mathrm{On})$ is the identity. Let $x \in M$ and find a set of ordinals $A \in M$ such that A codes x. Then $A = k(A)$ by Proposition 2.1, $k(A)$ codes $k(x)$ by elementarity, and so $k(x) = x$. Since x was arbitrary, $k = \mathrm{id}_M$.

Since $k = \mathrm{id}_M$, $M \cap \mathrm{On} = N \cap \mathrm{On}$ and $V_\beta^N = V_{k(\beta)}^N = k(V_\beta^M) = V_\beta^M$ for all $\beta \in M \cap \mathrm{On}$. So $M = N$. $\dashv$

From now on we will say that $k : M \longrightarrow N$ is *nontrivial* if $k \neq \mathrm{id}_M$.

2.4 Remark. It was crucial in Proposition 2.3 that k should map $M \cap \mathrm{On}$ cofinally into $N \cap \mathrm{On}$. For example the theory of sharps [43, Sect. 9] shows that if $0^\#$ exists then L_{ω_1} and L_{ω_2} are models of ZFC and $L_{\omega_1} \prec L_{\omega_2}$.

2.5 Remark. Let $k : M \longrightarrow N$ be elementary, where M is an inner model and N is transitive. Then N is an inner model, and the hypotheses of Proposition 2.3 are satisfied.

If $k : M \longrightarrow N$ is elementary then the least δ such that $k(\delta) > \delta$ (if it exists) is called the *critical point* of k and is denoted by $\mathrm{crit}(k)$. It is not hard to see that $\mathrm{crit}(k)$ is a regular uncountable cardinal in M.

It is natural to ask how much agreement there must be between the models M and N. The following proposition puts a lower bound on the level of agreement.

2.6 Proposition. *If $k : M \longrightarrow N$ is an elementary embedding between transitive models of* ZFC *and* $\mathrm{crit}(k) = \delta$*, then* $H^M_{\delta^+} \subseteq N$.

Proof. Let $x \in H^M_{\delta^+}$ and let $A \in M$ code x with $A \subseteq \delta$. Then for $\alpha < \delta$ we have

$$\alpha \in A \quad \Longleftrightarrow \quad k(\alpha) \in k(A) \quad \Longleftrightarrow \quad \alpha \in k(A),$$

so $A = k(A) \cap \delta \in N$. Therefore $x \in N$. ⊣

In general we cannot say much more, as illustrated by the following two examples. In Example 2.7 $M = N$, while in Example 2.8 M and N agree only to the extent indicated by Proposition 2.6.

2.7 Example. Suppose that $0^\#$ exists. Then there is a nontrivial elementary embedding $k : L \longrightarrow L$ [43, Sect. 9].

2.8 Example. It is consistent (from large cardinals) that there exist inner models M and N and an embedding $k : M \longrightarrow N$ such that $\mathrm{crit}(k) = \omega_1^M$ and $V_{\omega+1} \cap M \subsetneq V_{\omega+1} \cap N$. We will construct such an example in Theorem 10.2.

If the critical point is inaccessible in M we can say more:

2.9 Proposition. *If $k : M \longrightarrow N$ is an elementary embedding between transitive models of* ZFC*, and* $\mathrm{crit}(k) = \delta$ *where δ is inaccessible in M, then* $V_\delta \cap M = V_\delta \cap N$.

Proof. For $\alpha < \delta$, the set $V_\alpha \cap M$ is coded by a bounded subset of δ lying in M. In particular it is fixed by k, so as α is also fixed by elementarity $V_\alpha \cap M = V_\alpha \cap N$. ⊣

In the theory of large cardinals we are most interested in embeddings of the following type, where usually M will be an inner model.

2.10 Definition. An embedding $k : M \longrightarrow N$ is *definable* if and only if k and N are definable in M.

The analysis of these embeddings is due to Scott [61] and is summarized in the following proposition.

2.11 Proposition. *Let M and N be inner models and let $k : M \longrightarrow N$ be a nontrivial definable elementary embedding with* $\mathrm{crit}(k) = \delta$*. Let*

$$U = \{X \subseteq \delta : X \in M, \delta \in k(X)\}.$$

Then

1. *$U \in M$ and $M \models$ "U is a normal measure on δ".*
2. *$V^M_{\delta+1} = V^N_{\delta+1}$.*
3. *$k \restriction V^M_\delta = \mathrm{id}_{V^M_\delta}$.*

4. *For all* $A \in V^M_{\delta+1}$, $A = k(A) \cap V^M_\delta$.

Proof. See [43, Sect. 5]. ⊣

2.12 Remark. Neither of the embeddings from Examples 2.7 and 2.8 is definable.

3. Ultrapowers and Extenders

It will be important for us to be able to describe embeddings between models by ultrapowers and limit ultrapowers. We give a sketchy outline here and refer the reader to [43, Sects. 19 and 26] for the details.

Let M be a transitive model of ZFC, let $X \in M$ and let U be an ultrafilter on $P(X) \cap M$. Then we may form $\mathrm{Ult}(M, U)$, the collection of U-equivalence classes of functions $f \in M$ with $\mathrm{dom}(f) = X$. As usual we let $[f]_U$ denote the class of f, and for $x \in M$ we let $j_U(x) = [f_x]_U$ where f_x is the function with domain X and constant value x. $\mathrm{Ult}(M, U)$ is made into a structure for the language of set theory by defining

$$[f]_U E [g]_U \quad \iff \quad \{x : f(x) \in g(x)\} \in U,$$

and we make a mild abuse of notation by writing "$\mathrm{Ult}(M, U)$" for the structure $(\mathrm{Ult}(M, U), E)$.

3.1 Remark. When M is an inner model $[f]_U$ is typically a proper class, which makes the definition of $\mathrm{Ult}(M, U)$ appear problematic. This can be fixed by *Scott's trick* in which $[f]_U$ is redefined as the set of functions with minimal rank which are equivalent to f modulo U. Similar remarks apply to ultrapowers throughout this chapter.

Since M is a model of ZFC Łoś's theorem holds, that is to say that for any formula $\phi(x_1, \ldots, x_n)$ and any functions $F_1, \ldots, F_n \in M$ with domain X,

$$\mathrm{Ult}(M, U) \models \phi([F_1]_U, \ldots, [F_n]_U)$$

if and only if

$$\{x : M \models \phi(F_1(x), \ldots, F_n(x))\} \in U.$$

In particular j_U is an elementary embedding from M to $\mathrm{Ult}(M, U)$. When $\mathrm{Ult}(M, U)$ is well-founded we will identify it with its transitive collapse. The following propositions are standard.

3.2 Proposition. *Let* $k : M \longrightarrow N$ *be an elementary embedding between transitive models of* ZFC, *let* $a \in N$ *and let* $B \in M$ *with* $a \in k(B)$. *Let* $E_a = \{A \subseteq B : A \in M, a \in k(A)\}$. *Then*

1. E_a *is an ultrafilter on* $P(B) \cap M$. *For notational convenience we define* $M_a = \mathrm{Ult}(M, E_a)$ *and* $j_a = j_{E_a}$.

2. *If we define* $k_a : M_a \longrightarrow N$ *by* $k_a([f]_{E_a}) = k(f)(a)$ *then* k_a *is a well-defined elementary embedding and* $k_a \circ j_a = k$. k_a *and* M_a *do not depend on the choice of* B.

3. M_a *is isomorphic via* k_a *to* X_a, *where*

$$X_a = \{k(F)(a) : F \in M, \mathrm{dom}(F) = B\}.$$

4. M_a *is well-founded and, when we identify it with its transitive collapse* k_a, *is the inverse of the transitive collapsing map on* X_a.

5. *If* k *is definable then* $E_a \in M$ *and* j_a *is definable.*

3.3 Proposition. *Let* $k : M \longrightarrow N$ *be an elementary embedding between transitive models of* ZFC. *Let* $a_1 \in k(B_1)$, $a_2 \in k(B_2)$ *and let* E_1, E_2 *be the associated ultrafilters. Suppose that* $F : B_2 \longrightarrow B_1$ *is such that* $k(F)(a_2) = a_1$. *Then* F *induces an elementary embedding*

$$F^* : \mathrm{Ult}(M, E_1) \longrightarrow \mathrm{Ult}(M, E_2),$$

where $F^*([g]_{E_1}) = [g \circ F]_{E_2}$. *Moreover* $j_{E_2} = F^* \circ j_{E_1}$.

3.4 Proposition. *Let* $\lambda \in N \cap \mathrm{On}$ *be such that* $\lambda \leq \sup(k``(M \cap \mathrm{On}))$. *For each* $a \in [\lambda]^{<\omega}$ *let* μ_a *be the least ordinal such that* $a \subseteq j(\mu_a)$ *and let*

$$E_a = \{A \subseteq [\mu_a]^{|a|} : A \in M, a \in k(A)\}.$$

Let M_a, j_a, k_a, *and* X_a *be as in Proposition 3.2. If* $a, b \in [\lambda]^{<\omega}$ *and* $a \subseteq b$ *then define*

$$F_{ab}(x) = \{\gamma \in x : \exists \gamma^* \in a \ \mathrm{ot}(x \cap \gamma) = \mathrm{ot}(b \cap \gamma^*)\}$$

for $x \in [\mu_b]^{|b|}$. *Then*

1. $F_{ab} : [\mu_b]^{|b|} \longrightarrow [\mu_a]^{|a|}$ *and* $k(F_{ab})(b) = a$. *We let* j_{ab} *denote the embedding from* M_a *to* M_b *induced by* F_{ab}.

2. $M_0 = M$, $k_0 = k$, $j_{0a} = j_a$.

3. *The system of structures* M_a *and embeddings* j_{ab} *is a directed system, so has a direct limit* M_∞. *There are elementary embeddings* $j_{a\infty} : M_a \longrightarrow M_\infty$ *such that* $M_\infty = \bigcup_a j_{a\infty}[M_a]$ *and* $j_{b\infty} \circ j_{ab} = j_{a\infty}$.

4. *There is an elementary embedding* $l : M_\infty \longrightarrow M$ *such that* $l \circ j_{a\infty} = k_a$ *for all* a.

5. M_∞ *is isomorphic via* l *to* $X_\infty = \bigcup_a X_a$, *and* l *is the inverse of the Mostowski collapsing map on* X_∞. *In particular* M_∞ *is well-founded.*

6. *If* k *is definable and* M *is an inner model then* $j_{0\infty}$ *is definable.*

$$\begin{tikzcd}
M \arrow[rr, "k"] \arrow[rrd, "j_{0\infty}"] \arrow[d, "j_a"'] \arrow[ddr, "j_b"] & & N \\
M_a \arrow[rru, "k_a"] \arrow[rr, "j_{a\infty}"] \arrow[dr, "j_{ab}"'] & & M_\infty \arrow[u, "l"'] \\
& M_b \arrow[ruu, "k_b"] \arrow[ru, "j_{b\infty}"'] &
\end{tikzcd}$$

If $k : M \longrightarrow N$ is elementary where M and N are inner models then we may make X_∞ contain arbitrarily large initial segments of N by choosing λ sufficiently large. M_∞ is the transitive collapse of X_∞, l is the inverse of the collapsing map and $l \circ j_{0\infty} = k$. It follows that we may make $j_{0\infty}$ approximate k to any required degree of precision by a suitable choice of λ.

3.5 Definition. Let $k : M \longrightarrow N$ be an elementary embedding between transitive models of ZFC with $\mathrm{crit}(k) = \delta$, and let $\lambda \le \sup(k``(M \cap \mathrm{On}))$. If

$$E = \{E_a : a \in [\lambda]^{<\omega}\}$$

where E_a is defined as above, then we call E the *M-(δ, λ)-extender derived from k*.

It is possible [43, Sect. 26] to give an axiomatization of the properties enjoyed by E as in Definition 3.5, thus arriving at the concept of an "M-(δ, λ)-extender". Given an M-(δ, λ)-extender E we can compute the limit ultrapower of M by E to get a well-founded structure $\mathrm{Ult}(M, E)$ and an embedding $j_E : M \longrightarrow \mathrm{Ult}(M, E)$.

If E is the extender derived from $k : M \longrightarrow N$ as in Proposition 3.4 then in the notation of that proposition, $\mathrm{Ult}(M, E) = M_\infty$ and $j_E = j_{0\infty}$. If E is an M-(δ, λ)-extender and E' is the M-(δ, λ)-extender derived from the ultrapower map $j_E : M \longrightarrow \mathrm{Ult}(M, E)$ then $E = E'$.

When E is a V-(δ, λ)-extender lying in V we will just refer to E as a "(δ, λ)-extender".

3.6 Definition. An M-(δ, λ)-extender E is called *short* if all the measures E_a concentrate on $[\delta]^{<\omega}$, or equivalently if $\lambda \le j_E(\delta)$.

We now make a couple of (non-standard) definitions which will give us a convenient way of phrasing some results later. See for example Propositions 3.9 and 15.1.

3.7 Definition. Let $k : M \longrightarrow N$ be an elementary embedding between transitive models of ZFC, and let μ be an ordinal. The embedding k *has width* $\le \mu$ if and only if every element of N is of the form $k(F)(a)$ for some $F \in M$, $a \in N$ where $M \models |\mathrm{dom}(F)| \le \mu$.

3.8 Definition. Let $k : M \longrightarrow N$ be an elementary embedding between transitive models of ZFC, and let $A \subseteq N$. The embedding k is *supported on* A if and only if every element of N is of the form $k(F)(a)$ for some $F \in M$ and $a \in A \cap \mathrm{dom}(k(F))$.

The following easy proposition will be useful later.

3.9 Proposition. *Let $k : M \longrightarrow N$ be an elementary embedding between transitive models of* ZFC *with* $\mathrm{crit}(k) = \kappa$*, and let*

$$U = \{X \subseteq \kappa : X \in M, \kappa \in k(X)\}.$$

Then k is the ultrapower map computed from M and U if and only if k is supported on $\{\kappa\}$.

4. Large Cardinal Axioms

We briefly review some standard large cardinal axioms and their formulation in terms of elementary embeddings and ultrapowers. Once again we refer the reader to Kanamori's book [43] for the details.

We start with the characterizations in terms of elementary embeddings.

- κ is *measurable* if and only if there is a definable $j : V \longrightarrow M$ such that $\mathrm{crit}(j) = \kappa$.
- κ is λ-*strong* if and only if there is a definable $j : V \longrightarrow M$ such that $\mathrm{crit}(j) = \kappa$, $j(\kappa) > \lambda$ and $V_\lambda \subseteq M$. κ is *strong* if and only if it is λ-strong for all λ.
- κ is λ-*supercompact* if and only if there is a definable $j : V \longrightarrow M$ such that $\mathrm{crit}(j) = \kappa$, $j(\kappa) > \lambda$ and ${}^\lambda M \subseteq M$. κ is *supercompact* if and only if it is λ-supercompact for all λ.
- κ is λ-*strongly compact* if and only if there is a definable $j : V \longrightarrow M$ such that $\mathrm{crit}(j) = \kappa$, $j(\kappa) > \lambda$ and there is a set $X \in M$ such that $M \models |X| < j(\kappa)$ and $j``\lambda \subseteq X$. κ is strongly compact if and only if it is λ-strongly compact for all λ.
- κ is *huge with target* λ if and only if there is a definable $j : V \longrightarrow M$ such that $\mathrm{crit}(j) = \kappa$, $j(\kappa) = \lambda$ and ${}^\lambda M \subseteq M$. κ is *almost huge with target* λ if and only if there is a definable $j : V \longrightarrow M$ such that $\mathrm{crit}(j) = \kappa$, $j(\kappa) = \lambda$ and ${}^{<\lambda} M \subseteq M$.

Each of these concepts can also be characterized using ultrafilters or extenders.

- κ is measurable if and only if there is a *measure on* κ (that is, a normal κ-complete non-principal ultrafilter on κ).

- Assuming GCH, κ is $(\kappa + \beta)$-strong if and only if there is a short $(\kappa, \kappa^{+\beta})$-extender E such that $V_{\kappa+\beta} \subseteq \mathrm{Ult}(V, E)$.
- For $\lambda \geq \kappa$, κ is λ-supercompact if and only if there is a normal, fine and κ-complete ultrafilter on $P_\kappa \lambda$. We will generally refer to such an object as a *supercompactness measure on* $P_\kappa \lambda$.
- For $\lambda \geq \kappa$, κ is λ-strongly compact if and only if there is a fine and κ-complete ultrafilter on $P_\kappa \lambda$. We will generally refer to such an object as a *strong compactness measure on* $P_\kappa \lambda$.
- For $\lambda \geq \kappa$, κ is huge with target λ if and only if there is a normal, fine and κ-complete ultrafilter on $P^\kappa \lambda$, where $P^\kappa \lambda$ is the set of $X \subseteq \lambda$ with order type κ. Almost-hugeness has a rather technical characterization in terms of a direct limit system of supercompactness measures on $P_\kappa \mu$ for $\mu < \lambda$.

4.1 Remark. If $j : V \longrightarrow M$ is a definable embedding such that $\mathrm{crit}(j) = \kappa$ and $j``\lambda \in M$, then $\{X \in P_\kappa \lambda : j``\lambda \in j(X)\}$ is a supercompactness measure.

4.2 Remark. Weak compactness may also be characterized in terms of elementary embeddings, we discuss this in Sect. 16.

For use later we record the definition of the *Mitchell ordering* $\lhd$ and a few basic facts about it.

4.3 Definition. Let κ be a measurable cardinal and let U_0 and U_1 be measures on κ. Then $U_0 \lhd U_1$ if and only if $U_0 \in \mathrm{Ult}(V, U_1)$.

The theory of the Mitchell ordering is developed in Mitchell's first chapter in this Handbook. The relation $\lhd$ is a strict well-founded partial ordering. If U is a measure then $o(U)$ is defined to be the height of U in $\lhd$, and the *Mitchell order* $o(\kappa)$ of κ is defined to be the height of $\lhd$. In the usual canonical inner models for large cardinals, $\lhd$ is a linear ordering.

The following propositions collect some easy but useful facts about the behavior of elementary embeddings.

4.4 Proposition. *Let $k : M \longrightarrow N$ be an elementary embedding between transitive models of* ZFC*, and let k have width $\leq \mu$. If $M \models \mathrm{cf}(\alpha) > \mu$ then $\sup(k``\alpha) = k(\alpha)$.*

If $\sup(k``\alpha) = k(\alpha)$ we will say that k is *continuous at α.*

4.5 Proposition. *If $U \in V$ is a countably complete ultrafilter on X, X has cardinality κ and $j : V \longrightarrow M$ is the associated ultrapower map then $|j(\mu)| < (|\mu|^\kappa)^+$ for all ordinals μ.*

4.6 Proposition. *If $E \in V$ is a short (κ, λ)-extender and $j : V \longrightarrow M$ is the associated ultrapower map then $|j(\mu)| < (\lambda \times |\mu|^\kappa)^+$ for all ordinals μ.*

4.7 Proposition. *Let M be an inner model of V. If ${}^{\lambda}M \subseteq M$ then the cardinals of V and M agree up to and including λ^+. If* GCH *holds, κ is inaccessible and $V_{\kappa+\beta} \subseteq M$ then the cardinals of V and M agree up to $\beth_\beta(\kappa)$.*

The following example illustrates how these ideas can be used. There are many similar calculations in later sections, where we will generally suppress the details.

4.8 Example. Let GCH hold and let U be a supercompactness measure on $P_\kappa \kappa^+$, with $j : V \longrightarrow M$ the associated ultrapower map. Then

1. j is continuous at κ^{++} and κ^{+++}.

2. $\kappa^{++} < j(\kappa)$.

3. $j(\kappa^{+++}) = \kappa^{+++}$.

Proof. $|P_\kappa \kappa^+| = \kappa^+$, so by Proposition 4.4 j is continuous at κ^{++} and κ^{+++}. By the definition of a supercompactness measure ${}^{\kappa^+}M \subseteq M$, and so by Proposition 4.7 $\kappa^{++} = \kappa^{++}_M$. By elementarity $j(\kappa)$ is an M-inaccessible cardinal greater than κ, and so $\kappa^{++} < j(\kappa)$.

For every $\eta < \kappa^{+++}$, Proposition 4.5 and GCH imply that $j(\eta) < \kappa^{+++}$. Since j is continuous at κ^{+++} we have $j(\kappa^{+++}) = \kappa^{+++}$ as required. ⊣

5. Forcing

We assume that the reader is familiar with forcing; in this section we establish our forcing conventions and review some of the basic definitions and facts. We will essentially follow the treatment of forcing in Kunen's text [46]. Proofs of all the facts that we mention in this section can be found in at least one of the texts by Kunen [46] or Jech [39].

Our approach to forcing is based on posets with a largest element. We justify this by the sociological observation that when a set theorist writes down a new set of forcing conditions it is almost always of this form.

For technical reasons we sometimes work with preordered sets rather than partially ordered sets; recall that a *preordering* is a transitive and reflexive relation, and that if $\leq$ is a preordering of $\mathbb{P}$ we may form the quotient by the equivalence relation

$$p \, E \, q \quad \iff \quad p \leq q \leq p$$

to get a partially ordered set. We refer to this as the *quotient poset*.

A *largest element* in a preordered set $\mathbb{P}$ is an element b such that $a \leq b$ for all a. A preordering may have many largest elements, which will all be identified when we form the quotient poset.

A *notion of forcing* is officially a triple $(\mathbb{P}, \leq_{\mathbb{P}}, 1_{\mathbb{P}})$ where $\leq_{\mathbb{P}}$ is a preordering of $\mathbb{P}$ and $1_{\mathbb{P}}$ is a largest element. A *forcing poset* is a notion of forcing where $\leq_{\mathbb{P}}$ is a partial ordering; if $\mathbb{P}$ is a notion of forcing then the quotient poset is a forcing poset. If p, q are conditions in a notion of forcing $\mathbb{P}$ then $p \leq q$ means that p is stronger than q.

5.1 Remark. It might seem more natural just to use forcing posets in our discussion of forcing. However this would cause irritating problems when we come to discuss iterated forcing; for example in a two-step iteration $\mathbb{P} * \dot{\mathbb{Q}}$ we may have $p \Vdash \dot{q}_1 = \dot{q}_2$, in which case the conditions $(p, \dot{q}_1)$ and $(p, \dot{q}_2)$ are equivalent but not identical.

For $p \in \mathbb{P}$ we denote by $\mathbb{P}/p$ the subset $\{q \in \mathbb{P} : q \leq p\}$ with the inherited ordering. It is a standard fact that there is a bijection between $\mathbb{P}$-generic filters G with $p \in G$, and $(\mathbb{P}/p)$-generic filters, in which G corresponds to $G \cap (\mathbb{P}/p)$. If $p \in G$ then $V[G] = V[G \cap (\mathbb{P}/p)]$.

We say $\mathbb{P} \subseteq \mathbb{Q}$ is *dense* if every condition in $\mathbb{Q}$ has an extension in $\mathbb{P}$. There is a bijection between $\mathbb{Q}$-generic filters G and $\mathbb{P}$-generic filters, in which G corresponds to $G \cap \mathbb{P}$ and $V[G] = V[G \cap \mathbb{P}]$.

If $\mathbb{P}$ is a notion of forcing then the class $V^{\mathbb{P}}$ of $\mathbb{P}$-names is defined recursively so that σ is a $\mathbb{P}$-name if and only if every element of σ has the form (τ, p) for some $\mathbb{P}$-name τ and condition $p \in \mathbb{P}$.

We denote by $i_G(\sigma)$ the result of interpreting the name σ with respect to the filter G, that is

$$i_G(\sigma) = \{i_G(\tau) : \exists p \in G \ (\tau, p) \in \sigma\}.$$

We let $\check{x}$ denote the standard forcing name for the ground model object x, that is $\check{x} = \{(\check{y}, 1_{\mathbb{P}}) : y \in x\}$. $\dot{G} = \{(\check{p}, p) : p \in \mathbb{P}\}$ is the standard name for the generic filter.

A notion of forcing is *non-trivial* if and only if it is forced by every condition that $V[G] \neq V$, or equivalently that $G \notin V$. *The trivial forcing* is the forcing poset with just one element; we usually denote the trivial forcing by "$\{1\}$".

It is easy to see that $p \Vdash \check{q} \in \dot{G}$ if and only if every extension of p is compatible with q; we will say that a notion of forcing is *separative* when $p \Vdash \check{q} \in \dot{G} \iff p \leq q$. It is routine to check that if $\mathbb{P}$ is a separative notion of forcing then the quotient forcing poset is also separative.

It is a standard fact that for any notion of forcing $\mathbb{P}$ there is a separative forcing poset $\mathbb{Q}$ and an order and incompatibility preserving surjection $h : \mathbb{P} \to \mathbb{Q}$. The map h and forcing poset $\mathbb{Q}$ are unique up to isomorphism, $\mathbb{Q}$ is called the *separative quotient* of $\mathbb{P}$ and forcing with $\mathbb{Q}$ is equivalent to forcing with $\mathbb{P}$.

If $\mathbb{P}$ is a separative forcing poset then the Boolean algebra $\mathrm{ro}(\mathbb{P})$ of regular open subsets of $\mathbb{P}$ is complete, and $\mathbb{P}$ is isomorphic to a dense set in $\mathrm{ro}(\mathbb{P}) \setminus \{0\}$. It follows that there is a bijection between $\mathbb{P}$-generic filters and $\mathrm{ro}(\mathbb{P})$-generic ultrafilters, so that forcing with the poset $\mathbb{P}$ is equivalent to forcing with the complete Boolean algebra $\mathrm{ro}(\mathbb{P})$. We sometimes abuse notation and write $\mathrm{ro}(\mathbb{P})$ for the regular open algebra of the separative quotient of a notion of forcing $\mathbb{P}$.

In general when $\mathbb{P}$ and $\mathbb{Q}$ are notions of forcing we will say that they are *equivalent* if and only if for every $\mathbb{P}$-generic filter G there is a $\mathbb{Q}$-generic filter H with $V[G] = V[H]$, and symmetrically for every $\mathbb{Q}$-generic filter H there is a $\mathbb{P}$-generic filter G with $V[H] = V[G]$. It is routine to see that this can be formulated in a first-order way which does not mention generic filters.

Complete Boolean algebras have the advantage that they allow a straightforward discussion of the relationship between different forcing extensions. If $\mathbb{P}$ and $\mathbb{Q}$ are notions of forcing then forcing with $\mathbb{P}$ is equivalent to forcing with $\mathbb{Q}$ if and only if $\mathrm{ro}(\mathbb{P})$ is isomorphic to $\mathrm{ro}(\mathbb{Q})$. For $\mathbb{C}$ a complete Boolean algebra and G a $\mathbb{C}$-generic ultrafilter over V, the models of ZFC intermediate between V and $V[G]$ are precisely the models of form $V[G \cap \mathbb{B}]$ for $\mathbb{B}$ a complete subalgebra of $\mathbb{C}$.

In particular when $\mathbb{B}$ is a complete subalgebra of $\mathbb{C}$ then $\dot{G}_{\mathbb{C}} \cap \mathbb{B}$ is a $\mathbb{C}$-name for a $\mathbb{B}$-generic ultrafilter. Conversely for any complete $\mathbb{B}$ and $\mathbb{C}$, a $\mathbb{C}$-name for a $\mathbb{B}$-generic ultrafilter gives a complete embedding of $\mathbb{B}$ into $\mathbb{C}$.

Since we are wedded to an approach to forcing via posets, it is helpful to have some sufficient conditions which guarantee that a $\mathbb{Q}$-generic extension contains a $\mathbb{P}$-generic one without mentioning the regular open algebras.

5.2 Definition. If $\mathbb{P}$ and $\mathbb{Q}$ are notions of forcing then a *projection* from $\mathbb{Q}$ to $\mathbb{P}$ is a map $\pi : \mathbb{Q} \to \mathbb{P}$ such that π is order-preserving, $\pi(1_{\mathbb{Q}}) = 1_{\mathbb{P}}$, and for all $q \in \mathbb{Q}$ and all $p \leq \pi(q)$ there is a $\bar{q} \leq q$ such that $\pi(\bar{q}) \leq p$.

The following facts are standard; see e.g. Abraham's chapter in this Handbook.

1. If H is $\mathbb{Q}$-generic over V then π"H generates a $\mathbb{P}$-generic filter G.

2. Conversely if G is $\mathbb{P}$-generic over V and we set

$$\mathbb{Q}/G = \{q \in \mathbb{Q} : \pi(q) \in G\},$$

with the partial ordering inherited from $\mathbb{Q}$, then any $H \subseteq \mathbb{Q}/G$ which is $\mathbb{Q}/G$-generic over $V[G]$ is $\mathbb{Q}$-generic over V.

5.3 Remark. In general if $\mathbb{Q}$ and $\mathbb{P}$ are forcing posets such that forcing with $\mathbb{Q}$ adds a generic object for $\mathbb{P}$, then there is a projection from $\mathbb{Q}$ to the poset of nonzero elements of $\mathrm{ro}(\mathbb{P})$.

5.4 Definition. If $\mathbb{P}$ and $\mathbb{Q}$ are notions of forcing then a *complete embedding* from $\mathbb{P}$ to $\mathbb{Q}$ is a function $i : \mathbb{P} \to \mathbb{Q}$ such that $i(1_{\mathbb{P}}) = 1_{\mathbb{Q}}$, and

$$p_1 \leq p_2 \quad \iff \quad i(p_1) \leq i(p_2)$$

for all p_1 and p_2 in $\mathbb{P}$, and for every $q \in \mathbb{Q}$ there is a condition $p \in \mathbb{P}$ such that $i(\bar{p})$ is compatible with q for all $\bar{p} \leq p$.

The following facts are standard [46]:

1. If H is $\mathbb{Q}$-generic over V then $G = i^{-1}``H$ is a $\mathbb{P}$-generic filter.
2. Conversely if G is $\mathbb{Q}$-generic over V and we set $\mathbb{Q}/G$ to be the set of $q \in \mathbb{Q}$ which are compatible with all elements of $i``G$, any H which is $\mathbb{Q}/G$-generic over $V[G]$ is $\mathbb{P}$-generic over V.

5.5 Remark. In the context of projections or complete embeddings as above $\mathbb{Q}/G$ may not be separative, even if $\mathbb{P}$ and $\mathbb{Q}$ both are.

5.6 Remark. We have overloaded the notation "$\mathbb{Q}/G$", defining it both in the setting of a projection from $\mathbb{Q}$ to $\mathbb{P}$ and of a complete embedding from $\mathbb{P}$ to $\mathbb{Q}$. This is (we assert) harmless in the sense that if we have both a projection $\pi : \mathbb{Q} \to \mathbb{P}$ and a complete embedding $i : \mathbb{P} \to \mathbb{Q}$, and $i \circ \pi = \mathrm{id}_{\mathbb{P}}$, then the two definitions of $\mathbb{Q}/G$ give equivalent notions of forcing.

We will make some use of the *Maximum Principle*: if $\mathbb{P}$ is a notion of forcing and $p \in \mathbb{P}$ forces $\exists x\ \phi(x)$, then there is a term $\dot{\tau} \in V^{\mathbb{P}}$ such that $p \Vdash \phi(\dot{\tau})$. This needs the Axiom of Choice, but that presents no obstacle for us.

When we say that $\mathbb{P}$ *adds* some kind of object or *forces* some statement to hold, we mean that this is forced by every condition in $\mathbb{P}$, or equivalently it is forced by $1_{\mathbb{P}}$. This is important because some natural notions of forcing are highly inhomogeneous.

We will frequently use the standard forcing posets for adding subsets to a regular cardinal κ, and for collapsing cardinals to have cardinality κ. Each forcing poset consists of a family of partial functions ordered by reverse inclusion.

5.7 Definition. Let κ be a regular cardinal, and let λ be any ordinal.

1. (Cohen forcing) $\mathrm{Add}(\kappa, \lambda)$ is the set of all partial functions from $\kappa \times \lambda$ to 2 of cardinality less than κ.
2. $\mathrm{Col}(\kappa, \lambda)$ is the set of all partial functions from κ to λ of cardinality less than κ.
3. (The Levy collapse) $\mathrm{Col}(\kappa, {<}\lambda)$ is the set of all partial functions p from $\kappa \times \lambda$ to λ such that
   (a) $|p| < \kappa$.
   (b) $p(\alpha, \beta) < \beta$ for all $(\alpha, \beta) \in \mathrm{dom}(p)$.

5.8 Definition. Let $\mathbb{P}$ be a notion of forcing and let κ be an uncountable cardinal. Then

1. $\mathbb{P}$ is *κ-chain condition (κ-c.c.)* if and only if $\mathbb{P}$ has no antichain of size κ.

2. $\mathbb{P}$ is *κ-closed* if and only if every decreasing sequence of conditions in $\mathbb{P}$ with length less than κ has a lower bound.

3. $\mathbb{P}$ is *(κ, ∞)-distributive* if and only if forcing with $\mathbb{P}$ adds no new $<\kappa$-sequence of ordinals.

4. $\mathbb{P}$ is *κ-directed closed* if and only if every directed set of size less than κ of conditions in $\mathbb{P}$ has a lower bound.

5.9 Remark. If $\mathbb{P}$ is separative, then $\mathbb{P}$ is (κ, ∞)-distributive if and only if every $<\kappa$-sequence of dense open subsets of $\mathbb{P}$ has a nonempty intersection.

The following fact is easy but crucial. See [39, 20.5] for a proof.

5.10 Fact (Easton's Lemma). Let κ be a regular uncountable cardinal. Let $\mathbb{P}$ be κ-c.c. and let $\mathbb{Q}$ be κ-closed. Then

1. $\Vdash_{\mathbb{P}\times\mathbb{Q}}$ "$\check{\kappa}$ is a regular uncountable cardinal".

2. $\Vdash_{\mathbb{Q}}$ "$\check{\mathbb{P}}$ is $\check{\kappa}$-c.c.".

3. $\Vdash_{\mathbb{P}}$ "$\check{\mathbb{Q}}$ is $(\check{\kappa}, \infty)$-distributive".

It is sometimes useful to consider a stronger form of the κ-c.c. See Kunen and Tall's paper [48] for more information about the following property.

5.11 Definition. Let κ be an uncountable regular cardinal. A poset $\mathbb{P}$ is *κ-Knaster* if and only if for every κ-sequence of conditions $\langle p_\alpha : \alpha < \kappa\rangle$ there is a set $X \subseteq \kappa$ unbounded such that $\langle p_\alpha : \alpha \in X\rangle$ consists of pairwise compatible conditions.

For example the standard Δ-system proof [46, Theorem 1.6] that the Cohen poset $\mathrm{Add}(\kappa, \lambda)$ is $(2^{<\kappa})^+$-c.c. actually shows that $\mathrm{Add}(\kappa, \lambda)$ is $(2^{<\kappa})^+$-Knaster. The following easy fact shows that the Knaster property is in some ways better behaved than the property of being κ-c.c. It is not in general the case that the product of two κ-c.c. posets is κ-c.c.

5.12 Fact. Let κ be regular and let $\mathbb{P}$, $\mathbb{Q}$ be two notions of forcing. Then

1. If $\mathbb{P}$ and $\mathbb{Q}$ are κ-Knaster then $\mathbb{P}\times\mathbb{Q}$ is κ-Knaster.

2. If $\mathbb{P}$ is κ-c.c. and $\mathbb{Q}$ is κ-Knaster then $\mathbb{P}\times\mathbb{Q}$ is κ-c.c.

5.13 Remark. In general the property of being κ-Knaster is stronger than that of being κ-c.c. For example if T is an ω_1-Suslin tree then $(T, \geq)$ is ω_1-c.c. but is not ω_1-Knaster, by Fact 5.12 and the easy remark that $T \times T$ is not ω_1-c.c.

We will also need some properties intermediate between κ-closure and (κ, ∞)-distributivity, involving the idea of a game on a poset. This concept was introduced by Jech [37] and studied by Foreman [18] and Gray [30] among others.

5.14 Definition. Let $\mathbb{P}$ be a notion of forcing and let α be an ordinal. We define $G_\alpha(\mathbb{P})$, a two-player game of perfect information. Two players Odd and Even take turns to play conditions from $\mathbb{P}$ for α many moves, with Odd playing at odd stages and Even at even stages (including all limit stages). Even must play $1_\mathbb{P}$ at move zero. Let p_β be the condition played at move β; the player who played p_β loses immediately unless $p_\beta \leq p_\gamma$ for all $\gamma < \beta$. If neither player loses at any stage $\beta < \alpha$, then player Even wins.

5.15 Definition. Let $\mathbb{P}$ be a notion of forcing and let κ be a regular cardinal.

1. $\mathbb{P}$ is *$<\kappa$-strategically closed* if and only if for all $\alpha < \kappa$, player Even has a winning strategy for $G_\alpha(\mathbb{P})$.
2. $\mathbb{P}$ is *κ-strategically closed* if and only if player Even has a winning strategy for $G_\kappa(\mathbb{P})$.
3. $\mathbb{P}$ is *$(\kappa+1)$-strategically closed* if and only if player Even has a winning strategy for $G_{\kappa+1}(\mathbb{P})$, where we note that it is player Even who must make the final move.

5.16 Remark. More general forms of strategic closure have been studied [18] and are sometimes useful, but this one is sufficient for us.

5.17 Remark. It is not difficult to see that the conclusions of Lemma 5.10 remain true when we weaken the hypothesis of κ-closure to κ-strategic closure. This *strategic Easton lemma* is part of the folklore.

6. Some Forcing Posets

It is easy to see that every κ-directed closed poset is κ-closed, every κ-closed poset is κ-strategically closed, every κ-strategically closed poset is $<\kappa$-strategically closed and every $<\kappa$-strategically closed poset is (κ, ∞)-distributive. The following examples illustrate that these concepts are distinct, and will all find some use later in this chapter.

The first example shows that κ-closure does not in general imply κ-directed closure.

6.1 Example (Adding a Kurepa tree at an inaccessible cardinal). Recall that if κ is inaccessible then a *κ-Kurepa tree* is a normal tree of height κ such that

- $|T_\alpha| \leq |\alpha| + \omega$ for $\alpha < \kappa$.
- T has at least κ^+ cofinal branches.

Devlin's book about constructibility [16] contains more information about Kurepa trees, including a discussion of when such trees exist in L. We note that if κ is *ineffable* (ineffability is a large cardinal axiom intermediate between weak compactness and measurability) then there is no κ-Kurepa tree, and that in L there is such a tree for every non-ineffable inaccessible κ.

6.2 Remark. It might have seemed more natural generalize the definition of a Kurepa tree to inaccessible κ by dropping the first condition and requiring only that it be a κ-tree with more than κ cofinal branches. But this would be uninteresting because the complete binary tree of height κ is always such a tree.

6.3 Remark. It is very easy to see that there is no κ-Kurepa tree for κ measurable. For if T is such a tree and $j : V \longrightarrow M$ is elementary with critical point κ, then the map which takes each cofinal branch b to the unique point of $j(b)$ on level κ is one-to-one, so in M level κ of $j(T)$ has more than κ points.

Given κ inaccessible we define a forcing poset $\mathbb{P}$ to add a κ-Kurepa tree. Conditions are pairs (t, f) where

1. t is a normal tree of height $\beta + 1$ for some $\beta < \kappa$.

2. $|t_\alpha| \leq |\alpha| + \omega$ for all $\alpha \leq \beta$.

3. f is a function with $\mathrm{dom}(f) \subseteq \kappa^+$, $\mathrm{ran}(f) = t_\beta$ and $|\mathrm{dom}(f)| \leq |\beta| + \omega$.

Intuitively $f(\delta)$ is supposed to be the point in which branch δ meets t_β. Accordingly we say that $(u, g) \leq (t, f)$ if and only if

1. t is an initial segment of u.

2. $\mathrm{dom}(f) \subseteq \mathrm{dom}(g)$.

3. For all $\delta \in \mathrm{dom}(f)$, $f(\delta) \leq_u g(\delta)$.

It is easy to see that $\mathbb{P}$ is κ-closed and κ^+-c.c. and that $\mathbb{P}$ adds a κ-Kurepa tree. We claim that $\mathbb{P}$ is not κ-directed closed. To see this, let $\{x_\alpha : \alpha < 2^\omega\}$ enumerate ${}^\omega 2$ and let S be the family of conditions (t, f) such that $t = {}^n 2$ for some finite n, f has domain a countable subset of 2^ω and $f(\delta) = x_\delta \restriction n$ for all $\delta \in \mathrm{dom}(f)$. S is directed and $|S| = 2^\omega < \kappa$. However S cannot have a lower bound because, if (t, g) is a lower bound for S then t must have 2^ω points on level ω.

6.4 Remark. Similar arguments show that $\mathbb{P}$ has no dense κ-directed closed dense subset, and is not κ-directed closed below any condition. We will see in Theorem 24.12 that it is consistent for there to exist a measurable cardinal κ whose measurability is preserved by any κ-directed closed forcing, while by contrast forcing with the κ-closed poset $\mathbb{P}$ always destroys the measurability of κ.

Our next example shows that in general κ-strategic closure is a weaker property than κ-closure.

6.5 Example (Adding a non-reflecting stationary set). Let $\kappa = \mathrm{cf}(\kappa) \geq \omega_2$. We define a forcing poset $\mathbb{P}$ which aims to add a *non-reflecting stationary set of cofinality ω ordinals in κ*, that is to say a stationary $S \subseteq \kappa \cap \mathrm{Cof}(\omega)$ such that $S \cap \alpha$ is non-stationary for all $\alpha \in \kappa \cap \mathrm{Cof}(> \omega)$. $p \in \mathbb{P}$ if and only if p is a function such that

1. $\mathrm{dom}(p) < \kappa$, $\mathrm{ran}(p) \subseteq 2$.
2. If $p(\alpha) = 1$, $\mathrm{cf}(\alpha) = \omega$.
3. If $\beta \leq \mathrm{dom}(p)$ and $\mathrm{cf}(\beta) > \omega$ then there exists a set $c \subseteq \beta$ club in β such that $\forall \alpha \in c\; p(\alpha) = 0$.

It is easy to see that $\mathbb{P}$ is countably closed, and that it adds the characteristic function of a stationary subset of κ. It is also easy to see that if we let S be any stationary set of limit ordinals in ω_1, let $\chi_S : \omega_1 \to 2$ be the characteristic function of S, and define $p_\alpha = \chi_S \restriction \alpha$ for $\alpha < \omega_1$, then $\langle p_\alpha : \alpha < \omega_1 \rangle$ is a decreasing sequence of conditions in $\mathbb{P}$ with no lower bound and so $\mathbb{P}$ fails to be ω_2-closed.

We now claim that $\mathbb{P}$ is κ-strategically closed, which we will prove by exhibiting a winning strategy for Even. At stage α Even will compute $\gamma_\alpha = \mathrm{dom}(\bigcup_{\beta<\alpha} p_\beta)$, and will then define p_α by setting $\mathrm{dom}(p_\alpha) = \gamma_\alpha + 1$, $p_\alpha \restriction \gamma_\alpha = \bigcup_{\beta<\alpha} p_\beta$ and $p_\alpha(\gamma_\alpha) = 0$. This strategy succeeds because at every limit stage β of uncountable cofinality the set $\{\gamma_\alpha : \alpha < \beta\}$ is club in γ_β, and Even has ensured that p_β is 0 at every point of this club set.

The following example shows that in general the property of $<\kappa$-strategic closure is weaker than that of κ-strategic closure. The forcing is due to Jensen.

6.6 Example (Adding a square sequence). Let λ be an uncountable cardinal. Recall that a *$\square_\lambda$-sequence* is a sequence $\langle C_\alpha : \alpha \in \lambda^+ \cap \mathrm{Lim} \rangle$ such that for all α

1. C_α is club in α.
2. $\mathrm{ot}(C_\alpha) \leq \lambda$.
3. $\forall \beta \in \lim(C_\alpha)\; C_\alpha \cap \beta = C_\beta$.

We define a forcing poset $\mathbb{P}$ to add such a sequence. Conditions are initial segments of successor length of such a sequence and the ordering is extension. More formally $p \in \mathbb{P}$ iff

- $\mathrm{dom}(p) = (\beta + 1) \cap \mathrm{Lim}$ for some $\beta \in \lambda^+ \cap \mathrm{Lim}$.
- $p(\alpha)$ is club in α, $\mathrm{ot}(p(\alpha)) \leq \lambda$ for all $\alpha \in \mathrm{dom}(p)$.
- If $\alpha \in \mathrm{dom}(p)$ then $\forall \beta \in \lim p(\alpha)\; p(\alpha) \cap \beta = p(\beta)$.

If $p, q \in \mathbb{P}$ then $q \le p$ if and only if $p = q \restriction \mathrm{dom}(p)$.

It can be checked that $\mathbb{P}$ is $<\lambda^+$-strategically closed, so that $\mathbb{P}$ preserves cardinals up to λ^+ and adds a $\square_\lambda$-sequence. The author's joint paper with Foreman and Magidor [14] has a detailed discussion of the poset $\mathbb{P}$ and several variations.

We claim that $\mathbb{P}$ is not in general λ^+-strategically closed. To see this we observe that if player Even can win $G_{\lambda^+}(\mathbb{P})$, then the union of the sequence of the moves in a winning play is actually a $\square_\lambda$-sequence. So if $\square_\lambda$ fails then $\mathbb{P}$ is not λ^+-strategically closed. Ishiu and Yoshinobu [36] have observed that the principle $\square_\lambda$ is in fact equivalent to the λ^+-strategic closure of $\mathbb{P}$.

6.7 Remark. The difference between the last two examples is essentially that "S is a stationary subset of κ" is a second-order statement in the structure (H_κ, S) while "$\vec{C}$ is a $\square_\lambda$-sequence" is a first-order statement in the structure $(H_{\lambda^+}, \vec{C})$. This difference was exploited in [9].

Our final example shows that in general (κ, ∞)-distributivity is weaker than $<\kappa$-strategic closure. This forcing is due to Baumgartner, Harrington and Kleinberg [7].

6.8 Example (Killing a stationary subset of ω_1). Let $S \subseteq \omega_1$ be stationary and co-stationary. We define a forcing $\mathbb{P}$ to destroy the stationarity of S. The conditions in $\mathbb{P}$ are the closed bounded subsets c of ω_1 ordered by end-extension such that $c \cap S = \emptyset$.

We claim that $\mathbb{P}$ is (ω_1, ∞)-distributive. To see this let $\vec{D} = \langle D_n : n < \omega \rangle$ be an ω-sequence of dense open sets and let $c \in \mathbb{P}$. Fix θ some large regular cardinal and $<_\theta$ a well-ordering of H_θ. Find an elementary substructure $N \prec (H_\theta, \in, <_\theta)$ such that

1. $c, \mathbb{P}, S, \vec{D} \in N$.
2. N is countable.
3. $N \cap \omega_1 \notin S$ (this is possible because S is co-stationary).

Let $\delta = N \cap \omega_1$ and fix $\langle \delta_n : n < \omega \rangle$ an increasing and cofinal sequence in δ. Now build a chain of conditions $\langle c_n : n < \omega \rangle$ as follows: $c_0 = c$ and c_{n+1} is the $<_\theta$-least condition d such that $d \le c_n$, $d \in D_n$ and $\max(d) \ge \delta_n$. An easy induction shows that $c_n \in N$, so in particular $\max(c_n) \in N \cap \omega_1 = \delta$. It follows that if $c_\infty = \bigcup_n c_n \cup \{\delta\}$ then $c_\infty \in \mathbb{P}$, and by construction $c_\infty \in D_n$ for all n.

On the other hand $\mathbb{P}$ is not $<\omega_1$-strategically closed. To see this we show that for any $\mathbb{Q}$, if Even wins $G_{\omega+1}(\mathbb{Q})$ then $\mathbb{Q}$ preserves stationary subsets of ω_1. Let σ be a winning strategy for Even in $G_{\omega+1}(\mathbb{Q})$. Let $T \subseteq \omega_1$ be stationary. Let $q \Vdash_{\mathbb{Q}}$ "$\dot{C}$ is club in ω_1" and let $q, \mathbb{Q}, T, \dot{C}, \sigma \in N \prec (H_\theta, \in, <_\theta)$, where N is countable with $\delta = N \cap \omega_1 \in T$. Let $\langle E_n : n < \omega \rangle$ enumerate the dense subsets of $\mathbb{Q}$ which lie in N.

Now consider a run $\langle q_n : n \le \omega \rangle$ of $G_{\omega+1}(\mathbb{Q})$ such that

1. $q_0 = 1_{\mathbb{P}}$ and $q_1 = q$.
2. Even plays according to σ.
3. For $n > 0$, q_{2n+1} is the $<_\theta$-least condition r such that $r \leq q_{2n}$ and $r \in E_{n-1}$.

It is easy to see that $q_n \in \mathbb{Q} \cap N$ for $n < \omega$. The condition q_ω forces that $\delta \in \lim(\dot{C})$, so $q_\omega \Vdash \delta \in \dot{C} \cap \check{T}$ and we have shown that the stationarity of T is preserved.

6.9 Remark. The question of preservation of stationarity by forcing is one to which we will return several times in this chapter. The argument of Example 6.8 shows that for any ordinal λ of uncountable cofinality, any stationary $S \subseteq \lambda \cap \mathrm{Cof}(\omega)$ and any $(\omega+1)$-strategically closed $\mathbb{Q}$, forcing with $\mathbb{Q}$ preserves the stationarity of S. The situation is more complex for uncountable cofinalities, because if we build a structure N as in the last part of Example 6.8 and then try to build a suitable chain of conditions in N, we may in general wander out of N after ω steps. We will return to this topic in Lemma 10.6 and the proof of Theorem 14.10.

It will be convenient to fix some notation for the kind of forcing poset constructed in Example 6.8.

6.10 Definition. Let κ be a regular cardinal and let T be a stationary subset of κ. Then $\mathrm{CU}(\kappa, T)$ is the forcing poset whose conditions are closed bounded subsets of T, ordered by end-extension.

The poset of Example 6.8 is $\mathrm{CU}(\omega_1, \omega_1 \setminus S)$. For $\kappa > \omega_1$ the poset $\mathrm{CU}(\kappa, T)$ may not be well-behaved, in particular it may collapse cardinals; consider for example the situation where $\kappa = \omega_2$ and $T = \omega_2 \cap \mathrm{Cof}(\omega_1)$. See Sect. 18 for a detailed discussion of this issue.

7. Iterated Forcing

In this section we review the definition of iterated forcing and some basic facts about iterated forcing constructions. We will basically follow Baumgartner's survey paper [6] in our treatment of iterated forcing. Many readers may have learned iterated forcing from the excellent account in Kunen's book [46], and for their benefit we point out that there is one rather significant difference between the Baumgartner and Kunen treatments.

This involves the precise definition of a two-step iteration $\mathbb{P} * \dot{\mathbb{Q}}$ where $\mathbb{P}$ is a notion of forcing and $\dot{\mathbb{Q}}$ is a $\mathbb{P}$-name for a notion of forcing. In [46] the elements of $\mathbb{P} * \dot{\mathbb{Q}}$ are all pairs $(p, \dot{q})$ such that $p \in \mathbb{P}$ and $\dot{\mathbb{Q}}$ contains some pair of the form $(\dot{q}, r)$; Baumgartner [6] adopts a more liberal definition in which $\dot{q}$ is chosen from some set X of $\mathbb{P}$-names such that every $\mathbb{P}$-name for a member of $\dot{\mathbb{Q}}$ is forced to be equal to some name in X. This distinction makes for some (essentially trivial) differences in the theory, for example it is possible with the definition from [46] that $\mathbb{P}$ is countably closed and $\Vdash_{\mathbb{P}}$ "$\dot{\mathbb{Q}}$ is countably closed" but $\mathbb{P} * \dot{\mathbb{Q}}$ is not countably closed.

In the interests of precision we make the following definition, which really amounts to specifying the set of names X from the last paragraph.

7.1 Definition. Let $\mathbb{P}$ be a notion of forcing.

- A $\mathbb{P}$-name $\dot{x}$ is *canonical* iff there is no $\dot{y}$ such that $|\operatorname{tc}(\dot{y})| < |\operatorname{tc}(\dot{x})|$ and $\Vdash_{\mathbb{P}} \dot{x} = \dot{y}$.
- If $\dot{\mathbb{Q}}$ is a $\mathbb{P}$-name for a notion of forcing then $\mathbb{P} * \dot{\mathbb{Q}}$ is the set of all pairs such that $p \in \mathbb{P}$, $\Vdash_{\mathbb{P}} \dot{q} \in \dot{\mathbb{Q}}$ and $\dot{q}$ is canonical.

The advantage of this convention will be that we get equality rather than just isomorphism in statements like Lemma 12.10 below.

We recall the standard facts about two step iterations:

1. $\mathbb{P} * \dot{\mathbb{Q}}$ is ordered as follows: $(p_0, \dot{q}_0) \leq (p_1, \dot{q}_1)$ if and only if $p_0 \leq p_1$ and $p_0 \Vdash \dot{q}_0 \leq \dot{q}_1$.
2. There is a bijection between V-generic filters for $\mathbb{P} * \dot{\mathbb{Q}}$ and pairs (G, H) where G is V-generic for $\mathbb{P}$, and H is $V[G]$-generic for $i_G(\dot{Q})$.

As we mentioned above we will follow the treatment of iterated forcing from Baumgartner's survey paper [6]. We give a brief review. We make the convention that whenever we have a $\mathbb{P}$-name $\dot{\mathbb{Q}}$ for a notion of forcing, $\dot{1}_{\mathbb{Q}}$ names the specified largest element of $\dot{\mathbb{Q}}$.

An iteration of length α is officially an object of the form

$$(\langle \mathbb{P}_\beta : \beta \leq \alpha \rangle, \langle \dot{\mathbb{Q}}_\beta : \beta < \alpha \rangle)$$

where for every $\beta \leq \alpha$

- $\mathbb{P}_\beta$ is a notion of forcing whose elements are β-sequences.
- If $p \in \mathbb{P}_\beta$ and $\gamma < \beta$ then $p \restriction \gamma \in \mathbb{P}_\gamma$.
- If $\beta < \alpha$ then $\Vdash_{\mathbb{P}_\beta}$ "$\dot{\mathbb{Q}}_\beta$ is a notion of forcing".
- If $p \in \mathbb{P}_\beta$ and $\gamma < \beta$, then $p(\gamma)$ is a $\mathbb{P}_\gamma$-name for an element of $\dot{\mathbb{Q}}_\gamma$.
- If $\beta < \alpha$ then $\mathbb{P}_{\beta+1} \simeq \mathbb{P}_\beta * \dot{\mathbb{Q}}_\beta$, via the map which takes $h \in \mathbb{P}_{\beta+1}$ to $(h \restriction \beta, h(\beta))$.
- If $p, q \in \mathbb{P}_\beta$ then $p \leq_{\mathbb{P}_\beta} q$ iff $p \restriction \gamma \Vdash_{\mathbb{P}_\gamma} p(\gamma) \leq_{\dot{\mathbb{Q}}_\gamma} q(\gamma)$ for all $\gamma < \beta$.
- $1_{\mathbb{P}_\beta}(\gamma) = \dot{1}_{\mathbb{Q}_\gamma}$ for all $\gamma < \beta$.
- If $p \in \mathbb{P}_\beta$, $\gamma < \beta$ and $q \leq_{\mathbb{P}_\gamma} p \restriction \gamma$ then $q ^\frown p \restriction [\gamma, \beta) \in \mathbb{P}_\beta$.

In a standard abuse of notation we will sometimes use "$\mathbb{P}_\alpha$" as a shorthand for the iteration $(\langle \mathbb{P}_\beta : \beta \leq \alpha \rangle, \langle \dot{\mathbb{Q}}_\beta : \beta < \alpha \rangle)$. We usually write "$\Vdash_\beta$" for "$\Vdash_{\mathbb{P}_\beta}$".

The key points in the definition of iteration are that if G_α is $\mathbb{P}_\alpha$-generic over V and $\beta < \alpha$ then

- $G_\beta =_{\mathrm{def}} \{p \restriction \beta : p \in G_\alpha\}$ is $\mathbb{P}_\beta$-generic over V.
- $g_\beta =_{\mathrm{def}} \{i_{G_\beta}(p(\beta)) : p \in G_\alpha\}$ is $i_{G_\beta}(\dot{\mathbb{Q}}_\beta)$-generic over $V[G_\beta]$.

7.2 Remark. It is sometimes useful to weaken the conditions in the definition of iteration and to admit as a forcing iteration any pair $(\vec{\mathbb{P}}, \vec{\mathbb{Q}})$ where

1. $\mathbb{P}_\beta$ is a forcing poset whose conditions are β-sequences.
2. $\dot{\mathbb{Q}}_\beta$ is a $\mathbb{P}_\beta$-name for a forcing poset.
3. $\mathbb{P}_{\beta+1} \simeq \mathbb{P}_\beta * \dot{\mathbb{Q}}_\beta$, via the map which takes $h \in \mathbb{P}_{\beta+1}$ to $(h \restriction \beta, h(\beta))$.
4. The restriction map from $\mathbb{P}_\beta$ to $\mathbb{P}_\gamma$ for $\gamma < \beta$ is a projection.

Note that the "key properties" from the last paragraph will still be true in this setting. An important example is Prikry iteration with Easton support (see [22]) which are iterations in this more general sense.

7.3 Remark. Some arguments which we need to do subsequently work most smoothly with forcing posets which are separative partial orderings. The poset absorption argument of Sect. 14 is an example. In our definition of iterated forcing $\mathbb{P}_\alpha$ is just a notion of forcing. However it is routine to check that if we form an iteration such that each factor $\dot{\mathbb{Q}}_i$ is forced to be a separative partial ordering, then the quotient poset of $\mathbb{P}_\alpha$ is separative. We will sometimes blur the distinction between the preordering $\mathbb{P}_\alpha$ and its associated quotient partial ordering.

If $p \in \mathbb{P}_\alpha$ then the *support of* p ($\mathrm{supp}(p)$) is $\{\beta < \alpha : p(\beta) \neq \dot{1}_{\mathbb{Q}_\beta}\}$.

Let λ be a limit ordinal and let an iteration of length λ be given. We define the *inverse limit* $\varprojlim \vec{\mathbb{P}} \restriction \lambda$ to be the set of sequences p of length λ such that $\forall \alpha < \lambda \; p \restriction \alpha \in \mathbb{P}_\alpha$. The *direct limit* $\varinjlim \vec{\mathbb{P}} \restriction \lambda$ is the subset of the inverse limit consisting of those p such that $p(\alpha) = \dot{1}_{\mathbb{Q}_\alpha}$ for all sufficiently large α. The definition of a forcing iteration implies that if we have an iteration of length greater than λ then

$$\varinjlim \vec{\mathbb{P}} \restriction \lambda \subseteq \mathbb{P}_\lambda \subseteq \varprojlim \vec{\mathbb{P}} \restriction \lambda.$$

To specify a forcing iteration it will suffice to describe the names $\dot{\mathbb{Q}}_\beta$ and to give a procedure for computing $\mathbb{P}_\lambda$ for λ limit. In many iterations the only kinds of limit which are used are direct and inverse ones.

7.4 Remark. Let κ be inaccessible, and suppose that we have an iteration of length κ where $\dot{\mathbb{Q}}_\beta \in V_\kappa$ for all $\beta < \kappa$ and a direct limit is taken at stage κ. Then

- $\mathbb{P}_\beta \subseteq V_\kappa$ for all $\beta < \kappa$.
- While it is not literally true that $\mathbb{P}_\kappa \subseteq V_\kappa$, for every $p \in \mathbb{P}_\kappa$ there exist $\beta < \kappa$ and $q \in \mathbb{P}_\beta$ such that $p(\alpha) = q(\alpha)$ for $\alpha < \beta$, $p(\alpha) = \dot{1}_{\mathbb{Q}_\alpha}$ for $\beta \leq \alpha < \kappa$. We will often blur the distinction between $\mathbb{P}_\kappa$ and $\bigcup_\alpha \mathbb{P}_\alpha$, which actually is a subset of V_κ.

7.5 Definition. If κ is regular then an *iteration with $<\kappa$-support* is an iteration in which direct limits are taken at limit stages of cofinality greater than or equal to κ, and inverse limits are taken at limit stages of cofinality less than κ. An *iteration with Easton support* is an iteration in which direct limits are taken at regular limit stages and inverse limits are taken elsewhere.

As this terminology would suggest, the support of a condition in an iteration with $<\kappa$-support has size less than κ. The support of a condition in an Easton iteration is an *Easton set*, that is to say a set of ordinals which is bounded in every regular cardinal.

The following are a few key facts about two-step iterations. Proofs are given in [6, Sect. 2] for 1 and 2, while the proofs for 3 are easy variations of the proof for 2.

7.6 Proposition. *Let $\kappa = \mathrm{cf}(\kappa) > \omega$, let $\mathbb{P}$ be a notion of forcing and let $\Vdash_{\mathbb{P}}$ "$\dot{\mathbb{Q}}$ is a notion of forcing".*

1. *$\mathbb{P} * \dot{\mathbb{Q}}$ is κ-c.c. iff $\mathbb{P}$ is κ-c.c. and $\Vdash_{\mathbb{P}}$ "$\dot{\mathbb{Q}}$ is κ-c.c.".*
2. *If $\mathbb{P}$ is κ-closed and $\Vdash_{\mathbb{P}}$ "$\dot{\mathbb{Q}}$ is κ-closed" then $\mathbb{P} * \dot{\mathbb{Q}}$ is κ-closed.*
3. *Let X be any of the properties "κ-directed closed", "$<\kappa$-strategically closed" or "κ-strategically closed". If $\mathbb{P}$ is X and $\Vdash_{\mathbb{P}}$ "$\dot{\mathbb{Q}}$ is X" then $\mathbb{P} * \dot{\mathbb{Q}}$ is X.*

7.7 Proposition. *Let κ be inaccessible and $\mathbb{P} \in V_\kappa$. If $\Vdash_{\mathbb{P}} \dot{\mathbb{Q}} \in \dot{V}_\kappa$ then $\mathbb{P} * \dot{\mathbb{Q}} \in V_\kappa$, and if $\Vdash_{\mathbb{P}} \dot{\mathbb{Q}} \subseteq V_\kappa$ then $\mathbb{P} * \dot{\mathbb{Q}} \subseteq V_\kappa$.*

In general the preservation of chain condition in iterations is a very delicate question. See [6, Sect. 4] and [62] to get an idea of the difficulties surrounding preservation of the ω_2-c.c. by countable support iterations. Fortunately we can generally get away with some comparatively crude arguments.

The following fact is proved in [6, Sect. 2].

7.8 Proposition. *Let α be limit and let $\mathbb{P}_\alpha = \varinjlim \vec{\mathbb{P}} \restriction \alpha$. Let $\kappa = \mathrm{cf}(\kappa) > \omega$. Suppose that*

- *For every $\beta < \alpha$, $\mathbb{P}_\beta$ is κ-c.c.*
- *If* $\mathrm{cf}(\alpha) = \kappa$ *then* $\{\gamma < \alpha : \mathbb{P}_\gamma = \varinjlim \vec{\mathbb{P}} \restriction \gamma\}$ *is stationary in α.*

Then $\mathbb{P}_\alpha$ is κ-c.c.

The following fact is proved in [6, Sect. 2] for the case when X equals "κ-closed". The proofs for the other closure properties are similar.

7.9 Proposition. *Let $\kappa = \mathrm{cf}(\kappa) > \omega$. Let X be any of the properties "κ-closed", "κ-directed closed", "$<\kappa$-strategically closed" or "κ-strategically closed". Suppose that*

- $\Vdash_\beta$ *"$\dot{\mathbb{Q}}_\beta$ is X" for $\beta < \alpha$.*
- *All limits are direct or inverse, and inverse limits are taken at every limit stage with cofinality less than κ.*

Then $\mathbb{P}_\alpha$ is X.

7.10 Remark. The moral of Proposition 7.8 is that one should take many direct limits to preserve chain condition properties; the moral of Proposition 7.9 is that one should take many inverse limits to preserve closure properties.

We will also need to analyze the quotient of an iteration by some initial segment. Once again we quote from [6, Sect. 5].

7.11 Proposition. *If $\beta < \alpha$ then there exists a term $\dot{\mathbb{R}}_{\beta,\alpha} \in V^{\mathbb{P}_\beta}$ such that*

1. $\Vdash_\beta$ *"$\mathbb{R}_{\beta,\alpha}$ is an iteration of length $\alpha - \beta$".*
2. *There is a dense subset of $\mathbb{P}_\beta * \dot{\mathbb{R}}_{\beta,\alpha}$ which is isomorphic to $\mathbb{P}_\alpha$.*

The definition of the iteration $\mathbb{R}_{\beta,\alpha}$ is simple at successor stages; we translate $\dot{\mathbb{Q}}_\gamma$ in the canonical way to a $\mathbb{P}_\beta$-name for an $\mathbb{R}_{\beta,\gamma}$-name for a notion of forcing and force with that poset at stage $\gamma - \alpha$. Limits are trickier because while a direct limit in V still looks like a direct limit in $V^{\mathbb{P}_\beta}$ the same may not be true in general of an inverse limit. We will usually write $\mathbb{P}_\alpha / G_\beta$ for $i_{G_\beta}(\dot{\mathbb{R}}_{\beta,\alpha})$.

The following proposition is proved in [6, Sect. 5] for the case when X equals "κ-closed", and once again can be proved in a very similar way for the other closure properties.

7.12 Proposition. *Let $\kappa = \mathrm{cf}(\kappa) > \omega$. Let X be any of the properties "κ-closed", "κ-directed closed", "$<\kappa$-strategically closed" or "κ-strategically closed". Let $\mathbb{P}_\alpha$ be an iteration of length α in which all limits are inverse or direct. Let $\beta < \alpha$ and suppose that*

1. *$\mathbb{P}_\beta$ is such that every set of ordinals of size less than κ in $V[G_\beta]$ is covered by a set of size less than κ in V.*

2. *For* $\beta \leq \gamma < \alpha$, $\Vdash_\gamma$ "$\dot{\mathbb{Q}}_\gamma$ *is* X".

3. *Inverse limits are taken at all limit* γ *such that* $\beta \leq \gamma < \alpha$ *and* $\mathrm{cf}(\gamma) < \kappa$.

Then $\Vdash_\beta$ "$\dot{\mathbb{R}}_{\beta,\alpha}$ *is* X".

The following result is easily proved by the methods of [6, Sect. 2].

7.13 Proposition. *Let* κ *be inaccessible and let* $\mathbb{P}_\kappa$ *be an iteration of length* κ *such that*

1. $\Vdash_\alpha \dot{\mathbb{Q}}_\alpha \in V_\kappa$ *for all* $\alpha < \kappa$.

2. *A direct limit is taken at* κ *and on a stationary set of limit stages below* κ.

Then

- $\mathbb{P}_\kappa$ *is* κ*-Knaster and has cardinality* κ.
- *If* $\delta < \kappa$ *then in* $V[G_\delta]$ *the quotient forcing* $\mathbb{R}_{\delta,\kappa}$ *is a* κ*-Knaster and has cardinality* κ.

7.14 Remark. The hypothesis 2 of Proposition 7.13 will be satisfied if the iteration is done with $<\lambda$-support for some $\lambda < \kappa$, and also if the iteration is done with Easton support and κ is Mahlo.

8. Building Generic Objects

A crucial fact about forcing is that if M is a countable transitive model of set theory and $\mathbb{P} \in M$ is a notion of forcing, then there exist filters which are $\mathbb{P}$-generic over M. We give an easy generalization of this fact, which will be used very frequently in the constructions to follow.

8.1 Proposition. *Let* M *and* N *be two inner models with* $M \subseteq N$ *and let* $\mathbb{P} \in M$ *be a non-trivial notion of forcing. Let* $\mathcal{A}$ *be the set of* $A \in M$ *such that* A *is an antichain of* $\mathbb{P}$, *and note that* $\mathcal{A} \in M$.

Let $p \in \mathbb{P}$ *and let* λ *be an* N*-cardinal. If*

$$N \models \text{“}\mathbb{P} \textit{ is } \lambda\textit{-strategically closed and } |\mathcal{A}| \leq \lambda\text{”}$$

then there is a set in N *of* N*-cardinality* 2^λ *of filters on* $\mathbb{P}$, *each one of which contains* p *and is generic over* M.

Proof. We work in N. Let $\langle A_\alpha : \alpha < \lambda\rangle$ enumerate $\mathcal{A}$. Let σ be a winning strategy for player Even in the game $G_\lambda(\mathbb{P}/p)$.

We now build a binary tree $\langle p_s : s \in {}^{<\lambda}2\rangle$ of conditions in $\mathbb{P}/p$ such that

1. $p_{\langle\rangle} = p$.

2. If $\mathrm{lh}(s)$ is even, say $\mathrm{lh}(s) = 2\alpha$, then $p_{s\frown 0}$ and $p_{s\frown 1}$ are incompatible and each of them refines some element of A_α.

3. If $\mathrm{lh}(s) = 2(1+\alpha)$, then p_s is the response dictated by σ at move 2α in the run of the game $G_\lambda(\mathbb{P}/p)$ where $p_{s\restriction(2+i)}$ is played at move i for $i < 2\alpha$.

Then every branch generates a generic filter, and any two branches contain incompatible elements so generate distinct filters. ⊣

The following easy propositions will be useful in applications of Proposition 8.1.

8.2 Proposition. *Let M and N be inner models of* ZFC *such that $M \subseteq N$. Let $N \models$ "κ is a regular uncountable cardinal". Then $N \models {}^{<\kappa}M \subseteq M$ if and only if $N \models {}^{<\kappa}\mathrm{On} \subseteq M$.*

8.3 Proposition. *Let M and N be inner models of* ZFC *such that $M \subseteq N$. Let $N \models$ "κ is a regular uncountable cardinal" and let $N \models {}^{<\kappa}M \subseteq M$. Let $\mathbb{P} \in M$ be a notion of forcing and let X be any of the properties "κ-directed closed", "κ-closed", "κ-strategically closed" and "$<\kappa$-strategically closed".*

If $M \models$ "$\mathbb{P}$ is X" then $N \models$ "$\mathbb{P}$ is X".

8.4 Proposition. *Let M and N be inner models of* ZFC *with $M \subseteq N$ and let $\mathbb{P} \in M$ be a notion of forcing.*

1. *If $N \models {}^{<\lambda}M \subseteq M$, $N \models$ "$\mathbb{P}$ is λ-c.c." and G is $\mathbb{P}$-generic over N then $N[G] \models {}^{<\lambda}M[G] \subseteq M[G]$.*

2. *If $V_\lambda \cap M = V_\lambda \cap N$ and*

$$N \models \text{“Every canonical } \mathbb{P}\text{-name for a member of } V_\lambda^{N^{\mathbb{P}}} \text{ is in } V_\lambda\text{”}$$

then $V_\lambda \cap M[G] = V_\lambda \cap N[G]$.

We digress from our main theme to give a sample application of Proposition 8.1, namely, building a generalized version of Prikry forcing.

8.5 Lemma. *Let κ be measurable with $2^\kappa = \kappa^+$, and let U be a normal measure on κ. Let $j : V \longrightarrow M = \mathrm{Ult}(V, U)$ be the ultrapower map constructed from U, and let $\mathbb{Q} = \mathrm{Col}(\kappa^{++}, {<}j(\kappa))_M$. Then there is a filter $g \in V$ which is $\mathbb{Q}$-generic over M.*

Proof. In M, $\mathbb{Q}$ is a forcing of size $j(\kappa)$ which is $j(\kappa)$-c.c. Since $j(\kappa)$ is measurable in M it is surely inaccessible in M, and so

$$M \models \text{“}\mathbb{Q} \text{ has } j(\kappa) \text{ maximal antichains”}.$$

By Proposition 4.5 $V \models |j(\kappa)| = 2^\kappa = \kappa^+$, so

$$V \models \text{“}\mathbb{Q} \text{ has } \kappa^+ \text{ maximal antichains lying in } M\text{”}.$$

Clearly $M \models$ "$\mathbb{Q}$ is κ^{++}-closed", and $V \models {}^{\kappa}M \subseteq M$. By Proposition 8.3 it follows that $V \models$ "$\mathbb{Q}$ is κ^{+}-closed". Applying Proposition 8.1 we may therefore construct $g \in V$ which is $\mathbb{Q}$-generic over M. ⊣

The forcing we are about to describe is essentially a special case of the forcing $\mathbb{P}^{\pi}$ from Foreman and Woodin's paper on failure of GCH everywhere [20], and is also implicitly present in Magidor's work on failure of SCH [53]. We learned this presentation from Woodin.

8.6 Example. Let κ be measurable with $2^{\kappa} = \kappa^{+}$. Then there is a κ^{+}-c.c. poset $\mathbb{P}$ such that $\Vdash_{\mathbb{P}} \check{\kappa} = \dot{\omega}_{\omega}$.

Sketch of Proof. Let U, $\mathbb{Q}$ and g be as in Lemma 8.5. Conditions in $\mathbb{P}$ have the form $(p_0, \kappa_1, p_1, \ldots, \kappa_n, p_n, H)$ where

- The κ_i are inaccessible with $\kappa_1 < \cdots < \kappa_n < \kappa$.
-
  - $p_0 \in \mathrm{Col}(\omega_2, {<}\kappa_1)$.
  - $p_i \in \mathrm{Col}(\kappa_i^{++}, {<}\kappa_{i+1})$ for $0 < i < n$.
  - $p_n \in \mathrm{Col}(\kappa_n, {<}\kappa)$.
- H is a function such that $\mathrm{dom}(H) \in U$, $H(\alpha) \in \mathrm{Col}(\alpha^{++}, {<}\kappa)$ for $\alpha \in \mathrm{dom}(H)$ and $[H]_U \in g$.

We refer to n as the *length* of this condition.

Intuitively H constrains the possibilities for adding in new objects in the same way as the measure one set constrains new points in Prikry forcing. Formally $(q_0, \lambda_1, q_1, \ldots, \lambda_m, q_m, I)$ extends $(p_0, \kappa_1, p_1, \ldots, \kappa_n, p_n, H)$ iff

- $m \geq n$.
- For every $i \leq n$, $\lambda_i = \kappa_i$ and q_i extends p_i.
- For every i with $n < i \leq m$, $\lambda_i \in \mathrm{dom}(H)$ and $q_i \leq H(\lambda_i)$.
- $\mathrm{dom}(I) \subseteq \mathrm{dom}(H)$ and $I(\lambda)$ extends $H(\lambda)$ for every $\lambda \in \mathrm{dom}(I)$.

The second condition will be called a *direct* extension of the first if and only if $m = n$.

It is easy to see that $\mathbb{P}$ is κ^{+}-c.c. because any two elements in g are compatible. The poset $\mathbb{P}$ adds an increasing ω-sequence $\langle \kappa_i : i < \omega \rangle$ cofinal in κ (which is actually a Prikry-generic sequence for the measure U) and a sequence $\langle g_i : i < \omega \rangle$ where g_i is $\mathrm{Col}(\kappa_i^{++}, {<}\kappa_{i+1})$-generic over V.

The key lemma about $\mathbb{P}$ is that any statement in the forcing language can be decided by a direct extension. This is proved by an argument very similar to that for Prikry forcing. It can then be argued as in Magidor's paper [53] that below κ only the cardinals in the intervals $(\kappa_i^{++}, \kappa_{i+1})$ have collapsed. Thus $\mathbb{P}$ is a κ^{+}-c.c. forcing poset which makes κ into the ω_ω of the extension. ⊣

9. Lifting Elementary Embeddings

A key idea in this chapter is that it is sometimes possible to take an elementary embedding of a model of set theory and extend it to an embedding of some generic extension of that model. This idea goes back to Silver's consistency proof for the failure of GCH at a measurable, a proof which we will outline in Sect. 12.

9.1 Proposition. *Let $k : M \longrightarrow N$ be an elementary embedding between transitive models of* ZFC*. Let $\mathbb{P} \in M$ be a notion of forcing, let G be $\mathbb{P}$-generic over M and let H be $k(\mathbb{P})$-generic over N. The following are equivalent:*

1. *$\forall p \in G\ k(p) \in H$.*
2. *There exists an elementary embedding $k^+ : M[G] \longrightarrow N[H]$, such that $k^+(G) = H$ and $k^+ \restriction M = k$.*

Proof. Clearly the second statement implies the first one. For the converse let $k``G \subseteq H$ and attempt to define k^+ by

$$k^+(i_G(\dot{\tau})) = i_H(k(\dot{\tau})).$$

To check that k^+ is well-defined, let $i_G(\dot{\sigma}) = i_G(\dot{\tau})$ and fix $p \in G$ such that $p \Vdash^M_{\mathbb{P}} \dot{\sigma} = \dot{\tau}$. Now by elementarity $k(p) \Vdash^N_{k(\mathbb{P})} k(\dot{\sigma}) = k(\dot{\tau})$, and since $k(p) \in H$ we have $i_H(k(\dot{\sigma})) = i_H(k(\dot{\tau}))$.

A similar proof shows that k^+ is elementary. If $x \in M$ and $\check{x}$ is the standard $\mathbb{P}$-name for x then $k(\check{x})$ is the standard $k(\mathbb{P})$-name for $k(x)$ and so $k^+(x) = k^+(i_G(\check{x})) = i_H(k(\check{x})) = k(x)$. Similarly if $\dot{G}$ is the standard $\mathbb{P}$-name for the $\mathbb{P}$-generic filter then $k(\dot{G})$ is the standard $k(\mathbb{P})$-name for the $k(\mathbb{P})$-generic filter, and so $k^+(G) = H$. ⊣

The following propositions give some useful structural information about the lifted embedding k^+. Recall that we defined the *width* and *support* of an embedding in Definitions 3.7 and 3.8.

9.2 Proposition. *Let $k : M \longrightarrow N$ be an elementary embedding between transitive models of* ZFC *and let G, H, $k^+ : M[G] \longrightarrow N[H]$ be as in Proposition 9.1. Then $N \cap \operatorname{ran}(k^+) = \operatorname{ran}(k)$.*

Proof. Let $y \in N$ with $y = k^+(x)$ for some $x \in M[G]$. If $\alpha = 1 + \operatorname{rk}(x)$ then by elementarity $y \in V^N_{k(\alpha)}$. Since k^+ extends k and k is an elementary embedding, $k^+(V^M_\alpha) = k(V^M_\alpha) = V^N_{k(\alpha)}$. So $k^+(x) \in k^+(V^M_\alpha)$, and since k^+ is elementary $x \in V^M_\alpha$. So $x \in M$ and $y = k^+(x) = k(x)$, thus $y \in \operatorname{ran}(k)$. ⊣

9.3 Proposition. *Let $k : M \longrightarrow N$, G, H, $k^+ : M[G] \longrightarrow N[H]$ be as in Proposition 9.1. If k has width $\leq \mu$ then k^+ has width $\leq \mu$. If k is supported on A then k^+ is supported on A.*

Proof. Suppose first that k has width $\leq \mu$. Let $y \in N[H]$, so that $y = i_H(\dot{\tau})$ for some $k(\mathbb{P})$-name $\dot{\tau} \in N$. By our assumptions about k, $\dot{\tau} = k(F)(a)$ where $F \in M$, $a \in N$ and $M \models |\operatorname{dom}(F)| \leq \mu$. Without loss of generality we may assume that $F(x)$ is a $\mathbb{P}$-name for all $x \in \operatorname{dom}(F)$.

Now we define a function $F^* \in M[G]$ by setting $\operatorname{dom}(F^*) = \operatorname{dom}(F)$ and $F^*(x) = i_G(F(x))$ for all $x \in \operatorname{dom}(F)$. By elementarity

$$k^+(F^*)(a) = i_{k^+(G)}(k^+(F)(a)) = i_H(\dot{\tau}) = y.$$

Therefore k^+ has width $\leq \mu$. The argument for the property "supported on A" is very similar. ⊣

In Sect. 4 we gave characterizations of various large cardinal axioms in terms of *definable* elementary embeddings. When we apply Proposition 9.1 to a definable embedding it is likely that definability will be lost; the next section gives an example of this phenomenon.

One of our major themes is forcing iterations which preserve large cardinal axiom, so we would like to preserve definability when applying Proposition 9.1. This motivates the following proposition, where the key hypothesis for getting a definable embedding is that we are choosing $H \in V[G]$.

9.4 Proposition. *Let $\kappa < \lambda$ and let $j : V \longrightarrow M$ be an elementary embedding with critical point κ. Let $\mathbb{P} \in V$ be a notion of forcing, and let G be $\mathbb{P}$-generic over V. Let H be $j(\mathbb{P})$-generic over M with $j``G \subseteq H$, and let $j^+ : V[G] \longrightarrow M[H]$ be the unique embedding with $j^+ \restriction V = j$ and $j^+(G) = H$. Let $H \in V[G]$.*

1. *If there is in V a short V-(κ, λ)-extender E such that j is the ultrapower of V by E, then there is in $V[G]$ a short $V[G]$-(κ, λ)-extender E^* such that j^+ is the ultrapower of $V[G]$ by E^*. Moreover $E_a = E^*_a \cap V$ for all $a \in [\lambda]^{<\omega}$.*

2. *If there is in V a supercompactness measure U on $P_\kappa\lambda$ such that j is the ultrapower of V by U, then there is in $V[G]$ a supercompactness measure U^* on $P_\kappa\lambda$ such that j^+ is the ultrapower of $V[G]$ by U^*. Moreover $U = U^* \cap V$.*

In both cases j^+ is definable.

Proof. Assume first that j is the ultrapower by some (κ, λ)-extender E. For each $a \in [\lambda]^{<\omega}$ let μ_a be minimal with $a \subseteq j(\mu_a)$. Arguing exactly as in the proof of Proposition 9.3,

$$M[H] = \{j^+(F)(a) : a \in [\lambda]^{<\omega}, F \in V[G], \operatorname{dom}(F) = [\mu_a]^{|a|}\}.$$

If we now let E^* be the (κ, λ)-extender derived from j^+ then it follows easily from the equation above and Proposition 3.4 that $\operatorname{Ult}(V[G], E^*) = M[H]$ and

$j_{E^*} = j^+$. Since $H \in V[G]$ we see that $E^* \in V[G]$ and so j^+ is definable. Finally if $X \in V$ and $X \subseteq [\kappa]^{|a|}$ then $j(X) = j^+(X)$, so

$$X \in E_a \iff a \in j(X) \iff a \in j^+(X) \iff X \in E^*_a,$$

that is to say $E_a = E^*_a \cap V$.

The argument for j arising from a supercompactness measure is similar. ⊣

9.5 Remark. Either clause of Proposition 9.4 can be used to argue that κ is measurable in $V[G]$. By Remark 4.1 we may use the second clause to conclude without further work that κ is λ-supercompact in $V[G]$; preservation of some strength witnessed by E will need some argument about the resemblance between $V[G]$ and $M[H]$.

In what follows we will see a number of ways of arranging that k"$G \subseteq H$. We start by proving a classical result by Levy and Solovay (which implies in particular that standard large cardinal hypotheses cannot resolve the Continuum Hypothesis).

9.6 Theorem (Levy and Solovay [50]). *Let κ be measurable. Let $|\mathbb{P}| < \kappa$ and let G be $\mathbb{P}$-generic. Then κ is measurable in $V[G]$.*

Proof. Let U be a measure on κ and let $j : V \longrightarrow M = \mathrm{Ult}(M, U)$ be the ultrapower map. Without loss of generality $\mathbb{P} \in V_\kappa$, so that $j \restriction \mathbb{P} = \mathrm{id}_{\mathbb{P}}$ and $j(\mathbb{P}) = \mathbb{P}$. In particular j"$G = G$, and since $M \subseteq V$ and $\mathbb{P} \in M$ we have that G is $\mathbb{P}$-generic over M. Now by Proposition 9.1 we may lift j to get a new map $j^+ : V[G] \longrightarrow M[G]$. By Proposition 9.4 j^+ is definable in $V[G]$. j^+ extends j and so $\mathrm{crit}(j^+) = \mathrm{crit}(j) = \kappa$, and thus κ is measurable in $V[G]$. ⊣

9.7 Remark. Usually when we lift an embedding we will denote the lifted embedding by the same letter as the original one.

The Levy-Solovay result actually applies to most other popular large cardinal axioms, for example "κ is λ-strong" or "κ is λ-supercompact".

9.8 Theorem. *Let $|\mathbb{P}| < \kappa$ and let $\lambda > \kappa$. Then forcing with $\mathbb{P}$ preserves the statements "κ is λ-strong" and "κ is λ-supercompact".*

Proof. Without loss of generality $\mathbb{P} \in V_\kappa$. Let G be $\mathbb{P}$-generic over V.

Suppose that κ is λ-strong. Let $j : V \longrightarrow M$ be such that $\mathrm{crit}(j) = \kappa$ and $V_\lambda \subseteq M$. Build $j^+ : V[G] \longrightarrow M[G]$ as in Theorem 9.6. By Proposition 8.4 we see that $V_\lambda^{V[G]} \subseteq M[G]$. By Proposition 9.4 j^+ is definable in $V[G]$. Since $\mathrm{crit}(j^+) = \kappa$, κ is λ-strong in $V[G]$.

The argument for λ-supercompactness is analogous. ⊣

9.9 Remark. Levy and Solovay also showed that small forcing cannot create instances of measurability. We prove a generalization of this in Theorem 21.1. In Theorem 14.6 a forcing poset of size κ makes a non-weakly compact cardinal κ measurable. See Sect. 21 for more discussion of these matters.

10. Generic Embeddings

It is a common situation that in some generic extension $V[G]$ we are able to define an elementary embedding $j : V \longrightarrow M \subseteq V[G]$. Such embeddings are usually known as *generic embeddings*. Foreman's chapter in this Handbook contains a wealth of information about generic embeddings, e.g. about the following situation.

10.1 Example. If I is an ω_2-saturated ideal on ω_1 and U is generic for the poset of I-positive sets, then in $V[U]$ the ultrapower $\mathrm{Ult}(V, U)$ is well-founded and we get a map $j : V \longrightarrow M \subseteq V[U]$ with $\mathrm{crit}(j) = \omega_1$ and $j(\omega_1) = \omega_2$.

We now honor a promise made in Sect. 2. The embedding that we describe is a generic embedding with critical point ω_1 and is added by a very simple poset. See Theorems 14.6, 23.2 and 24.11 for some applications of generic embeddings added by more elaborate posets.

10.2 Theorem. *Let κ be measurable, let U be a normal measure on κ and let $j : V \longrightarrow M = \mathrm{Ult}(V, U)$ be the ultrapower map. Let $\mathbb{P} = \mathrm{Col}(\omega, {<}\kappa)$ and let G be $\mathbb{P}$-generic. There is a forcing poset $\mathbb{Q} \in M$ such that*

1. *For any H a $\mathbb{Q}$-generic filter over $V[G]$, j can be lifted to an elementary embedding $j_G : V[G] \longrightarrow M[G * H]$.*
2. *If*
$$U_G = \{X \in P(\kappa) \cap V[G] : \kappa \in j_G(X)\},$$
then U_G is a $V[G]$-κ-complete $V[G]$-normal $V[G]$-ultrafilter on κ. Also $M[G * H] = \mathrm{Ult}(V[G], U_G)$ and j_G is the ultrapower map.

Proof. By elementarity $j(\mathbb{P}) = \mathrm{Col}(\omega, {<}j(\kappa))$. Let $\mathbb{Q}$ be the set of finite partial functions q from $\omega \times (j(\kappa) \setminus \kappa)$ to $j(\kappa)$ such that $q(n, \alpha) < \alpha$ for all $(n, \alpha) \in \mathrm{dom}(p)$, ordered by reverse inclusion. Clearly the map which sends p to $(p\restriction(\omega \times \kappa), p\restriction(\omega \times (j(\kappa) \setminus \kappa)))$ sets up an isomorphism in M between $j(\mathbb{P})$ and $\mathbb{P} \times \mathbb{Q}$.

Now let H be $\mathbb{Q}$-generic over $V[G]$, so that by the Product Lemma $G \times H$ is $\mathbb{P} \times \mathbb{Q}$-generic over V. Let H^* be the $j(\mathbb{P})$-generic object which is isomorphic to $G \times H$ via the isomorphism from the last paragraph, that is

$$H^* = \{r \in j(\mathbb{P}) : r\restriction(\omega \times \kappa) \in G, r\restriction(\omega \times (j(\kappa) \setminus \kappa)) \in H\}.$$

If $p \in G$ then $\mathrm{dom}(p)$ is a finite subset of $\omega \times \kappa$ and $p(n, \alpha) < \alpha < \kappa$ for all $(n, \alpha) \in \mathrm{dom}(p)$. It follows that $\mathrm{dom}(j(p)) = j(\mathrm{dom}(p)) = \mathrm{dom}(p)$, and what is more, if $p(n, \alpha) = \beta$ then $j(p)(n, \alpha) = j(p(n, \alpha)) = j(\beta) = \beta$. So $p = j(p) \in H^*$.

We now work in $V[G * H]$. By Proposition 9.1 we can lift j to get $j_G : V[G] \longrightarrow M[H^*] = M[G * H]$. It then follows from Proposition 3.9 $M[G * H] = \mathrm{Ult}(V[G], U_G)$ and j_G is precisely the ultrapower embedding. Of course U_G does not exist in $V[G]$; it is only definable in the generic extension $V[G * H]$. $\dashv$

10.3 Remark. This theorem provides an example of an elementary embedding $k : M_1 \longrightarrow M_2$ with critical point $\omega_1^{M_1}$ and $P(\omega) \cap M_1 \subsetneq P(\omega) \cap M_2$. This shows that Proposition 2.6 is sharp.

10.4 Remark. An important feature of the last proof was the product analysis of $j(\mathbb{P})$. In that proof we were careful to stress that $G \times H$ and H^* are isomorphic rather than identical.

In what follows we will follow the standard practice and be more cavalier about these issues. The cavalier way of writing the main point in the last proof is to say "$p \in G$ implies that $j(p) = p \in G \times H$".

Theorem 10.2 can be generalized in a way that is important for several later results.

10.5 Theorem. *Let κ be measurable, let U be a normal measure on κ and let $j : V \longrightarrow M = \mathrm{Ult}(V, U)$ be the ultrapower map. Let δ be an uncountable regular cardinal less than κ. Let $\mathbb{P} = \mathrm{Col}(\delta, {<}\kappa)$ and let G be $\mathbb{P}$-generic. There is a δ-closed forcing poset $\mathbb{Q} \in M$ such that for any H a $\mathbb{Q}$-generic filter, j can be lifted to an elementary embedding $j_G : V[G] \longrightarrow M[G * H]$.*

The proof is just like that of Theorem 10.2. It will be useful later to know that some reflection properties of the original measurable cardinal κ survive in $V^{\mathbb{P}}$. We need a technical lemma on the preservation of stationary sets by forcing.

10.6 Lemma. *Let δ be regular with $\delta^{<\eta} = \delta$ for all regular $\eta < \delta$, and let $S \subseteq \delta^+ \cap \mathrm{Cof}({<}\delta)$ be stationary. Then the stationarity of S is preserved by δ-closed forcing.*

Proof. Let $\mathbb{P}$ be δ-closed and let $p \in \mathbb{P}$ force that $\dot{C}$ is a club set in δ^+. Fix $\eta < \delta$ such that $S \cap \mathrm{Cof}(\eta)$ is stationary in δ^+ and a large regular θ, then build $M \prec (H_\theta, \in)$ such that $p, \mathbb{P}, \dot{C} \in M$, $|M| = \delta$, M is closed under ${<}\eta$-sequences and $\gamma = M \cap \delta^+ \in S \cap \mathrm{Cof}(\eta)$. Now build a decreasing sequence p_i for $i < \eta$ of conditions in $\mathbb{P} \cap M$, and a sequence γ_i of ordinals increasing and cofinal in γ, such that $p_{i+1} \Vdash \gamma_i \in \dot{C}$. The construction is easy, using elementarity at successor stages and the closure of M at limit stages. Since $\mathbb{P}$ is δ-closed we may choose q a lower bound for the p_i and then $q \Vdash \gamma \in \dot{C}$. $\dashv$

10.7 Remark. In general it is *not* true for $\delta > \omega_1$ and $\gamma > \delta$ that every stationary subset of $\gamma^+ \cap \mathrm{Cof}({<}\delta)$ is preserved by δ-closed forcing, even if we assume GCH. Shelah has given an incisive analysis of when we may expect stationarity to be preserved; the author's survey paper [10] contains an exposition of the resulting "$I[\lambda]$ theory".

10.8 Theorem (Baumgartner [5]). *In the model $V[G]$ of Theorem 10.5, where $\kappa = \delta^+$, every stationary $S \subseteq \kappa \cap \mathrm{Cof}({<}\delta)$ reflects to a point of cofinality δ.*

Proof. Consider the generic embedding $j_G : V[G] \longrightarrow M[G * H]$ where H is generic for δ-closed forcing. We know that $j_G(S) \cap \kappa = S$, and since $M[G] \subseteq V[G]$ and $V[G] \models {}^{\kappa}M[G] \subseteq M[G]$ the set S is a stationary subset of $\kappa \cap \mathrm{Cof}(<\delta)$ in $M[G]$. The conditions of Lemma 10.6 apply (in fact $\delta^{<\delta} = \delta$) so S is stationary in $M[G*H]$, and so by the elementarity of j_G the set S has a stationary initial segment. Finally $\mathrm{cf}(\kappa) = \delta$ in $M[G * H]$ and $j_G(\delta) = \delta$, so stationarity reflects to an ordinal of cofinality δ. ⊣

10.9 Remark. Actually the conclusion of Theorem 10.8 holds if κ is only weakly compact, and this was the hypothesis used by Baumgartner. If κ is supercompact and we force with $\mathrm{Col}(\omega_1, <\kappa)$, then Shelah [5] observed that we get a model where for every regular $\lambda > \omega_1$ every stationary subset of $\lambda \cap \mathrm{Cof}(\omega)$ reflects.

Shelah [63] has also shown that it is consistent that (roughly speaking) "all stationary sets that can reflect do reflect". This is tricky because of the preservation problems alluded to in Remark 10.7.

10.10 Remark. The fact that we needed Lemma 10.6 to complete the proof of Theorem 10.8 is an example of a very typical phenomenon in the theory of generic embeddings, where we often need to know that the forcing which adds the embedding is in some sense "mild". See Theorem 23.2 for an example where the needed preservation lemmas involve not adding cofinal branches to trees.

11. Iteration with Easton Support

When defining an iterated forcing one of the key parameters is the type of support which is to be used. Silver realized that iteration with Easton support (see Definition 7.5) is a very useful technique in doing iterations which preserve large cardinal axioms. Easton [17] had already used Easton sets as the supports in products of forcings defined in V; the method of iteration with Easton supports has often been called "reverse Easton", "backwards Easton" or "upwards Easton" to distinguish it from Easton's product construction.

We give an example of forcing with Easton support which is due in a slightly different form to Kunen and Paris [47]. The goal is to produce a measurable cardinal κ with the maximum possible number of normal measures; if we assume GCH for simplicity, then the maximal possible number of normal measures is $2^{2^\kappa} = \kappa^{++}$. Kunen's work on iterated ultrapowers [44] shows that if κ is measurable then in the canonical minimal model $L[U]$ in which κ is measurable, κ carries exactly one normal measure.

The arguments of Levy and Solovay [50] show that if κ is measurable a forcing of size less than κ cannot increase the number of normal measures on κ. It follows that we need to force with a forcing poset of size at least κ. The simplest such poset which does not obviously destroy the measurability of κ is $\mathrm{Add}(\kappa, 1)$, however it is not hard to see that if we force over $L[U]$ this poset destroys the measurability of κ.

We will build an iterated forcing of size κ which adds subsets to many cardinals less than κ. As we will see shortly, we need the initial segments of the iteration to have a reasonable chain condition, and the final segments to have a reasonable degree of closure. Silver realized that the right balance between closure and chain condition could be achieved by doing an iteration with Easton support. We will assume that GCH holds in V. Assuming GCH is no burden because GCH is true in $L[U]$.

11.1 Theorem. *Let κ be measurable and let* GCH *hold. Then there exists $\mathbb{P}$ such that*

1. $|\mathbb{P}| = \kappa$.
2. $\mathbb{P}$ *is κ-c.c.*
3. GCH *holds in $V^{\mathbb{P}}$.*
4. *κ is measurable in $V^{\mathbb{P}}$.*
5. *κ carries κ^{++} normal measures in $V^{\mathbb{P}}$.*

The proof will occupy the rest of this subsection.

Let $A \subseteq \kappa$ be the set of those $\alpha < \kappa$ such that α is the successor of a singular cardinal. Let $j : V \longrightarrow M = \mathrm{Ult}(V, U)$ be the ultrapower map. Since $M \subseteq V$ we see that κ is inaccessible in M, so that $\kappa \notin j(A)$ or equivalently $A \notin U$. In the iteration we will add subsets to cardinals lying in A. The exact choice of A is irrelevant so long as it is a set of regular cardinals less than κ and is a set of measure zero for U.

We will now let $\mathbb{P} = \mathbb{P}_\kappa$ be an iteration of length κ with Easton support. For $\alpha < \kappa$ we let $\dot{\mathbb{Q}}_\alpha$ be a name for the trivial forcing unless $\alpha \in A$, in which case $\dot{\mathbb{Q}}_\alpha$ names $\mathrm{Add}(\alpha, 1)_{V^{\mathbb{P}_\alpha}}$. By Proposition 7.13, if $\delta \leq \kappa$ and δ is Mahlo then $\mathbb{P}_\delta$ is δ-c.c.

11.2 Lemma. *Let $\delta \leq \kappa$ be Mahlo and let $\lambda = \delta^{+\omega+1}$. As in Proposition 7.11 let $\dot{\mathbb{R}}_{\delta,\kappa}$ name the canonical iteration of length $\kappa - \delta$ such that $\mathbb{P}_\kappa \simeq \mathbb{P}_\delta * \dot{\mathbb{R}}_{\delta,\kappa}$. Then $V[G_\delta] \models$ "$\mathbb{R}_{\delta,\kappa}$ is λ-closed".*

Proof. If we fix $\delta \leq \kappa$ a Mahlo cardinal then it follows from the chain condition of $\mathbb{P}_\delta$ that every set of ordinals of size less than δ in $V[G_\delta]$ is covered by a set of size less than δ in V. $\lambda = \min(A \setminus \delta)$ and the iteration is only non-trivial at points of A, and so for all γ with $\delta \leq \gamma < \kappa$ we see that $\Vdash_\gamma$ "$\dot{\mathbb{Q}}_\gamma$ is λ-closed". By Proposition 7.12, $\mathbb{R}_{\delta,\kappa}$ is λ-closed in $V[G_\delta]$. ⊣

11.3 Remark. We already have enough information to see that all Mahlo cardinals $\delta \leq \kappa$ are preserved by $\mathbb{P}$. A more delicate analysis as in Hamkins' paper [31] shows that in fact this iteration preserves all cardinals and cofinalities.

11.4 Lemma. GCH *holds in* $V[G_\kappa]$ *above* κ.

Proof. If $\lambda \geq \kappa$ and $\Vdash_{\mathbb{P}} \dot{\tau} \subseteq \lambda$ then the interpretation of $\dot{\tau}$ is determined by $\{(p, \alpha) : p \Vdash \check{\alpha} \in \dot{\tau}\}$. There are only $2^{\kappa \times \lambda} = \lambda^+$ possibilities for this set. ⊣

11.5 Remark. With more care we can show that GCH holds everywhere.

We now need to compare $j(\mathbb{P})$ with $\mathbb{P}$. Elementarity implies that from the point of view of M, $j(\mathbb{P})$ is an Easton iteration of length $j(\kappa)$, with Easton support, in which we add a Cohen subset to each $\alpha \in j(A)$.

11.6 Lemma. $j(\mathbb{P})_\kappa = \mathbb{P}_\kappa$ *and* $j(\mathbb{P})_{\kappa+1} = \mathbb{P}_\kappa * \{1\}$.

Proof. If $\alpha < \kappa$ then $\mathbb{P}_\alpha \in V_\kappa$ and so $j(\mathbb{P})_\alpha = j(\mathbb{P})_{j(\alpha)} = j(\mathbb{P}_\alpha) = \mathbb{P}_\alpha$. κ is inaccessible in M so a direct limit is taken at stage κ in the construction of $j(\mathbb{P})$. The direct limit construction is absolute so $j(\mathbb{P})_\kappa = \mathbb{P}_\kappa$. Finally $\kappa \notin j(A)$ and so $j(\mathbb{P})_{\kappa+1} = \mathbb{P}_\kappa * \{1\}$. ⊣

Let G be $\mathbb{P}$-generic over V. Since $M \subseteq V$ and $\mathbb{P} \in M$, G is $\mathbb{P}$-generic over M and $M[G] \subseteq V[G]$.

11.7 Lemma. *Let* $\mathbb{R} = i_G(\dot{\mathbb{R}}_{\kappa, j(\kappa)})$.

$V[G] \models$ "$\mathbb{R}$ *is* κ^+*-closed and has* κ^+ *maximal antichains lying in* $M[G]$".

Proof. By Lemma 11.2 applied in M to $j(\mathbb{P})$, if $\lambda = \kappa^{+\omega+1}_{M[G]}$ then

$$M[G] \models \text{“}\mathbb{R} \text{ is } \lambda\text{-closed”}.$$

Since $\mathbb{P}$ is κ-c.c. it follows from Proposition 8.4 that $V[G] \models {}^\kappa M[G] \subseteq M[G]$. So $V[G] \models$ "$\mathbb{R}$ is κ^+-closed".

$\mathbb{P}$ is κ-c.c. forcing poset with size κ, and in M we have $j(\mathbb{P}) \simeq \mathbb{P} * \dot{\mathbb{R}}$. It follows from Proposition 7.13 that in $M[G]$, $\mathbb{R}$ is $j(\kappa)$-c.c. forcing with size $j(\kappa)$, so if Z is the set of maximal antichains of $\mathbb{R}$ which lie in $M[G]$ then $M[G] \models |Z| = j(\kappa)$.

V is a model of GCH and so $V \models |j(\kappa)| = 2^\kappa = \kappa^+$. Therefore

$$V[G] \models \text{“}\mathbb{R} \text{ has } \kappa^+ \text{ maximal antichains lying in } M[G]\text{”}.$$

⊣

From now on we work in $V[G]$. Applying Proposition 8.1 we construct a sequence $\langle H_\alpha : \alpha < \kappa^{++} \rangle$ of κ^{++} distinct $\mathbb{R}$-generic filters over $M[G]$. For each α the set $G * H_\alpha$ is $\mathbb{P} * \dot{\mathbb{R}}$-generic over M, and since $\mathbb{P} * \dot{\mathbb{R}}$ is canonically isomorphic to $j(\mathbb{P})$ in M we will regard $G * H_\alpha$ as a $j(\mathbb{P})$-generic filter over M.

11.8 Lemma. *For all* $p \in G$ *and all* $\alpha < \kappa^{++}$, $j(p) \in G * H_\alpha$.

Proof. $\mathbb{P}_\kappa = \varinjlim \vec{\mathbb{P}} \restriction \kappa$. Fix $\beta < \kappa$ such that $p(\gamma) = 1$ for $\beta \le \gamma < \kappa$, and observe that $j(\beta) = \beta$ and so by elementarity $j(p)(\gamma) = 1$ for $\beta \le \gamma < j(\kappa)$. What is more $p \restriction \beta \in V_\kappa$ and so $j(p) \restriction \beta = j(p \restriction \beta) = p \restriction \beta$. It follows that $j(p) \in G * H_\alpha$. ⊣

Accordingly we can find κ^{++} extensions $j_\alpha : V[G] \longrightarrow M[G * H_\alpha]$ with $j_\alpha \restriction V = j$ and $j_\alpha(G) = G * H_\alpha$. They are distinct because the filters H_α are distinct. $H_\alpha \in V[G]$ and so by Proposition 9.4 j_α is definable in $V[G]$. We will be done if we can show that each j_α is an ultrapower map computed from some normal measure on κ in $V[G]$.

11.9 Lemma. *For every α, j_α is the ultrapower of $V[G]$ by U_α where*

$$U_\alpha = \{X \subseteq \kappa : X \in V[G], \kappa \in j_\alpha(X)\}.$$

Proof. j is the ultrapower of V by the normal measure U, so that by Proposition 3.9 j is supported on $\{\kappa\}$. By Proposition 9.3 j_α is also supported on $\{\kappa\}$. By Proposition 3.9 again j_α is the ultrapower of $V[G]$ by U_α. ⊣

12. Master Conditions

We are now in a position to give Silver's proof that GCH can fail at a measurable cardinal. We will need Silver's idea of the *master condition*, which is a technique for arranging the compatibility between generic filters required to apply Proposition 9.1.

12.1 Definition. Let $k : M \longrightarrow N$ be elementary and let $\mathbb{P} \in M$. A *master condition for k and* $\mathbb{P}$ is a condition $q \in k(\mathbb{P})$ such that for every dense set $D \subseteq \mathbb{P}$ with $D \in M$, there is a condition $p \in D$ such that q is compatible with $k(p)$.

Suppose that q is a master condition for k, and H is any N-generic filter on $\mathbb{Q}$ with $q \in H$. It is routine to check that k^{-1}“H generates an M-generic filter G such that k“$G \subseteq H$, and so again Proposition 9.1 can be applied to lift k. In general different choices of H will give different filters G.

12.2 Definition. Let $k : M \longrightarrow N$ be elementary and let $\mathbb{P} \in M$. A *strong master condition for k and* $\mathbb{P}$ is a condition $q \in k(\mathbb{P})$ such that for every dense set $D \subseteq \mathbb{P}$ with $D \in M$, there is a condition $p \in D$ such that $q \le k(p)$.

If q is a strong master condition then let $G = \{p \in \mathbb{P} : q \le k(p)\}$. It is routine to check that G is an M-generic filter, and that k^{-1}“$H = G$ for any N-generic filter H on $\mathbb{Q}$ with $q \in H$. Under these circumstances we will often say that q is a *strong master condition for k and G*.

12.3 Remark. A similar distinction occurs in the theory of proper forcing. See Remarks 24.4 and 24.5 for more on this.

12.4 Remark. Most of the master conditions which we build will be of the strong persuasion.

For use later we record a remark on the connection between existence of strong master conditions and distributivity.

12.5 Theorem. *Let $\pi : M \longrightarrow N$ be elementary, let $\mathbb{P} \in M$, let G be $\mathbb{P}$-generic, and let $q \in j(\mathbb{P})$ be such that $q \leq j``G$. Then for every $\delta < \mathrm{crit}(\pi)$, M and $M[G]$ have the same δ-sequences of ordinals.*

Proof. Suppose not, and fix $p \in G$ and $\dot{\tau} \in M$ such that p forces $\dot{\tau}$ to be a new δ-sequence of ordinals. For each $i < \delta$ there is a condition $p_i \in G$ such that p_i determines $\dot{\tau}(i)$. By elementarity $\pi(p_i)$ determines $\pi(\dot{\tau})(i)$ for each $i < \pi(\delta) = \delta$, and so since $q \leq \pi(p_i)$ we have that q determines $\pi(\dot{\tau})(i)$ for all $i < \delta$, that is, q forces that $\pi(\dot{\tau})$ is equal to some element of N; but $q \leq \pi(p)$ and by elementarity $\pi(p)$ forces that $\pi(\dot{\tau})$ is a new sequence of ordinals, contradiction. $\dashv$

It is easy to see that if U is a normal measure on κ and $2^\kappa \geq \kappa^{+n}$ then $\{\alpha < \kappa : 2^\alpha \geq \alpha^{+n}\} \in U$. In the light of this remark and the result of the last section, a natural strategy for producing a failure of GCH at a measurable is to start with a model of GCH with a measurable κ, and to do an iteration of length $\kappa + 1$ violating GCH on $A \cup \{\kappa\}$ for some suitably large A.

This strategy can be made to work but it is necessary to use a fairly strong large cardinal assumption. We will give here a version of Silver's original proof, using the hypothesis that GCH holds and there is a cardinal κ which is κ^{++}-supercompact. In Sects. 13 and 25 we will see how to weaken this large cardinal assumption.

12.6 Theorem. *Let* GCH *hold and let κ be κ^{++}-supercompact. Then there is a forcing poset $\mathbb{P}$ such that*

1. *$|\mathbb{P}| = \kappa^{++}$.*
2. *$\mathbb{P}$ is κ^+-c.c.*
3. *κ is measurable in $V^{\mathbb{P}}$.*
4. *$2^\kappa = \kappa^{++}$ in $V^{\mathbb{P}}$.*

Proof. Let U be a κ-complete normal fine ultrafilter on $P_\kappa\kappa^{++}$, and define $j : V \longrightarrow M$ to be the associated ultrapower map. Arguing exactly as in Example 4.8, we have

1. $j(\kappa) > \kappa^{+++}$.
2. $j(\kappa^{+4}) = \kappa^{+4}$.

Let A be the set of inaccessible cardinals less than κ. As in the last section the exact choice of A is more or less irrelevant, so long as A is a set of inaccessible cardinals and $A \in U_0$, where $U_0 = \{X \subseteq \kappa : \kappa \in j(X)\}$.

We now let $\mathbb{P} = \mathbb{P}_{\kappa+1}$ be the iteration of length $\kappa+1$ with Easton supports in which $\dot{\mathbb{Q}}_\alpha$ names $\mathrm{Add}(\alpha, \alpha^{++})_{V^{\mathbb{P}_\alpha}}$ if $\alpha \in A \cup \{\kappa\}$, and names the trivial forcing otherwise. Let G_κ be $\mathbb{P}_\kappa$-generic over V, let g_κ be $\mathbb{Q}_\kappa$-generic over $V[G]$ and let $G_{\kappa+1} = G_\kappa * g_\kappa$.

The next lemma is similar to Lemma 11.2 from the last section, the crucial difference being that this time $\delta \in A$ and so the iteration $\mathbb{P}$ acts at stage δ.

12.7 Lemma. *Let $\delta < \kappa$ be Mahlo. Then*

1. *$\mathbb{P}_\delta$ is δ-c.c.*
2. *$\mathbb{P}_{\delta+1}$ is δ^+-c.c.*
3. *If λ is the least inaccessible greater than δ then*

$$V[G_{\delta+1}] \models \text{“}\mathbb{R}_{\delta+1,\kappa} \textit{ is } \lambda\textit{-closed”}.$$

Proof. By Proposition 7.13 $\mathbb{P}_\delta$ is δ-c.c. and has size δ. Then $V[G_\delta] \models \delta^{<\delta} = \delta$, and so $\Vdash_\delta$ “$\mathbb{Q}_\delta$ is δ^+-c.c.”. By Proposition 7.6 $\mathbb{P}_{\delta+1}$ is δ^+-c.c.

Since A is a set of inaccessible cardinals we are guaranteed that $\dot{\mathbb{Q}}_\alpha$ names the trivial forcing for $\delta < \alpha < \lambda$. Every set of ordinals of size less than λ in $V[G_{\delta+1}]$ is covered by a such a set in V, so by Proposition 7.12 $\mathbb{R}_{\delta+1,\kappa}$ is λ-closed in $V[G_{\delta+1}]$. ⊣

The next lemma follows by exactly the same argument as that for Lemma 11.4 in the last section.

12.8 Lemma. *$\mathbb{P}_\kappa$ is κ-c.c. with size κ, and* GCH *holds above κ in $V^{\mathbb{P}_\kappa}$.*

The standard arguments counting names also give us

12.9 Lemma. *$\mathbb{P}$ is κ^+-c.c. with size κ^{++}, and* GCH *holds above κ^+ in $V^{\mathbb{P}}$.*

We now need to analyze the iteration $j(\mathbb{P})$.

12.10 Lemma. $j(\mathbb{P})_{\kappa+1} = \mathbb{P}_{\kappa+1}$.

Proof. We can argue exactly as in Lemma 11.6 that $j(\mathbb{P})_\kappa = \mathbb{P}_\kappa$. By Proposition 8.4 we see that $V[G] \models {}^{\kappa^{++}}M[G] \subseteq M[G]$, so that

$$\mathrm{Add}(\kappa, \kappa^{++})_{V[G]} = \mathrm{Add}(\kappa, \kappa^{++})_{M[G]}.$$

Every condition in $\mathrm{Add}(\kappa, \kappa^{++})_{V^{\mathbb{P}_\kappa}}$ has a name which lies in $H_{\kappa^{+++}}$, and $H_{\kappa^{+++}} \subseteq M$ so that $j(\mathbb{P})_{\kappa+1} = \mathbb{P}_{\kappa+1}$. ⊣

12.11 Lemma. *Let* $\mathbb{R} = i_{G_{\kappa+1}}(\dot{\mathbb{R}}_{\kappa+1,j(\kappa)})$. *Then*

$$V[G_{\kappa+1}] \models \text{“}\mathbb{R} \textit{ is } \kappa^{+++}\textit{-closed”}$$

and

$$V[G_{\kappa+1}] \models \text{“}\mathbb{R} \textit{ has } \kappa^{+++} \textit{ maximal antichains lying in } M[G_{\kappa+1}]\text{”}.$$

Proof. By Lemma 12.7 applied in M to $j(\mathbb{P}_\kappa)$, if λ is the least M-inaccessible greater than κ then $M[G_{\kappa+1}] \models$ “$\mathbb{R}$ is λ-closed”. Since $\mathbb{P}$ is κ^+-c.c. it follows from Proposition 8.4 that $V[G_{\kappa+1}] \models {}^{\kappa^{++}}M[G_{\kappa+1}] \subseteq M[G_{\kappa+1}]$. So $V[G_{\kappa+1}] \models$ “$\mathbb{R}$ is κ^{+++}-closed”.

$\mathbb{P}_\kappa$ is κ-c.c. with size κ, and in M we have $j(\mathbb{P}_\kappa) \simeq \mathbb{P}_{\kappa+1} * \dot{\mathbb{R}}$. It follows from Proposition 7.13 that in $M[G_{\kappa+1}]$, $\mathbb{R}$ is $j(\kappa)$-c.c. with size $j(\kappa)$, so if Z is the set of maximal antichains of $\mathbb{R}$ which lie in $M[G_{\kappa+1}]$ then $M[G_{\kappa+1}] \models |Z| = j(\kappa)$.

By Proposition 4.5, $V \models |j(\kappa)| = \kappa^{+++}$. So

$$V[G_{\kappa+1}] \models \text{“}\mathbb{R} \text{ has } \kappa^{+++} \text{ maximal antichains in } M[G_{\kappa+1}]\text{”}.$$

$\dashv$

Applying Proposition 8.1 we may find a filter $H \in V[G_{\kappa+1}]$ such that H is $\mathbb{R}$-generic over $M[G_{\kappa+1}]$. Let $G_{j(\kappa)} = G_{\kappa+1} * H$, so that $G_{j(\kappa)}$ is $j(\mathbb{P}_\kappa)$-generic over M. The argument of Lemma 11.8 shows that $j``G_\kappa \subseteq G_{j(\kappa)}$, so that by Proposition 9.1 we may lift $j : V \longrightarrow M$ and obtain an elementary embedding $j : V[G_\kappa] \longrightarrow M[G_{j(\kappa)}]$.

To finish the proof we need to construct a filter $h \in V[G_{\kappa+1}]$ such that

1. h is $\mathrm{Add}(j(\kappa), j(\kappa^{++}))_{M[G_{j(\kappa)}]}$-generic over $M[G_{j(\kappa)}]$.
2. $j``g_\kappa \subseteq h$.

The first of these conditions can be met using methods we have seen already, once we have done some counting arguments.

12.12 Lemma. $V[G_{\kappa+1}] \models {}^{\kappa^{++}}M[G_{j(\kappa)}] \subseteq M[G_{j(\kappa)}]$.

Proof. $\mathbb{P}_{\kappa+1}$ is κ^+-c.c. and so $V[G_{\kappa+1}] \models {}^{\kappa^{++}}\mathrm{On} \subseteq M[G_{\kappa+1}]$ by Proposition 8.4. $M[G_{\kappa+1}] \subseteq M[G_{j(\kappa)}]$ so $V[G_{\kappa+1}] \models {}^{\kappa^{++}}\mathrm{On} \subseteq M[G_{j(\kappa)}]$. The result follows by Proposition 8.2. $\dashv$

12.13 Lemma. *Let* $\mathbb{Q} = \mathrm{Add}(j(\kappa), j(\kappa^{++}))_{M[G_{j(\kappa)}]}$. *Then*

$$V[G_{\kappa+1}] \models \text{“}\mathbb{Q} \textit{ is } \kappa^{+++}\textit{-closed”}$$

and

$$V[G_{\kappa+1}] \models \text{“}\mathbb{Q} \textit{ has } \kappa^{+++} \textit{ maximal antichains in } M[G_{j(\kappa)}]\text{”}.$$

Proof. $M[G_{j(\kappa)}] \models$ "$\mathbb{Q}$ is $j(\kappa)$-closed", so by Proposition 8.3 it follows that $V[G_{\kappa+1}] \models$ "$\mathbb{Q}$ is κ^{+++}-closed".

Lemma 12.8 and an easy counting argument give that

$$V[G_\kappa] \models \text{“}\mathrm{Add}(\kappa, \kappa^{++}) \text{ has } \kappa^{+++} \text{ maximal antichains”}.$$

$j : V[G_\kappa] \longrightarrow M[G_{j(\kappa)}]$ is elementary and so

$$M[G_{j(\kappa)}] \models \text{“}\mathbb{Q} \text{ has } j(\kappa^{+++}) \text{ maximal antichains”}.$$

Since $V \models |j(\kappa^{+++})| = \kappa^{+++}$,

$$V[G_{\kappa+1}] \models \text{“}\mathbb{Q} \text{ has } \kappa^{+++} \text{ maximal antichains in } M[G_{j(\kappa)}]\text{”}$$

and we are done. ⊣

We can now build $h \in V[G_{\kappa+1}]$ which is suitably generic. To ensure that $j``g_\kappa \subseteq h$ we use the "strong master condition" idea from Definition 12.2.

12.14 Lemma. *There is a strong master condition for the elementary embedding $j : V[G_\kappa] \longrightarrow M[G_{j(\kappa)}]$ and the generic object g_κ.*

Proof. If $p \in g_\kappa$ then p is a partial function from $\kappa \times \kappa^{++}$ to 2 with size less than κ, so in particular $j(p) = j``p$. $g_\kappa \in M[G_{j(\kappa)}]$ and $j \restriction (\kappa \times \kappa^{++}) \in M$, so that $j``g_\kappa \in M[G_{j(\kappa)}]$. Working in $M[G_{j(\kappa)}]$ the cardinality of $j``g_\kappa$ is $\kappa^{++}$, $j``g_\kappa$ is a directed subset of $\mathbb{Q}$ and $\mathbb{Q}$ is $j(\kappa)$-directed closed; it follows that we may find a condition $r \in \mathbb{Q}$ such that $r \leq j(p)$ for all $p \in g_\kappa$. ⊣

12.15 Remark. We can give an explicit description of an r with this property; let $\mathrm{dom}(r) = \kappa \times j``\kappa^{++}$ and $r(\alpha, j(\beta)) = j(F(\alpha, \beta)) = F(\alpha, \beta)$ where $F : \kappa \times \kappa^{++} \longrightarrow 2$ is given by $F = \bigcup g_\kappa$.

We now use Proposition 8.1 to build h which is $\mathbb{Q}$-generic over $M[G_{j(\kappa)}]$ with $r \in h$. Let $G_{j(\kappa)+1} = G_{j(\kappa)} * h$. Then by construction we have $j``g \subseteq h$, so that we may lift $j : V[G_\kappa] \longrightarrow M[G_{j(\kappa)}]$ to $j : V[G_{\kappa+1}] \longrightarrow M[G_{j(\kappa)+1}]$. $G_{j(\kappa)+1} \in V[G_{\kappa+1}]$ and so by Proposition 9.4 the elementary embedding $j : V[G_{\kappa+1}] \longrightarrow M[G_{j(\kappa)+1}]$ is definable in $V[G_{\kappa+1}]$, that is to say it is a definable embedding in the sense of Definition 2.10. It follows that κ is measurable in $V[G_{\kappa+1}]$. ⊣

12.16 Remark. By Proposition 9.4 and Remark 4.1, κ is actually κ^{++}-supercompact in $V[G_{\kappa+1}]$.

12.17 Remark. If we had forced with $\mathrm{Add}(\alpha, 1)$ instead of $\mathrm{Add}(\alpha, \alpha^{++})$ at each stage in $A \cup \{\kappa\}$, then we could have proved that the measurability of κ was preserved assuming only that GCH holds and κ is measurable in the ground model. Of course we would not have violated GCH this way, and indeed it is known [59, 24] that to violate GCH at a measurable cardinal requires the strength of a cardinal κ with Mitchell order κ^{++}.

13. A Technique of Magidor

In this section we describe a technique due to Magidor [54] for lifting elementary embeddings in situations where we do not have enough closure to build a strong master condition. The trick will be to build an "increasingly masterful" sequence of conditions into our final generic filter. As an example we will redo the result from the last section from a weaker large cardinal hypothesis.

We assume that GCH holds and that κ is κ^+-supercompact, and we let $j : V \longrightarrow M$ be the ultrapower map arising from some κ^+-supercompactness measure on $P_\kappa \kappa^+$. As in Example 4.8 we see that

- $\kappa^{++} = \kappa^{++}_M < j(\kappa) < j(\kappa^+) < j(\kappa^{++}) < j(\kappa^{+++}) = \kappa^{+++}$.
- j is continuous at κ^{++} and κ^{+++}.
- j is discontinuous at every limit ordinal of cofinality κ^+.

We now perform exactly the same forcing construction as in the last section, namely, we perform an Easton support iteration of length $\kappa + 1$ in which we add α^{++} Cohen subsets to every inaccessible $\alpha \leq \kappa$. We let G_κ be $\mathbb{P}_\kappa$-generic over V and g_κ be $\mathbb{Q}_\kappa$-generic over $V[G_\kappa]$.

As in Lemma 12.10 from the last section we see that $j(\mathbb{P})_{\kappa+1} = \mathbb{P}_{\kappa+1}$. As in the last section we let $\mathbb{R} = i_{G_{\kappa+1}}(\dot{\mathbb{R}}_{\kappa+1,j(\kappa)})$, that is to say $\mathbb{R}$ is the forcing that one would do over $M[G_{\kappa+1}]$ to produce a $j(\mathbb{P}_\kappa)$-generic object extending $G_{\kappa+1}$.

Modifying the proof of Lemma 12.11 we see that

$$V[G_{\kappa+1}] \models \text{"}\mathbb{R} \text{ is } \kappa^{++}\text{-closed"}$$

and

$$V[G_{\kappa+1}] \models \text{"}\mathbb{R} \text{ has } \kappa^{++} \text{ maximal antichains lying in } M[G_{\kappa+1}]\text{"}.$$

By Proposition 8.1 we build a filter $H \in V[G_{\kappa+1}]$ which is $\mathbb{R}$-generic over $M[G_{\kappa+1}]$, and lift $j : V \longrightarrow M$ to get $j : V[G_\kappa] \longrightarrow M[G_{j(\kappa)}]$ where $G_{j(\kappa)} = G_\kappa * g_\kappa * H$. We observe that $V[G_{\kappa+1}] \models {}^{\kappa^+}M[G_{j(\kappa)}] \subseteq M[G_{j(\kappa)}]$.

As in the last section we may apply Proposition 8.1 to build $h \in V[G_{\kappa+1}]$ which is $j(\mathbb{Q}_\kappa)$-generic over $M[G_{j(\kappa)}]$, and the remaining problem is to build h is such a way that $j``g_\kappa \subseteq h$. At this point we can no longer imitate the proof of the last section because we no longer have enough closure.

We do some analysis of an antichain A of $j(\mathbb{Q}_\kappa)$ with $A \in M[G_{j(\kappa)}]$. Let $A = j(F)(j``\kappa^+)$ where $F \in V[G_\kappa]$, $\mathrm{dom}(F) = P_\kappa \kappa^+$, and without loss of generality $F(x)$ is a maximal antichain in $\mathbb{Q}_\kappa$ for all x. Working in $V[G_\kappa]$, for each $\zeta < \kappa^{++}$ we let $X_\zeta = \mathrm{Add}(\kappa, \zeta)$, so that $X_\zeta \subseteq \mathbb{Q}_\kappa$, $|X_\zeta| = \kappa^+$, and $\mathbb{Q}_\kappa = \bigcup_\zeta X_\zeta$. A routine argument in the style of the Löwenheim-Skolem theorem shows that for each x there is a club subset C_x of κ^{++} such that for all $\alpha \in C_x \cap \mathrm{Cof}(\kappa^+)$ the antichain $F(x) \cap X_\alpha$ is maximal in X_α. Let C be the intersection of the C_x for $x \in P_\kappa \kappa^+$, then C is club and for every $\alpha \in C \cap \mathrm{Cof}(\kappa^+)$ the antichain A is maximal in $j(X_\alpha) = \mathrm{Add}(j(\kappa), j(\alpha))_{M[G_{j(\kappa)}]}$.

Now we work in $V[G_{\kappa+1}]$ to build a suitable filter h. Define Q a partial function from $j(\kappa) \times j``\kappa^{++}$ by setting $Q$ to be the union of $j(p)$ for $p \in g_\kappa$. It is routine to check that $\mathrm{dom}(Q) = \kappa \times j``\kappa^{++}$, and while Q is not even in $M[G_{j(\kappa)}]$, for all $\zeta < \kappa^{++}$ the partial function $q_\zeta = Q \restriction (j(\kappa) \times j(\zeta))$ is in $j(X_\zeta)$ and is a strong master condition for j and $g_\kappa \cap X_\zeta$.

Working in $V[G_{\kappa+1}]$, we may enumerate all the maximal antichains of $j(\mathbb{Q}_\kappa)$ as $\langle A_i : i < \kappa^{++} \rangle$. Using the analysis of such antichains given above we choose an increasing sequence $\alpha_i \in \kappa^{++} \cap \mathrm{Cof}(\kappa^+)$ such that $A_i \cap j(X_{\alpha_i})$ is maximal in $j(X_{\alpha_i})$ for all $i < \kappa^{++}$. Now we build a decreasing sequence of conditions $r_i \in j(\mathbb{Q}_\kappa)$ such that for each $i < \kappa^{++}$

1. $r_i \in j(X_{\alpha_i})$.
2. $r_i \le q_{\alpha_i}$.
3. r_i extends some member of A_i.

The construction of r_i goes as follows. We start by forming $r = \bigcup_{j<i} r_j$, where we note that the support of r is contained in $j(\kappa) \times \sup_{j<i} j(\alpha_j)$. We claim that r is compatible with q_{α_i}. To see this let $(\delta, j(\gamma))$ be an arbitrary point in the domain of q_{α_i}, that is, $\gamma < \alpha_i$ and $\delta < \kappa$. If $\gamma < \alpha_j$ for some j then since $r \le r_j \le q_j$ we have

$$q_{\alpha_i}(\delta, j(\gamma)) = Q(\delta, j(\gamma)) = r(\delta, j(\gamma)),$$

while if $\gamma \ge \alpha_j$ for all $j < i$ then $(\delta, j(\gamma)) \notin \mathrm{dom}(r)$.

So we may take the union $r \cup q_{\alpha_i}$ to get a condition in $j(X_{\alpha_i})$ and since $A_i \cap j(X_{\alpha_i})$ is maximal in $j(X_{\alpha_i})$ we may choose $r_i \le r \cup q_{\alpha_i}$ so that $r_i \in j(X_{\alpha_i})$ and r_i extends some condition in A_i.

It is now easy to see that the sequence of r_i generates a generic filter h with $h \supseteq j``g$. We may then proceed as in the previous section to lift the embedding to $V[G_{\kappa+1}]$.

13.1 Remark. In fact κ is still κ^+-supercompact in $V[G_{\kappa+1}]$.

13.2 Remark. The forcing technique described here has many applications in the theory of precipitous and saturated ideals. See Sects. 17 and 18, and also Foreman's chapter in this Handbook.

14. Absorption

In this section we discuss an idea which is used in many forcing constructions (for example in building Solovay's model in which every set is Lebesgue measurable [65]) and is particularly useful for our purposes, namely, the idea of embedding a complex poset into a simple one. This is one area of the subject where the presentation of forcing in terms of complete Boolean algebras is very helpful.

The "simple posets" into which we typically absorb more complex ones are the Cohen forcing $\mathrm{Add}(\kappa, \lambda)$ and the collapsing poset $\mathrm{Col}(\kappa, \lambda)$. We note that for any regular κ the forcing $\mathrm{Col}(\kappa, \kappa)$ is equivalent to $\mathrm{Add}(\kappa, 1)$ so we phrase our whole discussion in terms of the collapsing poset.

The following universal property of the collapsing poset is key:

14.1 Theorem. *Let κ be regular. Let $\lambda \geq \kappa$ and let $\mathbb{P}$ be a separative forcing poset such that $\mathbb{P}$ is κ-closed, $|\mathbb{P}| = \lambda$, every condition in $\mathbb{P}$ has λ incompatible extensions and $\mathbb{P}$ adds a surjection from κ to λ.*

Then $\mathbb{P}$ is equivalent to the collapsing poset $\mathrm{Col}(\kappa, \lambda)$.

Notice that if $\lambda > \kappa$ and λ is regular, then the demand that $\mathbb{P}$ adds a surjection from κ to λ implies that for no $p \in \mathbb{P}$ can $\mathbb{P}/p$ be λ-c.c., and so the demand that every condition should have λ incompatible extensions follows from the other conditions.

Proof. Let $\dot{f}$ name a surjective map from κ to $\dot{G}$, where $\dot{G}$ names the generic filter on $\mathbb{P}$. We will build a dense subset of $\mathrm{ro}(\mathbb{P}) \setminus \{0\}$ which is isomorphic to $\mathrm{Col}(\kappa, \lambda)$. Let $\mathbb{P}^*$ be the canonical isomorphic copy of $\mathbb{P}$ in $\mathrm{ro}(\mathbb{P})$, so that $\mathbb{P}^*$ is a dense κ-closed subset of $\mathrm{ro}(\mathbb{P}) \setminus \{0\}$.

We will build a family b_s indexed by $s \in \mathrm{Col}(\kappa, \lambda)$ with the following properties:

1. $b_0 = 1$, and $b_s \in \mathrm{ro}(\mathbb{P}) \setminus \{0\}$ for all s.
2. For all s and t, $t \leq s$ implies that $b_t \leq b_s$.
3. For all $\alpha < \kappa$, $\{b_s : \mathrm{dom}(s) = \alpha\}$ is a maximal antichain.
4. For all s with $\mathrm{dom}(s)$ a successor ordinal, $b_s \in \mathbb{P}^*$.
5. For all $\alpha < \kappa$ and s with domain α, b_s determines $\dot{f} \restriction \alpha$.
6. For all s with $\mathrm{dom}(s)$ a limit ordinal μ, $b_s = \bigwedge_{i<\mu} b_{s \restriction i}$.

We will construct $\{b_s : \mathrm{dom}(s) = \alpha\}$ by recursion on α. At successor stages we construct $\{b_{s ^\frown j} : j < \lambda\}$ to be a maximal antichain below b_s, consisting of conditions that lie in $\mathbb{P}^*$ and determine $\dot{f} \restriction (\mathrm{dom}(s) + 1)$.

For limit μ we define (as we are compelled to) b_s as the infimum of $\{b_{s \restriction i} : i < \mu\}$ for all s with $\mathrm{dom}(s) = \mu$. By κ-closure of $\mathbb{P}$, $b_s \neq 0$. Clearly $\{b_s : \mathrm{dom}(s) = \mu\}$ is an antichain. To show it is maximal, it will suffice to show that it meets every generic G. Let G be generic, and let $s : \mu \to \lambda$ be the unique function with $b_{s \restriction i} \in G$ for all $i < \mu$; by closure $s \in V$, so s is a condition in $\mathrm{Col}(\kappa, \lambda)$ and by genericity $b_s \in G$.

This completes the construction, and it remains to see that the set of all b_s is dense. Let $p \in \mathbb{P}$, so that p forces $p \in G$, and find a condition $q \leq p$ and an ordinal $i < \kappa$ such that $q \Vdash \dot{f}(i) = p$. The condition q is compatible with b_s for s such that $\mathrm{dom}(s) = i + 1$. Now b_s determines $\dot{f}(i)$, so b_s forces that $\dot{f}(i) = p$, in particular $b_s \Vdash p \in G$ and so by separativity $b_s \leq p$. ⊣

In particular a separative κ-closed forcing poset of cardinality κ is equivalent to $\mathrm{Add}(\kappa, 1)$ and a separative forcing poset of size λ which makes λ countable is equivalent to $\mathrm{Col}(\omega, \lambda)$. Moreover if $\mathbb{P}$ is κ-closed then for a sufficiently large μ we see that $\mathbb{P} \times \mathrm{Col}(\kappa, \mu)$ is equivalent to $\mathrm{Col}(\kappa, \mu)$; this is the key point in Theorems 14.2 and 14.3.

Theorem 14.1 has the following corollaries. We separate the cases of $\mathrm{Col}(\omega, {<}\kappa)$ and $\mathrm{Col}(\delta, {<}\kappa)$ for uncountable δ because (as detailed below) we may say significantly more in the former case.

14.2 Theorem. *Let κ be an inaccessible cardinal and let $\mathbb{C} = \mathrm{Col}(\omega, {<}\kappa)$. Let $\mathbb{P}$ be a separative forcing poset with $|\mathbb{P}| < \kappa$ and let $\dot{\mathbb{Q}}$ be a $\mathbb{P}$-name for a separative forcing poset of size less than κ. Then*

1. *There is a complete embedding $i : \mathrm{ro}(\mathbb{P}) \to \mathrm{ro}(\mathbb{C})$.*
2. *For any such i and any $\mathbb{P}$-generic g, $\mathbb{C}/i(g)$ is equivalent in $V[g]$ to $\mathrm{Col}(\omega, {<}\kappa)$.*
3. *Any such i may be extended to a complete $j : \mathrm{ro}(\mathbb{P} * \dot{\mathbb{Q}}) \to \mathrm{ro}(\mathbb{C})$.*

In the general case we have:

14.3 Theorem. *Let κ be an inaccessible cardinal, let $\delta < \kappa$ be regular and let $\mathbb{D} = \mathrm{Col}(\delta, {<}\kappa)$. Let $|\mathbb{P}| < \kappa$ where $\mathbb{P}$ is a δ-closed separative forcing poset, and let $\dot{\mathbb{Q}}$ be a $\mathbb{P}$-name for a δ-closed separative forcing poset of size less than κ. Then*

1. *There is a complete embedding $i : \mathrm{ro}(\mathbb{P}) \to \mathrm{ro}(\mathbb{D})$ such that $\mathbb{D}/i(g)$ is equivalent in $V[g]$ to $\mathrm{Col}(\delta, {<}\kappa)$.*
2. *Any such i may be extended to a complete $j : \mathrm{ro}(\mathbb{P} * \dot{\mathbb{Q}}) \to \mathrm{ro}(\mathbb{D})$ such that $\mathbb{D}/i(g * h)$ is equivalent in $V[g * h]$ to $\mathrm{Col}(\delta, {<}\kappa)$.*

Notice that Theorem 14.2 asserts that *however* we embed the small poset $\mathbb{P}$ in the collapse $\mathrm{Col}(\omega, {<}\kappa)$, the quotient forcing is $\mathrm{Col}(\omega, {<}\kappa)$. Theorem 14.3 just asserts that there is *some* way of embedding the small δ-closed poset $\mathbb{P}$ in the collapse $\mathrm{Col}(\delta, {<}\kappa)$, so that the quotient forcing is $\mathrm{Col}(\delta, {<}\kappa)$.

To underline the difference between these theorems we consider the following example, which implies that we can find an embedding of $\mathrm{Add}(\omega_1, 1)$ into $\mathrm{Add}(\omega_1, 1)$ where the quotient is not countably closed or even proper.

14.4 Example. Let CH hold, let $\mathbb{P} = \mathrm{Add}(\omega_1, 1)$. If $F : \omega_1 \to 2$ is the function added by $\mathbb{P}$ and $S = \{\alpha : F(\alpha) = 1\}$ then we claim that S is stationary in $V[F]$. To see this let p force that $\dot{C}$ is club and build a chain of extensions $p_0 = p \geq p_1 \geq p_2 \geq \cdots$ so that p_{n+1} forces some ordinal

$\alpha_n > \mathrm{dom}(p_n)$ into $\dot{C}$. Then if $p^* = \bigcup p_n$ and $\alpha^* = \sup_n \alpha_n$ we have that $\mathrm{dom}(p^*) = \alpha^*$ and $p^* \Vdash \alpha^* \in \dot{C}$, and may then extend to force that $\alpha^* \in S$. A similar argument shows that S^c is also stationary.

Working in $V[F]$, we now let $\mathbb{Q}$ be the forcing from Example 6.8 to add a club set $D \subseteq S^c$. We claim that $\mathbb{P} * \dot{\mathbb{Q}}$ has a countably closed dense subset of size ω_1, namely, the set of pairs $(p, \check{c})$ where $\mathrm{dom}(p) = \max(c) + 1$ and $p(\alpha) = 0$ for all $\alpha \in c$: the proof is just like the proof that S is stationary from the last paragraph. So now $\mathbb{P} * \mathbb{Q}$ is equivalent to $\mathrm{Add}(\omega_1, 1)$, while $\mathbb{Q}$ destroys the stationarity of S so is not countably closed (or even proper).

Now we give some examples of the absorption idea in action. The first one is due to Kunen [45]. Since there is a detailed account in Foreman's chapter in this Handbook we shall only sketch the result.

As motivation we recall some facts about saturated ideals, weakly compact cardinals, and stationary reflection.

1. If κ is strongly inaccessible and carries a λ-saturated ideal for some $\lambda < \kappa$ then κ is measurable [45].

2. If κ is weakly compact and carries a κ-saturated ideal then κ is measurable [45].

3. If κ is weakly compact then every stationary subset of κ reflects.

4. If $V = L$ then for every regular κ, κ is weakly compact if and only if every stationary subset of κ reflects [42].

5. If $\mathbb{P} \times \mathbb{P}$ is κ-c.c. and κ is measurable in $V^{\mathbb{P}}$ then κ is measurable in V (see Theorem 21.1).

In the model which we present there is an inaccessible cardinal κ which carries a κ-saturated ideal and reflects stationary sets, and there is also a κ-Suslin tree T (so in particular κ is not weakly compact). It follows that 1 and 2 above are close to optimal, and that in general the conclusion of 4 fails. The key property of the model will be that adding a branch through the κ-Suslin tree T resurrects the measurability of κ so that 5 is also close to optimal.

We will use a standard device due to Kunen [45] for manufacturing saturated ideals.

14.5 Lemma. *Let $\mathbb{P}$ be λ-c.c. and let $\dot{U}$ be a $\mathbb{P}$ name for a V-ultrafilter on κ. Let I be the set of those $X \in P(\kappa) \cap V$ such that $\Vdash_{\mathbb{P}} \kappa \setminus X \in \dot{U}$. Then*

1. *I is a λ-saturated ideal.*

2. *If $\dot{U}$ is forced to be V-κ-complete then I is κ-complete, and if $\dot{U}$ is forced to be V-normal then I is normal.*

Often we have a $\mathbb{P}$-name for a generic embedding $j : V \longrightarrow M \subseteq V[G_{\mathbb{P}}]$, and U will be $\{X \in P(\kappa) \cap V : \kappa \in j(X)\}$. This kind of *induced ideal* is discussed at length in Foreman's chapter in this Handbook.

We use a result by Kunen [45].

14.6 Fact. Let α be inaccessible. Then there is a forcing poset $\mathbb{P}_0(\alpha)$ such that

1. $\mathbb{P}_0(\alpha)$ has cardinality α and adds an α-Suslin tree T_α.
2. If $\mathbb{P}_1(\alpha) \in V^{\mathbb{P}_0(\alpha)}$ is the forcing poset $(T_\alpha, \geq_{T_\alpha})$, then $\mathbb{P}_0(\alpha) * \dot{\mathbb{P}}_1(\alpha)$ has a dense subset isomorphic to the Cohen poset $\mathrm{Add}(\alpha, 1)$.

We assume that κ is measurable and GCH holds. We do an iteration with Easton support of length $\kappa+1$. For $\alpha < \kappa$ we let $\dot{\mathbb{Q}}_\alpha$ name the trivial forcing unless α is inaccessible, in which case $\dot{\mathbb{Q}}_\alpha$ names $\mathrm{Add}(\alpha, 1)_{V^{\mathbb{P}_\alpha}}$. We let $\dot{\mathbb{Q}}_\kappa$ name $\mathbb{P}_0(\kappa)_{V^{\mathbb{P}_\kappa}}$ where $\mathbb{P}_0(\kappa)$ is the forcing from Fact 14.6.

As usual, let G_κ be $\mathbb{P}_\kappa$-generic over V and let g_κ be $\mathbb{Q}_\kappa$-generic over $V[G_\kappa]$.

14.7 Claim. *In $V[G_{\kappa+1}]$:*

- *κ is not weakly compact.*
- *κ carries a normal κ-saturated ideal.*
- *κ reflects stationary sets.*

Proof. Let T be the tree added by the $\mathbb{P}_0(\kappa)$-generic filter g_κ. Since T is a κ-Suslin tree in $V[G_{\kappa+1}]$, κ is not weakly compact in $V[G_{\kappa+1}]$.

Let H be generic over $V[G_{\kappa+1}]$ for $\mathbb{P}_1(\kappa)$, that is to say $(T, \geq_T)$. Since T is a κ-Suslin tree, H is generic for κ-c.c. (κ, ∞)-distributive forcing over $V[G_{\kappa+1}]$.

Since $\mathbb{P}_0(\kappa) * \mathbb{P}_1(\kappa)$ is isomorphic to $\mathrm{Add}(\kappa, 1)$, $V[G_{\kappa+1} * H]$ is a model obtained by forcing with $\mathrm{Add}(\alpha, 1)_{V[G_\alpha]}$ at every inaccessible $\alpha \leq \kappa$. By Remark 12.17 κ is measurable in $V[G_{\kappa+1} * H]$, and we may fix $U \in V[G_{\kappa+1} * H]$ which is a normal measure on κ. Let $\dot{U}$ be a $\mathbb{P}_1(\kappa)$-name for U.

Working in $V[G_{\kappa+1}]$ we now define an ideal I on κ by

$$X \in I \iff \Vdash_{\mathbb{P}_1(\kappa)} \kappa \setminus X \in U.$$

By Lemma 14.5 this is a normal κ-saturated ideal.

Finally let $V[G_{\kappa+1}] \models$ "S is a stationary subset of κ". κ-c.c. forcing preserves the stationarity of stationary subsets of κ and so S is stationary in $V[G_{\kappa+1} * H]$. Measurable cardinals reflect stationary sets and so there is an ordinal $\alpha < \kappa$ such that $V[G_{\kappa+1} * H] \models$ "$S \cap \alpha$ is a stationary subset of α". It follows easily that

$$V[G_{\kappa+1}] \models \text{“}S \cap \alpha \text{ is a stationary subset of } \alpha\text{”}.$$

$\dashv$

As our second example we sketch a result from the author's program of joint work [13, 12] with Džamonja and Shelah on *strong non-reflection*. The argument has the interesting feature that we are creating a strong master condition by forcing.

14.8 Definition. Let $\kappa < \lambda < \mu$ be regular cardinals. Then the *Strong Non Reflection* principle $\mathrm{SNR}(\kappa, \lambda, \mu)$ is the assertion that there is a function F from $\mu \cap \mathrm{Cof}(\kappa)$ to λ, such that for every $\delta \in \mu \cap \mathrm{Cof}(\lambda)$ there is a set C club in δ with $F \restriction (C \cap \mathrm{Cof}(\kappa))$ strictly increasing.

It is easy to see that if F witnesses $\mathrm{SNR}(\kappa, \lambda, \mu)$, $S \subseteq \mu \cap \mathrm{Cof}(\kappa)$ is stationary and we use Fodor's Lemma to find stationary $T \subseteq S$ with F constant on T, then T reflects at no point of cofinality λ. The next theorem shows that this idea can be used to make fine distinctions between stationary reflection principles. The hypothesis can be improved to the existence of a weakly compact cardinal with a little more work.

14.9 Theorem. *Suppose that it is consistent that there exists a measurable cardinal. Then it is consistent that every stationary subset of* $\omega_3 \cap \mathrm{Cof}(\omega)$ *reflects to a point of cofinality* ω_2*, while at the same time every stationary subset of* $\omega_3 \cap \mathrm{Cof}(\omega_1)$ *contains a stationary set which reflects at no point of cofinality* ω_2*.*

Proof. We start with κ a measurable cardinal. Fix U a normal measure on κ and let $j : V \longrightarrow M$ be the ultrapower map. We let $\mathbb{P} = \mathrm{Col}(\omega_2, {<}\kappa)$. As we saw in Theorem 10.8 in $V^{\mathbb{P}}$ every stationary subset of $\omega_3 \cap (\mathrm{Cof}(\omega) \cup \mathrm{Cof}(\omega_1))$ reflects to a point of cofinality ω_2.

Let $\mathbb{Q}$ be the natural poset to add a witness to $\mathrm{SNR}(\omega_1, \omega_2, \omega_3)$ by initial segments. More precisely the elements of $\mathbb{Q}$ are partial functions f with domain an initial segment of $\omega_3 \cap \mathrm{Cof}(\omega_1)$ and the property that if $\alpha \leq \mathrm{dom}(f)$ and $\alpha \in \mathrm{Cof}(\omega_2)$ then there is a set C club in α with $f \restriction (C \cap \mathrm{Cof}(\omega_1))$ strictly increasing. The ordering is end-extension.

It is easy to see that $\mathbb{Q}$ is ω_2-closed and that player II wins the strategic closure game of length $\omega_2 + 1$; to see the second claim consider a strategy where player II moves as follows: at every stage $\alpha \in \omega_2 \cap \mathrm{Cof}(\omega_1)$, player II extends the existing function f_α to $f_{\alpha+1} = f_\alpha \cup \{\mathrm{dom}(f_\alpha), \alpha)\}$. In particular $\mathbb{Q}$ adds no ω_2-sequences and so preserves cardinals up to and including ω_3.

We now make a suggestive false start. As usual we factor $j(\mathbb{P}) = \mathbb{P} \times \mathbb{R}$ where $\mathbb{R}$ is an ω_2-closed forcing poset collapsing cardinals in the interval $[\kappa, j(\kappa))$. If G is $\mathbb{P}$-generic and g is $\mathbb{Q}$-generic then by Theorem 14.3 we may absorb $\mathbb{P} * \dot{\mathbb{Q}}$ into $j(\mathbb{P})$ so that the quotient is ω_2-closed, and so build an embedding $j : V[G] \longrightarrow M[G * g * h]$ where h is generic for ω_2-closed forcing.

If F is the function added by g then $F = \bigcup g = \bigcup j``g$. It is natural to try and use F as a strong master condition. Since $\mathrm{cf}(\kappa) = \omega_2$ in $M[G * g * h]$ we need to know that F is increasing on a club set to see that $F \in j(\mathbb{Q})$, but this is not immediately clear.

To resolve this problem we work in $V[G * g]$ and define a poset $\mathbb{S}$ as follows: conditions in $\mathbb{S}$ are closed bounded subsets c of κ such that $|c| \le \omega_1$ and $F \restriction (c \cap \mathrm{Cof}(\omega_1))$ is strictly increasing. It is easy to see that $\mathbb{S}$ is countably closed in $V[G * g]$. We claim that in $V[G]$ there is a dense ω_2-closed set of conditions in $\mathbb{Q} * \dot{\mathbb{S}}$, consisting of those conditions $(f, \check{c})$ such that $\mathrm{dom}(f) = (\max(c) + 1)) \cap \mathrm{Cof}(\omega_1)$ and f is strictly increasing on $c \cap \mathrm{Cof}(\omega_1)$. The proof is routine.

We now force over $V[G * g]$ with $\mathbb{S}$ to obtain a club set $C \subseteq \kappa$ such that C has order type ω_2 and $F \restriction (C \cap \mathrm{Cof}(\omega_1))$ is increasing. Since $\mathbb{Q} * \dot{\mathbb{S}}$ has an ω_2-closed dense set we may absorb $G * g * C$ into $j(\mathbb{P})$ with an ω_2-closed quotient and then lift to obtain $j : V[G] \longrightarrow M[G * g * C * h]$ where h is generic for ω_2-closed forcing. C serves as witness that $F \in j(\mathbb{Q})$ so we may force with $j(\mathbb{Q})/F$ to obtain a generic g^+ and then lift to get $j : V[G * g] \longrightarrow M[G * g * C * h * g^+]$.

This elementary embedding exists in a generic extension of $V[G * g]$ by countably closed forcing, so exactly as in Theorem 10.8 in $V[G * g]$ every stationary set in $\kappa \cap \mathrm{Cof}(\omega)$ reflects to a point of cofinality ω_2. By construction we also have $\mathrm{SNR}(\omega_1, \omega_2, \omega_3)$ in $V[G * g]$ so we are done. ⊣

As a third example we sketch Magidor's proof that consistently every stationary subset of $\omega_{\omega+1}$ reflects.

14.10 Theorem. *If it is consistent that there exist ω supercompact cardinals then it is consistent that every stationary subset of $\omega_{\omega+1}$ reflects.*

Proof. We start by fixing an increasing sequence $\langle \kappa_n : 0 < n < \omega \rangle$ of supercompact cardinals. We also fix $j_n : V \longrightarrow M_n$ witnessing that κ_n is λ^+-supercompact where $\lambda = \sup_n \kappa_n$. We then define a full support iteration of length ω by setting $\mathbb{P}_1 = \mathbb{Q}_0 = \mathrm{Col}(\omega, {<}\kappa_1)$, $\mathbb{Q}_n = \mathrm{Col}(\kappa_n, {<}\kappa_{n+1})_{V^{\mathbb{P}_n}}$ for all $n > 0$, $\mathbb{P}_{n+1} = \mathbb{P}_n * \mathbb{Q}_n$, $\mathbb{P}_\omega = \varprojlim \mathbb{P}_n$.

Let G_ω be $\mathbb{P}_\omega$ generic, let G_n be the $\mathbb{P}_n$-generic filter induced by G_ω and let g_n be the corresponding $\mathbb{Q}_n$-generic filter over $V[G_n]$. The following claims are easy:

- $\kappa_n = \omega_n$, $\lambda = \omega_\omega$, and $\lambda^+ = \omega_{\omega+1}$ in $V[G_\omega]$.
- For every n, $\mathbb{P}_\omega / G_n$ is κ_n-directed-closed in $V[G_n]$.
- For every $n > 0$ let us factor G_ω as $G_{n-1} * g_{n-1} * H_n$. Then j_n can be lifted to an elementary embedding $j_n : V[G_{n-1}] \longrightarrow M_n[G_{n-1}]$, and in $V[G_{n-1}]$ we may embed $\mathbb{P}_\omega / G_{n-1}$ into $j_n(\mathbb{Q}_n)$ so that the quotient forcing is κ_{n-1}-closed.

It follows from this discussion that we may lift j_n to an embedding with domain $V[G_\omega]$ in three steps:

1. Lift to $j_n : V[G_{n-1}] \longrightarrow M_n[G_{n-1}]$.

2. Lift to $j_n : V[G_{n-1} * g_{n-1}] \longrightarrow M_n[G_{n-1} * g_{n-1} * H_n * I_n] = M_n[j_n(G_n)]$ where I_n is generic over $V[G_\omega]$ for κ_{n-1}-closed forcing.

3. Use the closure of M_n to show that j_n“$H_n \in M_n[j_n(G_n)]$, and then use the fact that $j_n(\kappa_n) > |H_n|$ and directedness to find a suitable strong master condition r. Then force with $j_n(\mathbb{P}_\omega/G_n)/r$ and lift once more to $j_n : V[G_n * H_n] \longrightarrow M_n[j_n(G_n) * j_n(H_n)]$.

The key points are that

1. By forcing over $V[G_\omega]$ with κ_{n-1}-closed forcing we have added a generic embedding $j_n : V[G_\omega] \longrightarrow M_n[j_n(G_\omega)]$ with critical point κ_n.

2. j_n“$\lambda^+ \in M_n$.

It remains to argue that in $V[G_\omega]$ every stationary subset of λ^+ reflects. By the completeness of the club filter, every stationary set in λ^+ has a stationary subset of ordinals with a constant cofinality, so it will suffice to show that for all n any stationary subset S of $\lambda^+ \cap \mathrm{Cof}(\omega_n)$ reflects.

We consider the generic embedding $j_{n+2} : V[G_\omega] \longrightarrow M_n[j_n(G_\omega)]$ constructed above. It is easy to see that if $\gamma = \sup j_n$“λ^+ then $\gamma < j_n(\lambda^+)$ and j“$S \cap \gamma$ is stationary in $M_n[G_\omega]$, because the map j_{n+2} is continuous at points of cofinality κ_n. The only problem is to see that S (and hence j“$S \cap \gamma$) is still stationary in $M_n[j_n(G_\omega)]$, so it will certainly suffice to see that the stationarity of S is preserved by any ω_{n+1}-closed forcing.

Unfortunately it is not true in general [10] that κ^+-closed forcing preserves stationary subsets of $\mu \cap \mathrm{Cof}(\kappa)$ when μ is the successor of a singular cardinal. We address this problem using an idea of Shelah to show that in our model $V[G_\omega]$ every stationary subset of $\omega_{\omega+1} \cap \mathrm{Cof}(\omega_n)$ is preserved by ω_{n+1}-closed forcing.

We start by fixing in V for every $\beta < \lambda^+$ a decomposition $\beta = \bigcup_{i<\omega} b_i^\beta$ where the b_i^β are disjoint and $|b_i^\beta| \leq \kappa_i$. We define $F(\alpha, \beta)$ to be the unique $i < \omega$ with $\alpha \in b_i^\beta$. The key technical claim is that in $V[G_\omega]$ any ordinal $\rho < \lambda^+$ with uncountable cofinality contains an unbounded homogeneous set for F.

We fix such a ρ and let n be the unique integer such that in V we have $\kappa_n \leq \mathrm{cf}(\rho) < \kappa_{n+1}$. We note that if $\sigma =_{\mathrm{def}} \sup(j_n$“$\rho)$ then $\sigma < j(\rho)$, and so we may define in V an ultrafilter $U =_{\mathrm{def}} \{A \subseteq \rho : \sigma \in j(A)\}$. Clearly $\rho \setminus \alpha \in U$ for all $\alpha < \rho$, and U is κ_n-complete in V.

We now fix for each $\alpha \in \rho$ a U-large set A_α on which $F(\alpha, -)$ is constant. In $V[G_\omega]$ we have that $\mathrm{cf}(\rho) = \kappa_n$, and we will build by recursion an increasing and cofinal sequence $\langle \alpha_i : i < \kappa_n \rangle$ in ρ such that $\alpha_j \in A_{\alpha_i}$ for $i < j$. This is possible because $\langle A_{\alpha_i} : i < j \rangle$ is in $V[G_n]$ so is covered by a subset Y_j of U which lies in V and has size less than κ_n; the intersection of Y_j is in U, and any element of this intersection will do as α_j. It is then easy to thin out the “tail homogeneous” sequence of α_i to a cofinal homogeneous set.

To finish we show the needed stationary preservation fact. We work in $V[G_\omega]$. Let $T \subseteq \lambda^+ \cap \mathrm{Cof}(\kappa_n)$ be stationary, let $\mathbb{Q}$ be κ_{n+1}-closed, let $\dot{C}$ be $\mathbb{Q}$-name for a club subset of λ^+. We build $N \prec H_\theta$ for some large θ such that N contains all the relevant parameters, $|N| = \lambda$, all bounded subsets of λ are in N and $\delta = N \cap \lambda^+ \in T$. Fix $A \subseteq \delta$ a cofinal set of order type κ_n and $i \in \omega$ so that A is i-homogeneous for F. We claim that all proper initial segments of A lie in N: for if $\beta \in A$ then $A \cap \beta \subseteq b_i^\beta$, and since $b_i^\beta \in N$ with $|b_i^\beta| \leq \kappa_i$ and also $P(\kappa_i) \subseteq N$ we see easily that $A \cap \beta \in N$.

The endgame of the argument is now very similar to the proof of Lemma 10.6. We enumerate the elements of A in increasing order as α_i for $i < \kappa_n$. We then build a decreasing sequence $\langle q_j : j < \kappa_n \rangle$ of conditions in $\mathbb{Q} \cap N$, where q_j is the least condition which both determines $\min(\dot{C} \setminus \alpha_j)$ and is below q_i for all $i < j$. We need to see that $q_j \in N$ for all $j < \kappa_n$; the key point is that $\langle q_i : i < j \rangle$ is definable from $A \cap \alpha_j$, and so can be computed in N. To finish we choose q a lower bound for $\langle q_i : i < \kappa_n \rangle$, and observe that $q \Vdash \alpha \in \dot{C} \cap T$. $\dashv$

15. Transfer and Pullback

It is sometimes possible to transfer a generic filter over one model to another model along an elementary embedding, and then to lift that elementary embedding. The following proposition makes this precise

15.1 Proposition. *Let $k : M \longrightarrow N$ have width $\leq \mu$, and let $\mathbb{P} \in M$ be a separative notion of forcing such that*

$$M \models \text{“}\mathbb{P} \textit{ is } (\mu^+, \infty)\textit{-distributive”}.$$

Let G be $\mathbb{P}$-generic over M and let H be the filter on $k(\mathbb{P})$ which is generated by k“G. Then H is $k(\mathbb{P})$-generic over N.

Proof. Let $D \in N$ be a dense open subset of $k(\mathbb{P})$. Let $D = k(F)(a)$ for some $a \in N$ and some $F \in M$ such that $M \models |\mathrm{dom}(F)| \leq \mu$; we may as well assume that for every $x \in \mathrm{dom}(F)$, $F(x)$ is a dense open subset of $\mathbb{P}$.

Now let $E = \bigcap_{x \in \mathrm{dom}(F)} F(x)$. By the distributivity assumption E is a dense subset of $\mathbb{P}$, and clearly $E \in M$, so that $E \cap G \neq \emptyset$. If $p \in G \cap E$ then $k(p) \in k(F)(a) = D$, so that $H \cap D \neq \emptyset$ and so H is generic as claimed. $\dashv$

15.2 Remark. Given the conclusion of the last proposition, it follows from Proposition 9.1 that k can be lifted to get $k^+ : M[G] \longrightarrow N[H]$.

As an example of this proposition in action, we prove a result reminiscent of Lemma 8.5.

15.3 Lemma. *Let* GCH *hold. Let E be a (κ, κ^{++}) extender and let the map $j : V \longrightarrow M = \mathrm{Ult}(V, E)$ be the ultrapower. Let $\mathbb{Q} = \mathrm{Col}(\kappa^{+++}, {<}j(\kappa))_M$. Then there is a filter $g \in V$ which is $\mathbb{Q}$-generic over M.*

Proof. Let $U = \{X \subseteq \kappa : \kappa \in j(X)\}$ and let $i : V \longrightarrow N = \mathrm{Ult}(V, U)$. As in Proposition 3.2 we may define an elementary embedding $k : N \longrightarrow M$ by $k([F]_U) = j(F)(\kappa)$, and $j = k \circ i$.

Let $\lambda = \kappa_N^{++}$. It is easy to see that

$$\begin{aligned} M &= \{j(F)(a) : a \in [\kappa^{++}]^{<\omega}, \mathrm{dom}(F) = [\kappa]^{|a|}\} \\ &= \{k(H)(a) : a \in [\kappa^{++}]^{<\omega}, \mathrm{dom}(H) = [\lambda]^{|a|}\}. \end{aligned}$$

It follows that k is an embedding of width at most λ.

Now let $\mathbb{Q}_0 = \mathrm{Col}(\lambda^+, {<}i(\kappa))_N$, and notice that $k(\mathbb{Q}_0) = \mathbb{Q}$. By exactly the same argument as in Lemma 8.5 there is $g_0 \in V$ which is $\mathbb{Q}_0$-generic over N. By Proposition 15.1 $k``g_0$ generates a filter g which is $\mathbb{Q}$-generic over M. ⊣

15.4 Remark. This lemma can be used to construct posets along the lines of the generalized Prikry forcing from Example 8.6, collapsing κ to become for example ω_{ω_1}. See [8] and [27] for details.

15.5 Remark. See Sects. 22 and 25 for applications of Proposition 15.1 in reverse Easton constructions.

Proposition 15.1 admits a kind of dual in which the traffic goes the other way:

15.6 Proposition. *Let $k : M \longrightarrow N$ have critical point δ, let $\mathbb{P} \in M$ be a notion of forcing such that*

$$M \models \text{“}\mathbb{P} \text{ is } \delta\text{-c.c.”}.$$

Let H be $k(\mathbb{P})$-generic over N and let $G = k^{-1}``H$. Then G is $\mathbb{P}$-generic over M.

Proof. Let $A \in M$ be a maximal antichain of $\mathbb{P}$. Then $k(A) = k``A$ and it is maximal in $k(\mathbb{P})$, so $k``A$ meets H and hence A meets G. It is routine to check that G is a filter. ⊣

16. Small Large Cardinals

One of the main themes of this chapter has been preservation of large cardinal axioms in forcing extensions, using the characterization of those large cardinal axioms in terms of elementary embeddings. It might seem that this method can only work for large cardinal hypotheses at least as strong as the existence of a measurable cardinal, because after all the critical point of any definable $j : V \longrightarrow M$ is always measurable (and even the existence of a generic embedding $j : V \longrightarrow M \subseteq V[G]$ implies the existence of an inner model with a measurable cardinal).

However it turns out that we can get down to the level of weakly compact cardinals by working with elementary embeddings whose domains are sets which do not contain the full power set of the critical point. We record a number of equivalent characterizations of weak compactness. The last one (which is due to Hauser [34]) has the surprising feature that the target model of the embedding contains the embedding itself, a fact which can be used to good effect in master condition arguments [35, 34].

16.1 Theorem. *The following are equivalent for an inaccessible cardinal κ:*

1. *κ is weakly compact.*
2. *κ is Π^1_1-indescribable.*
3. *κ has the tree property.*
4. *For every transitive set M with $|M| = \kappa$, $\kappa \in M$ and ${}^{<\kappa}M \subseteq M$ there is an elementary embedding $j : M \longrightarrow N$ where N is transitive, $|N| = \kappa$, ${}^{<\kappa}N \subseteq N$ and $\mathrm{crit}(j) = \kappa$.*
5. *For every transitive set M with $|M| = \kappa$, $\kappa \in M$ and ${}^{<\kappa}M \subseteq M$ there is an elementary embedding $j : M \longrightarrow N$ where N is transitive, $|N| = \kappa$, ${}^{<\kappa}N \subseteq N$, $\mathrm{crit}(j) = \kappa$ and in addition j and M are both elements of N.*

Proof. The equivalence of the first four statements is standard [43]. So we only show that the last one follows from weak compactness. Given M a transitive set with $|M| = \kappa \in M$ and ${}^{<\kappa}M \subseteq M$ we find a transitive $\bar{M}$ with the same properties so that $M \in \bar{M}$. We fix in $\bar{M}$ a well founded relation E on κ so that (κ, E) collapses to $(M, \in)$.

By weak compactness we may find an embedding $j : \bar{M} \longrightarrow \bar{N}$ with critical point κ such that $|\bar{N}| = \kappa$ and ${}^{<\kappa}\bar{N} \subseteq \bar{N}$. Let $N = j(M)$ and $i = j\restriction M$ so that $i : M \longrightarrow N$ is elementary. Since $j(E) \in \bar{N}$ it is easy to see that M and i are both in $\bar{N}$; but by elementarity N is closed under κ-sequences in $\bar{N}$ so that M and i are in N. ⊣

16.2 Example. We show that it is consistent for the first failure of GCH to occur at a weakly compact cardinal. This needs a little work. For example if $V = L$ and we add κ^{++} Cohen subsets to a weakly compact cardinal κ then this destroys the weak compactness of κ. The point is that for $X \subseteq \kappa$ the statement "$X \notin L$" is Π^1_1 in $(V_\kappa, \in, X)$, so that if κ is weakly compact and $X \notin L$ then by Π^1_1-indescribability some initial segment of X is not in L.

We will assume that GCH holds in V and that κ is weakly compact. We will force with Easton support to add α many Cohen subsets to each inaccessible $\alpha < \kappa$, and will then add κ^{++} many Cohen subsets to κ. Let $\mathbb{P}_\kappa$ be the iteration up to κ and let $\mathbb{Q} = \mathrm{Add}(\kappa, \kappa^{++})_{V^{\mathbb{P}_\kappa}}$. Let G be $\mathbb{P}_\kappa$-generic over V and let g be $\mathbb{Q}$-generic over $V[G]$.

For the sake of variety we show that κ has the tree property in $V[G * g]$. Let $T \in V[G*g]$ be a κ-tree. T is essentially a subset of κ, and so by the κ^+-c.c. there is in V a set $X \subseteq \kappa^{++}$ with $|X| = \kappa$ such that $T \in V[G * g_0]$ where $g_0 = g \restriction (\kappa \times X)$. Without loss of generality we may as well assume that $X = \kappa$. So now $T \in V[G * g_0]$, where $g_0 = g \restriction (\kappa \times \kappa)$ and g_0 is $\mathbb{Q}_0 = \mathrm{Add}(\kappa, \kappa)$-generic.

Working in V we fix a suitable transitive model M such that $\dot{T} \in M$, and then choose $j : M \longrightarrow N$ as in clause 5 of Theorem 16.1. We now proceed to lift j. We need to be slightly careful about issues of closure. Our models are less closed than in the context of measurable cardinals, but since they are themselves small sets this is not a problem.

Since $\mathbb{P}_\kappa$ is κ-c.c. and $V \models {}^{<\kappa}N \subseteq N$, we have by Proposition 8.4 that $V[G] \models {}^{<\kappa}N[G] \subseteq N[G]$. $\mathbb{Q}_0$ adds no $<\kappa$-sequences so by Proposition 8.2 $V[G * g_0] \models {}^{<\kappa}N[G * g_0] \subseteq N[G * g_0]$. Since $|N[G * g_0]| = \kappa$ and the factor iteration $j(\mathbb{P}_\kappa)/G * g_0$ is $<\kappa$-closed in $V[G * g_0]$, we may as usual build $H \in V[G * g_0]$ suitably generic and lift to get $j : M[G] \longrightarrow N[G * g_0 * H]$. As usual $V[G * g_0] \models {}^{<\kappa}N[G * g_0 * H] \subseteq N[G * g_0 * H]$. Finally since $j \restriction g_0 = \mathrm{id}_{g_0}$ we may use $r = \bigcup g_0$ as a strong master condition, construct a suitable generic filter for $j(\mathbb{Q}_0)/R$ and lift the embedding onto $M[G * g_0]$. Since $j(T) \restriction \kappa = T$, we may use any point on level κ of $j(T)$ to generate a cofinal branch of T lying in $V[G * g_0]$.

17. Precipitous Ideals I

In this section we prove some theorems about precipitous ideals due to Jech, Magidor, Mitchell and Prikry [41]. As a warm-up we show it is consistent that there exists a precipitous ideal (precipitousness is defined below) on ω_1, then we show that the non-stationary ideal on ω_1 can be precipitous. The hypothesis used is the existence of a measurable cardinal, which is known [41] to be optimal.

The proof has several very interesting technical features including:

- The use of the universal properties of the Levy collapsing poset, an idea which goes back to Solovay's proof that every set of reals can be measurable [65].
- The use of forcing to add simultaneously filters G and H such that an embedding $M \longrightarrow N$ lifts to an embedding $M[G] \longrightarrow N[H]$.
- The use of an iterated club-shooting forcing to make the club filter exhibit properties that are characteristic of filters derived from elementary embeddings.

17.1. A Precipitous Ideal on ω_1

We refer readers to Foreman's chapter in this Handbook for the basic theory of precipitous ideals. We recall that if I is an ideal on κ then we may force with the forcing poset $P(\kappa)/I \setminus \{0\}$ (equivalence classes of I-positive sets modulo I) to add a V-ultrafilter U such that $U \cap I = \emptyset$. Working in $V[U]$ we may then form $\mathrm{Ult}(V, U)$ using functions in V ordered modulo U. The ideal I is said to be *precipitous* if and only if $\mathrm{Ult}(V, U)$ is forced to be well-founded. We will follow a common practice and abuse notation by saying that the ultrafilter U is "$P(\kappa)/I$-generic".

The following fact is key for us: to show that an ideal I on a cardinal κ is precipitous, it suffices to produce (typically by forcing) for every $A \notin I$ a V-ultrafilter U on κ such that $A \in U$, U is $P(\kappa)/I$-generic, and $\mathrm{Ult}(V, U)$ is well-founded. The point is that if I fails to be precipitous there is $A \notin I$ which forces this, and for such an A no U as above can exist.

We will reuse an example from earlier in this chapter. Assume that κ is measurable, and let $j : V \longrightarrow M = \mathrm{Ult}(V, U)$ be the ultrapower map from a normal measure U on κ. Let $\mathbb{P} = \mathrm{Col}(\omega, {<}\kappa)$. Then as we saw in Theorem 10.2:

1. $j(\mathbb{P})$ is isomorphic to $\mathbb{P} \times \mathbb{Q}$ where $\mathbb{Q}$ is the poset which adds a surjection from ω onto each ordinal in $[\kappa, j(\kappa))$ with finite conditions. We will usually be careless and identify the posets $j(\mathbb{P})$ and $\mathbb{P} \times \mathbb{Q}$.

2. If G is $\mathbb{P}$-generic over V and H is $\mathbb{Q}$-generic over $V[G]$ then $G * H$ is $j(\mathbb{P})$-generic over V, and $j``G \subseteq G * H$, so in $V[G * H]$ we can lift our original j to $j_G : V[G] \longrightarrow M[G * H]$ with $j_G(G) = G * H$. So from the point of view of $V[G]$ the embedding j_G is a generic embedding added by forcing with $\mathbb{Q}$.

3. Since $M = \{j(f)(\kappa) : f \in V\}$ we have that
$$M[G * H] = \{j_G(f)(\kappa) : f \in V[G]\},$$
so that $M[G * H]$ is the ultrapower $\mathrm{Ult}(V[G], U_G)$ where
$$U_G = \{X \in P(\kappa) \cap V[G] : \kappa \in j_G(X)\}.$$
Here U_G is a $V[G]$-normal $V[G]$-κ-complete $V[G]$-ultrafilter and j_G is the associated ultrapower map.

Foreman's chapter in this Handbook gives a rather general framework for defining precipitous ideals by way of generic elementary embeddings. In the interests of being self-contained, we describe how this plays out in the setting of the embedding from Theorem 10.2.

We caution the reader that the following arguments involve viewing the universe $V[G * H]$ both as an extension of V by $j(\mathbb{P})$ and an extension of $V[G]$ by $\mathbb{Q}$. We are quietly identifying $j(\mathbb{P})$-names in V with $\mathbb{Q}$-names in $V[G]$, resolving any possible confusion by making explicit which model we are forcing over and with which poset.

Working in $V[G]$ we define an ideal I on $\omega_1^{V[G]} (= \kappa)$ by
$$I = \{X \subseteq \kappa : \Vdash_{\mathbb{Q}}^{V[G]} \kappa \notin j_G(X)\}.$$

Equivalently I consists of those sets which are forced by $\mathbb{Q}$ not to be in the ultrafilter U_G.

Working in $V[G]$ we define a Boolean algebra homomorphism from $P(\kappa)$ to $\mathrm{ro}(\mathbb{Q})$ which maps X to the truth value $[X \in \dot{U}_G]_{\mathrm{ro}(\mathbb{Q})}$. The kernel of this map is exactly I so we may induce a map ι from $P(\kappa)/I$ to $\mathrm{ro}(\mathbb{Q})$.

The key point is that, as we see in a moment, the range of ι is dense. From this it follows that for any H which is $\mathbb{Q}$-generic over $V[G]$, the ultrafilter U_G is $P(\kappa)/I$-generic over $V[G]$; in fact it follows from the truth lemma that $X \in U_G \iff \iota(X) \in H$, so that in a very explicit way forcing with $\mathbb{Q}$ is equivalent to forcing with $P(\kappa)/I$.

To establish that the range of ι is dense recall that $\mathbb{Q}$ is densely embedded in $\mathrm{ro}(\mathbb{Q})$. Let $q \in \mathbb{Q}$, so that $q = j(F)(\kappa)$ where $F \in V$ is a function such that $F(\alpha) \in \mathrm{Col}(\omega, [\alpha, \kappa))$ for all $\alpha < \kappa$. Working in $V[G]$, define $X = \{\alpha : F(\alpha) \in G\}$. Since j_G extends j, $q = j_G(F)(\kappa)$ and so for any H we have that

$$\iota(X) \in H \quad \iff \quad \kappa \in j_G(X) \quad \iff \quad q \in j_G(G) \quad \iff \quad q \in H.$$

It is an immediate conclusion that I must be precipitous. For if $A \notin I$ then we may choose H inducing j_G such that $\kappa \in j_G(A)$. Arguing as above we get that U_G is $P(\kappa)/I$-generic with $A \in U_G$, so we are done.

It is interesting to note that the ideal I is precisely the ideal generated in $V[G]$ by the ideal dual to the ultrafilter U. It is immediate that I contains this ideal, so we only need to prove that I is contained in this ideal.

Let $p \Vdash^V_{\mathbb{P}} \dot{X} \in \dot{I}$. We claim that if we define $A = \{\alpha : p \Vdash \alpha \notin \dot{X}\}$ then $A \in U$. For if not then we may define a function F on A^c such that $F(\alpha) \leq p$ and $F(\alpha) \Vdash \alpha \in \dot{X}$. But then if we let $q = j(F)(\kappa)$ and force to get $G * H$ containing q, we obtain a situation in which $p \in G$ and yet $\kappa \in j_G(X)$, so that $X \in U_G$ and we have a contradiction.

17.1 Remark. Really we have just worked through a very special case of Foreman's Duality Theorem. See Foreman's chapter in this Handbook for more on this subject.

17.2. Iterated Club Shooting

In Sect. 17.1 we produced a precipitous ideal I on ω_1. It is not hard to see that this ideal is not the non-stationary ideal. For example if in V we define $S = \kappa \cap \mathrm{Cof}(\omega)$, then S is stationary in $V[G]$ by the κ-c.c. of the collapsing poset $\mathbb{P}$. Since $\kappa \notin j(S)$ we see that $\Vdash_{\mathbb{Q}} \check{S} \notin \dot{U}_G$, so that $S \in I$.

To make the non-stationary ideal precipitous, we will iteratively shoot clubs so as to destroy the stationarity of inconvenient sets such as the set S from the last paragraph. The argument is somewhat technical so we give an overview before launching into the details.

Overview

Working in $V[G]$ we build a countable support iteration $\mathbb{R}$ of length κ^+ (which is the ω_2 of $V[G]$). At each stage we shoot a club set through some stationary subset of ω_1. A key point will be that this iteration adds no ω-sequences of ordinals; from this it will follow that

1. ω_1 is preserved.

2. At each stage of the iteration $\mathbb{R}$, the conditions in the club shooting forcing used at that stage (which are closed and bounded subsets of ω_1) actually lie in the model $V[G]$.

Recall from Sect. 17.1 that $\mathbb{P} = \mathrm{Col}(\omega, <\kappa)$, $j(\mathbb{P}) = \mathbb{P} \times \mathbb{Q}$, and for any H which is $\mathbb{Q}$-generic over $V[G]$ we may lift $j : V \to M$ and get $j_G : V[G] \to M[G*H]$. It is the existence of these generic embeddings which is responsible for the precipitousness of I in $V[G]$.

For each α we will find an embedding of $\mathbb{P} * \mathbb{R}_\alpha$ into $j(\mathbb{P})$, and we will use this to produce generic embeddings $j_\alpha : V[G * g_\alpha] \to M[G * H * h_\alpha]$ where g_α is $\mathbb{R}_\alpha$-generic and $G * g_\alpha$ is embedded into $G * H$. From these embeddings j_α we will define normal ideals $I_\alpha \in V[G * g_\alpha]$ which are analogous to the ideal I; the construction will be organized so that

1. I_α increases with α.

2. In the final model $\bigcup_\alpha I_\alpha$ is the non-stationary ideal.

To finish, we will use the embeddings j_α to show that the non-stationary ideal is precipitous. This argument, which is similar to but more complicated than that of Sect. 17.1, appears as Lemma 17.3 below.

Details

Working in $V[G]$ we construct by induction on $\alpha < \kappa^+$

1. A countable support iteration $\mathbb{R}_\alpha$.

2. An embedding $i_\alpha : \mathbb{P} * \mathbb{R}_\alpha \to j(\mathbb{P})$ extending the identity embedding of $\mathbb{P}$ into $j(\mathbb{P})$. Our convention in what follows is that H is always some $\mathbb{Q}$-generic filter over $V[G]$ and g_α is always the $\mathbb{R}_\alpha$-generic filter induced by H via the embedding i_α.

3. A $\mathbb{Q}$-name $\dot{D}_\alpha$ for a strong master condition appropriate for the embedding $j_G : V[G] \to M[G * H]$ and generic object g_α; that is to say $\dot{D}_\alpha$ names a condition in $j(\mathbb{R}_\alpha)$ which is a lower bound for $j``g_\alpha$.

4. A $\mathbb{Q} * j(\mathbb{R}_\alpha)/D_\alpha$-name for $j_\alpha : V[G * g_\alpha] \to M[G * H * h_\alpha]$ extending $j_G : V[G] \to M[G * H]$.

5. An $\mathbb{R}_\alpha$-name $\dot{I}_\alpha$ for a normal ideal on κ; this is defined as a *master condition ideal* of the sort discussed in Foreman's chapter of this Handbook; to be more precise, it is defined to be the set of those $X \subseteq \kappa$ in $V[G * g_\alpha]$ such that it is forced over $V[G * g_\alpha]$ by $j(\mathbb{P})/(G * g_\alpha) * j(\mathbb{R}_\alpha)/D_\alpha$ that $\kappa \notin j_\alpha(X)$.

6. An $\mathbb{R}_\alpha$-name $\dot{S}_\alpha$ for a set in the filter dual to the ideal I_α.

We will maintain the hypotheses that

1. $\mathbb{R}_\alpha$ adds no ω-sequences of ordinals and has the κ^+-c.c.

2. For $\beta < \gamma \leq \alpha$

   (a) i_γ extends i_β (from which it follows that g_γ extends g_β).

   (b) It is forced over $V[G]$ (by the appropriate forcing posets) that $D_\gamma \restriction j(\beta) = D_\beta$, $j_\gamma \restriction V[G * g_\beta] = j_\beta$, and $I_\gamma \cap V[G_\beta] = I_\beta$.

3. The set of *flat* conditions is dense in $\mathbb{R}_\alpha$, where a condition r in $\mathbb{R}_\alpha$ is *flat* if

   (a) For every η in the support of r, $r(\eta)$ is a canonical $\mathbb{R}_\eta$-name $\check{d}_\eta$ for some $d_\eta \in V[G]$, where d_η is a closed and bounded subset of κ.

   (b) There is an ordinal $\gamma < \kappa$ such that $\gamma = \max(d_\eta)$ for every η in the support of p.

We will explain why some of the hypotheses are maintained and then give the details of the construction. Since D_α is a strong master condition for $\mathbb{R}_\alpha$ it follows from Theorem 12.5 that forcing with $\mathbb{R}_\alpha$ adds no ω-sequences of ordinals. As we see shortly D_α is flat, and since $D_\alpha \leq j``g_\alpha$ it follows from elementarity that the set of flat conditions is dense. Standard Δ-system arguments show that the set of flat conditions has the κ^+-c.c. and so since this set is dense $\mathbb{R}_\alpha$ has the κ^+-c.c. The remaining "coherence" hypotheses will be satisfied by construction.

- At successor stages we take $\mathbb{R}_{\alpha+1} \simeq \mathbb{R}_\alpha * \mathrm{CU}(\kappa, S_\alpha)$. For α limit, $\mathbb{R}_\alpha$ is constructed as the direct limit of $\langle \mathbb{R}_\beta : \beta < \alpha \rangle$ if α has uncountable cofinality and the inverse limit if α has countable cofinality.

- i_α is defined using the universal properties of the Levy collapse as in Theorem 14.2.

- Recall that j_α exists in the extension of $V[G * g_\alpha]$ by the forcing poset $j(\mathbb{P})/(G * g_\alpha) * j(\mathbb{R}_\alpha)/D_\alpha$. Working in $V[G * g_\alpha]$ we define I_α to be the ideal of those $X \subseteq \kappa$ such that it is forced over $V[G * g_\alpha]$ by $j(\mathbb{P})/(G * g_\alpha) * j(\mathbb{R}_\alpha)/D_\alpha$ that $\kappa \notin j_\alpha(X)$.

- Let $\langle C_\eta : \eta < \alpha \rangle$ be the sequence of club sets added by g_α. We construct D_α as follows: the support of D_α is $j``\alpha$, and $D_\alpha(j(\eta))$ is the canonical $j(\mathbb{R}_\eta)$-name for $C_\eta \cup \{\kappa\}$.

  Of course we need to check that D_α is a strong master condition. The salient points are that

  - Since $\alpha < \kappa^+$, $j``\alpha \in M$.
  - Since $\kappa^+ < j(\kappa)$, $j``\alpha$ is countable in $M[G * H]$. In particular D_α has countable support.
  - If $f \in g_\alpha$ then $f \in V[G]$ and the support of f has size less than $\mathrm{crit}(j_G)$. Hence the support of $j_G(f)$ is $j``\mathrm{dom}(f)$.
  - For every $\beta < \alpha$, $D_\beta = D_\alpha \restriction j(\beta)$ is a lower bound for $j``g_\beta$. In particular it is immediate for α limit that D_α is a strong master condition, so we may concentrate on the case when $\alpha = \beta + 1$.

    Recall that by induction $\mathbb{P}_\beta$ adds no ω-sequences of ordinals. Let $r \in g_\alpha$, then it follows from the distributivity of $\mathbb{P}_\beta$ that we may write $r = r_0 {}^\frown r_1$ where $r_0 \in g_\beta$ and (without loss of generality) r_1 is the canonical name for $C_\beta \cap (\eta + 1)$ where $\eta \in C_\beta$. By induction $D_\beta \leq j(r_0)$. By the distributivity of $\mathbb{P}_\beta$ again, every initial segment of C_β is in $V[G]$, and is fixed by j_G. So $D_\beta(= D_\alpha \restriction j(\beta))$ forces that $D_\alpha(j(\beta))$ is an end-extension of $j(r_1)$.

    It only remains to check that D_β forces that $C_\beta \cup \{\kappa\}$ is a legitimate condition in $j_\beta(\mathrm{CU}(\kappa, S_\beta))$. But this is immediate because S_β was chosen to lie in the filter dual to I_β.

- D_α is flat. This is straightforward: we have already checked that it is a condition, and by construction each entry is a canonical name for a closed set of ordinals with maximum element κ.

- j_α is defined in the standard way as a lifting of $j_G : V[G] \to M[G * H]$. The fact that D_α is a strong master condition ensures the necessary compatibility of generic filters.

- The sets S_α are chosen according to a suitable book-keeping scheme so that after κ^+ steps it is forced that every element of $\bigcup_\alpha I_\alpha$ has become non-stationary.

17.2 Remark. The trick of using a dense subset of conditions which are "flat" (in a suitable sense) is very often useful in situations when we are iteratively shooting clubs through stationary sets. It would have been tempting to define $\mathbb{P}_\alpha$ as the set of flat conditions with a suitable ordering, but this raises problems of its own; in particular we would have needed to verify that the flat poset is an iteration of club shooting forcing, which amounts to showing that flat conditions are dense.

In several subsequent arguments that involve iterated club shooting we have cheated (in a harmless way) by just defining the set of flat conditions, and leaving it to the reader to check that this set is dense in the corresponding iteration. See in particular Lemma 17.3 and the results of Sects. 18 and 19.

Precipitousness

It remains to see that the non-stationary ideal is precipitous in $V[G * g_{\kappa^+}]$. The argument runs parallel to that for the precipitous ideal in the preceding section, but is harder because we now need a generic elementary embedding with domain $V[G * g_{\kappa^+}]$. The main technical difficulties are that

1. $j``\kappa^+ \notin M$, indeed it is cofinal in $j(\kappa^+)$, so that we cannot hope to cover it by any countable set in $M[G * H]$. So there is no chance of building a strong master condition.

2. The method for doing without a strong master condition which we described in Sect. 13 uses a reasonably large amount of closure but $\mathbb{P}_{\kappa^+}$ is not even countably closed.

3. $\mathbb{P}_{\kappa^+}$ is not sufficiently distributive to transfer a generic object as in Sect. 15, nor does it obey a strong enough chain condition to pull back a generic object as in Proposition 15.6.

Since we will use the same set of ideas again in Sect. 18 when we build a model in which NS_{ω_2} is precipitous, we state a rather general lemma about constructing precipitous ideals by iterated club-shooting. This is really just an abstraction of an argument from [41]. In the applications which we are making of this lemma the preparation forcing $\mathbb{P}$ will make κ into the successor of some regular $\delta < \kappa$.

17.3 Lemma. *Suppose that κ is measurable and $2^\kappa = \kappa^+$. Let U be a normal measure on κ and let $j : V \longrightarrow M$ be the associated ultrapower map. Let $\mathbb{P}$ be a κ-c.c. poset with $\mathbb{P} \subseteq V_\kappa$. As usual $\mathbb{P}$ is completely embedded in $j(\mathbb{P})$, so that if G is $\mathbb{P}$-generic and H is $j(\mathbb{P})/G$-generic then $j : V \longrightarrow M$ can be lifted to an elementary embedding $j_G : V[G] \longrightarrow M[G * H]$.*

Let $\langle \dot{\mathbb{Q}}_\alpha : \alpha \leq \kappa^+ \rangle$ be an $\mathbb{P}$-name for a sequence of forcing posets such that in $V[G]$

1. $\mathbb{Q}_\alpha$ is a complete subposet of $\mathbb{Q}_\beta$ for $\alpha \leq \beta \leq \kappa^+$.

2. Forcing with $\mathbb{Q}_\alpha$ adds no $<\kappa$-sequences of ordinals.

3. $\mathbb{Q}_{\kappa^+}$ is κ^+-c.c.

4. Every condition in $\mathbb{Q}_\alpha$ is a partial function q such that $\mathrm{dom}(q) \subseteq \alpha$, $|\mathrm{dom}(q)| < \kappa$ and $q(\eta)$ is a closed and bounded subset of κ for all $\eta \in \mathrm{dom}(q)$.

5. If g is a $\mathbb{Q}_\alpha$-generic filter then $\bigcup g$ is a sequence $\langle C_\beta : \beta < \alpha \rangle$ of club subsets of κ.

Suppose further that there are sequences $\langle i_\alpha : \alpha < \kappa^+ \rangle$ and $\langle \dot{D}_\alpha : \alpha < \kappa^+ \rangle$ such that

1. i_α is a complete embedding of $\mathbb{P} * \dot{\mathbb{Q}}_\alpha$ into $j(\mathbb{P})$, with $i_0 = \mathrm{id}$.

2. i_β extends i_α for $\alpha \leq \beta \leq \kappa^+$.

3. $\dot{D}_\alpha$ is a $j(\mathbb{P})/\mathbb{P} * \dot{\mathbb{Q}}_\alpha$-name for a condition $Q \in j_G(\mathbb{Q}_\alpha)$ such that $\mathrm{dom}(Q) = j``\alpha$, and for every $\eta \in j``\alpha$ $Q(\eta) = C_\eta \cup \{\kappa\}$, where $\langle C_\beta : \beta < \alpha \rangle$ is the sequence of club subsets of κ added by $\mathbb{Q}_\alpha$.

4. It is forced that $\dot{D}_\beta$ extends $\dot{D}_\alpha$ for $\alpha \leq \beta \leq \kappa^+$.

Let G be $\mathbb{P}$-generic over V, and let H be $j(\mathbb{P})/G$-generic over $V[G]$. For each $\alpha < \kappa^+$, let g_α be the filter on $\mathbb{Q}_\alpha$ induced by i_α and H (so that g_α is $V[G]$-generic).

For each $\nu < \kappa^+$ the hypotheses above imply that it is forced over $V[G * g_\nu]$ by $j(\mathbb{P})/G * g_\nu * j_G(\mathbb{Q}_\nu)/D_\nu$ that j_G can be extended to a generic embedding j_ν with domain $V[G * g_\nu]$. Let $J_\nu \in V[G * g_\nu]$ be the ideal of those $X \subseteq \kappa$ such that it is forced that $\kappa \notin j_\nu(X)$. Let $g = \bigcup_\nu g_\nu$ and $J = \bigcup_\nu J_\nu$.

Then

1. g is $\mathbb{Q}_{\kappa^+}$-generic over $V[G]$.

2. J is precipitous in $V[G * g]$.

17.4 Remark. In the intended applications, J will end up being the non-stationary ideal. However it may be (as will be the case in Sect. 18) that this is accomplished by a more sophisticated strategy than arranging that every $A \in J$ is disjoint from some C_i.

Proof. The induced filters g_ν are compatible in the sense that if $\rho \leq \sigma$ then $g_\rho = g_\sigma \cap \mathbb{Q}_\rho$. It follows easily from the κ^+-c.c that if we set $g = \bigcup_\rho g_\rho$ then g is $\mathbb{Q}_{\kappa^+}$-generic. Let D_ρ be the strong master condition computed from g_ρ.

We will construct K which is $j_G(\mathbb{Q}_{\kappa^+})$-generic over $M[G * H]$, and is compatible with g in the sense that $j_G``g \subseteq K$. We do this as follows: define $\mathbb{Q}^*$ to be the subset of $j_G(\mathbb{Q}_{\kappa^+})$ consisting of those F such that for some $\mu < \kappa^+$ we have $F \in j_G(\mathbb{Q}_\mu)/D_\mu$. Of course $\mathbb{Q}^* \subseteq M[G * H]$, but $\mathbb{Q}^* \notin M[G * H]$ since its definition requires a knowledge of $j \restriction \kappa^+$.

We force to get K_0 which is $\mathbb{Q}^*$-generic over $V[G * H]$. Let K be the upwards closure of K_0 in $j_G(\mathbb{Q}_{\kappa^+})$, then we claim that K is $j_G(\mathbb{Q}_{\kappa^+})$-generic over $M[G * H]$. Let $A \in M[G * H]$ be a maximal antichain in $j_G(\mathbb{Q}_{\kappa^+})$. We will show that conditions extending some element of A are dense in $\mathbb{Q}^*$. Let $F \in \mathbb{Q}^*$, and fix μ such that $F \in j_G(\mathbb{Q}_\mu)/D_\mu$. By a familiar chain condition argument we may fix a $\rho > \mu$ such that A is a maximal antichain in $j_G(\mathbb{Q}_\rho)$. Working in $M[G * H]$ we first extend F to $F' = F \cup D_\rho \in j_G(\mathbb{Q}_\rho)/D_\rho$, and then extend F' to a condition $F'' \in j(\mathbb{Q}_\rho)$ which also extends some member of A.

In the usual way we may now extend $j_G : V[G] \longrightarrow M[G * H]$ to an embedding $j^* : V[G * g] \longrightarrow M[G * H * K]$. From the point of view of the model $V[G * g]$ this is a generic embedding added by forcing with $j(\mathbb{P})/(G * g) * \mathbb{Q}^*$. It is routine to check that J is the ideal on κ induced by this generic embedding; more explicitly for every $X \in V[G * g]$

$$X \in J \quad \Longleftrightarrow \quad \Vdash^{V[G*g]}_{j(\mathbb{P})/(G*g)*\mathbb{Q}^*} \kappa \notin j^*(X).$$

For any $X \notin J$ we may therefore force to obtain some embedding j^* such that $\kappa \in j(X)$. To finish it will suffice to show that for any generic embedding j^* as above, if we define a $V[G * g]$-ultrafilter U^* by

$$U^* = \{Y : \kappa \in j^*(Y)\}$$

then U^* is $P(\kappa)/J$-generic over $V[G * g]$ and gives a well-founded ultrapower. Since as in the last section we have $\mathrm{Ult}(V[G * g], U^*) = M[G * H * K]$, the well-foundedness is immediate.

The argument that U^* is $P(\kappa)/J$-generic is similar to that from the last section but there are some extra subtleties. We note in particular that the embedding j^* is defined in a generic extension of V by $j(\mathbb{P}) * \mathbb{Q}^*$, but is a lifting of j to a map from the extension of V by $\mathbb{P} * \mathbb{Q}_{\kappa^+}$ to the extension of M by $j(\mathbb{P}) * j(\mathbb{Q}_{\kappa^+})$.

Let $\dot{\mathcal{A}}$ be a $\mathbb{P} * \mathbb{Q}_{\kappa^+}$-name for a maximal antichain of J-positive sets and suppose towards a contradiction that some condition $(P, \dot{F}) \in j(\mathbb{P}) * \mathbb{Q}^*$ forces that for every $B \in \mathcal{A}$, $\kappa \notin j^*(B)$. We will find a J-positive set T which has J-small intersection with every $B \in \mathcal{A}$, contradicting the maximality of $\mathcal{A}$.

Since $\mathbb{Q}^* \subseteq j(\mathbb{P}_{\kappa^+})$ we see that $(P, \dot{F}) \in j(\mathbb{P} * \mathbb{Q}_{\kappa^+})$, and so we may choose in V a function $R : \kappa \to \mathbb{P} * \mathbb{Q}_{\kappa^+}$ such that $j(R)(\kappa) = (P, \dot{F})$. Let $\dot{T}$ name the set $\{\alpha : R(\alpha) \in G * g\}$; then it is easy to see that it is forced by $j(\mathbb{P}) * \mathbb{Q}^*$ that for every $B \in \mathcal{A}$, $\kappa \notin j^*(B \cap T)$; the key point is that by construction $\kappa \in j^*(T) \iff (P, F) \in G * H * K$.

We now force to get $G * H$ which is $j(\mathbb{P})$-generic over V with $P \in G * H$, and from this we obtain as usual a g which is $\mathbb{Q}_{\kappa^+}$-generic over $V[G]$. Moving to $V[G * g]$ and using the fact that J is the ideal induced by j^*, we see that $B \cap T \in J$ for all $B \in \mathcal{A}$.

To finish the argument we show that $T \notin J$. By forcing over $V[G * H]$ with $\mathbb{Q}^*/F$ we obtain an elementary embedding $j^* : V[G * g] \longrightarrow M[G * H * K]$ where $(P, F) \in G * H * K$, so that $\kappa \in j^*(T)$ by the construction of R and T. Since J is the ideal induced by j^*, $T \notin J$ and we are done. $\dashv$

17.5 Remark. The technique used in this lemma is discussed in a more general and abstract setting in Foreman's chapter of this Handbook.

18. Precipitous Ideals II

In this section we discuss some work of Moti Gitik in which he obtains various results of the form "$\mathrm{NS}_\kappa \restriction \mathrm{Cof}(\mu)$ can be precipitous" from hypotheses which are optimal or close to optimal. We will describe in some detail the proof of

18.1 Theorem (Gitik [23]). *The precipitousness of* NS_{ω_2} *is equi-consistent with the existence of a cardinal of Mitchell order two.*

We will then give a much less detailed discussion of some of Gitik's consistency and equi-consistency results for cardinals greater than ω_2, which use many of the same ideas. Throughout this section, we will be using the general machinery of Lemma 17.3 to construct precipitous ideals. We will focus on the technical problems that need to be overcome to invoke this machinery, and on their solutions.

18.2 Remark. As discussed in Foreman's chapter in this Handbook, the simplest known model [21] for the precipitousness of NS_κ is obtained by taking a Woodin cardinal $\delta > \kappa$ and forcing with $\mathrm{Col}(\kappa, {<}\delta)$. The point here is to use the optimal hypotheses, which turn out to be much weaker.

18.3 Remark. We note that NS_{ω_2} is precipitous if and only if both of the restrictions $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega)$ and $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$ are precipitous.

18.1. A Lower Bound

We start by sketching a proof of a lower bound for the strength of "NS_{ω_2} is precipitous". Suppose for a contradiction that NS_{ω_2} is precipitous and there is no inner model with a cardinal κ such that $o(\kappa) = 2$, and let K be the core model for sequences of measures constructed by Mitchell [59]. Let $\lambda = \omega_2^V$ and let $\mathcal{F}$ be the measure sequence of K. We recall the key facts that K is definable and invariant under set forcing, and that any elementary $i : K \longrightarrow N \subseteq V$ is an iterated ultrapower of K by $\mathcal{F}$.

By precipitousness of $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$, we may force to get a V-ultrafilter U which concentrates on ordinals of cofinality ω_1 and has $M = \mathrm{Ult}(V, U)$ well-founded. Let $j : V \longrightarrow M \subseteq V[U]$ be the ultrapower map. By the usual arguments $\mathrm{crit}(j) = \lambda = [\mathrm{id}]_U$, $P(\lambda)^V \subseteq M$, and $\mathrm{cf}^M(\lambda) = \omega_1^M = \omega_1^V$. Note also that if A is an ω-club subset of λ in V, then the same is true of A in M.

Let $i = j \restriction K$, then by the properties of K mentioned above we know that $i : K \longrightarrow K' = K^M$ and i is an iterated ultrapower of K with critical point λ. In particular λ is measurable in K, and so $\mathcal{F}(\lambda, 0)$ exists. By our initial hypotheses λ is not measurable in K', and so in K the only measure on λ is $\mathcal{F}(\lambda, 0)$. Note also that $P(\lambda)^K = P(\lambda)^{K'}$.

Let C be the ω-club filter on λ as computed in V, let $A \in \mathcal{F}(\lambda, 0)$ and let W be an arbitrary V-generic ultrafilter added by forcing with C-positive sets. Then by precipitousness of $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega)$, we get an elementary embedding $j_W : V \longrightarrow \mathrm{Ult}(V, W)$, and if $i_W = j_W \restriction K$ then i_W is an iterated ultrapower of K with critical point λ; since in K the only measure on λ is $\mathcal{F}(\lambda,0)$, we see that $\kappa \in j_W(A)$, that is, $A \in W$. Since it is forced that $A \in W$, we have that $A \in C$. So $\mathcal{F}(\lambda,0) \subseteq C \cap K$, and since the left hand side is a K-ultrafilter in fact $\mathcal{F}(\lambda,0) = C \cap K$.

Now let D be the ω-club filter on λ as computed in M. This makes sense because $\mathrm{cf}^M(\lambda) = \omega_1$. We know that $C \subseteq D$ and $P(\lambda)^K = P(\lambda)^{K'}$, so easily $\mathcal{F}(\lambda,0) = D \cap K'$. Since D is a countably complete filter in M we see that $M' = \mathrm{Ult}(K', \mathcal{F}(\lambda,0))$ is wellfounded and we get in M an elementary embedding $j' : K' \longrightarrow M'$ with critical point λ; since $K' = K^M$ this is an iteration of K', but that is impossible because λ is not measurable in K'.

18.2. Precipitousness for $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$

We have established that if NS_{ω_2} is precipitous then there is an inner model with a cardinal κ such that $o(\kappa) = 2$. We will prove that this is an equiconsistency, but before we do that we warm up with a sketch of the easier argument that starting from a measurable cardinal $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$ can be precipitous [41].

We have already introduced in Sect. 17 most of the ideas needed to show that $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$ can be precipitous. What is still missing is a discussion of how we should shoot club sets through stationary subsets of ω_2. The arguments of Lemmas 18.5 and 18.6 are due to Stavi (see [3]).

As we saw in Sect. 6 if S is a stationary subset of ω_1 then it is possible to add a club set C with $C \subseteq S$, using a forcing poset which does not add any ω-sequences of ordinals. Suppose now that instead S is a stationary subset of ω_2. In general we may not be able to shoot a club set through S without collapsing cardinals, for example if $S = \omega_2 \cap \mathrm{Cof}(\omega_1)$.

In a way the rather trivial example from the last paragraph is misleading. If we aim to make $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$ precipitous then we need to take a stationary $S \subseteq \omega_2 \cap \mathrm{Cof}(\omega_1)$ and add, without collapsing ω_1 or ω_2, a club subset C of ω_2 such that $C \cap \mathrm{Cof}(\omega_1) \subseteq S$. This is fairly easy.

We recall that $\mathrm{CU}(\delta, A)$ is the forcing poset whose conditions are closed bounded subsets of δ which are contained in A, ordered by end-extension. We will need a technical lemma on the existence of countably closed structures.

18.4 Lemma. *Let* CH *hold and let $S \subseteq \omega_2 \cap \mathrm{Cof}(\omega_1)$ be stationary. Let θ be a large regular cardinal and let $x \in H_\theta$. Then there exists $N \prec H_\theta$ such that $\omega_1 \cup \{x\} \subseteq N$, $|N| = \omega_1$, ${}^\omega N \subseteq N$ and $N \cap \omega_2 \in S$.*

Proof. We build an increasing and continuous chain $\langle N_j : j < \omega_2 \rangle$ such that $N_j \prec H_\theta$, $\omega_1 \cup \{x\} \subseteq N_0$, $|N_j| = \omega_1$ and ${}^\omega N_j \subseteq N_{j+1}$. Since $\omega_1 \subseteq N_j$ we see that $N_j \cap \omega_2 \in \omega_2$, and so by continuity and the stationarity of S we may choose j such that $\mathrm{cf}(j) = \omega_1$ and $N_j \cap \omega_2 \in S$; it is easy to see that ${}^\omega N_j \subseteq N_j$. ⊣

18.5 Lemma. *Let* CH *hold, and let $S \subseteq \omega_2 \cap \mathrm{Cof}(\omega_1)$ be stationary. Let $\mathbb{P} = \mathrm{CU}(\omega_2, (\omega_2 \cap \mathrm{Cof}(\omega)) \cup S)$. Then $\mathbb{P}$ is countably closed and adds no ω_1-sequences of ordinals.*

Proof. Countable closure is immediate, so suppose that c forces that $\dot{\tau}$ is a function from ω_1 to On. By Lemma 18.4 we may find $N \prec H_\theta$ for some large θ so that N contains everything relevant, $|N| = \omega_1$, ${}^\omega N \subseteq N$, and $\delta =_{\mathrm{def}} N \cap \omega_2$ lies in S. Now we build a decreasing chain of conditions $\langle c_i : i < \omega_1 \rangle$ so that $c_i \in N$, c_{i+1} decides $\tau(i)$ and the sequence $\langle \delta_i : i < \omega_1 \rangle$ where $\delta_i =_{\mathrm{def}} \max(c_i)$ is cofinal in δ. If $\lambda < \omega_1$ is a limit stage there is no problem because ${}^\omega N \subseteq N$, and we may safely choose $\delta_\lambda = \sup_{i<\lambda} \delta_i$, $c_\lambda = \bigcup_{i<\lambda} c_i \cup \{\delta_\lambda\}$. To finish we choose $d = \bigcup_{i<\omega_1} c_i \cup \{\delta\}$, which is legal since $\delta \in S$, and then d is a condition which refines c and determines $\dot{\tau}$. $\dashv$

An equivalent formulation would be that we are shooting an ω_1-club set through S by forcing with bounded ω_1-closed subsets of S. Using the forcing of Lemma 18.5 and the ideas of Sect. 17, it is now fairly straightforward to show that starting with a measurable cardinal κ we may produce a model where $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$ is precipitous. We force first with $\mathrm{Col}(\omega_1, <\kappa)$ and then iterate club shooting, absorb forcing posets and construct strong master conditions more or less exactly as in Sect. 17.

If we are interested in the full ideal NS_{ω_2} then we need to shoot club sets rather than ω_1-club sets. This is more subtle; a little thought shows that if $S \subseteq \omega_2$ and we wish to shoot a club set through S without adding ω_1-sequences, then there must be stationarily many $\alpha \in S \cap \mathrm{Cof}(\omega_1)$ such that $S \cap \alpha$ contains a closed cofinal set of order type ω_1. The next result shows that (at least under CH) this is the only obstacle.

18.6 Lemma. *Let* CH *hold, and let $S \subseteq \omega_2$ be such that for stationarily many $\alpha \in S \cap \mathrm{Cof}(\omega_1)$ there exists a set $C \subseteq S \cap \alpha$ with C club in α. Let $\mathbb{P} = \mathrm{CU}(\omega_2, S)$. Then $\mathbb{P}$ adds no ω_1-sequences of ordinals.*

Proof. The proof is similar to that of Lemma 18.5. Let T be the stationary set of $\alpha \in S \cap \mathrm{Cof}(\omega_1)$ such that there exists a set $C \subseteq S \cap \alpha$ with C club in α. Suppose that c forces that $\dot{\tau}$ is a function from ω_1 to On. Build an elementary $N \prec H_\theta$ for some large θ so that N contains everything relevant, $|N| = \omega_1$, ${}^\omega N \subseteq N$, and $\alpha =_{\mathrm{def}} N \cap \omega_2 \in T$. By hypothesis there is a set $C \subseteq S \cap \alpha$ with C club in α. We build a strictly decreasing chain of conditions $\langle c_i : i < \omega_1 \rangle$ so that $c_i \in N$, c_{i+1} decides $\tau(i)$ and $\delta_i \in C$ where $\delta_i =_{\mathrm{def}} \max(c_i)$. To finish we choose $d = \bigcup_{i<\omega_1} c_i \cup \{\alpha\}$, so that d is a condition which refines c and determines $\dot{\tau}$. $\dashv$

18.3. Outline of the Proof and Main Technical Issues

We will use measures $U_0 \lhd U_1$ of Mitchell orders zero and one respectively. We let B be the set of $\alpha < \kappa$ with $o(\alpha) = 1$, so that $B \in U_1$ and $B \notin U_0$. We fix measures W_i for $i \in B$ so that W_i is a measure of order zero on i (so in particular $B \cap i \notin W_i$) and $\langle W_i : i \in B\rangle$ represents U_0 in $\mathrm{Ult}(V, U_1)$, or more concretely for $X \subseteq \kappa$

$$X \in U_0 \iff \{i : X \cap i \in W_i\} \in U_1.$$

The rough idea is this: we start with some preparation forcing which adds no reals, makes κ into ω_2, makes all inaccessible α lying in B into ordinals of cofinality ω_1, and makes all inaccessible α not lying in B into ordinals of cofinality ω. We then iterate shooting club sets so that U_0 extends to the ω-club filter and U_1 extends to the ω_1-club filter. Roughly speaking U_0 will be responsible for the precipitousness of $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega)$ and U_1 will be responsible for the precipitousness of $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$.

There are several technical obstacles to be overcome.

- In the proof sketched above that $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$ can be precipitous, the forcing which is being iterated to shoot ω_1-club subsets of ω_2 is countably closed. In particular it can be absorbed into any sufficiently large countably closed collapsing poset. This means that the "preparation stage" of the preceding construction can be the simple forcing $\mathrm{Col}(\omega_1, {<}\kappa)$. In the construction to follow we will be shooting club subsets of ω_2 in a way which destroys stationary subsets of $\omega_2 \cap \mathrm{Cof}(\omega)$, so that the forcing can not be embedded into any countably closed forcing (or even any proper forcing). This is one reason why the preparation stage for the construction to follow has to be more complicated.

- The measure U_0 will be extended to become the ω-club filter. So we need to shoot ω-club sets through (at least) all $A \in U_0$, and we will therefore need to shoot closed sets of order type ω_1 through many initial segments of A, in order to appeal to a suitable version of Lemma 18.6. We need some way of organizing the construction so that all $A \in U_0$ are anticipated.

  Recall that if $A \in U_0$ then there are many $i \in B$ such that $A \cap i \in W_i$. At many $i \in B$ we will add a club subset of i which has order type ω_1, and is eventually contained in every member of W_i.

- To build the preparation forcing, we need some way of iterating forcings which change cofinality without adding reals. This will require an appeal to Shelah's machinery of revised countable support iteration.

- In the arguments for the precipitousness of NS_{ω_1} and $\mathrm{NS}_{\omega_2} \restriction \mathrm{Cof}(\omega_1)$, we iterated to shoot club sets through stationary sets which were measure one for certain "master condition ideals" (in the sense of Foreman's chapter) arising along the way. In the current setting it is not clear that we can do this in a distributive way, so we finesse the question and shoot club sets through some more tractable sets, then argue that this is enough.

To be a bit more precise, suppose that $V[G_\kappa]$ is the result of the preparation stage. We will build a κ^+-c.c. iteration $\mathbb{Q}_{\kappa^+}$, shooting club sets through subsets of κ. At successor stages we will shoot club sets through certain sets of inaccessibles from the ground model of the form $X \cup Y$ where $X \in U_0$, $Y \in U_1$, $X \subseteq \kappa \setminus B$ and $Y \subseteq B$.

As the construction proceeds we will show, by induction on ν, that the embeddings j_i can be lifted onto the extension of $V[G_\kappa]$ by $\mathbb{Q}_\nu$. For limit ν we will write $\mathbb{Q}_\nu$ as the union $\bigcup_{\alpha<\kappa} \mathbb{Q}^\alpha_\nu$ of a continuous sequence of subsets each of size less than κ. The existence of the lifted embeddings implies that if H_ν is $\mathbb{Q}_\nu$-generic over $V[G_\kappa]$, then there are many $\alpha < \kappa$ such that $H_\nu \cap \mathbb{Q}^\alpha_\nu$ is $\mathbb{Q}^\alpha_\nu$-generic over $V[G_\alpha]$; we will ensure that a club set is shot through each such set of "generic points".

We then argue that using the club sets which are added in this process, for each set in one of the relevant master condition ideals we may define a club set which is disjoint from it. Below, at the end of Sect. 18.6, we will work through a toy example which illustrates this central idea.

- In order to realize the idea of the last item, we need that the closed sets of order type ω_1 added to points of B during the preparation stage have an additional property. Namely, if $i \in B$ and c is the club set in i which is added at stage i during the preparation, then we require that for every $\beta \in \lim(c)$ the set $c \cap \beta$ must intersect every club subset of β which lies in $V[G_\beta]$.
- Let $j_i : V \longrightarrow M_i$ be the ultrapower by U_i for $i = 0, 1$. We will need to embed $\mathbb{P}_\kappa * \mathbb{Q}_\nu$ into both $j_0(\mathbb{P}_\kappa)$ and $j_1(\mathbb{P}_\kappa)$. Naturally the iterations $j_0(\mathbb{P}_\kappa)$ and $j_1(\mathbb{P}_\kappa)$ differ at stage κ; the forcing at stage κ will change the cofinality of κ to the values ω and ω_1 respectively.

18.4. Namba Forcing, RCS Iteration and the S and $\mathbb{I}$ Conditions

Several important ingredients in the proof come from Shelah's work [64] on iterated forcing. The technical issue is that in the preparation stage we need to iterate forcing posets which change cofinalities to ω and add no reals, in such a way that the whole iteration adds no reals. A detailed discussion of Shelah's techniques would take us too far afield, so we content ourselves with a very brief overview.

The preparation iteration will be done using Shelah's *Revised Countable Support* (RCS) technology. This is a version of countable support iteration in which (very roughly speaking) we allow the supports of conditions used in the iteration to be countable sets which are not in the ground model, but arise in the course of the iteration: the point of doing this is to cope gracefully with iteration stages δ such that $\mathrm{cf}(\delta) > \omega$ in V but the cofinality of δ is changed to ω in the course of the iteration.

For motivation, consider the case of Namba forcing. The conditions are trees $T \subseteq {}^{<\omega}\omega_2$ with a unique *stem element* stem(T), such that every element of T is comparable with stem(T) and every element extending stem(T) has ω_2 immediate successors in T. Forcing with these conditions adds an ω-sequence cofinal in ω_2.

Namba [60] showed that under CH this forcing poset adds no reals; we sketch an argument for this which is due to Shelah. Let $\dot{r}$ be a name for a real and let S be a condition. We first find a refinement $T \leq S$ such that stem(T) = stem(S), and T forces that $\dot{r}(n)$ is determined by the first n points of the generic branch. We then appeal to a partition theorem for trees (proved from CH, by applying Borel determinacy to each of a family of ω_1 "cut and choose" games played on T) to find a refinement $U \subseteq S$ such that stem(U) = stem(S) and every branch through U determines the same real r, so that $U \Vdash \dot{r} = \check{r}$.

The decisive points for the arguments of the last paragraph were that Namba forcing satisfies a version of the fusion lemma and that (under CH) the ideal of bounded subsets of ω_2 is $(2^\omega)^+$-complete. Motivated by these ideas Shelah formulated a technical condition on forcing posets known as the *S-condition*, where S is some set of regular cardinals; this is an abstract form of fusion, saying *very* roughly that a tree of conditions which has cofinally many λ-branching points for each $\lambda \in S$ can be fused. Shelah also showed that under the right circumstances an RCS iteration of S-condition forcing does not add reals. The variant of Namba forcing in which conditions are subtrees of ${}^{<\omega}\omega_2$ such that cofinally many points have ω_2 successors satisfies the S-condition for $S = \{\omega_2\}$.

An important ingredient in the proof we are describing that NS_{ω_2} can be precipitous is a variant Nm' of Namba forcing. Conditions in Nm' are subtrees T of ${}^{<\omega}\omega_3$, such that for $i \in \{2, 3\}$ there are cofinally many points $t \in T$ with $\{\alpha : t^\frown\alpha \in T\}$ an unbounded subset of ω_i.

The salient facts about Nm' are encapsulated in the following result. The first fact in this list is quite hard, but the remaining ones follow easily.

18.7 Lemma. *Let* CH *hold. Then*

1. Nm' *satisfies Shelah's S-condition for $S = \{\omega_2, \omega_3\}$, in particular it adds no reals (and so preserves ω_1).*
2. Nm' *adds cofinal ω-sequences in ω_2^V and ω_3^V.*
3. *In the generic extension ω_3^V can be written as the union of ω many sets which each lie in V and have V-cardinality ω_1.*
4. *Assuming that $2^{\omega_2} = \omega_3$ in V, in the generic extension by* Nm' *there is an ω-sequence $\langle E_n \rangle$ such that*
   - (a) *$E_n \in V$ and $V \models$ "E_n is a club subset of ω_2" for each $n < \omega$.*
   - (b) *For every $E \in V$ such that $V \models$ "E is a club subset of ω_2" there is an integer n such that $E_n \subseteq E$.*

5. *Assuming that* $2^{\omega_2} = \omega_3$ *in* V, *if* $\mathbb{R}$ *is any forcing poset of size* ω_2 *which adds no* ω_1*-sequences then forcing with* Nm' *adds a generic filter for the poset* $\mathbb{R}$.

For use later we note that Gitik and Shelah defined a generalized version of the S-condition known as the $\mathbb{I}$-*condition*, where $\mathbb{I}$ is a family of ideals on some set S of regular cardinals. The $\mathbb{I}$-condition is just like the S-condition except that the branching in the fusion trees now has to be positive cofinally often with respect to every ideal in $\mathbb{I}$. Gitik and Shelah extended the iteration theorems for RCS iteration which we mentioned above to cover the $\mathbb{I}$-condition, subject to additional technical conditions.

18.5. The Preparation Iteration

We will start by forcing with an RCS iteration $\mathbb{P}_\kappa$. Among the important features of this forcing poset will be that

1. $\mathbb{P}_\kappa$ adds no reals.

2. For every inaccessible $\alpha \leq \kappa$,

   (a) $\mathbb{P}_\alpha$ is isomorphic to the direct limit of $\langle \mathbb{P}_\beta : \beta < \alpha \}$.

   (b) $\mathbb{P}_\alpha \subseteq V_\alpha$.

   (c) $\mathbb{P}_\alpha$ is α-c.c.

   (d) $\mathbb{P}_\alpha$ collapses α to become $\omega_2^{V[G_\alpha]}$.

   (e) After forcing with $\mathbb{P}_{\alpha+1}$, α is an ordinal of cardinality ω_1, which has cofinality ω for $\alpha \notin B$ and cofinality ω_1 for $\alpha \in B$.

   (f) For $\alpha \in B$, $V[G_\alpha]$ and $V[G_{\alpha+1}]$ have the same ω-sequences of ordinals.

18.8 Remark. It follows from the properties of $\mathbb{P}_\kappa$ we just listed that

1. All bounded subsets of κ in $V[G_\kappa]$ appear in $V[G_\beta]$ for some $\beta < \kappa$.

2. All elements of ${}^\omega\alpha$ which are in $V[G_\kappa]$ already appear in $V[G_{\alpha+1}]$, and if $\alpha \in B$ then such ω-sequences are actually in $V[G_\alpha]$.

As usual it suffices to define the poset which is used at each stage i of the iteration.

- Case 1: If i is not inaccessible we force with $\mathrm{Col}(\omega_1, 2^{\omega_1})^{V[G_i]}$.

- Case 2: If i is inaccessible and $i \notin B$ then we force with $(\mathrm{Nm}')^{V[G_i]}$ (where we note that in $V[G_i]$ we will have $i = \omega_2$ and $i^+ = \omega_3$).

- Case 3: If i is inaccessible and $i \in B$ then we force with $\mathbb{P}^*[W_i]$ defined as follows: conditions are pairs (c, A) such that c is a countable closed subset of $(\kappa \setminus B) \cap i$ consisting of V-inaccessibles, $A \subseteq (\kappa \setminus B) \cap i$ with $A \in W_i$, and for every $\beta \in \lim(c)$ the set $c \cap \beta$ meets every club subset of β lying in the model $V[G_\beta]$. The condition (c', A') extends (c, A) if and only if c' end-extends c, $A' \subseteq A$ and $c' - c \subseteq A$.

18.9 Remark. Let i fall under case 3, let g be a $V[G_i]$-generic subset of $\mathbb{P}^*[W_i]$ and let $e = \bigcup\{c : \exists A\ (c, A) \in g\}$. Then e is a club subset of i with order type ω_1, e is eventually contained in every element of W_i, and every element of e falls under case 2.

18.10 Remark. The definition of $\mathbb{P}^*[W_i]$ can be simplified by the observation that (by the β-c.c.) every club subset of β in $V[G_\beta]$ contains a club subset of β in V.

A key technical point (which we are glossing over here) is that the poset $\mathbb{P}^*[W_i]$ satisfies a suitable version of Gitik and Shelah's $\mathbb{I}$-condition [28]. In fact the argument we are describing was one of the main motivations for the development of the $\mathbb{I}$-condition. Once it is has been checked that Nm' has the S-condition and $\mathbb{P}^*[W_i]$ satisfies the $\mathbb{I}$-condition for suitable S and $\mathbb{I}$, an appeal to standard facts about RCS iterations lets us conclude that $\mathbb{P}_\kappa$ has the properties listed above.

18.11 Lemma. *If $i \in B$ then forcing with $\mathbb{P}^*[W_i]$ adds no ω-sequences of ordinals to $V[G_i]$.*

Sketch of Proof. Take a $\mathbb{P}_i$-name for a sequence $\langle D_n : n < \omega\rangle \in V[G_i]$ of dense open subsets of $\mathbb{P}^*[W_i]$. Working in V we fix an elementary chain of models M_β for $\beta \in i$ such that $M_\beta \prec (H_\theta, \dots)$, M_0 contains everything relevant and $M_\beta \cap i \in i$. Now we choose an inaccessible $\beta \notin B$ such that $M_\beta \cap i = \beta$ and $\beta \in A$ for every $A \in M_\beta \cap W_i$. Since $\mathbb{P}_\beta$ is β-c.c. and $\mathbb{P}_\beta \subseteq M_\beta$, routine arguments as in the theory of proper forcing show that $M_\beta[G_\beta] \prec H_\theta[G_\kappa]$ and $M_\beta[G_\beta] \cap V = M_\beta$.

As we observed already β must fall under case 2 in the definition of the preparation iteration $\mathbb{P}_\kappa$, so that by Lemma 18.7 there is in $V[G_i]$ an ω-sequence $\langle E_m : m < \omega\rangle$ which "diagonalizes" the club subsets of β lying in $V[G_\beta]$. We may now construct a sequence $\langle (c_n, A_n) : n < \omega\rangle$ of conditions in $\mathbb{P}^*[W_i] \cap M_\beta[G_\beta]$ such that $c_{2n+1} \in D_n$ and $\max(c_{2n+2}) \in E_n$. Let $d =_{\mathrm{def}} \bigcup_n c_n \cup \{\beta\}$ and $A^* = \bigcap(M_\beta \cap W_i)$, then (d, A^*) is a condition in $\mathbb{P}^*[W_i]$ which lies in the intersection of the D_n. ⊣

18.6. A Warm-up for the Main Iteration

Throughout the discussion that follows we are working in $V[G_\kappa]$, in particular $\kappa = \omega_2$ and $\kappa^+ = \omega_3$. We will eventually describe an iteration of length κ^+ in which we shoot club sets through subsets of κ without adding bounded subsets of κ. Before we do that, for purposes of motivation we will describe a much simpler three step iteration $\mathbb{R}_0 * \dot{\mathbb{R}}_1 * \dot{\mathbb{R}}_2$ of club-shooting forcing, and sketch proofs of its salient properties which contain most of the ideas needed for the full iteration.

To describe $\mathbb{R}_0$ we fix sets of inaccessibles $X \in U_0$ and $Y \in U_1$ such that $X \subseteq \kappa \setminus B$ and $Y \subseteq B$. Let $A = X \cup Y$ and define $\mathbb{R}_0 = \mathrm{CU}(\kappa, A)$, the poset of closed and bounded subsets of A ordered by end-extension.

18.12 Lemma. *Forcing with $\mathbb{R}_0$ over $V[G_\kappa]$ adds no ω_1-sequences of ordinals.*

Proof. Working in V, let $T = \{\beta \in Y : X \cap \beta \in W_\beta\}$. Then $T \in U_1$, because $X \in U_0$ and U_0 is represented by $\langle W_i : i \in B\rangle$ in $\mathrm{Ult}(V, U_1)$. In particular T is stationary in κ. The poset $\mathbb{P}_\kappa$ is κ-c.c. and so T is stationary in $V[G_\kappa]$. For each $\beta \in T$, the preparation forcing added a closed set of order type ω_1 which is contained in $X \cap \beta$, and we are done by Lemma 18.6. ⊣

One of the key ideas in Gitik's arguments is that of a "local master condition". We give a more precise formulation in a moment, but the rough idea is to look at conditions which induce generic filters over a submodel of the universe for subposets of a forcing poset. The idea is similar to that of a strongly generic condition in proper forcing (see Remark 24.5) but the relevant submodels here are the classes $V[G_\beta]$ for $\beta < \kappa$. We will construct our iterations so that there are many local master conditions; as we see at the end of this section, this is vital when it comes to lifting the elementary embeddings j_0 and j_1 in the required way.

The set T defined in the proof of Lemma 18.12 is stationary, so by the usual reflection arguments the set of points where T reflects is a measure one set for any normal measure. We let $A' = X' \cup Y'$, where

$$X' = \{\beta \in X : T \cap \beta \text{ is stationary in } \beta\},$$
$$Y' = \{\beta \in Y : T \cap \beta \text{ is stationary in } \beta\}.$$

For $\beta < \kappa$ we define $\mathbb{R}_{0,\beta}$ to be the set of $d \in \mathbb{R}_0$ such that $\max(d) < \beta$ and $d \in V[G_\beta]$. It is easy to see that $\mathbb{R}_0 = \bigcup_{\beta<\kappa} \mathbb{R}_{0,\beta}$, and that

$$\mathbb{R}_{0,\gamma} = \textstyle\bigcup_{\beta<\gamma} \mathbb{R}_{0,\beta} = \mathbb{R}_0 \cap V_\gamma[G_\gamma]$$

when γ is V-inaccessible.

18.13 Remark. By the usual conventions, for λ an uncountable regular cardinal and X a set with $|X| = \lambda$, a *filtration* of X is an increasing and continuous sequence $\langle X_i : i < \lambda\rangle$ such that $X_i \subseteq X$, $X = \bigcup_i X_i$, and $|X_i| < \lambda$. The key property is that given filtrations X_i, X'_i we have $X_j = X'_j$ for a club set of j.

Technically the sequence of posets $\mathbb{R}_{0,\beta}$ is not a filtration of $\mathbb{R}_0$ because it is only continuous at V-inaccessible points. Until the end of this section we will abuse notation and refer to such sequences as filtrations.

A local version of the argument of Lemma 18.12 shows immediately that

18.14 Lemma. *For every $\beta \in A'$, forcing with $\mathbb{R}_{0,\beta}$ over $V[G_\beta]$ adds no ω_1-sequences of ordinals.*

The next lemma can be seen as a more refined version of this result. Let $\beta \in A'$. We will say that $c \in \mathbb{R}_0$ is a *β-master condition for* $\mathbb{R}_0$ if $\max(c) = \beta$, and $\{c \cap (\alpha+1) : \alpha \in \beta \cap \lim(c)\}$ is a $V[G_\beta]$-generic subset of $\mathbb{R}_{0,\beta}$.

18.15 Lemma. *For every $\beta \in A'$ and every $d \in \mathbb{R}_{0,\beta}$ there is a β-master condition $c \leq d$ with $c \in V[G_{\beta+2}]$.*

Proof. In $V[G_\beta]$ we have $\beta = \omega_2$ and $(\beta^+)^V = \omega_3$. By the previous lemma, $\mathbb{R}_{0,\beta}$ is (ω_1, ∞)-distributive in $V[G_\beta]$. We distinguish the cases $\beta \in X'$ and $\beta \in Y'$.

$\beta \in X'$: At stage β in the preparation forcing we forced with Nm'. So we are done by an appeal to clause 5 of Lemma 18.7, and in fact we can build a suitable c in $V[G_{\beta+1}]$.

$\beta \in Y'$: Again $\mathbb{R}_{0,\beta}$ is (ω_1, ∞)-distributive in $V[G_\beta]$. In $V[G_{\beta+2}]$ we have $\mathrm{cf}(\beta) = \mathrm{cf}(\beta^+) = \omega_1$; so if $\mathcal{D}$ is the set of dense open subsets of $\mathbb{R}_{0,\beta}$ which lie in $V[G_\beta]$, working in $V[G_{\beta+2}]$ we may write $\mathcal{D} = \bigcup_{i<\omega_1} \mathcal{D}_i$ where $\mathcal{D}_i \in V[G_\beta]$ and $V[G_\beta] \models |\mathcal{D}_i| = \omega_1$.

We fix $D \in V[G_{\beta+2}]$ such that D is a club subset of β of order type ω_1 and $D \subseteq X \cap \beta$. Now we build a chain of conditions $c_i \in \mathbb{R}_{0,\beta}$ such that $\max(c_i) \in D$ and $c_{i+1} \in \bigcap \mathcal{D}_i$ for all i. Since $V[G_{\beta+2}]$ and $V[G_\beta]$ have the same ${}^\omega\beta$, there is no problem at limit stages. As usual we may now set $c = \bigcup_i c_i \cup \{\beta\}$ to finish. $\dashv$

We now define $\mathbb{R}_1$. Let E be the generic club subset of κ added by $\mathbb{R}_0$. Then $\mathbb{R}_1$ is the set of those closed bounded sets d such that $d \subseteq E \cap A'$, and $E \cap (\beta+1)$ is a β-master condition for every $\beta \in d$.

18.16 Remark. We remind the reader of the discussion of the "flat condition trick" in Remark 17.2. We will be using that trick heavily in what follows. In particular when we get to the main construction in Sect. 18.7 we will just define the set of flat conditions and leave all the details to the reader.

We define a suitable concept of flatness for conditions in the two-step iteration $\mathbb{R} =_{\mathrm{def}} \mathbb{R}_0 * \dot{\mathbb{R}}_1$. The flat conditions are pairs $(c, \check{d})$ where $c \in \mathbb{R}_0$, $c \Vdash \check{d} \in \mathbb{R}_1$ and $\max(c) = \max(d)$. We define $\mathbb{R}_\gamma = \mathbb{R} \cap V_\gamma[G_\gamma]$ for inaccessible $\gamma < \kappa$.

18.17 Lemma. *Forcing with $\mathbb{R}$ over $V[G_\kappa]$ adds no ω_1-sequences of ordinals, and the set of flat conditions is dense in $\mathbb{R}$.*

Proof. Working in V we fix a $\mathbb{P}_\kappa$-name $\dot{D}$ for an ω_1-sequence of dense subsets of $\mathbb{R}$, where we may as well assume that $\dot{D} \subseteq V_\kappa$. By routine arguments there is a club set $F \subseteq \kappa$ in V such that for every inaccessible $\gamma \in F$, $\dot{D} \cap V_\gamma$ is a $\mathbb{P}_\gamma$-name for a sequence of dense sets in $\mathbb{R}_\gamma$.

Now we choose $\gamma \in Y'$ such that $F \cap X' \cap \gamma \in W_\gamma$. By the definition of the preparation forcing there is a club set $e \subseteq \gamma$ in $V[G_{\gamma+1}]$ such that $\mathrm{ot}(e) = \omega_1$, $e \subseteq F \cap X'$, and for every $\beta \in \lim(e)$ the set $e \cap \beta$ meets every club subset of β lying in $V[G_\beta]$.

We will now work in $V[G_\kappa]$. Let r be an arbitrary condition in $\mathbb{R}$; we will show that r can be extended to a flat condition which lies in the intersection of the dense sets D_i for $i < \omega_1$, establishing both of our claims about $\mathbb{R}$. We will build a decreasing sequence of conditions $(c_i, \dot{d}_i)$ for $i \leq \omega_1$, such that

1. $r = (c_0, \dot{d}_0)$.
2. For every $i < \lambda$,
   (a) $(c_i, \dot{d}_i) \in \mathbb{R}_\gamma$.
   (b) The condition c_{i+1} determines $\dot{d}_i$, that is, $c_{i+1} \Vdash \dot{d}_i = \check{d}_i$ for some $d_i \in V[G_\kappa]$.
   (c) $(c_{i+1}, \dot{d}_{i+1}) \in D_i$.
   (d) The condition c_{i+1} forces that $\max(\dot{d}_{i+1}) > \max(c_i)$.
   (e) The ordinal $\beta_i =_{\mathrm{def}} \max(c_i)$ lies in the set e, and c_i is a β_i-master condition.
3. The sequence $\langle \beta_i : i \leq \omega_1 \rangle$ is increasing and continuous.
4. For every limit $\lambda \leq \omega_1$, $(c_\lambda, \dot{d}_\lambda)$ is a flat condition.

The successor steps in this construction are easy by an appeal to Lemmas 18.14 and 18.15, and the fact we reflected the density of the dense sets down to each β_j.

The subtle point is that for a limit ordinal $\lambda \leq \omega_1$ we are safe to set $\beta_\lambda = \sup_{i<\lambda} \beta_i$, $c_\lambda = \bigcup_{i<\lambda} c_i \cup \{\beta_\lambda\}$ and $\dot{d}_\lambda$ equal to the canonical name for $d_\lambda = \bigcup_{i<\lambda} d_i \cup \{\beta_\lambda\}$. The issue is to check that c_λ is a β_λ-master condition, so we set $\beta = \beta_\lambda$ and fix a $\mathbb{P}_\beta$ name $Z \subseteq V_\beta$ for a dense subset of $\mathbb{R}_{0,\beta}$. We then find a club set $C_Z \subseteq \beta$ such that if $\alpha \in C_Z$ is inaccessible then $Z \cap V_\alpha$ names a dense subset of $\mathbb{R}_{0,\alpha}$. Now the key point is that $\beta \in \lim(e)$ so $e \cap \beta$ meets C_Z, and we have $i < \lambda$ such that $\beta_i \in C_Z$. Let $\alpha = \beta_i$, then we are done since c_i is an α-master condition and it generates a filter which meets the dense set named by $Z \cap \mathbb{R}_{0,\alpha}$ (which is an initial segment of the dense set named by Z itself). ⊣

We may now define the notion of a β-master condition for $\mathbb{R}$ and prove analogues of Lemmas 18.15 and 18.17. To be a bit more explicit, we say that (c, d) is a *β-master condition* for $\mathbb{R}$ if and only if it is flat, $\max(c) = \max(d) = \beta$, and $\{(c \cap (\alpha+1), d \cap (\alpha+1)) : \alpha \in d\}$ is $\mathbb{R}_\beta$-generic over $V[G_\beta]$. We define T', X'', Y'', A'' from X' and Y' in just the same way that

T, X', Y', A' were defined from X and Y. Then the analogue of Lemma 18.15 says that if $\beta \in A''$ any condition in $\mathbb{R}_\beta$ extends to a β-master condition, and there is a similar generalization of Lemma 18.17.

We now sketch the main ideas in the argument that we can make the restriction of NS_{ω_2} to $\mathrm{Cof}(\omega)$ precipitous. Similar arguments apply to the restriction to $\mathrm{Cof}(\omega_1)$.

Applying the elementary embedding j_0 to the result of Lemma 18.15, we obtain the result that every condition in $\mathbb{R}_0$ can be extended in M_0 to a κ-master condition in $j_0(\mathbb{R}_0)$. Implicitly this defines an embedding of $\mathbb{P}_\kappa * \mathbb{R}_0$ into $j_0(\mathbb{P}_\kappa)$, and a strong master condition suitable for lifting the elementary embedding j_0 to the extension by $\mathbb{P}_\kappa * \mathbb{R}_0$. A similar argument applies to the iteration $\mathbb{R}_0 * \mathbb{R}_1$.

We now return to a point which we already mentioned in Sect. 18.3, namely, that can achieve the same kind of effect as in the construction of Sect. 17.2 by performing an iteration where every step is either like $\mathbb{R}_0$ or like $\mathbb{R}_1$. To fix ideas let H_0 be $\mathbb{R}_0$-generic over $V[G_\kappa]$, and let $a \in V[G_\kappa * H_0]$ be in the master condition ideal for j_0. Explicitly this means that it is forced that $\kappa \notin j_0^+(a)$ where j_0^+ is the lifting of j_0 onto $V[G_\kappa * H_0]$ described in the preceding paragraph. We will show how to add an ω-club set disjoint from a.

Let $\dot{a}$ be a $\mathbb{P}_\kappa * \dot{\mathbb{R}}_0$-name for a and let $(p, q) \in G_\kappa * H_0$ force that $\dot{a}$ is in the master condition ideal. That is to say, (p, q) forces that "it is forced that $\kappa \notin j_0^+(a)$". Analyzing the lifting construction and viewing p now as a condition in $j_0(\mathbb{P}_\kappa)$, p forces over M_0 that for every κ-master condition $Q \leq j_0(q)$, Q forces that $\kappa \notin j_0(\dot{a})$.

Now let C be the set of $\alpha < \kappa$ such that

1. $q \in \mathbb{R}_{0,\alpha}$.
2. p forces (over V for the forcing poset $\mathbb{P}_\kappa$) that for every $Q \leq q$ which is an α-master condition for $\mathbb{R}_0$, Q forces (over $V[G_\kappa]$ for the forcing poset $\mathbb{R}_0$) that $\alpha \notin \dot{a}$.

By Łoś's theorem we see that $C \in U_0$.

Define $\mathbb{R}_2$ to be similar to $\mathbb{R}_0$, adding a club contained in $C \cup D$ for some $D \in U_1$. One can do an analysis of $\mathbb{R}_0 * \mathbb{R}_1 * \mathbb{R}_2$ which is similar to the analyses of $\mathbb{R}_0$ and $\mathbb{R}_0 * \mathbb{R}_1$ given above. Let E_i be the club set added by $\mathbb{R}_i$. Then

- By the construction of $\mathbb{R}_1$, $E_0 \cap (\alpha + 1)$ is an α-master condition for every $\alpha \in E_1$.
- By the construction of $\mathbb{R}_2$, for every $\alpha \in E_2 \cap \mathrm{Cof}(\omega)$ we have $\alpha \in C$.
- So for every $\alpha \in E_1 \cap E_2 \cap \mathrm{Cof}(\omega)$, it follows from the definition of C that $\alpha \notin a$.

We have argued that in the extension by $\mathbb{R}_0 * \mathbb{R}_1 * \mathbb{R}_2$ there is an ω-club set disjoint from a. In the next subsection we will show how to iterate and achieve the same effect for every set which appears in some master condition ideal during the course of the iteration.

18.7. The Main Iteration

Recall from the last section that we defined $\mathbb{R}_0$ from a set $A = X \cup Y$ and then $\mathbb{R}_1$ from a set $A' \subseteq A$, where $\beta \in A'$ if $\beta \in A$ and there are stationarily many $\gamma < \beta$ such that $X \cap \gamma \in W_\gamma$. The poset $\mathbb{R}_0$ shot a club set E through A, and the poset $\mathbb{R}_1$ shot a club set through the set of points $\beta \in E \cap A'$ such that $E \cap \beta$ was $\mathbb{R}_{0,\beta}$-generic over $V[G_\beta]$. The main iteration, which we will only describe in outline, can be viewed as iterating this kind of construction many times for every possible A simultaneously. The main difficulty in defining the iteration is that when we have iterated ν times and have obtained an iteration $\mathbb{Q}_\nu$, we need to define a suitable notion of *β-master condition for* $\mathbb{Q}_\nu$; this requires choosing a filtration of $\mathbb{Q}_\nu$, and the filtrations for different values of ν must fit together nicely.

The main iteration is defined from some parameters $\langle A_\nu, i_\nu, C_\nu : \nu < \kappa^+\rangle$, which are chosen in V. They must satisfy a long list of technical conditions, most of which we are omitting. In particular

1. A_ν is the union of sets of inaccessibles $X_\nu \subseteq \kappa \setminus B$ and $Y_\nu \subseteq B$, with $X_\nu \in U_0$ and $Y_\nu \in U_1$.

2. Every set of inaccessibles $X \subseteq \kappa \setminus B$ with $X \in U_0$ is enumerated as X_ν for some successor ν, and similarly every set of inaccessibles $Y \subseteq B$ with $Y \in U_1$ is enumerated as Y_ν for some successor ν.

3. i_ν is a surjection from κ to ν, which is also injective for $\nu \geq \kappa$. Note that for any normal measure on κ, the map which takes $\beta < \kappa$ to the order-type of $i_\nu``\beta$ represents ν in the ultrapower.

4. C_ν is club in κ.

5. If $\kappa \leq \nu_1 < \nu_2$, $\beta \in C_{\nu_2}$ and $\nu_1 \in i_{\nu_2}``\beta$, then $\beta \in C_{\nu_1}$.

We define $X_{\nu,\beta} = i_\nu``\beta$ for $\beta < \kappa$, so that the $X_{\nu,\beta}$'s form a filtration of ν.

We define by recursion posets $\mathbb{Q}_\nu$ for $\nu < \kappa^+$, and for each $\mathbb{Q}_\nu$ also a filtration in which $\mathbb{Q}_\nu$ is written as the union of subsets $\mathbb{Q}_{\nu,\beta}$ for $\beta < \kappa$.

18.18 Remark. Once again the remarks about the "flat condition trick" in Remark 17.2 are somewhat applicable. We are defining a sequence of posets, whose conditions are comprised of closed bounded sets from the ground model, and claiming that they can be considered as an iteration. However in this instance it would be hard to write down a genuine iteration and then identify our conditions as a dense subset. To give a complete account of the proof we would have to check that the sequence of posets $\mathbb{Q}_\nu$ can be considered as an iteration, but this is only one of many details that we are omitting.

Conditions in $\mathbb{Q}_\nu$ are sequences of the form $q = \langle q_\alpha : \alpha \in X_{\nu,\beta} \rangle$ where (omitting one condition for the moment)

I. $\beta \in C_\nu$ (we will denote this ordinal β by β_q in what follows).

II. For successor α in the support of q, $q_\alpha \in \mathrm{CU}(\kappa, A_\alpha)$.

III. For limit α in the support of q, $q_\alpha \in \mathrm{CU}(\kappa, A_\alpha \cap C_\alpha)$.

IV. For limit α in the support of q, for every $\eta \in q_\alpha$,

   (a) $\eta \leq \beta_q$.

   (b) $X_{\alpha,\eta} \subseteq X_{\nu,\beta_q}$.

   (c) $\eta \in q_\tau$ for every $\tau \in X_{\alpha,\eta}$.

To qualify as a member of $\mathbb{Q}_\nu$ a sequence q as above must satisfy a fifth property (property V), whose description we defer until we have made a few definitions.

Once we have defined $\mathbb{Q}_\nu$, we define $\mathbb{Q}_{\nu,\beta}$ for $\beta < \kappa$ to be the set of those $p \in \mathbb{Q}_\nu$ such that

1. $p \in V[G_\beta]$.

2. $\beta_p < \beta$.

3. For every τ in the support X_{ν,β_p} of p, p_τ is bounded in β.

If $q \in \mathbb{Q}_\nu$, α is a limit ordinal in the support X_{ν,β_q} of q and $\beta \in q_\alpha$ then we define $q\restriction(\alpha, \beta) = \langle q_\tau \cap (\beta + 1) : \tau \in X_{\alpha,\beta} \rangle$. Notice that by the conditions we imposed on q we have that the support $X_{\alpha,\beta}$ of $q\restriction(\alpha, \beta)$ is contained in the support X_{ν,β_q} of q; also $\beta \in q_\tau$ for all $\tau \in X_{\alpha,\beta}$.

The intuition here is that $q\restriction(\alpha, \beta)$ is of the right general shape to be a β-*master condition* for $\mathbb{Q}_\alpha$. To be a bit more formal we say that r is a β-master condition for $\mathbb{Q}_\alpha$ if

1. The support of r is $X_{\alpha,\beta}$.

2. For every $\tau \in X_{\alpha,\beta}$, $\beta = \max(r_\tau)$.

3. The set of conditions $p \in \mathbb{Q}_\alpha\restriction\beta$ such that p_τ is an initial segment of $r_\tau \cap \beta$ for all τ is a $V[G_\beta]$-generic filter on $\mathbb{Q}_\alpha\restriction\beta$.

Now we can complete the description of $\mathbb{Q}_\nu$. Intuitively the following condition says that at limit stages we are shooting clubs through certain sets of “generic points”.

V. For every limit α in the support X_{ν,β_q} of q and every $\beta \in q_\alpha$, $q\restriction(\alpha, \beta)$ is a β-master condition for $\mathbb{Q}_\alpha$.

If $p, q \in \mathbb{Q}_\nu$ then $p \leq_\nu q$ iff $\beta_p \geq \beta_q$ and p_α end-extends q_α for all $\alpha \in X_{\nu,\beta_q}$.

The key lemmas are proved by similar means to those used in the last section.

18.19 Lemma. *For $\nu < \mu < \kappa^+$, $\mathbb{Q}_\nu$ is a complete subordering of $\mathbb{Q}_\mu$. Defining $\mathbb{Q}_{\kappa^+} = \bigcup_\nu \mathbb{Q}_\nu$, $\mathbb{Q}_{\kappa^+}$ has the κ^+-c.c.*

The following lemma is the technical heart of the whole construction. The proof (which we omit) is by a very intricate double induction on the pairs (μ, β) with $\beta \in A_\mu \cap C_\mu$, ordered lexicographically.

18.20 Lemma. *If ν is limit, $\alpha \in A_\nu \cap C_\nu$, $p \in \mathbb{Q}_{\nu,\alpha}$ then there exists a condition $q = \langle q_\tau : \tau \in X_{\nu,\alpha} \rangle \leq_\nu p$ in $V[G_{\alpha+2}]$ such that q is an α-master condition for $\mathbb{Q}_\nu$.*

The following is an easy corollary:

18.21 Lemma. *Let $\nu < \kappa^+$ be limit and let $\alpha \in A_\nu \cap C_\nu$. Forcing over $V[G_\alpha]$ with $\mathbb{Q}_{\nu,\alpha}$ adds no ω_1-sequence of ordinals.*

Let $j_i : V \longrightarrow M$ be the ultrapower by the normal measure U_i, and observe that since $V \models {}^\kappa M \subseteq M$ and $\mathbb{P}_\kappa$, $V[G_\kappa] \models {}^\kappa M_i[G_\kappa] \subseteq M_i[G_\kappa]$. Observe also that by normality $\kappa \in j(A_\nu \cap C_\nu)$ for all limit $\nu < \kappa^+$. Accordingly we see that

18.22 Lemma. *For every limit $\nu < \kappa^+$, in $M_i[G_{\kappa+1}]$ there is a condition $q \in \mathbb{Q}_{j(\nu)}$ such that $q = \langle q_\tau : \tau \in j``\nu \rangle$, $q$ induces a $j(\mathbb{Q})_{\nu,\kappa}$-generic filter over $V[G_\kappa]$, and $\max(q_\tau) = \kappa$ for every $\tau \in j``\nu$.*

Each condition in $\mathbb{Q}_\nu$ is an object of size less than κ. It follows easily that

18.23 Lemma. *For every limit $\nu < \kappa^+$ and every $\alpha \in A_\nu \cap C_\nu$, there is an isomorphism between $\mathbb{Q}_{\nu,\alpha}$ and $j(\mathbb{Q})_{\nu,\alpha}$ in $M_i[G_\kappa]$.*

18.24 Lemma. *There exists an isomorphism between $\mathbb{Q}_\nu$ and $j(\mathbb{Q})_{\nu,\kappa}$ in $M_i[G_\kappa]$.*

Putting these various pieces of information together, we get

18.25 Lemma. *For every limit $\nu < \kappa^+$, there is a $\mathbb{Q}_\nu$-generic filter over $V[G_\kappa]$ in $M_i[G_{\kappa+1}]$, which is induced by a condition as in Lemma 18.22.*

18.8. Precipitousness of the Non-Stationary Ideal

We are now in precisely the situation of Lemma 17.3, so we have produced two precipitous ideals I_0 and I_1, where I_a concentrates on points of cofinality ω_a. It remains to be seen that these are in fact restrictions of the non-stationary ideal. We will show that the ideal I_0 induced by the construction with j_0 is the ω-nonstationary ideal, the argument for I_1 is exactly the same. We worked through a simple case of the argument at the end of Sect. 18.6, the idea here is very similar.

Let H be generic over $V[G_\kappa]$ for $\mathbb{Q}_{\kappa^+}$. We work in $V[G_\kappa * H]$. We denote by $H \restriction \nu$ the $\mathbb{Q}_\nu$-generic object induced by H. Let t_j be the club set added by H at stage j.

Since I_0 is a normal ideal concentrating on points of cofinality ω, I_0 must contain the ω-nonstationary ideal. The other direction is trickier, since we did not explicitly shoot ω-club sets through every I_0-large set.

18.26 Claim. *I_0 is contained in the ω-nonstationary ideal.*

Proof. Suppose that a is in I_0. Unwrapping the definition, this means that at some stage ν we have that $a \in V[G_\kappa * H_\nu]$ and it is forced that $\kappa \notin j_{0,\nu}(a)$ where $j_{0,\nu}$ is the lifting of j_0 to $V[G_\kappa * H_\nu]$.

We now fix $\dot{a}$ a $\mathbb{P}_\kappa * \mathbb{Q}_\nu$-name for a and a condition $(p, q) \in G_\kappa * H_\nu$ forcing (over M_0 for $\mathbb{P}_\kappa * \mathbb{Q}_\nu$) that "it is forced (over $M_0[\dot{G}_\kappa][\dot{H}_\nu]$ by the forcing poset $(j_{0,\nu}(\mathbb{P}_\kappa)/\dot{G}_\kappa * \dot{H}_\nu) * j_{0,\nu}(\mathbb{Q}_\nu)/\dot{m}_\nu$, where m_ν is the master condition) that $\kappa \notin j_{0,\nu}(\dot{a})$". Regarding p as a condition in $j_0(\mathbb{P}_\kappa)$, p forces (over M_0 for $j_0(\mathbb{P}_\kappa)$) that for every κ-master condition $Q \leq j_0(q)$ for $j_0(\mathbb{Q})_\nu$, Q forces (over $M_0[\dot{G}_{j_0(\kappa)}]$ for $j_0(\mathbb{Q})_\nu$) that $\kappa \notin j_0(\dot{a})$.

Now we apply Łoś's theorem to see that $R \in U_0$, where R is the set of α such that $q \in \mathbb{Q}_{\nu,\alpha}$ and p forces (over V for $\mathbb{P}_\kappa$) that for every $Q \leq q$ with Q an α-master condition for $\mathbb{Q}_\nu$, Q forces (over $V[\dot{G}_\kappa]$ for $\mathbb{Q}_\nu$) that $\alpha \notin \dot{a}$.

Let $\eta > \nu$ be some limit stage. The construction of the forcing poset implies that for all sufficiently large $\alpha \in t_\eta$, there is a condition $Q \leq q$ in H which is an α-master condition for $\mathbb{Q}_\nu$. So for all sufficiently large $\alpha \in t_\eta \cap R$, $\alpha \notin a$.

In the construction we enumerated R as $X_{\bar{\eta}}$ for some $\bar{\eta}$. By definition $A_{\bar{\eta}} = X_{\bar{\eta}} \cup Y_{\bar{\eta}}$, and in $V[G_\kappa]$ the preparation forcing arranged that all points of $X_{\bar{\eta}}$ have cofinality ω while all points of $Y_{\bar{\eta}}$ have cofinality ω_1. At stage $\bar{\eta}$ in the main iteration we added a club set $t_{\bar{\eta}} \subseteq A_{\bar{\eta}}$, so $t_{\bar{\eta}} \cap \mathrm{Cof}(\omega) \subseteq R$.

Combining these results, all sufficiently large $\alpha \in t_\eta \cap t_{\bar{\eta}} \cap \mathrm{Cof}(\omega)$ fail to be in a. We conclude that a is ω-nonstationary in $V[G_\kappa * H]$, as required. $\dashv$

18.9. Successors of Larger Cardinals

Gitik [25, 26] has also obtained rather similar equi-consistency results for regular cardinals $\kappa > \omega_2$. The idea is broadly the same, but the preparation forcing is an iteration of Prikry-style forcing with Easton supports followed by an iteration of Cohen forcing (for κ inaccessible) or a Lévy collapse (for κ a successor cardinal). The main iteration is essentially the same.

We content ourselves with quoting some of the main results. When stating the lower bounds we assume throughout that there is no inner model with a cardinal λ such that $o(\lambda) = \lambda^{++}$, and we let K be the Mitchell core model for sequences of measures and $\mathcal{F}$ its measure sequence. Let $\vec{U}$ be a coherent sequence of measures. An ordinal α is an (ω, δ) *repeat point over* κ if and only if $\mathrm{cf}(\alpha) = \omega$ and for every $A \in \bigcap\{U(\kappa, \zeta) : \alpha \leq \zeta < \alpha + \delta\}$ there are unboundedly many $\gamma < \alpha$ such that $A \in \bigcap\{U(\kappa, \zeta') : \gamma \leq \zeta' < \gamma + \delta\}$.

The result for successors of regular cardinals greater than ω_1 is exact.

18.27 Theorem (Gitik [26]). *Let $\lambda = \mathrm{cf}(\lambda) < \kappa$ and suppose that* GCH *holds and there is a measure sequence with an $(\omega, \lambda + 1)$-repeat point over κ. Then there is a generic extension in which* GCH *holds, cardinals up to and including λ are preserved, $\kappa = \lambda^+$ and NS_κ is precipitous.*

18.28 Theorem (Gitik [25]). *Suppose that $\mu = \mathrm{cf}(\mu) > \omega_1$,* GCH *holds and NS_κ is precipitous where $\kappa = \mu^+$. Then in K there is an $(\omega, \mu + 1)$-repeat point over κ.*

Interestingly enough, the proof uses only the precipitousness of the restrictions of NS_κ to cofinality ω and cofinality μ. When κ is inaccessible the strength of "NS_κ is inaccessible" is bounded from above by an $(\omega, \kappa + 1)$-repeat and from below by an $(\omega, {<}\kappa)$-repeat.

19. More on Iterated Club Shooting

In this section we give sketches of two more theorems obtained by iterated club shooting. The first theorem is due to Jech and Woodin [40] and shows that it is consistent for $\mathrm{NS}_\kappa \restriction \mathrm{Reg}$ to be a κ^+-saturated ideal. The second is due to Magidor [55] and shows that it is consistent for every stationary subset of $\omega_2 \cap \mathrm{Cof}(\omega)$ to reflect at almost every point of $\omega_2 \cap \mathrm{Cof}(\omega_1)$. Apart from their intrinsic interest we have included them because they illustrate some new ideas: the theorem by Jech and Woodin involves embedding one iteration in another "universal" iteration, while the theorem by Magidor gives another example of shooting clubs to make a natural filter (defined in this case via stationary reflection) become the club filter.

As some motivation for Theorem 19.1 we sketch a proof that if κ is weakly compact then $\mathrm{NS}_\kappa \restriction \mathrm{Reg}$ is not κ^+-saturated. We start by recalling a classical result of Solovay: if κ is a regular uncountable cardinal and $S \subseteq \kappa$ is stationary then $T = \{\alpha \in S : S \cap \alpha \text{ is non-stationary in } \alpha\}$ is stationary (given a club C look at the first place where $\lim(C)$ meets S). In particular $T \cap \alpha$ is non-stationary in α for every $\alpha \in T$, in what follows we refer to stationary sets which reflect at no point of themselves as *thin.*

We now consider an ordering on stationary subsets of inaccessible cardinals investigated by Jech [38]. Given an inaccessible cardinal κ and stationary subsets $S, T \subseteq \kappa$ we write $S < T$ when $S \cap \alpha$ is stationary for almost every $\alpha \in T$ (modulo the club filter). It is easy to check that $<$ is well-founded, and by the result of Solovay from the last paragraph $<$ is irreflexive. If $S < T$ with S and T both thin, then clearly $S \cap T$ is non-stationary.

Assume now that κ is weakly compact. We will produce a $<$-increasing sequence $\langle S_\alpha : \alpha < \kappa^+ \rangle$ of thin stationary sets of regular cardinals. Let $S_0 =$

$\kappa \cap \text{Reg}$. At stage α fix a surjection f from κ to α, and use Π^1_1-indescribability to show that

$$S = \{\delta : \forall \gamma < \delta \ S_{f(\gamma)} \cap \delta \text{ is stationary in } \delta\}$$

is stationary. Then choose S_α to be a thin stationary subset of this set S. If $\beta < \alpha$ then $S_\beta \cap \delta$ is stationary for all large $\delta \in S_\alpha$, so $S_\beta < S_\alpha$. Since the S_α for $\alpha < \kappa^+$ have pairwise non-stationary intersections, $\text{NS}_\kappa \restriction \text{Reg}$ is not κ^+-saturated.

The proof we just gave shows essentially that if κ is κ^+-Mahlo then $\text{NS}_\kappa \restriction \text{Reg}$ is not κ^+-saturated. Jech and Woodin showed [40] that for any $\alpha < \kappa^+$ we may have κ which is α-Mahlo with $\text{NS}_\kappa \restriction \text{Reg}$ κ^+-saturated, starting from a measurable cardinal of Mitchell order α. This is known [38] to be optimal.

19.1 Theorem. *Let κ be measurable and let* GCH *hold. Then in a suitable generic extension* $\text{NS}_\kappa \restriction \text{Reg}$ *is κ^+-saturated.*

Proof. Let δ be inaccessible and let $S \subseteq \text{Reg} \cap \delta$. We define a forcing poset $\text{CU}_{\text{Reg}}(\delta, S) = \text{CU}(\delta, (\text{Sing} \cap \delta) \cup S)$; to be more explicit conditions are closed bounded subsets c of δ such that $c \cap \text{Reg} \subseteq S$, ordered by end-extension.

It is easy to see that for every $\gamma < \delta$ the set of conditions c with $\max(c) > \gamma$ is dense and γ-closed, so that $\text{CU}_{\text{Reg}}(\delta, S)$ forces that almost every regular cardinal is in S while adding no $<\delta$-sequences.

We now describe a kind of "universal" iteration of this forcing. To be more precise we define by recursion $\mathbb{Q}_\alpha$ for $\alpha \leq \delta^+$ and $\mathbb{Q}_\alpha$-names $\dot{S}_\alpha$ for $\alpha < \delta^+$ so that

1. $f \in \mathbb{Q}_\alpha$ if and only if
   (a) f is a partial function on α.
   (b) $\text{dom}(f)$ has size less than δ, and $f(\beta)$ is a closed bounded subset of δ for all $\beta \in \text{dom}(f)$.
   (c) For all $\alpha \in \text{dom}(f)$, $f \restriction \alpha \Vdash_{\mathbb{Q}_\alpha} f(\alpha) \cap \text{Reg} \subseteq \dot{S}_\alpha$.
2. For conditions $f, g \in \mathbb{Q}_\alpha$, $f \leq g$ if and only if $\text{dom}(g) \subseteq \text{dom}(f)$ and $f(\beta)$ end-extends $g(\beta)$ for all $\beta \in \text{dom}(g)$.
3. (Universality) Every $\mathbb{Q}_{\delta^+}$-name for a subset of δ is equivalent to $\dot{S}_\alpha$ for unboundedly many $\alpha < \delta^+$.

For every α, $\mathbb{Q}_\alpha$ is δ^+-c.c by an easy Δ-system argument. Also for all γ and α the set of $f \in \mathbb{Q}_\alpha$ such that $\max(f(\beta)) > \gamma$ for all $\beta \in \text{dom}(f)$ is dense and γ-closed. The GCH assumption and the δ^+-c.c make it possible to satisfy universality.

19.2 Remark. We are cheating slightly, in the sense that we should really verify that $\mathbb{Q}_\alpha$ is equivalent to an iteration of club-shooting forcing. See the remarks on the "flat condition trick" in Sect. 17.

19.3 Lemma. *Let $\mathbb{Q}^*_{\delta^+}$ be built in a similar way from a sequence of names $\dot{S}^*_\alpha$ satisfying clauses 1 and 2 above. Then there is a complete embedding of $\mathbb{Q}^*_{\delta^+}$ into $\mathbb{Q}_{\delta^+}$.*

Sketch of Proof. This is almost immediate if we use the flat conditions trick to regard $\mathbb{Q}_{\delta^+}$ and $\mathbb{Q}^*_{\delta^+}$ as dense sets in iterations of club shooting forcing. We may also proceed quite explicitly by constructing for each α a complete embedding i_α of $\mathbb{Q}_\alpha$ into $\mathbb{Q}^*_{\beta_\alpha}$ for a suitable $\alpha < \delta^+$. At successor stages we use i_α to identify the $\mathbb{Q}^*_\alpha$-name $\dot{S}^*_\alpha$ with a $\mathbb{Q}_{\beta_\alpha}$-name, use universality to find $\gamma > \beta_\alpha$ such that this name is $\dot{S}_\gamma$, and then set $\beta_{\alpha+1} = \gamma + 1$ and extend to $i_{\alpha+1} : \mathbb{Q}^*_{\alpha+1} \to \mathbb{Q}_{\gamma+1}$ in the obvious way; at limits we just take a suitable limit of the embeddings i_α and check that everything works. ⊣

We are now ready to build the model. We will do a reverse Easton iteration of length $\kappa + 1$. For $\alpha < \kappa$ we let $\dot{\mathbb{Q}}_\alpha = \{0\}$ unless α is inaccessible, in which case we let $\dot{\mathbb{Q}}_\alpha$ name some universal iteration as above for α.

We fix some normal measure U and let $j : V \longrightarrow M$ be the associated ultrapower map. Let $\dot{\mathbb{Q}}$ be the member of M represented by $\langle \mathbb{Q}_\alpha : \alpha < \kappa \rangle$. Since ${}^\kappa M[G_\kappa] \subseteq M[G_\kappa]$, it is routine to check that $\mathbb{Q}$ is a universal iteration in $V[G_\kappa]$; we let $\dot{S}_j$ be the set which is used at stage j.

The last step $\mathbb{Q}_\kappa$ in our iteration will be a certain sub-iteration of $\mathbb{Q}$. The idea is to build a submodel $V[G * g_0]$ of $V[G * g]$ (where g is $\mathbb{Q}$-generic) and an embedding j which is defined in $V[G * g]$ and has domain $V[G * g_0]$, in such a way that if $S \in V[G * g_0]$ then $\Vdash \kappa \in j(S)$ if and only if S contains a club. A slightly subtle point is that as the construction proceeds we can anticipate in $V[G_\kappa]$ which of the names $\dot{S}_i$ are naming sets S of this type, and pick out the sub-iteration $\mathbb{Q}_\kappa$ so that we shoot a club through each one.

By the usual arguments $\mathbb{P}_\kappa * \mathbb{Q}$ is an initial segment of $j(\mathbb{P}_\kappa)$. If $G_\kappa * g$ is $\mathbb{P}_\kappa * \mathbb{Q}$-generic then as usual we may build in $V[G_\kappa * g]$ a $M[G_\kappa * g]$-generic filter H for the factor iteration $j(\mathbb{P}_\kappa)/G * g$, and then extend to get $j : V[G_\kappa] \longrightarrow M[G_\kappa * g * H]$.

Working in $V[G_\kappa]$, we construct an increasing sequence $\langle \alpha_i : i < \kappa^+ \rangle$ of ordinals, subiterations $\mathbb{Q}^*_i$ of $\mathbb{Q}$ and names for conditions $r_i \in j(\mathbb{Q}^*_i)$ as follows:

1. $\mathbb{Q}^*_i$ is the subiteration of $\mathbb{Q}$ which adds a club subset $C_j \subseteq \kappa$ with $C_j \cap \mathrm{Reg} \subseteq S_{\alpha_j}$ for each $j < i$.

2. r_i is a $j(\mathbb{P}_\kappa)$-name for a condition in $j(\mathbb{Q}^*_i)$ which is a strong master condition for j and the $\mathbb{Q}^*_i$-generic object g_i.

3. α_i is chosen least so that S_{α_i} is a $\mathbb{Q}^*_i$-name and
$$\Vdash_{(j(\mathbb{P}_\kappa)/(\mathbb{P}_\kappa * \mathbb{Q}^*_i)) * (j(\mathbb{Q}^*_i)/r_i)} \kappa \in j(S_{\alpha_i}).$$

4. The domain of r_i is $j``i$, and if $\langle C_k : k < i \rangle$ is the sequence of club sets added by $\mathbb{Q}^*_i$ then $r(j(k)) = C_k \cup \{\kappa\}$.

The construction is very similar to that of Sect. 17.2 and we omit all details.

Let $\mathbb{Q}_\kappa = \mathbb{Q}^*_{\kappa^+}$ and let g_0 be $\mathbb{Q}_\kappa$-generic over $V[G_\kappa]$. By forcing over $V[G_\kappa * g_0]$ with $\mathbb{Q}/g_0$ we may obtain g which is $\mathbb{Q}$-generic over $V[G]$, and working in $V[G * g]$ we may lift to get $j : V[G] \longrightarrow M[G * g * H]$ as above. Using Magidor's method from Sect. 13 and the sequence of partial strong master conditions r_i, we may build in $V[G*g]$ an $M[G*g*H]$-generic filter I on $j(\mathbb{Q}_\kappa)$ with $j``g_0 \subseteq I$ and then lift to get $j : V[G*g_0] \longrightarrow M[G*g*H*I]$.

The construction guarantees that for any $T \in V[G*g_0]$ with $T \subseteq \mathrm{Reg} \cap \kappa$, T is non-stationary if and only if $\Vdash_{\mathbb{Q}/g_0} \kappa \notin j(T)$. Since $\mathbb{Q}/g_0$ has the κ^+-c.c. it follows by Lemma 14.5 that $\mathrm{NS}\restriction\mathrm{Reg}$ is κ^+-saturated. ⊣

We now sketch Magidor's result that consistently every stationary subset of $\omega_2 \cap \mathrm{Cof}(\omega)$ reflects almost everywhere in $\omega_2 \cap \mathrm{Cof}(\omega_1)$. The construction is quite similar to that for the precipitousness of NS_{ω_1}; we use this as the pretext for omitting many details.

19.4 Remark. Magidor used the optimal hypothesis of weak compactness; to simplify the exposition we use a measurable cardinal.

19.5 Theorem. *If κ is measurable, then in some generic extension $\kappa = \omega_2$ and for every $S \subseteq \omega_2 \cap \mathrm{Cof}(\omega)$ there is a club set C such that $S \cap \alpha$ is stationary for all $\alpha \in C \cap \mathrm{Cof}(\omega_1)$.*

Proof. Let $\mathbb{P} = \mathrm{Col}(\omega_1, {<}\kappa)$ and let $j : V \longrightarrow M$ be the ultrapower map arising from some normal measure U on κ. The idea of the proof is that after forcing with $\mathbb{P}$ every stationary set reflects stationarily often, and we may then shoot club sets to arrange the desired result. Of course new stationary sets will arise as we iterate so some care is required.

Much as in Sect. 17.2 we will work in $V[G]$ where G is $\mathbb{P}$-generic over V, and define $\mathbb{Q}$ which has the effect of iterating club-shooting with supports of size ω_1. We will be constructing certain strong master conditions as we go, whose existence will imply by Theorem 12.5 that no ω_1-sequences of ordinals are added to $V[G]$ by $\mathbb{Q}$. This is why we can set things up so that the conditions in $\mathbb{Q}$ are just functions in $V[G]$.

Explicitly in $V[G]$ we define by recursion $\mathbb{Q}_\alpha$ and $\mathbb{Q}_\alpha$-names $\dot{S}_\alpha$ such that

1. $\dot{S}_\alpha$ is a $\mathbb{Q}_\alpha$-name for a stationary subset of $\omega_2 \cap \mathrm{Cof}(\omega)$.
2. $f \in \mathbb{Q}_\alpha$ if and only if
   (a) f is a partial function on α with $|\mathrm{dom}(f)| \leq \omega_1$.
   (b) For all $\alpha \in \mathrm{dom}(f)$, $f(\alpha)$ is a closed bounded subset of ω_2 and $f\restriction\beta$ forces that
$$f(\beta) \subseteq \mathrm{Cof}(\omega) \cup \{\gamma \in \mathrm{Cof}(\omega_1) : S_\beta \cap \gamma \text{ is stationary in } \gamma\}.$$

Clearly $\mathbb{Q}_\alpha$ is countably closed and an easy Δ-system argument shows that it is κ^+-c.c.

19.6 Remark. Once again we are cheating slightly in the definition of the forcing by using only "flat" conditions. See the remarks on the "flat condition trick" in Sect. 17.

Exactly as in Sect. 17.2 we will build embeddings i_α of $\mathbb{P} * \mathbb{Q}_\alpha$ into $j(\mathbb{P})$, with the added wrinkle that we use Theorem 14.3 to ensure that the quotient forcing for prolonging a $\mathbb{P} * \mathbb{Q}_\alpha$-generic to a $j(\mathbb{P})$-generic is countably closed. As we see soon this is crucial for the success of the master condition argument.

At a stage $\alpha < \kappa^+$, if $\langle C_\beta : \beta < \alpha \rangle$ is the sequence of club sets added by $\mathbb{Q}_\alpha$, then we define r_α as follows: $\mathrm{dom}(r_\alpha) = j``\alpha$, and $r_\alpha(j(\beta)) = C_\beta \cup \{\kappa\}$ for every $\beta < \alpha$. We verify that r_α is a strong master condition just as in Sect. 17.2, the only sticky point is that since $\mathrm{cf}(\kappa) = \omega_1$ after forcing with $j(\mathbb{P})$ we need to know that r_β forces that $j(S_\beta) \cap \kappa$ is stationary. This is easy because (by virtue of being a master condition) r_β forces that $j(S_\beta) \cap \kappa = S_\beta$, and since we are in a countably closed extension of $V[G * g_\beta]$ we see that the stationarity of S_β is preserved.

It is now easy to see that forcing with $\mathbb{Q}_{\kappa^+}$ adds no ω_1-sequences of ordinals to $V[G]$, so that κ is preserved. By the usual book-keeping we may arrange that every $\mathbb{Q}_{\kappa^+}$-name for a stationary subset of $\kappa \cap \mathrm{Cof}(\omega)$ appears as S_α for some $\alpha < \kappa^+$. If H is $\mathbb{Q}_{\kappa^+}$-generic over $V[G]$ then $V[G * H]$ is as required. $\dashv$

20. More on Collapses

We have seen many applications of the Levy collapse. In this section we discuss two situations where the Levy collapse cannot be used, one involving master conditions and the other involving absorbing "large" forcing posets into a collapsing poset. We shall describe some more exotic collapsing posets which can sometimes be used in these situations, namely, the Silver collapse and Kunen's universal collapse. We then show how these can be applied by sketching Kunen's consistency proof [45] for an ω_2-saturated ideal on ω_1.

We have seen many situations where we are given $\mathbb{P} = \mathrm{Col}(\delta, {<}\kappa)$ and an elementary embedding j with critical point κ, and wish to lift j to the extension by $\mathbb{P}$. Here there is no master condition issue because $j \restriction \mathbb{P} = \mathrm{id}_{\mathbb{P}}$ and $\mathbb{P}$ is just an initial segment of $j(\mathbb{P})$.

But now consider the following situation: $k : M \longrightarrow N$ has critical point κ, $\mathbb{P} = \mathrm{Col}(\kappa, {<}\lambda)_M$, G is $\mathbb{P}$-generic over M and both G and $k \restriction \lambda$ are in N. Certainly we may form in N a partial function $Q = \bigcup k``G$, where $\mathrm{dom}(Q) = \kappa \times k``\lambda$; but if $\lambda \geq k(\kappa)$ then Q has the wrong shape to be a condition in $k(\mathbb{P})$.

To fix this we consider a cardinal collapsing poset due to Silver, which was first used by him in the consistency proof for Chang's Conjecture.

20.1 Definition. Let κ be inaccessible and let $\delta = \mathrm{cf}(\delta) < \kappa$. The *Silver collapse* $\mathbb{S}(\delta, {<}\kappa)$ is the set of those partial functions f on $\delta \times \kappa$ such that $\mathrm{dom}(f) = \alpha \times X$ for some $\alpha < \delta$ and some $X \in [\kappa]^\delta$, and $f(\beta, \gamma) < \gamma$ for all $\beta < \alpha$ and $\gamma \in X$. The ordering is extension.

It is easy to see that $\mathbb{S}(\delta, {<}\kappa)$ is δ-closed and κ-c.c.

Returning for a moment to the discussion preceding Definition 20.1, if we let $\mathbb{P} = \mathbb{S}(\kappa, {<}\lambda)$ where $\lambda = k(\kappa)$ then it *is* possible to build a strong master condition. We will use this shortly, but first we discuss another problem with the Levy collapse.

Suppose that $\mathbb{P} = \mathrm{Col}(\omega, {<}\kappa)$ and that $\mathbb{B}$ is a complete subalgebra of $\mathrm{ro}(\mathbb{P})$. Then as we saw in Theorem 14.2 we can embed $\mathbb{B} * \dot{\mathbb{C}}$ into $\mathbb{P}$ when $\dot{\mathbb{C}}$ names an algebra of size less than κ. However there is no guarantee that this is possible when $\dot{\mathbb{C}}$ has size κ, even if $\mathbb{C}$ is forced to have the κ-c.c.

Kunen [45] showed that it is possible to construct a poset with stronger universal properties. We sketch a version of his construction. Let κ be an inaccessible cardinal, and let U be a function which returns for each complete Boolean algebra $\mathbb{B}$ of size less than κ a $\mathbb{B}$-name $U(\mathbb{B})$ for a κ-Knaster poset of size κ. We aim to build a κ-c.c. poset $\mathbb{P}$ of size κ such that for every complete subalgebra $\mathbb{B}$ of $\mathrm{ro}(\mathbb{P})$ with size less than κ, the inclusion embedding of $\mathbb{B}$ into $\mathrm{ro}(\mathbb{P})$ extends to a complete embedding of $\mathbb{B} * \mathrm{ro}(U(\mathbb{B}))$ into $\mathrm{ro}(\mathbb{P})$.

To construct the universal collapse we build a finite support κ-c.c. iterated forcing poset $\mathbb{P}_\kappa$ of length and cardinality κ, where each step $\mathbb{P}_\alpha$ is κ-c.c. with cardinality κ. At stage α we choose by some book-keeping scheme some $\mathbb{B}_\alpha$ which is a complete subalgebra of $\mathrm{ro}(\mathbb{P}_\alpha)$ with $|\mathbb{B}_\alpha| < \kappa$. Given an $\mathbb{B}_\alpha$-generic filter g we may form in $V[g]$ the product $\mathbb{P}_\alpha/g \times U(\mathbb{B}_\alpha)$, which is κ-c.c. by Theorem 5.12. Back in V we see that $\mathbb{B}_\alpha * (\mathbb{P}_\alpha/\dot{g} \times U(\mathbb{B}_\alpha))$ is κ-c.c. and embeds both $\mathbb{P}_\alpha$ and $\mathbb{B}_\alpha * U(\mathbb{B}_\alpha)$, and choose $\mathbb{P}_{\alpha+1}$ accordingly. With appropriate book-keeping we may arrange that every small subalgebra of $\mathrm{ro}(\mathbb{P}_\kappa)$ has appeared as $\mathbb{B}_\alpha$ for some α, giving the desired universal property for $\mathbb{P}_\kappa$. Preservation of κ-c.c. is easy since we are iterating with finite support.

20.2 Remark. The construction of the universal collapse is an example of "iteration with amalgamation", a technique which is frequently used in forcing constructions to build saturated ideals. Note that in the construction we amalgamated $\mathbb{P}_\alpha$ and $U(\mathbb{B}_\alpha)$ over $\mathbb{B}_\alpha$. The point in applications will typically be that we can absorb an iteration $\mathbb{P} * \dot{\mathbb{Q}}$ into $j(\mathbb{P})$ in a context where $\mathbb{P} * \dot{\mathbb{Q}}$ is "large".

20.3 Remark. Laver showed that it is sometimes possible to build λ-closed collapsing posets with similar universal properties. Naturally one needs to be a little more careful about the chain condition.

We are now ready to sketch Kunen's consistency proof for an ω_2-saturated ideal on ω_1. More details will be found in Foreman's chapter in this Handbook.

20.4 Theorem. *Let κ be a huge cardinal with target λ. Then in some generic extension κ is ω_1, $\lambda = \omega_2$ and there is an ω_2-saturated ideal on ω_1.*

Proof. We fix an elementary embedding $j : V \longrightarrow M$ such that $\mathrm{crit}(j) = \kappa$, $j(\kappa) = \lambda$, and ${}^{\lambda}M \subseteq M$. We start by constructing as above a κ-c.c. poset $\mathbb{P}$

of size κ such that for every subalgebra $\mathbb{B}$ of $\mathrm{ro}(\mathbb{P})$ with $|\mathbb{B}| < \kappa$, the inclusion embedding extends to an embedding of $\mathbb{B} * \mathrm{ro}(\mathbb{S}(\omega_1^{V^{\mathbb{B}}}, {<}\kappa))$. For convenience we assume (as we clearly may) that $\mathbb{P} \subseteq V_\kappa$.

It is easy to see that after forcing with $\mathbb{P}$, κ is the new ω_1. Let G be generic for $\mathbb{P}$, let $\mathbb{Q} = \mathbb{S}(\kappa, {<}\lambda)_{V[G]}$ and let H be $\mathbb{Q}$-generic over $V[G]$.

We will show that there is a λ-saturated ideal on κ in $V[G * H]$. Working in M we fix an embedding of $\mathrm{ro}(\mathbb{P} * \mathbb{Q})$ into $\mathrm{ro}(j(\mathbb{P}))$ extending the identity embedding of $\mathrm{ro}(\mathbb{P})$. Since $V[G * H] \models {}^\lambda M[G * H] \subseteq M[G * H]$, we see that $j(\mathbb{P})/G * H$ is λ-c.c. in $V[G * H]$. Forcing with this poset over $V[G * H]$, we obtain an embedding $j^+ : V[G] \longrightarrow M[G * H * I]$ in $V[G * H * I]$. Since $\mathbb{Q}$ is a Silver collapse, and H and $j \restriction \lambda$ are both in M, we may construct a strong master condition $r = \bigcup j``H \in j(\mathbb{Q})$ and force with $j(\mathbb{Q})/r$ to obtain a compatible generic object J and an embedding $j^{++} : V[G * H] \longrightarrow M[G * H * I * J]$.

Unfortunately this is not quite enough because the $V[G * H]$-ultrafilter $U = \{X \in P(\kappa) \cap V[G * H] : \kappa \in j^{++}(X)\}$ lives in the extension by $j(\mathbb{P})/G * H * j(\mathbb{Q})/r$, which is not λ-c.c. in $V[G * H]$. To fix this we note that in $V[G * H * I]$ the $V[G * H]$-powerset of κ has size λ, and $j^+(\mathbb{Q})$ is λ-closed; so we may build a decreasing sequence $\langle r_i : i < \lambda \rangle$ with $r_0 = r$ deciding whether $\kappa \in j^{++}(X)$ for all $X \in P(\kappa) \cap V[G * H]$, and then let $U_0 = \{X : \exists i \; r_i \Vdash \kappa \in j^{++}(X)\}$. Then U_0 is a $V[G * H]$-ultrafilter which lives in $V[G * H * I]$, so that we may derive a λ-saturated ideal by Lemma 14.5. $\dashv$

20.5 Remark. A Woodin cardinal is all that is required to get the consistency of an ω_2-saturated ideal on ω_1. The argument given here was generalized by Laver to get saturated ideals on larger cardinals. Magidor [54] showed that the kind of argument given here can be done from an almost huge cardinal.

21. Limiting Results

In this section we sketch some results which put limits on the effects which we can achieve in reverse Easton constructions. We are not sure to whom the following result should be attributed; it has a family resemblance to some results by Kunen [45] on the question of whether an inaccessible cardinal λ can carry a λ-saturated ideal.

21.1 Theorem. *If $\mathbb{P} \times \mathbb{P}$ is κ-c.c. and $\mathbb{P}$ forces that κ is measurable then κ is measurable.*

Proof. Clearly κ is inaccessible in V. Let $\dot{U}$ name a normal measure and suppose that κ is not measurable in V. If A is a potential member of $\dot{U}$ then it can be split into two disjoint potential members of $\dot{U}$, otherwise we could read off a measure on κ in V. Using this we build a binary tree of height κ with root node κ such that the levels form increasingly fine partitions of κ into fewer than κ many pieces. At successor steps every node is partitioned by its two immediate successors, and if a node is a potential member of $\dot{U}$ then so are both of its immediate successors; at limit steps λ, every branch through the binary tree of height λ which has been constructed so far is continued by putting at level λ the intersection of the nodes on that branch.

Now let G be $\mathbb{P}$-generic and realize $\dot{U}$ as U_G; then there is a unique branch through the tree consisting of members of U_G. Choosing for each A on the branch a condition which forces the successor of A which is not in U_G into $\dot{U}$, we build an antichain of size κ in $\mathbb{P}$, contradicting our assumption that $\mathbb{P} \times \mathbb{P}$ has the κ-c.c. $\dashv$

We now sketch some results of Hamkins [33]. The key technical result is Theorem 21.3 which involves two notions of resemblance between inner models of ZFC.

21.2 Definition. Let M and N be inner models of ZFC with $M \subseteq N$. Let δ be a regular uncountable cardinal in N. Then

1. *δ-covering holds between M and N* if and only if for every set $A \subseteq \mathrm{On}$ such that $A \in N$ and $N \models |A| < \delta$, there exists a set $B \subseteq \mathrm{On}$ such that $B \in M$, $A \subseteq B$ and $M \models |B| < \delta$.

2. *δ-approximation holds between M and N* if and only if for every $A \subseteq \mathrm{On}$ with $A \in N$, if $A \cap a \in M$ for all $a \in M$ with $M \models |a| < \delta$, then $A \in M$.

21.3 Theorem. *Let V and $\bar{V}$ be inner models with $V \subseteq \bar{V}$. Let $j : \bar{V} \longrightarrow \bar{M}$ be a definable elementary embedding with* $\mathrm{crit}(j) = \kappa$, *and let $M = \bigcup j``V$ so that $j \restriction V$ is an elementary embedding from V to M.*

If there is a cardinal $\delta < \kappa$ regular in $\bar{V}$ such that $\bar{V} \models {}^{\delta}\bar{M} \subseteq \bar{M}$, and the δ-covering and δ-approximation properties hold between V and $\bar{V}$, then

1. *$M = \bar{M} \cap V$, in particular $V \models {}^{\delta}M \subseteq M$.*

2. *$j \restriction A \in V$ for all $A \in V$.*

Proof. Throughout the proof we work in $\bar{V}$. In particular all cardinalities are computed in $\bar{V}$ unless otherwise specified. By elementarity and the fact that $\delta < \kappa$, the δ-covering and δ-approximation properties hold between M and $\bar{M}$.

We claim that every set of ordinals A with $|A| < \delta$ is contained in a set of ordinals $B \in V \cap M$ such that $|B| \leq \delta$. To see this we build (starting with A) an increasing and continuous chain of length δ consisting of sets of size less than δ, with even successor elements in V and odd successor elements in M. If B is the union then by the approximation property $B \in V \cap M$.

Next we claim that for every set of ordinals A with $|A| < \delta$, $A \in V$ if and only if $A \in M$. To see this find a set $B \in V \cap M$ with $A \subseteq B$ and $\gamma = \mathrm{ot}(B) < \delta^+$. Since $\gamma < \kappa$ and κ is inaccessible in V, it follows from Proposition 2.9 that $P(\gamma) \cap M = P(\gamma) \cap V$.

Now we claim that $M = \bar{M} \cap V$. Let $A \in M$ where by Proposition 2.2 we may assume that A is a set of ordinals. Clearly $A \in \bar{M}$. Let $a \in V$ with $|a| < \delta$. Applying the preceding claim $a \in M$, hence $A \cap a \in M$, hence by another application of the preceding claim $A \cap a \in V$. By the approximation property $A \in V$. Conversely let $A \in \bar{M} \cap V$ be a set of ordinals; arguing just as before $A \cap a \in M$ for all $a \in M$ with $|a| < \delta$, so that $A \cap a \in M$.

To finish we show that $j \restriction A \in V$ for all sets of ordinals $A \in V$. By approximation it will suffice to show that $j \restriction a \in V$ for all $a \in V$ with $a \subseteq A$ and $|a| < \delta$. Since $\mathrm{ot}(a) < \kappa$ we see that $j``a = j(a) \in M \subseteq V$, and since $j \restriction a$ is the order-isomorphism between $a$ and $j``a$ we have $j \restriction a \in V$. $\dashv$

21.4 Corollary. *Under the hypotheses of Theorem 21.3, if $\bar{V}$ is a set-generic extension of V then $j \restriction V$ is definable in V. It is also easy to see that if j witnesses the λ-supercompactness or λ-strongness of κ in $\bar{V}$ then $j \restriction V$ will do the same in V.*

Of course the interest of Theorem 21.3 hinges on there being some examples of extensions with the covering and approximation properties. The following result [33] shows that many extensions by reverse Easton iterations have these properties.

21.5 Theorem. *Let δ be a cardinal. Let $\mathbb{P} * \dot{\mathbb{Q}}$ be a forcing iteration where $|\mathbb{P}| \leq \delta$, $\mathbb{P}$ is non-trivial and $\mathbb{P}$ forces that $\dot{\mathbb{Q}}$ is $(\delta+1)$-strategically closed. Then the δ^+-covering and δ^+-approximation properties hold between V and the extension by $\mathbb{P} * \dot{\mathbb{Q}}$.*

Proof. The covering is easy so we concentrate on the approximation. Let $G * H$ be a $\mathbb{P} * \dot{\mathbb{Q}}$-generic filter and let $S : \theta \to 2$ be such that $S \in V[G * H]$ and $S \restriction a \in V$ for all $a \in V$ with $|a| \leq \delta$. By induction we may assume that $S \restriction \lambda \in V$ for all $\lambda < \theta$. Let $\dot{S}$ name S.

If $\mathrm{cf}(\theta) \leq \delta$ then $S \in V[G]$, so without loss of generality $\dot{S}$ is a $\mathbb{P}$-name. Consider the tree T of potential proper initial segments of $\dot{S}$; it is easy to see that there are at most δ many sequences t such that both $t^\frown 0$ and $t^\frown 1$ are in T. So by specifying δ many bits in S we determine S, hence $S \in V$.

If $\mathrm{cf}(\theta) > \delta$ in V, we note that this remains true in $V[G * H]$. So since $|G| \leq \delta$, there is a condition $p \in G$ such that for all $i < \theta$ there is a condition $q \in H$ so that (p, q) determines $\dot{S} \restriction i$. We may thus find a condition $(p, \dot{q}_0) \in G * H$ forcing that $\dot{S} \notin \check{V}$ and that p has this property; so easily for all i and all $(p, \dot{q}_1) \leq (p, \dot{q}_0)$ there is a condition $(p, \dot{q}_2) \leq (p, \dot{q}_1)$ determining $\dot{S} \restriction i$.

Using the non-triviality of $\mathbb{P}$ we can find a function $h \in V[G] \setminus V$ such that $h : \beta \to 2$ for some $\beta \leq \delta$, where (by choosing β to be minimal) we may also assume that $h \restriction j \in V$ for all $j < \beta$. Using the strategic closure of $\dot{Q}$, the choice of p and the fact that $\dot{S}$ is forced to be new we build $\langle \dot{q}_t : t \in {}^{<\beta}2 \rangle$ and $\langle \dot{\beta}_t : t \in {}^{<\beta}2 \rangle$ such that

1. For each t, $\dot{q}_t$ is a $\mathbb{P}$-name for a condition in $\mathbb{Q}$, and $\dot{\beta}_t$ is a $\mathbb{P}$-name for an element of ${}^{<\theta}2 \cap V$.

2. The sequences $\langle \dot{q}_t : t \in {}^{<\beta}2 \rangle$ and $\langle \dot{\beta}_t : t \in {}^{<\beta}2 \rangle$ lie in V.

3. It is forced by p that for any branch x of the tree ${}^{<\beta}2 \cap V$, the sequence $\langle q_{x \restriction j} : j < \beta \rangle$ has a lower bound.

4. $(p, q_{t^\frown i})$ forces that $\beta_t^\frown i$ is an initial segment of S.

Now working in $V[G]$ we choose a lower bound q for $\langle q_{h \restriction j} : j < \beta \rangle$. If we force so that H contains q we obtain a situation in which h can be computed from a proper initial segment of S, contradiction! $\dashv$

As an example of these ideas in action we sketch an easy case of the *superdestructibility* theorem of Hamkins [32]. A supercompact cardinal κ is said to be *Laver indestructible* if it is supercompact in every extension by κ-directed closed forcing; we show in Sect. 24 that any supercompact cardinal can be made indestructible.

21.6 Corollary. *Let κ be supercompact and let $\mathbb{P} = \mathrm{Add}(\omega, 1)$. Then κ is not Laver indestructible after forcing with $\mathbb{P}$.*

Proof. Let g be $\mathbb{P}$-generic, and let $\mathbb{Q} = \mathrm{Add}(\kappa, 1)_{V[g]}$. Let G be $\mathbb{Q}$-generic over $V[g * G]$. we show that κ is not measurable in $V[g * G]$.

Let $\bar{V} = V[g*G]$ and suppose that $j : \bar{V} :\longrightarrow \bar{M}$ is the ultrapower by some normal measure in $\bar{V}$. By Theorems 21.5 and 21.3 we have $j \restriction V : V \longrightarrow M$ where $M \subseteq V$. Now easily $\bar{M} = M[g * j(G)]$, by the closure of ultrapowers $G \in \bar{M}$, and by the closure of $j(\mathbb{Q})$ we have $G \in M[g]$. This is impossible as $M \subseteq V$ and $G \notin V[g]$. $\dashv$

22. Termspace Forcing

In this section we introduce a very useful idea due to Laver, that of the *term forcing* or *termspace forcing*. The idea is roughly that given a two-step iteration $\mathbb{P} * \dot{\mathbb{Q}}$ we can add by forcing over V a sort of "universal generic object", from which given any G which is $\mathbb{P}$-generic over V we may compute in a uniform way an H which is $i_G(\dot{\mathbb{Q}})$-generic over $V[G]$.

Magidor [52] showed by iterated Prikry forcing that the least measurable cardinal can be strongly compact. In unpublished work Magidor [51] gave an alternative proof, using termspace forcing and an Easton iteration of the forcing from Example 6.5. We outline the proof here, a more detailed account is given in a joint paper by Apter and the author [4] which further exploits these ideas.

22.1 Definition. Let $\mathbb{P}$ be a notion of forcing and let $\dot{\mathbb{Q}}$ be a $\mathbb{P}$-name for a notion of forcing. Then $\mathrm{A}(\mathbb{P}, \dot{\mathbb{Q}})$ is the notion of forcing whose underlying set is the set of canonical $\mathbb{P}$-terms for members of $\dot{\mathbb{Q}}$, with the ordering being given by

$$\dot{\sigma} \leq_{\mathrm{A}(\mathbb{P},\dot{\mathbb{Q}})} \dot{\tau} \quad \iff \quad \Vdash_{\mathbb{P}} \dot{\sigma} \leq_{\dot{\mathbb{Q}}} \dot{\tau}.$$

22.2 Remark. Several notations for the termspace forcing are in use, for example $\mathbb{Q}^*$ and $\mathbb{Q}^{\mathbb{P}}$. We follow Foreman's paper [19] in using $\mathrm{A}(\mathbb{P}, \dot{\mathbb{Q}})$, emphasizing the importance of $\mathbb{P}$.

The following proposition is the key to the applications of term forcing.

22.3 Proposition. *Let G be $\mathbb{P}$-generic over V and let H be $\mathrm{A}(\mathbb{P}, \dot{\mathbb{Q}})$-generic over V. Define $I = \{i_G(\dot{\tau}) : \dot{\tau} \in H\}$. Then I is an $i_G(\dot{\mathbb{Q}})$-generic filter over $V[G]$.*

Proof. We begin by checking that I is a filter. If $\dot{\sigma}$ and $\dot{\tau}$ are in H then there is a term $\dot{\rho} \in H$ such that $\Vdash_{\mathbb{P}} \dot{\rho} \leq \dot{\sigma}, \dot{\tau}$. It follows that $i_G(\dot{\rho}) \leq i_G(\dot{\sigma}), i_G(\dot{\tau})$ so that I is a directed set.

If $i_G(\dot{\sigma}) \leq i_G(\dot{\tau})$ with $\dot{\sigma} \in H$ then we fix $p \in G$ such that $p \Vdash_F P\dot{\sigma} \leq \dot{\tau}$. Let $\dot{\rho}$ be a name which is interpreted as $\dot{\tau}$ if p is in the generic filter and as the trivial condition otherwise, so that $p \Vdash_F P\dot{\rho} = \dot{\tau}$ and $\Vdash_{\mathbb{P}} \dot{\sigma} \leq \dot{\rho}$. Then $\dot{\tau} \in H$ and so $i_G(\dot{\rho}) = i_G(\dot{\tau}) \in I$. It follows that I is upwards closed, and so is a filter.

Finally let $D = i_G(\dot{D})$ where $\dot{D}$ is forced to be a dense subset of $\dot{\mathbb{Q}}$. If $E = \{\dot{\sigma} : \Vdash_{\mathbb{P}} \dot{\sigma} \in \dot{D}\}$ then by the Maximum Principle E is a dense subset of $\mathrm{A}(\mathbb{P}, \dot{\mathbb{Q}})$. We find a term $\dot{\sigma} \in E \cap H$, and observe that $i_G(\dot{\sigma}) \in D \cap I$. It follows that I is $i_G(\dot{\mathbb{Q}})$-generic over $V[G]$ as required. $\dashv$

The next result is an easy application of the Maximum Principle.

22.4 Proposition. *If it is forced by $\mathbb{P}$ that $\dot{\mathbb{Q}}$ is κ-strategically closed then $\mathrm{A}(\mathbb{P}, \mathbb{Q})$ is κ-strategically closed.*

Foreman's paper "More saturated ideals" [19] contains a wealth of other structural results about $\mathrm{A}(\mathbb{P}, \dot{\mathbb{Q}})$. We quote some here.

22.5 Proposition. *Let $\mathbb{P}$ be a poset and $\dot{\mathbb{Q}}$ a $\mathbb{P}$-name for a poset.*

1. *If $\mathbb{P}$ is non-trivial and it is not forced that $\dot{\mathbb{Q}}$ is κ-c.c. then $\mathrm{A}(\mathbb{P}, \dot{\mathbb{Q}})$ is not 2^κ-c.c.*
2. *If κ is inaccessible, $\mathbb{P}$ is κ-c.c. and it is forced that $\mathbb{Q}$ is κ-c.c. then $\mathrm{A}(\mathbb{P}, \dot{\mathbb{Q}})$ is κ-c.c.*
3. *If $\langle P_i, \dot{\mathbb{Q}}_i \rangle$ is a forcing iteration with supports in an ideal I, then the limit of the iteration can be completely embedded in the product of the termspace posets $\mathrm{A}(\mathbb{P}_i, \dot{\mathbb{Q}}_i)$ taken with supports in I.*

We will now use termspace forcing to give a proof (due to Magidor) that the least measurable cardinal can be strongly compact. The idea of the proof is to shoot a non-reflecting stationary set through each measurable cardinal below a supercompact cardinal κ, and then argue that the strong compactness of κ is preserved and no new measurable cardinals are created.

To get an embedding witnessing strong compactness we use the following easy result.

22.6 Proposition. *Let $j : V \longrightarrow M$ be an embedding with critical point κ, and let $\lambda \geq \kappa$ be such that $j``\lambda \in M$ and $\lambda < j(\kappa)$. Let $k : M \longrightarrow N$ be any embedding with* $\mathrm{crit}(k) \geq \kappa$ *and let $X = k(j``\lambda)$. Then* $\mathrm{crit}(k \circ j) = \kappa$, *$X \in N$, $(k \circ j)``\lambda \subseteq X$ and $N \models \mathrm{ot}(X) < k \circ j(\kappa)$.*

In particular, if $k \circ j$ is definable then $k \circ j$ witnesses that κ is λ-strongly compact. If $V[G]$ is a generic extension of V, and $i : V[G] \longrightarrow M[H]$ is an embedding definable in $V[G]$ extending $k \circ j$, then i witnesses that κ is λ-strongly compact in $V[G]$.

We now fix a ground model in which GCH holds, κ is supercompact, and there is no measurable cardinal greater than κ. This last hypothesis is a technical one which simplifies some later arguments; it entails no loss of generality because we can truncate the universe at the least measurable greater than κ if such a cardinal exists. Notice that since κ is supercompact there are unboundedly many measurable cardinals less than κ.

Let A be the set of $\alpha < \kappa$ which are measurable in V. We will define an iteration $\mathbb{P}_\kappa$ of length κ with Easton support, in which $\dot{\mathbb{Q}}_\alpha$ names the trivial forcing unless $\alpha \in A$. If $\alpha \in A$ then $\dot{\mathbb{Q}}_\alpha$ names the poset from Example 6.5 to add a non-reflecting stationary set to α, as defined in $V[G_\alpha]$. It is clear that this iteration will destroy the measurability of every α in A. We will show that no new measurable cardinals are created.

Let G_κ be $\mathbb{P}_\kappa$-generic over V and suppose for a contradiction that $\alpha < \kappa$ and α is measurable in $V[G_\kappa]$. By construction $\alpha \notin A$, and if γ is the least measurable greater than α then arguments as in Lemma 11.2 show that $V[G_\kappa]$ is an extension of $V[G_\alpha]$ by γ-strategically closed forcing. In particular α is measurable in $V[G_\alpha]$, from which it easily follows that α must be a Mahlo cardinal in V. Since α is Mahlo, by Proposition 7.13 $\mathbb{P}_\alpha$ is α-Knaster. It follows that $\mathbb{P}_\alpha \times \mathbb{P}_\alpha$ is α-c.c. By Theorem 21.1 α must be measurable in V, which is a contradiction as $\alpha \notin A$.

To finish, we show that κ is still strongly compact in $V[G_\kappa]$. We fix a regular cardinal $\lambda > \kappa$ and let $j : V \longrightarrow M$ be the ultrapower of V by a supercompactness measure on $P_\kappa\lambda$. The argument of Example 4.8 shows that $V \models |j(\kappa)| = \lambda^+$.

By GCH $\lambda \geq 2^\kappa$ and so κ is measurable in M, and we may find a measure U on κ such that $U \in M$ and U is minimal in the Mitchell ordering [58]; we let $k : M \longrightarrow N$ be the ultrapower of M by U, so that in particular $N \models$ "κ is not measurable". It is easy to see that $\kappa \notin k \circ j(A)$.

Consider the iteration $j(\mathbb{P}_\kappa)$, which is an iteration defined in M in which a non-reflecting stationary set is added to each $\alpha \in j(A)$. The cardinal κ is measurable in M, so $\kappa \in j(A)$ and $j(\mathbb{P})_\kappa$ adds a set at κ. There are no measurable cardinals above κ in V and $P(\lambda) \subseteq M$, so if γ is the least M-measurable cardinal greater than κ then $\gamma > \lambda$.

Notice that since we are aiming to show that κ is strongly compact (and so a fortiori measurable) in $V[G_\kappa]$ we cannot hope to find a $\mathbb{Q}_\kappa$-generic filter over $M[G_\kappa]$ in $V[G_\kappa]$. It is at this point that we use termspace forcing.

Working in M we may factor $j(\mathbb{P}_\kappa)$ as $\mathbb{P}_\kappa * \dot{\mathbb{Q}} * \dot{\mathbb{R}}$, where $\dot{\mathbb{Q}}$ adds a non-reflecting stationary subset of κ. Working in $M[G_\kappa]$ we get a factorization of the rest of the iteration as $\mathbb{Q} * \dot{\mathbb{R}}$.

22.7 Lemma. *$\dot{\mathbb{R}}$ is $j(\kappa)$-c.c. and γ-strategically closed in $M[G_\kappa]^{\mathbb{Q}}$.*

Proof. It follows from Proposition 7.13 that $\mathbb{R}$ is $j(\kappa)$-c.c. The closure follows from Proposition 7.12. ⊣

22.8 Lemma. *In $M[G_\kappa]$, $\mathrm{A}(\mathbb{Q}, \dot{\mathbb{R}})$ is $j(\kappa)$-c.c. and λ^+-strategically closed.*

Proof. We work in the model $M[G_\kappa]$. The strategic closure follows by Proposition 22.4.

For the chain condition, assume for a contradiction that $\langle \dot{r}_\alpha : \alpha < j(\kappa)\rangle$ is an antichain in $\mathrm{A}(\mathbb{Q}, \dot{\mathbb{R}})$. If $\alpha < \beta$ then $\dot{r}_\alpha$ and $\dot{r}_\beta$ are incompatible, which means that there is no term for a condition forced to refine both of them; by the Maximum Principle this is equivalent to saying that $\dot{r}_\alpha$ and $\dot{r}_\beta$ are not forced to be compatible in $\dot{\mathbb{R}}$.

For $\alpha < \beta$ we choose $q_{\alpha\beta} \in \mathbb{Q}$ such that $q_{\alpha\beta} \Vdash^{M[G_\kappa]}_{\mathbb{Q}} \dot{r}_\alpha \perp \dot{r}_\beta$. $j(\kappa)$ is measurable in M and so by the Levy-Solovay Theorem [50] $j(\kappa)$ is measurable in $M[G_\kappa]$. By Rowbottom's theorem we may therefore find a fixed $q \in \mathbb{Q}$ and $X \subseteq j(\kappa)$ unbounded such that $q_{\alpha\beta} = q$ for all $\alpha, \beta \in X$. q forces that $\{\dot{r}_\alpha : \alpha \in X\}$ is an antichain of size $j(\kappa)$ in $\mathbb{R}$, contradicting Lemma 22.7. So $\mathrm{A}(\mathbb{Q}, \dot{\mathbb{R}})$ is $j(\kappa)$-c.c. in $M[G_\kappa]$. ⊣

Appealing to Proposition 8.1 we may now build $H \in V[G_\kappa]$ which is $\mathrm{A}(\mathbb{Q}, \dot{\mathbb{R}})$-generic over $M[G_\kappa]$.

We now consider the embedding k and the iteration $k(\mathbb{P}_\kappa)$. Since κ is not a point at which this iteration adds a set, we may argue exactly as in Sect. 11 to build $g \in M[G_\kappa]$ such that $G_\kappa * g$ is $k(\mathbb{P}_\kappa)$-generic over $N[G_\kappa]$, and may lift to get $k : M[G_\kappa] \longrightarrow N[G_\kappa * g]$. By similar arguments we may also build $h \in M[G_\kappa]$ which is $k(\mathbb{Q})$-generic over $N[G_\kappa * g]$.

By Proposition 9.3 this lifted embedding has width $\leq \kappa$, so by Proposition 15.1 we may transfer H along k to get H^+ which is $k(\mathrm{A}(\mathbb{Q}, \dot{\mathbb{R}}))$-generic over $N[G_\kappa * g]$. If we let $I = \{i_h(\dot{\sigma}) : \dot{\sigma} \in H^+\}$ then I is $k(\mathbb{R})$-generic over $N[G_\kappa * g * h]$.

Putting everything together we get $G_\kappa * g * h * I$ which is $k \circ j(\mathbb{P}_\kappa)$-generic over N, and then as in Sect. 11 we may lift $k \circ j$ to get a map from $V[G_\kappa]$ to $N[G_\kappa * g * H * I]$. This map is definable by Proposition 9.4, and so by Proposition 22.6 we see that κ is λ-strongly compact in $V[G_\kappa]$.

23. More on Termspace Forcing and Collapsing

In this section we show that the termspace forcing ideas of Sect. 22 may be used to analyze iterations. We also introduce yet another cardinal collapsing poset, this time one due to Mitchell [57].

We give an outline of Mitchell's model [57] in which there are no ω_2-Aronszajn trees. Our treatment of this material owes much to Abraham [2]. For simplicity we build the model using a measurable cardinal. Mitchell actually used a weakly compact cardinal and this is known to be optimal [57].

Throughout this section we assume that κ is measurable. We recall the easy proof that κ has the tree property; let T be a κ-tree, let $j : V \longrightarrow M$ have critical point κ, then $j(T)\restriction\kappa$ is isomorphic to T and any point on level κ of $j(T)$ gives us a branch through T.

We start by making an instructive false start. Let $\mathbb{P} = \mathrm{Col}(\omega_1, {<}\kappa)$ and as in Theorem 10.5 factor $j(\mathbb{P})$ as $\mathbb{P} \times \mathbb{Q}$. If $G * H$ is $j(\mathbb{P})$-generic then we may build as usual an embedding $j : V[G] \longrightarrow M[G * H]$. If $T \in V[G]$ is a κ-tree then as above $j(T)\restriction\kappa$ is isomorphic to κ, so by choosing any point on level κ we may determine a branch b of T.

It is well-known that CH implies there is a special ω_2-Aronszajn tree, and since $V[G]$ is a model of CH and $\kappa = \omega_2$ there is a κ-Aronszajn tree in $V[G]$. This is not a contradiction to the argument of the previous paragraph; the point is that $j(T)$ only exists in $M[G*H]$, so the branch b that we constructed is a member of $V[G * H]$ but not in general a member of $V[G]$.

To put the problem more abstractly, we need to create a situation in which a generic embedding with critical point ω_2 is added by a poset which does not add any branches through any ω_2-Aronszajn tree. By the remarks made above we also need the continuum to be at least ω_2.

Before the main argument we need a technical fact about trees.

23.1 Lemma. *Let $2^\omega = \omega_2$ and let T be an ω_2-Aronszajn tree. Let $\mathbb{S}$ and $\mathbb{T}$ be forcing posets such that*

1. *$\mathbb{T}$ is countably closed forcing and collapses ω_2.*
2. *$\mathbb{S}$ is ω_1-Knaster in $V^{\mathbb{T}}$.*

Then forcing with $\mathbb{S} \times \mathbb{T}$ does not add a cofinal branch of T.

Proof. Let $G_{\mathbb{S}} \times G_{\mathbb{T}}$ be $\mathbb{S} \times \mathbb{T}$-generic. We claim first that T has no cofinal branch in $V[G_{\mathbb{T}}]$. To see this suppose $p \in \mathbb{T}$ forces that $\dot{b}$ is a cofinal branch, and use the fact that $b \notin V$ to build a binary tree $\langle p_s : s \in {}^{<\omega}2\rangle$ and increasing $\langle \alpha_n : n < \omega\rangle$ such that $p_0 = p$ and for each n the conditions $\{p_s : s \in {}^n2\}$ decide where $\dot{b}$ meets level α_n in 2^n different ways. Then let $\alpha = \sup_n \alpha_n$ and observe that level α must have at least 2^ω elements, contradicting our assumptions that T is an ω_2-tree and $2^\omega = \omega_2$.

Choose in $V[G_{\mathbb{T}}]$ a sequence β_j for $j < \omega_1$ which is cofinal in ω_2^V. Suppose for a contradiction that some $q \in \mathbb{S}$ forces over $V[G_{\mathbb{T}}]$ that $\dot{c}$ is cofinal in T, and then choose for each j a condition $q_j \leq q$ deciding where the branch $\dot{c}$ meets level β_j. In $V[G_{\mathbb{T}}]$ a subfamily of size ω_1 of $\{q_j\}$ must be pairwise compatible, but this implies that there is a cofinal branch in $V[G_{\mathbb{T}}]$. ⊣

23.2 Theorem. *Let κ be measurable. Then in some ω_1-preserving generic extension, $2^\omega = \omega_2 = \kappa$ and κ has the tree property.*

Proof. Let

$$\mathbb{P} = \mathrm{Add}(\omega, \kappa), \qquad \mathbb{P}_\alpha = \mathrm{Add}(\omega, \alpha), \qquad \mathbb{R}_\alpha = \mathrm{Add}(\omega_1, 1)_{V^{\mathbb{P}_\alpha}}.$$

We define $\mathbb{Q}$ as follows; a condition is a pair (p, f) where $p \in \mathbb{P}$, f is a partial function on κ with countable support, and $f(\alpha)$ is a $\mathbb{P}_\alpha$-name for a condition in $\mathbb{R}_\alpha$. $(p_2, f_2) \leq (p_1, f_1)$ iff $p_2 \leq p_1$ in $\mathbb{P}$, $\mathrm{supp}(f_1) \subseteq \mathrm{supp}(f_2)$, and $p_2 \restriction (\omega \times \alpha) \Vdash f_2(\alpha) \leq f_1(\alpha)$ for all $\alpha \in \mathrm{supp}(f_1)$.

It is easy to see that $\mathbb{Q}$ is κ-c.c. Since adding a Cohen subset of ω_1 collapses the continuum to ω_1, it is also easy to see that $\mathbb{Q}$ collapses every α between ω_1 and κ. It may not be immediately clear that $\mathbb{Q}$ preserves ω_1. This will fall out from the product analysis of $\mathbb{Q}$ which we give below.

For any inaccessible $\delta < \kappa$ we may truncate the forcing at δ in the obvious way, to get $\mathbb{Q} \restriction \delta$ which forces $2^\omega = \omega_2 = \delta$. We note that if G_δ is $\mathbb{Q} \restriction \delta$-generic then $\mathbb{Q}/G_\delta$ is very similar to $\mathbb{Q}$.

To analyze $\mathbb{Q}$ we define a variation of the sort of termspace forcing we studied in Sect. 22. Let $\mathbb{R}$ be the set of g such that g is a function on κ with countable support, and $g(\alpha)$ is $\mathbb{P}_\alpha$-name for an element of $\mathbb{R}_\alpha$. Order $\mathbb{R}$ by setting $r_2 \leq r_1$ if and only if $\mathrm{supp}(r_1) \subseteq \mathrm{supp}(r_2)$, and $\Vdash r_2(\alpha) \leq r_1(\alpha)$ for all $\alpha \in \mathrm{supp}(r_1)$. It is routine to check that the identity is a projection map from $\mathbb{P} \times \mathbb{R}$ to $\mathbb{Q}$. It follows that if G is $\mathbb{Q}$-generic with projection g on the first coordinate then we may view $V[G]$ as a submodel of $V[g \times h]$ where $g \times h$ is $\mathbb{P} \times \mathbb{R}$-generic. By Easton's Lemma all countable sequences from $V[G]$ are in $V[g]$, so in particular ω_1 is preserved.

We now finish the argument by showing there are no ω_2-Aronszajn trees in $V[G]$. To do this we start by noting that (morally speaking) $\mathbb{Q} \subseteq V_\kappa$, so that we may regard $\mathbb{Q}$ as an initial segment of $j(\mathbb{Q})$ where $j : V \longrightarrow M$ is the ultrapower by some normal measure on κ. As usual we may then build a generic embedding $j : V[G] \longrightarrow M[G * H]$ where H is $j(\mathbb{Q})/G$-generic.

Suppose for contradiction that $T \in V[G]$ is a κ-tree. By the usual chain condition arguments $T \in M[G]$, and since $j(T) \in M[G * H]$ we see that forcing over $M[G]$ with $j(\mathbb{Q})/G$ has added a branch to the κ-Aronszajn tree T. We observe that in $M[G]$ we have that $2^\omega = \kappa = \omega_2$. It is not hard to see that $j(\mathbb{Q})/G$ is susceptible exactly to the same kind of product analysis as $\mathbb{Q}$ or $j(\mathbb{Q})$, so that by Lemma 23.1 it is not possible for $j(\mathbb{Q})/G$ to add a branch through T. This concludes the proof. $\dashv$

23.3 Remark. Abraham [2] showed that it is consistent for both ω_2 and ω_3 to simultaneously have the tree property. Foreman and the author [11] built a model where ω_n has the tree property for $1 < n < \omega$. Magidor and Shelah [56] showed that $\omega_{\omega+1}$ may have the tree property. Foreman and the author [11] constructed a model where ω_ω is strong limit and $\omega_{\omega+2}$ has the tree property.

Mitchell also showed that if κ is Mahlo and we force with the poset $\mathbb{Q}$ of Theorem 23.2, then in the extension there is no special ω_2-Aronszajn tree. By work of Jensen there is a special ω_2-Aronszajn tree if and only if the weak square principle $\square^*_{\omega_1}$ holds, so in Mitchell's model $\square^*_{\omega_1}$ fails. We sketch a proof (due to Mitchell) that an even weaker version of square fails in the model; for more on the ideal $I[\lambda]$ see [10].

Recall that $I[\omega_2]$ is the (possibly improper) ideal of $A \subseteq \omega_2$ such that there exist $\langle x_\alpha : \alpha < \omega_2 \rangle$ and a club set $C \subseteq \omega_2$, such that for every $\alpha \in C \cap A \cap \mathrm{Cof}(\omega_1)$ there is a set $d \subseteq \alpha$ with d club in α, $\mathrm{ot}(d) = \omega_1$, and every proper initial segment of d appearing as x_β for some $\beta < \alpha$. It is easy to see that if $\square^*_{\omega_1}$ then $\omega_2 \in I[\omega_2]$.

23.4 Theorem. *If κ is Mahlo and we force with $\mathbb{Q}$ as in Theorem 23.2 then in the extension $\omega_2 \notin I[\omega_2]$.*

Proof. Let G be $\mathbb{Q}$-generic. An argument similar to that of Theorem 21.5 shows that if $\alpha < \kappa$ is inaccessible and $X \in P(\alpha) \cap V[G]$ with $X \cap \beta \in V[G_\alpha]$ for all $\beta < \alpha$, then $X \in V[G_\alpha]$. Suppose for contradiction that $\langle x_\alpha : \alpha < \kappa \rangle$ and C witness in $V[G]$ that $\omega_2 \notin I[\omega_2]$.

Then since β is Mahlo and $\mathbb{Q}$ is β-c.c. there is a V-inaccessible cardinal $\beta \in C$ such that $\langle x_\alpha : \alpha < \beta \rangle \in V[G_\beta]$, and so there is in $V[G]$ a club subset $d \subseteq \beta$ such that $\mathrm{ot}(d) = \omega_1$ and every initial segment of d is in $V[G_\beta]$. By the remarks of the last paragraph we have $d \in V[G_\beta]$, which is impossible because $\beta = \omega_2^{V[G_\beta]}$. ⊣

24. Iterations with Prediction

In this section we look at some theorems proved using the powerful reflection properties of supercompact cardinals. Both of the results we prove depend on the following theorem of Laver [49] which may be viewed as a kind of diamond principle.

24.1 Theorem. *Let κ be a supercompact cardinal. Then there exists a function $f : \kappa \to V_\kappa$ such that for all $\lambda \geq \kappa$ and all $x \in H_{\lambda^+}$ there is a supercompactness measure U on $P_\kappa \lambda$ such that $j_U(f)(\kappa) = x$.*

Proof. Fix a well-ordering $\prec$ of V_κ. We define $f(\alpha)$ by recursion on α. We set $f(\alpha) = 0$ unless there exists a cardinal λ with $\alpha \leq \lambda < \kappa$ and $x \in H_{\lambda^+}$, such that for no supercompactness measure U on $P_\alpha \lambda$ does $j_U(f \restriction \alpha)(\alpha) = x$. In this case we choose the minimal such λ and then the $\prec$-minimal such $x \in H_{\lambda^+}$, and set $f(\alpha) = x$.

Suppose for a contradiction that there exist $\lambda \geq \kappa$ and $x \in H_{\lambda^+}$ such that for no supercompactness measure U on $P_\kappa \lambda$ does $j_U(f)(\kappa) = x$. Let $\rho = 2^{2^\lambda}$, let W be a supercompactness measure on $P_\kappa \rho$, and let the ultrapower by W be $j : V \longrightarrow N = \mathrm{Ult}(V, W)$. Observe that $H_{\lambda^+} \subseteq (V_{j(\kappa)})_N$.

All supercompactness measures on $P_\kappa\lambda$ and all functions from $P_\kappa\lambda$ to V_κ lie in N. It follows easily that

$$N \models \text{"for no supercompactness measure } U \text{ on } P_\kappa\lambda \text{ does } j_U(f)(\kappa) = x\text{"}.$$

Let μ be minimal such that for some $y \in H_{\mu^+}$ there is no supercompactness measure U on $P_\kappa\mu$ with $j_U(f)(\kappa) = y$; clearly $\mu \leq \lambda$, so in particular $y \in (V_{j(\kappa)})_N$. Let y be $j(\prec)$-minimal such $y \in H_{\mu^+}$. By elementarity, the definition of f, and the agreement between V and N we may conclude that $j(f)(\kappa) = y$.

Now we define $U = \{X \subseteq P_\kappa\mu : j``\mu \in j(X)\}$ so that $U$ is a supercompactness measure on $P_\kappa\mu$. Let $i : V \longrightarrow M = \mathrm{Ult}(V, U)$ be the ultrapower map, and observe that by Proposition 3.2 there is an elementary embedding $k : M \longrightarrow N$ given by $k : [F]_U = j(F)(j``\mu)$. We also have that $k \circ i = j$.

We now analyze the embedding k. The definition of k gives easily that $j``V \subseteq \mathrm{ran}(k)$ and $j``\mu \in \mathrm{ran}(k)$. If $X \subseteq \mu$ then

$$X = \{\mathrm{ot}(\gamma \cap j``\mu) : \gamma \in j``\mu \cap j(X)\},$$

so that $X \in \mathrm{ran}(k)$. It follows that $H_{\mu^+} \subseteq \mathrm{ran}(k)$ and so in particular $k \restriction H_{\mu^+} = \mathrm{id}_{H_{\mu^+}}$.

Since $y \in H_{\mu^+}$, $k(y) = y$. We also know that $k(\kappa) = \kappa$ and $k \circ i = j$, so $k(i(f)(\kappa)) = j(f)(\kappa) = y$. Contradiction!

It follows that for all $\lambda \geq \kappa$ and all $x \in H_{\lambda^+}$ there is a supercompactness measure U on $P_\kappa\lambda$ with $j_U(f)(\kappa) = x$. $\dashv$

24.2 Remark. Using extenders in the place of supercompactness measures it is possible to prove a similar result for strong cardinals. See Gitik and Shelah's paper [29] for this result and some applications.

In this section we prove the consistency of the Proper Forcing Axiom (defined below) and of the statement "the supercompactness of κ is indestructible under κ-directed closed forcing". These statements have in common that they involve a universal quantification over a proper class; they will both be proved by doing a set forcing and using some reflection arguments.

In each of the two consistency proofs we will begin with a supercompact cardinal κ. We fix a function f as in Theorem 24.1 (a *Laver function*) and use this function as a guide in building an iteration of length κ which anticipates a proper class of possibilities for what may happen at stage κ.

The details of the constructions are of course somewhat different, but they each involve taking a generic object for some forcing we may do stage κ, and copying it via some supercompactness embedding j to a filter on the image of that forcing under j. In the argument for the Proper Forcing Axiom the existence of this filter is reflected back to give a witness for the truth of the axiom, while in the indestructibility theorem the filter is used to construct a strong master condition and lift the embedding j.

We now give Baumgartner's consistency proof [15] for the Proper Forcing Axiom. We begin with a brief review of proper forcing.

24.3 Definition. Let θ be regular with $\mathbb{P} \in H_\theta$. Let $<_\theta$ be a well-ordering of H_θ and let $\mathbb{P} \in N \prec (H_\theta, \in, <_\theta)$ where N is countable. $p \in \mathbb{P}$ is $(N, \mathbb{P})$-*generic* if and only if for every maximal antichain A of $\mathbb{P}$ with $A \in N$, $A \cap N$ is predense below p.

24.4 Remark. This notion is closely related to the ideas about lifting embeddings from Proposition 9.1. Let $\bar{N}$ be the Mostowski collapse of N, let $\pi : \bar{N} \longrightarrow N$ be the inverse of the Mostowski collapse and let $\bar{x}$ be the collapse of x for $x \in N$.

Then it is easy to see that p is $(N, \mathbb{P})$-generic if and only if p forces that $\bar{G} =_{\text{def}} \{\bar{p} : p \in G \cap N\}$ is $\bar{\mathbb{P}}$-generic over $\bar{N}$; that is, p is a master condition for π in the sense of Definition 12.1. The definition of $\bar{G}$ implies that $\pi``\bar{G} \subseteq G$. Therefore if p is $(N, \mathbb{P})$-generic and $p \in G$ for some G which is $\mathbb{P}$-generic over V, then π can be lifted to a map $\pi^+ : \bar{N}[\bar{G}] \longrightarrow N[G]$ which is the inverse of the Mostowski collapse map for $N[G]$.

We note that for example in the Martin's Maximum paper [21] $(N, \mathbb{P})$-generic conditions are referred to as "$(N, \mathbb{P})$-master conditions". We have chosen to follow the conventions of Shelah's book on proper forcing [64].

24.5 Remark. In the study of proper forcing it is often interesting to look at conditions which are *strongly* $(N, \mathbb{P})$-*generic*, where (adopting the notation of the last remark) a condition $p \in \mathbb{P}$ is strongly $(N, \mathbb{P})$-generic if and only if $g_p =_{\text{def}} \{\bar{q} : q \in N \cap \mathbb{P}, p \leq q\}$ is $\bar{\mathbb{P}}$-generic over $\bar{N}$. Such a condition is precisely a strong master condition for g_p and π in the sense of Definition 12.2.

24.6 Definition. $\mathbb{P}$ is *proper* if and only if for all large θ, all countable N with $\mathbb{P} \in N \prec (H_\theta, \in, <_\theta)$, and all $p \in \mathbb{P} \cap N$ there exists a condition $q \leq p$ which is $(N, \mathbb{P})$-generic.

See Abraham's chapter in this Handbook for an exposition of proper forcing. The only fact about properness we will need is that a countable support iteration of proper forcing is proper.

24.7 Definition. The Proper Forcing Axiom (PFA) is the statement: for every proper $\mathbb{P}$ and every sequence $\langle D_\alpha : \alpha < \omega_1 \rangle$ of dense subsets of $\mathbb{P}$ there exists a filter F on $\mathbb{P}$ such that $F \cap D_\alpha \neq \emptyset$ for all $\alpha < \omega_1$.

Before we prove the consistency of PFA we make a few remarks.

24.8 Remark. It would be hopeless to ask to meet ω_2 sets in the statement of PFA, because we could then apply the axiom to the proper forcing poset $\text{Col}(\omega_1, \omega_2)$ and produce a surjection from ω_1 onto ω_2.

24.9 Remark. The axiom PFA is known [66] to have a very high consistency strength. One way of seeing this is that by work of Todorčević [67] PFA implies the failure of $\square_\kappa$ for κ singular, which implies in turn that the weak covering lemma fails over any reasonable core model.

24.10 Remark. In the consistency proof for MA_{ω_1} [6] the first step is to observe that we only need to deal with forcing posets of size ω_1. The point is that the property of being c.c.c. is inherited by any completely embedded subposet, and so to deal with ω_1 dense subsets of an arbitrary $\mathbb{P}$ we may as well work in some subposet Q of size ω_1 in which all those dense sets remain dense.

This is not so for proper forcing. Notice that by Example 6.6 we may force $\square_\kappa$ without changing H_{κ^+}, so that PFA cannot in general be "localised" to a statement in H_{κ^+} for any κ.

24.11 Theorem. *Let κ be supercompact. Then there is a forcing iteration of length κ such that in $V^{\mathbb{P}_\kappa}$*

1. PFA *holds.*
2. $2^\omega = \kappa = \omega_2$.

Proof. Let $f : \kappa \longrightarrow V_\kappa$ be a function as in Theorem 24.1. The poset $\mathbb{P}_\kappa$ will be an inductively defined iteration of length κ with countable support, with each $\mathbb{Q}_\alpha$ forced to be proper in $V^{\mathbb{P}_\alpha}$. The name $\dot{\mathbb{Q}}_\alpha$ will name the trivial forcing unless $f(\alpha)$ is a $\mathbb{P}_\alpha$-name for a proper forcing poset, in which case $\mathbb{Q}_\alpha = f(\alpha)$.

By the Properness Iteration Theorem [1] the poset $\mathbb{P}_\kappa$ is proper, so preserves ω_1. By Proposition 7.13 $\mathbb{P}_\kappa$ is κ-c.c. with cardinality κ, so in particular κ is preserved.

Now let $\dot{Q}$ be the standard $\mathbb{P}_\kappa$-name for $\mathrm{Add}(\omega, 1)$. Let $\lambda = 2^{2^\kappa}$ and find a supercompactness measure U on $P_\kappa\lambda$ such that $j_U(f)(\kappa) = \dot{Q}$. Arguing as in Lemma 11.6, $j_U(\mathbb{P}_\kappa)$ is an iteration of length $j(\kappa)$ in $\mathrm{Ult}(V, U)$ whose first κ stages are exactly those of $\mathbb{P}_\kappa$.

$\mathrm{Ult}(V, U)$ agrees that $\dot{Q}$ is a $\mathbb{P}_\kappa$-name for $\mathrm{Add}(\omega, 1)$, so by the usual reflection argument there are unboundedly many $\alpha < \kappa$ such that $f(\alpha)$ is a $\mathbb{P}_\alpha$-name for $\mathrm{Add}(\omega, 1)$. Since $\mathrm{Add}(\omega, 1)$ is proper, there are unboundedly many α where $\dot{\mathbb{Q}}_\alpha$ is a $\mathbb{P}_\alpha$-name for $\mathrm{Add}(\omega, 1)$, so that in the course of the iteration $\mathbb{P}_\kappa$ we add κ many subsets of ω. A very similar argument shows that $\mathbb{Q}_\alpha = \mathrm{Col}(\omega_1, \alpha)_{V^{\mathbb{P}_\alpha}}$ for many $\alpha < \kappa$, so that $2^\omega = \kappa = \omega_2$ in $V^{\mathbb{P}_\kappa}$.

To finish the proof we need to show that PFA holds in $V^{\mathbb{P}_\kappa}$. Let G be $\mathbb{P}_\kappa$-generic over V, and let $\mathbb{Q} = i_G(\dot{\mathbb{Q}})$ where $\dot{\mathbb{Q}}$ is a $\mathbb{P}_\kappa$-name for a proper forcing poset. Find a cardinal λ such that $\dot{\mathbb{Q}} \in H_\lambda$, let $\mu = 2^{2^\lambda}$, and let U be a supercompactness measure on $P_\kappa\mu$ such that $j_U(f)(\kappa) = \dot{\mathbb{Q}}$. Let $j : V \longrightarrow M = \mathrm{Ult}(V, U)$ be the ultrapower map.

By Proposition 8.4 we see that $V[G] \models {}^\mu M[G] \subseteq M[G]$, so in particular $\Vdash^M_{\mathbb{P}_\kappa}$ "$\dot{\mathbb{Q}}$ is proper". It follows that in the iteration $j(\mathbb{P}_\kappa)$, the forcing which is used at stage κ is precisely $\dot{\mathbb{Q}}$.

Now let g be $\mathbb{Q}$-generic over $V[G]$. Working in $M^{\mathbb{P}_\kappa * \dot{\mathbb{Q}}}$ let $\dot{\mathbb{R}}$ name the canonical forcing such that $j(\mathbb{P}_\kappa) \simeq \mathbb{P}_\kappa * \dot{\mathbb{Q}} * \dot{\mathbb{R}}$, and let $\mathbb{R} = i_{G*g}(\dot{\mathbb{R}})$. Let H be $\mathbb{R}$-generic over $V[G * g]$.

Since $\mathbb{P}_\kappa$ is an iteration with countable support, the support of every condition in G is bounded in κ. This implies that $j``G \subseteq G * g * H$, and so we may lift j to get a map $j_G : V[G] \longrightarrow M[G * g * H]$.

Now let $\vec{D} = \langle D_\alpha : \alpha < \omega_1 \rangle$ be an ω_1-sequence of dense subsets of $\mathbb{Q}$, with $\vec{D} \in V[G]$. Since g is generic over $V[G]$, $g \cap D_\alpha \neq \emptyset$ for each α. By the choice of μ and U we know that $j \restriction \dot{\mathbb{Q}} \in M$, from which it follows by the definition of j_G in Proposition 9.1 that $j_G \restriction \mathbb{Q} \in M[G * g * H]$.

Now let F be the filter on $j_G(\mathbb{Q})$ generated by $j_G``g$. By the arguments of the last paragraph we see that $F \in M[G{*}g{*}H]$. Since $\mathrm{crit}(j_G) = \mathrm{crit}(j) = \kappa$, we see that $j_G(\vec{D}) = \langle j_G(D_\alpha) : \alpha < \omega_1 \rangle$. By genericity $g \cap D_\alpha \neq \emptyset$ for all $\alpha < \omega_1$, and so by elementarity $F \cap j_G(D_\alpha) \neq \emptyset$ for all $\alpha < \omega_1$.

It follows that

$$M[G * g * H] \models \text{“}F \text{ meets every set in } j_G(\vec{D})\text{”}.$$

By the elementarity of j_G,

$$V[G] \models \text{“}\exists f\ f \text{ meets every set in } \vec{D}\text{”}.$$

It follows that $V[G]$ is a model of PFA. ⊣

We will prove the following theorem of Laver on making any supercompact cardinal Laver indestructible.

24.12 Theorem (Laver [49]). *Let κ be supercompact and let $\delta < \kappa$. There is a forcing iteration $\mathbb{P}_\kappa$ of length κ such that*

1. *κ is supercompact in $V^{\mathbb{P}_\kappa}$, and in any extension of $V^{\mathbb{P}_\kappa}$ by κ-directed closed forcing.*
2. *$\mathbb{P}_\kappa$ has cardinality κ, is κ-c.c. and is δ-directed closed.*

24.13 Remark. The proof of Theorem 24.12 is similar in its outline to the consistency proof for PFA. One significant difference is that we will leave long gaps in the iteration in which nothing happens. This is natural when we consider that

- κ is supposed to be supercompact in $V^{\mathbb{P}_\kappa}$.
- $\mathbb{P}_\kappa$ will have no effect above κ on cardinals, cofinalities and the continuum function.

An easy reflection argument shows that there should be arbitrarily long intervals (α, β) below κ in which $V^{\mathbb{P}_\kappa}$ should resemble V.

Proof. Let $f : \kappa \longrightarrow V_\kappa$ be a function as in Theorem 24.1. The poset $\mathbb{P}_\kappa$ will be an iteration of length κ with Easton support, such that for each α

$$\Vdash_\alpha \text{“}\dot{\mathbb{Q}}_\alpha \text{ is } \alpha\text{-directed closed”}.$$

$\dot{\mathbb{Q}}_\alpha$ will name the trivial forcing unless

1. $\alpha \geq \delta$.
2. $f(\alpha)$ is a pair $(\lambda, \mathbb{Q})$ where $\mathbb{Q}$ is a $\mathbb{P}_\alpha$-name for an α-directed closed forcing poset and λ is an ordinal.
3. For all $\beta < \alpha$, if $f(\beta)$ is an ordered pair whose first entry $f(\beta)_0$ is an ordinal, then $f(\beta)_0 < \alpha$.

In this case we let $\mathbb{Q}_\alpha = \mathbb{Q}$.

By Proposition 7.13 $\mathbb{P}_\kappa$ is κ-c.c. with cardinality κ, and by Proposition 7.9 $\mathbb{P}_\kappa$ is δ-directed closed.

Let G be $\mathbb{P}_\kappa$-generic over V. We need to show that the supercompactness of κ is indestructible; accordingly we fix $\mathbb{Q} \in V[G]$ such that

$$V[G] \models \text{“}\mathbb{Q} \text{ is a } \kappa\text{-directed closed forcing poset”},$$

and a cardinal λ with $\lambda \geq \kappa$, and we prove that κ is λ-supercompact in $V[G]^{\mathbb{Q}}$. Notice that the trivial forcing is (trivially) κ-directed closed, so that our proof will show in particular that κ is supercompact in $V[G]$.

Let $\mathbb{Q} = i_G(\dot{\mathbb{Q}})$, where (increasing λ if necessary) we may as well assume that $\dot{\mathbb{Q}} \in H_\lambda$. Let $\mu = 2^{2^\lambda}$. Let W be a supercompactness measure on $P_\kappa\mu$ such that $j_W(f)(\kappa) = (\mu, \mathbb{Q})$. Let $j = j_W$ and $N = \mathrm{Ult}(V, W)$.

Let g be $\mathbb{Q}$-generic over V. Working in N let $\dot{\mathbb{R}}$ be the standard name for the iteration such that $\mathbb{P}_\kappa * \dot{\mathbb{Q}} * \dot{\mathbb{R}} \simeq j(\mathbb{P}_\kappa)$, let $\mathbb{R} = i_{G*g}(\dot{\mathbb{R}})$ and let H be $\mathbb{R}$-generic over $V[G*g]$.

Arguing exactly as in the consistency proof for PFA, we may lift j to get $j_G : V[G] \longrightarrow N[G*g*H]$. We may also argue exactly as before that $M[G] \models |Q| < \lambda$, $V[G*g] \models {}^\mu M[G*g] \subseteq M[G*g]$ and $j_G \restriction \mathbb{Q} \in M[G*g*H]$.

We now need to lift j_G to an embedding of $V[G*g]$, which we will do using Silver's master condition argument as in the proof of Theorem 12.6. By the last paragraph j_G“$g \in M[G*g*H]$, and clearly j_G“g is a directed set of conditions in $j_G(\mathbb{Q})$. We recall that $j(\kappa) > \lambda$, $M[G] \models |\mathbb{Q}| < \lambda$ and by the elementarity of j_G

$$M[G*g*H] \models \text{“}j(\mathbb{Q}) \text{ is } j(\kappa)\text{-directed closed”}.$$

It follows that there is a condition $q \in j_G(\mathbb{Q})$ such that $\forall p \in g\ q \leq j(p)$, that is to say q is a strong master condition for g and j_G. Let h be $j_G(\mathbb{Q})$-generic over $V[G*g*G]$ with $q \in h$. We may lift j_G as usual to get an elementary embedding $j^{++} : V[G*g] \longrightarrow M[G*g*H*h]$.

The argument is not finished at this point because j^{++} can only be defined in $V[G*g*H*h]$. The final stage of the proof is to find an approximation to j^{++} which can be defined in $V[G*g]$. For notational simplicity let $V^* = V[G*g]$ and $M^* = M[G*g*H*h]$. Let

$$U = \{X \subseteq P_\kappa\lambda : X \in V^*, j\text{“}\lambda \in j^{++}(X)\}.$$

As in Proposition 3.2 we may factor j^{++} as $k \circ j_U$ where j_U is the ultrapower of V^* by U.

Recall that $|\mathbb{P}_\kappa * \dot{\mathbb{Q}}| < \lambda$. The definition of the iteration $j(\mathbb{P}_\kappa)$ and the fact that $j(f)(\kappa) = (\mu, \dot{\mathbb{Q}})$ together imply that in the iteration $j(\mathbb{P}_\kappa)$ we do trivial forcing at every stage between κ and μ. It follows that

$$M[G * g] \models \text{“}\mathbb{R} * j(\dot{\mathbb{Q}}) \text{ is } \mu\text{-closed”}.$$

Since $V^* \models {}^{\mu}M[G * g] \subseteq M[G * g]$, V^* agrees that $\mathbb{R} * j(\dot{\mathbb{Q}})$ is μ-closed.

Now since $V^* \models \lambda^{<\kappa} < \mu$, the arguments of the last paragraph imply that $U \in V^*$. It is easy to check that

$$V^* \models \text{“}U \text{ is a supercompactness measure on } P_\kappa\lambda\text{”}.$$

This concludes the proof that κ is λ-supercompact in $V[G * g]$. $\dashv$

24.14 Remark. It is easy to see that if κ is measurable then there is no κ-Kurepa tree. Since Example 6.1 shows that a κ-Kurepa tree can be added by a κ-closed forcing poset for any inaccessible κ, it is not possible to improve Laver's result to cover all κ-closed forcing posets.

25. Altering Generic Objects

In this final section we introduce an idea due to Woodin, namely, that it is sometimes possible to alter generic objects so as to enforce the compatibility requirements of Proposition 9.1. Returning to the theme of failure of GCH at a measurable cardinal, we will prove a result of Woodin which gets GCH to fail at a measurable cardinal from the optimal large cardinal hypothesis.

25.1 Theorem. *Let* GCH *hold and let $j : V \longrightarrow M$ be a definable embedding such that $\mathrm{crit}(j) = \kappa$, ${}^{\kappa}M \subseteq M$ and $\kappa^{++} = \kappa^{++}_M$. Then there is a generic extension in which κ is measurable and* GCH *fails.*

25.2 Remark. The hypotheses of Theorem 25.1 can easily be had from a cardinal κ which is $(\kappa + 2)$-strong. Work of Gitik [24] shows that they can be forced starting with a model of $o(\kappa) = \kappa^{++}$, and by work of Mitchell [59] this is optimal.

Proof of Theorem 25.1. By the arguments of Sect. 3, we may assume that $j = j^V_E$ for some (κ, κ^{++})-extender E. We define $U = \{X : \kappa \in j(X)\}$ and form the ultrapower map $i : V \longrightarrow N \simeq \mathrm{Ult}(V, U)$. We write $j = k \circ i$ where $k : N \longrightarrow M$ is given by $k([F]) = j(F)(\kappa)$.

Let $\lambda = \kappa^{++}_N$. Then $\lambda < i(\kappa)$, since $i(\kappa)$ is inaccessible in N. Since GCH holds $i(\kappa) < \kappa^{++}$. On the other hand $k(\lambda) = \kappa^{++}_M = \kappa^{++}$, so that $\mathrm{crit}(k) = \lambda$. It is also easy to see that k is an embedding of width $\leq \lambda$.

As before we will let $\mathbb{P} = \mathbb{P}_{\kappa+1}$ be an iteration with Easton support, where for $\alpha \leq \kappa$ we let $\mathbb{Q}_\alpha = \mathrm{Add}(\alpha, \alpha^{++})_{V[G_\alpha]}$ for α inaccessible and let it be the trivial forcing otherwise.

Let G be $\mathbb{P}_\kappa$-generic over V and let g be $\mathbb{Q}_\kappa$-generic over $V[G]$. The iterations $\mathbb{P}$, $i(\mathbb{P})$ and $j(\mathbb{P})$ agree up to stage κ.

The following lemmas are easy.

25.3 Lemma. $j(\mathbb{P})_{\kappa+1} = \mathbb{P}_{\kappa+1}$.

25.4 Lemma. $i(\mathbb{P})_{\kappa+1} = \mathbb{P}_\kappa * \dot{\mathbb{Q}}^*_\kappa$, *where* $\mathbb{Q}^*_\kappa = \mathrm{Add}(\kappa, \lambda)_{V[G_\kappa]}$.

Let $g_0 = g \cap \mathbb{Q}^*_\kappa$, then g_0 is $\mathbb{Q}^*_\kappa$-generic over $V[G]$ and also over $N[G]$. It follows from Proposition 8.4 that $V[G * g_0] \models {}^\kappa N[G * g_0] \subseteq N[G * g_0]$.

Let $\mathbb{R}_0 = \mathbb{R}^N_{\kappa+1, i(\kappa)}$ be the factor forcing to prolong $G * g_0$ to a generic object for $i(\mathbb{P}_\kappa)$. By Proposition 8.1 we may build $H_0 \in V[G * g_0]$ which is $\mathbb{R}_0$-generic over $N[G * g_0]$.

Since $\mathrm{crit}(k) = \lambda$ it is easy to see that $k``G = G$, and we may lift $k : N \longrightarrow M$ to get $k : N[G] \longrightarrow M[G]$. Since $\lambda = \kappa^{++}_N$, if $q \in \mathbb{Q}^*_\kappa$ then the support of $q$ is contained in $\kappa \times \mu$ for some $\mu < \lambda$, and so $k(q) = q$. It follows that $k``g_0 = g_0 \subseteq g$, and so we may lift again to get $k : N[G * g_0] \longrightarrow M[G * g]$.

Since $N[G * g_0] \models$ "$\mathbb{R}_0$ is λ^+-closed" and we bounded the width of k, we may now appeal to Proposition 15.1 and transfer H_0 along k. We obtain H which is $\mathbb{R}$-generic over $M[G * g]$, where $\mathbb{R} = \mathbb{R}^M_{\kappa+1 j(\kappa)}$. We may then build a commutative triangle

$$\begin{tikzcd} V[G] \arrow[r, "j"] \arrow[dr, "i"'] & M[G * g * H] \\ & N[G * g_0 * H_0] \arrow[u, "k"'] \end{tikzcd}$$

Let $\mathbb{S}_0 = i(\mathbb{Q}_\kappa)$, that is, $\mathbb{S}_0 = \mathrm{Add}(i(\kappa), i(\kappa^{++}))_{N[G * g_0 * H_0]}$.

25.5 Lemma. $\mathbb{S}_0$ *is* κ^+*-closed and* κ^{++}*-Knaster in the model* $V[G * g_0]$.

Proof. The closure is easy because $V[G * g_0] \models {}^\kappa N[G * g_0] \subseteq N[G * g_0]$. Let $\langle p_\alpha : \alpha < \kappa^{++} \rangle$ be a sequence of conditions, and let $p_\alpha = i(f_\alpha)(\kappa)$ where $f_\alpha : \kappa \longrightarrow \mathbb{Q}_\kappa$, $f_\alpha \in V[G]$. An easy Δ-system argument shows that κ^{++} of the functions f_α are pointwise compatible, from which it follows that κ^{++} of the conditions p_α are compatible. ⊣

25.6 Remark. A more delicate analysis shows that $\mathbb{S}_0$ is isomorphic to $\mathrm{Add}(\kappa^+, \kappa^{++})_{V[G * g_0]}$.

25.7 Lemma. $\mathbb{S}_0$ *is* (κ^+, ∞)*-distributive and* κ^{++}*-c.c. in* $V[G * g]$.

Proof. $V[G * g]$ is a generic extension of $V[G * g_0]$ by a forcing isomorphic to $\mathbb{Q}_\kappa$. The poset $\mathbb{Q}_\kappa$ is κ^+-c.c. in $V[G * g_0]$ and so by Easton's Lemma $\mathbb{S}_0$ is (κ^+, ∞)-distributive in $V[G * g]$. By Proposition 5.12 $\mathbb{S}_0 \times \mathbb{Q}_\kappa$ is κ^{++}-c.c. in $V[G * g_0]$ and so by Easton's Lemma again $\mathbb{S}_0$ is κ^{++}-c.c. in $V[G * g]$. ⊣

Now we force over $V[G * g]$ with $\mathbb{S}_0$, and denote the generic object by f_0. By the last lemma forcing with $\mathbb{S}_0$ preserves cardinals. Since k has width $\leq \lambda$, we may use Proposition 15.1 and transfer f_0 to get f which is $\mathbb{S}$-generic over $M[G * g * H]$, where $\mathbb{S} = \mathrm{Add}(j(\kappa), j(\kappa^{++}))$. The problem is now that we wish to lift j, but it may not be the case that $j``g \subseteq f$.

There is no hope of using any of our previous methods for doing without a master condition, since f_0 is built by forcing (and even if we could build f_0 in a suitably compatible way, this would not guarantee compatibility for f). We adopt a different approach based on the observation that we only need to adjust any given condition in f on a small set to make it agree with $j``g$. We will work in $V[G * g * f_0]$ and construct a suitable f^*, by altering each element of f to conform with j and g.

To be precise let $Q = \bigcup j``g$, so that $Q$ is a partial function from $\kappa \times j``\kappa^{++}$ to 2. Let $p \in f$, so that $p = j(P)(a)$ for some $a \in [\kappa^{++}]^{<\omega}$ and some function $P : [\kappa]^{|a|} \to \mathbb{Q}_\kappa$ with $P \in V[G]$. If $(\gamma, j(\delta)) \in \mathrm{dom}(p)$ then by elementarity $(\gamma, \delta) \in \mathrm{dom}\, P(x)$ for at least one $x \in [\kappa]^{|a|}$, so that there are at most κ many points in the intersection of $\mathrm{dom}(Q)$ and $\mathrm{dom}(p)$. If we then define p^* to be the result of altering p on $\mathrm{dom}(p) \cap \mathrm{dom}(Q)$ to agree with Q, then since $V[G * g] \models {}^{\kappa}M[G * g * H] \subseteq M[G * g * H]$ we see that $p^* \in M[G * g]$ and hence $p^* \in j(\mathbb{Q}_\kappa)$.

It remains to see that $f^* = \{p^* : p \in f\}$ is $j(\mathbb{Q}_\kappa)$-generic over $M[G * g * H]$. To see this we work temporarily in $V[G]$. Let $\delta < \kappa$ and let D be dense in $\mathbb{Q}_\kappa$. Let E be the set of those $p \in D$ such that every q obtained by altering p on a set of size δ is in D. An easy argument shows that E is also dense. Returning to $M[G * g * H]$ and applying this remark with κ in place of δ, we see that f^* meets every dense set in $M[G * g * H]$.

We may now lift to get $j : V[G * g] \longrightarrow M[G * g * H * f^*]$. We are not quite done because f^* only exists in the extension $V[G * g * f_0]$. However since f_0 is generic for (κ, ∞)-distributive forcing and j has width $\leq \kappa$, we may transfer f_0 to get a suitable generic object h and finish by lifting to get $j : V[G * g * f_0] \longrightarrow M[G * g * H * f^* * h]$. $\dashv$

1. Introduction

This chapter covers the technique of generic elementary embeddings. These embeddings are closely analogous to conventional large cardinal embeddings, the difference being that they are definable in forcing extensions of V rather than in V itself. The advantage of allowing the embeddings to be generic is that the critical points of the embeddings can be quite small, even as small as ω_1. For this reason they have many consequences for accessible cardinals, settling many classical questions of set theory.

In analogy to conventional large cardinals, two parameters help describe the strength of a generic elementary embedding $j : V \to M$: where j sends ordinals and the closure properties of M. For generic embeddings we have a third parameter: the nature of the forcing required to define j. This chapter focuses on how the "three parameters" interact to determine the impact j has on the universe.

An Overview of the Chapter

In Sect. 2, we introduce the basic techniques of generic embeddings and generic ultrapowers and describe briefly the relationship to ideals. Topics include criteria for precipitousness, the disjointing property, normality, limitations on closure, canonical functions, selectivity and use of generic embeddings for reflection. Starting with Sect. 2.3, unless otherwise specified, we will assume that our ideals are countably complete.

Section 3 gives examples of relevant ideals and describes a distinction between *natural* and *induced* ideals; the latter bear close resemblance to the duals of conventional large cardinal ultrafilters that have been collapsed by forcing. The nonstationary ideal (in its modern sense) is described along with several lesser known natural ideals. The analogies between induced ideals and proper forcing are explored via master condition ideals and the idea of *goodness*. The relationship between *self-genericity* and saturation is first introduced here and is exploited in later sections on the nonstationary ideal on ω_1 and towers.

In Sect. 4, we look more closely at the theory of generic ultrapowers. Topics include presaturation, layered ideals, Rudin-Keisler projections, computations of where ordinals go under generic embeddings, and the sizes of sets of measure one. It is shown how to iterate embeddings coming from ideals, and generic elementary embeddings arising from towers of ideals are introduced.

In Sect. 5, we consider the consequences of "generic large cardinals". Generic large cardinals, taken together with their prototypical cousins, conventional large cardinals, tend to give a coherent collection of answers to many of the classical questions of set theory. There is one extremely important counterexample: the assumption that the nonstationary ideal on ω_1 is $\aleph_2$-saturated. Topics include CH, GCH and SCH, graph and partition theory, Chang's Conjecture and Jónsson cardinals, square, stationary set reflection, Suslin and Kurepa trees, descriptive set theory, and non-regular ultrafilters.

In Sect. 6, we discuss limitations on generic large cardinal assumptions. These results play a role analogous to the Kunen limitation on conventional large cardinals. Because generic large cardinals have more parameters, the limitations involve such issues as the nature of the forcing required for the generic embeddings. Given the ubiquitous consequences of generic large cardinals, it is not surprising that this topic is more involved than with conventional large cardinals.

Sections 7 and 8 deal with consistency results for generic large cardinals. These are split as far as possible into consistency results for induced ideals and consistency results for natural ideals. Forcing constructions are given for ideals with strong properties in all three parameters. Special attention is paid to results that show the consistency of properties that are either used as hypotheses in Sect. 5 or that show that results in Sect. 6 are sharp. There is a general theorem (the Duality Theorem) that describes how to compute the forcing necessary to construct an elementary embedding coming from an induced ideal. This result allows one to control the third parameter in consistency results. Various corollaries are drawn such as the indestructibility of the generic supercompactness of ω_1 under proper forcing. An attempt is made to unify the treatment of various forcing techniques constructing precipitous and saturated ideals. The section ends with a brief discussion of methods for destroying precipitous and saturated ideals.

Section 8 deals with consistency results for natural ideals. Unfortunately, due to time and space limitations, consistency results that are proved by adding choice to determinacy models are not included, although some references are given. Starting with large cardinals, consistency results for natural ideals are shown in two ways. Both methods are explored in this section. The first is to take an induced ideal and by some technique, such as shooting closed unbounded sets, turning it into a natural ideal while preserving its generic embedding. The second technique arose from [47] and uses inherent properties of the natural ideal. The notions of *goodness* and *self-genericity* are important for taking an existing natural ideal and making it have nice properties. The section focuses on the two natural ideals for which good consistency results are known: the nonstationary ideals and the club guessing ideals. The section includes results from Martin's Maximum and about $\square_\kappa$ and c.c.c.-destructible and indestructible ideals.

Section 9 gives a brief introduction to tower forcing. It discusses induced towers, giving an example of a saturated tower. Then it goes on to natural towers. The notion of catching an antichain is discussed and connections with the forcing for making the nonstationary ideal on ω_1 saturated are made, as is the notion of self-genericity in this context. Woodin's towers are shown to be presaturated, and generalizations first considered by Douglas Burke are discussed. Some applications are given and an example due to Burke of a non-precipitous tower is given.

Section 10 deals with the consistency strength of generic ideal assumptions. The most cogent results of this section are covered in the chapters of this Handbook devoted to inner model theory. They exposit results that show fine structural inner models with large cardinals exist, under various ideal assumptions. For this reason, this section focuses on results that are of a different flavor. These results state that the existence of generic embeddings j with the property that the images of a very small finite number of sets are determined independently of the generic object imply inner models with very large (supercompact or huge) cardinals. Results are also quoted that show that there is a strict hierarchy of consistency strength among the ideal axioms involving the ω_n's.

Section 11 is a speculative discussion of the possibility of adopting generalized large cardinals along with conventional large cardinals as additional axioms for mathematics.

Apology and Acknowledgments

This chapter was first conceived as a 40-page introduction to the theory of generic elementary embeddings. As I began to outline the chapter and look at references it became clear that there was no general survey of the area in the literature. At that moment the chapter began to grow.

There are several decisions that had to be made early on. My belief is that long lists of theorems without indications of the ideas of the proofs are not very useful. I have never been able to read such a "survey". The first decision was to try to include at least sketches of arguments for almost all of the results.

Secondly, the existing literature included a lot of overlap and duplication of ideas under different names, ad hoc arguments for special cases and the use of generic embeddings in the middle of arguments for other theorems. Rather than repeat many variations of the same argument, I decided to try to isolate common lemmas that could be used repeatedly.

A corollary of the attempt to unify a lot of disparate literature was that the logical structure of the chapter became tree-like. Most of the latter sections depend on elements introduced in the earlier sections. Without the background information in the first four sections, it is hard to motivate or illuminate the deeper results in the later sections. For this reason alone, more detail is given to the earlier sections. Moreover, reading the later sections may require glancing back over definitions and results in the earlier parts of the chapter.

The main aim of the chapter is to illustrate that there is a coherent *theory* here, that there are unifying fundamental ideas that occur frequently in many different contexts. These include master condition ideals, natural and induced ideals, disjointing, self-genericity, the role of diagonal unions for representing Boolean sums, good elementary substructures—the list is long.

The third decision was to try to organize the theory around a few basic principles. These include the categorization of ideals as natural and induced and the "three parameters" that determine a generic elementary embedding $j : V \to M$, which again are: where j sends ordinals, the closure properties of M, and the nature of the forcing required to define j.

The three parameters provide a backbone for the chapter. There are sections and examples devoted to each of them, and a range of ideal-theoretic properties, like the various saturation and normality properties, are explored in terms of the three parameters.

Despite the attempt to give arguments in as much detail as space allows, there are parts of the chapter that do little more than adumbrate results. This reflects my ignorance and lack of energy. I have attempted to give accurate references for results that the reader may want to learn on his or her own. I apologize also to authors whose results were left out due to my ignorance or sloth.

Given the problematic length of the chapter, several people have suggested that it be expanded to a stand-alone book. As this would require that near complete arguments be given, I estimate such a book might need 800 to 900 pages. I will leave this for others.

Many people have been incredibly generous with their time and criticism. I especially want to thank Aki Kanamori for his continuing support and encouragement. James Cummings, Joel Hamkins and Tetsuya Ishiu provided ongoing corrections that were very useful. Ishiu was involved with the chapter since its inception. Many other people, including David Aspero, Andrés Caicedo, Neus Castells, Moti Gitik, Paul Larson, Rich Laver, Luis Pereira, John Rapalino, Hugh Woodin and Martin Zeman gave me substantial commentary and feedback.

I would also like to thank Menachem Magidor, Saharon Shelah and Hugh Woodin for their help in understanding some of the topics in this chapter. Magidor's views on generic elementary embeddings influenced me a great deal.

Some Conventions Used in the Chapter

In describing generic elementary embeddings, Boolean algebras of the form $P(Z)/I$ occur naturally as forcing notions. Moreover, via Łoś's theorem, the Boolean value of a forcing statement is frequently very easily computed directly as a subset of Z. In this context the "Boolean valued" approach to forcing has its advantages. In several places, an elementary familiarity with Boolean algebras may be useful to the reader. To convert the language of Boolean algebras to other approaches to forcing, one can very roughly say that Σ translates to an infinite disjunction and $\prod$ translates into an infinite conjunction. Rigorously, if $\mathbb{B}$ is a Boolean algebra, and $A \subseteq \mathbb{B}$, then ΣA is the least upper bound of A and $\prod A$ is the greatest lower bound. The obvious De Morgan's laws apply. If $\mathbb{B}$ is not complete, then ΣA and $\prod A$ need not exist.

An effort was made to keep notation as conventional as possible. Although $\omega_\alpha = \aleph_\alpha$, we try to use the former when regarding it as a set of ordinals and the latter when appealing to its cardinality aspect. Some notation that may not be standard include the use of "$\mathrm{Cof}(\kappa)$" and "$\mathrm{Cof}({<}\kappa)$" for the classes of ordinals of cofinality κ and less than κ respectively. To denote the cofinality of a particular ordering $(I, <)$ we write $\mathrm{cf}(I)$. If $g : Z \to A$, we denote the corresponding element of the ultrapower A^Z/U as $[g]$ or $[g]^U$. If $V^Z/U \cong M$ and the isomorphism with M is understood from the context then we will write $[g]^M$ for the image of $[g]$ in M. If $\mathfrak{A}$ is a structure with domain A that has canonical Skolem functions and $z \subseteq A$ we will write $\mathrm{Sk}^{\mathfrak{A}}(z)$ for the elementary substructure of $\mathfrak{A}$ generated by z. We will follow current practice by taking $H(\theta)$ to stand for a structure in a countable language expanding $\langle H(\theta), \in, \Delta\rangle$ with domain the collection of sets of hereditary cardinality less than θ and where Δ is a fixed-in-advance well-ordering of the domain. Unless otherwise stated, the convention is that θ is a very large regular cardinal reflecting all relevant statements from the universe V. We use the abbreviation $\mathrm{ot}(X)$ for the order type of X. We lapse into jargon from time to time; for example we will write $\kappa \ll \lambda$ to mean that λ is substantially larger than κ. "Substantially larger" will depend on context, but usually means that λ is a regular cardinal at least $(2^\kappa)^+$. We will be sloppy in our notation in the following way: if $\dot\tau$ is a $\mathbb{P}$-term for an element of a generic extension $V[G]$ we will write $\dot\tau^{V[G]}$ for its realization by G. This is strictly speaking incorrect as the interpretation of τ depends on G, rather than the model $V[G]$. Similarly we will often omit the traditional ˇ's and ˙'s whenever the context makes them clear.

Throughout this chapter we will assume, without loss of generality, that all of our partial orderings have the property that for all compatible conditions p, q there is a greatest lower bound, which we will denote $p \wedge q$. We will say that $p \wedge q = 0$ if p and q are not compatible.

If $e : \mathbb{P} \to \mathbb{Q}$ is an order-preserving map and $G \subseteq \mathbb{P}$ is generic, then we can define a partial ordering $\mathbb{Q}/G$ by setting the domain of $\mathbb{Q}/G$ to be $\{q \in \mathbb{Q} : \text{for all } p \in G, q \wedge e(p) \neq 0\}$ and the ordering of $\mathbb{Q}/G$ to be $\leq_{\mathbb{Q}}$. An order-preserving map e will be said to be a *regular embedding* iff e preserves incompatibility and takes maximal antichains to maximal antichains.

Despite the fact that $\mathbb{Q}/G$ can be a strange non-separative partial ordering, if e is a regular embedding it is always the case that:

$$\mathbb{Q} \sim \mathbb{P} * \mathbb{Q}/G.$$

We assume general familiarity with the combinatorial principles $\diamondsuit$ and $\square$, much discussed in the various Handbook chapters. We refer to the early sections of Cummings' chapter for basic definitions and notations for forcing and (conventional) large cardinals. We will use the following partial orderings: $\mathrm{Add}(\kappa, \lambda)$ is the set of partial functions from $\kappa \times \lambda$ to 2 of cardinality less than κ. This is the usual notion of forcing for adding λ Cohen subsets of κ. We write $\mathrm{Add}(\kappa)$ for $\mathrm{Add}(\kappa, 1)$. $\mathrm{Col}(\kappa, \lambda)$ is the set of partial functions from κ to λ of cardinality less than κ, the usual notion of forcing for collapsing λ to κ. $\mathrm{Col}(\kappa, <\lambda)$ is the set of partial functions p from $\kappa \times \lambda$ to λ of cardinality less that κ such that $p(\alpha, \beta)$ when defined is less than β. This is the usual notion of forcing, the Levy collapse, for collapsing all cardinals below λ to κ. A property is *c.c.c.-destructible* if it can be destroyed by a c.c.c. forcing. We often regard large cardinal axioms as providing elementary embeddings, with phrases like "supercompact embedding" and "almost huge embedding" meaning the elementary embedding with the closure properties associated with supercompact or almost huge cardinals.

2. Basic Facts

We begin with some classical algebraic definitions about Boolean algebras. See, for example, Sikorski's book [108] for more details. We recall that a *Boolean algebra* is a structure $\mathbb{B} = \langle F, \wedge, \vee, \neg, 0, 1\rangle$ that is isomorphic to a field of sets with the operations of $\cup, \cap$ and complement, and with 0 denoting $\emptyset$ and 1 denoting the complement of the empty set. In such a structure we can define an ordering by setting $b \le c$ iff $b \wedge c = b$.

The class of Boolean algebras is an elementary class. A Boolean algebra $\mathbb{B}$ will be called *κ-complete* iff for all sets $A \subseteq F$ of size less than κ there is an element of $\mathbb{B}$, denoted ΣA, that is a least upper bound for all of the elements of A. This is equivalent to the requirement that for all $A \subseteq F$ of cardinality less than κ there is a greatest lower bound ΠA for all elements of A. Of course, ΣA and ΠA correspond to infinite unions and intersections respectively. The significance of this for forcing is that $\Sigma A \Vdash \dot{G} \cap A \neq \emptyset$.

A *homomorphism* between Boolean algebras $\mathbb{B}$ and $\mathbb{C}$ is a function from the domain of $\mathbb{B}$ to the domain of $\mathbb{C}$ that preserves the operations $\wedge, \vee, \neg$. A homomorphism will be called *κ-complete* iff it preserves the infinitary operation of ΣA for $A \subseteq \mathbb{B}$ having cardinality less than κ. A κ-complete homomorphism preserves ΠA as well, for $A \subseteq \mathbb{B}$ of cardinality less than κ.

The Boolean algebra will be *complete* iff it is κ-complete for all κ. It is a standard fact (see [63]) that if $\mathbb{P}$ is a separative partial ordering then there is a complete Boolean algebra, which we denote by $\mathcal{B}(\mathbb{P})$, that has a dense subset $D \subseteq \mathcal{B}(\mathbb{P})$ such that $(D, \le_{\mathcal{B}(\mathbb{P})}) \cong \mathbb{P}$. Moreover, for any partial ordering $\mathbb{P}$ there is an equivalence relation $\sim$ such that the map $p \to [p]_\sim$ is order preserving, forcing with $\mathbb{P}$ is equivalent to forcing with $\mathbb{P}/\sim$ and, $\mathbb{P}/\sim$ is separative. In an abuse of notation we will write $\mathcal{B}(\mathbb{P})$ for $\mathcal{B}(\mathbb{P}/\sim)$.

2.1 Definition. Let $\mathbb{B} = \langle B, \wedge, \vee, \le, \neg, 0, 1\rangle$ be a Boolean algebra. A non-empty set $I \subseteq \mathbb{B}$ is an *ideal* on $\mathbb{B}$ if it is closed under finite joins and $\le$. The dual of an ideal I is $\breve{I} = \{\neg A : A \in I\}$. It is called a *filter*. If $S \subseteq \mathbb{B}$ we will denote the ideal generated by S as $\bar{S}$. An ideal is *proper* iff $1 \notin I$.

In most contexts the Boolean algebra $\mathbb{B}$ will be of the form $P(Z)$ for some set Z. In this case we will say that I is an ideal *on* Z.[1] Clearly I is an ideal on Z iff I is closed under finite unions and subsets. I is proper iff $Z \notin I$.

A maximal proper ideal is called *prime* and its dual is an *ultrafilter*. We will usually assume without further comment that our ideals and filters are proper and, if $\mathbb{B} \subseteq P(Z)$, that the ideals contain all singletons of elements from Z.

The ideal I is called *κ-complete* provided that it is closed under joins (unions) of size less than κ. Ideals that are ω_1-complete are also called *countably complete* or *σ-additive*. For a proper ideal I the *completeness* of I is the least cardinal κ such that there is a collection $\{X_\alpha : \alpha < \kappa\} \subseteq I$ such that $\bigcup_{\alpha<\kappa} X_\alpha \notin I$. The completeness of an ideal is easily seen to be a regular cardinal. We will denote the completeness of the ideal I by $\mathrm{comp}(I)$.

If I is an ideal on Z and $Y \subseteq Z$ we say that the ideal I (or its dual filter) *concentrates on* Y iff $Y \in \breve{I}$.

---

[1] This is clearly an abuse of terminology, but follows standard practice. It might be better to follow [69] and say that I is an ideal *over* Z.

An ideal I on Z is *uniform* iff every subset of Z of cardinality smaller than the cardinality of Z is in I.

Given an ideal I on Z we will be concerned with the Boolean algebra $P(Z)/I$. Elements of this algebra are equivalence classes of subsets of Z under the relation $S \sim_I T$ iff $S\Delta T \in I$ and are denoted $[S]_I$, the subscript deleted when clear from the context. The usual operations of union and intersection are well-defined modulo this equivalence relation and the result is a Boolean algebra. It is a standard fact that if the ideal I is κ-complete then the resulting Boolean algebra is κ-complete.

The collection of subsets of Z not in I are called the *I-positive* sets and are denoted I^+. If $S \subseteq Z$ is in I^+ we define $I\restriction S$ to be the ideal $I \cap P(S)$. Depending on context, we occasionally want to view $I\restriction S$ as an ideal on Z. In this context we define $I\restriction S$ to be the ideal $\overline{I \cup \{Z \setminus S\}}$ generated by I and the single set $Z \setminus S$. The rationalization for this ambiguity is the canonical Boolean algebra isomorphism $P(Z)/(\overline{I \cup \{Z \setminus S\}}) \cong P(S)/(I \cap P(S))$. Note that the completeness of $I\restriction S$ is at least as large as the completeness of I.

An ideal I is *non-principal* iff every singleton from Z is a member of I and *atomless* iff $P(Z)/I$ has no atoms. Being atomless is equivalent to the property that every $S \subseteq Z$ that is not in I contains at least two disjoint subsets not in I. Clearly, if I is atomless it is non-principal. Further, if $[S] \in P(Z)/I$ is an atom, then I induces an ultrafilter on S in a natural way.

For the rest of this chapter, take "proper and non-principal" as part of the definition of ideal or filter, unless otherwise indicated.

We will use the locution "I is nowhere φ" to mean that no I-positive subset of Z has property φ. So, for example, an ideal is "nowhere prime" means that there is no positive set S such that $I\restriction S$ is prime.

An important property of any Boolean algebra is its chain condition, or equivalently, in a complete Boolean algebra, its antichain condition. Recall that an *antichain* in a Boolean algebra is a collection of elements A such that the meet of any pair of distinct elements of A is empty.

2.2 Definition. The *saturation* of an ideal I on Z, $\mathrm{sat}(I)$, is the least cardinal κ such that every antichain $\mathcal{A} \subseteq P(Z)/I$ has cardinality less than κ. The ideal I is said to be *λ-saturated* iff $\mathrm{sat}(I) \leq \lambda$.

It is a result of Tarski [117] that the saturation of a Boolean algebra is always a regular cardinal.

2.1. The Generic Ultrapower

An important modern application of the theory of ideals is that of *generic ultrapowers*. This technique was developed by Solovay [111] in order to show that the existence of a real-valued measurable cardinal implies the existence of an inner model with a measurable cardinal. The essence of this technique was isolated in the definition of a *precipitous ideal* due to Jech and Prikry [62, 64].

The technique uses forcing to build an ultrafilter G over V and then take the V-ultrapower by G. If we remove the zero element from $P(Z)/I$, then the usual Boolean algebra partial ordering on $P(Z)/I$ gives a separative partial ordering that is appropriate for forcing. This can be defined explicitly by setting $[X]_I \leq [Y]_I$ iff $X \setminus Y \in I$. Call the resulting partial ordering $\mathbb{B}$.

In general, in the context of forcing, we will be sloppy about distinguishing between $P(Z)/I$ and $\mathbb{B}$. The reader also has the option of viewing this as Boolean-valued forcing. An equivalent, pre-partial ordering has as elements I^+ under the ordering $A \leq B$ iff $A \setminus B \in I$.

Forcing with $\mathbb{B}$ gives an ultrafilter $G \subseteq \mathbb{B}$ that is V-complete in the following sense: if $\langle X_j : j \in J \rangle \subseteq P(Z)/I$ is a maximal antichain in V below some element $Y \in G$, then there is a j with $X_j \in G$. If $P(Z)/I$ is complete, this is equivalent to the statement that whenever $\langle Y_j : j \in J \rangle \in V$ and for all j, $Y_j \in G$ then $\prod Y_j \in G$.

We can interpret G as an ultrafilter G' on $P(Z)^V$ by taking all subsets of Z that belong to an I equivalence class that belongs to G. The forcing to produce G' is equivalent to the forcing to produce G and we will not, in general, distinguish between G and G'.

In $V[G]$, we can use this ultrafilter to form the ultrapower of V by G using functions from V. More formally: Let $f, g : Z \to V$ be elements of V. Then $\{z \in Z : f(z) = g(z)\}$ and $\{z \in Z : f(z) \in g(z)\}$ lie in V and hence are "G-measurable". Define an equivalence relation of the collection of such functions by setting $f \sim g$ iff $\{z \in Z : f(z) = g(z)\} \in G$. For equivalence classes $[f], [g]$, we set $[f]\, E\, [g]$ iff $\{z \in Z : f(z) \in g(z)\} \in G$; E is "the ultrapower of the $\in$ relation". It is easy to check that this is well-defined.

Let $(V^Z/G, E)$ denote the resulting class ultrapower. The "usual tricks" are employed to deal with the fact that each equivalence class is a proper class, exactly as in the case of measurable cardinals.

The appropriate version of Łoś's Theorem is easily verified and as a consequence, there is a canonical elementary embedding

$$j : V \to V^Z/G$$

that lies in $V[G]$.

The next lemma is an important tool for computing generic ultrapowers:

2.3 Lemma. *Suppose that I is an ideal on a set Z. Let $G \subseteq P(Z)/I$ be generic and $j : V \to V^Z/G$ be the generic elementary embedding. Let* $\mathrm{id} : Z \to Z$ *be the identity function, given by* $\mathrm{id}(z) = z$ *for $z \in Z$. Then*

1. *for $A \subseteq Z$, $A \in G$ iff $[\mathrm{id}]^{V^Z/G}\, E\, j(A)$, where E is the ultrapower of the $\in$ relation and*
2. *for all $g : Z \to V$ with $g \in V$, we have $[g]^{V^Z/G} = j(g)([\mathrm{id}]^{V^Z/G})$.*

The identity function thus plays a pivotal role. As we consider various Z's, id will continue to denote the corresponding identity function with the Z implicit.

In some lucky cases V^Z/G is well-founded:

2.4 Definition (Jech-Prikry [64]). An ideal I on Z is *precipitous* iff for all generic $G \subseteq P(Z)/I$, the ultrapower V^Z/G is well-founded.

In the case where V^Z/G is well-founded, we replace it by its transitive collapse, M. Note that $M \subseteq V[G]$. In a slight abuse of notation we consider j as an elementary embedding from V to M, $j : V \to M$. Moreover, if $g : Z \to V$ with $g \in V$ we will denote the unique element of M corresponding to g by $[g]^M$.

Recall that if $j : V \to M \subseteq V[G]$ is elementary then the critical point of j, denoted $\mathrm{crit}(j)$, is the least ordinal moved by j. A standard fact is that if M and N are two well-founded models of ZFC that have the same ordinals and $j : M \to N$ is an elementary embedding that does not move ordinals, then $M = N$ and j is the identity map.[2]

We now compute the critical point of j in terms of the completeness of the ideal.

2.5 Proposition. *Let I be a precipitous ideal on Z. Let $G \subseteq P(Z)/I$ be generic and $j : V \to M \subseteq V[G]$ the generic elementary embedding. Then j is not the identity map and the critical point of j is the largest κ such that there is an $S \in G$ with the completeness of $I{\restriction}S$ equal to κ.*

Proof. As we observed above, if $S \subseteq T$ then $\mathrm{comp}(I{\restriction}S) \geq \mathrm{comp}(I{\restriction}T)$.

Let G be generic. A simple density argument shows that there is a $Y \in G$, and a sequence $\langle A_\alpha : \alpha < \gamma\rangle \subseteq I$, where γ is the completeness of $I{\restriction}Y$, such that $\bigcup_{\alpha<\gamma} A_\alpha \in G$. By the observation, this γ is the largest κ such that for some $S \in G$, $\mathrm{comp}(I{\restriction}S) = \kappa$.

Let $W = \bigcup_{\alpha<\gamma} A_\alpha$. Let $F : Z \to \gamma$ be defined by:

$$F(z) = \begin{cases} 0 & \text{if } z \notin W, \\ \alpha & \text{if } \alpha \text{ is least such that } z \in A_\alpha. \end{cases}$$

Then, for each $\alpha < \gamma$, $\{z \in Z : F(z) \leq \alpha\} \subseteq (\bigcup_{\beta\leq\alpha} A_\beta \cup Z \setminus W) \in I{\restriction}W$. Hence, by Łoś's Theorem, $[F]^M > j(\alpha) \geq \alpha$. On the other hand for every $z \in Z$, $F(z) \in \gamma$, and hence $[F] < j(\gamma)$. Thus the critical point of j exists and is less than or equal to γ. We have shown that there is a set $Y \in G$ such that $\mathrm{crit}(j) \leq \mathrm{comp}(I{\restriction}Y)$. In particular, $\mathrm{crit}(j) \leq \sup\{\mathrm{comp}(I{\restriction}Y) : Y \in G\}$.

To finish, for all generic G there is an $S \in G$ such that for some κ, $[S] \Vdash \mathrm{crit}(j) = \kappa$ and for some function $F : Z \to V$, with $F \in V$ we have $[S] \Vdash [F]^M = \kappa$. It suffices to show that $\mathrm{comp}(I{\restriction}S) \leq \mathrm{crit}(j)$. For each $\alpha < \kappa$, consider $A_\alpha = \{z \in S : F(z) < \alpha\}$. Then $A_\alpha \in I{\restriction}S$, but $\bigcup_{\alpha<\kappa} A_\alpha = S$. Hence the completeness of $I{\restriction}S$ is less than or equal to κ. Using the observation and the fact that S was arbitrary deciding F and κ, we have shown that the crit(j) is at least as big as the completeness of $I{\restriction}S$ for any $S \in G$. ⊣

[2] We include the case where M and N are proper classes.

2.6 Corollary. *Every precipitous ideal is countably complete.*

We now describe a combinatorial criterion for an ideal to be precipitous due to Jech and Prikry [64].

Let $\mathbb{P}$ be a partial ordering. A *tree of maximal antichains* is a sequence $\langle \mathcal{A}_n : n \in \omega \rangle$ of maximal antichains of $\mathbb{P}$ such that $\mathcal{A}_{n+1}$ refines $\mathcal{A}_n$. A *branch* through a tree of maximal antichains is a decreasing sequence of conditions $\langle p_n : n \in \omega \rangle$ such that $p_n \in \mathcal{A}_n$.

In the case that $\mathbb{P} = (P(Z)/I) \setminus \{[\emptyset]\}$ and $\mathcal{A}_n \subseteq P(Z)$ we will say that $\langle \mathcal{A}_n : n \in \omega \rangle$ is a *tree of maximal antichains* iff $\langle \mathcal{A}'_n : n \in \omega \rangle$ is a tree of maximal antichains in $\mathbb{P}$ where $\mathcal{A}'_n = \{[a] : a \in \mathcal{A}_n\}$.

2.7 Proposition (Jech-Prikry [64]). *Let I be an ideal. Then I is precipitous iff for any I-positive set S and any sequence $\langle \mathcal{A}_n : n \in \omega \rangle$ with $\mathcal{A}_n \subseteq P(Z)$ that forms a tree of maximal antichains below $[S]$ there is a sequence $\langle a_n : n \in \omega \rangle$ such that:*

1. *$a_n \in \mathcal{A}_n$,*
2. *$\langle [a_n]_I : n \in \omega \rangle$ is a branch through the tree,*
3. *$\bigcap_n a_n \neq \emptyset$.*

Proof. Suppose that I is precipitous. Consider a tree of maximal antichains $\langle \mathcal{A}_n : n \in \omega \rangle$ below a condition $[S]$. Let $j : V \to M \subseteq V[G]$ be a generic elementary embedding where M is transitive, $M \cong V^Z/G$ and $[S] \in G$. In M, consider the tree $\mathcal{T}$ of sequences

$$\{(a_0, \ldots, a_n) : a_i \in j(\mathcal{A}_i),\ [\mathrm{id}]^M \in a_i,\ [a_{i+1}]_{j(I)} \leq [a_i]_{j(I)}\}.$$

For each n, there is a unique $a^*_n \in \mathcal{A}_n$ such that $[\mathrm{id}]^M \in j(a^*_n)$. Hence the sequence $\langle j(a^*_n) : n \in \omega \rangle$ is an infinite branch through $j(\mathcal{T})$ lying in $V[G]$. Since M is well-founded there is a branch through this tree in M. Hence $M \models$ "there is a sequence $\langle a_n : n \in \omega \rangle$ with $a_n \in j(\mathcal{A}_n)$ and $\bigcap_{n\in\omega} a_n \neq \emptyset$". By the elementarity of j we get such a sequence in V.

Suppose that I is not precipitous. Let $[S] \Vdash$ "V^I/G is ill-founded". Choose terms $\dot{F}_n$ such that $[S] \Vdash \dot{F}_n : \check{Z} \to V$, $[S] \Vdash \dot{F}_n \in V$ and $[S] \Vdash [\dot{F}_{n+1}]\, E\, [\dot{F}_n]$, where E is the ultrapower of the $\in$ relation.

Inductively build a tree of antichains $\mathcal{A}_n \subseteq P(Z)$ (with $\mathcal{A}_{-1} = \{S\}$) such that:

1. the collection $\{[a]_I : a \in \mathcal{A}_{n+1}\}$ is a maximal antichain below $[S]$ that refines $\{[a]_I : a \in \mathcal{A}_n\}$,
2. for all $a \in \mathcal{A}_n$, there is an $f^n_a \in V$ such that $[a]_I \Vdash \check{f}^n_a \restriction a = \dot{F}_n \restriction a$, and
3. if $a \in \mathcal{A}_{n+1}$, $b \in \mathcal{A}_n$ and $[a]_I \leq_I [b]_I$ then $a \subseteq b$ and for all $z \in a$, $f^{n+1}_a(z) \in f^n_b(z)$.

Then the sequence $\langle \mathcal{A}_n : n \in \omega \rangle$ has no branch with non-empty intersection; for if b were a branch through the $\langle \mathcal{A}_n : n \in \omega \rangle$ and $z \in \bigcap b$ then $\langle f^n_a(z) : a \in b \cap \mathcal{A}_n \rangle$ is a descending $\in$-sequence in V. ⊣

2.2. Game Characterization of Precipitousness

Let I be a proper countably complete ideal on a set Z. Consider the following game: Players W and B alternate playing subsets:

$$W_0 \supseteq B_0 \supseteq W_1 \supseteq B_1 \cdots$$

of Z that form a decreasing sequence of I-positive sets. Player B wins the game iff $\bigcap_{i\in\omega} B_i \neq \emptyset$.

Galvin, Jech and Magidor proved the following useful characterization of precipitousness:

2.8 Theorem (Galvin et al. [50]). *I is a precipitous ideal iff W does not have a winning strategy.*

2.3. Disjointing Property and Closure of Ultrapowers

An important tool in investigating the precipitousness of an ideal as well as the closure of the generic ultrapower is the *disjointing property* and its weaker relatives. We begin with an easy proposition:

2.9 Proposition. *Let κ be a cardinal. Suppose that I is κ^+-saturated and κ-complete. Then every antichain in $P(Z)/I$ has a pairwise disjoint system of representatives.*

Proof. Let $\mathcal{A} = \langle A_\alpha : \alpha < \kappa\rangle$ be an antichain. For all α, let $A'_\alpha = A_\alpha \setminus \bigcup_{\beta<\alpha} A_\beta$. Then $A'_\alpha \sim_I A_\alpha$ and the sequence $\langle A'_\alpha : \alpha < \kappa\rangle$ is pairwise disjoint. ⊣

2.10 Definition. An ideal I has the *disjointing property* iff every antichain $\mathcal{A}$ in $P(Z)/I$ has a pairwise disjoint system of representatives, i.e. $\{S_a : a \in \mathcal{A}\}$ such that each $S_a \in a$ and $S_a \cap S_b = \emptyset$ for $a \neq b$.

2.11 Example. If $\mu : P(\kappa) \to [0, 1]$ is a measure witnessing that κ is real-valued measurable and I is the ideal of null sets of μ, then I is $\aleph_1$-saturated. Hence I has the disjointing property. In this case we have $\aleph_1$-completeness and $\aleph_1$-saturation, which is stronger than necessary to apply Proposition 2.9.

One of the main consequences of the disjointing property is embodied in the following proposition, due to Solovay [111].

2.12 Proposition. *Suppose that I has the disjointing property. Let $\mathbb{B} = P(Z)/I$ and $\dot{f}$ be a $\mathbb{B}$-term whose realization in the generic extension is a function from Z to V that lies in V. Then there is a $g : Z \to V$ with $g \in V$ such that for all generic $G \subseteq \mathbb{B}$, $[\dot{f}]^{V^Z/G} = [\check{g}]^{V^Z/G}$.*

The conclusion can be restated equivalently by saying that for all generic G, $V[G] \models \{z : \dot{f}(z) = \check{g}(z)\} \in G$.

Proof. Choose a maximal antichain $\mathcal{A}$ such that for each $a \in \mathcal{A}$ there is a function g_a such that $a \Vdash \dot{f} = \check{g_a}$. By the disjointing property we can find a pairwise disjoint system of representatives $\{S_a : a \in \mathcal{A}\}$ of elements of $\mathcal{A}$. Define a function

$$g(z) = \begin{cases} g_a(z) & \text{if } z \in S_a \text{ for some } a, \\ 0 & \text{otherwise.} \end{cases}$$

Then g is well-defined since the S_a's are pairwise disjoint, and for each $a \in \mathcal{A}$, $a \Vdash [\dot{f}]^{V^Z/G} = [\check{g}]^{V^Z/G}$. Since $\mathcal{A}$ is a maximal antichain, we are done. ⊣

2.13 Remark. The disjointing property is equivalent to the conclusion of Proposition 2.12. For if we are given an antichain $\mathcal{A} = \langle A_\alpha : \alpha \in \lambda \rangle$, we can take $\dot{f}$ to be the term for the function with constant value α where $A_\alpha \in G$. If we take $g : Z \to V$ such that $1 \Vdash [\dot{f}]^{V^Z/G} = [\check{g}]^{V^Z/G}$, then $A_\alpha =_I \{z \in Z : g(z) = \alpha\}$.

The importance of the disjointing property is expressed by the following proposition:

2.14 Proposition. *Suppose that I is a countably complete ideal with the disjointing property. Then*

1. *I is precipitous, and*
2. *if $G \subseteq P(Z)/I$ is generic, $j : V \to M \subseteq V[G]$ is the generic ultrapower and $\mathrm{crit}(j) = \kappa$, then $M^\kappa \cap V[G] \subseteq M$.*

Proof. To see that I is precipitous, we use Proposition 2.7. Let $\{\mathcal{A}_n : n \in \omega\}$ be a tree of maximal antichains below some $S \in I^+$.

Using the disjointing property we can proceed by induction on n to refine each element B of $\mathcal{A}_n$ to a B' such that

1. $B' \subseteq B$,
2. $B' \sim_I B$,
3. for each $A \in \mathcal{A}_{n-1}$, B' is either disjoint from A' or included in A', and
4. $\{B' : B \in \mathcal{A}_n\}$ is pairwise disjoint.

We thus assume our original sequence of $\mathcal{A}_n$'s have this property.

Since each $\mathcal{A}_n$ is a maximal antichain, every $\bigcup \mathcal{A}_n$ is in the dual of $I \restriction S$. Hence, by the countable completeness of I, $\bigcap_n \bigcup \mathcal{A}_n$ is in the dual of $I \restriction S$. Let $z \in \bigcap_n \bigcup \mathcal{A}_n$. Then for each n there is a unique B'_n in $\mathcal{A}_n$ such that $z \in B'_n$. Then $\langle B'_n : n \in \omega \rangle$ is a branch through the tree with $z \in \bigcap B'_n$.

To establish the second part of the proposition, it suffices to see that if $S = \langle x_\alpha : \alpha < \kappa \rangle \subseteq M$ is a subset of M that lies in $V[G]$, then $S \in M$. Let $\dot{S} = \langle \dot{x}_\alpha : \alpha < \kappa \rangle$ be a $\mathbb{B}$-term for such an S. Let $[Y] \in G$ with

$[Y] \Vdash \mathrm{crit}(j) = \kappa$. By Proposition 2.12, there is a $k : Z \to V$ such that $k \in V$ and $[Y] \Vdash [k]^M = \kappa$.

Again, by Proposition 2.12, we can find $\langle g_\alpha : \alpha < \kappa\rangle$ with $g_\alpha : Z \to V$ such that for all generic G, $[g_\alpha]^M = \dot{x}_\alpha^{V[G]}$. Define $g : Z \to V$ by setting $g(z) = \langle g_\alpha(z) : \alpha < k(z)\rangle$. Then $[g]^M = \dot{S}^{V[G]}$. ⊣

As an illustration of a technique, we now prove the following result due to Tarski [117].

2.15 Theorem. *Suppose that I is a κ-complete, κ^+-saturated ideal on κ. Then $P(\kappa)/I$ is a complete Boolean algebra.*

Proof. To establish completeness it suffices to show that for every antichain $\mathcal{A}$ there is a least upper bound $\Sigma\mathcal{A}$ for $\mathcal{A}$.

By the disjointing property, there is a function $f : \kappa \to \kappa$ such that for all generic $G \subseteq P(\kappa)/I$, if $j : V \to M \subseteq V[G]$ is the generic embedding then $[f]^M = \kappa$. If $\mathcal{A} = \{a_\alpha : \alpha < \kappa\}$ is an antichain, we choose representatives A_α of a_α. We can assume that $A_\alpha \cap \{\beta : f(\beta) \leq \alpha\} = \emptyset$. Define the "$f$-diagonal union" to be $A = \{\beta : \text{for some } \alpha < f(\beta),\ \beta \in A_\alpha\}$.

We claim that the f-diagonal union is the Boolean sum of $\mathcal{A}$. It is clear that $A \geq_I A_\alpha$, for all $\alpha < \kappa$. Suppose that $B \subseteq \kappa$ is above every A_α, but $A \setminus B \notin I$. Let G be generic with $A \setminus B \in G$. Let $j(\{A_\alpha : \alpha < \kappa\}) = \{A^j_\alpha : \alpha < j(\kappa)\}$. Then $[\mathrm{id}]^M \in j(A \setminus B)$. Hence $M \models$ "there is an $\alpha < j(f)([\mathrm{id}]^M)$ so that $[\mathrm{id}]^M \in A^j_\alpha$". Since $j(f)([\mathrm{id}]^M) = \kappa$, there is an $\alpha < \kappa$, $[\mathrm{id}]^M \in A^j_\alpha$. Hence there is an $\alpha < \kappa$ such that $A_\alpha \in G$. But $B \notin G$ and hence $B \not\geq A_\alpha$. ⊣

The more general fact has an easier proof:

2.16 Theorem. *Suppose that $I \subseteq P(Z)$ is an ideal that has the disjointing property. Then $P(Z)/I$ is a complete Boolean algebra.*

Proof. Let κ be the minimal cardinality of a set $\mathcal{B} \subseteq P(Z)/I$ for which ΣB does not exist. Enumerating $\mathcal{B}$ as $\langle b_\alpha : \alpha < \kappa\rangle$ and applying induction we can replace each b_α by $a_\alpha = b_\alpha \setminus \Sigma_{\beta<\alpha} b_\beta$. Then $\mathcal{A} = \{a_\alpha : \alpha < \kappa \text{ and } a_\alpha = [A]$ for an $A \notin I\}$ is an antichain with $\Sigma\mathcal{A} = \Sigma\mathcal{B}$, if either sum exists.

Choose a $\mathcal{C} \subseteq P(Z)/I$ so that $\mathcal{A} \cup \mathcal{C}$ forms a maximal antichain. Choose a pairwise disjoint system of representatives for elements of $\mathcal{A} \cup \mathcal{C}$, $\{A_\alpha : \alpha < \kappa\} \cup \{C_\delta : \delta < \gamma\}$. Let $A = \bigcup_{\alpha<\kappa} A_\alpha$. We claim that $[A]_I = \Sigma\mathcal{A}$.

If not, there is a set U such that $A_\alpha \subseteq_I U$ for all $\alpha < \kappa$ and such that $A \setminus U \notin I$. Since $A \setminus U \notin I$ there is either an α such that $(A \setminus U) \cap A_\alpha \notin I$ or a δ such that $(A \setminus U) \cap C_\delta \notin I$. The former is impossible because $A_\alpha \subseteq_I U$ and the latter is impossible since $A \cap C_\delta = \emptyset$ for all $\delta < \gamma$. ⊣

2.4. Normal Ideals

If we add more structure to Z, we can achieve the disjointing property by a generalization of Proposition 2.9. If we assume that $Z \subseteq P(X)$ for some set X, we can define the notion of a *normal* ideal on Z.

2.17 Definition. If $A \subseteq P(X)$ for some set X and $f : A \to X$, then f is *regressive* iff for all $a \in A$, $f(a) \in a$. Let I be an ideal on Z, where $Z \subseteq P(X)$ for some set X.[3] Then I is *normal* iff for every set $A \in I^+$ and every regressive function $f : A \to X$, there is an I-positive set $B \subseteq A$ and an $x \in X$ such that for all $a \in B$, $f(a) = x$. An ideal is *fine* iff for every $x \in X$, $\{z \in Z : x \in z\} \in \breve{I}$.

We will give several examples of such ideals in the next section. "Most" natural ideals are normal and fine. We will often relativize the notion of normality to an inner model of set theory. For example, for such a model W if $X, Z \in W$ and I is an ideal on Z, then we will say that I is W*-normal* iff for all $A \in W \cap P(Z)$ not in I and all regressive functions $f : A \to X$ lying in W, there is an I-positive set $B \subseteq A$ on which f is constant. Note that if such a B exists we can assume $B \in W$. Similarly, I will be said to be κ*-complete for* W iff whenever $\beta < \kappa$ and $\{A_\alpha : \alpha < \beta\} \subseteq I$ and $\{A_\alpha : \alpha < \beta\} \in W$, we have $\bigcup\{A_\alpha : \alpha < \beta\} \in I$.

There is a closely related definition:

2.18 Definition. Let $\mathcal{A} = \langle A_x : x \in X\rangle$ be a sequence of subsets of $Z \subseteq P(X)$. Then the *diagonal union* of $\mathcal{A}$, denoted $\triangledown\mathcal{A}$, is defined to be $\{z \in Z :$ for some $x \in z,\ z \in A_x\}$. The *diagonal intersection* of $\mathcal{A}$, denoted $\Delta\mathcal{A}$, is $\{z \in Z :$ for all $x \in z,\ z \in A_x\}$.

The next proposition is standard:

2.19 Proposition. *Let X be a set and I an ideal on $Z \subseteq P(X)$. Then:*

1. *I is normal iff I is closed under diagonal unions iff the filter dual to I is closed under diagonal intersections.*

2. *If $\kappa \subseteq X$ and I is a normal, fine ideal, then I is κ-complete iff for each $\alpha < \kappa$, $\{z : \alpha \not\subseteq z\} \in I$. Moreover, in this case $\{z : z \cap \kappa \notin \kappa + 1\} \in I$.*

If I is a normal, fine, countably complete ideal on $Z \subseteq P(X)$ and $f : X \to X$ is a function then almost every $z \in Z$ is closed under f. For if there were a positive set $A \subseteq Z$ of z that are not closed under f, then we could define a regressive function g on A by setting $g(z) = x$ for some $x \in z$ for which $f(x) \notin z$. This function would have to be constant on an I-positive subset $B \subseteq A$, say with value x_0. Let $y = f(x_0)$. By fineness, $\hat{y} = \{z : y \in z\} \in \breve{I}$. Hence $\hat{y} \cap B \neq \emptyset$, a contradiction.

Using the countable completeness of the ideal one can extend this to functions of several variables and to countable collections of functions. Thus we get:

2.20 Proposition. *Suppose that I is a normal, fine, countably complete ideal on $Z \subseteq P(X)$ and $\{f_i : i \in \omega\}$ is a countable sequence of functions where $f_i : X^{n_i} \to X$. Then $\{z \in Z :$ for all $i,\ z$ is closed under $f_i\} \in \breve{I}$.*

[3] So $I \subseteq P(Z) \subseteq P(P(X))$.

At first glance it may appear as though $\triangledown\{a_x : x \in X\}$ depends on the indexing of $\langle a_x : x \in X\rangle$. However, modulo a normal ideal I any two indexings give the same element of $P(Z)/I$. By Proposition 2.20 if $f : X \to X$ is a bijection, then $\{z \in Z : z$ is closed under $f, f^{-1}\} \in \breve{I}$. Hence:

2.21 Proposition. *Let I be a normal, fine ideal on $Z \subseteq P(X)$ and $\mathcal{A} = \langle a_x : x \in X\rangle$. Suppose that $f : X \to X$ is a bijection. Let $D = \{z :$ for some $x \in z,\ z \in a_{f(x)}\}$. Then $[D]_I = [\triangledown\mathcal{A}]_I$.*

Under the same assumptions on I, let $\langle v_x : x \in X\rangle$ be a one-to-one enumeration of the finite sequences of elements of X. By Proposition 2.20 $\{z \in Z : \{v_x : x \in z\}$ is an enumeration of the finite sequences of elements of $z\}$ belongs to $\breve{I}$. If we have a collection of sets $\mathcal{A} = \langle A_{\vec{x}} : \vec{x} \in X^{<\omega}\rangle \subseteq I$, we can use the enumeration $\langle v_x : x \in X\rangle$ to index $\mathcal{A}$ by elements of X. Since for typical z the enumeration restricted to z gives all finite sequences from z, we see that $\{z :$ for some $\vec{x} \in z^{<\omega},\ z \in A_{\vec{x}}\} \in I$.

Thus, for example, if $\mathcal{A} = \langle A_{x,y} : x, y \in X\rangle \subseteq I$ then the "diagonal union", $\{z :$ for some $x, y \in z,\ z \in A_{x,y}\}$, belongs to I. Dually, the "diagonal intersection" of a collection of sets $\{C_{x,y} : x, y \in X\} \subseteq \breve{I}$ defined as $\{z :$ for all $x, y \in z$, $z \in C_{x,y}\} \in \breve{I}$.

In the interplay between the forcing and combinatorial properties of the Boolean algebra it is very convenient to be able to compute Boolean sums. For example, the Boolean value of an infinite disjunction is the sum of the Boolean values of the disjuncts. For quotients by normal ideals, this has an elegant formulation.

2.22 Proposition. *Suppose that $Z \subseteq P(X)$ and I is a normal, fine ideal on Z. Suppose that $A = \{[a_x] : x \in X\} \subseteq P(Z)/I$. Then*

$$\Sigma A = [\triangledown\{a_x : x \in X\}]_I$$

in the Boolean algebra $P(Z)/I$.

Proof. Let $[a_x] \in A$, then $\hat{x} =_{\text{def}} \{z : x \in z\} \in \breve{I}$, and $a_x \cap \hat{x} \subseteq \triangledown\{a_x : x \in X\}$ so $a_x \leq_I \triangledown\{a_x : x \in X\}$. For the other direction, it suffices to show that if $b \leq_I \triangledown\{a_x : x \in X\}$ and b is not in I, then there is an $x \in X$ such that $b \cap a_x \notin I$. Without loss of generality we can assume that $b \subseteq \triangledown\{a_x : x \in X\}$. For each $z \in b$ there is an $x(z) \in z$ such that $z \in a_{x(z)}$. So the map from b to X defined by $z \mapsto x(z)$ is regressive. Hence there is a positive set $b' \subseteq b$ and a fixed x such that for all $z \in b'$, $x(z) = x$. But then $b' \subseteq a_x$ as desired. $\dashv$

Normal ideals frequently have the disjointing property.

2.23 Proposition. *Suppose that $Z \subseteq P(X)$ and I is a normal, fine ideal on Z. Then:*

1. *I is $|X|^+$-saturated implies that,*
2. *I has the disjointing property, which in turn implies that,*

3. I is $|Z|^+$-saturated.

Proof. Assume that I is $|X|^+$-saturated. Suppose that $\mathcal{A} \subseteq P(Z)/I$ is an antichain. Then we can index a collection of representatives of elements of $\mathcal{A}$ by elements of X, i.e. for some $X' \subseteq X$, $\mathcal{A} = \{[A_x] : x \in X'\}$. Since I is fine, we can assume that for all $x \in X'$ and all $z \in A_x$, $x \in z$.

For each pair x, y of distinct elements of X' there is a set $C_{x,y}$ in $\breve{I}$, such that $A_x \cap A_y \cap C_{x,y} = \emptyset$. Let $C = \Delta C_{x,y}$. Then for all $x, y \in X'$, $A_x \cap A_y \cap C = \emptyset$. We get a sequence of disjoint representatives by taking $A'_x = A_x \cap C$.

The second implication is immediate. ⊣

Thus we see:

2.24 Theorem. *Suppose that I is a normal, fine $|X|^+$-saturated ideal on $Z \subseteq P(X)$. Then $P(Z)/I$ is a complete Boolean algebra. Given any set $\mathcal{A} \subseteq P(Z)/I$ there is a subset $\mathcal{B} \subseteq \mathcal{A}$ having cardinality at most $|X|$ such that $\Sigma\mathcal{B} = \Sigma\mathcal{A}$. The join of a collection of elements of $P(Z)/I$ of size at most $|X|$ is given by its diagonal union and the meet is given by diagonal intersection.*

We remark that the completeness of the Boolean algebra $P(Z)/I$ is quite convenient. It implies that for each term τ in the forcing language and each formula ϕ there is a set $b \subseteq Z$ such that for all generic $G \subseteq P(Z)/I$ we have $[b] \in G$ iff $V[G] \models \phi(\tau)$. We will refer to the set b as the *Boolean value* of $\phi(\tau)$.

Normal, fine ideals that have the disjointing property have generic ultrapowers with strong closure properties.

2.25 Theorem. *Suppose that I is a normal, fine, precipitous*[4] *ideal on $Z \subseteq P(X)$, where $|X| = \lambda$. Let $G \subseteq P(Z)/I$ be generic, and M the generic ultrapower of V by G. Then $P(\lambda) \cap V \subseteq M$. Further, if I has the disjointing property, then $M^\lambda \cap V[G] \subseteq M$.*

Proof. Note that without loss of generality $X = \lambda$. Consider the generic embedding $j : V \to M$.

2.26 Claim. *Let I be a normal, fine ideal on $Z \subseteq P(X)$.*[5] *Let G be generic for $P(Z)/I$ and $M = V^Z/G$. Then the identity function* $\mathrm{id} : Z \to Z$ *represents the j-image of λ, which we denote by $j``\lambda$.*

Proof. By fineness, for all $\alpha \in \lambda$, $\{z : \alpha \in z\} \in \breve{I}$. Thus $j``\lambda \subseteq^M [\mathrm{id}]^M$. By normality, together with a density argument, if $f \in V$ and $R = \{z : f(z) \in z\} \in I^+$ then the collection of $W \subseteq Z$ such that f is constant on W is dense below R. Hence if $f \in V$ and $[f]^M \in^M [\mathrm{id}]^M$, there is a $W \in G$ on which f has some constant value α. Hence $[f]^M = j(\alpha)$. ⊣

[4] Using Proposition 2.34, we can weaken the assumption that I is precipitous to I being countably complete.

[5] In this claim we do not assume that I is precipitous.

Suppose that $A \subseteq \lambda$. Since j is an elementary embedding, the function $f_A(z) = A \cap z$ represents $j(A) \cap j``\lambda$. Hence, $M$ contains both $j``\lambda$ and $j(A) \cap j``\lambda$, from which $M$ can easily decode $A$ as the image of $j(A) \cap j``\lambda$ under the canonical isomorphism between $j``\lambda$ and λ, i.e. j^{-1}.

Now suppose that I has the disjointing property. Let $\dot{A} = \langle \dot{a}_\alpha : \alpha < \lambda \rangle$ be a term for a λ-sequence of elements of M. By the disjointing property, there is a sequence of functions $\mathcal{G} = \langle g_\alpha : \alpha < \lambda \rangle$ such that for all generic $G \subseteq \mathbb{B}$, $[g_\alpha]^M = \dot{a}_\alpha^G$. Denote $j(\mathcal{G})$ by $\langle j(g)_\alpha : \alpha < j(\lambda) \rangle$.

Define a function $g : Z \to V$ by setting $g(z) = \langle g_\alpha(z) : \alpha \in z \rangle$. Then by Lemma 2.3, $[g]^M = j(g)(j``\lambda) = \langle j(g)_\beta(j``\lambda) : \beta \in j``\lambda \rangle$. Hence the function that sends $\alpha$ to $j(g_\alpha)(j``\lambda)$ (for $\alpha < \lambda$) lies in M and gives the realization of the sequence $\dot{A}^G$. ⊣

2.27 Remark. From Claim 2.26, it is easy to see that for $\alpha < \lambda$, the function $f(z) = \mathrm{ot}(z \cap \alpha)$ represents α in every transitive $M \cong V^Z/G$.

Weak Normality

We now discuss a variant of normality that is useful in considering non-regular ultrafilters among other topics.

2.28 Definition. Suppose that I is an ideal on $Z \subseteq P(\lambda)$. Then I is *weakly normal* iff for any regressive function $f : Z \to \lambda$ there is an $\alpha < \lambda$ such that $\{z \in Z : f(z) < \alpha\} \in \breve{I}$.

2.29 Proposition. *Let λ be a regular cardinal. Suppose that I is a normal, λ-saturated ideal on $Z \subseteq P(\lambda)$. Then I is weakly normal.*

Proof. Let f be a regressive function defined on Z. Then there is a maximal antichain $\mathcal{A} \subseteq P(Z)/I$ such that for all $a \in \mathcal{A}$, f is constant on a. By saturation $|\mathcal{A}| < \lambda$, and hence there is a $\beta < \lambda$ such that f is bounded by β on a set in $\breve{I}$. ⊣

2.5. More General Facts

We now establish a limitation on the closure of M, which is a standard fact in the case of ordinary ultrapowers:

2.30 Proposition. *Suppose that I is a proper non-principal ideal on $Z \subseteq P(X)$. Let $j : (V, \in) \to (V^Z/G, E)$ be the elementary embedding induced by a generic $G \subseteq P(Z)/I$. Then there is no $A \in V^Z/G$ such that for all $a \in V^Z/G$, $a \, E \, A$ iff $a = j(\beta)$ for some $\beta < (|Z|^+)^V$.*

Note that in the case that V^Z/G is well-founded and M is the transitive collapse this is saying that $j``|Z|^+ \notin M$.

Proof. Suppose not. Let $a \Vdash [f]^{V^Z/G} = A$. Let $L = \{z \in a : |f(z)| > |Z|\}$ and $S = \{z \in a : |f(z)| \leq |Z|\}$. Then $|\bigcup_{z \in S} f(z)| \leq |Z|$, so we can find an ordinal $\alpha \in |Z|^+$ such that $\alpha \notin \bigcup_{z\in S} f(z)$. Let $g : a \to |Z|^+$ be defined so that:

1. $g(z) = \alpha$ when $z \in S$, and
2. g is an injective function on L with $g(z) \in f(z)$ for all $z \in L$.

This is possible since $|f(z)| > |Z|$ for $z \in L$.

Suppose that $S \in G$. Then $j(\alpha)$ is not in the E relation with $[f]^{V^Z/G}$. If $L \in G$, then $[g]^{V^Z/G}\, E\, [f]^{V^Z/G}$, but $[g]^{V^Z/G} \neq j(\beta)$ for any $\beta \in |Z|^+$. $\dashv$

The properties of the forcing used to create a generic elementary embedding interact with the behavior of that embedding on the ordinals. We illustrate this by discussing continuity points of embeddings, where an ordinal δ is called a *continuity point* of j iff $\sup(j``\delta) = j(\delta)$.

We borrow a fact from the study of Chang's Conjecture:

2.31 Proposition. *Suppose that $j : W \to W'$ is an elementary embedding with critical point κ and that W and W' are models of a sufficiently large fragment of* ZFC*. Then:*

1. *An ordinal δ is a continuity point of j iff $\mathrm{cf}(\delta)^W$ is a continuity point of j,*
2. *every ordinal δ with W-cofinality less than κ is a continuity point of j,*
3. *if $\eta < \kappa$ is regular, $\mathrm{Cof}(\eta)^W \cap \lambda = \mathrm{Cof}(\eta)^{W'} \cap \lambda$, and $j``\delta \in W'$ for all $\delta < \lambda$ then $j``\lambda$ is η-closed, in particular,*
4. *if*
   - *(a) $\eta < \kappa$ is regular,*
   - *(b) $Z \subseteq P(\lambda)$ and $I \in W$ is a normal ideal on Z,*
   - *(c) $W' \cong W^Z/G$ for a W-generic ultrafilter $G \subseteq P(Z)/I$ and j is the ultrapower embedding,*
   - *(d) $\mathrm{Cof}(\eta)^W \cap \lambda = \mathrm{Cof}(\eta)^{W'} \cap \lambda$, and*
   - *(e) $(W')^\eta \cap W[G] \subseteq W'$,*

   then $j``\lambda$ is η-closed in $W[G]$.

Proof. Suppose that δ has cofinality η in W. Let $\langle \delta_i : i \in \eta\rangle \in W$ be an increasing cofinal sequence in δ. Since $j(\langle \delta_i : i \in \eta\rangle)$ is an increasing cofinal sequence in $j(\delta)$ of length $j(\eta)$ the following are equivalent:

a. δ is a continuity point of j,

b. $\langle j(\delta)_{j(i)} : i \in \eta\rangle$ is cofinal in $j(\delta)$,

c. $\langle j(i) : i \in \eta\rangle$ is cofinal in $j(\eta)$, and

d. η is a continuity point of j.

If $W \models \mathrm{cf}(\delta) = \eta$ and $\eta < \kappa$, then $j \restriction \eta$ is the identity map and hence $j(\langle \delta_i : i \in \eta \rangle) = \langle j(\delta)_i : i \in \eta \rangle$. Hence $\langle j(\delta)_i : i \in \eta \rangle$ is cofinal in $j(\delta)$ and δ is a continuity point.

Supposing the hypotheses of clause 3 we show that $j``\lambda$ is $\eta$-closed. If not, a counterexample is an ordinal $\alpha$ that is a limit point of $j``\lambda$, $\alpha \notin j``\lambda$ and $W' \models \mathrm{cf}(\alpha) = \eta$. Let $\delta$ be the least element of $\lambda$ such that $j(\delta) > \alpha$. Then $j``\delta \cup P(\delta)^W \subseteq W'$ and, moreover, $\{j``\delta\}$ is cofinal in α. Hence if $\mu = \mathrm{cf}(\delta)^W$, then $\mathrm{cf}(\mu)^{W'} = \eta$. Since W and W' agree about which ordinals have cofinality η, we must have $\mu = \eta$. But then δ must be a continuity point by clause 2, a contradiction.

Clause 4 is immediate from the other clauses, since it implies that $\mathrm{cf}(\eta)$ is absolute between W' and $W[G]$. ⊣

We have a converse to Proposition 2.31:

2.32 Proposition. *Suppose that $j : V \to M \subseteq V[G]$ is a generic elementary embedding with critical point κ, $j``\lambda$ is η-closed (as a class of ordinals) in $V[G]$ and $M^\eta \cap V[G] \subseteq M$. Then for all ordinals $\alpha < \lambda$, $V \models \mathrm{cf}(\alpha) = \eta$ iff $V[G] \models \mathrm{cf}(\alpha) = \eta$.*

Proof. Let μ be the least counterexample. Then μ must be a regular cardinal, since otherwise the cofinality of $\mathrm{cf}(\mu)^V$ is a smaller counterexample. Thus $M \models$ "$j(\mu)$ is regular". But μ is a continuity point of j by the hypothesis that $j``\lambda$ is η-closed. Thus $\mathrm{cf}(j(\mu))^{V[G]} = \mathrm{cf}(\mu)^{V[G]} = \eta$. Hence $M \models$ "$\mathrm{cf}(j(\mu)) = \eta$" and so $j(\mu) = \eta$. But $\eta < \mu$, a contradiction. ⊣

2.6. Canonical Functions

An important technical tool in studying normal ideals is the sequence of canonical functions: a sequence of canonical representatives for the ordinals less than λ^+ in the generic ultrapower with respect to any countably complete normal ideal I on $Z \subseteq P(\lambda)$.

We define $\langle f_\alpha : \alpha < \lambda^+ \rangle$ by induction on α. For $\alpha < \lambda$, we let

$$f_\alpha(z) = \mathrm{ot}(z \cap \alpha).$$

Suppose that we have defined $f_{\alpha'}$ for $\alpha' < \alpha$. Let $g : \lambda \to \alpha$ be a bijection. Define

$$f_\alpha(z) = \sup\{f_{g(\eta)}(z) + 1 : \eta \in z\}.$$

If g_1, g_2 are two bijections between λ and α, then the collection of z such that $\{g_1(\eta) : \eta \in z\} = \{g_2(\eta) : \eta \in z\}$[6] belongs to the dual of any normal ideal. As a consequence, modulo every normal ideal, the definition of f_α is independent of the choice of g.

[6] Using Proposition 2.20 one can prove that this set is closed and unbounded, in the sense of Example 3.2.

2.33 Definition. The functions $\langle f_\alpha : \alpha < \lambda^+ \rangle$ are called the *canonical functions* for normal ideals on Z.

This definition is slightly misleading as the canonical functions are only well-defined modulo the nonstationary ideal.

2.34 Proposition. *Suppose that $\lambda = |X|$. Let I be a normal, fine, countably complete ideal on $Z \subseteq P(X)$. Let G be generic for $P(Z)/I$. Then the well-founded part of the ordinals in V^Z/G includes $(\lambda^+)^V$ and for each $\alpha \in \lambda^+$, $[f_\alpha]^G = \alpha$.*

Proof. Without loss of generality we can assume that $X = \lambda$. As in Claim 2.26, we see that if $i : V \to V^Z/G$ is the generic embedding, then $[\mathrm{id}]^G = i``\lambda$. Hence V^Z/G is a model of ZFC with a well-founded set of order type λ. This implies that the ordinals of V^Z/G are well-founded up to λ. To see that the well-founded part of V^Z/G includes λ^+ we need to look more closely.

Let $\langle f_\alpha : \alpha < \lambda^+ \rangle$ be a sequence of canonical functions. Then:

1. for $\alpha < \alpha', \{z \in P(\lambda) : f_\alpha(z) < f_{\alpha'}(z)\} \in \breve{I}$,
2. for any normal, countably complete ideal I and $\alpha < \lambda^+$, if $h(z) < f_\alpha(z)$ for all z in a set $A \in I^+$, then there is a dense collection of $B \subseteq_I A$ such that there is an $\alpha(B) < \alpha$ with $h(z) = f_{\alpha(B)}(z)$ for all $z \in B$.

Hence for a generic G, $\{[f_\alpha]^G : \alpha < \lambda^+\}$ form a well-ordered initial segment of the V^Z/G ordinals that has order type λ^+. ⊣

A fact slightly stronger than Proposition 2.34 is true: if $N \subseteq V$ and I is a fine ideal on $P(\lambda)^N$ that lies in V that is normal and countably complete for sequences of sets that lie in N, then for all generic $G \subseteq P(\lambda)^N/I$ and all $\alpha < (\lambda^+)^N$, $[f_\alpha]^G = \alpha$.

The next example is well-known.

2.35 Example. Let M be a well-founded model of $V = L$ and suppose that $G \subseteq (P(\omega_1)/\mathrm{NS}_{\omega_1})^M$ is generic over M. Let N be the generic ultrapower of M by G. By Proposition 2.34, N is well-founded to ω_2^M. Moreover, if $\alpha = \omega_1^M$, $N \models$ "α is countable". Hence there is an $x \in N$ such that $N \models$ "x is the least countable ordinal such that there is a subset of ω constructed at stage x that codes a bijection between α and ω". Clearly x must be bigger than the first ω_2^M many ordinals of N.

Define $f : \omega_1 \to \omega_1$ in M, by setting $f(\alpha)$ to be the least β such that there is a subset of ω in $L^M_{\beta+1}$ that codes a bijection between α and ω. Then $x = [f]_G > [f_\delta]_G$ for any canonical function f_δ, where $\delta < \omega_2^M$. Since G is arbitrary we see that for all $\delta < \omega_2^M, \{\alpha : f(\alpha) > f_\delta(\alpha)\}$ contains a closed unbounded set.

The consistency strength of having the canonical functions from ω_1 to ω_1 bound every function from ω_1 to ω_1 is exactly an inaccessible limit of measurable cardinals: Larson and Shelah [81] showed that from a model with an inaccessible limit of measurable cardinals one can force a model of CH such that every function from ω_1 to ω_1 is bounded by a canonical function. Deiser and Donder [20] showed that if every function is bounded by a canonical function, then ω_2 is an inaccessible limit of measurable cardinals in an inner model of set theory.

2.7. Selectivity

The following definition comes from Baumgartner, Taylor and Wagon [9], where the notions of *selective, P-* and *Q*-ideals are explored in detail. In particular they showed that if $2^{\omega_1} = \omega_2$ and the nonstationary ideal on ω_1 is $\aleph_2$-saturated, then an ideal on a cardinal κ is selective iff it is isomorphic to a normal ideal on κ. One direction of this is shown below.

2.36 Definition. Let I be an ideal on κ. Then I is *selective* iff whenever $f : \kappa \to V$ is a function that is not constant on any I-positive set, then there is a set $A' \in \breve{I}$ such that f is one-to-one on A'.

2.37 Lemma. *Suppose that $j : N \to M$ is an elementary embedding with critical point δ, where M is a model of* ZF$^-$ *(*ZF *minus Power Set) that is well-founded to $\delta + 1$. Suppose that $f \in N$ is a function with domain $A \subseteq \delta$ such that $\delta \in j(A)$. Then either:*

1. *there is an $c \in N$ such that $\delta \in j(\{\alpha : f(\alpha) = c\})$, or*
2. *there is an $A' \subseteq A$ with $A' \in N$ such that $\delta \in j(A')$ and f is one-to-one on A'.*

Moreover, if I is a normal ideal on a cardinal κ, then I is selective.

Proof. Define $g : A \to A$ by setting $g(\alpha) = \min\{\beta : f(\beta) = f(\alpha)\}$. Then $g \in N$. Let $A' = \{\alpha : g(\alpha) = \alpha\}$. If $\delta \notin j(A')$, let $\beta = j(g)(\delta)$. Then $\beta < \delta$ and $c = f(\beta)$ belongs to N. Moreover $j(f)(\delta) = j(f)(\beta) = j(c)$, and so $\delta \in j(\{\alpha : f(\alpha) = c\})$.

Suppose that I is a normal ideal on κ. Given an $f : \kappa \to V$, define g and A' as in the previous paragraph. If $A' \notin \breve{I}$, then g is a regressive function on the I-positive set $\kappa \setminus A'$. By normality, g is constant on an I-positive set. ⊣

The notions in [9] have not been explored on normal, fine ideals on $Z \subseteq P(X)$ other than κ-complete ideals on $Z = \kappa$. In particular, the analogue of Lemma 2.37 is not immediately clear. We ask the general question: what one can say about P-, Q- and selective ideals on $[\lambda]^{<\kappa}$ or $[\lambda]^{\kappa}$?

2.8. Ideals and Reflection

The utility of ideals lies largely in their ability to capture many of the reflection properties of large cardinals, with the additional advantage that they can "live" on relatively small sets such as ω_1 or $\mathbb{R}$. This will be a recurring theme in this chapter; we mention here only the basic idea for deducing such reflection.

Let I be an ideal and $j : V \to V^Z/G$ be the canonical elementary embedding. We can view the generic ultrapower V^Z/G as having an *ideal element*, namely the element $i = [\mathrm{id}]^G$, where again $\mathrm{id} : Z \to Z$ is the identity function. This element is handy in relating the elementary embedding j to the ultrapower. For example, Lemma 2.3 shows that $[f] = j(f)(i)$ and that for every $Y \subseteq Z$, $Y \in G$ iff $i\, E\, j(Y)$, where again E is the ultrapower of the $\in$ relation in the possibly ill-founded generic ultrapower.

As a consequence of Łoś's Theorem, the properties of the ideal element i are reflected to the sets that the ideal I concentrates on. Explicitly, suppose that $\phi(x, y)$ is a formula in the language of set theory, and $X \subseteq Z$ is such that $[X]_I \Vdash$ "$V^Z/G \models \phi(i, j(\check{a}))$"; then for almost every $z \in X$, $V \models \phi(z, a)$.

Hence, for example, if $A \in P(Z)/I$ forces that $i \in [j(\lambda)]^{<j(\kappa)}$, the ideal $I{\restriction}A$ can be taken to be an ideal on $[\lambda]^{<\kappa}$. Similarly if $A \Vdash i \in [j(\lambda)]^{j(\kappa)}$, then $I{\restriction}A$ can be taken to be an ideal on $[\lambda]^{\kappa}$.

To put this in better focus, suppose that I is a normal, fine, κ-complete precipitous ideal on a cardinal κ. Then the ideal element represents κ in the generic ultrapower. If the ideal concentrates on ordinals α that are regular cardinals, then κ is regular in M. Otherwise, by normality, there will be a set $Y \in G$ consisting of ordinals of a fixed cofinality $\gamma < \kappa$. Then $j(\gamma) = \gamma$ and hence $M \models \mathrm{cf}(\kappa) = \gamma$.

As another example of this technique, suppose that $Z = [\lambda]^{<\kappa}$ and I is a normal, fine, precipitous ideal on Z. We know that i represents $j``\lambda$ in $M$. If $\eta < \lambda$, $\mu < \kappa$ and $I$ concentrates on $\{z : \mathrm{ot}(z \cap \eta) = \mu\}$, then we know that $M \models \mathrm{ot}(i \cap j(\eta)) = j(\mu)$. Since $i = j``\lambda$, the order type of $i \cap j(\eta)$ is η. Hence $j(\mu) = \eta$. Similar remarks can be made using inequalities. For example, if I concentrates on the collection of z where the order type of $z \cap \eta$ is less than μ, then $j(\mu) > \eta$.

We now illustrate this by giving a reflection argument that we will use later:

2.38 Lemma. *Suppose that I is a normal, fine, precipitous ideal on $[\lambda]^{<\kappa}$. Let $G \subseteq P([\lambda]^{<\kappa})/I$ be generic.*

1. *Let μ and ν be less than κ and A be the collection of $z \in [\lambda]^{<\kappa}$ such that*

   (a) $z \cap \kappa \in \kappa$,

   (b) $|z| = |z \cap \kappa|$,

   (c) $\mathrm{cf}(z \cap \kappa) = \mu$, *and*

   (d) $\mathrm{cf}(\sup(z)) = \nu$.

   If $A \in G$ then in M, μ and ν are regular cardinals, $|\lambda| = |\kappa|$, $\mathrm{cf}(\kappa) = \mu$ and $\mathrm{cf}(\lambda) = \nu$.

2. Let $\kappa = \rho^+$ and B be the collection of $z \in [\lambda]^{<\kappa}$ such that

(a) $z \cap \kappa \in \kappa$,

(b) $|z| = |z \cap \kappa|$, and

(c) $\mathrm{cf}(z \cap \kappa) = \mathrm{cf}(\sup(z)) \neq \mathrm{cf}(\rho)$.

If $B \in G$, then in M, ρ and $\mathrm{cf}(\rho)$ are preserved and $|\lambda| = |\kappa| = \rho$, $\mathrm{cf}(\lambda) = \mathrm{cf}(\kappa)$ and $\mathrm{cf}(\lambda) \neq \mathrm{cf}(\rho)$.

Moreover, were I to be λ^+-saturated, then we can draw the same conclusions about $V[G]$ as we did about M.

Proof. Let $j : V \to M$ be the generic ultrapower. By Theorem 2.25, $j``\lambda \in M$, $P(\lambda)^V \subseteq M$ and if $I$ is $\lambda^+$-saturated, $M^\lambda \cap V[G] \subseteq M$. Hence all cardinals and cofinalities below $\kappa$ are preserved between $V$ and $M$. Moreover, $[\mathrm{id}]^M = j``\lambda$.

We can now see that the critical point of j is κ. To see that it is at least κ we note that for each $\beta < \kappa, \{z : \beta \in z\} \in G$. Hence, by assumption, $\{z : \beta + 1 \subseteq z\} \in G$. By the elementarity of j, $j(\beta + 1) \subseteq j``\lambda$. But then the critical point of $j$ must be at least $j(\beta + 1)$ which is greater than or equal to $\beta + 1$. If the critical point of $j$ is bigger than $\kappa$, then $\kappa + 1 \subseteq j``\lambda$. Since $j\restriction(\kappa + 1)$ is the identity, $\{z : \kappa + 1 \subseteq z\} \in G$. But this contradicts the assumption that $\{z : z \cap \kappa \in \kappa\} \in G$.

If $A \in G$, using Łoś's Theorem we see that in M, $\mathrm{cf}(j``\lambda \cap j(\kappa)) = \mu$. Since $j``\lambda \cap j(\kappa) = \kappa$, $\mathrm{cf}(\kappa) = \mu$. Finally, another application of Łoś's Theorem implies that $\mathrm{cf}(\sup(j``\lambda)) = \nu$. Since $\mathrm{cf}(\sup(j``\lambda)) = \mathrm{cf}(\lambda)$, $\mathrm{cf}(\lambda) = \nu$.

If $B \in G$, $|j``\lambda| = |j``\lambda \cap j(\kappa)| = |\kappa|$. Since $\kappa = \rho^+$ in V and is moved by j, we must have $|\kappa|^M = \rho$. On the other hand $\mathrm{cf}(\lambda)^M = \mathrm{cf}(j``\lambda)^M \neq \mathrm{cf}(\rho)$.

If I is λ^+-saturated, then the closure of M implies that these statements also hold in $V[G]$. $\dashv$

From examining in detail the order properties of the sets in a typical element of the generic ultrapower, one can generally get a complete picture of where j sends cardinals. The variations on this technique are myriad, and will be explored further in Sects. 5 and 6.

3. Examples

In this section we give examples of ideals. These ideals fall into roughly two categories: the ideals that have an intrinsic definition (such as the nonstationary ideal, or the ideal of null sets for Lebesgue measure) and those ideals that are defined extrinsically in terms of an elementary embedding. We will refer to the former as "natural" ideals, the latter as "induced" ideals.

Our main concern in this chapter is with ideals that give rise to generic elementary embeddings into transitive models. These ideals will always be the induced ideals from their own embeddings. Thus, if a "natural" ideal gives rise to a well-founded ultrapower, it is also an "induced" ideal. Another way induced ideals frequently arise is as remnants of large cardinal embeddings that can be generically extended even after the associated large cardinal has been modified by forcing.

Various induced ideals' existence is often posited as non-constructive existence principles, similar in spirit to the supposition of the existence of large cardinal ultrafilters. These ideals can function in two ways, as existence principles in their own right and as intermediaries in relative consistency results.

3.1. Natural Ideals

We begin by describing several natural ideals.

3.1 Example. Let κ be a regular cardinal. The collection of subsets of κ that have cardinality less than κ forms a κ-complete ideal on κ called the *bounded ideal* or the *ideal of bounded sets*. Jech and Prikry [64] showed that this ideal is never precipitous.

Similarly, if $\lambda \geq \kappa$ then there is a smallest κ-complete, fine ideal on $[\lambda]^{<\kappa}$, namely $I_{\kappa\lambda} = \{X \subseteq [\lambda]^{<\kappa} : \text{for some } a \in [\lambda]^{<\kappa},\ X \cap \{b : a \subseteq b\} = \emptyset\}$. Matsubara and Shioya showed that $I_{\kappa\lambda}$ is never precipitous. We show here that the bounded ideal on κ is not precipitous, but postpone the second assertion to Sect. 6, Corollary 6.30.

Let I be the bounded ideal, and let $G \subseteq P(\kappa)/I$ be generic. A density argument shows that in $V[G]$ there is a sequence $\langle Y_n : n \in \omega\rangle \subseteq G$ such that if $f_n : Y_n \to \kappa$ is the unique order-preserving bijection between Y_n and κ, then for all $\alpha \in Y_{n+1}$, $f_{n+1}(\alpha) < f_n(\alpha)$. But then, the sequence $[f_n]^{V^Z/G}$ is an infinite decreasing sequence of ordinals in V^Z/G.

The Closed Unbounded Filter and the Nonstationary Ideal

We now discuss the nonstationary ideal. This ideal is covered in some depth in Jech's chapter in this Handbook. The definition given here was used implicitly by Shelah since the early 1980's, appeared in [47] and was exploited dramatically by Woodin in 1989 in his work on stationary towers.

3.2 Example. We fix a base set X, and define an ideal on $Z = P(X)$. By an *algebra* on X we will mean a structure $\mathfrak{A} = \langle X, f_n\rangle_{n\in\omega}$ where each $f_n : X^k \to X$, for some k.[7] For notational purposes, and without loss of generality, we will usually assume that f_n is an n-ary function. For such an algebra $\mathfrak{A}$, we let $C_{\mathfrak{A}}$ be the collection of all $z \subseteq X$ that are closed under all of the functions f_n. Following [47] such $C_{\mathfrak{A}}$ will be called *strongly closed unbounded* and the filter generated by the collection of all $C_{\mathfrak{A}}$ will be called the *strongly closed unbounded filter* on $P(X)$.

[7] In the sequel, we will refer to structures $\mathfrak{B}$ in an arbitrary countable language as *algebras*, when strictly speaking, we are referring to an algebra of Skolem functions for $\mathfrak{B}$.

Using Skolem functions this filter can also be generated by taking as a typical generating set the collection of all elementary substructures of an arbitrary structure $\mathfrak{A}$ in a countable language with universe X. This is sometimes a more convenient definition.

The *strongly nonstationary* ideal on $P(X)$ is the ideal dual to the strongly closed unbounded filter. Positive sets for this ideal are called *weakly stationary* sets.

We now show that this filter is quite well-behaved and provides a nice generalization of the classical closed unbounded filter. Moreover its restriction to various weakly stationary sets yields exactly the classical filter.

If $F : [\lambda]^{<\omega} \to \lambda$ we let $C_F = \{x \in P(\lambda) : x \text{ is closed under } F\}$. We note that for every algebra $\mathfrak{A}$ on λ there is a function F such that $C_F \subseteq C_{\mathfrak{A}}$ and vice versa.

3.3 Lemma. *The filter $\mathcal{F}$ of strongly closed unbounded sets is normal and fine.*

Proof. The proof of this theorem is an illustration of a standard trick.

First, the collection of generating sets is clearly closed under countable intersection: a countable collection of algebras can be merged into a single algebra. If $\mathcal{F}$ were not normal then there would be a weakly stationary set A and a regressive function $g : A \to X$ such that for all $x \in X$, $\{z \in A : g(z) = x\}$ is not weakly stationary. This means that for all $x \in X$ we can associate an algebra $\mathfrak{A}_x = \langle X, f_n^x \rangle_{n\in\omega}$ such that no $z \in A$ that is closed under the functions of $\mathfrak{A}_x$ has $g(z) = x$. Define an algebra $\mathfrak{A} = \langle X, f_n \rangle_{n\in\omega}$, by setting $f_n(x, x_0, \ldots, x_{n-2}) = f_{n-1}^x(x_0, \ldots, x_{n-2})$. Now suppose that $z \in A$ is closed under all of the functions f_n. Then for all $x \in z$, z is closed under all of the f_n^x. In particular, if $g(z) = x$ we have that z is closed under the functions of $\mathfrak{A}_x$. This is a contradiction.

Fineness is trivial, for if $x \in X$, then any algebra containing the constant function with value x gives a set in the filter, all of whose elements contain x. $\dashv$

We now discuss the relationship between the definition of the strongly closed unbounded filter and the more customary definitions of the filters of closed unbounded sets. First, it is clear that this notion is distinct: by the downward Löwenheim-Skolem theorem, every strongly closed unbounded set contains countable sets. However when we restrict this filter to standard sets we recover the various definitions of closed unbounded set. We now look at some examples where this is true.

The most common objects called the closed unbounded filter and the nonstationary ideal are defined on regular cardinals κ and are κ-complete. We want to see that these are given by the strongly closed unbounded filter restricted to a weakly stationary set. To do this we consider a regular cardinal κ, not as a collection of ordinals, but as a collection of subsets of κ.

3.4 Example. Let $X = \kappa$ where κ is a regular cardinal. Then $K = \{z \subseteq \kappa : z \cap \kappa \in \kappa\}$ is a weakly stationary set that is canonically isomorphic with κ via the identity map. Moreover, an elementary substructure argument shows that the filter of strongly closed sets restricted to K gives the usual closed unbounded filter on κ.

3.5 Example. Jech [61] generalized the notion of closed unbounded filter from a filter on a regular cardinal κ to a filter on the base set $[\lambda]^{<\kappa}$ for regular κ.[8] A generating set for this filter is a set C that is:

1. *closed* in the sense that C is closed under unions of chains of length less than κ, and

2. *unbounded* in the sense that for all $y \subseteq \lambda$ having cardinality less than κ, there is an $x \in C$ such that $y \subseteq x$.

The first clause is equivalent to the statement that C is closed under directed unions of size less than κ. The second clause states that $C \cap [\lambda]^{<\kappa}$ is cofinal in the structure $\langle [\lambda]^{<\kappa}, \subseteq \rangle$.

Before we prove the next theorem, we discuss a fundamental Skolemization trick used in the proof of that theorem and in many other contexts such as the study of projections of ideals. The trick is used where we have sets $X \subseteq Y$ and a structure $\mathfrak{A}$ with domain Y in a countable language. By adding countably many functions to the type of $\mathfrak{A}$ we can assume that $\mathfrak{A}$ is fully Skolemized, and that the functions mentioned in the type of $\mathfrak{A}$ are closed under all possible compositions.

List the functions mentioned in $\mathfrak{A}$ as $\langle f_n : n \in \omega \rangle$ where $f_n : Y^{k_n} \to Y$. Fix an element $x_0 \in X$. Define $g_n : X^{k_n} \to X$ by

$$g_n(\vec{x}) = \begin{cases} f_n(\vec{x}\,) & \text{if } f_n(\vec{x}\,) \in X, \\ x_0 & \text{otherwise.} \end{cases}$$

Using the fact that the f_n's are closed under compositions, if we take a set $B \subseteq X$ that is closed under all of the g_n's and has $x_0 \in B$, then $\mathrm{Sk}^{\mathfrak{A}}(B) \cap X = B$.

The following theorem of Kueker [76] is fundamental:

3.6 Theorem. *Suppose that $D \subseteq [\lambda]^{<\kappa}$ is closed unbounded in the sense of Jech. Then there is a function $F_D : \lambda^{<\omega} \to \lambda$ such that $\{z : z \cap \kappa \in \kappa$ and z is closed under the function $F_D\} \subseteq D$.*

Proof (Sketch). Fix $\rho \gg \lambda$. Let $\mathfrak{B} = \langle H(\rho), \in, \Delta_\rho, D \rangle$, where Δ_ρ is a well-ordering of $H(\rho)$. Suppose that $N \prec \mathfrak{B}$ has cardinality less than κ and $N \cap \kappa \in \kappa$. We observe that:

[8] For more on this filter see Jech's chapter in this Handbook.

1. $N \cap D$ is directed,
2. for all $\alpha \in N \cap \lambda$ there is a $y \in D \cap N$ with $\alpha \in y$, and
3. since $N \cap \kappa \in \kappa$, if $x \in N \cap [\lambda]^{<\kappa}$, then $x \subseteq N \cap \lambda$.

Hence $N \cap \lambda = \bigcup(N \cap D)$. Since D is closed under directed unions, $N \cap \lambda$ belongs to D. By the Skolemization trick we can find an $F : \lambda^{<\omega} \to \lambda$ such that if $A \subseteq \lambda$ is closed under F and A' is the Skolem hull of A in $\mathfrak{B}$, then $A = A' \cap \lambda$. Then F satisfies the conclusion of the theorem. ⊣

The next lemma appears in [47].

3.7 Lemma. *The filter of closed unbounded sets in the sense of Jech is the filter on $[\lambda]^{<\kappa}$ generated by the strongly closed unbounded filter and $\{x : x \cap \kappa \in \kappa\}$.*

Proof. Clearly $\{z \subseteq \lambda : z \cap \kappa \in \kappa\}$ is closed and unbounded in Jech's sense. Moreover, given a function $F : \lambda^{<\omega} \to \lambda$, C_F is closed and unbounded in the sense of Jech. Hence every set in the filter generated by the strongly closed unbounded filter and $\{x : x \cap \kappa \in \kappa\}$ is in the closed unbounded filter in the sense of Jech.

For the other direction, if D is closed unbounded in the sense of Jech we consider F_D as in Kueker's theorem. Then $C_F \subseteq D$ and belongs to the filter generated by the strongly closed unbounded filter and $\{N : N \cap \kappa \in \kappa\}$. ⊣

From this lemma we see that the strongly closed unbounded filter on $[\lambda]^{<\kappa}$ is distinct from the Jech closed unbounded filter exactly when $\{z \in [\lambda]^{<\kappa} : z \cap \kappa \notin \kappa\}$ is weakly stationary. Thus if $\kappa = \omega_1$ the two filters coincide.

As noted earlier if $\kappa > \omega_1$, the filters differ for trivial cardinality reasons, most prominently because the collection of countable subsets of λ is weakly stationary. To rule out such cardinality reasons for the difference we can take $\kappa = \rho^+ > \omega_1$ and look at those elements of $[\lambda]^{<\kappa}$ of cardinality ρ. This is a closed unbounded set in the sense of Jech, and it makes sense to discuss the strongly closed unbounded filter restricted to this set, which we call T.

The two filters differ on T iff for all algebras $\mathfrak{A}$ on λ, there is an elementary substructure $z \prec \mathfrak{A}$ such that z has cardinality ρ, but $\rho \not\subseteq z$. By the Skolemization trick, this can be equivalently rephrased as stating that $\{z \in [\rho^+]^{<\rho^+} : \rho \not\subseteq z\}$ is weakly stationary.

We now digress to define Chang's Conjecture properties. We will use the following notation: $(\kappa_n, \ldots, \kappa_0) \twoheadrightarrow (\lambda_n, \ldots, \lambda_0)$ is the statement that every structure $\mathfrak{A} = \langle \kappa_n; f_i, R_j, c_k \rangle_{i,j,k \in \omega}$ in a countable language has an elementary substructure $\mathfrak{B}$ of cardinality λ_n such that for all i, $|\mathfrak{B} \cap \kappa_i| = \lambda_i$. The same notation with "λ_i" replaced by "$<\lambda_i$" for some of the i's changes the cardinality requirement to $|\mathfrak{B} \cap \kappa_i| < \lambda_i$. Statements of this form are called *Chang's Conjectures.*

The classical Chang's Conjecture is the statement $(\aleph_2, \aleph_1) \twoheadrightarrow (\aleph_1, \aleph_0)$. It is easily seen to be equivalent to the statement that

$$\{z \in [\omega_2]^{<\omega_2} : |z| = \omega_1 \text{ and } z \cap \omega_2 \notin \omega_2\}$$

is weakly stationary. In particular Chang's Conjecture is equivalent to the statement that the strongly closed unbounded filter on $[\omega_2]^{<\omega_2}$ differs from the Jech closed unbounded filter. It was pointed out in [47] that by fixing the parameters κ, λ, one can describe every instance of Chang's Conjecture by asking that the appropriate set be weakly stationary.

Closely related to Chang's Conjecture are Jónsson cardinals. A cardinal κ is said to be *Jónsson* iff every structure $\mathfrak{A}$ with domain κ in a countable language has a proper elementary substructure of cardinality κ. A counterexample to κ being Jónsson is called a *Jónsson algebra*.[9]

Jónsson cardinals are also relevant to the discussion of the difference between weak stationarity and Jech stationarity. For simplicity we take $\rho = \aleph_\omega$. Since $\aleph_\omega$ is a limit cardinal, $\{z : z \in [\aleph_{\omega+1}]^{<\aleph_{\omega+1}} : |z| = \aleph_\omega \text{ and } \aleph_\omega \not\subseteq z\}$ is weakly stationary iff $\{z : z \in [\aleph_\omega]^{\aleph_\omega}, z \neq \aleph_\omega\}$ is weakly stationary. The latter statement is just a rephrasing of the statement that $\aleph_\omega$ is Jónsson.

Summarizing: each difference between the strongly closed unbounded filter restricted to T and the Jech closed unbounded filter is an instance of a form of Chang's Conjecture or of ρ being Jónsson. All instances of Chang's Conjecture imply the existence of an inner model with a Rowbottom cardinal (and many instances are considerably stronger[10]). Thus, if there is a difference between the two filters restricted to T, then at least mild large cardinals exist.

The next example of a natural filter expands on this:

3.8 Example. Suppose that $(\kappa_n, \dots, \kappa_0) \twoheadrightarrow (\lambda_n, \dots, \lambda_0)$ holds. Then the strongly closed unbounded filter restricted to $\{z \subseteq \kappa_n : \text{for all } i,\ |z \cap \kappa_i| = \lambda_i\}$ is called the *Chang filter* and the dual ideal, the *Chang ideal.*

In many cases we can assume that the Chang ideal has the maximal degree of completeness. We now discuss this situation. The following proposition appears in [32] and is an application of ideas of Shelah.

3.9 Proposition. *Let $\kappa_n > \kappa_{n-1} > \cdots > \kappa_0$ and $\lambda_n > \lambda_{n-1} > \cdots > \lambda_0$ be regular cardinals. Suppose that either:*

1. GCH *holds, or*

2. *there are at most countably many cardinals between λ_0 and κ_n,*

and that $(\kappa_n, \dots, \kappa_1, \kappa_0) \twoheadrightarrow (\lambda_n, \dots, \lambda_1, {<}\lambda_0)$. Let $X \supseteq \kappa_n$ be a set. Then the nonstationary ideal restricted to $Z =_{\text{def}} \{z \in P(X) : |z \cap \kappa_i| = \lambda_i \text{ for } i > 0, |z \cap \kappa_0| < \lambda_0 \text{ and } z \cap \lambda_0 \in \lambda_0\}$ is a proper, λ_0-complete, normal, fine ideal.

For any regular λ and set $X \supseteq \lambda$ it is not difficult to check that the strongly nonstationary ideal restricted to $\{z \subseteq X : z \cap \lambda \in \lambda\}$ is λ-complete. Hence the issue in Proposition 3.9 is whether or not the ideal is proper. To show that the ideal is proper, one must show that if $\mathfrak{B}$ is a structure with

[9] No $\aleph_n$ can be Jónsson for finite n. It is a prominent open problem whether $\aleph_\omega$ can be Jónsson.

[10] See Sect. 10 for more details.

domain X, then there is an elementary substructure z of $\mathfrak{B}$ with the property that $|z \cap \kappa_i| = \lambda_i$ for $i > 0$, $|z \cap \kappa_0| < \lambda_0$ and $z \cap \lambda_0 \in \lambda_0$.

We content ourselves here to showing a lemma that easily implies Proposition 3.9 in the case that there are only finitely many cardinals between λ_0 and κ_n.

3.10 Lemma. *Let $\lambda \leq \kappa \ll \theta$ be cardinals with λ and θ regular and with $\mathrm{cf}(\kappa) \geq \lambda$. Let $\mathfrak{A}$ be a structure expanding $\langle H(\theta), \in, \Delta, \{\kappa, \lambda\}\rangle$ and $N_0 \prec \mathfrak{A}$. Let $N_1 = \mathrm{Sk}^{\mathfrak{A}}(N_0 \cup \sup(N_0 \cap \lambda))$. Then*

$$\sup(N_1 \cap \kappa) = \sup(N_0 \cap \kappa).$$

Proof. Let τ be a Skolem function for $\mathfrak{A}$. Since we are considering the intersection of N_1 with κ, without loss of generality we can assume that

$$\tau : H(\theta) \times \lambda \to \kappa.$$

We must show that for each $a \in N_0$ and $\delta \in \sup(N_0 \cap \lambda)$ there is a $\beta \in N_0$ with $\beta \geq \tau(a, \delta)$.

Fix such an $a \in N_0$ and δ. Choose a $\gamma \in N_0 \cap \lambda$ with $\delta < \gamma$. Let

$$\beta = \sup\{\tau(a, \alpha) : \alpha < \gamma\}.$$

Then β is definable in N_0 and is clearly at least $\tau(a, \delta)$, as required. ⊣

Proof of Proposition 3.9. We now explain how to prove Proposition 3.9 using Lemma 3.10 in the case that $\kappa_n = \lambda_0^{+l}$ for some $l \in \omega$. We are given a structure $\mathfrak{B}$ with domain X and we assume that Chang's Conjecture holds. We must find a suitable $z \prec \mathfrak{B}$. Let $\theta \gg \sup X$, and take $\mathfrak{A}$ to expand $\langle H(\theta), \in, \Delta, \{\kappa_n, \kappa_{n-1}, \ldots, \kappa_0, \lambda_n, \lambda_{n-1}, \ldots, \lambda_0\}, \mathfrak{B}\rangle$. By the Chang's Conjecture assumption we can find an $N_0 \prec \mathfrak{A}$ such that $|N_0| = |N_0 \cap \kappa_n| = \lambda_n$; for all $1 \leq i \leq n$, $|N_0 \cap \kappa_i| = \lambda_i$; and $|N_0 \cap \kappa_0| < \lambda_0$.

Let $N_1 = \mathrm{Sk}^{\mathfrak{A}}(N_0 \cup \sup(N_0 \cap \lambda_0))$. By Lemma 3.10, $N_1 \cap \lambda_0 = \sup(N_0 \cap \lambda_0)$ and for all $0 \leq j < \omega$, $\sup(N_1 \cap \lambda_0^{+j}) = \sup(N_0 \cap \lambda_0^{+j})$. From this one sees inductively that for $0 \leq j < \omega$, $|N_1 \cap \lambda_0^{+j}| = |N_0 \cap \lambda_0^{+j}|$. In particular, $|N_1 \cap \kappa_i| = |N_0 \cap \kappa_i|$ for $0 \leq i \leq n$.

Let $z = N_1 \cap X$. Since $\mathfrak{B}$ is definable in $\mathfrak{A}$, we must have $z \prec \mathfrak{B}$. Since $z \cap \kappa_i = N_1 \cap \kappa_i$, the proposition follows. ⊣

There is a converse to Proposition 3.9:

3.11 Proposition. *Let $\kappa_n > \kappa_{n-1} > \cdots > \kappa_0$ and $\lambda_n > \lambda_{n-1} > \cdots > \lambda_0$ be regular cardinals and $X \supseteq \kappa_n$. If there is a proper, normal, fine, countably complete ideal concentrating on $Z =_{\mathrm{def}} \{z \in P(X) : |z \cap \kappa_i| = \lambda_i$ for $i > 0$, $|z \cap \kappa_0| < \lambda_0$ and $z \cap \lambda_0 \in \lambda_0\}$, then $(\kappa_n, \ldots, \kappa_1, \kappa_0) \twoheadrightarrow (\lambda_n, \ldots, \lambda_1, {<}\lambda_0)$.*

Proof. This follows easily from the fact that if $F : [X]^{<\omega} \to X$ and I is normal, fine and countably complete, then $\{z : z$ is closed under $F\}$ belongs to $\breve{I}$. ⊣

We will denote the nonstationary ideal concentrating on z's with $|z \cap \kappa_i| = \lambda_i$ by $\mathrm{CC}(\vec{\kappa}, \vec{\lambda})$. Note that the ideal $\mathrm{CC}((\kappa, \lambda, \mu), (\kappa', \lambda', \mu'))$ projects[11] to the ideal $\mathrm{CC}((\lambda, \mu), (\lambda', \mu'))$ via the map $z \mapsto z \cap \lambda$. We can also define an ideal $\mathrm{CC}((\kappa, \lambda), (\kappa', {<}\lambda'))$ by restricting the nonstationary ideal to those N where $|N \cap \kappa| = \kappa'$ and $|N \cap \lambda| < \lambda'$ and $N \cap \lambda' \in \lambda'$. By Proposition 3.9, we see that this ideal is λ'-complete. If $\lambda' = \mu^+$ then $\mathrm{CC}((\kappa, \lambda), (\kappa', {<}\lambda'))$ is equal to $\mathrm{CC}((\kappa, \lambda), (\kappa', \mu))$ restricted to those z such that $\mu \subseteq z$.

Stipulation. These examples help illustrate the idea that the ideal of strongly nonstationary sets is a generalization of several particular notions of the "nonstationary ideal". By restricting the strongly nonstationary ideal to particular weakly stationary sets we recover the particular ideals. **We will use this as a rationalization to drop the adjective "strongly", and refer to this ideal as "the ideal of nonstationary sets" and its dual filter as the "filter of closed unbounded sets".** When the underlying set X is clear from the context, we will denote the nonstationary ideal by simply NS and this ideal restricted to a (weakly) stationary set $Y \subseteq P(X)$ by $\mathrm{NS}\restriction Y$ or NS_Y. In particular, for regular uncountable cardinals κ, NS_κ will denote the usual ideal of nonstationary subsets of κ.

The closed unbounded filter is the minimal normal and fine filter:

3.12 Lemma. *Suppose that I is a normal, fine, countably complete ideal on a set $Z \subseteq P(X)$. If $A \subseteq Z$ is nonstationary, then $A \in I$.*

Proof. Suppose that $\mathfrak{A} = \langle X, f_n \rangle_{n \in \omega}$ is an algebra witnessing the nonstationarity of A, and suppose that $A \notin I$. Then no element of A is closed under every function from $\mathfrak{A}$. Hence for each $z \in A$, there is a function f_n and $\{x_0, \ldots, x_{n-1}\} \subseteq z$ such that the point $f_n(x_0, \ldots, x_{n-1}) \notin z$. For each $z \in A$ choose such a $(x_0, \ldots, x_{n-1})$. By the normality and countable completeness of I, there is an I-positive set $B \subseteq A$ such that n and $(x_0, \ldots, x_{n-1})$ are constant for all $z \in B$. Let $x = f_n(x_0, \ldots, x_{n-1})$. Then by fineness, there is a $z \in B$ such that $x \in z$, a contradiction. $\dashv$

In Sect. 4.4 we show how to condition the nonstationary ideal on an ideal on a smaller set, while preserving properties similar to Lemma 3.12.[12]

Natural Ideals on $P(\mathbb{R})$

The next two examples of ideals are quite well-known:

3.13 Example. The ideal of null sets for a countably additive measure on the unit interval. This ideal becomes precipitous if the measure is defined on all subsets of the unit interval. In this case the ideal is $\aleph_1$-saturated and countably complete, hence has the disjointing property.

[11] The definition of a *projection* is officially given by Definition 4.17.

[12] The conditional nonstationary ideals are analogous to the ideals arising from conditional probability functions analysis.

This example is not totally misrepresentative; a consequence of the Hahn-Banach theorem is that if I is an ideal on Z then there is a finitely additive probability measure $\mu : P(Z) \to [0,1]$, such that I is the ideal of sets of μ-measure zero. Inspired by this remark, in the sequel we will use phrases such as "almost all" and "almost every", and "in a set of measure one" to refer to sets in $\breve{I}$. So for example, "almost every element of $X \ldots$" means that "there is a set $C \in \breve{I}$ such that for all $z \in C \cap X \ldots$".

3.14 Example. The ideal of meager subsets of the unit interval.

It is not known if either the ideal of Lebesgue null sets or the ideal of meager sets can be precipitous. However Komjáth [73] has shown that it is consistent, relative to a measurable cardinal, that there is a non-meager set $A \subseteq \mathbb{R}$ such that $P(A)/\{\text{meager sets}\}$ is c.c.c. It follows that the ideal of meager subsets of A forms a precipitous ideal on $P(A)$. We give a sketch of Komjáth's argument in Sect. 8.

$I[\lambda]$ and Related Ideals

We now describe several interesting examples due to Shelah. The first is the ideal $I[\lambda]$. This example is particularly interesting on successors of singular cardinals. Doing justice to the significance of this ideal is beyond the scope of this chapter. The author notes that the exposition here is not as thorough as the treatment of these ideals given by Shelah.[13]

3.15 Example. Let λ be a regular cardinal. Let θ be a regular cardinal "much larger" than λ and Δ a well-ordering of $H(\theta)$. A generating set for the ideal $I[\lambda]$ is determined by a structure $\mathfrak{A}$ in a countable language that expands the structure $\langle H(\theta), \in, \Delta\rangle$.

An ordinal α is *approachable* with respect to $\mathfrak{A}$ iff $\mathrm{Sk}^{\mathfrak{A}}(\alpha) \cap \lambda = \alpha$ and there is a sequence $\langle \alpha_i : i \in \mathrm{cf}(\alpha)\rangle$ that is cofinal in α and is such that for all $j < \mathrm{cf}(\alpha)$, $\langle \alpha_i : i < j\rangle \in \mathrm{Sk}^{\mathfrak{A}}(\alpha)$.

The set $S_{\mathfrak{A}}$ determined by $\mathfrak{A}$ is the collection of ordinals α such that either $\mathrm{Sk}^{\mathfrak{A}}(\alpha) \cap \lambda \neq \alpha$ or α is approachable with respect to $\mathfrak{A}$. We let $I[\lambda]$ be the ideal generated by all of the $S_{\mathfrak{A}}$'s.

Clearly this ideal includes the ideal of bounded subsets of λ. Moreover we get an equivalent definition if we allow the structures $\mathfrak{A}$ to vary over expansions of $H(\theta)$ that have languages of size less than λ.

Since λ is regular, we can merge any small collection $\langle \mathfrak{A}_\delta : \delta < \eta < \lambda\rangle$ of structures in various languages of cardinality less than λ into a single structure $\mathfrak{A}$, in a language of cardinality less than λ. An ordinal $\alpha > \eta$ that is approachable with respect to some $\mathfrak{A}_\delta$ remains approachable with respect to $\mathfrak{A}$. Thus we can argue that the ideal $I[\lambda]$ is λ-complete.

[13] See Shelah's book [105], and his many related papers, for extensive information. An exposition of these results is given in Eisworth's chapter in this Handbook.

Arguments similar to those given in Lemma 3.3 can be extended to show that the ideal $I[\lambda]$ is normal and extends the nonstationary ideal on λ.

This ideal may fail to be proper however. For example, if there is a square sequence $\langle C_\alpha : \alpha < \lambda\rangle$ of length λ then the collection of ordinals that are approachable with respect to the algebra $\mathfrak{A} = \langle H(\theta), \in, \Delta, \langle C_\alpha : \alpha < \lambda\rangle\rangle$ is closed unbounded. Hence the ideal $I[\lambda]$ is not a proper ideal.

To see this, suppose that we have a typical α and we assume that C_α is closed and unbounded in α and has order type less than α. Using the coherence of the square sequence, we see that every initial segment of C_α is in $\mathrm{Sk}^{\mathfrak{A}}(\alpha)$. If $\gamma = \mathrm{ot}(C_\alpha)$ then $\mathrm{Sk}^{\mathfrak{A}}(\alpha)$ contains a closed unbounded subsequence $D \subseteq \gamma$ that has order type the cofinality of α. Copying D over inside C_α, we get a sequence cofinal in α and of order type the cofinality of α such that every initial segment is in $\mathrm{Sk}^{\mathfrak{A}}(\alpha)$.

Similar arguments show for example, that if GCH holds and κ is regular then $I[\kappa^+]$ is not proper.

Shelah has shown that if $\mu^+ < \lambda$ and μ is regular, then there is always a stationary set of approachable ordinals of cofinality μ. Moreover, if $\lambda^{<\lambda} = \lambda$, $I[\lambda]$ is the nonstationary ideal restricted to a single stationary set that contains ordinals of all cofinalities less than λ. As a consequence, we can view the approachable ordinals as being a canonical stationary set. This stationary set is closed unbounded just in case the ideal is not a proper ideal.

It is consistent that the approachable ordinals constitute a co-stationary set. To make this happen at μ^+, where μ is regular, one collapses a weakly compact cardinal greater than μ to be the successor of μ in the manner of Mitchell's model [96] for no Aronszajn trees on μ^+. This result is presented in Cummings' chapter in this Handbook. At the successor of a singular cardinal larger than a supercompact, the approachable ordinals are always co-stationary. To arrange a model where the approachable ordinals are co-stationary in $\aleph_{\omega+1}$, one Levy collapses a supercompact cardinal to be $\aleph_2$.[14]

An important property of $I[\lambda]$ is the following:

3.16 Theorem (Foreman and Magidor [42]). *Let $\kappa < \lambda$ be regular cardinals such that $\kappa^{<\kappa} = \kappa$. Let $S \subseteq \lambda \cap \mathrm{Cof}(\kappa)$ be a stationary set. Then the following are equivalent:*

1. *For all $<\kappa^+$-closed partial orderings $\mathbb{P}$ and for all generic $G \subseteq \mathbb{P}$, $V[G] \models S \subseteq \lambda$ is stationary.*
2. *There is a set $T \in I[\lambda]$ such that $S \cap T$ is stationary.*

We remind the reader that a set N of regular cardinality κ is *internally approachable of length* κ iff there is a sequence $\langle N_\alpha : \alpha < \kappa\rangle$ such that:

1. $|N_\alpha| < \kappa$,
2. for all $\alpha < \beta < \kappa$, $N_\alpha \subseteq N_\beta \subseteq N$,

[14] See [43] for further information and references.

3. for all $\beta < \kappa$, $\langle N_\alpha : \alpha < \beta \rangle \in N$, and
4. $N = \bigcup_{\alpha<\kappa} N_\alpha$.

Another natural ideal discovered by Shelah is closely related to $I[\lambda]$.

3.17 Example. Let $\lambda > \kappa$ be regular cardinals. We define the ideal $I_d(\lambda, \kappa)$. Fix a large regular $\theta \gg \lambda$. $I_d(\lambda, \kappa)$ will be generated by sets $S_{\mathfrak{A}}$ as $\mathfrak{A}$ ranges over expansions of $\langle H(\theta), \in, \Delta \rangle$ in a countable language. Given such a structure, we define $S_{\mathfrak{A}}$ to be the collection of δ such that there is no internally approachable $N \prec \mathfrak{A}$ of cardinality and length κ with $\sup(N \cap \lambda) = \delta$.

Familiar arguments show that $I_d(\lambda, \kappa)$ is a proper, normal ideal on λ. The ideal $I_d(\lambda, \kappa)$ is orthogonal to the ideal $I[\lambda]\restriction\mathrm{Cof}(\kappa)$ in the following sense:

3.18 Lemma (Shelah). *If $S_1 \in I[\lambda]\restriction\mathrm{Cof}(\kappa)$ and $S_2 \in I_d(\lambda, \kappa)$ then $S_1 \cap S_2$ is nonstationary.*

See [43] for a proof of this lemma.

Club Guessing Ideals

We now turn to the class of *guessing* ideals. We exhibit some samples, the *club guessing ideals*. Here, as elsewhere, we use $\subseteq^*$ to mean eventual inclusion.

3.19 Example. Let $\kappa > \mu$ be regular cardinals and $S \subseteq \kappa \cap \mathrm{Cof}(\mu)$. Let $\langle C_\alpha : \alpha \in S \rangle$ be a sequence such that C_α is unbounded in α. We define two filters, the *club guessing filter* and the *tail club guessing filter* on S.

For $D \subseteq \kappa$ closed unbounded, let $G(D) = \{\alpha \in S : C_\alpha \subseteq D\}$ and $E(D) = \{\alpha \in S : C_\alpha \subseteq^* D\}$.

1. The club guessing filter on S is the filter generated by the sets $\{G(D) : D \text{ is closed unbounded}\}$ together with the closed unbounded sets.
2. The tail club guessing filter on S is the filter generated by the sets $\{E(D) : D \text{ is closed unbounded}\}$ together with the closed unbounded sets.

The sequence $\langle C_\alpha : \alpha \in S \rangle$ is *club guessing* iff the club guessing filter on S is a proper filter, and *tail club guessing* iff the tail club guessing filter on S is a proper filter.

The next lemma was observed by Ishiu; the third clause was proved earlier in Shelah's work [105]:

3.20 Lemma. *Let $\langle C_\alpha : \alpha \in S \rangle$ be a club guessing sequence. Then:*

1. *The smallest normal filter containing the club guessing filter is not proper.*

2. *The club guessing filter is incompressible.*[15]

3. *The tail club guessing filter is normal.*

It was shown by Ishiu [59] that if one collapses a Woodin cardinal to be the successor of a regular cardinal μ, then every tail club guessing filter is precipitous. Foreman and Komjáth [40] showed that it is consistent relative to an almost huge cardinal to have a club guessing filter on any given regular cardinal μ be μ^+-saturated.

Example 3.19 can easily be generalized: If $\mathcal{F}$ is a filter on a regular cardinal κ and $\langle C_\alpha : \alpha \in \kappa\rangle$ is any sequence, we can define a new filter $\mathcal{G}$ generated by sets of the form:

$$G(A) = \{\alpha < \kappa : C_\alpha \subseteq^* A \cap \alpha\}$$

for $A \in \mathcal{F}$. If $\mathcal{F}$ is normal, then $\mathcal{G}$ is normal. If $\mathcal{F}$ is a normal filter and $\langle C_\alpha\rangle$ is a diamond sequence that guesses on positive sets for $\mathcal{F}$, then the corresponding filter $\mathcal{G}$ is proper.

Ideals of Sets Without Guessing Sequences

A different kind of ideal is given by the non-diamond ideal.

3.21 Example. Let κ be a regular cardinal. Recall that for $A \subseteq \kappa$, $\langle S_\alpha : \alpha \in A\rangle$ is a $\Diamond(A)$-*sequence* iff for any $X \subseteq \kappa$, $\{\alpha \in A : X \cap \alpha = S_\alpha\}$ is stationary in κ, and $\Diamond_\kappa$ is the assertion that there is a $\Diamond(\kappa)$ sequence. Let I be the collection of sets $A \subseteq \kappa$ such that there is no diamond sequence defined on A. Explicitly, $A \in I$ iff there is no $\langle S_\alpha : \alpha \in A\rangle$ that is a $\Diamond(A)$ sequence. I is called the *non-diamond ideal.*

Let $\langle\ ,\ \rangle : \kappa \times \kappa \to \kappa$ be a bijective pairing function and $\langle S_\alpha : \alpha \in B\rangle$ be a $\Diamond(B)$ sequence. Suppose that $B = \bigtriangledown\langle B_\gamma : \gamma < \kappa\rangle$. Define $\langle S^\beta_\alpha : \alpha \in B_\beta\rangle$ by $S^\beta_\alpha = \{\gamma < \alpha : \langle\beta, \gamma\rangle \in S_\alpha\}$. Then it is easy to see that there is a β such that $\langle S^\beta_\alpha : \alpha \in B_\beta\rangle$ is a $\Diamond(B_\beta)$ sequence. This establishes that this ideal is normal and κ-complete.

For the next proposition we need $\Diamond_\kappa$ to see that the non-diamond ideal is proper.

3.22 Proposition (Abraham-Magidor). *Suppose that κ is a regular cardinal and $\Diamond_\kappa$. Then the non-diamond ideal on κ is nowhere κ^+-saturated.*

Proof. We show that if there is an almost disjoint family of subsets of κ that has size λ, then below any positive set there is an antichain of size λ. Fix a bijective pairing function $\langle\ ,\ \rangle : \kappa \times \kappa \to \kappa$.

[15] This means that there is a minimal non-constant function $f : \kappa \to \kappa$ with respect to the club guessing filter.

If A is a positive set, then $\diamondsuit(A)$ holds. Let $\langle S_\alpha : \alpha \in A\rangle$ be a $\diamondsuit(A)$ sequence. For $Y \subseteq \kappa$ define $S^Y_\alpha = z$ iff $z \subseteq \alpha$ is such that S_α is the image of $(Y \cap \alpha) \times z$ under the map $\langle\ ,\ \rangle$. Let $A_Y = \{\alpha : S^Y_\alpha$ is defined$\}$. We claim that for all $Y \subseteq \kappa$, $\langle S^Y_\alpha : \alpha \in A_Y\rangle$ is a $\diamondsuit(A_\gamma)$ sequence.

Let $X \subseteq \kappa$. Let X' be the image of $Y \times X$ under $\langle\ ,\ \rangle$. Then the set of α such that the $\langle\ ,\ \rangle$-image of $(Y \cap \alpha) \times (X \cap \alpha)$ is $X' \cap \alpha$ is closed unbounded. Choose an α where this holds and where $S_\alpha = X' \cap \alpha$. Then S^Y_α is defined and $S^Y_\alpha = X \cap \alpha$.

To finish the non-saturation argument note that if $Y \cap Y'$ has cardinality less than κ, then $A_Y \cap A_{Y'}$ is nonstationary. Hence taking a large almost disjoint family of Y's yields a large antichain in the non-diamond ideal. ⊣

There is another example of a natural normal ideal, the non-weak diamond ideal.

Recall that weak diamond at λ is the statement that for all $F : 2^{<\lambda} \to 2$ there is a $g : \lambda \to 2$ such that for all $f : \lambda \to 2$, the collection $\{\alpha : g(\alpha) = F(f\restriction\alpha)\}$ is stationary in λ. The idea is that g is guessing information about F. Devlin and Shelah [22] showed that weak diamond holds at a successor cardinal $\lambda = \kappa^+$ iff $2^\kappa < 2^\lambda$.

3.23 Example. Let λ be a regular cardinal. Let $F : 2^{<\lambda} \to 2$. We can define an ideal I_F by putting $S \in I_F$ iff for all $g : \lambda \to 2$ there is an $f : \lambda \to 2$ such that $\{\alpha \in S : g(\alpha) = F(f\restriction\alpha)\}$ is nonstationary. The union of the ideals I_F can be verified to be a λ-complete ideal, which we call the *non-weak diamond ideal*. The ideal consists of those sets on which weak diamond fails. Thus it is a proper ideal just in case weak diamond holds at λ.

3.24 Theorem (Devlin-Shelah [22]). *Let λ be a regular uncountable cardinal. Then the non-weak diamond ideal is a normal λ-complete ideal.*

Proof. We will verify the normality of the ideal. The proof of λ-completeness is similar, but easier. Suppose that $\langle S_\alpha : \alpha < \lambda\rangle$ is a sequence of sets in the non-weak diamond ideal. We need to see that $S =_{\mathrm{def}} \triangledown_{\alpha<\lambda} S_\alpha$ is in the non-weak diamond ideal. Fix $\langle F_\alpha : \alpha < \lambda\rangle$ such that F_α witnesses that S_α is small.

Let $\langle\ ,\ \rangle : \lambda \times \lambda \to \lambda$ be a pairing function. We will work on the closed unbounded collection C of ξ such that $\langle\ ,\ \rangle : \xi \times \xi \to \xi$ is a bijection. For $\gamma : \xi \to 2$ we let $\gamma^\alpha(\beta) = \gamma(\langle\alpha, \beta\rangle)$. We define a function F as follows: for $\xi \in \triangledown S_\alpha \cap C$, let $\alpha < \xi$ be the least ordinal such that $\xi \in S_\alpha$. Define $F(\gamma) = F_\alpha(\gamma^\alpha)$.

Suppose now that there is a g such that for all $f : \lambda \to 2$, there are stationarily many $\xi \in S$ such that $g(\xi) = F(f\restriction\xi)$. Fix such a g. Then for each $\alpha < \lambda$ there is an f_α such that the collection of $\xi \in S_\alpha$ with $g(\xi) = F_\alpha(f_\alpha\restriction\xi)$ is nonstationary. Define $f : \lambda \to \lambda$ by setting $f(\langle\alpha, \beta\rangle) = f_\alpha(\beta)$. Note that for this $f, (f\restriction\xi)^\alpha = f_\alpha\restriction\xi$.

Since there are stationarily many $\xi \in S$ with $g(\xi) = F(f\restriction\xi)$, there is an α such that for stationarily many $\xi \in S_\alpha \setminus \bigcup_{\alpha'<\alpha} S_{\alpha'}$ we have $g(\xi) = F(f\restriction\xi)$.

But then for these ξ,

$$g(\xi) = F(f{\restriction}\xi) = F_\alpha((f{\restriction}\xi)^\alpha) = F_\alpha(f_\alpha{\restriction}\xi)$$

a contradiction. ⊣

Shelah has generalized the non-weak diamond ideal to the analogous ideal for colorings into n colors for $n \in \omega$. Surprisingly, it is not true in general that the ideals are identical for different finite numbers of colors. We refer the reader to [26] and [103] for further information.

Uniformization Ideals

Barney considered closely related ideals, the *uniformization ideals*. We describe his work on such ideals on ω_1. Let $S \subseteq \omega_1$ be a set of limit ordinals. We consider a *ladder system on* S to be a sequence of functions η_δ for $\delta \in S$ where η_δ is an increasing and cofinal map from ω into δ. An α*-coloring* of the ladder system is a sequence of functions $\langle c_\delta : \delta \in S\rangle$ where $c_\delta : \omega \to \alpha$. If $f : \omega \to \omega$, then an f-coloring is an ω-coloring such that for all $\delta \in S$ and $n \in \omega$, $c_\delta(n) \in f(n)$. A *monochromatic* α*-coloring* is an α-coloring with the property that each c_δ is a constant function.

An α-coloring is *uniformized* if there is an $h : \omega_1 \to \alpha$ such that for all $\delta \in S$ and all but finitely many n, $h(\eta_\delta(n)) = c_\delta(n)$.

We let Unif_α be the collection of sets S such that there is a ladder system on S such that every α-coloring $\langle c_\delta : \delta \in S\rangle$ of the ladder system can be uniformized. The sets $\mathrm{mUnif}_\alpha, \mathrm{Unif}_f$ are defined similarly for monochromatic colorings and f-colorings.

Shelah showed that weak diamond on a set S implies that for every ladder system on S, there is a monochromatic 2-coloring that is not uniformizable. Hence mUnif_2 is a subset of the weak diamond ideal, which is denoted WD_2 in what follows to emphasize 2-colorings.

Barney proved:

3.25 Proposition (Barney). *For $\alpha \in \omega + 1$ and $f : \omega \to \omega$, the sets* Unif_α, mUnif_α, *and* Unif_f *are normal, countably complete ideals. Moreover:*

$$\mathrm{Unif}_\omega \subseteq \mathrm{Unif}_f \subseteq \mathrm{Unif}_n \subseteq \mathrm{Unif}_2 \subseteq \mathrm{mUnif}_2 \subseteq \mathrm{WD}_2.$$

Unlike the case for the weak diamond ideal, it is not possible to separate the uniformization ideals for finitely many colors or even f-colorings:

3.26 Proposition (Barney). *Let $f : \omega \to \omega \setminus \{0, 1\}$. Then* $\mathrm{Unif}_2 = \mathrm{Unif}_f$.

However this is all one can prove:

3.27 Theorem (Barney). *There is a partial ordering $\mathbb{P}$ such that in $V^{\mathbb{P}}$,*

$$\mathrm{W}D_2 \neq \mathrm{mUnif}_2 \neq \mathrm{Unif}_2 \neq \mathrm{Unif}_\omega,$$

i.e. all of the inclusions are proper.

Weakly Compact and Ineffable Ideals

There is a family of natural ideals definable on large cardinals, such as ineffable cardinals. We give two examples here, one is the weakly compact filter.

Recall that κ is weakly compact iff for all Π^1_1 formulas, $\phi(x,y)$, $a \in V_\kappa$, and $A \subseteq V_\kappa$, if $V_\kappa \models \phi(A,a)$, then there is a stationary set of $\alpha < \kappa$ such that $V_\alpha \models \phi(A \cap V_\alpha, a)$.

3.28 Example. Suppose that κ is weakly compact. The *weakly compact filter* on κ is generated by sets of the form $R = \{\alpha : V_\alpha \models \phi(A \cap V_\alpha, a)\}$, where $A \subseteq V_\kappa$, $a \in V_\kappa$, ϕ is a Π^1_1 formula and $V_\kappa \models \phi(A,a)$. This filter is proper, normal and κ-complete. The *weakly compact ideal* is the dual ideal to the weakly compact filter.

We show in Proposition 6.4 that the weakly compact filter on a weakly compact cardinal κ is not κ-saturated. A. Hellsten, in unpublished work, has shown that it is consistent that there be weakly compact cardinal κ such that the weakly compact ideal on κ is κ^+-saturated.

A variant on the weakly compact ideal is the ineffable ideal.

3.29 Example. Let κ be an ineffable cardinal. Then for all sequences $\vec{A} = \langle A_\alpha : \alpha < \kappa \rangle$ with $A_\alpha \subseteq \alpha$, there is a stationary set $S_{\vec{A}}$ such that for $\alpha < \beta$ both in $S_{\vec{A}}$, $A_\alpha = A_\beta \cap \alpha$. Then the collection of $S_{\vec{A}}$ generate a normal κ-complete filter on κ.

As far as the author knows the properties of the generic ultrapowers by this filter have not been investigated.

3.2. Induced Ideals

Most induced ideals arise as special cases of the following observation:

3.30 Example. Let X, Z be sets with $Z \subseteq P(X)$. Let $\mathbb{Q}$ be a partial ordering such that for all $H \subseteq \mathbb{Q}$ that are generic, the $\mathbb{Q}$-term $\dot{U}$ denotes a V-normal, fine, V-κ-complete filter on $P(Z)^V$. Then in V, we can define an ideal I by setting $A \in I$ iff every condition in $\mathbb{Q}$ forces that A is in the dual of $\dot{U}$. This ideal is easily seen to be normal, fine and κ-complete in V. Moreover for all generic $H \subseteq \mathbb{Q}$, $\dot{U}^{V[H]} \supseteq \check{I}$. If $\mathbb{Q}$ is κ-c.c. then the Boolean algebra $P(Z)/I$ is κ-c.c.

The example is a special case of a more general fact: If $\mathcal{B}$ is a Boolean algebra and $\dot{U}$ is a term for an ultrafilter on $\mathcal{B}$ in a κ-c.c. forcing extension $\mathbb{P}$ and we let I be the ideal of elements of b such that $1 \Vdash_{\mathbb{P}} b \notin \dot{U}$, then $\mathcal{B}/I$ is κ-c.c.

In slightly more generality we can see:

3.31 Lemma. *Let X, Z be sets with $Z \subseteq P(X)$. Suppose that $\mathbb{P}$ is a κ-c.c. partial ordering and $\dot{J}$ is a $\mathbb{P}$ term for a κ-saturated ideal on $P(Z)^{V^{\mathbb{P}}}$.*

Define an ideal I in V by setting $A \in I$ iff $\|A \in \dot{J}^+\|_{\mathbb{P}} = 0$. Then I is a κ-saturated ideal on $P(Z)$. Moreover if $V^{\mathbb{P}} \models$ "$\dot{J}$ is normal and fine", then I is a normal and fine ideal.

We note that the statement $\|A \in \dot{J}^+\|_{\mathbb{P}} = 0$ is equivalent to $\|A \in \dot{J}\|_{\mathbb{P}} = 1$. In certain circumstances this version is easier to work with.

In many situations the filter U is an ultrafilter associated with an elementary embedding that is defined in the extension $V[H]$:

3.32 Definition. Let M and N be models of a sufficient amount of set theory[16] with $i \in N$ and $Z \in M$. If $j : M \to N$ is an elementary embedding and $i \in j(Z)$ then i generates an ultrafilter $U(j, i)$ on $P(Z)^M$. Namely, for $A \subseteq Z$

$$A \in U(j, i) \quad \text{iff} \quad i \in j(A).$$

In our previous language, the element i is functioning as an "ideal element". This ultrafilter can be used to induce ideals in various ways. We begin with a typical example that follows immediately in one direction from Lemma 3.31 applied to $U(j, \kappa)$ and in the other by taking a generic ultrapower.

3.33 Example. The following are equivalent:

1. There is an elementary embedding $j : V \to M \subseteq V[G]$ defined in $V[G]$ such that:
   (a) $\mathrm{crit}(j) = \kappa$, and
   (b) $G \subseteq \mathbb{P}$ is V-generic where $\mathbb{P}$ is κ^+-c.c.
2. There is a normal, fine, κ-complete, κ^+-saturated ideal on $P(\kappa)$.

The next example is very general.

3.34 Example. Suppose that N expands $\langle H(\lambda), \in, \Delta\rangle$ where Δ is a well-ordering of $H(\lambda)$. Suppose that M is the transitive collapse of an elementary substructure of N and j is the inverse of the collapsing map. Then the M-ultrafilter $U(j, i)$ induces a filter (and hence an ideal) on $P(Z)^V$. If the critical point of j is α, then this filter is M-α-complete. If $\kappa < \alpha$ and $M^{<\kappa} \subseteq M$, then this filter is κ-complete.

This example was used very fruitfully in the case $i = \mathrm{crit}(j)$ by Baumgartner, Hajnal and Todorčević [7].

Continuing with an elementary embedding $j : M \to N$:

3.35 Definition. Suppose that $\mathbb{P}$ is a partial ordering in M. A condition $m \in j(\mathbb{P})$ is called a *master condition* (or an *M-generic condition*) iff for all dense subsets D of $\mathbb{P}$ with $D \in M$ and all $q \leq m$ belonging to $j(\mathbb{P})$ there is a $p \in D$ such that $j(p)$ is compatible with q.

[16] ZF$^-$, ZF minus Power Set, is more than enough.

If there is a master condition for j and $H \subseteq j(\mathbb{P})$ is a filter, we define a filter $G \subseteq \mathbb{P}$ by setting $p \in G$ iff $j(p) \in H$.[17] If H is sufficiently generic then G is generic over M and the elementary embedding j can be extended to an elementary embedding

$$\hat{j} : M[G] \to N[H].$$

This idea comes up in several contexts: If $\mathbb{Q}$ is a partial ordering and λ is a regular cardinal much bigger than $|\mathbb{Q}|$, let $N = \langle H(\lambda), \in, \Delta, \mathbb{Q}\rangle$ and M be the transitive collapse of a countable elementary substructure and $\mathbb{P}$ be the collapse of $\mathbb{Q}$. Let j be the inverse of the collapse map. Then the notion of a master condition coincides exactly with the notion of a generic condition in the sense of proper forcing. The properness of $\mathbb{Q}$ is equivalent to the statement:

> For all such M and all $p \in \mathbb{P}$ there is an $m \leq j(p)$ such that for all generic $H \subseteq \mathbb{Q}$, with $m \in H$, if $G = j^{-1}(H)$ then G is M generic and j extends to an elementary embedding
>
> $$\hat{j} : M[G] \to H(\lambda)[H].$$

Semiproperness can be formulated similarly. The link between properness, semiproperness and ideals is not a coincidence [47].

The next example is the usual way that strong ideals are manufactured from the remnants of a large cardinal using master conditions and a forcing construction.

3.36 Example. Suppose that $j : V \to M$ is a large cardinal embedding such that $j``X \in M$. Let $Z \subseteq P(X)$ be such that $j``X \in j(Z)$. Suppose that $\mathbb{P} \in V$ is a partial ordering and $m \in j(\mathbb{P})$ is a master condition. Then forcing over V with $j(\mathbb{P})$ below m we get a generic $H \subseteq j(\mathbb{P})$ such that $G = j^{-1}(H) \subseteq \mathbb{P}$ is generic over V. Then j can be extended to an elementary embedding $\hat{j} : V[G] \to M[H]$.

In $V[G]$ we define an ideal on Z by setting $A \in I$ iff whenever $H \subseteq j(\mathbb{P})$ is generic and extends $j``G \cup \{m\}$ we have $A \notin U(\hat{j}, j``X)$. This ideal is called the *master condition ideal*. If we let $\mathbb{Q}$ be the partial ordering consisting of those conditions in $j(\mathbb{P})/j``G$ that are below m, we have:

$$A \in I \quad \text{iff} \quad \|A \in U(\hat{j}, j``X)\|_{\mathbb{Q}} = 0.$$

Thus we are in the context of Example 3.30.

In Example 7.7 we will see that if we collapse a supercompact cardinal to be ω_1 then every proper forcing in $V[G]$ of cardinality κ gives rise to a precipitous master condition ideal on $[\lambda]^{<\omega_1}$ for every $\lambda > 2^\kappa$.

[17] We will abuse notation and write $j^{-1}(H)$ for this G.

General Induced Ideals

We now summarize this discussion by describing the general situation in which induced ideals arise.

3.37 Example. Let $H \subseteq \mathbb{Q}$ be generic and suppose that in $V[H]$ there is an elementary embedding $j : V \to M \subseteq V[H]$, where M is transitive. Let i be a $\mathbb{Q}$-name for an element of M and Z a set such that $\|i \in j(Z)\|_{\mathbb{Q}} = 1$. Then in V we can define an ideal $I \subseteq P(Z)$ by setting $A \in I$ iff every condition in $\mathbb{Q}$ forces $A \notin U(j, i)$. For all generic $H \subseteq \mathbb{Q}$ the ultrafilter $U(j, i)$ extends $\breve{I}$.

3.38 Proposition. *Assume the hypotheses of Example 3.37. Suppose that for all V-generic $G \subseteq \mathbb{Q}$, $V[G] \models i = j``X$. Then the ideal I is a normal, fine, countably complete ideal on $Z = P(X)$.*

3.39 Definition. We will call any elementary embedding j that is definable in a forcing extension of V a *generic* elementary embedding. We will call the ideal defined in Example 3.37 the ideal *induced by j and i.*[18] If I is an ideal induced by a generic elementary embedding we will call I *pre-precipitous.*

The dual of every pre-precipitous ideal can be extended to an ultrafilter lying in a generic extension that has a well-founded ultrapower.

There are examples of partial orderings $\mathbb{Q}$ and generic $G \subseteq \mathbb{Q}$ where $U(j, i)$ is not generic for the partial ordering $P(Z)/I$. In these examples, the pre-precipitous ideal I is not precipitous. This is discussed in Sect. 7.3.

Burke [12] showed that if I is *any* countably complete ideal on a set Z and there is a Woodin cardinal $\delta > |Z|$,[19] then there is a partial ordering $\mathbb{P}$ which produces an ultrafilter U on $P(Z)$ such that V^Z/U is well-founded, $\breve{I} \subseteq U$ and if $j : V \to N \cong V^Z/U$ is the canonical embedding, then $\mathrm{crit}(j) = \mathrm{comp}(I)$. A small improvement of his argument actually shows that every countably complete ideal is pre-precipitous. We show this in Proposition 9.44.

3.40 Proposition. *Suppose that I is an ideal on a set Z. Then the following are equivalent:*

1. *I is precipitous.*
2. *There is a partial ordering $\mathbb{P}$ such that for all generic $G \subseteq \mathbb{P}$ there is a $j : V \to M \subseteq V[G]$ and a $\mathbb{P}$-term i such that:*
   - *(a) I is the ideal induced by j and i, and*
   - *(b) $U(j, i)$ is generic for $P(Z)/I$.*

Proof. Suppose that I is precipitous. Let $\mathbb{P} = P(Z)/I$, $j : V \to M$ the generic ultrapower embedding and i a term for $[\mathrm{id}]^M$.

[18] Usually, $\mathbb{Q}$ is implicit in the definition of j.

[19] Woodin cardinals occur prominently in several Handbook chapters. We defer the actual definition to Definition 9.22 where we use it for the first time.

For the other direction, note that the map $\iota : P(Z) \to \mathcal{B}(\mathbb{P})$ defined by setting

$$\iota(A) = \|A \in U(j,i)\|$$

has kernel I. Hence we can view $\iota : P(Z)/I \to \mathcal{B}(\mathbb{P})$. The hypothesis (b) implies that ι is a regular embedding. By factoring $\mathcal{B}(\mathbb{P})$ as $P(Z)/I * \mathcal{B}(\mathbb{P})/\iota``U$ we see that whenever $U \subseteq P(Z)/I$ is generic there is a generic $G \subseteq \mathbb{P}$ such that $U(j,i)^{V[G]} = U$.

Let U be generic for $P(Z)/I$. We need to see that the ultrapower V^Z/U is well-founded. Let $G \subseteq \mathbb{P}$ be such that $U(j,i) = U$. Then there is a commuting diagram:

$$\begin{tikzcd} & V \arrow[dl, "j'"'] \arrow[dr, "j"] & \\ V^Z/U(j,i) \arrow[rr, "k"'] & & M \end{tikzcd}$$

where j' is the ultrapower map and k is defined by setting

$$k(f) = j(f)(i).$$

Since M is well-founded we see that $V^Z/U(j,i)$ is well-founded. $\dashv$

3.41 Remark. Any large cardinal embedding is a generic elementary embedding, as we can take $\mathbb{Q}$ to be the trivial partial ordering. The ultrafilters used to define standard large cardinal axioms are of the form $U(j,i)$ and hence their duals are "induced ideals" from the trivial partial ordering.

Goodness and Self-Genericity

A very powerful situation can arise when a natural ideal is simultaneously an induced ideal. For this to happen we need a criterion for genericity, which we give in the "reflected" form. Attempts to make natural ideals be induced[20] use the idea of self-genericity, to be defined below. The next example sets the stage for this important definition.

3.42 Example. Suppose that J is a countably complete ideal on a set $Z^* \subseteq P(X)$. Let θ be a regular cardinal much larger than the cardinality of Z^*, and suppose that $M' \prec \langle H(\theta), \in, \Delta, J, Z^*, \ldots \rangle$. Let M be the transitive collapse of M' and $j : M \to H(\theta)$ be the inverse of the collapse map. Suppose that $Z = j^{-1}(Z^*)$ and $I = j^{-1}(J)$. Letting $i = M' \cap X$, if $i \in Z^*$ we can build the M-ultrafilter $U(j,i) \subseteq P(Z)$.

We want to consider the ultrafilter $U(j,i)$ and its associated ideal both in the situation of extension via an elementary embedding $j : V \to M$ and in the situation of reflection via taking elementary submodels. For this reason we give the definition of "goodness" in a way that highlights the role of j.

[20] E.g. by making them precipitous.

3.43 Definition. The model M' is *good* iff

$$M' \cap X \in \bigcap\{j(A) : A \subseteq Z \text{ and } A \in \breve{I}\}.$$

We can say this another way: taking $i = M' \cap X$ the goodness of M' is equivalent to $U(j,i) \supseteq \breve{I}$. Proposition 3.44 shows that goodness is also equivalent to the condition that $M' \cap X \in \bigcap\{B : B \in \breve{J} \text{ and } B \in M'\}$. This latter condition is sometimes easier to verify in practice.

The point of the definition is that it describes what happens in every generic ultrapower. Let I be a normal, fine ideal I on $Z \subseteq P(\mu)$ for some $\mu \ll \theta$. Let $j : V \to N \cong V^Z/G \subseteq V[G]$ be the ultrapower map coming from a generic $G \subset P(Z)/I$. Then $M' =_{\text{def}} j``H(\theta)$ is a good elementary substructure of $j(H(\theta))$ for the ideal $J = j(I)$.

The next proposition shows that most $z \in Z^*$ generate good elementary substructures of $H(\theta)$.

3.44 Proposition. *Let $\mathfrak{A}$ be an algebra expanding $\langle H(\theta), \in, \Delta, J, Z^*, \ldots\rangle$ and suppose that J is a normal, fine, countably complete ideal. Then:*

1. *There is a set $C \in \breve{J}$ such that for all $z \in C$ if $M' = \mathrm{Sk}^{\mathfrak{A}}(z)$, then M' is good.*
2. *If M' is good, then $\{j(A) : A \in U(j,i)\} \supseteq \breve{J} \cap M'$, where $i = M' \cap X$.*

Proof. We can assume that $\mathfrak{A}$ has a complete set of Skolem functions. By normality there is a set $D \in \breve{J}$ such that for all $z \in D$, $\mathrm{Sk}^{\mathfrak{A}}(z) \cap X = z$. Suppose that there is a J-positive set B of counterexamples z. Using the countable completeness of J, we can assume that there is a particular Skolem function f such that for all $z \in B$ there is an $a \in [z]^{<\omega}$ such that $f(a)$ is a set in $\breve{J}$ and $z \notin f(a)$. Applying normality again, we can assume that there is a fixed a such that for all $z \in B$, $a \subseteq z$ and $z \notin f(a)$. But this contradicts $B \in J^+$.

For the second assertion, suppose that M' is good. By definition, $\breve{J} \cap M' = \{j(A) : A \in \breve{I}\}$ and since M' is good, $M' \cap X \in \bigcap\{j(A) : A \in \breve{I}\} = \bigcap\{B : B \in \breve{J} \cap M'\}$. Thus $M' \cap X$ belongs to every set in $\breve{J} \cap M'$ and hence $\breve{J} \cap M' \subseteq \{j(A) : A \in U(j,i)\}$. ⊣

3.45 Definition. If $U(j, M' \cap X)$ is generic over M for $P(Z)/I$, we say that M' is *self-generic*.

This idea first appeared in [47]. Note that a good M' is self-generic iff for every $A \subseteq P(Z^*)$ that is a maximal antichain in $P(Z^*)/J$ and lies in M', there is an $a \in A \cap M'$ such that $M' \cap X \in a$.[21] Equivalently, if $A \subseteq P(Z)$ belongs to M and is an M-maximal antichain in $P(Z)/I$ there is an $a \in A$ such that $M' \cap X \in j(a)$.

[21] See Definition 8.19 and Proposition 8.20 in Sect. 8.

A guiding idea for making various nonstationary ideals have some degree of saturation, presaturation or precipitousness is to use devices such as semiproperness to create some degree of self-genericity. The next lemma shows that goodness and self-genericity give a condition equivalent to saturation.

3.46 Lemma. *Let $Z^* \subseteq P(X)$ for some set X and J be a normal, fine, countably complete ideal on $P(Z^*)$. Suppose that $\mathfrak{A}$ is an algebra expanding $\langle H(\theta), \in, \Delta, J, Z^*, \ldots\rangle$.*

1. *If the ideal J is the nonstationary ideal on $P(X)$ restricted to a stationary set Z^*, then every $M' \prec \mathfrak{A}$ with $M' \cap X \in Z^*$ is good.*
2. *If the ideal J is normal, fine and $|X|^+$-saturated, then every good $M' \prec \mathfrak{A}$ is self-generic.*
3. *Suppose that every good $M' \prec \mathfrak{A}$ is self-generic and $|Z^*| \leq |X|$. Then J is $|X|^+$-saturated.*

Note that in most interesting cases $|Z^*| = |X|$ and in these cases, the third assertion is an exact converse to the second.

Proof. If $C \in \breve{I}$, then $C \in M$ and C is closed and unbounded. Let $\mathfrak{B} \in M$ be an algebra on $j^{-1}(X)$ such that every elementary substructure of $\mathfrak{B}$ is in C. Since $M' \cap X$ is an elementary substructure of $j(\mathfrak{B})$, we see that $M' \cap X \in j(C)$.

To establish the second assertion, suppose that $\mathcal{A} \subseteq P(Z)$ is a maximal antichain relative to I. Since I is $|X|^+$-saturated, $\mathcal{A}$ has cardinality at most $|X|$ and we can let $C = \triangledown\mathcal{A}$. Then C is in $\breve{I}$. Hence, by elementarity, $j(\mathcal{A})$ is a maximal antichain in $P(Z^*)/J$ and $j(C) \in \breve{J}$. Since M' is good, $M' \cap X \in j(C)$. By the definition of diagonal union, this implies that there is an $a' \in j(\mathcal{A}) \cap M'$ such that $M' \cap X \in a'$. Letting $a = j^{-1}(a')$, we see that $a \in U(j, M' \cap X) \cap \mathcal{A}$. Thus $U(j, M' \cap X)$ has non-empty intersection with every maximal antichain in $P(Z)/I$ that lies in M and hence $U(j, M' \cap X)$ is generic for $P(Z)/I$.

To establish the third assertion, indirectly assume that $\mathcal{A}$ is a maximal antichain in $P(Z^*)/J$ of size at least $|X|^+$. We can assume without loss of generality that $\mathcal{A}$ is definable in $\mathfrak{A}$. Let $C \in \breve{J}$ be such that for all $z \in C$, $\mathrm{Sk}^{\mathfrak{A}}(z)$ is good and $\mathrm{Sk}^{\mathfrak{A}}(z) \cap X = z$. Let $\mathcal{B} = \{a \in \mathcal{A} :$ for some $z \in C,\ a \in \mathrm{Sk}^{\mathfrak{A}}(z)\}$. Note that $\mathcal{B}$ has cardinality at most $|X| \cdot |Z^*| = |X|$. Hence we will be done if we can show that $\mathcal{B} \supseteq \mathcal{A}$.

If not, let $a \in \mathcal{A} \backslash \mathcal{B}$. For each $b \in \mathcal{B}$ choose a $D_b \in \breve{J}$ such that $D_b \cap b \cap a = \emptyset$. Let $D = \Delta_{b \in \mathcal{B}} D_b$, and $z \in (a \cap C \cap D)$. Since $\mathrm{Sk}^{\mathfrak{A}}(z)$ is self-generic there is a $c \in \mathcal{A} \cap \mathrm{Sk}^{\mathfrak{A}}(z)$ such that $z \in c$. Since $z \in C$ we have that $c \in \mathcal{B}$. Since $c \in z$, $z \in D_c$. But then $z \in D_c \cap c \cap a$, a contradiction. ⊣

A special case of the example above may be illustrative.

3.47 Example. Suppose that the nonstationary ideal on ω_1 is $\aleph_2$-saturated. Let θ be a large regular cardinal, and $M' \prec \langle H(\theta), \in, \Delta, \ldots \rangle$ be a countable elementary substructure. Let $\delta = M' \cap \omega_1$. Then $U(j, \delta)$, the *critical point ultrafilter*, is generic over M, the transitive collapse of M', for the partial ordering $P(\omega_1)/\mathrm{NS}_{\omega_1}$ as computed in M. Moreover, the ultrapower of M by $U(j, \delta)$ is isomorphic to $\mathrm{Sk}^{H(\theta)}(M' \cup \{\delta\})$.

Conversely, if $\lambda \geq (2^{\omega_1})^+$ and there is a closed unbounded set $C \subseteq [H(\lambda)]^{<\omega_1}$ such that every $M \in C$ is self-generic, then NS_{ω_1} is $\aleph_2$-saturated.

Example 3.47 foreshadows techniques from [47] that played an important role in work of Woodin.

4. A Closer Look

In this section we explore further the various properties an ideal can have. These include various saturation properties, both strengthening and weakening conventional saturation. Some of these are preserved under *projection*, an operation that is closely related to factoring the generic ultrapower through smaller generic ultrapowers. We will touch on *towers* of ideals, mostly in relation to ideals on fixed sets.

4.1. A Structural Property of Saturated Ideals

We begin with some theorems that give some insight into the structure of saturated ideals. These theorems are due to Baumgartner, Taylor and Wagon [8] in the case that the ideal is κ-complete. We present the first theorem in slightly greater generality.

4.1 Theorem. *Let κ be a regular cardinal. Suppose that $I \subseteq P(P(\kappa))$ is a normal, fine, countably complete, κ^+-saturated ideal. If I is contained in $J \subseteq P(P(\kappa))$ where J is a normal countably complete ideal, then there is an I-positive set A such that:*

$$J = I \restriction A.$$

In particular, J is saturated.[22]

Proof. Let $\gamma \leq \kappa$ and $\langle B_\alpha : \alpha < \gamma \rangle$ be a maximal I-antichain of elements of J. Let $B = \triangledown B_\alpha$. We claim that J is the ideal generated by I and B.

Since J is normal, $B \in J$. Hence $\overline{I \cup \{B\}} \subseteq J$. Suppose that there is a set $C \in J$ not in the ideal generated by $I \cup \{B\}$. Then $C \setminus B \notin I$. Replacing C by $C \setminus B$ we can assume that $C \cap B_\alpha \in I$ for all $\alpha < \gamma$. This shows that $\langle B_\alpha : \alpha < \gamma \rangle$ is not a maximal I-antichain of elements of J, a contradiction. $\dashv$

[22] We remind the reader that $I \restriction A$ can be viewed both as $I \cap P(A)$ and as the ideal generated by $I \cup \{P(\kappa) \setminus A\}$. See Sect. 2 for a discussion of this.

In the rarer situation where the ideal I is κ-complete and κ-saturated, normality is not needed:

4.2 Theorem. *Let κ be a regular cardinal. Suppose that I is a κ-complete, κ-saturated ideal on a set Z. If $J \supseteq I$ is a κ-complete ideal extending I, then there is a set $A \in I^+$ such that $J = I \restriction A$.*

Proof. Let $\langle A_\alpha : \alpha < \beta \rangle$ be a maximal antichain in I^+ of elements of J. Then $\beta < \kappa$, so $[\bigcup_{\alpha<\beta} A_\alpha]_I = \Sigma_{\alpha<\beta}[A_\alpha]$ in $P(X)/I$. Hence $J = I \restriction (Z \setminus A)$, where $A = \bigcup_{\alpha<\beta} A_\alpha$. ⊣

4.2. Saturation Properties

We now enumerate a hierarchy of saturation properties of ideals. Many of these properties were explored in papers by Baumgartner and Taylor [5, 6], although we have modified the terminology very slightly. The saturation properties of ideals are in direct correspondence to the chain condition properties of arbitrary partial orderings, for obvious reasons. Let $\mathbb{B} = P(Z)/I$.[23] We define some properties that $\mathbb{B}$ may have; we will say that an ideal I or a tower of ideals $\mathcal{T}$ has a property iff the corresponding partial ordering $\mathbb{B}$ has the property.

The partial ordering $\mathbb{B}$ is:

- κ-*dense* iff $\mathbb{B}$ has a dense subset of cardinality κ,
- (κ, λ)-*centered* iff $\mathbb{B} = \bigcup_{\alpha<\kappa} F_\alpha$, where each F_α is a λ-complete filter on $\mathbb{B}$. I is κ-*centered* iff I is $(\kappa, \aleph_0)$-centered,
- (κ, η, λ)-*saturated* iff every subset A of $\mathbb{B}$ having cardinality κ contains a subset B of cardinality η such that the meet (intersection) of any λ elements of B is non-zero, and
- κ-*linked* iff $\mathbb{B} = \bigcup_{\alpha<\kappa} F_\alpha$, where the intersection of any two elements of F_α is not in I.

These properties are listed in roughly descending order of strength, provided that the parameters are set correctly. For example, if I is κ-dense then I is (κ, λ)-centered for all λ. Hence $P(Z)$ can be written as a union of κ many filters that are comp(I)-complete. Similarly, if I is (κ, λ)-centered, then I is $(\kappa^+, \kappa^+, \gamma)$-saturated for all $\gamma < \lambda$. We leave it to the reader to explore the possibilities. These ideal properties were defined or used variously in [123, 83, 35, 126].

Taylor showed:

4.3 Theorem (Taylor [119, 120]). *The following are equivalent:*

1. *There is a countably complete, $\aleph_1$-dense ideal on ω_1.*

[23] As usual we will be sloppy in not carefully distinguishing between the Boolean algebra $P(Z)/I$ and the partial ordering $\langle P(Z)/I, \subseteq_I \rangle$, with the 0 element removed.

2. *(Ulam's Problem for normal ideals) There is a collection $\mathcal{I}$ of countably complete, normal ideals on ω_1 with $|\mathcal{I}| = \aleph_1$ such that for all $A \subseteq \omega_1$, there is an $I \in \mathcal{I}, A \in I \cup \breve{I}$.*

Moreover, both properties fail if MA_{ω_1} *holds.*

We now give a characterization of κ-dense ideals due to Shelah [102] in the particular case that an ideal on κ is normal and κ-complete. The equivalence of properties 1 and 2 is also implicit in Taylor [119]. Note the analogy between the third part of the characterization and (μ^+, μ^+, μ)-saturation.

4.4 Theorem. *Let I be a normal, fine, countably complete ideal on $Z \subseteq P(X)$ and suppose that $\kappa \leq |X|$ is a regular cardinal. Then the following are equivalent:*

1. *$P(Z)/I$ has a dense set of size $\leq \kappa$.*

2. *There are normal, fine, countably complete ideals $\langle J_i : i < \kappa \rangle$ such that $I \subseteq J_i$ for each i and every set in I^+ belongs to $\bigcup_i \breve{J}_i$.*

If in addition $2^\kappa = \kappa^+$, these are also equivalent to:

3. *Whenever $\{A_l : l \in \kappa^+\}$ is a collection of I-positive sets there is a set $L \subseteq \kappa^+$ of cardinality κ^+ such that the diagonal intersection of any $L' \subseteq L$ of size κ is I-positive.*

Proof. That property 1 implies property 2 is immediate.

Assume property 2, towards showing property 1. Then $P(Z)/I$ is κ^+-c.c. For each i, let $\{A_\beta : \beta \in \gamma\} \subseteq \breve{J}_i$ be maximal and strictly I-decreasing. Then $|\gamma| \leq \kappa$. Hence $A_i =_{\mathrm{def}} \Delta_{\beta \in \gamma} A_\beta \in \breve{J}_i$ and is the I-minimal element of $\breve{J}_i$, i.e. $J_i = I \restriction A_i$. Since every element of I^+ belongs to some $\breve{J}_i$, $\{[A_i]_I : i < \kappa\}$ is a dense subset of $P(Z)/I$.

Assume property 2, towards showing property 3. If we are given a sequence $\{A_l : l \in \kappa^+\}$ of I-positive sets, then there must be some j such that $L =_{\mathrm{def}} \{l : A_l \in \breve{J}_j\}$ has cardinality κ^+. Since J_j is normal, property 3 follows.

Assume property 3 and $2^\kappa = \kappa^+$, and towards showing property 1, that I does not have a dense set of size $\leq \kappa$. Then we can build a sequence of sets $\langle A_\alpha : \alpha < \kappa^+ \rangle$ such that:

1. if $D \in [\kappa^+]^\kappa$, and $\Delta_{\alpha \in D} A_\alpha \neq \emptyset$, then there is a $\beta < \kappa^+$ such that $A_\beta = \Delta_{\alpha \in D} A_\alpha$, and

2. for $\alpha < \beta$, $A_\alpha \nsubseteq_I A_{\beta+1}$.

Using property 3, we can find an unbounded set $L \subseteq \kappa^+$ of successor ordinals such that for all $D \in [L]^\kappa$, $\Delta_{\alpha \in D} A_\alpha \neq_I \emptyset$. For $\beta < \kappa^+$, let $B_\beta = \Delta_{L \cap \beta} A_\alpha$. By the κ^+-saturation of I there is a β such that for all $\beta' > \beta$, $B_\beta =_I B_{\beta'}$. Suppose that $B_\beta = A_\gamma$. Choose an $\alpha \in L \setminus (\gamma + 1)$. Then $B_\beta \subseteq_I A_\alpha$, since $B_\beta =_I B_{\alpha+1}$, but $A_\gamma \nsubseteq_I A_\alpha$, a contradiction. ⊣

The next few properties are weaker than saturation.

4.5 Definition. An ideal I, with corresponding $\mathbb{B} = P(Z)/I$, is:

- *κ-preserving* iff the forcing $\mathbb{B}$ preserves the cardinal κ,
- *cardinal preserving* iff $\mathbb{B}$ preserves all cardinals greater than or equal to $|Z|^+$ and below the completeness of I,
- *κ-presaturated* iff I is precipitous and κ-preserving,
- *presaturated* iff $|Z| = \kappa$ and $\mathbb{B}$ is κ^+-presaturated, and
- *weakly (λ, κ)-saturated* iff for any $\gamma < \lambda$ and any collection of antichains $\{\mathcal{A}_\alpha : \alpha < \gamma\}$ in $\mathbb{B}$ there is a dense collection of $Y \in \mathbb{B}$ such that for all $\alpha < \gamma$, $|\{b \in \mathcal{A}_\alpha : Y \wedge b \neq 0\}| < \kappa$.

The first and last properties are abstract properties of the partial ordering $\mathbb{B}$, and do not depend on $\mathbb{B}$ being of the form $P(Z)/I$. Indeed, the following is a forcing exercise:

4.6 Proposition. *Suppose that $\gamma < \kappa$ are regular cardinals and $\mathbb{P}$ is a partial ordering of size less than or equal to κ. Then the following are equivalent:*

1. *$\mathbb{P}$ is weakly (γ^+, κ)-saturated.*
2. *If $G \subseteq \mathbb{P}$ is generic, then $\mathrm{cf}(\kappa) > \gamma$ in $V[G]$.*

Proof. To see that weak saturation implies that $\mathrm{cf}(\kappa) > \gamma$, suppose that $b \Vdash$ "$\dot{f}$ is a term for a cofinal function from γ into κ". Let A_α be a maximal antichain below b deciding $\dot{f}(\alpha)$. Let $c \leq b$ be such that for all $\alpha < \gamma$, $|\{a \in A_\alpha : c \wedge a \neq 0\}| < \kappa$. Let $\xi = \sup_{\alpha<\gamma}\{\beta :$ there is an $a \in A_\alpha$ such that $c \wedge a \neq 0$ and $a \Vdash \dot{f}(\alpha) = \beta\}$. Then $c \Vdash$ "for all α, $f(\alpha) < \xi$", a contradiction.

Now suppose that $\langle A_\alpha : \alpha < \gamma\rangle$ is a sequence of maximal antichains and $b \in \mathbb{P}$. Enumerate A_α as $\{a_\alpha^\beta : \beta < |A_\alpha|\}$. Define a term $\dot{f}$ for a function by setting $\|\dot{f}(\alpha) = \beta\| = a_\alpha^\beta$. Let $c \leq b$ be such that for some $\xi < \kappa$, $c \Vdash$ "$\dot{f}$ is bounded by ξ". Then for all α, $|\{\beta : c \wedge a_\alpha^\beta \neq 0\}| \leq |\xi| < \kappa$. ⊣

4.7 Lemma. *Suppose that $\mathbb{P}$ is a partial ordering and κ is regular. Let $\rho < \kappa$ be the least cardinal such that there are maximal antichains $\langle \mathcal{A}_\alpha : \alpha < \rho\rangle$ such that the collection of Y such that for all $\alpha < \rho$, $|\{b \in \mathcal{A}_\alpha : Y \wedge b \neq 0\}| < \kappa$ is not dense. Then ρ is a regular cardinal.*

Proof. Suppose not. Let $\eta = \mathrm{cf}(\rho)$ and $\langle \rho_i : i \in \eta\rangle$ be a cofinal sequence in ρ. For each $i \in \eta$ we can define a maximal antichain $\mathcal{B}_i$ such that for all $Y \in \mathcal{B}_i$ and all $\alpha < \rho_i$, $|\{b \in \mathcal{A}_\alpha : Y \wedge b \neq 0\}| < \kappa$. Since $\eta < \rho$, we can find a dense collection D of Y such that for each $i \in \eta$, $|\{c \in \mathcal{B}_i : Y \wedge c \neq 0\}| < \kappa$.

Let $Y \in D$, and $\alpha < \rho$. Let $C_i = \{c \in \mathcal{B}_i : Y \wedge c \neq 0\}$. Let $\mu = \sup_{i\in\eta} |C_i|$. For each $c \in C_i$ let $\mathcal{A}_c = \{b \in \mathcal{A}_\alpha : b \wedge c \neq 0\}$. Let $\gamma = \sup_{c\in C_i, i<\eta} |\mathcal{A}_c|$. Then $\{b \in \mathcal{A}_\alpha : Y \wedge b \neq 0\}$ has cardinality at most $\mu \times \gamma < \kappa$, a contradiction. ⊣

With some favorable cardinal arithmetic, Baumgartner and Taylor [6] showed that these properties are equivalent. Most of the results in this subsection are an elaboration of theorems from that paper.

4.8 Proposition. *Assume* GCH *and that I is a normal, fine, countably complete ideal on $Z \subseteq P(\kappa)$ with $|Z| \leq \kappa$. Let λ be regular cardinal less than or equal to κ. Then the following are equivalent:*

1. *For all generic $G \subseteq P(Z)/I$, $V[G] \models \mathrm{cf}(\kappa^+) > \lambda$.*
2. *I is weakly (λ^+, κ^+)-saturated.*
3. *If $\{\mathcal{A}_\alpha : \alpha < \lambda\}$ is a collection of maximal antichains in $P(Z)/I$, then there is a dense collection of Y in $P(Z)/I$, such that for each α there is a pairwise disjoint collection of representatives for $\mathcal{A}_\alpha \restriction Y = \{b \in \mathcal{A}_\alpha : Y \cap b \notin I\}$.*
4. *I is precipitous and for all generic $G \subseteq P(Z)/I$ if $j : V \to M \subseteq V[G]$ is the generic elementary embedding, then $M \models \mathrm{cf}(\kappa^+) > \lambda$ and $M^\lambda \cap V[G] \subseteq M$.*

We note that the only part of the following proof that uses GCH is the implication that property 1 implies property 2. Weaker assumptions than GCH suffice for proving 2, for example the assumption that $2^\kappa < \kappa^{+\omega}$ and that for all $n \in \omega$, $\mathrm{cf}(\kappa^{+n})^{V[G]} > \lambda$. We leave this to the reader. See [18] for some sufficient conditions involving pcf theory. We do point out that the argument given below can be easily generalized without any GCH assumption under the hypothesis that I is a normal, fine, countably complete, $\kappa^{+\omega}$-saturated ideal on $Z \subseteq P(\kappa)$ with $|Z| \leq \kappa$ that preserves every cardinal κ^{+n} for $n \geq 1$.

Proof. To see the proposition, assume property 1 and fix maximal antichains $\langle \mathcal{A}_\alpha : \alpha < \lambda \rangle$. Then each $\mathcal{A}_\alpha$ has cardinality less than or equal to κ^+. Enumerate $\mathcal{A}_\alpha$ as $\langle a^\alpha_\beta : \beta < \gamma_\alpha \rangle$ in a one-to-one way so that $\gamma_\alpha \leq \kappa^+$. Define a function $f : \lambda \to \kappa^+$ lying in $V[G]$ for generic $G \subseteq P(Z)/I$, by setting $f(\alpha) = \beta$ iff $G \cap \mathcal{A}_\alpha = \{a^\alpha_\beta\}$. Then, since κ^+ has cofinality greater than λ in $V[G]$, there is a set $Y \subseteq Z$ such that $[Y] \Vdash \sup(f``\lambda) = \eta$. Then for all α, $\sup\{\beta : Y \cap a^\alpha_\beta \notin I\} \leq \eta$. Hence we have verified that I is weakly (λ^+, κ^+)-saturated.

Now suppose that I is weakly (λ^+, κ^+)-saturated, i.e. property 2. Then arguments similar to Proposition 2.23 show that if $|\{b \in \mathcal{A}_\alpha : b \cap Y \notin I\}| \leq \kappa$, then we can choose a system of disjoint representatives for $\{b \cap Y : b \in \mathcal{A}_\alpha \text{ and } b \cap Y \notin I\}$. Hence given a collection of antichains $\langle \mathcal{A}_\alpha : \alpha < \lambda \rangle$, there is a dense collection of $Y \in P(Z)/I$ such that for all $\alpha < \lambda$ there is a disjoint system of representatives for $\{b \cap Y : b \in \mathcal{A}_\alpha \text{ and } b \cap Y \notin I\}$.

As in the proof that the disjointing property implies precipitousness (see Proposition 2.14), this immediately gives that I is precipitous. Moreover, it shows that the analogue of Proposition 2.12 holds: given $P(Z)/I$ terms $\{\dot{f}_\alpha : \alpha < \lambda\}$ for functions in V with domain Z, there is a dense collection $D \subseteq P(Z)/I$ such that for each $Y \in D$ there is a sequence of functions $\{g_\alpha : \alpha < \lambda\}$ that lies in V such that $[Y] \Vdash [\dot{f}_\alpha]^M = [\check{g}_\alpha]^M$. Using normality, this suffices to argue the closure of the ultrapower as in Proposition 2.14.

Finally, it is easy to check that property 4 implies property 1. ⊣

To summarize we get the following corollaries:

4.9 Corollary. *Assume* GCH *and that I is a normal, fine, countably complete ideal on $Z \subseteq P(\kappa)$ with $|Z| = \kappa$ such that $P(Z)/I$ preserves κ^+. Then I is precipitous. If $G \subseteq P(Z)/I$ is generic and $j : V \to M$ is the generic embedding then $M^\kappa \cap V[G] \subseteq M$.*[24]

4.10 Corollary. *In addition to the hypotheses of Proposition 4.8, assume that I is λ^{++}-complete and weakly (λ^+, κ^+)-saturated. Then every cardinal and cofinality less than λ^+ is preserved.*

We now show a small generalization of a theorem Solovay proved about c.c.c. ideals:

4.11 Proposition. *If I is a countably complete ideal on $P(\kappa)$ such that $P(\kappa)/I$ is a proper partial ordering, then I is weakly $(\aleph_1, \aleph_1)$-saturated. Thus, I is precipitous and the corresponding generic ultrapower is closed under ω-sequences.*

Proof. Suppose that $P(\kappa)/I$ is a proper partial ordering. Let $\{\mathcal{A}_n : n \in \omega\}$ be a collection of maximal antichains and $S \in I^+$. Let $N \prec H(\theta)$ be countable with $I, \kappa, \{\mathcal{A}_n : n \in \omega\} \in N$ and T a generic condition for N. Then $\{a \in \mathcal{A}_n : a \cap T \notin I\} \subseteq N$ and hence is countable. Since I is countably complete we can disjointify the $\mathcal{A}_n$'s below T, and proceed as in Proposition 4.8. ⊣

The saturation properties of the ideals often greatly restrict the possible partial orderings that can arise as the quotient $P(Z)/I$. An extreme example is:

4.12 Example. Suppose that I is a countably complete, $\aleph_1$-dense ideal. Then $P(Z)/I$ is a complete Boolean algebra that collapses ω_1 and has a dense set of size $\aleph_1$. Hence it is isomorphic to the complete Boolean algebra generated by $\mathrm{Col}(\omega, \omega_1)$.

We note that Balcar and Franek showed that if I is an ideal on ω_1 that is nowhere precipitous and $\mathcal{B}(P(\omega_1)/I)$ has a dense set of size ω_2, then $\mathcal{B}(P(\omega_1)/I) \cong \mathcal{B}(\mathrm{Col}(\omega, \omega_2))$.

[24] Note that we do not assume that the critical point of j is κ.

4.3. Layered Ideals

The quotient algebras of certain saturated ideals are organized enough to allow powerful inductive constructions of ultrafilters. (See e.g. [48, 36] and Sects. 5.9 and 7.4.) The main notion is that of a layered ideal.

4.13 Definition. Let I be a normal, fine, κ-complete ideal on κ. Then I is *layered* iff $\mathcal{B}(P(\kappa)/I) = \bigcup_{\alpha<\kappa^+} \mathcal{B}_\alpha$ where:

1. each $\mathcal{B}_\alpha$ is a Boolean subalgebra of $\mathcal{B}(P(\kappa)/I)$ with $|\mathcal{B}_\alpha| = \kappa$,
2. if $\alpha < \beta$ then $\mathcal{B}_\alpha \subseteq \mathcal{B}_\beta$,
3. for limit β, $\mathcal{B}_\beta = \bigcup_{\alpha<\beta} \mathcal{B}_\alpha$, and
4. for stationarily many $\alpha \in \kappa^+ \cap \operatorname{Cof}(\kappa)$, $\mathcal{B}_\alpha$ is a regular subalgebra of $\mathcal{B}(P(\kappa)/I)$.

A sequence $\langle \mathcal{B}_\alpha : \alpha < \kappa^+ \rangle$ is called a *filtration* if it satisfies clauses 1 to 3 in the definition. A filtration that also satisfies clause 4 is a *layering sequence*.

4.14 Remark (Shelah). If I is a layered ideal on κ then I is κ^+-saturated.

Proof. Suppose that $\mathcal{A} \subseteq \mathcal{B}(P(\kappa)/I)$ is a maximal antichain. Then for a closed unbounded set of $\alpha < \kappa^+$, $\mathcal{A} \cap \mathcal{B}_\alpha$ is a maximal antichain in $\mathcal{B}_\alpha$. For such an α where $\mathcal{B}_\alpha$ is a regular subalgebra of $\mathcal{B}$, we must have $\mathcal{A} \cap \mathcal{B}_\alpha$ maximal in $\mathcal{B}$. In particular, $\mathcal{A} \cap \mathcal{B}_\alpha = \mathcal{A}$ and hence $|\mathcal{A}| \leq \kappa$. ⊣

4.15 Definition. A layered ideal I is *strongly layered* iff there is a layering sequence $\langle \mathcal{B}_\alpha : \alpha < \kappa^+ \rangle$ such that there is a closed unbounded set $C \subseteq \kappa^+$ such that for all $\alpha \in C \cap \operatorname{Cof}(\kappa)$, $\mathcal{B}_\alpha$ is a regular subalgebra of $\mathcal{B}$.

If $\langle \mathcal{B}_\alpha : \alpha < \kappa^+ \rangle$ witnesses strong layering then we can pass to a subsequence with the property that for *all* $\alpha \in \operatorname{Cof}(\kappa)$, $\mathcal{B}_\alpha$ is a regular subalgebra of $\mathcal{B}$.

It is well-known that if $A \subseteq \kappa^+ \cap \operatorname{Cof}(\kappa)$ is stationary, then there is a partial ordering $\mathbb{P}$ that adds a closed unbounded set $C \subseteq \kappa^+$ to V with $C \cap \operatorname{Cof}(\kappa) \subseteq A$ in such a way that $\mathbb{P}$ adds no new κ-sequences to V. As a consequence, if I is a layered ideal on κ and A is the stationary subset witnessing clause 4 of the definition of "layered", we can add a closed unbounded subset of A without changing $P(\kappa)$. In the resulting extension I is strongly layered. Thus it is a consequence of the following theorem that if we have $\kappa^{<\kappa} = \kappa$, and a layered ideal I on κ, there is a (κ^+, ∞)-distributive forcing extension in which I is κ-centered. The following is a result of Shelah.

4.16 Theorem (Shelah [102]). *If I is a strongly layered ideal on κ and $\kappa^{<\kappa} = \kappa$ then I is κ-centered.*

We prove this theorem for the case CH and $\kappa = \omega_1$. After the proof we briefly discuss how to extend the theorem to arbitrary κ.

Proof. We begin with a review of the elementary theory of Boolean algebras. Suppose that $\mathcal{B}$ and $\mathcal{C}$ are complete Boolean algebras, $\mathbb{P}$ is dense in $\mathcal{B}$ and $\mathbb{Q}$ is dense in $\mathcal{C}$. If there is a regular embedding i of $\mathbb{P}$ into $\mathbb{Q}$ then there is a complete embedding $\iota : \mathcal{B} \to \mathcal{C}$ extending i. In this case we can define a map $\pi_\iota : \mathcal{C} \to \mathcal{B}$ by setting $\pi(c) = \prod\{b : \iota(b) \geq c\}$. Then $\pi \circ \iota = \mathrm{id}$ and $\iota \circ \pi \geq \mathrm{id}$. Moreover, if $b \in \mathcal{B}$ and $b \leq \pi(c)$ then $\iota(b) \wedge c \neq 0$. The map π will be called a projection of $\mathcal{C}$ to $\mathcal{B}$.

Suppose now that we have complete embeddings $\iota_0 : \mathcal{B} \to \mathcal{C}$ and $\iota_1 : \mathcal{C} \to \mathcal{D}$ where $\mathcal{B}, \mathcal{C}, \mathcal{D}$ are all complete Boolean algebras. Then it is easy to check that if π_0 and π_1 are the projections associated with ι_0 and ι_1, then $\pi_0 \circ \pi_1$ is the projection associated with $\iota_1 \circ \iota_0$.

If $i : \mathbb{P} \to \mathbb{Q}$ is a regular embedding, then for $q \in \mathbb{Q}$ we define the "preprojection"

$$\mathrm{pp}_{\mathbb{P}}(q) = \{p \in \mathbb{P} : p \leq \pi(q)\}.$$

For $p \in \mathbb{P}$, $\mathrm{pp}_{\mathbb{P}}(i(p)) = \{r \in \mathbb{P} : r \leq p\}$ and for all $q \in \mathbb{Q}$,

$$\sum\nolimits^{\mathcal{B}(\mathbb{P})} \mathrm{pp}_{\mathbb{P}}(q) = \pi(q).$$

If we have a further regular embedding $j : \mathbb{Q} \to \mathbb{R}$, then for all $r \in \mathbb{R}$:

$$\sum\nolimits^{\mathcal{B}(\mathbb{P})} \bigcup\{\mathrm{pp}_{\mathbb{P}}(q) : q \in \mathrm{pp}_{\mathbb{Q}}(r)\} = \pi_i \circ \pi_j(r).$$

Inductively, given a sequence of Boolean algebras $\{\mathcal{B}_\alpha : \alpha \in \{\alpha_0, \ldots, \alpha_n\}\}$ indexed by an increasing sequence of ordinals α_i and a commuting system of regular embeddings $\iota_{\alpha,\alpha'} : \mathcal{B}_\alpha \to \mathcal{B}_{\alpha'}$ for $\alpha < \alpha'$ and $b \in \mathcal{B}_{\alpha_n}$, we can define $\mathrm{pp}_{\vec{\alpha}}(b)$ to be

$$\begin{aligned}&\bigcup\{\mathrm{pp}_{\alpha_0}(q_1) : q_1 \in \bigcup\{\mathrm{pp}_{\alpha_1}(q_2) : \ldots \\ &\qquad q_{n-2} \in \bigcup\{\mathrm{pp}_{\alpha_{n-2}}(q_{n-1}) : q_{n-1} \in \mathrm{pp}_{\alpha_{n-1}}(b)\}\} \ldots\}.\end{aligned}$$

Then $\sum \mathrm{pp}_{\vec{\alpha}}(b) = \pi_{\alpha_0}(b)$ and if $\vec{\alpha}'$ is a subsequence of $\vec{\alpha}$ then $\mathrm{pp}_{\vec{\alpha}}(b) \subseteq \mathrm{pp}_{\vec{\alpha}'}(b)$.

Let $\mathcal{B} = P(\omega_1)/I$ and let $\langle \mathcal{B}_\alpha : \alpha \in \omega_2\rangle$ be a filtration such that for all $\alpha \in \mathrm{Cof}(\omega_1)$, $\mathcal{B}_\alpha$ is a regular subalgebra of $\mathcal{B}$. Fix a large regular cardinal θ and $b \in \mathcal{B}$, let

$$\mathfrak{A}_b = \langle H(\theta), \in \Delta, \mathcal{B}, \langle \mathcal{B}_\alpha : \alpha \in \omega_2\rangle, \dot{b}\rangle,$$

where $\dot{b}^{\mathfrak{A}_b} = b$.

Claim. For each well-founded countable model $N \equiv \mathfrak{A}_b$ there is a filter U_N on $\mathcal{B}^N$, with $\dot{b}^N \in U_N$ such that for all decreasing sequences $\vec{\alpha} \in [(\mathrm{Cof}(\omega_1) \cap \omega_2)^N]^{<\omega}$ and all $d \in U_N$, there is a $c \in \mathrm{pp}_{\vec{\alpha}}(d) \cap U_N$.

To see this, we build U_N by finite approximations. We can assume that N is transitive. Enumerate $(\mathrm{Cof}(\omega_1) \cap \omega_2)^N$ as $\langle \beta_n : n \in \omega\rangle$. Using the remarks above about preprojections, inductively build an increasing sequence of finitely generated filters so that at stage n, the filter is generated by a set $\{d_i : i < i(n)\}$ containing $\dot{b}^N$ with the property that for all decreasing sequences $\vec{\alpha}$ chosen from $\{\beta_k : k < n\}$ and all i, there is a j such that $d_j \in \mathrm{pp}_{\vec{\alpha}}(d_i)$.

We now describe the centering of $\mathcal{B}$. Let $\langle N_\gamma : \gamma \in \omega_1\rangle$ enumerate the transitive countable N that for some $b \in \mathcal{B}$, N is elementarily equivalent to $\mathfrak{A}_b$. These are the transitive countable models satisfying the hypothesis of the claim. Each N_γ and its associated U_{N_γ} will act as a template for a filter $\mathcal{F}_\gamma$ on $\mathcal{B}$. The collection of filters witnessing the centering is $\langle \mathcal{F}_\gamma : \gamma \in \omega_1\rangle$.

For $b \in \mathcal{B}$, let $N_b = \mathrm{Sk}^{\mathfrak{A}_b}(\emptyset)$. Clearly N_b satisfies the hypothesis of the claim. We let $\mathcal{F}_\gamma$ be the filter generated by those b for which $N_b \cong N_\gamma$. Since the transitive collapse of each N_b is among the N_γ's, each b belongs to some $\mathcal{F}_\gamma$. We must see that $\mathcal{F}_\gamma$ is a proper filter.

Fix a particular γ. We will be done if we can show that if $b_0, \dots, b_{n-1} \in \mathcal{F}_\gamma$ then $\prod_{i<n} b_i \neq 0$. Fix such a collection $\{b_0, \dots, b_{n-1}\}$. For notational simplicity, write N_{b_i} as N_i.

We look at how the traces of the N_i's on ω_2 fit together. Note that any two N_i's have the same intersection with ω_1, namely $\omega_1^{N_\gamma}$. For $i, j < n$, $N_i \cap N_j \cap \omega_2$ is an initial segment of $N_i \cap \omega_2$. After this common initial segment they are disjoint below ω_2 and thus N_j divides N_i into intervals that contain no elements of N_j.

If $\beta \in N_j \cap \omega_2 \setminus N_i \cap \omega_2$ and there is an $\alpha \in N_i \cap \omega_2$ that is bigger than β then the least such α is a limit ordinal of uncountable cofinality and there are unboundedly many ordinals of cofinality ω_1 in $N_i \cap \alpha$. If $d \in N_i \cap \mathcal{B}_\alpha$ then there is a $\delta \in N_i \cap \mathrm{Cof}(\omega_1)$ such that $d \in N_i \cap \mathcal{B}_\delta$. Furthermore, if $d \in \mathrm{pp}_\alpha(c)$ for some $c \in \mathcal{B} \cap N_i$, then $d \in \mathrm{pp}_\beta(c)$ for all $\delta \leq \beta \leq \alpha$.

When we have three or more N_i's the picture is a bit more complicated as the initial segments of $N_i \cap \omega_2$ coming from the intersections with N_j and N_k can differ. With this in mind we define the *stem* of N_i to be those ordinals α in $N_i \cap \omega_2$ with the property that for all $j \neq i$, every $\beta \in N_j \cap \alpha$ belongs to N_i. We will take the *stem* of a collection of N_i's to be the longest stem among the stems of the N_i's in the collection.

Let $\pi_i : N_i \cong N_\gamma$ be the transitive collapse. Let U_i be the π_i inverse image of U_{N_γ}. Then $U_i \subseteq N_i$ and satisfies the conclusion of the claim. Because $N_i \cap N_j \cap \omega_2$ is an initial segment of $N_i \cap \omega_2$ and $N_j \cap \omega_2$, the transitive collapses of N_i and N_j agree on $\mathcal{B}_\alpha$ for all α in $N_i \cap N_j \cap \omega_2$. Hence, if $d \in N_i \cap N_j \cap \mathcal{B}$, then $d \in U_i$ iff $d \in U_j$.

For $i \leq n$, define decreasing sequences of ordinals $\vec{\alpha}_i = \alpha_0^i, \alpha_1^i, \dots$ and elements $c_m^i \in \mathcal{B}_{\alpha_m^i}$ such that:

1. $c_o^i = b_i$ and α_0^i is equal to the least $\alpha \in \mathrm{Cof}(\omega_1)$ such that $b_i \in \mathcal{B}_\alpha$,

2. both α_j^i and c_j^i belong to N_i and α_j^i is the least ordinal α of uncountable cofinality such that $c_j^i \in \mathcal{B}_\alpha$,

3. the last ordinal on each sequence belongs to the stem of a collection of N_i's,

4. $c^i_{m+1} \in \mathrm{pp}_{\alpha^i_{m+1}}(c^i_m) \cap U_i$ (and hence inductively, we see that $c^i_m \in \mathrm{pp}_{\alpha^i_0,\alpha^i_1,\dots,\alpha^i_m}(b_i) \cap U_i$ for all α^i_m), and

5. if $i \neq j$ and $\alpha^i_k > \alpha^j_{k'}$ with $\alpha^j_{k'} \notin N_i$, then there is an l such that $c^i_l \in \mathrm{pp}_\beta(c^i_k)$ where β is the least element of $N_i \cap \omega_2$ above $\alpha^j_{k'}$.

We note that $c^i_l \in \mathrm{pp}_\delta(c^i_k)$ for some $\delta \in \omega_2 \cap \beta$. This $\delta < \alpha^j_{k'}$ and hence $c^i_l \in \mathrm{pp}_{\alpha^j_{k'}}(c^i_k)$.

These sequences are built by induction simultaneously for all i with exactly one $\vec{\alpha}_i$ being extended at each step of the induction. At the inductive step, one considers the greatest $\alpha^j_{k'}$ for which there is an α^i_k for which the clause 5 does not hold (if such a bad $\alpha^j_{k'}$ exists). We can assume inductively that k is the length of the sequence $\vec{\alpha}_i$ defined so far. Let β be the least ordinal in N_i above $\alpha^j_{k'}$. Let c^i_{k+1} be an element of $\mathrm{pp}_\beta(c^i_k) \cap U_i$. Let α^i_{k+1} be the least $\rho \in \mathrm{Cof}(\omega_1) \cap \omega_2$ such that $c^i_{k+1} \in \mathcal{B}_\rho$.

If there is no bad $\alpha^j_{k'}$ at some step in the induction, we claim that among the least elements of the sequences $\vec{\alpha}_j$ there is at most one that is not in the stem. Otherwise we would have $\alpha^i_k > \alpha^j_{k'}$ such that α^i_k and $\alpha^j_{k'}$ are the least elements of $\vec{\alpha}_i$ and $\vec{\alpha}_j$ respectively and neither one is in the stem of the system. Then $\alpha^j_{k'} \notin N_i$, and hence there is an α^i_k for which the clause 5 does not hold for $\alpha^j_{k'}$; i.e. $\alpha^j_{k'}$ is bad.

The induction continues until either all of the least elements of the sequences $\vec{\alpha}_i$ belong to the stem, or until there are no counterexamples to item 5. If the latter case holds and α^i_k is the only last element not in the stem, we let β be the least element of N_i above the stem, $c^i_{k+1} \in \mathrm{pp}_\beta(c^i_k) \cap U_i$, and α^i_{k+1} the least ordinal ρ of cofinality ω_1 such that $c^i_{k+1} \in \mathcal{B}_\rho$.

Claim. For all ordinals ρ in $\bigcup_i \vec{\alpha}^i$, if $\{d_0, \dots, d_l\}$ are the elements $\{c^i_m\}_{i,m}$ of $\mathcal{B}$ that belong to $\mathcal{B}_\alpha$ for α in $\rho + 1 \cap \bigcup_i \vec{\alpha}^i$, then $\prod d_j \neq 0$.

The claim suffices, since we can take $\rho = \max \bigcup \vec{\alpha}$, and see that $\prod b_i \neq 0$, finishing the proof.

We establish the claim by induction on $\rho \in \bigcup_i \vec{\alpha}^i$. Let ρ be the greatest ordinal in $\bigcup_i \vec{\alpha}^i$ that lies in the stem of the system of N_i's and suppose that $\rho \in N_k$. Then π_k agrees with each of the other π_i's on the stem of N_i. In particular, if $\{d_0, \dots, d_l\}$ are the elements of $\mathcal{B}$ associated with ordinals in the stems of all of the N_i's then $\{d_0, \dots, d_l\} \subseteq U_k$. Thus $\prod_{i \le l} d_i \neq 0$.

Suppose that we succeed with the induction to ρ and $\{d_0, \dots, d_l\}$ the elements of $\mathcal{B}$ associated with the ordinals in $\rho + 1 \cap \bigcup_i \vec{\alpha}^i$. Let α be the least element of $\bigcup_i \vec{\alpha}^i$ greater than ρ and let c be the element of $\mathcal{B}$ associated with α. Suppose that $\alpha = \alpha^i_k \in N_i$. Then α^i_{k+1} and c^i_{k+1} are built in one of two ways corresponding to whether they are the result of a bad $\alpha^j_{k'}$ or not. The first possibility is that α^i_k is the least element of $\bigcup_i \vec{\alpha}_i$ not in the stem. If β is the least element of N_i above the stem, then $c^i_{k+1} \in \mathcal{B}_\beta$. But $\prod_{i \le l} d_i \le c^i_{k+1} \in \mathrm{pp}_\beta(c^i_k)$. Hence $\prod_{i \le l} d_i \cap c^i_k \neq 0$.

The other way that α^i_{k+1} can be constructed is as a result of a bad $\alpha^j_{k'} \in \{d_0, \dots, d_l\}$. In this case if β is the least element of N_i above $\alpha^j_{k'}$ then $c^i_{k+1} \in \mathrm{pp}_\beta(c^i_k)$. Thus, as in the other case $\prod_{i\le l} d_i \le c^i_{k+1} \in \mathrm{pp}_\beta(c^i_k)$ and so $\prod_{i\le l} d_i \cap c^i_k \ne 0$. ⊣

We now describe the modifications necessary for $\kappa > \omega_1$. By replacing countable structures N with structures N' of cardinality less than κ with $N' \cap \kappa \in \kappa$, most of the proof above goes through without change. The main problem is the construction of the filters U_N. To remedy this problem, in the Claim we use structures N with the property that $N = \bigcup_{n\in\omega} N_n$ where $N_n \in N_{n+1}$ and $|N_n| < \kappa$ and $N_n \cap \kappa$ an initial segment of $N_{n+1} \cap \kappa$.

We may assume without loss of generality that for each $\alpha \in \mathrm{Cof}(\kappa)$, $\mathcal{B}_\alpha$ is closed under sums of size less than κ. In particular, if $N \prec \mathfrak{A}_b$ is the union of an increasing sequence N_n with $N_n \in N_{n+1}$, $N_n \cap \kappa \in \kappa$, and $\vec{\alpha}$ is a decreasing sequence in $\mathrm{Cof}(\kappa) \cap N_l$ with $c \in \mathcal{B} \cap N_l$, then $c_{\vec{\alpha},n} = \sum(\mathrm{pp}_{\vec{\alpha}}(c) \cap N_n)$ exists in N_l for all $n < l$. One can then check that for $N \equiv \mathfrak{A}_b$, the set $\{b_{\vec{\alpha},n} : \vec{\alpha} \in N_l \cap \mathrm{Cof}(\kappa)^N, n < l\}$ generates a filter U_N that makes the rest of the argument work.

4.4. Projections

We now investigate ideals under the Rudin-Keisler ordering. We establish an important result of Burke stating that any ideal is the projection of the nonstationary ideal restricted to a stationary set. Our priority is to see which of the properties listed above are preserved under projections, rather than the structure of the Rudin-Keisler ordering itself. The latter topic has been explored extensively in [9].

4.17 Definition. Let $\pi : Z \to Z'$ and I be an ideal on Z. Then the *projection* of I to Z' is the ideal I' defined by setting $B \in I'$ iff $\pi^{-1}(B) \in I$. It is easy to check that if I is κ-complete then its projection I' is also κ-complete.

Let $\langle A, <_A\rangle$ be a linearly ordered set. Given a collection of sets $\langle Z_a : a \in A\rangle$ and a commuting sequence of functions $\pi_{a,a'} : Z_a \to Z_{a'}$ for $a' <_A a$, the sequence of ideals $\langle I_a : a \in A\rangle$ is a *tower* iff for all $a' < a$, $I_{a'}$ is the projection of I_a by the function $\pi_{a,a'}$.

We consider some standard examples:

4.18 Example. Let $\kappa < \lambda' < \lambda$ be cardinals, with κ regular. Define the function $\pi : [\lambda]^{<\kappa} \to [\lambda']^{<\kappa}$ by setting $\pi(z) = z \cap \lambda'$. Then a normal, fine, γ-complete ideal I on $[\lambda]^{<\kappa}$ projects to a normal, fine, γ-complete ideal on $[\lambda']^{<\kappa}$.

The ideal of nonstationary sets on $[\lambda]^{<\kappa}$ projects to the ideal of nonstationary sets on $[\lambda']^{<\kappa}$ (see [47]). Hence the nonstationary ideals form a tower of ideals. More can be said (see [42]): the nonstationary ideals restricted to $\{x : x \cap \mathrm{On}$ is ω-closed$\}$ form a tower, as do the nonstationary ideals restricted to the internally approachable sets. It is not true in general that if $S \subseteq [\lambda]^{<\kappa}$ is a stationary set and $\lambda' < \lambda$ then the projection of the nonstationary ideal to $[\lambda']^{<\kappa}$ is the nonstationary ideal on the projection of S to λ'. Corollary 4.21 below shows that this is false in the most dramatic way.

Example 4.18 is not special to $[\lambda]^{<\kappa}$. If $\lambda > \lambda'$ define $\pi : P(\lambda) \to P(\lambda')$ by setting $\pi(z) = z \cap \lambda'$. Then π projects the nonstationary ideal on $P(\lambda)$ to the nonstationary ideal on $P(\lambda')$.

Going in the other direction, ideals on sets $Z \subseteq P(X)$ naturally give ideals on sets $P(X')$ for $X' \supseteq X$:

4.19 Definition. Suppose that J is a normal, fine, κ-complete ideal on $Z \subseteq P(X)$ and suppose that $X' \supseteq X$. Then the *conditional closed unbounded filter on $P(X')$ relative to J* is defined to be the smallest normal, fine, κ-complete filter on $P(X')$ projecting to $\breve{J}$ by the map $\pi(N) = N \cap X$. The nonstationary ideal conditioned on J is the dual of the conditional closed unbounded filter.

The terminology "conditional" is taken in analogy with probability theory, where one conditions one σ-algebra on another and takes the ideals of null sets.

For sufficiently large θ relative to $|Z|$, we can characterize conditional closed unbounded filters[25] which take a particularly simple form.

4.20 Proposition. *Suppose that J is a normal, fine, κ-complete filter on $Z \subseteq P(X)$ and that θ is a regular cardinal with $J, P(Z) \in H(\theta)$. Then the conditional closed unbounded filter on $H(\theta)$ relative to J is the closed unbounded filter on $H(\theta)$ restricted to*

$$\{N \prec H(\theta) : N \cap X \in Z \textit{ and } N \textit{ is good for } J\}.$$

Proof. Without loss of generality we can assume that $\kappa \subseteq X$. Since J is normal, fine and κ-complete, we can assume that for all $z \in Z$, $z \cap \kappa \in \kappa + 1$.

Let I be the closed unbounded filter restricted to $\{N \prec H(\theta) : N \cap X \in Z$ and N is good for $J\}$. By Proposition 3.44, I is a proper ideal. Clearly I is normal and fine. Since it concentrates on those N such that $N \cap X \in Z$ it is κ-complete. We need to see that it projects to J.

Suppose that $A \subseteq H(\theta)$ is positive with respect to I. Let $D \in \breve{J}$. Then $\{N \subseteq H(\theta) : D \in N\} \in \breve{I}$ and for every good $N \in A$ with $D \in N$ we have $N \cap X \in D$. Hence $\pi``A \in J^+$.

For the other direction, let $B \in J^+$ and $\mathfrak{A}$ an algebra on $H(\theta)$. Then by Proposition 3.44, for J-almost all $z \in B$, $\mathrm{Sk}^{\mathfrak{A}}(z)$ is good. In particular, there is a $z \in B$ such that $\mathrm{Sk}^{\mathfrak{A}}(z) \cap X = z$ and $\mathrm{Sk}^{\mathfrak{A}}(z)$ is good. Hence $\pi^{-1}(B) \in I^+$. This shows that I is a normal ideal that projects to J.

Suppose that I' is a normal ideal projecting to J. Then a normality argument easily shows for all $\mathfrak{A}$, the collection of those N that are good and are elementary substructures of $\mathfrak{A}$ belongs to the dual of I'. Hence $I \subseteq I'$. ⊣

[25] See Lemma 3.12 for the basic result on unconditional club filters.

We draw the following corollary due to Burke [11], using somewhat different methods.

4.21 Corollary. *Suppose that I is a normal, fine ideal on a stationary set $Z \subseteq P(X)$. Then for all $Y \supseteq X$ with $|Y| \geq 2^Z$, there is a stationary set $Z' \subseteq P(Y)$ such that I is the projection of the nonstationary ideal on Y restricted to Z'.*

Note that Proposition 4.20 allows us to characterize the conditional closed unbounded filter on arbitrary sets $P(X')$ for $X' \supseteq X$ as the projection to $P(X')$ of the conditional closed unbounded filter on some $H(\theta)$ with θ large and regular. Thus the conditional closed unbounded filter exists on all $X' \supseteq X$.

We now explore projections in terms of generic elementary embeddings. The following proposition is an exercise in standard large cardinal techniques.

4.22 Proposition. *Suppose that I is an ideal on a set Z and $\pi : Z \to Z'$ yields a projection of I to an ideal I'. If $j : V \to M = V^Z/G$ is the ultrapower embedding given by a generic $G \subseteq P(Z)/I$,*[26] *i is the ideal element $[\mathrm{id}]^M$ and $i' = j(\pi)(i)$ then I' is the ideal induced by j and the ideal element i'. Moreover if M' is the ultrapower $V^{Z'}/U(j, i')$, then the map $k : M' \to M$ defined by $k(f) = j(f)(i')$ is a well-defined elementary embedding making the following diagram commute:*

$$\begin{tikzcd} & V \arrow[dl, "j'"'] \arrow[dr, "j"] & \\ M' \cong V^{Z'}/U(j,i') \arrow[rr, "k"'] & & M \end{tikzcd}$$

In particular, if M is well-founded then M' is.

We note that Proposition 4.22 should not be interpreted as claiming that I' is precipitous. This is false in general, as shown by Theorem 7.8. The next example shows that we can often find normal ideals as projections of precipitous ideals.

4.23 Example. Suppose that I is a precipitous ideal on $Z \subseteq P(X)$. Let $X' \subseteq X$. Suppose that for all generic $G \subseteq P(Z)/I$, if $j : V \to M$ is the associated generic embedding, then $j``X' \in M$. Then there is a dense collection of $Y \subseteq Z$ such that $I \restriction Y$ projects to a normal ideal on $P(X')$. In particular, if κ is the critical point of j for all generic G, then densely often I projects to a normal, κ-complete ideal on κ.

Proof. To see this, suppose that $[Y] \Vdash$ "$[f]$ represents $j``X'$". Then f is *incompressible* in the sense of [111], namely if g is any function with domain Y such that for all $z \in Y$, $g(z) \in f(z)$ then g is constant on an I-positive subset

[26] For this proposition we do not assume that V^Z/G is well-founded.

of Y. Define a projection map from $I\restriction Y$ to a normal ideal on $P(X')$ by setting $\pi(z) = f(z)$ for $z \in Y$. Let J be the projection of I to $Z' = P(X')$. It is easy to check that $W \in J$ iff there is no $Y' \subseteq Y$ such that $[Y'] \Vdash j``X' \in j(W)$. Since f is incompressible, the ideal J is normal. $\dashv$

Note that this example shows that if I is a κ-complete precipitous ideal on κ, then for a dense set of $[Y] \in P(\kappa)/I$, there is a projection of $I\restriction Y$ to a normal κ-complete ideal on κ.

Given a projection map $\pi : Z \to Z'$ and ideals I and I' such that I' is the projection of I, we can consider the Boolean algebras $\mathcal{B} = P(Z)/I$ and $\mathcal{B}' = P(Z')/I'$. The map $\iota : \mathcal{B}' \to \mathcal{B}$ given by $\iota([Y']) = [\pi^{-1}(Y')]$ is a well-defined Boolean algebra homomorphism. In particular, ι sends antichains to antichains. We thus can make the following observation:

4.24 Remark. Suppose that $\pi : Z \to Z'$, I is an ideal on Z that is λ-saturated and I' is the projection of I to an ideal on Z'. Then I' is λ-saturated.

The function ι is not necessarily a regular embedding. However the next proposition gives a criterion for when it is.

4.25 Proposition. *Suppose that $X' \subseteq X$, $Z \subseteq P(X)$, $Z' = \{z \cap X' : z \in Z\}$ and $\pi : Z \to Z'$ is defined by $\pi(z) = z \cap X'$. Let I be a normal, fine, countably complete ideal on Z and I' be the projection of I to Z'. If I' is $|X'|^+$-saturated then ι is a regular embedding.*

Proof. Let $\{a_x : x \in X\}$ be a maximal antichain in $P(Z')/I'$. Then $\bigtriangledown_{x\in X} a_x \in \breve{I}'$. Since $\iota(\bigtriangledown_{x\in X} a_x) = \bigtriangledown_{x\in X}\iota(a_x)$ we see that $\bigtriangledown_{x\in X}\iota(a_x) \in \breve{I}$. Hence $\{\iota(a_x) : x \in X\}$ is a maximal antichain in $P(Z)/I$. $\dashv$

It is easy to check that the properties of (κ, λ)-centeredness, (κ, η, λ)-saturation, κ-linkedness and κ-saturation are all preserved under projections. (See [111, 6].) As a consequence, the existence of an ideal I with one of these properties implies that the projection of I to a normal ideal on the completeness of I inherits that property. So, for example, the existence of a κ-complete, κ^+-saturated ideal on κ implies the existence of a normal, κ-complete, κ^+-saturated ideal on κ.

Following [35] we give a sample of these types of arguments:

4.26 Lemma. *Suppose that $X' \subseteq X$, $Z \subseteq P(X)$, $Z' = \{z \cap X' : z \in Z\}$ and $\pi : Z \to Z'$ is defined by $\pi(z) = z \cap X'$. Let I be a normal, fine, countably complete ideal on Z and I' be the projection of I to Z'. Let $\mu \le |X'|$. Then if I is μ-dense, so is I'.*

Proof. Define $\Pi : P(Z) \to P(Z')$ by setting $\Pi(A) = \{\pi(z) : z \in A\}$. Let $D \subseteq P(Z)/I$ be a dense set of size μ. Choose representatives $\langle A_d : d \in D\rangle$ with $A_d \subseteq Z$ and $[A_d]_I = d$. For each $C \in \breve{I}$, let $b^d_C = Z' \setminus \Pi(C \cap A_d)$.

By the μ^+-saturation of I', we can find $\langle b^d_{C_\alpha} : \alpha < \mu\rangle$ such that

$$\nabla_{\alpha<\mu} b^d_{C_\alpha} \supseteq_{I'} b^d_C$$

for all $C \in \check{I}$. Let $C_d = \Delta_{\alpha<\mu} C_\alpha$. Then for all $C \in \check{I}$, $\Pi(C_d \cap A_d) \cap b^d_C \in I'$.

Let

$$E = \{[\Pi(C_d \cap A_d)]_{I'} : d \in D\}.$$

We claim that E is dense in $P(Z')/I'$. Choose an arbitrary $B \in P(Z')/I'$. Then there is a d such that $A_d \setminus \{z : \pi(z) \in B\} \in I$. Choose a C such that $\Pi(A_d \cap C) \subseteq B$. Then $\Pi(C_d \cap A_d) \subseteq_{I'} \Pi(C \cap A_d) \subseteq B$. ⊣

We give a sample corollary:

4.27 Corollary. *Suppose that there is a countably complete, uniform, $\aleph_1$-dense ideal on ω_n. Then there is a weakly normal, countably complete, uniform, $\aleph_1$-dense ideal on ω_n.*

Not all of the desirable properties of ideals are preserved under projections. Laver [85] showed that if the existence of a supercompact cardinal is consistent then it is consistent to have a precipitous ideal on $[\omega_2]^{<\omega_1}$ such that its canonical projection to a normal ideal on ω_1 is not precipitous. This is Theorem 7.8 in Sect. 7.

Gitik, in recent unpublished work, gave an example of a precipitous ideal on ω_1 such that the canonical projection to a normal ideal on ω_1 is not precipitous.

By Laver's example, we know that precipitous ideals are not closed under projection. As far as the author knows it is open whether presaturated ideals are closed under projection, even in the presence of GCH.

4.5. Where the Ordinals Go

In this section we give some examples of techniques for determining where the ordinals are sent by generic elementary embeddings. These examples are chosen to be representative and are easy to generalize to handle any particular situation.

4.28 Proposition. *Let κ be a successor cardinal, $n \in \omega$ and I be a uniform κ-complete, κ^+-saturated ideal on a set $Z \subseteq P(\kappa^{+n})$ that has cardinality at least κ^{+n}. Suppose that either:*

1. *Z has cardinality κ^{+n}, or*

2. *I is normal and fine.*

Let $j : V \to M$ be a generic embedding induced by the ultrapower of V by a generic $G \subseteq P(Z)/I$. Then the critical point of j is κ and for all $i \leq n$, $j(\kappa^{+i}) = \kappa^{+i+1}$.

Proof. Let $\lambda = \mathrm{crit}(j)$.

Suppose that $|Z| = \kappa^{+n}$. Then there are functions $\langle f_\alpha : \alpha < \kappa^{+n+1}\rangle$ such that $f_\alpha : Z \to Z$ and for all $\alpha < \beta$, $|\{z \in Z : f_\alpha(z) \geq f_\beta(z)\}| < \kappa^{+n}$. Hence $j(\kappa^{+n}) \geq (\kappa^{+n+1})^V$ so $\lambda \leq \kappa^{+n}$.

Suppose now that I is normal and fine. Define $f(z)$ to be the least element of $\kappa^{+n} \setminus z$ and let $\mathrm{id} : Z \to Z$ be the identity map. Then $j(\kappa^{+n}) > [f] \notin [\mathrm{id}]^M = j``\kappa^{+n}$. Hence $\lambda \leq \kappa^{+n} < j(\kappa^{+n})$. Moreover, $P(\kappa^{+n})^V \subseteq M$, so $j(\kappa^{+n}) \geq \kappa^{+n+1}$.

In either case, $\lambda = \kappa^{+i}$ for some $i \leq n$ and $j(\kappa^{+n}) \geq \kappa^{+n+1}$. If $\lambda = \kappa^{+i}$ for some $i > 0$, then we have $j(\lambda) = (\kappa^{+i})^M$, but $j(\lambda) > \lambda$ and this is impossible without collapsing some cardinal greater than or equal to κ^+. Hence $\lambda = \kappa$ and $j(\lambda) = (\kappa^+)^V$. Counting cardinals shows that $j(\kappa^{+i}) = \kappa^{+i+1}$. ⊣

4.29 Example. Suppose that I is a normal, κ-complete, κ^+-saturated ideal on a successor cardinal κ. Let $j : V \to M$ be a generic embedding induced by the ultrapower of V by a generic $G \subseteq P(\kappa)/I$. Then:

1. $j(\kappa) = \kappa^+$,
2. $j(\kappa^+) \in ((\kappa^+)^V, (\kappa^{+2})^V)$, $j``\kappa^+$ is cofinal in $j(\kappa)^+$,
3. for all $i \in [2, \omega]$, $j(\kappa^{+i}) = (\kappa^{+i})^V$, and
4. there is a $<\kappa$-closed and unbounded subset of κ^{+i} lying in V consisting of ordinals α such that for all generic G, $j(\alpha) = \alpha$.

Proof. Since κ is the critical point of j and κ is a successor cardinal, if $j(\kappa) > \kappa^+$, the forcing would collapse κ^+, a contradiction. Since $P(\kappa)^V \subseteq M$, $j(\kappa) \geq \kappa^+$ and hence $j(\kappa) = \kappa^+$.

Let $f : \kappa \to \kappa^+$. Then the range of f is bounded by some ordinal $\alpha < \kappa^+$, and hence $[f]^M < j(\alpha)$. Thus $j``\kappa^+$ is cofinal in $j(\kappa^+)$. Since κ^{+2} is preserved by the forcing, we see that $j(\kappa^+) \leq (\kappa^{+2})^V$. But in $V[G]$ the cofinality of $j(\kappa^+)$ is equal to the cofinality of $(\kappa^+)^V$, and hence $j(\kappa^+)$ must lie between κ^+ and κ^{+2}. Since κ^{+2} is preserved, $j(\kappa^+) < (\kappa^{+2})^V$.

Since $j(\kappa^{+2}) \geq (\kappa^{+2})^V$ we must have $j(\kappa^{+2}) = (\kappa^{+2})^V$. Similarly we must have $j(\kappa^{+n}) = \kappa^{+n}$.

For each $n > 2$ and each ordinal $\alpha < \kappa^{+n}$ there is a $\gamma(\alpha) < \kappa^{+n}$ such that $j(\alpha) < \gamma(\alpha)$ for all generic G. Let α^* be a closure point of the function $\alpha \mapsto \gamma(\alpha)$ having cofinality less than κ. Let $\langle \alpha_\xi : \xi \in \delta\rangle$ be increasing and cofinal in α^*, where $\delta < \kappa$. Then

$$\alpha^* \leq j(\alpha^*) = \sup\{j(\alpha_\xi) : \xi \in \delta\} = \alpha^*.$$

Thus the set of closure points that have cofinality less than κ in V is a $<\kappa$-closed unbounded set $F \subseteq \kappa^{+n}$ with $F \in V$ consisting of ordinals that are fixed by every embedding j. ⊣

4.30 Example. Let κ be a successor cardinal. Suppose that I is a normal, fine, κ-complete, κ^+-saturated ideal on $Z \subseteq P(\kappa^{+n})$. Let $j : V \to M$ be a generic embedding induced by taking the ultrapower of V by a generic $G \subseteq P(Z)/I$. Then:

1. for all $i \leq n$, $j(\kappa^{+i}) = \kappa^{+i+1}$, and
2. I concentrates on the collection of $x \in P(\kappa^{+n})$ such that for all $i \leq n-1$, $\mathrm{ot}(x \cap \kappa^{+i+1}) = \kappa^{+i}$.

If $|Z| = \kappa^{+n}$, then

3. $j``\kappa^{+n+1}$ is cofinal in $j(\kappa^{+n+1})$.

For all $i > n+1$,

4. $j(\kappa^{+i}) = \kappa^{+i}$, and
5. there is a $<\kappa$-closed unbounded subset of κ^{+i} lying in V consisting of ordinals α such that for all generic G, $j(\alpha) = \alpha$.

Remark. The hypothesis that $|Z| = \kappa^{+n}$ is redundant as we shall see later in Corollary 4.43, as such an I always concentrates on a set Z with $|Z| = \kappa^{+n}$.

Proof. Note that the critical point of j is κ by Proposition 4.28. Since $M^{\kappa^{+n}} \cap V[G] \subseteq M$, we know that $j(\kappa) \geq \kappa^+$ and can show inductively that for all $i \leq n$, $j(\kappa^{+i}) \geq \kappa^{+i+1}$. Since κ^{+i+1} is preserved by the forcing, we must have $j(\kappa^{+i}) = \kappa^{+i+1}$.

By the remarks in Sect. 2.8, we see that I concentrates on the collection of $x \in P(\kappa^{+n})$ such that for all $i \leq n-1$, $\mathrm{ot}(x \cap \kappa^{+i+1}) = \kappa^{+i}$.

Suppose that $|Z| = \kappa^{+n}$ and argue as before: Suppose that $f : Z \to \kappa^{+n+1}$. Then f is bounded by a constant function. Hence $j``\kappa^{+n+1}$ is cofinal in $j(\kappa^{+n+1})$. Since $j(\kappa^{+n+1}) > \kappa^{+n+1}$ we see that $j(\kappa^{+n+1})$ is singular in $V[G]$. Since cardinals are not collapsed, $j(\kappa^{+n+1}) < \kappa^{+n+2}$.

The rest of the example is exactly parallel to the previous one. ⊣

The next example is slightly different but uses similar ideas:

4.31 Example. Suppose that I is a normal, fine, κ-complete ideal on $Z \subseteq [\kappa^{+n}]^{<\kappa}$ that is κ^{+n+1}-saturated. Suppose that $2^{|Z|} = \kappa^{+n+1}$. Let $j : V \to M$ be the generic embedding induced by the ultrapower of V by a generic $G \subseteq P(Z)/I$, then:

1. κ is the critical point of j,
2. $j(\kappa) = \kappa^{+n+1}$, and
3. for all $i \geq n+2$, κ^{+i} is a fixed point of j.

Without normality we can still get results:

4.32 Example. Suppose that κ is a successor cardinal and I is a uniform, κ-complete, κ^+-saturated ideal on κ^{+n}. Let $j : V \to M$ be a generic embedding induced by the ultrapower of V by a generic $G \subseteq P(Z)/I$, then for all $0 \le i \le n-1$,

1. $j(\kappa^{+i}) = \kappa^{+i+1}$,
2. $j(\kappa^{+n}) \le \kappa^{+n+1}$, and
3. for all $i \ge 2$, $j(\kappa^{+n+i}) = (\kappa^{+n+i})^V$.

4.6. A Discussion of Large Sets

In earlier lemmas we have frequently had the hypothesis that an ideal I concentrates on some set $Z \subseteq P(X)$ with $|Z| \le |X|$. With one important exception, in every case we consider one can simply prove that $|Z| \le |X|$. In many cases there are closed unbounded sets of small cardinality, as shown by Baumgartner [4].

The exceptional case is when we are dealing with closed unbounded sets relative to the countable subsets of a cardinal $\kappa \ge \omega_2$. In Corollary 6.16 we see that every closed unbounded subset of $[\kappa]^\omega$ has cardinality $\kappa^{\aleph_0}$. The more typical situations are covered in this section.

We begin by discussing the situation with precipitous ideals before proceeding to saturated ideals where the situation is much simpler. First some prerequisites:

4.33 Definition. For K a collection of regular cardinals, define the *characteristic function* of a set X on K, $\chi_X^K : K \to \mathrm{On}$, by setting:

$$\chi_X^K(\kappa) = \sup(X \cap \kappa).$$

We will say that X is *weakly ω_1-uniform on K* if for all $\kappa \in K$, $\mathrm{cf}(X \cap \kappa) > \omega$.

The following lemma is standard and easy to prove (see e.g. [18]).

4.34 Lemma. *Suppose that K is a collection of regular cardinals between μ and ρ for some cardinals μ, ρ with μ regular. Then there is a closed unbounded set of $C \subseteq \{z \in P(\rho) : z \cap \mu \in \mu\}$ such that for all $z_1, z_2 \in C$ if:*

1. *z_1, z_2 both are weakly ω_1-uniform on K, and*
2. *$\chi_{z_1}^K = \chi_{z_2}^K$,*

then $z_1 = z_2$. Thus, if $\rho = \mu^{+n}$ for some $n \in \omega$ and I is a normal, fine, countably complete ideal concentrating on $\{z : z \cap \mu \in \mu$ and for all $0 \le i \le n$, $\mathrm{cf}(z \cap \mu^{+i}) > \omega\}$, then there is a set $A \in \breve{I}$ that is canonically well-ordered by the $n+1$-tuple $(z \cap \mu, z \cap \mu^+, \ldots, z \cap \mu^{+n})$. In particular, $|A| = \rho$.

We will use the following result from [42] (Theorem 2.15):

4.35 Theorem. *Suppose that $\kappa < \lambda < \mu$ are three consecutive cardinals. Then there is a closed unbounded set $C \subseteq P(\mu)$ such that for all $z \in C$ if $|z| = \lambda$ and $|z \cap \lambda| = \kappa$, then $\mathrm{cf}(z \cap \lambda) = \mathrm{cf}(\kappa)$.*

We see as a corollary:

4.36 Lemma. *If κ is regular, uncountable, and $(\kappa^{+n}, \kappa^{+}) \twoheadrightarrow (\kappa^{+n-1}, \kappa)$, then:*

1. *$(\kappa^{+n}, \kappa^{+n-1}, \ldots, \kappa^{+}) \twoheadrightarrow (\kappa^{+n-1}, \kappa^{+n-2}, \ldots, \kappa)$,*
2. *there is a closed unbounded set of $z \in [\kappa^{+n}]^{\kappa^{+n-1}}$ such that if $|z \cap \kappa^{+}| = \kappa$ then z is weakly ω_1-uniform on the interval $K = [\kappa^{+}, \kappa^{+n}]$, and*
3. *there is a closed unbounded $C \subseteq \kappa^{+n}$ such that for all $z_1, z_2 \in C \cap [\kappa^{+n}]^{\kappa^{+n-1}}$ if:*
   (a) $\kappa \subseteq z_1 \cap z_2$,
   (b) $|z_1 \cap \kappa^{+}| = |z_2 \cap \kappa^{+}| = \kappa$, and
   (c) $\chi^K_{z_1} = \chi^K_{z_2}$,

   then $z_1 = z_2$.

In particular, each $z \in C \cap [\kappa^{+n}]^{\kappa^{+n-1}}$ with $\kappa \subseteq z$ is determined by the finite sequence of ordinals $\sup(z \cap \kappa^{+i}), 1 \leq i \leq n$.

As a corollary we immediately see:

4.37 Theorem. *Suppose that κ is a regular uncountable cardinal and I is a normal, fine, κ^{+}-complete ideal on $[\kappa^{+n}]^{\kappa^{+n-1}}$. Then there is a set $Z \subseteq [\kappa^{+n}]^{\kappa^{+n-1}}$ such that $Z \in \breve{I}$ and $|Z| = \kappa^{+n}$.*

Proof. We note that if I is a proper ideal then $(\kappa^{+n}, \kappa^{+}) \twoheadrightarrow (\kappa^{+n-1}, \kappa)$, since any normal, fine ideal extends the nonstationary ideal. For $1 \leq i \leq n$, let $A_i = \{z : z \cap \kappa^{+i} \in \kappa^{+i}\}$. Then by Proposition 2.19, $\bigcup_{1 \leq i \leq n} A_i \in \breve{I}$ and for all $B \subseteq A_i$ with $B \in I^{+}$, $\mathrm{comp}(I \restriction B) = \kappa^{+i}$. Applying Lemma 4.36, we see that on each A_i almost every z is determined by the finite sequence of ordinals $\{\sup(z \cap \kappa^{+i}), \sup(z \cap \kappa^{+i+1}), \sup(z \cap \kappa^{+i+2}) \ldots\}$. Hence almost every element $z \in [\kappa^{+n}]^{\kappa^{+n-1}}$ is determined by a finite sequence of ordinals less than κ^{+n}. $\dashv$

4.38 Remark. Suppose that $n > 0$ is an integer and I is a normal, fine, countably complete ideal on $Z \subseteq P(\kappa^{+n})$ where κ is a regular cardinal. If $\{z : z \not\supseteq \kappa\} \in \breve{I}$ then for all $i \geq 1$, $\{z : |z \cap \kappa^{+i}| < \kappa^{+i}\} \in \breve{I}$. For otherwise, κ^{+i} would be a Jónsson cardinal, but no successor of a regular cardinal is Jónsson [122, 124]. Similar remarks are true for κ a singular cardinal, not the limit of measurable cardinals [105].

It is often useful to know when an ideal concentrates on sets of ordinals that are μ-closed.

4.39 Proposition. *Let $\mu \leq \lambda$. Suppose that $\mathbb{P}$ is a partial ordering such that for all generic $G \subseteq \mathbb{P}$, $j : V \to M \subseteq V[G]$ is a generic elementary embedding with critical point κ with $M^{j(\mu)} \cap V[G] \subseteq M$. Suppose that $j``\lambda \in M$. Then the following are equivalent:*

1. *For all generic $G \subseteq \mathbb{P}$, $j``\lambda$ is $j(\mu)$-closed in $V[G]$.*
2. *The ideal induced by $j, \mathbb{P}$, and $j``\lambda$ concentrates on $\{z : z \subseteq \lambda$ and z is μ-closed$\}$.*

Moreover, if $\mu < \kappa$ then these are also equivalent to

3. *For all cardinals $\rho < \lambda$, $\mathrm{cf}(\rho)^V = \mu$ iff for all generic $G \subseteq \mathbb{P}$, $\mathrm{cf}(\rho)^{V[G]} = \mu$.*

Proof. That the first two clauses are equivalent is an easy consequence of remarks in Sect. 2.8 and the fact that $M^{j(\mu)} \cap V[G] \subseteq M$.

The equivalence between clause 1 and clause 3 follows from Propositions 2.32 and 2.31. ⊣

4.40 Corollary. *Let $\mu \leq \kappa \leq \lambda$. Suppose that $\mathbb{P}$ is a partial ordering such that for all generic $G \subseteq \mathbb{P}$, $j : V \to M \subseteq V[G]$ is a generic elementary embedding with critical point κ with $M^{<\mu} \cap V[G] \subseteq M$. Suppose that $j``\lambda \in M$. Then the following are equivalent:*

1. *For all generic $G \subseteq \mathbb{P}$, $j``\lambda$ is $<\mu$-closed in $V[G]$.*
2. *The ideal induced by $j, \mathbb{P}, j``\lambda$ concentrates on $\{z : z \subseteq \lambda$ and z is $<\mu$-closed$\}$.*
3. *For all cardinals $\rho < \lambda$, $\mathrm{cf}(\rho)^V \geq \mu$ iff for all generic $G \subseteq \mathbb{P}$, $\mathrm{cf}(\rho)^{V[G]} \geq \mu$.*

4.41 Proposition (Baumgartner [4]). *Suppose that*

$$N \prec \langle H(\kappa^{+n}), \in, \Delta, f_i, \ldots \rangle$$

with $N \cap \kappa \in \kappa$. Suppose that $\eta \notin \{\mathrm{cf}(N \cap \kappa), \mathrm{cf}(N \cap \kappa^+), \ldots, \mathrm{cf}(N \cap \kappa^{+n})\}$. Then $N \cap \mathrm{On}$ is η-closed.

Proof. Let $\langle \xi_i : i < \eta \rangle$ be an increasing sequence of ordinals in N. Let $\psi \in N$ be the least element above each ξ_i. Such a ψ exists by the cofinality assumptions. Let $\nu = \mathrm{cf}(\psi)$. Then $\nu < \psi$, $\nu \in N$, and $N \models \nu = \mathrm{cf}(\psi)$. Hence, $\eta = \mathrm{cf}(N \cap \psi) = \mathrm{cf}(N \cap \nu)$. Since ν is regular, we must have either $\nu < N \cap \kappa$ or $\nu = \kappa^{+i}$ some i. The latter cannot happen by the cofinality assumptions. Hence $\nu < N \cap \kappa$, and so $\eta = \nu$. Thus $\psi = \sup\{\xi_i : i < \eta\}$ as desired. ⊣

From this we can deduce the following result:

4.42 Theorem. *Suppose that κ is a regular cardinal and I is a normal, fine, κ-complete, κ^{+n}-saturated ideal on $Z \subseteq P(\kappa^{+n})$ and there is an infinite cardinal $\lambda < \kappa$ such that for all $0 \le i \le n$, $\{z : \mathrm{cf}(z \cap \kappa^{+i}) \ne \lambda\} \in \breve{I}$. Then there is an $A \in \breve{I}$ such that the function $z \mapsto \sup(z)$ is one-to-one on A.*

Proof. By normality we can assume that for all $z \in Z$, if N is the Skolem hull of z in $H(\kappa^{+n})$, then $N \cap \kappa^{+n} = z$. Hence by Proposition 4.41, we can assume that every z in Z is λ-closed.

Partition the ordinals in κ^{+n} of cofinality λ into κ^{+n} disjoint stationary sets, $\{S_\alpha : \alpha \in \kappa^{+n}\}$.

Let $G \subseteq P(Z)/(I{\restriction}Z)$ be generic and $j : V \to M \subseteq V[G]$ be the generic elementary embedding. Then $\mathrm{crit}(j) \ge \kappa$. Let S^j_δ be the δth member of $j(\{S_\alpha : \alpha \in \kappa^{+n}\})$. We claim that in M for all $\alpha < j(\kappa^{+n})$:

$$S^j_\alpha \cap \sup(j``\kappa^{+n}) \text{ is stationary iff } \alpha \in j``\kappa^{+n}.$$

By the κ^{+n}-c.c., the forcing $P(Z)/(I{\restriction}Z)$ preserves stationary subsets of κ^{+n}. By Proposition 4.39, we see that $j``\kappa^{+n}$ is $j(\lambda)$-closed. Since $\lambda < \kappa$, $j(\lambda) = \lambda$. Thus in $V[G]$, $\lambda$ is a cardinal and $j``\kappa^{+n}$ is λ-closed.

For $\beta \in \kappa^{+n}$, $S_\beta \subseteq (\kappa^{+n})^V$ is still stationary in $V[G]$, so $j``S_\beta$ is stationary in $\sup(j``\kappa^{+n})$. Since $j``S_\beta \subseteq S^j_{j(\beta)}$ we have shown one direction of the result.

Suppose that S^j_δ is stationary in $\sup(j``\kappa^{+n})$. Since $j``\kappa^{+n}$ is λ-closed, there is a γ such that $j(\gamma) \in S^j_\delta \cap j``\kappa^{+n}$. But $\gamma \in S_\alpha$ for a unique α, so $j(\alpha) = \delta$, as required.

By reflection, $\{N \in Z : \alpha \in N \text{ iff } S_\alpha \cap \sup(N) \text{ is stationary}\} \in \breve{I}$. Hence there is a measure one subset of Z on which the supremum function is one-to-one. ⊣

4.43 Corollary. *Under the assumptions of the theorem, there is a set $Z \in \breve{I}$ such that $|Z| = \kappa^{+n}$.*

4.44 Corollary. *Suppose that κ is a regular cardinal and I is a normal, fine, κ-complete, κ^{+n}-saturated ideal on $Z \subseteq P(\kappa^{+n})$, and either:*

1. *$\kappa > \omega_1$ is a successor cardinal and I is κ^+-saturated, or*

2. *$\kappa > \omega_{n+1}$.*

Then there is a finite partition P of an $A \in \breve{I}$ such that the supremum function is one-to-one on each element of P.

Proof. If the first hypothesis holds then by Proposition 4.28, we see that for all $0 < i \le n$, κ^{+i} is preserved, and $\mathrm{ot}(z \cap \kappa^{+i}) = \kappa^{+i-1}$ for almost every $z \in Z$. Since $\kappa > \omega_1$, we see that at least one of $\lambda = \omega$ or $\lambda = \omega_1$ satisfies the hypothesis of Theorem 4.42. Hence there is a set $A \in \breve{I}$ on which the supremum function is one-to-one.

If $\kappa > \omega_n$, then we can divide Z into $\{A_i : 0 \leq i \leq n\}$ where $\bigcup A_i \in \breve{I}$ and for all $z \in A_i$ we have $\aleph_i \notin \{\mathrm{cf}(z \cap \kappa), \mathrm{cf}(z \cap \kappa^+), \ldots, \mathrm{cf}(z \cap \kappa^{+n-1}), \mathrm{cf}(z)\}$. We can then apply Theorem 4.42 to each $I \restriction A_i$ separately. ⊣

4.45 Proposition. *Suppose that κ is an uncountable regular cardinal and $\delta \geq \kappa$ is a cardinal. Let I be a normal, fine, κ-complete ideal on $Z \subseteq P(\delta)$ such that $P(Z)/I$ contains a dense countably closed set. Then there is a set $Z \in \breve{I}$ such that the function $z \mapsto \sup(z)$ is one-to-one.*

Proof. If $P(Z)/I$ contains a countably closed dense set, then

1. $M^\omega \cap V[G] \subseteq M$,
2. $\mathrm{cf}(\alpha)^V = \omega$ iff $\mathrm{cf}(\alpha)^{V[G]} = \omega$, and
3. $j``\delta$ is ω-closed.

Taking $\lambda = \omega$ we can follow the proof Theorem 4.42. ⊣

The hypotheses of the previous theorem typically hold for induced ideals with critical point at least ω_2 that arise from collapsing large cardinals.

So far we have not addressed the issue of ideals whose associated elementary embedding has critical point ω_1. By Corollary 6.16, the analogue to the previous proposition cannot hold for ideals that are not $\aleph_2$-complete. We must content ourselves to note that by Theorem 5.9 if there is a countably complete $\aleph_1$-dense ideal on ω_2 then CH holds. In particular:

4.46 Proposition. *Suppose that I is a normal, fine, countably complete, $\aleph_1$-dense ideal on $P(\omega_n)$, then there is a set $Z \in \breve{I}$ that has cardinality $\aleph_n$.*

Proof. By Example 4.30, I concentrates on $[\omega_n]^{\omega_{n-1}}$. By Theorems 5.9 and 5.10, GCH holds below ω_n. In particular, $[\omega_n]^{\omega_{n-1}}$ has cardinality ω_n. ⊣

4.7. Iterating Ideals

We now give a brief discussion of the theory of iterations of embeddings induced by ideals.[27] The theory is highly analogous to that of iterating large cardinal embeddings discovered by Gaifman [49] and Kunen [77]; however, one has to take into account the forcing. We will discuss the case where we are iterating the embeddings coming from a single ideal. The reader can generalize this to more complicated situations, such as generic iteration trees.

For the rest of this discussion, let I be a precipitous ideal on a set Z lying in a transitive model M of a sufficiently strong subtheory of ZFC. We do not assume that M contains all of the ordinals. A *generic iteration* of M by I is a triple

$$\{\langle M_\alpha : \alpha \leq \mu\rangle, \langle j_{\alpha,\alpha'} : \alpha < \alpha' \leq \mu\rangle, \langle G_\alpha : \alpha < \mu\rangle\}$$

with the following properties:

[27] Iterations of generic embeddings were first used in [35].

1. $j_{\alpha,\alpha'} : M_\alpha \to M_{\alpha'}$ is an elementary embedding for all $\alpha < \alpha' \leq \mu$ and the family of embeddings commutes,
2. $M_0 = M$,
3. G_α is generic for $j_{0,\alpha}(P(Z)/I)$ over M_α,
4. $M_{\alpha+1}$ is the generic ultrapower of M_α by G_α and $j_{\alpha,\alpha+1}$ is the canonical embedding from the ultrapower, and
5. for α' a limit ordinal, $M_{\alpha'}$ is the direct limit of the M_α for $\alpha < \alpha'$.

An obvious question is whether generic iterations yield well-founded models. Since the ideal I is precipitous, its images are precipitous in the appropriate models. Hence $M_{\alpha+1}$ is well-founded provided that M_α is.

The following theorem of Woodin extends work of Gaifman [49] and Solovay (see [35]):

4.47 Theorem (Woodin [126]). *Suppose that*

$$\{\langle M_\alpha : \alpha \leq \mu\rangle, \langle j_{\alpha,\alpha'} : \alpha < \alpha' \leq \mu\rangle, \langle G_\alpha : \alpha < \mu\rangle\}$$

is a generic iteration and $\mu < \mathrm{On} \cap M$. Then M_μ is well-founded.

Proof. We outline the proof of the theorem. The first step is to show that if there is an ill-founded generic iteration of M then there is one in a generic extension of M. To see this we note that if there is an ill-founded iteration of M of length μ, then in $V^{\mathrm{Col}(\omega,2^{2^\mu})}$ all of the data required to define this information is countable. Hence in $M^{\mathrm{Col}(\omega,2^{2^\mu})}$ there is a tree whose ill-foundedness is equivalent to the existence of an ill-founded generic iteration of M. Hence the existence of such an iteration is absolute between V and $M^{\mathrm{Col}(\omega,2^{2^\mu})}$, and the first step is accomplished.[28]

The second step is to use a variation of Gaifman's arguments about iterated ultrapowers: In M, let μ be the smallest ordinal such that there is a generic iteration of length μ lying in a forcing extension of M that is ill-founded. Let η be the least ordinal such that there is a some generic iteration of length μ such that $j_{0,\mu}(\eta)$ is above a decreasing infinite sequence of "ordinals" in M_μ.

Arguments similar to the argument of the first step show that η, μ have absolute definitions; i.e. M correctly defines η and μ.

Consider an ill-founded generic iteration of length μ witnessing the definitions of η and μ. Then μ is a limit ordinal, so for some $\alpha < \mu$, there is an ordinal $\eta' < j_{0,\alpha}(\eta)$ such that $j_{\alpha,\mu}(\eta')$ is above an infinite decreasing sequence of M_μ-ordinals. Let η' be the least such.

But again, we can argue that M_α correctly identifies η' as the least ordinal above an infinite decreasing sequence of "ordinals" in the shortest ill-founded generic iteration beginning at M_α. However, $\eta' < \eta$, contradicting the elementarity of $j_{0,\alpha}$. ⊣

[28] Note that we have used the fact that the length of the iteration is less than the supremum of the ordinals of M.

4.8. Generic Ultrapowers by Towers

The concept of a *tower* of ideals was given in Definition 4.17. We now explore generic ultrapowers by towers of ideals.

Suppose that $\langle U, <_U\rangle$ is a linearly ordered set and we have a tower of ideals $\mathcal{T} = \langle I_a : a \in U\rangle$ on sets $\langle Z_a : a \in U\rangle$ via projections $\langle \pi_{a,a'} : a' <_U a\rangle$. Let $\mathcal{B}_a = P(Z_a)/I_a$. For $a' <_U a$ we get a well-defined embedding $i_{a',a} : \mathcal{B}_{a'} \to \mathcal{B}_a$ given by the formula, $i_{a',a}([A']_{I_{a'}}) = [\{z \in Z_a : \pi_{a,a'}(z) \in A'\}]_{I_a}$. We can form the direct limit of the system of Boolean algebras $\langle \mathcal{B}_a, i_{a',a}\rangle$ and call it $\mathcal{B}_\infty(\mathcal{T})$.

By a slight modification of Proposition 4.22, we see that a generic $G \subseteq \mathcal{B}_\infty(\mathcal{T})$ yields ultrafilters $G_a \subseteq \mathcal{B}_a$ and if N_a is the ultrapower V^{Z_a}/G_a and $j_a : V \to N_a$ is the canonical embedding then there are embeddings $k_{a',a} : N_{a'} \to N_a$ ($a' <_U a$) such that the following commutes:

$$\begin{tikzcd} & V \arrow[dl, "j_{a'}"'] \arrow[dr, "j_a"] & \\ N_{a'} \arrow[rr, "k_{a',a}"'] & & N_a \end{tikzcd}$$

We will call $N_\infty = \lim\limits_{\to}\langle N_a, k_{a',a} : a' <_U a\rangle$ the *generic ultrapower of* V *by the tower*.

In concrete terms, we usually have $Z_\alpha \subseteq P(\alpha)$ for some collection U of ordinals α and $\pi_{\alpha,\alpha'}(z) = z \cap \alpha'$. We can define a partial ordering $\mathcal{P}_\mathcal{T}$ whose domain is a quotient of $\bigcup_{\alpha\in U} P(Z_\alpha)$ by an equivalence relation. For $\alpha' < \alpha$ and $A' \in P(Z_{\alpha'})$ and $A \in P(Z_\alpha)$ we set $A' \sim A$ iff $\iota_{\alpha',\alpha}([A']_{I_{\alpha'}}) = [A]_{I_\alpha}$ and $[A'] \le [A]$ iff $\iota_{\alpha',\alpha}(A') \subseteq_{I_\alpha} A$.

Viewing $\mathcal{P}_\mathcal{T}$ as the direct limit of the partial orderings $P(Z_\alpha)/I_\alpha$, the non-zero elements of $\mathcal{B}_\infty(\mathcal{T})$ can be identified with elements of $P_\mathcal{T}$. With $\delta = \sup(U)$, $\mathcal{B}_\infty(\mathcal{T})$ can also be described as equivalence classes of those subsets $a \subseteq P(\delta)$ such that for some $\alpha \in U$ and all $z, z' \in P(\delta)$, if $z \cap \alpha = z' \cap \alpha$, then $z \in a$ iff $z' \in a$. The ordinal α can be viewed as a *support* of a. If a is a subset of $P(\delta)$ with support α then for any $\beta > \alpha$, we can identify a with $[\{z \cap \beta : z \in a\}]_{I_\beta}$ and consider its class in $P(Z_\beta)/I_\beta$. If $a, b \subseteq P(\delta)$ have supports less than δ we can consider any β that is a support of both a and b and set $a \le_\infty b$ iff $[a]_{I_\beta} \le [b]_{I_\beta}$. The ordering $\le_\infty$ is well-defined since the ideals form a tower, and $\mathcal{B}_\infty(\mathcal{T})$ is isomorphic to the separative quotient of the resulting partial ordering.

4.48 Remark. We note that we will often write formulas like "$N \in S$", where $S \subseteq P(\alpha)$ but N is not a subset of α. This will be interpreted as "$N \cap \alpha \in S$". Thus in the context of towers, we view sets $S \subseteq P(\alpha)$ as subsets of $P(\beta)$ for $\beta > \alpha$.

We can check the following lemma using the proof of Lemma 2.22:

4.49 Lemma. *Suppose that δ is a limit cardinal, $U \subseteq \delta$ is unbounded and $\langle I_\alpha \subseteq P(P(\alpha)) : \alpha \in U\rangle$ is a tower of normal ideals. If $A \subseteq P(P(\alpha))$ for some $\alpha \in U$ then $\Sigma A = \bigtriangledown A$ in $\mathcal{B}_\infty(\mathcal{T})$.*

For notational simplicity we will use the partial ordering $\mathcal{P}_{\mathcal{T}}$ (defined above) instead of $\mathcal{B}_\infty(\mathcal{T})$. For most towers the index set U will be a collection of ordinals and for $\alpha \in U$, I_α will be an ideal on $P(\alpha)$. In this case we will call $\sup(U)$ the *height* of the tower $\mathcal{T}$ and it will usually be denoted δ. Burke [11] proved the following result as a generalization of Corollary 4.21:

4.50 Proposition. *Suppose that $\mathcal{T}$ is a tower of normal ideals of height δ, which is an inaccessible cardinal. Then there is a stationary set $S \subseteq P(\delta)$ such that for all $\alpha \in U$, I_α is the projection to $P(\alpha)$ of the nonstationary ideal on $P(\delta)$ restricted to S.*

4.51 Definition. The tower $\mathcal{T}$ is said to be *precipitous* iff for all generic $G \subseteq \mathcal{P}_{\mathcal{T}}$, the direct limit N_∞ of the ultrapowers N_α is well-founded.

The combinatorial criterion for precipitousness of towers takes a slightly different form than that as would be given by forcing with individual ideals. The analogue of Proposition 2.7 in the context of towers of ideals is:

4.52 Proposition. *Let $\mathcal{T}$ be a tower of ideals. Then $\mathcal{T}$ is precipitous iff whenever $[X] \in \mathcal{P}_{\mathcal{T}}$ and $\mathcal{A}_n \subseteq \bigcup_{a\in U} P(Z_a)$ for $n \in \omega$ form a tree of maximal antichains in $\mathcal{P}_{\mathcal{T}}$ below $[X]$, there are $\langle a_n : n \in \omega\rangle$ and $s : \omega \to U$ such that:*

1. *$a_n \in \mathcal{A}_n \cap P(Z_{s(n)})$,*
2. *$\langle [a_n]_{I_{s(n)}} : n \in \omega\rangle$ is a branch through the tree, and*
3. *there is a sequence $z_n \in Z_{s(n)}$ with $\pi_{s(n+1),s(n)}(z_{n+1}) = z_n$ and $z_n \in a_n$.*

In the concrete case where U is a set of ordinals, $Z_\alpha \subseteq P(\alpha)$ and $\pi_{\alpha,\alpha'}(z) = z \cap \alpha'$, the conditions of Proposition 4.52 can be stated by taking $s(n)$ to be the support of a_n and demanding that there is a set N such that for all n, $N \cap P(s(n)) \in a_n$.

Burke proved the game theoretic version of precipitousness for towers corresponding to Theorem 2.8:

4.53 Theorem (Burke [11]). *Let $\mathcal{T}$ be a tower of ideals on $P(\alpha)$ for $\alpha \in U$ such that for $\alpha' < \alpha$, $\pi_{\alpha,\alpha'}(z) = z \cap \alpha'$. Then the following are equivalent:*

1. *$\mathcal{T}$ is precipitous.*
2. *Player I does not have a winning strategy in the following game: I and II alternately play sets $p_n \in \bigcup_{\alpha\in U} P(\alpha)$ such that:*
   (a) *if $p_n \in P(\alpha)$ then $[p_n]_{I_\alpha} \in \mathcal{P}_{\mathcal{T}}$, and*
   (b) *$p_0 \geq_{\mathcal{P}_{\mathcal{T}}} p_1 \geq_{\mathcal{P}_{\mathcal{T}}} p_2 \geq_{\mathcal{P}_{\mathcal{T}}} \dots, p_n, \dots$.*

II wins iff there is an $a \subseteq \sup(U)$ *such that* $a \cap \mathrm{supp}(p_n) \in p_n$ *for every* n*.*

Somewhat surprisingly, in fairly general circumstances, towers of ideals automatically have the disjointing property:

4.54 Theorem (Burke [11]). *Suppose that* $\mathcal{T}$ *is a tower of ideals of height* δ *where* δ *is inaccessible. Then for all antichains* $\mathcal{A} \subseteq \mathcal{P}_\mathcal{T}$ *there is a pairwise disjoint collection of sets* $B \subseteq \bigcup_{\alpha\in U} P(\alpha)$ *such that each* $b \in B$ *has support less than* δ *and for all* $a \in \mathcal{A}$ *there is a* $b \in B$ *with* $[b]_{I_{\mathrm{supp}(b)}} = a$ *in* $\mathcal{P}_\mathcal{T}$*.*

Proof (Sketch). Enumerate $\mathcal{A}$ as $\langle a_i : i < \gamma \leq \delta\rangle$. Build $B = \langle b_i : i < \gamma\rangle$ by induction so that $[b_i]_{\mathcal{P}_\mathcal{T}} = a_i$, $b_i \subseteq P(s_i)$ for some $s_i \in U$. If we have built $\langle b_j : j < i\rangle$, we construct b_i by choosing an $s_i \in U$ larger than $\sup\{s_j : j < i\}$ and larger than $\mathrm{supp}(a_i)$. Let a be a representative of $[a_i]$ in $P(\mathrm{supp}(a_i))$ and $b_i = \{z \subseteq P(s_i) : b \cap \mathrm{supp}(a_i) \in a \text{ and } \sup\{s_j : j < i\} \in b_i\}$. ⊣

Unfortunately the disjointing property for towers of ideals is not as useful as for individual ideals: In Sect. 9 we give examples due to Burke of towers of ideals of inaccessible height that are not precipitous.

The property analogous to the disjointing property for individual ideals is the *bounded disjointing property*, i.e. that given any antichain $\mathcal{A} \subseteq \mathcal{P}_\mathcal{T}$ there is a pairwise disjoint collection B of representatives for members of $\mathcal{A}$ such that $\sup\{\mathrm{supp}(b) : b \in B\} < \delta$. This is equivalent to the tower $\mathcal{T}$ being δ-saturated, a fairly rare occurrence in our current state of knowledge. However, being able to locally disjointify a collection of antichains with representatives of bounded support follows from weak saturation properties and yields closure of the generic ultrapower. This is the usual situation for presaturated towers. The following is the analogue of Proposition 4.8 in the context of towers, and can be proved similarly:

4.55 Proposition. *Suppose that* $\mathcal{T} = \langle I_\alpha : \alpha \in U\rangle$ *is a tower of normal, fine ideals with height* δ*,* δ *is inaccessible and* $\mathcal{P}_T$ *is weakly* $(\aleph_1, \delta)$*-saturated. Then* $\mathcal{T}$ *is precipitous. Further, if* $\mathcal{P}_\mathcal{T}$ *is weakly* (η^+, δ)*-saturated* $(\omega \leq \eta < \delta)$*, and* $G \subseteq \mathcal{P}_T$ *is generic then* $N_\infty^\eta \cap V[G] \subseteq N_\infty$*.*

Proof (Sketch). Suppose that $\mathcal{T}$ is weakly $(\aleph_1, \delta)$-saturated. Let $\langle \mathcal{A}_n : n \in \omega\rangle$ be a tree of maximal antichains and $[S] \in \mathcal{T}$ a condition. By the weak saturation we can find a $[T] \leq_{\mathcal{P}_\mathcal{T}} [S]$ such that for each n, $\kappa_n =_{\mathrm{def}} |\{a \in \mathcal{A}_n : [a \cap T] \in \mathcal{P}_\mathcal{T}\}| < \delta$. Since δ is inaccessible we can find an $\alpha < \delta$ such that for all n and all $a \in \mathcal{A}_n$, if a is compatible with $[T]$ then the support of a is an ordinal less than α. Moreover, by increasing α slightly we can assume that α is regular and $\kappa_n < \alpha$.

By the normality of I_α, we can disjointify $a \in \mathcal{A}_n$ by choosing subsets of each a that have support α. Call the resulting antichains $\mathcal{A}'_n$. By shrinking still further we can assume that the $\mathcal{A}'_n$ still form a tree of antichains. Since $\mathcal{A}'_n$ is an I_α maximal antichain below $[T]$,

$$T =_{I_\alpha} \bigcap_n \bigcup \mathcal{A}'_n.$$

If $z \in T \cap \bigcap_n \bigcup \mathcal{A}'_n$ then z determines a branch through $\mathcal{A}'$ and hence a branch through $\mathcal{A}$. Let $a_n \in \mathcal{A}_n$ be the element of $\mathcal{A}_n$ given by z. Let $s(n)$ be the support of a_n and $z_n = z \cap s(n)$. Applying Proposition 4.52, we see that $\mathcal{T}$ is precipitous.

If $\mathcal{P}_\mathcal{T}$ is weakly (η^+, δ)-saturated, and $\langle \mathcal{A}_\alpha : \alpha \in \eta \rangle$ is a sequence of maximal antichains, then densely often in $\mathcal{P}_\mathcal{T}$ we can find a $[T]$ such that for all α, $\mathcal{A}_\alpha$ can be disjointified below $[T]$. It follows that if we are given a set $\{\dot{F}_\alpha : \alpha < \eta\}$ of terms for elements of N_∞ then there is a dense collection of $[T]$ for which we can find a sequence of functions $\{f_\alpha : \alpha < \eta\}$ such that the domain of each f_α is $Z_{\mathrm{supp}(T)}$ and

$$[T] \Vdash [\dot{F}_\alpha]_{N_\infty} = [f_\alpha]_{N_\infty}.$$

Let $\beta \in U$ be bigger than $\max(\mathrm{supp}(T), \eta)$ and let $: Z_\beta \to V$ be defined by setting

$$g(z) = \{f_\alpha(z \cap \mathrm{supp}(T)) : \alpha \in z \cap \eta\}.$$

Then $[g]_{N_\infty} = \{[\dot{F}_\alpha]_{N_\infty} : \alpha \in \eta\}$. ⊣

Tracking where ordinals go in ultrapowers by towers is highly analogous to the situation when forcing with individual ideals. One can easily verify:

4.56 Proposition. *Let $\mathcal{T}$ be a precipitous tower of normal and fine ideals of height δ. Let ρ and $\lambda < \delta$, $G \subseteq \mathcal{P}_\mathcal{T}$ be generic and $j : V \to M$ be the canonical generic embedding determined by G. Then:*

1. *if $\{z : z \cap \rho \in \rho\} \in G$, then $\mathrm{crit}(j) = \rho$,*
2. *if each I_α is λ-complete, then $\mathrm{crit}(j) \geq \lambda$,*
3. *if $\{z : \mathrm{ot}(z \cap \lambda) = \rho\} \in G$, then $j(\rho) = \lambda$, and*
4. *if $\{z : \mathrm{ot}(z \cap \lambda) < \rho\} \in G$, then $j(\rho) > \lambda$.*

From Propositions 4.56 and 4.55, we can get most of the information about the "three parameters" determining the strength of a generic embedding. For example, if $\mathcal{T}$ is a tower of height δ and:

1. for all α, I_α concentrates on $[\alpha]^{<\rho}$ and is ρ-complete, and
2. the tower $\mathcal{P}_\mathcal{T}$ is weakly (ρ, δ)-saturated,

then the critical point of j is ρ, $j(\rho) = \delta$ and M is closed under $<\rho$-sequences from $V[G]$.

If in addition, $\rho = \mu^+$ in V, then all of the ordinals less than δ have cardinality μ in $V[G]$. Hence closure under $<\rho$ sequences from $V[G]$ implies closure under $<\delta$ sequences from $V[G]$.

There is an intimate relationship between towers of ideals and ideals on a single set in a generic extension of the universe. For example, suppose that $\mathcal{T}$ is a tower of μ-complete ideals on $\langle P(\lambda_\alpha) : \alpha \in U \rangle$ and $\sup\{\lambda_\alpha \mid \alpha \in U\} = \delta$, where δ is an inaccessible cardinal. Then in $V^{\mathrm{Col}(\mu,<\delta)}$, each ideal I_α becomes isomorphic to an ideal on $P(\mu)$ and these ideals cohere in the obvious way. Unfortunately, the normal closure of the union of the ideals may fail to remain proper.

However there are circumstances where the limit ideal on μ can be shown to be proper. This occurs, for example, in the stationary tower of ideals restricted to the internally approachable sets. The resulting limit ideal is the nonstationary ideal on μ in the extension. An example of this is given in Proposition 9.4.

These topics are discussed at length in Sect. 9.

5. Consequences of Generic Large Cardinals

In this section we discuss various consequences of the existence of strong ideals. Indeed these consequences are so ubiquitous and striking that ideal axioms have been proposed as candidates for axioms for set theory. We discuss this in Sect. 11.

In our current state of knowledge, ideal assumptions divide into two mutually contradictory collections. One can loosely be termed "generic large cardinals".[29] These are the axioms that can be stated in terms of the "three parameters" that determine a generic elementary embedding $j : V \to M$, which again are: where j sends ordinals, the closure properties of M, and the nature of the forcing required to define j. The consequences of generic large cardinals affect virtually all of set theory and settle many of the classical problems of set theory. These ideal properties are easily seen to be rather straightforward generalizations of conventional large cardinal axioms, suitably modified so that they can "live" on relatively small cardinalities such as ω_1.

The second collection of ideal assumptions has just one essential element that we know of: the assumption that the nonstationary ideal on ω_1 is $\aleph_2$-saturated. In the presence of a measurable cardinal, this assumption implies that the Continuum Hypothesis fails in a particularly dramatic way, and that $L(\mathbb{R})$ is quite close to the universe, in a precise way. This assumption fits well with the $\mathbb{P}_{\max}$ theory of Woodin.[30]

At the moment the author has no strongly compelling reason to prefer the former collection of results over the latter. One could hope perhaps, that there is some happy reconciliation such as was devised between the Axiom of Choice and the Axiom of Determinacy.

5.1. Using Reflection

We illustrate the use of reflection in the context of saturated ideals with two simple examples.

[29] As this chapter went to the publishers, Woodin showed that there were more incompatible pairs of generic large cardinal axioms.
[30] See P. Larson's chapter in this Handbook for more information.

5.1 Theorem. *Suppose that there is a partial ordering $\mathbb{P}$ such that for all generic $G \subseteq \mathbb{P}$ there is an elementary embedding $j : V \to M$ such that for some $n \in \omega$:*

1. $j(\omega_{n-1}) = \omega_n$,
2. $j``\omega_n \in M$, *and*
3. $\mathbb{P}$ *is* $\aleph_1$*-centered.*

Then:

1. *If G is a graph on ω_k with $1 < k \leq n$ and G has chromatic number $\omega_{k'}$ with $1 < k' \leq k$, then G has an induced subgraph of cardinality ω_{k-1} and chromatic number $\omega_{k'-1}$, and*
2. *if G is a group (resp. Abelian group) of cardinality ω_k with $1 \leq k \leq n$ and every subgroup of G of cardinality less than ω_k is free*[31] *(resp. free Abelian), then $G = \bigcup_{\alpha<\omega_1} G_\alpha$ where G_α is free (free Abelian).*

For a given graph or group G, we can draw the same conclusions as Theorem 5.1 if we weaken the assumptions to asking that the critical point of j is ω_1 and the forcing for producing j is of the form $\mathbb{P} * \mathbb{Q}$ where $\mathbb{P}$ is $\aleph_1$-centered and $\mathbb{Q}$ is $|G|^V$-closed in $V^{\mathbb{P}}$. An example of this type of result is the next theorem whose hypotheses are shown consistent in Theorem 7.70.

5.2 Theorem. *Suppose that there is a partial ordering of the form $\mathbb{P} * \mathbb{Q}$ such that if $G * H \subseteq \mathbb{P} * \mathbb{Q}$ is generic, then in $V[G * H]$ there is a generic elementary embedding $j : V \to M$ such that:*

1. $\mathrm{crit}(j) = \omega_1$,
2. $j``\omega_2 \in M$, *and*
3. $\mathbb{P}$ *is* $\aleph_1$*-centered and* $\mathbb{Q}$ *is* $<(\omega_2)^V$*-closed in* $V[G]$.

Then

1. *If G is a graph on ω_2 with chromatic number ω_2 then G has a subgraph of size $\aleph_1$ and chromatic number ω_1, and*
2. *if G is a group of cardinality $\aleph_2$ and every subgroup of cardinality $\aleph_1$ is free, then $G = \bigcup_{\alpha<\omega_1} G_\alpha$, where each G_α is a free group.*

Proof of Theorem 5.1. Let $j : V \to M \subseteq V[H]$ be the elementary embedding associated with a generic $H \subseteq \mathbb{P}$. Since $\mathbb{P}$ is $\aleph_1$-centered, $\mathbb{P}$ preserves all cardinals above ω_1, and hence the critical point of j must be ω_1. It follows that for all $0 < k < n$, $j(\omega_k) = \omega_{k+1}^V$. The assumption that $j``\omega_n \in M$ implies that $P(\omega_n)^V \subseteq M$.

[31] I.e. G an almost free group.

Let $\mathbb{P} = \bigcup_{\alpha<\omega_1} F_\alpha$ where F_α is a filter on $\mathbb{P}$. Suppose that G is a graph on ω_k of chromatic number $\omega_{k'}$. Then G is isomorphic to the graph on $j``G$ induced by $j(G)$ on $j``\omega_k$ and $j``G$ has cardinality $\omega^M_{k-1}$. By elementarity, it suffices to show that $j``G$ has chromatic number $\omega_{k'-1}$ in M.

If this fails then there is a coloring $C : j``G \to \kappa$ lying in M where $\kappa < \omega^M_{k'-1} = \omega^V_{k'}$. For each $g \in G$ choose a $p_g \in \mathbb{P}$ such that $p_g \Vdash \dot{C}(j(g)) = \alpha$ for some $\alpha < \kappa$. In V, define $C' : G \to \kappa \times \omega_1$ by setting $C'(g) = (\alpha, \beta)$ where $p_g \in F_\beta$ and $p_g \Vdash \dot{C}(j(g)) = \alpha$. Then this is a coloring of G into $|\kappa \times \omega_1| < \omega_{k'}$ colors, a contradiction.

Now suppose that G is a group of cardinality ω_k such that every subgroup of cardinality ω_{k-1} is free. Then $j``G$ is a subgroup of G of cardinality ω^M_{k-1}, and hence G is free in M. Let $\dot{A}$ be a term for a free generating set for G. In V, for $\alpha < \omega_1$, let G_α be the subgroup of G generated by $\{g :$ for some $p \in F_\alpha, p \Vdash g \in A\}$. ⊣

Results of the type of 2 are clearly general for many algebraic objects where there is a suitable notion of freeness.

5.2. Chang's Conjectures, Jónsson Cardinals and Square

We begin with a simple remark [35]:

5.3 Proposition. *Let $j : V \to M$ be a generic elementary embedding.*

1. *If $\mathfrak{A}$ is a structure on a cardinal λ, then $j``\lambda \prec j(\mathfrak{A})$.*
2. *If $\lambda' < \lambda$ is a cardinal, and*
   - *(a) $j``\lambda \in M$,*
   - *(b) $j(\kappa) = \mathrm{ot}(j``\lambda)$, and*
   - *(c) $j(\kappa') = \mathrm{ot}(j``\lambda')$,*

   then $(\lambda, \lambda') \twoheadrightarrow (\kappa, \kappa')$.

Proof. Let $\mathfrak{A}$ be an algebra on a cardinal λ. We can assume that $\mathfrak{A}$ is fully Skolemized. Let f be a Skolem function and $\vec{\alpha} \in [j``\lambda]^{<\omega}$. Then there is a $\vec{\beta}$ such that $j(\vec{\beta}) = \vec{\alpha}$. Let $\beta^* = f(\vec{\beta})$ and $\alpha^* = j(\beta^*)$. Then $\alpha^* = j(f)(\vec{\alpha})$ and $\alpha^* \in j``\lambda$. Thus $j``\lambda$ is closed under the Skolem functions of $j(\mathfrak{A})$.

For the second assertion, we see that $M \models \mathrm{ot}(j``\lambda) = j(\kappa)$, and $\mathrm{ot}(j``\lambda \cap j(\lambda')) = j(\kappa')$. Thus we know that $M \models$ "there is an elementary substructure of $j(\mathfrak{A})$ of type $(j(\kappa), j(\kappa'))$". The result now follows from the elementarity of j. ⊣

We saw in Proposition 3.9, that $(\lambda, \lambda') \twoheadrightarrow (\kappa, \kappa')$ is equivalent to the existence of a proper, normal, fine, countably complete ideal on $P(\lambda)$ concentrating on $\{z : \mathrm{ot}(z) = \kappa$ and $\mathrm{ot}(z \cap \lambda') = \kappa'\}$, namely the Chang ideal.

A sort of converse of Proposition 5.3 is true: If there is a Woodin cardinal μ above λ and $(\lambda,\lambda') \twoheadrightarrow (\kappa,\kappa')$, then in $V^{\mathrm{Col}(\lambda,<\mu)}$, the Chang ideal is precipitous (Theorem 8.37). This was shown in [47] when μ is a supercompact cardinal. The version of the theorem with the optimal hypothesis stated here was published in [58].

Since Chang's Conjecture principles and square principles are antithetical combinatorial properties, we get the next corollary. This result and more general versions appear in [37].

5.4 Corollary. *Let $\mu < \kappa$ be cardinals and $\kappa < \aleph_{\mu^+}$. Suppose that there is a proper, normal, fine ideal on $[\kappa^+]^{\mu^+}$ that concentrates on $\{x : \mathrm{ot}(x \cap \kappa) = \mu\}$. Then $\square_\kappa(\mathrm{Cof}(\leq\mu))$ fails. Hence:*

If there is a generic elementary embedding $j : V \to M$ such that

1. *$j``\kappa^+ \in M$, and*
2. *$j(\mu) = \mathrm{ot}(j``\kappa)$,*

then $\square_\kappa(\mathrm{Cof}(\leq\mu))$ fails.

By adjusting the cardinals involved in Chang's Conjecture we get many consequences, as we shall prove later. For example, if κ is regular and $(\kappa^+,\kappa) \twoheadrightarrow (\kappa,<\kappa)$, then there are no Kurepa trees on κ. Hence, for example, if there is a generic elementary embedding $j : V \to M$ such that $j(\omega_1) = \omega_2$ and $j``\omega_2 \in M$, then there are no Kurepa trees on ω_1.

Chang's Conjecture also has GCH consequences: If $(\lambda^{+2},\lambda) \twoheadrightarrow (\kappa^{+2},\kappa)$ and $2^\kappa = \kappa^+$, then $2^\lambda = \lambda^+$.

It is also possible to see that Jónsson cardinals exist assuming the appropriate generic elementary embeddings:

5.5 Proposition. *Suppose that there is a generic elementary embedding $j : V \to M$ such that:*

1. *$\mathrm{crit}(j) < \kappa$,*
2. *$j``\kappa \in M$, and*
3. *$j(\kappa) = \kappa$,*

then κ is Jónsson.

Again, this is almost an equivalence: If $\mu > \kappa$ is Woodin then κ is Jónsson iff $V^{\mathrm{Col}(\kappa^+,<\mu)} \models$ "there is a proper, normal, fine, precipitous ideal on $[\kappa^+]^{<\kappa^+}$ concentrating on $\{z : |z \cap \kappa| = \kappa$ and $\kappa \not\subseteq z\}$". This follows from Theorem 8.37.

If we have an elementary embedding $j : V \to M$ we define the sequence of cardinals by setting $\kappa_0 = \mathrm{crit}(j)$ and $\kappa_{n+1} = j(\kappa_n)$, and finally $\kappa_\omega = \sup\{\kappa_n : n \in \omega\}$. To see that κ_ω is Jónsson, formally less than the previous proposition is required:

5.6 Theorem. *Suppose that $\langle \kappa_i : i \in \omega \rangle$ is an increasing sequence of uncountable cardinals with supremum κ_ω. Suppose that there is a sequence of normal, fine, countably complete ideals I_n on $P([\kappa_{n+1}]^{\kappa_n})$ such that the I_n's form a precipitous tower $\mathcal{T}$ of ideals.*[32] *Then κ_ω is Jónsson.*

Proof. Suppose that $\mathfrak{A}$ is a structure with domain κ_ω. By Skolemizing we can assume that if $\mathfrak{A}_n$ is the structure with domain κ_n determined by restricting the functions of $\mathfrak{A}$ to κ_n, and $B \subseteq \kappa_n$ is the domain of an elementary substructure of $\mathfrak{A}_n$, then $\mathrm{Sk}^{\mathfrak{A}}(B) \cap \kappa_n = B$.

Let S be the tree of finite sequences $(z_0, z_1, \ldots, z_n)$ such that:

1. $z_i \in [\kappa_{i+1}]^{\kappa_i}$,
2. $z_{i+1} \cap \kappa_{i+1} = z_i$, and
3. $z_i \prec \mathfrak{A}_{i+1}$

ordered by extension. It suffices to see that S is an ill-founded tree.

Let $G \subseteq \mathcal{P}_{\mathcal{T}}$ be generic for the tower of ideals and $j : V \to N_\infty$ be the generic ultrapower of V by the tower. We claim that $j(S)$ is ill-founded in N_∞. Since N_∞ is well-founded, by absoluteness, it suffices to show that $j(S)$ is ill-founded in $V[G]$. But this is immediate since the sequence $\langle j``\kappa_{i+1} : i \in \omega \rangle$ is a branch through $j(S)$. ⊣

5.3. Ideals and GCH

In this section we consider the consequences strong ideals can have on the Generalized Continuum Hypothesis, deferring the case of the nonstationary ideal on ω_1 to its own subsection.

We begin with an easy example of an axiom that implies instances of GCH:

5.7 Proposition. *Suppose that there is a generic elementary embedding $j : V \to M$ with critical point κ^+ in a (κ, ∞)-distributive forcing extension of V. Then $\kappa^{<\kappa} = \kappa$ holds.*

Since it is easy to see the consistency of the statement there is a normal $\aleph_2$-complete ideal I on ω_2 such that $P(\omega_2)/I$ has a dense countably closed subset, it is interesting to note the following corollary:

5.8 Corollary. *Suppose that there is an ideal I on a set Z that has completeness ω_2 such that $P(Z)/I$ has a dense countably closed subset. Then* CH *holds.*

Proof of Proposition 5.7. Let $\vec{r} = \langle r_\alpha : \alpha < \kappa^{<\kappa} \rangle$ be a one-to-one enumeration of $[\kappa]^{<\kappa}$. If $\kappa^{<\kappa} > \kappa$, then $j(\vec{r}) \neq \vec{r}$ and hence there is an element of $[\kappa]^{<\kappa}$ in M that is not in V. This contradicts the distributivity of the forcing. ⊣

We note that the axiom stating that "ω_n is generically supercompact by $<\omega_n$-closed forcing" implies the hypothesis of Example 5.7 and hence that $\omega_n^{<\omega_n} = \omega_n$.

[32] See Definition 4.51.

Woodin's Theorem Showing CH Holds

Perhaps the first clue that $\aleph_1$-dense ideals can have an affect on the value of $2^{\aleph_0}$ was Taylor's Theorem 4.3, which showed that if there is a countably complete, $\aleph_1$-dense ideal on ω_1 then MA_{ω_1} fails.

In [35], the author showed that strong ideal axioms implied GCH. In later work the author showed that if there is a generic elementary embedding $j : V \to M \subseteq V[G]$ where $G \subseteq \mathbb{P}$ is generic and:

1. $j(\omega_1) = \omega_2$,
2. $j``\omega_2 \in M$, and
3. $\mathbb{P} = \mathrm{Col}(\omega, \omega_1)$,

then the Continuum Hypothesis holds. Woodin improved both of these by showing that the existence of an $\aleph_1$-dense ideal on ω_2 implies the Continuum Hypothesis.

5.9 Theorem (Woodin). *Suppose that there is a uniform, countably complete $\aleph_1$-dense ideal on ω_2. Then the Continuum Hypothesis holds.*

Proof (Sketch). We will use the forthcoming Lemma 6.23, essentially due to Gitik and Shelah. That lemma is shown in its appropriate context in Sect. 6.6, where it serves as the main ingredient for the proof of Theorem 6.22 there. Woodin made the appropriate modifications in the lemma so that it now serves also to prove the present theorem. The thrust of the proof is that Lemma 6.23 shows that four hypotheses I–IV cannot jointly hold, yet the existence of the dense ideal together with the failure of CH implies that these hypotheses simultaneously hold after all.

Since I has the disjointing property, it is precipitous and if $G \subseteq P(\omega_2)/I$ is generic and $j : V \to M \subseteq V[G]$ is the generic ultrapower then $M^\omega \cap V[G] \subseteq M$.

In V, we can define an ideal I' by setting $X \in I'$ iff $1 \Vdash_{P(\omega_2)/I} \omega_1 \notin j(X)$. Then I' is the induced ideal from the ultrafilter $U(j, \omega_1^V)$. By the results in Sect. 4, I' is a projection of I and there is a natural embedding ι from $P(\omega_1)/I'$ to $P(\omega_2)/I$ sending $[X]$ to the Boolean value $\|\omega_1 \in j(X)\|$ in the complete Boolean algebra $P(\omega_2)/I$. Moreover, I' is $\aleph_1$-dense and ι is a complete embedding. For generic $G \subseteq P(\omega_2)/I$ the ultrafilter $U = U(j, \omega_1^V)$ is generic for $P(\omega_1)/I'$.

Form the ultrapower V^{ω_1}/U, and let N be its transitive collapse, and $i : V \to N$ be the canonical embedding. Then $N^\omega \cap V[U] \subseteq N$. Let k be the natural factor map from this ultrapower to M given by $k([f]) = j(f)(\omega_1)$. Then $j = k \circ i$:

$$\begin{tikzcd} & V \arrow[dl, "i"'] \arrow[dr, "j"] & \\ N \arrow[rr, "k"'] & & M \end{tikzcd}$$

As in Examples 4.28 and 4.29:

1. $\omega_1^N = \omega_2^V = \omega_1^M$,
2. $(\omega_2)^{V[G]} = (\omega_2)^{V[U]} = \omega_3^V$,
3. $\sup(i``\omega_2^V)$ is cofinal in $i(\omega_2^V)$,
4. $i(\omega_2^V) < \omega_3^V$,
5. $\omega_3^N = i(\omega_3^V) = \omega_3^V$ and there is a set $C \subseteq \omega_3$ in V that is ω-closed in V and for all $\alpha \in C$, $i(\alpha) = \alpha$,
6. $j(\omega_2^V) = \omega_3^V$, and
7. $\mathrm{crit}(k) = \omega_2^N$.

In particular, the cardinal successor of the ordinal ω_2^N computed in N is the same as the cardinal successor of ω_2^N computed in $V[U]$.

We now assume the Continuum Hypothesis fails, and derive a contradiction. Let $\vec{x} = \langle x_\alpha : \alpha < 2^{\aleph_0}\rangle$ be a one-to-one enumeration of the real numbers in V. Then $i(\vec{x})$ is an enumeration of all of the real numbers in $V[U]$ and has length at least $\omega_2^N = \mathrm{crit}(k)$. Hence $k(i(\vec{x})) \neq i(\vec{x})$ and the range of $k(i(\vec{x}))$ differs from the range of $i(\vec{x})$. Since the diagram commutes, $k(i(\vec{x})) = j(\vec{x})$ is an enumeration of the reals in M. Since M has all of the reals of $V[G]$, we see that the collection of real numbers in $V[U]$ is different from the collection of real numbers in $V[G]$. Hence the embedding $\iota : P(\omega_1)/I' \to P(\omega_2)/I$ does not map onto a dense set: $V[U]$ is a proper subclass of $V[G]$.

The relationship between forcing with $P(\omega_1)/I'$ and $P(\omega_2)/I$ is easy to describe. Since both are $\aleph_1$-dense, each forcing is equivalent to forcing with $\mathrm{Col}(\omega, \omega_1)$. If we first force with $P(\omega_1)/I'$, then $P(\omega_2)/I$ has a countable dense set. Hence the quotient forcing from the embedding ι is equivalent to Cohen forcing.[33] If $U \subseteq P(\omega_1)/I'$ is generic, then one can force over $V[U]$ with Cohen forcing to produce a generic real s. In $V[U][s]$ we can recover G, M and k.

This is the main idea of the proof: by adding a Cohen real to $V[U]$ we can force the existence of a non-trivial generic embedding with domain N. Were $N = V[U]$ this would give an immediate contradiction to Theorem 6.22. The heart of this theorem is arguing that N is close enough to $V[U]$ to derive a similar contradiction.

We now verify the hypotheses I–IV that Lemma 6.23 shows are impossible. We will follow the notation given there. We take the model $W = V[U]$, and the N in the lemma to be the N that is isomorphic to V^{ω_1}/U. That N is closed under ω-sequences from $V[U]$ is immediate from Proposition 2.14. Let $\kappa = \omega_2^N$. Then $(\kappa^+)^N = (\kappa^+)^W = \omega_3^V$.

[33] See the forcing fact mentioned in Sect. 1.

Let $J \in V[U]$ be the ideal on $P(\kappa)^N$ induced by κ and k. Then J is normal and κ-complete for functions that lie in N. Since the forcing producing s is c.c.c., Example 3.30 shows that $P(\kappa)^N/J$ is c.c.c. in $V[U]$.

If $\mathcal{A} \subseteq P(\kappa)^N/J$ is a maximal antichain lying in $V[U]$, then $\mathcal{A}$ is countable and hence there is a disjoint collection $\mathcal{R} \subseteq P(\kappa)^N$ of representatives of $\mathcal{A}$ that lies in $V[U]$. Since N is ω-closed $\mathcal{R}$ belongs to N and $\bigcup \mathcal{R} \in \breve{J}$. Hence there is a unique element A of $\mathcal{R}$ such that $\kappa \in k(A)$. From this we conclude that $H = \{[A] : \kappa \in k(A)\} \subseteq P(\kappa)^N/J$ is generic over W.

Thus the forcing $P(\kappa)^N/J$ is a regular subalgebra of the Boolean algebra for adding a single Cohen real. Since every subalgebra of the Cohen algebra is again a Cohen algebra, we see that $P(\kappa)^N/J$ has a countable dense subset in W.

Let $H \subseteq P(\kappa)^N/J$ be generic over W. Then we can do further forcing to produce s, G, M and k so that $H = \{[A] : \kappa \in k(A)\}$. Hence there is an elementary embedding of N^κ/H into M. In particular, N^κ/H is well-founded. Let N' be the transitive collapse of N^κ/H, i' be the ultrapower embedding of N into N' and $k' : N' \to M$ by $k'([f]^{N'}) = k(f)(\kappa)$. Then we get a commutative diagram of elementary embeddings:

$$\begin{tikzcd}
 & V \arrow[dl, "i"'] \arrow[dr, "j"] & \\
N \arrow[rr, "k"'] \arrow[dr, "i'"] & & M \\
 & N' \arrow[ur, "k'"'] &
\end{tikzcd}$$

The next claim finishes our reduction to Lemma 6.23, by establishing Hypothesis IV. To each generic $H \subseteq P(\kappa)^N/J$ we can canonically associate a Cohen real $r = r(H)$ such that $W[H] = W[r]$, and vice versa. In the notation of the hypotheses for Lemma 6.23, $\langle r_\xi : \xi < \kappa\rangle \in N$ is a one-to-one sequence such that for all generic $H \subseteq P(\kappa)/J$, $k'(\langle r_\xi : \xi < \kappa\rangle)(\kappa) = r$. We let $k'(\langle r_\xi : \xi < \kappa\rangle) = \langle r_\xi^{k'} : \xi < k'(\kappa)\rangle$. A sequence of Cohen terms $\langle s_\alpha : \alpha < \kappa^+\rangle \in W$ is chosen so that $1 \Vdash^W s_\xi = r_\xi^{k'}$ for all $\xi < \kappa^+$. To each Cohen term t we canonically associate a Borel function $T : \omega^\omega \to \omega^\omega$ in the usual way. Since s_α and s_β represent distinct reals, $\{x : S_\alpha(x) = S_\beta(x)\}$ is meager.

Let $X \in V[U]$ be a set of Borel functions with $|X| = \omega_1^{V[U]}$. Then for any unbounded set $Y \subseteq \omega_3$ in $V[U]$, there is an $\alpha \in Y$ such that for all $T \in X$, $\{x : T(x) = S_\alpha(x)\}$ is meager. For otherwise, there would be $T \in X$ and a $B \subseteq Y$ of cardinality ω_3^V such that for all $\alpha \in B$, $\{x : T(x) = S_\alpha(x)\}$ is non-meager. Hence there would be a single $p \in \omega^{<\omega}$ and $\alpha < \beta \in B$ such that $\{x \in [p] : S_\beta(x) = S_\alpha(x) = T(x)\}$ is comeager in $[p]$ a contradiction.

Claim. There is a sequence of Cohen terms $\langle t_\alpha : \alpha < \omega_3^V\rangle \in N$ such that:

(a) for a cofinal set of $\alpha < \omega_3^N$, $1 \Vdash t_\alpha = s_\alpha$, and

(b) for all $\alpha < \beta < \omega_3^N$, $\{x : T_\alpha(x) = T_\beta(x)\}$ is meager.

We are viewing Cohen terms for real numbers as hereditarily countable objects, so that each $s_\alpha \in N$. Working in V, for each $\alpha < \omega_3$ let $f_\alpha : \omega_1 \to H(\omega_1)$ be such that $1 \Vdash_{P(\omega_1)/I'} [f_\alpha]^N = s_\alpha$. Define

$$F : \omega_3 \times \omega_1 \to H(\omega_1)$$

by setting $F(\alpha, \xi) = f_\alpha(\xi)$.

In N, define a sequence of Cohen terms $\langle t_\alpha : \alpha < \omega_3^V \rangle$ by induction. Let $t_0 = s_0$. Suppose that we have defined $\langle t_\alpha : \alpha < \alpha_0 \rangle$.

Let Y be the set of fixed points of i below ω_3. By the previous paragraphs there is a $\beta \in Y \setminus \alpha_0$ such that S_β disagrees with each T_α on a comeager set. Since β is a fixed point of i, $i(F)(\beta, \omega_1^V) = s_\beta$. Hence the Borel function associated with $i(F)(\beta, \omega_1^V)$ disagrees with each of the T_α on a comeager set. Let β_0 be the least ordinal $\beta \geq \alpha_0$ such that $i(F)(\beta, \omega_1^V)$ has this property and $t_{\alpha_0} = i(F)(\beta_0, \omega_1^V)$. Clearly for $\alpha < \beta < \omega_3^V, \{x : T_\alpha(x) = T_\beta(x)\}$ is meager.

It remains to see that $\{\alpha : t_\alpha = s_\alpha\}$ is cofinal in ω_3^V. Suppose that this fails. Let η be a fixed point of i. If s_η is not on the sequence $\langle t_\alpha : \alpha < \omega_3 \rangle$, then there is a $\beta < \eta$ such that S_η agrees with T_β on a non-meager set. Since the set Y of fixed points of i is $V[U]$-stationary, we can find a stationary set $Z \subseteq Y$ and a fixed β such that for $\alpha \in Z$, S_α agrees with T_β on a non-meager set. In particular, we can find a fixed $p \in \omega^{<\omega}$ and $\alpha_0 < \alpha_1 \in Z$ such that both S_{α_0} and S_{α_1} agree with T_β on a comeager subset of $[p]$. But this means that S_{α_0} and S_{α_1} agree on a non-meager set, a contradiction.

We have now verified the hypotheses I–IV that Lemma 6.23 (proved in Sect. 6) shows are impossible. $\dashv$

We now describe how to use ideal assumptions to transfer CH to GCH. The first theorem of this sort was due to Jech and Prikry [64], who showed that if CH holds and there is an $\aleph_2$-saturated ideal on ω_1, then $2^{\aleph_1} = \aleph_2$. The more general version of this theorem appears in Foreman [35]:

5.10 Theorem. *Assume that $2^\kappa = \kappa^+$. Suppose that either:*

1. $(\lambda^{+2}, \lambda) \twoheadrightarrow (\kappa^{+2}, \kappa)$, *or*
2. *there is an elementary embedding $j : V \to M \subseteq V[G]$ where $G \subseteq \mathbb{P}$ is generic such that*
   - *(a)* $j(\kappa^+) = \lambda$,
   - *(b)* $j``\lambda \in M$, *and*
   - *(c)* $\mathbb{P}$ *is* λ^+*-c.c.*

Then $2^\lambda = \lambda^+$.

Proof. Assume the first hypothesis and suppose that $\langle x_\alpha : \alpha < \lambda^{+2}\rangle$ is a sequence of distinct subsets of λ. Then there is an elementary substructure $\mathfrak{A}$ of $\langle H(\theta), \in, \langle x_\alpha : \alpha < \lambda^{+2}\rangle\rangle$ such that the order type of $\mathfrak{A}$ intersected with λ^{+2} is κ^{+2} and the intersection of $\mathfrak{A}$ with λ has cardinality κ. Then $\langle x_\alpha : \alpha \in \mathfrak{A} \cap \lambda^{+2}\rangle$ is a sequence of κ^{+2} distinct subsets of $\lambda \cap \mathfrak{A}$. Hence $2^\kappa \geq \kappa^{+2}$, a contradiction.

Let j be the embedding from the second hypothesis. If I is the ideal induced by j and $j``\lambda$, then I is a normal, fine, countably complete, λ^+-saturated ideal on $[\lambda]^{\kappa^+}$. We can assume that j comes from an ultrapower of V by a generic $G \subseteq P([\lambda]^{\kappa^+})/I$. From this assumption, we can conclude that $M^\lambda \cap V[G] \subseteq M$. Since $M \models |P(\lambda)| = \lambda^+$ we must have $V[G] \models |P(\lambda)| = \lambda^+$. Since all cardinals greater than or equal to λ^+ are preserved we see that $2^\lambda = \lambda^+$ in V. $\dashv$

Moreover, since all Chang's Conjectures are consequences of the appropriate ideal hypothesis, we can formulate other axioms that "transfer" instances of GCH. For example, $(\lambda^{+2}, \lambda) \twoheadrightarrow (\kappa^{+2}, \kappa)$ and $2^\kappa = \kappa^+$ implies $2^\lambda = \lambda^+$. Hence:

5.11 Proposition (Foreman [35]). *Suppose that there is a pre-precipitous ideal on $[\lambda^+]^{\kappa^+}$ concentrating on $[\lambda]^\kappa$. Then $2^\kappa = \kappa^+$ implies $2^\lambda = \lambda^+$.*

Abe's Results on SCH

Abe [1] found another way of deducing instances of GCH and the Singular Cardinals Hypothesis (SCH) from ideal assumptions.[34] These arguments follow Solovay's proof of SCH above a supercompact cardinal, weakening Solovay's assumption of the existence of a normal ultrafilter on $[\lambda]^{<\kappa}$ to the existence of a weakly normal ideal on $[\lambda]^{<\kappa}$. The first theorem deals with regular cardinals and implicitly SCH by considering the successor of a singular cardinal.

5.12 Theorem. *If λ is regular and there is a weakly normal, fine, κ-complete ideal I on $[\lambda]^{<\kappa}$. Then $\lambda^{<\kappa} = \lambda \cdot 2^{<\kappa}$.*

5.13 Corollary. *Suppose that λ is regular and there is a normal, fine, κ-complete, λ-saturated ideal on $[\lambda]^{<\kappa}$. Then $\lambda^{<\kappa} = \lambda \cdot 2^{<\kappa}$.*

Proof of Theorem 5.12. Let U be the dual of I and D be the projection of U to a filter on λ via the map $z \mapsto \sup(z)$. Then D is a uniform, weakly normal, κ-complete filter on λ concentrating on ordinals of cofinality less than κ.

For ordinals $\alpha \in \lambda \cap \mathrm{Cof}({<}\kappa)$, let $A_\alpha \subseteq \alpha$ be a cofinal subset of α of order type the cofinality of α. Define an increasing continuous sequence of ordinals $\langle \eta_\xi : \xi < \lambda\rangle$ by induction by letting $\eta_0 = 0$, and $\eta_{\xi+1}$ the least

[34] Informally speaking, SCH asserts that 2^λ for a singular λ is the least possibility given by cardinal arithmetic and the powers of smaller regular cardinals. It is much discussed in various chapters of this Handbook.

ordinal such that $\{\alpha : A_\alpha \cap [\eta_\xi, \eta_{\xi+1}) \neq \emptyset\} \in D$. (Such an $\eta_{\xi+1}$ exists by the weak normality of D.)

Let $M_\alpha = \{\xi < \lambda : A_\alpha \cap [\eta_\xi, \eta_{\xi+1}) \neq \emptyset\}$. Then $M_\alpha \in [\lambda]^{<\kappa}$ and for each ξ, $\{\alpha : \xi \in M_\alpha\} \in D$. Hence, by the κ-completeness for all $z \in [\lambda]^{<\kappa}$ there is an α with $z \subseteq M_\alpha$. In particular, $[\lambda]^{<\kappa} = \bigcup_{\alpha<\lambda} P(M_\alpha)$. $\dashv$

Abe gets two more results directly addressing the case of singular cardinals:

5.14 Theorem. *Suppose that λ is a singular cardinal and there is a weakly normal, fine, κ-complete ideal on $[\lambda]^{<\kappa}$. Then*

1. *if* $\mathrm{cf}(\lambda) < \kappa$, *then* $\lambda^{<\kappa} = \lambda^+ \cdot 2^{<\kappa}$, *and*
2. *if* $\mathrm{cf}(\lambda) = \kappa$, *then* $\lambda^{<\kappa} = \lambda \cdot 2^{<\kappa}$.

The Value of Θ

We now turn to more subtle ideas about the continuum. Let M be a model of ZF but not necessarily the Axiom of Choice. We define Θ^M to be the supremum of all ordinals α for which there is a surjection $f : \mathbb{R}^M \to \alpha$ with $f \in M$. If M is a model of the Axiom of Choice, then $\Theta^M = (\mathfrak{c}^+)^M$, where $\mathfrak{c} = 2^{\aleph_0}$. In [42] the following analogue of the Continuum Hypothesis was considered:

5.15 Definition. The *Constructive Continuum Hypothesis* is the assertion that $\Theta^{L(\mathbb{R})} \leq \omega_2$.

Thus the Constructive Continuum Hypothesis asserts that it is not possible to effectively construct a counterexample to the Continuum Hypothesis in $L(\mathbb{R})$. If there are measurable cardinals, then $\Theta^{L(\mathbb{R})}$ has cofinality ω and consequently is either strictly larger than ω_2 or strictly smaller than ω_2.

In Sect. 5.11, we will prove Woodin's theorem that it is a consequence of the statement "the nonstationary ideal on ω_1 is $\aleph_2$-saturated and there is a measurable cardinal", that $\underset{\sim}{\delta}^1_2 = \omega_2$. Since $\underset{\sim}{\delta}^1_2$ is much smaller than $\Theta^{L(\mathbb{R})}$ this shows that there is a constructive/effective counterexample to the Continuum Hypothesis. However, we work in the other direction for the moment.

5.16 Definition. A partial ordering $\mathbb{P}$ is *reasonable* iff for all ordinals α and all V-generic $G \subseteq \mathbb{P}$, $([\alpha]^{<\omega_1})^V$ is stationary in $V[G]$.

It is easy to verify many standard classes of partial orderings are reasonable. For example, any proper partial ordering is reasonable and any $\aleph_\omega$-c.c. partial ordering that preserves all cardinals is reasonable [42].

5.17 Lemma. *Suppose that I is an $\aleph_n$-complete, $\aleph_\omega$-saturated, cardinal preserving ideal on ω_n. If there is a set $A \in I[\omega_n]$ with $A \subseteq \mathrm{Cof}(\omega_{n-1})$ and $A \in \breve{I}$, then $P(\omega_n)/I$ is reasonable.*

Proof. We must see that if α is an ordinal, $G \subseteq P(\omega_n)/I$ is generic, and $\mathfrak{A} \in V[G]$ is a structure in a countable language with domain α, then there is a countable set $z \in V$ such that $z \prec \mathfrak{A}$.[35] We can assume that α is cardinal in V.

Using the downward Löwenheim-Skolem theorem, it is easy to verify the following general result due to Abraham:

Fact. Suppose that $V \subseteq W$ are models of set theory and $\alpha \in \mathrm{On}$ with $(\alpha^+)^V$ a cardinal in W. If $V \cap [\alpha]^{<\omega_1}$ is stationary in W then so is $V \cap [\alpha^+]^{<\omega_1}$.

Abraham's fact together with the hypothesis that I is cardinal preserving implies that for all $\beta \leq \omega_{n-1}$, $([\beta]^{<\omega})^V$ remains stationary after forcing with $P(\omega_n)/I$.

By a theorem of Tarski [117] the saturation of a Boolean algebra is always a regular cardinal. Hence $P(\omega_n)/I$ is $\aleph_k$-c.c. for some $k \in \omega$. This implies that if $G \subseteq P(\omega_n)/I$ is generic and $\mathfrak{A} \in V[G]$ is a structure with domain some $\lambda \geq \omega_k$, then there is a set $N \in V$ with $|N|^V = \aleph_k$ such that $N \prec \mathfrak{A}$. Since ω_k is ω_n^{+j} for some finite j, the lemma is reduced to seeing that if ρ is ω_n^V, then $([\rho]^{<\omega_1})^V$ is stationary in $V[G]$.

Let $\langle f_\gamma : \gamma \in [\omega_{n-1}, \omega_n]^V \rangle \in V$ such that for each $\gamma \in [\omega_{n-1}, \omega_n]^V$, $f_\gamma : \omega_{n-1}^V \to \gamma$ is a bijection. Let $\mathfrak{A}$ be an expansion of a large $H(\theta)$ witnessing that $A \in I[\omega_n]$.

Let $G \subseteq P(A)/I$ be generic and $j : V \to M \subseteq V[G]$ be the generic elementary embedding. Let $\mathfrak{B} \in V[G]$ be a structure in a countable language with domain ρ. We must find a countable $z \subseteq \rho$ lying in V such that $z \prec \mathfrak{B}$.

For all $\gamma < \rho$, $\mathrm{Sk}^{j(\mathfrak{A})}(\gamma) \cap \rho^{<\rho} = \mathrm{Sk}^{\mathfrak{A}}(\gamma) \cap \rho^{<\rho}$. Hence, $\mathrm{Sk}^{j(\mathfrak{A})}(\rho) \cap \rho^{<\rho} = \mathrm{Sk}^{\mathfrak{A}}(\rho) \cap \rho^{<\rho} \subseteq V$. Since $A \in G$, there is a sequence $\langle \rho_i : i \in \omega_{n-1} \rangle \in V[G]$ cofinal in ρ such that every initial segment $\langle \rho_i : i \in j \rangle \in \mathrm{Sk}^{j(\mathfrak{A})}(\rho)$. In particular, we see that for $j \in \omega_{n-1}$, $\langle \rho_i : i \in j \rangle$ is in V.[36]

Let $X_j = \bigcup_{i<j} f_{\rho_i}``j$. Then each $X_j \in V$ and in $V[G]$ the sequence $\langle X_j : j < \omega_{n-1} \rangle$ is an increasing, continuous sequence of sets of cardinality less than ω_{n-1} whose union is ρ. In particular, there is a j such that X_j is an elementary substructure of $\mathfrak{B}$.

Since $([X_j]^{<\omega_1})^V$ is stationary in $P(X_j)^{V[G]}$, there is a $z \in ([X_j]^{<\omega_1})^V$ such that $z \prec \mathfrak{B}$. $\dashv$

A somewhat easier argument shows:

5.18 Lemma. *Suppose that $P(\omega_n)/I$ is $\aleph_{n+1}$-saturated, where I is the non-stationary ideal on ω_n restricted to the ordinals of cofinality ω_{n-1}. Then $P(\omega_n)/I$ is reasonable.*

Foreman and Magidor established the following result [42, Theorem 3.4]:

[35] More precisely, z is the domain of an elementary substructure of $\mathfrak{A}$.
[36] This is where we use the hypothesis that I concentrates on a set in $I[\omega_n]$.

5.19 Theorem. *Suppose that $\sim$ is a κ-weakly homogeneously Suslin equivalence relation, and $\mathbb{P}$ is a reasonable partial ordering of cardinality less than κ. Suppose that there is a $\tau \in V[G] \cap \omega^\omega$ such that for all $f \in V \cap \omega^\omega$, $\tau \not\sim f$. Then in V, there is a perfect set of $\sim$ inequivalent elements of ω^ω.*

Suppose that $f : \omega^\omega \to \rho$ is a function in $L(\mathbb{R})$, where $\rho \in \mathrm{On}$. Then f induces an equivalence relation on ω^ω defined by setting $x \sim_f y$ iff $f(x) = f(y)$. Given a sufficient number of conventional large cardinals, this equivalence relation is κ-weakly homogeneously Suslin for some measurable cardinal κ.

Suppose that $\sim$ is a κ-weakly homogeneously Suslin equivalence relation on ω^ω with at least $\aleph_n$ classes. Enumerate the classes as $\langle [x_\alpha] : \alpha < \gamma \rangle$. Let I be a precipitous ideal on ω_n. Let $G \subseteq P(\omega_n)/I$ be generic, and $j : V \to M \subseteq V[G]$ be the generic elementary embedding. Then one can show that the ω_nth equivalence class on the sequence $j(\langle [x_\alpha] : \alpha < \gamma \rangle)$ is a new class for $\sim$.

As a corollary we get the following results:

5.20 Theorem. *Suppose that any of the following hypotheses (together with conventional large cardinal hypotheses):*

1. *there is an $\aleph_n$-complete, cardinal preserving ideal I on ω_n that is $\aleph_\omega$-saturated with an element $A \in I[\omega_n] \cap I^+$, or*
2. *the nonstationary ideal on ω_n restricted to cofinality ω_{n-1} is $\aleph_{n+1}$-saturated, or*
3. *there is an $\aleph_1$-complete ideal I on ω_n such that the forcing $P(\omega_n)/I$ is proper.*

Then $\Theta^{L(\mathbb{R})} < \omega_n$.

There are a host of other possible hypotheses that work as well as 1–3 in Theorem 5.20.

Woodin used this result to prove the following:

5.21 Theorem. *Suppose that there is an $\aleph_2$-saturated, uniform ideal I on ω_2 and sufficiently many conventional large cardinals. Then $\Theta^{L(\mathbb{R})} < \omega_2$.*

Proof. Let $\sim$ be a weakly homogeneous equivalence relation with at least ω_2 classes. We show that there is a perfect set of $\sim$ inequivalent reals.

As in the proof of Theorem 5.9, there is a normal, $\aleph_2$-saturated ideal I' on ω_1 defined by setting $X \in I'$ iff $1 \Vdash_{P(\omega_2)/I} \omega_1 \notin j(X)$, where $j : V \to M$ is the elementary embedding induced by a generic ultrafilter for $P(\omega_2)/I$. Moreover, I' is a projection of I and $P(\omega_1)/I'$ is regularly embedded in $P(\omega_2)/I$. Let $G \subseteq P(\omega_2)/I$ be generic and U be the projection to a generic object for $P(\omega_1)/I$. We note that G is in a c.c.c. extension of $V[U]$, since $\omega_2^V = \omega_1^{V[U]}$. In particular, the forcing creating G over $V[U]$ is reasonable. We argue that it adds a new $\sim^{V[U]}$ equivalence class.

If $i : V \to N$ is the generic elementary embedding induced by I' and the ultrapower by U then there is an elementary embedding $k : N \to M$ making the following diagram commute:

$$\begin{tikzcd} & V \arrow[dl, "i"'] \arrow[dr, "j"] & \\ N \arrow[rr, "k"'] & & M \end{tikzcd}$$

Again, as in Theorem 5.9, the critical point of k is ω_2^N. Let $\langle [x_\alpha] : \alpha < \gamma\rangle \in N$ be an enumeration of the $\sim^N$ equivalence classes. Since $N \cap \mathbb{R} = V[U] \cap \mathbb{R}$, and $\sim$ is weakly homogeneous, we see that this is also an enumeration of the $\sim^{V[U]}$ equivalence classes.

Moreover, the ω_2^N element of $k(\langle [x_\alpha] : \alpha < \gamma\rangle)$ is a new $\sim$ equivalence class. Hence we can apply Theorem 5.19, to see that there is a perfect set of inequivalent reals. ⊣

5.4. Stationary Set Reflection

Generic embeddings imply the same stationary set reflection as the corresponding large cardinal embedding, provided that the forcing preserves stationarity. One example of this phenomenon is the following proposition:

5.22 Proposition. *Suppose that there is a generic elementary embedding with critical point κ^+ in a $<\kappa$-closed forcing extension of V. Then if $S \subseteq \kappa^+ \cap \mathrm{Cof}(<\kappa)$ is stationary, there is a $\gamma < \kappa^+$ such that $S \cap \gamma$ is stationary.*

Proof. Let $j : V \to M \subseteq V[G]$ have critical point κ^+. Since $\kappa^{<\kappa} \cap V = \kappa^{<\kappa} \cap V[G]$ we must have $V \models \kappa^{<\kappa} = \kappa$. It follows that $<\kappa$-closed forcing preserves stationary subsets $S \subseteq \kappa^+ \cap \mathrm{Cof}(<\kappa)$. Consequently, if S is a stationary subset of κ^+ consisting of ordinals of cofinality less than κ, S remains stationary in $V[G]$.

Since, $j(S) \cap \kappa^+ = S$, we know that $M \models$ "there is a $\gamma < j(\kappa)$ such that $j(S) \cap \gamma$ is stationary". By the elementarity of j, this holds in V. ⊣

Note that the hypothesis of Proposition 5.22 holds if there is a normal, κ^+-complete ideal I on κ^+ such that $P(\kappa^+)/I$ has a dense $<\kappa$-closed subset.

Since proper forcing preserves stationary sets of ordinals of cofinality ω, the proof of Proposition 5.22 gives the following observation:

5.23 Proposition. *Suppose that $j : V \to M$ is an elementary embedding with critical point κ in a generic extension of V by proper forcing. Suppose that $P \subseteq \kappa$ with $\|\kappa \in j(P)\| \neq 0$ and $S \subseteq \kappa \cap \mathrm{Cof}(\omega)$ is stationary, then there is an $\alpha \in P$ such that $S \cap \alpha$ is stationary.*

It follows from Proposition 5.23 that if I is a normal κ-complete ideal on κ such that $P(\kappa)/I$ is proper, then for every stationary set $S \subseteq \kappa \cap \mathrm{Cof}(\omega)$ and every $P \in I^+$, there is an $\alpha \in P$ such that $S \cap \alpha$ is stationary.

The interested reader can easily formulate other generic embedding assumptions that yield every ordinal reflection property at successor of regular cardinals.

An interesting assumption at a successor of a singular cardinal is:

5.24 Theorem. *Suppose that there are partial orderings $\langle \mathbb{P}_n : n \in \omega \rangle$ such that $\mathbb{P}_n$ is $<\omega_n$-closed and whenever $G \subseteq \mathbb{P}_n$ there is a generic elementary embedding $j : V \to M$ with critical point ω_n such that $j(\omega_n) > \aleph_{\omega+1}$ and $j``\aleph_{\omega+1} \in M$. Suppose further that $\aleph_{\omega+1} \in I[\aleph_{\omega+1}]$. Then every stationary subset of $\aleph_{\omega+1}$ reflects to an ordinal α.*

5.25 Corollary. *Suppose that for all n there is a normal, fine, countably complete ideal $I_n \subseteq [\aleph_{\omega+1}]^{<\omega_n}$ such that $P([\aleph_{\omega+1}]^{<\omega_n})/I$ is $<\omega_n$-closed and $\aleph_{\omega+1} \in I[\aleph_{\omega+1}]$. Then every stationary subset of $\aleph_{\omega+1}$ reflects.*

Magidor showed that the hypothesis of this theorem is consistent relative to large cardinal assumptions in [91]; see Cummings' or Eisworth's chapter in this Handbook for a proof of this fact.

Proof. Suppose that $S \subseteq \aleph_{\omega+1}$ is stationary. Then there is a stationary subset of S consisting of ordinals of a fixed cofinality ω_n. We assume that S has this property. Let $m > n$ and suppose that j_m is the generic embedding with critical point ω_m, arising from a generic object $G \subseteq \mathbb{P}_m$.

By Theorem 3.16, S is still stationary in $V[G]$. Let $\gamma = \sup(j``\aleph_{\omega+1})$. Since $j``\aleph_{\omega+1}$ is $\aleph_n$-closed unbounded in γ, we see that $j``S$ is stationary in $\gamma$. Since $j``S \subseteq j(S)$,

$$M \models j(S) \cap \gamma \text{ is stationary in } \gamma.$$

By elementarity, $V \models$ there is a $\delta, S \cap \delta$ is stationary in δ. $\dashv$

A. Sharon has proved that if every stationary subset of $\omega_n \cap \mathrm{Cof}(\omega)$ reflects, then $I[\aleph_{\omega+1}] \restriction \mathrm{Cof}(\omega_n)$ contains a closed unbounded set. The proof extends to show that if there is a normal, $\aleph_n$-complete ideal I on ω_n such that $P(\omega_n)/I$ contains a dense set that is $<\omega_{n-1}$-closed, then $I[\aleph_{\omega+1}] \restriction \mathrm{Cof}(\omega_n)$ contains a club. In particular, the hypothesis of Corollary 5.25 can be weakened to the assumption that the ideals I_n exist and that $I[\aleph_{\omega+1}] \restriction \mathrm{Cof}(\omega_1)$ contains a relative club.

One can also prove the following with analogous techniques:

5.26 Theorem. *Suppose that there is a normal, fine, $\aleph_2$-complete ideal I on $Z = [\lambda]^{<\omega_2}$ such that $P(Z)/I$ is a proper forcing. Then for every countable collection of stationary subsets $\{S_i : i \in \omega\}$ of $P_{\omega_1}(\lambda)$, there is an X of cardinality ω_1 with $\omega_1 \subseteq X$ such that for all i, $S_i \cap P_{\omega_1}(X)$ is stationary and for all regular γ, $\mathrm{cf}(X \cap \gamma) = \omega_1$.*

Note that the hypotheses of the theorem hold if $P(Z)/I$ has a dense countably closed subset. Foreman and Todorčević [45] showed that the type of reflection in the conclusion of this theorem implies the Singular Cardinals Hypothesis.

Burke and Matsubara have shown that hypothesis on the closure of the quotient algebra can be replaced with chain conditions, even for non-normal ideals. Strengthening standard results about strongly compact cardinals they showed:

5.27 Theorem (Burke-Matsubara [13]). *Suppose that $\kappa < \lambda$ are uncountable regular cardinals and there is a fine, κ-complete, λ-saturated ideal on $[\lambda]^{<\kappa}$. Then every stationary subset of $\lambda \cap \mathrm{Cof}(<\kappa)$ reflects.*

Proof. Let I be a λ-saturated, fine, κ-complete ideal on $[\lambda]^{<\kappa}$. Define an ideal I' on λ by putting $A \in I'$ iff $\{z \in [\lambda]^{<\kappa} : \sup(z) \in A\} \in I$. Then I' is a uniform λ-saturated, κ-complete ideal on λ. We show that the existence of such an I' implies the desired reflection.

Let $A \subseteq \lambda \cap \mathrm{Cof}(<\kappa)$ be stationary. Suppose that A does not reflect. Without loss of generality we can assume that there is a fixed $\eta < \kappa$ such that $A \subseteq \lambda \cap \mathrm{Cof}(\eta)$. For each $\alpha \in A$ choose an increasing sequence $\langle \alpha_i : i \in \eta \rangle$ cofinal in α.[37]

Using the fact that for each limit point $\beta \in \lambda$ there is a closed unbounded set $C_\beta \subseteq \beta$ disjoint from A, one can show by induction that for all $\beta \in \lambda$ there is an $f_\beta : \beta \cap A \to \eta$ such that for $\delta, \rho \in A \cap \beta$

$$\{\rho_i : i > f_\beta(\rho)\} \cap \{\delta_i : i > f_\beta(\delta)\} = \emptyset.$$

Force with $P(\lambda)/I'$ to get a generic G. Then for each $\delta \in A$, there is an $X \in G$ and an $i(\delta)$ such that for all $\beta \in X$, $f_\beta(\delta) = i(\delta)$. But then for all $\rho, \delta \in A$

$$\{\rho_i : i > i(\rho)\} \cap \{\delta_i : i > i(\delta)\} = \emptyset.$$

This contradicts the fact that A is stationary in $V[G]$. ⊣

5.5. Suslin and Kurepa Trees

The author noticed that if there is a normal, fine, countably complete $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$ then there is a Suslin tree on ω_1. To see this note that Shelah showed that if c is Cohen generic over V then there is a Suslin tree on ω_1 in $V[c]$. View $P([\omega_2]^{\omega_1})/I$ as the Boolean completion of $\mathrm{Col}(\omega, \omega_1)$. Let $G \subseteq \mathrm{Col}(\omega, \omega_1)$ be generic. Then we can write $G \sim G_0 * G_1$, where G_0 is V-generic for $\mathrm{Col}(\omega, \omega_1)$ and G_1 is Cohen generic over $V[G_0]$. Hence by Shelah's theorem there is a Suslin tree T in $V[G]$. Let $j : V \to M \subseteq V[G]$ be the generic embedding induced by G. By the closure of M, we must have that $T \in M$ and is a Suslin tree in M. Since $\omega_1^{V[G]} = \omega_2^V = j(\omega_1^V)$ we can apply elementarity to see that there is a Suslin tree on ω_1 in V.

Woodin [126] proved:

[37] I.e. a ladder system.

5.28 Theorem. *Suppose that there is a countably complete, $\aleph_1$-dense ideal on ω_1. Then there is a Suslin tree on ω_1.*

Proof. Since the canonical projection of an $\aleph_1$-dense ideal to a normal ideal is also $\aleph_1$-dense, we can assume we start with a normal $\aleph_1$-dense ideal I. Let $G \subseteq P(\omega_1)/I$ be generic. By Example 4.12 we can consider G to be a generic subset of $\mathrm{Col}(\omega, \omega_1)$, i.e. a surjective function from $\omega \to \omega_1$.

Suppose now that $Z = \omega_1$, and $j : V \to M$ is the generic elementary embedding. Then $G \in M$ and we can choose a function $f : \omega_1 \to \omega_1^\omega$ such that the empty condition forces that $[f]^M = G$. We can assume that for all limit ordinals α, $f(\alpha) : \omega \to \alpha$ is a surjection.

We construct a tree T and show that it is Suslin. The elements of T at level α will be the ordinals $[\alpha\omega, (\alpha+1)\omega)$. We will denote level α by $(T)_\alpha$.

At successor stages $\alpha = \beta + 1$ we arbitrarily assign successors to each γ at level β so that each γ has countably many successors.

At a limit stage α we will have defined a countable tree $(T)_{<\alpha}$ and we must decide which branches through $(T)_{<\alpha}$ we extend to level α. Given a $\gamma \in (T)_{<\alpha}$ and $f(\alpha)$ we have an attempt at a branch b_γ through $(T)_{<\alpha}$ defined as follows:

1. Let $b_0(\gamma) = \gamma$.

2. Suppose that $b_n(\gamma)$ is defined and k is the least natural number such that $f(\alpha)(k) = b_n(\gamma)$. Let l be the least element of ω greater than k such that $b_n(\gamma) <_T f(\alpha)(l)$, and $b_{n+1}(\gamma) = f(\alpha)(l)$.

Let $b_\gamma = \langle b_n(\gamma) : n \in \omega \rangle$.

Case 1. For all $\gamma \in (T)_{<\alpha}$, b_γ is a branch through $(T)_{<\alpha}$ that is cofinal in α.

In this case we put a $\delta \in (\alpha+1)\omega$ above each b_γ.

Case 2. Otherwise.

In this case we arbitrarily choose a countable collection of branches through $(T)_{<\alpha}$ that are cofinal in α and such that every $\gamma \in (T)_{<\alpha}$ belongs to one of them.

We claim that this defines a Suslin tree on ω_1. The following suffices:

Claim. Let A be a maximal antichain in T. Then there is an $\alpha < \omega_1$ such that Case 1 holds, and for every $\gamma \in (T)_{<\alpha}$ there is an element $a \in A$ and an n such that $a < b_n(\gamma)$.

To see the claim, fix an antichain A and let $j : V \to M$ be the generic elementary embedding induced by a generic $G \subseteq \mathrm{Col}(\omega, \omega_1)$. Note that $j(A) \cap \omega_1 = A$, $j(T) \cap \omega_1 = T$ and $j(f)(\omega_1^V) = G$. An easy density argument yields that from the point of view of M, ω_1^V is in Case 1 and that for all $\gamma \in (\omega_1)^V$ there is an n and an $a \in A$ such that $a <_{j(T)} b_n(\gamma)$. Reflecting this to V finishes the proof of the claim. ⊣

This theorem easily generalizes to show:

5.29 Theorem. *Suppose that there is a κ^+-complete, normal ideal I on $P(\kappa^+)$ so that there is a dense subset of $P(\kappa^+)/I$ isomorphic to* $\mathrm{Col}(\kappa,\kappa^+)$. *Then there is a Suslin tree on κ^+.*

Recall that a Kurepa tree on κ is a normal tree T on κ such that each level has cardinality less than κ but T has at least κ^+ branches.

We have a couple of ways of showing that there are no Kurepa trees:

5.30 Theorem. *Suppose that $(\kappa^+,\kappa) \twoheadrightarrow (\kappa,{<}\kappa)$. Then there is no Kurepa tree on κ.*

Proof. Let $\theta \gg \kappa$ and $\mathcal{T}$ be a Kurepa tree on κ. Let $\langle b_\alpha : \alpha < \kappa^+\rangle$ enumerate distinct branches through $\mathcal{T}$ of length κ. Let $\mathfrak{A} \prec \langle H(\theta), \in, \Delta, \mathcal{T}\rangle$ be such that $|\mathfrak{A} \cap \kappa^+| = \kappa$ and $|\mathfrak{A} \cap \kappa| < \kappa$.

Let $\delta = \sup(\mathfrak{A}\cap\kappa)$. For $\alpha \neq \beta$ with α and $\beta \in \mathfrak{A}\cap\kappa^+$, there is a $\gamma \in \mathfrak{A}\cap\kappa$ such that b_α and b_β differ at level γ. Hence b_α and b_β differ at level δ. But this means that level δ must have cardinality at least κ, a contradiction. $\dashv$

5.31 Theorem. *Suppose that $\kappa = \mu^+$ is a successor cardinal and there is an elementary embedding $j : V \to M \subseteq V[G]$ where $G \subseteq \mathbb{P}$ is generic where:*

1. $\mathrm{crit}(j) = \kappa$, *and*

2. $\mathbb{P}$ *is κ^+-c.c.*

Then there is no Kurepa tree on κ.

Proof. Let $j : V \to M \subseteq V[G]$ be the generic elementary embedding of V to M. Since κ is a successor cardinal, $j(\kappa) = \kappa^+$. Suppose that $\mathcal{T}$ is a Kurepa tree on κ. Let $\langle b_\alpha : \alpha < \kappa^+\rangle$ enumerate distinct branches of length κ through $\mathcal{T}$.

Then for all α, $j(b_\alpha) \cap \kappa = b_\alpha$ and there is a point $\tau_\alpha \in j(\mathcal{T})$ at level κ that belongs to the branch $j(b_\alpha)$. This τ_α lies above every element of b_α. In particular, for $\alpha \neq \beta, \tau_\alpha \neq \tau_\beta$. Hence there are at least $(\kappa^+)^V$ points at level κ in $j(\mathcal{T})$. Since $M \models j(\mathcal{T})$ is Kurepa, $V[G] \models |(\kappa^+)^V| = \mu$, a contradiction. $\dashv$

5.6. Partition Properties

In this section we discuss the use of ideals for proving partition properties.[38] We remind the readers of some definitions:

Let κ be a cardinal, γ and $\langle \kappa_\nu : \nu < \gamma\rangle$ be ordinals. Then $\kappa \to (\kappa_\nu)^r_\gamma$ iff for every function $f : [\kappa]^r \to \gamma$ there is a $\nu < \gamma$ and a set $X \subseteq \kappa$ of order type κ_ν

[38] We refer the reader to the chapter by Hajnal and Larson in this Handbook for an extensive discussion of partition relations.

such that f has constant value ν on $[X]^r$. The set X is called *homogeneous* for f. If all of the κ_ν's are constantly λ then $\kappa \to (\lambda)^r_\gamma$.

Baumgartner, Hajnal and Todorčević in [7] showed how to use ideal theory effectively to simplify classical proofs of partition theorems and to prove new strong partition theorems. We will content ourselves to mention two applications of the theory and relations to generic elementary embeddings.

As noted in Sect. 4, for a κ-complete ideal $I \subseteq P(\kappa)$, the following properties are decreasing in strength:

1. I is prime.[39]
2. I is κ-dense.
3. I is $(\kappa^+, \kappa^+, \kappa)$-saturated.

These various properties yield decreasing amounts of partition strength.

5.32 Definition. Let κ be a measurable cardinal. Then $\Omega(\kappa)$ is the least ordinal greater than κ that is a uniform indiscernible for bounded subsets of κ.[40]

We note that $\Omega(\kappa)$ is a very large ordinal; for example, $L_{\Omega(\kappa)} \models \text{ZFC}$. Thus $\Omega(\kappa)$ is closed under primitive recursive set functions, and much more.

The following theorems use the theory of ideals developed by Baumgartner, Hajnal and Todorčević [7] along with assumptions about ideals that use generic embeddings:

5.33 Theorem (Foreman-Hajnal [39]). *Suppose that κ carries a κ-complete prime ideal. Then for all $\rho < \Omega(\kappa)$ and $m \in \omega$,*

$$\kappa^+ \to (\rho)^2_m.$$

Weaker hypotheses give weaker conclusions:

5.34 Theorem (Foreman-Hajnal [39]). *Suppose that there is a κ-complete κ-dense ideal on κ and $\kappa^{<\kappa} = \kappa$. Then:*

$$\kappa^+ \to (\kappa^2 + 1, \alpha)^2_2 \quad \textit{for all } \alpha < \kappa^+.$$

Laver and later Kanamori independently showed:

5.35 Theorem (Kanamori [68]). *Suppose that $\kappa^{<\kappa} = \kappa$ and there is a $(\kappa^+, \kappa^+, \kappa)$-saturated ideal on κ. Then:*

$$\kappa^+ \to (\kappa \times 2 + 1, \alpha)^2_2 \quad \textit{for all } \alpha < \kappa^+.$$

[39] I.e. κ is measurable.

[40] For each $\alpha < \kappa$ and $a \subseteq \alpha$, the measurability of κ implies that there is a closed unbounded class of indiscernibles C_a for the structure $\langle L[a], \in, a, \xi\rangle_{\xi \leq \alpha}$. (One proceeds here in direct analogy to the development of the canonical indiscernibles for L and the theory $0^\#$.) Then $\Omega(\kappa)$ is the least member of $\bigcap\{C_a : a \subseteq \alpha \text{ for some } \alpha < \kappa\}$. For a broader, combinatorial definition of $\Omega(\kappa)$ see Definition 5.6 of the Hajnal-Larson chapter in this Handbook.

As usual with strong ideal axioms, the advantage of Theorems 5.34 and 5.35 is that the existence of these strong ideals is consistent at small cardinals such as ω_1. For example, a corollary of Theorem 5.33 is that it is consistent that $\omega_2 \to (\omega_1^2 + 1, \alpha)^2$ for all $\alpha < \omega_2$.

To illustrate how strong ideal assumptions could be relevant we outline the proof of the following theorem of Laver, dealing with the partition property:

$$\binom{\omega_2}{\omega_1} \to \binom{\omega_1}{\omega_1}_\omega$$

which says that whenever $f : \omega_2 \times \omega_1 \to \omega$ there are uncountable sets $A \subseteq \omega_1$ and $B \subseteq \omega_2$ such that f is constant on $A \times B$.[41]

5.36 Theorem (Laver [83]). *Assume* CH *and that there is a normal, countably complete* $(\aleph_2, \aleph_2, \aleph_0)$*-saturated ideal* I *on* ω_1*. Then:*

$$\binom{\omega_2}{\omega_1} \to \binom{\omega_1}{\omega_1}_\omega .$$

Proof. Fix an $f : \omega_1 \times \omega_2 \to \omega$. For each $k < \omega$ and $\beta < \omega_2$, let $f_k(\beta) = \{\alpha \in \omega_1 : f(\alpha, \beta) = k\}$. Then there is a set O of size $\aleph_2$ and a $k \in \omega$ such that for all $\beta \in O, f_k(\beta) \in I^+$. By the saturation we can find a set $S \subseteq O$ of size $\aleph_2$ such that for all countable sets $S' \subseteq S$, $|\bigcap_{\beta \in S'} f_k(\beta)| = \omega_1$. Let $\langle \rho_\eta : \eta < \omega_2 \rangle$ enumerate S in order.

Let θ be a large regular cardinal, $N \prec \langle H(\theta), \in, \Delta, f, I, S, \ldots \rangle$ be an elementary substructure of cardinality $\aleph_1$ with $N^\omega \subseteq N$ and $\xi = N \cap \omega_2$.

We build sequences of ordinals $\langle \alpha_i : i \in \omega_1 \rangle$ and $\langle \beta_i : i \in \omega_1 \rangle$ with the α_i's countable and the β_i's from $S \cap N$ by induction on i. At stage j we will assume the following:

1. for all $i < j$, $\alpha_i \in f_k(\rho_\xi)$, and
2. for all i and i' less than j, $\alpha_{i'} \in f_k(\beta_i)$.

Having defined $\langle \alpha_i : i < j \rangle$ and $\langle \beta_i : i < j \rangle$ satisfying these inductive hypotheses, we need to define β_j and α_j. By our assumptions on S, $|\bigcap_{i<j} f_k(\beta_i) \cap f_k(\rho_\xi)| = \omega_1$. Choose $\alpha_j > \sup_{i<j} \alpha_i$ in this intersection. We can then reflect the statement "$\{\alpha_i : i \leq j\} \subseteq f_k(\rho_\xi)$" to find a $\rho_{\xi'} > \sup_{i<j} \beta_i$ with $\xi' \in N$ satisfying "$\{\alpha_i : i \leq j\} \subseteq f_k(\rho_{\xi'})$". Let $\beta_j = \rho_{\xi'}$. ⊣

The next theorem has nothing directly to do with ideals:

5.37 Theorem (Hajnal-Juhasz). *Suppose that* $G \subseteq \mathrm{Add}(\omega, \omega_1)$ *is generic for the partial ordering adding* ω_1 *Cohen reals. Then:*

$$V[G] \models \binom{\omega_2}{\omega_1} \not\to \binom{\omega}{\omega_1}_2 .$$

[41] Variants of this partition property appearing elsewhere in this chapter have the expected analogous meaning.

Proof. View $G : \omega_1 \to 2$. Let $\langle A_\alpha : \alpha < \omega_2\rangle$ be a sequence of elements of $[\omega_1]^{\omega_1}$ such that for all $\alpha \neq \beta$, $|A_\alpha \cap A_\beta| \leq \aleph_0$. For each $\alpha \in \omega_2$ let $\langle \rho^\alpha_i : i \in \omega_1\rangle$ enumerate A_α in increasing order.

Define a function $f : \omega_1 \times \omega_2 \to 2$ by $f(\gamma, \alpha) = j$ iff $G(\rho^\alpha_\gamma) = j$. We claim that for all countably infinite sets $S \subseteq \omega_2$ there is a tail of $\gamma < \omega_1$ such that there are $\alpha, \beta \in S$, $f(\gamma, \alpha) \neq f(\gamma, \beta)$. Indeed, suppose that S is a countably infinite set. Choose a γ_0 such that for all $\gamma > \gamma_0$ and all $\alpha, \beta \in S$ we have $\rho^\alpha_\gamma \neq \rho^\beta_\gamma$. Since G is generic we can find $\alpha, \beta \in S$ such that $G(\rho^\alpha_\gamma) \neq G(\rho^\beta_\gamma)$, as desired. ⊣

As Woodin pointed out, it follows from these results that the following three properties are collectively inconsistent:

1. CH,
2. there is a normal, fine, countably complete, $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$, and
3. there is a normal, fine, countably complete ideal on $[\omega_2]^{\omega_1}$ with quotient algebra $\mathrm{Col}(\omega, \omega_1) * \mathrm{Add}(\omega, \omega_2^V)$.

Since Woodin's argument only used the positive partition property to deduce his inconsistency, property 2 can be replaced by the assumption that there is an $(\aleph_2, \aleph_2, \aleph_0)$-saturated ideal on ω_1.

5.38 Corollary. *The following are inconsistent with each other:*

1. *There is a normal* $(\aleph_2, \aleph_2, \aleph_0)$*-saturated ideal on* ω_1.
2. *There is a normal, fine, countably complete ideal on* $[\omega_2]^{\omega_1}$ *such that* $P([\omega_2]^{\omega_1})/I$ *has a dense subset isomorphic to* $\mathrm{Col}(\omega, \omega_1) * \mathrm{Add}(\omega, \omega_2^V)$.

Proof. The first ideal assumption implies CH and that there is an $(\aleph_2, \aleph_2, \aleph_0)$-saturated ideal on ω_1. Hence $\binom{\omega_2}{\omega_1} \not\to \binom{\omega_1}{\omega_1}_\omega$. Assume the second ideal exists. Let $G \subseteq \mathrm{Col}(\omega, \omega_1) * \mathrm{Add}(\omega, \omega_2^V)$ be generic and $j : V \to M$ be the generic embedding associated with G. Then $G \in M$. Write $G = G_0 * G_1$ where $G_0 \subseteq \mathrm{Col}(\omega, \omega_1)$ and $G_1 \subseteq \mathrm{Add}(\omega, \omega_2^V)$. Then G_0 and G_1 are both in M. Let f be the example built from G_1 in $V[G_0 * G_1]$ that shows $\binom{\omega_2}{\omega_1} \not\to \binom{\omega}{\omega_1}_{<\omega}$. Since the construction of f is sufficiently absolute relative to a subset of ω_1^M coding an almost disjoint sequence of sets we see that $f \in M$. By the elementarity of j, $V \models \binom{\omega_2}{\omega_1} \not\to \binom{\omega}{\omega_1}_2$. ⊣

5.39 Remark. It is easy to see from Theorem 7.14 that if I is a normal, fine, $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$ in V and $G \subseteq \mathrm{Add}(\omega, \omega_1)$ is V-generic then in $V[G]$, $P([\omega_2]^{\omega_1})/I$ has a dense subset isomorphic to $\mathrm{Col}(\omega, \omega_1) * \mathrm{Add}(\omega, \omega_2^V)$. Hence if it is consistent that there is an $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$, then there are two consistent ideal properties that are mutually inconsistent.

In Sect. 7, Example 7.25 shows that it is consistent that CH holds and there is an inaccessible cardinal λ and a normal, fine, countably complete ideal $I \subseteq [\lambda]^{\omega_1}$ such that

$$P([\lambda]^{\omega_1})/I \cong \mathcal{B}(\mathrm{Col}(\omega, {<}\lambda)).$$

The argument for Corollary 5.38, works equally well to show that such an ideal implies

$$\binom{\omega_2}{\omega_1} \not\to \binom{\omega}{\omega_1}_2.$$

By Theorem 7.40, we see that it is consistent that CH holds and there is an $(\aleph_2, \aleph_2, \aleph_0)$-saturated ideal. Hence, assuming the consistency of a huge cardinal, we see that there are two individually consistent, but mutually inconsistent ideal assumptions.

5.7. The Normal Moore Space Conjecture and Variants

In this section we describe how to prove the Normal Moore Space Conjecture and related properties from generic large cardinals.[42] The generic embeddings posited here stand in stark contrast to the other axioms in that they imply that the continuum is larger than the first weakly Mahlo cardinal. We note that their statements can be distinguished from other generic large cardinal postulations in that the “three parameters” directly refer to the value of $2^{\aleph_0}$. They thus “settle” CH in a somewhat circular way.

5.40 Definition. We give the basic definitions:

1. A *development* of a topological space (X, τ) is a collection $\{\mathcal{U}_n : n \in \omega\}$ of open coverings such that for every $x \in X$ and every open neighborhood O of x, there is an n such that:

$$\bigcup\{U \in \mathcal{U}_n : x \in U\} \subseteq O.$$

2. A *Moore Space* is a regular space with a development.

We note that if (X, τ) is metrizable, then it has a development. If a space (X, τ) has a development then every point in X has a countable neighborhood base. “Developments” are an attempt to capture the difference between metrizability and first countability.

The Normal Moore Space Conjecture [97] is the following statement:

Every normal Moore space is metrizable.

[42] The author would like to thank Alan Dow for helpful correspondence and certification of the results in this section.

The question of metrizability was reduced to a set-theoretic context by work of Bing [10] who showed that collectionwise normal Moore spaces are metrizable. Thus the conjecture follows if normal implies collectionwise normal. This was just the beginning: the apparently innocuous statement of the Normal Moore Space Conjecture involves a considerable amount of set theory. For example, assuming MA_{ω_1}, Silver [116] showed that the Normal Moore Space Conjecture is false. Fleissner [29] showed that it failed assuming the Continuum Hypothesis and proved [28] that the Normal Moore Space Conjecture implies that there are inner models with measurable cardinals. In the positive direction, work of Kunen; Nyikos [98]; and Dow, Tall, and Weiss [25] and others have shown it is true after forcing over of models of ZFC that have supercompact cardinals.[43]

Given that the proofs rely on computing the quotient algebra of a generic elementary embedding, it is not surprising that it is possible to make an axiomatic statement that suffices to prove the Normal Moore Space Conjecture and its more sophisticated variants.

The following result is a simple codification of the reflection results necessary to prove the Normal Moore Space Conjecture in a generic extension of V by Cohen or random reals.

5.41 Theorem. *Suppose that for all $\lambda \geq 2^{\aleph_0}$ there is a $2^{\aleph_0}$-complete, normal, fine ideal $I \subseteq [\lambda]^{<2^{\aleph_0}}$ such that $P([\lambda]^{<2^{\aleph_0}})/I$ is either the Boolean algebra for adding Cohen reals or random reals. Then:*

1. *Every normal space of character less than $2^{\aleph_0}$ is collectionwise normal. In particular the Normal Moore Space Conjecture is true.*
2. *(Balogh) Every normal, locally compact space is collectionwise normal.*

5.8. Consequences in Descriptive Set Theory

As we have seen, assumptions about the existence of generic elementary embeddings prove many combinatorial properties that are relevant to fine structure and the core model theory. For example, the existence of generic embeddings constructed in sufficiently closed forcing extensions imply that every stationary subset of a successor of a singular cardinal reflects. (Theorems 5.22 and 5.24.) Thus, using core model theory Projective Determinacy holds.

Woodin has shown that the existence of a countably complete, $\aleph_1$-dense ideal on ω_1 implies that the Axiom of Determinacy (AD) holds in $L(\mathbb{R})$. Ketchersid showed that stronger ideal axioms imply AD^+, a stronger form of the axiom due to Woodin, holds in an inner model containing the real numbers with Θ relatively large. We are content here to show a very easy result from [35], one that foreshadowed later, much more impressive results.[44]

[43] Theorem 2(1) of [25].

[44] Even before this result, Magidor [90] also had results showing that ideal axioms gave the Lebesgue measurability of Σ^1_4-sets.

5.42 Theorem. *If there is a normal, fine, $2^{\aleph_0}$-dense ideal I on $[(2^{\aleph_0})^+]^{\omega_1}$ or on $[2^{\aleph_0}]^{<\omega_1}$, then the following are true in $L(\mathbb{R})$:*

1. *Every set of reals is Lebesgue measurable, completely Ramsey and has the property of Baire.*

2. *The partition relation $\omega \to (\omega)^\omega$.*

Woodin showed, somewhat earlier:

5.43 Theorem. *If* CH *holds and there is a countably complete, $\aleph_1$-dense ideal on ω_1, then every set of reals in $L(\mathbb{R})$ is Lebesgue measurable, has the property of Baire and $L(\mathbb{R}) \models \omega \to (\omega)^\omega$.*

Proof. Both theorems have essentially the same proof: In either case, by forcing with $\mathrm{Col}(\omega, 2^{\aleph_0})$, we get a generic object G and an elementary embedding $j : V \to M \subseteq V[G]$, where $M^\omega \cap V[G] \subseteq M$ and $|\mathbb{R}|^V = \omega$. In each case $j : L(\mathbb{R})^V \to L(\mathbb{R})^{V[G]}$. Let $\phi(x, y_1, \dots, y_n, z_1, \dots, z_m)$ define a set of real numbers in $L(\mathbb{R})^V$ by

$$A = \{r : \phi^{L(\mathbb{R})}(r, a_1, \dots, a_n, \alpha_1, \dots, \alpha_m)\}$$

where $a_1, \dots, a_n \in \mathbb{R}$ and $\alpha_1, \dots, \alpha_m \in \mathrm{On}$. Then $j(A)$ is the set of reals defined in $L(\mathbb{R})^{V[G]}$ by ϕ, the a's and $j(\alpha_1), \dots, j(\alpha_m)$. Hence $j(A)$ is a set that is definable in $L(\mathbb{R})^{V[G]}$ using reals in V. Since G is the result of forcing with a Levy collapse, $j(A)$ must be Lebesgue measurable (see Solovay [110]). By elementarity, A must be measurable.

The results for the property of Baire and the partition property follow the same outline. ⊣

5.9. Connections with Non-Regular Ultrafilters

Early investigations into ultraproducts [15] were concerned with the coarsest possible property: their cardinality. In this section we focus on ultraproducts of structures whose domains have cardinality $\aleph_0$ and $\aleph_1$. The generalizations to structures with larger domains are straightforward. The main result of the section are Theorems 5.47 and 5.51, which for $\kappa \in \{\omega_1, \omega_2\}$ give the existence of an ultrafilter F on κ such that $|\omega^\kappa/F| = \aleph_1$.

If U is a countably complete ultrafilter, then ω^κ/U has cardinality $\aleph_0$. On the other hand, for countably incomplete ultrafilters the "obvious" cardinality of an ultrapower ω^κ/U is 2^κ. It became a prominent question whether the "obvious" cardinality was always obtained [72, 15].

We begin with a simple result:

5.44 Proposition. *Suppose that U is an ultrafilter on a cardinal κ that is not countably complete. Then $|\omega^\kappa/U| \geq 2^{\aleph_0}$.*

Proof. Let $\langle X_n : n \in \omega\rangle$ be a partition of κ into sets that are not in U. For $\alpha \in \kappa$ let $n(\alpha)$ be such that $\alpha \in X_{n(\alpha)}$. For $A \subseteq \omega$, let $\langle m_i : i \in \omega\rangle$ enumerate A in increasing order, and $\langle p_i : i \in \omega\rangle$ enumerate the prime numbers. Define a function $f_A : \kappa \to \omega$ by setting $f_A(\alpha) = \prod_{m_i < n(\alpha)} p_i^{m_i}$.

We claim that if $A \neq B$, then $[f_A] \neq [f_B]$. For if $A \neq B$, we can find an $n \in A\Delta B$. For all $\alpha \in \bigcup_{n' \geq n} X_{n'}$, $f_A(\alpha) \neq f_B(\alpha)$. ⊣

The following is the negation of a standard condition that implies maximal cardinalities for ultrapowers.

5.45 Definition. An ultrafilter U on Z is (μ, γ)-*non-regular* iff whenever $\langle X_\alpha : \alpha < \gamma\rangle \subseteq U$, there is an $S \subseteq \gamma$ with $|S| = \mu$ and $\bigcap_{\alpha \in S} X_\alpha \neq \emptyset$.

Any fine ultrafilter on $[\kappa]^{<\omega}$ is easily seen to be (ω, κ)-regular. Hence for each cardinal κ, there is a regular ultrafilter on $P(\kappa)$. If U is an (ω, κ)-regular ultrafilter on a set Z of size κ, then ω^Z/U has cardinality 2^κ [15].

Duals of ideals with nice quotient algebras turn out to be filters that can be extended to highly non-regular ultrafilters. The first example of a theorem of this type is due to Magidor. We shall see in Theorem 7.43 that the hypotheses of the next theorem are consistent.

5.46 Theorem (Magidor [89]). *Assume* GCH. *Suppose that I is a normal, fine, countably complete, $\aleph_3$-saturated, $\aleph_3$-dense ideal on $[\omega_3]^{\omega_1}$, and let F be any ultrafilter on $[\omega_3]^{\omega_1}$ extending $\breve{I}$. Then $|\omega^{[\omega_3]^{\omega_1}}/F| = \aleph_3$, and even $|\omega_1^{[\omega_3]^{\omega_1}}/F| = \aleph_3$.*

Note that since GCH implies that $|[\omega_3]^{\omega_1}| = \aleph_3$, the result yields an ultrafilter $F' \subseteq P(\omega_3)$ such that $\omega_1^{\omega_3}/F'$ has cardinality $\aleph_3$.

Proof. Let $Z = [\omega_3]^{\omega_1}$. We show the stronger fact that the reduced product ω^Z/I has cardinality $\aleph_3$.

Since there is a canonical bijection between functions $f : [\omega_3]^{\omega_1} \to \omega$ (modulo I) and partitions $\langle A_n : n \in \omega\rangle$ of $P(Z)/I$, it suffices to count partitions. Let $D = \{d_\alpha : \alpha < \omega_3\} \subseteq P(Z)/I$ be a dense set of size $\aleph_3$. By the $\aleph_3$-c.c., $P(Z)/I$ is a complete Boolean algebra, and for each $A \in P(Z)/I$ there is a $\beta < \omega_3$ and a set $B \subseteq \beta$ such that $A = \bigtriangledown_{\alpha \in B} d_\alpha$. Hence for all partitions $\langle A_n : n \in \omega\rangle$, there is a $\beta < \omega_3$ and sets $B_n \subseteq \beta$ such that for all n, $A_n = \bigtriangledown_{B_n} d_\alpha$. Hence the cardinality of the set of partitions is $\aleph_3 \times (2^{\aleph_2})^{\aleph_0} = \aleph_3$.

To see the stronger claim that ω_1^Z/I has cardinality $\aleph_3$ we show that there is a cofinal subset of ω_1^Z/I that has cardinality $\aleph_3$. This suffices, since if $f \in \omega_1^Z$, the previous results show $|\prod_{z \in Z} f(z)/I| = \aleph_3$.

For $\alpha \in \omega_3$ let

$$f_\alpha : \{z : \alpha \in z\} \to \omega_1$$

by setting $f_\alpha(z) = \gamma$ iff α is the γth element of z. Clearly if $\alpha < \beta$ then $\{z : f_\alpha(z) < f_\beta(z)\} \in \breve{I}$. Let $g : Z \to \omega_1$ be arbitrary. Define h by setting $h(z) = \gamma$ where γ is the $g(z)$th element of z. Then h is a regressive function and hence we can find a maximal antichain of I-positive sets on which h is constant. By the $\aleph_3$-saturation of I, there is an α bigger than all of these constant values. The function f_α dominates g on each element of the antichain and hence on a set in $\breve{I}$. $\dashv$

Magidor proved a quite delicate result that if I is a normal, fine, countably complete, $\aleph_3$-dense, $\aleph_3$-saturated ideal on $[\omega_3]^{\omega_1}$ in V, and $G \subseteq \mathrm{Col}(\omega, \omega_1)$ is generic, then in $V[G]$ any ultrafilter F extending $\breve{I}$ satisfies $|\omega^{\omega_2}/F| = \aleph_2$. This consistency result is improved by Theorem 5.51.

The first result getting an ultrapower of ω to have cardinality ω_1 is due to Laver [84]:

5.47 Theorem. *Suppose that $\diamondsuit_{\omega_1}$ holds and there is a countably complete, $\aleph_1$-dense ideal on ω_1. Then there is an (ω, ω_1)-non-regular ultrafilter D such that $|\omega^{\omega_1}/D| = \aleph_1$.*

Laver's construction yielded the stronger property that there is an $\aleph_1$-generated ultrafilter over the $\aleph_1$-dense ideal. Woodin later eliminated the diamond assumption for getting an $\aleph_1$-generated ultrafilter although CH is needed to get the small ultrapower. Laver's result was improved by Kanamori to:

5.48 Theorem (Kanamori [67]). *Assume that there is an $\aleph_1$-dense ideal I on ω_1 and $\diamondsuit_{\omega_1}$. Suppose that D is any non-principal ultrafilter on ω, and $f : \omega_1 \to \omega$ is a map such that $f^{-1}(\{n\}) \in I^+$ for all $n \in \omega$. Then there is an $\aleph_1$-generated ultrafilter U over ω_1 extending I^* such that $f_*(U) = D$.*

Kanamori showed that for regular λ, there is a weakly normal ultrafilter U on λ^+ concentrating on $\mathrm{Cof}(\lambda)$ iff there is a (λ, λ^+) non-regular ultrafilter on λ^+.

In [48], it was shown that:

5.49 Theorem. *Suppose that there is a layered ideal I on $\kappa = \lambda^+$ and $\diamondsuit_\kappa$. Then there is a (κ^+, ∞)-distributive partial ordering $\mathbb{P}$ that adds a weakly normal ultrafilter on κ extending $\breve{I}$.*

Since a saturated ideal on κ concentrates on $\mathrm{Cof}(\lambda)$ this result yields a fully non-regular ultrafilter. For ultrafilters with small ultrapower, a strongly layered ideal can be used:

5.50 Theorem (Foreman et al. [48]). *Suppose that $\diamondsuit_{\omega_1}$ and there is a strongly layered ideal I on ω_1. Then there is an (ω_2, ∞)-distributive forcing adding an ultrafilter $D \supseteq \breve{I}$ such that $|\omega^{\omega_1}/D| = \aleph_1$.*

As remarked before Theorem 4.16, it is easy to force a strongly layered ideal from a layered ideal.

Fully Non-Regular Ultrafilters on ω_2

In this section we consider some ideal properties shown to be consistent in Sect. 7.

Corollary 7.66 says: if κ is regular, $\kappa^{<\kappa} = \kappa$ and there is a very strongly layered ideal I on κ^+, $\square_{\kappa^+}$ and $\diamondsuit_{\kappa^+}(\mathrm{Cof}(\kappa))$, then for all uniform ideals J on κ, there is a uniform ideal K on κ^+ such that:

$$P(\kappa^+)/K \;\cong\; P(\kappa)/J.$$

Furthermore, the degree of completeness of K equals the degree of completeness of J, and if J is κ^+-saturated then K is weakly normal.

By Theorem 7.63, the hypotheses of Corollary 7.66 are consistent with $\kappa = \omega_1$ and the existence of an $\aleph_1$-dense ideal on ω_1. Moreover, in unpublished work, the author showed that the $\square$ assumption is not necessary.

Thus the hypotheses of the following theorem are consistent:

5.51 Theorem. *Assume* GCH. *Suppose that ω_1 carries a countably complete uniform, $\aleph_1$-dense ideal on ω_1, and there is a very strongly layered ideal on ω_2. Then there is an ultrafilter F on ω_2 such that $|\omega^{\omega_2}/F| = \aleph_1$ and $|\omega_1^{\omega_2}/F| = \aleph_2$.*

Proof (Sketch). By Corollary 7.66, we can start with a uniform, countably complete, $\aleph_1$-dense ideal I on ω_2. Woodin's proof of Laver's $\diamondsuit_{\omega_1}$ result gives in ZFC that if $\mathcal{B}$ is a Boolean algebra with a dense subset $\mathcal{D}$ of size $\aleph_1$, then there is an ultrafilter $\tilde{F} \subseteq \mathcal{B}$ such that for any $A \subseteq \mathcal{D}$ with $\bigvee A = 1$ then there is a countable $B \subseteq A$ such that $\bigvee B \in \tilde{F}$. Suppose that $\mathcal{B} = P(\omega_2)/I$ has a dense set $\mathcal{D}$ of size $\aleph_1$ and $\tilde{F}$ is such an ultrafilter. Let F be the ultrafilter on ω_2 induced by $\tilde{F}$ over $\breve{I}$. Suppose that $f : \omega_2 \to \omega$ is an arbitrary function. Let A_n be those elements of $\mathcal{D}$ below $f^{-1}(\{n\})$. Then there is a countable collection $B \subseteq \bigcup_n A_n$ such that $\bigvee B \in \tilde{F}$. Choose disjoint representatives $\{b_m : m \in \omega\}$ for the elements of B. Define $g : \bigcup B \to \omega$, by setting $g(\alpha) = n$ iff $\alpha \in b_m$ and $b_m \subseteq A_n$. Then $g \equiv f \pmod{\tilde{F}}$. Since there are only $\aleph_1$ many such g's $(\mathrm{mod}\ \tilde{F})$ we see that ω^{ω_2}/F has cardinality $\aleph_1$.

It is a general fact that if $|\lambda^\kappa/U| = \delta$ then $|(\lambda^+)^\kappa/U| \leq \delta^+$. We know that $|\omega_1^{\omega_2}| \geq \aleph_2$ and hence $\omega_2 \leq |\omega_1^{\omega_2}/F| \leq \aleph_2$. ⊣

Taking $\mu = \omega_1$ in the model of Theorem 7.63, Corollary 7.66 shows that there is a uniform, weakly normal, countably complete ideal K on ω_2 such that $P(\omega_2)/K$ has a dense subset of size $\aleph_1$. Thus we get the following corollary:

5.52 Corollary. *Suppose that there are almost huge embeddings j_0, j_1 with critical points κ_0, κ_1 respectively such that $j_0(\kappa_0) = \kappa_1$. Then there is a forcing extension in which* GCH *holds and there is an ultrafilter F on ω_2 such that $|\omega^{\omega_2}/F| = \aleph_1$ and $|\omega_1^{\omega_2}/F| = \aleph_2$.*

Layered ideals on ω_2 also give the following generalization of Theorem 5.48:

5.53 Theorem. *Suppose* $\diamondsuit_{\omega_2}(\mathrm{Cof}(\omega_1))$ *and that there is a very strongly layered ideal* I *on* ω_2*. Then for all functions* $f : \omega_2 \to \omega_1$ *which are not bounded in* ω_1 *on a set in* $\breve{I}$ *there is a uniform, weakly normal, countably complete ideal* K *on* ω_2 *such that:*

1. $P(\omega_2)/K \cong P(\omega_1)/\{\text{countable sets}\}$*, and*

2. *for all* $g : \omega_2 \to \omega_1$ *there is a* $h : \omega_1 \to \omega_1$ *with* $g \equiv_K h \circ f$*.*

Kanamori [67] calls the function f in the theorem a *finest partition* relative to K. We note the following corollary:

5.54 Corollary. *Under the hypotheses of Theorem 5.53 together with the assumption that* $2^{\omega_1} = \omega_2$*, there is a uniform, countably complete ideal* K *on* ω_2 *such that if* F *is any ultrafilter extending* $\breve{K}$ *then*

$$|\omega_1^{\omega_2}/F| = \aleph_2.$$

For cardinals $\kappa > \omega_2$, the cardinality of ultrapowers ω^κ/F is remains a mystery for the most part. For more information on non-regular ultrafilters we refer the reader to [119, 71, 67].

5.10. Graphs and Chromatic Numbers

Erdős and Hajnal defined the following graph in the early 1960's:

$$\mathfrak{G}(\kappa, \lambda) = \langle \{f | f : \kappa \to \lambda\}, \perp \rangle,$$

where $f \perp g$ iff $|\{\alpha : f(\alpha) = g(\alpha)\}| < \kappa$. This graph is of interest partly because Erdős and Hajnal showed that if G is a graph of cardinality ω_2 such that each subgraph has countable chromatic number, then G can be embedded into $\mathfrak{G}(\omega_2, \omega)$ as a subgraph.[45]

In particular, they showed that CH implies that $\mathfrak{G}(\omega_2, \omega)$ has uncountable chromatic number and asked whether this graph could have chromatic number $\aleph_1$. It is immediate that if there is a uniform ultrafilter F on ω_2 such that ω^{ω_2}/F has cardinality ω_1, then $\mathfrak{G}(\omega_2, \omega)$ has chromatic number $\aleph_1$. To see this one colors an element of $\mathfrak{G}(\omega_2, \omega)$ by the member of the ultrapower it determines. Connected elements of $\mathfrak{G}(\omega_2, \omega)$ are functions that eventually differ and hence are in different classes of the ultrapower by any uniform ultrafilter.

In particular, we get:

5.55 Theorem (Foreman [36]). *Assume* GCH *and that there is a uniform, countably complete,* $\aleph_1$*-dense ideal on* ω_2*. Then the Erdős-Hajnal graph has chromatic number* ω_1*.*

5.56 Corollary. *Assume* GCH *and that there is a uniform countably complete,* $\aleph_1$*-dense ideal on* ω_2*. If* G *is a graph of cardinality* ω_2 *and chromatic number* ω_2*, then* G *has an induced subgraph of cardinality* ω_1 *and chromatic number* ω_1*.*

[45] The image of G is not necessarily an *induced* subgraph.

5.11. The Nonstationary Ideal on ω_1

We now will consider the family of assumptions around the statement "the nonstationary ideal on ω_1 is $\aleph_2$-saturated". This statement seems singular in that there are no known analogues at other cardinals. For example, the assertion that the nonstationary ideal on ω_2 is $\aleph_3$-saturated is inconsistent.[46] Weakening this a bit, one can imagine that the nonstationary ideal on ω_2 restricted to the collection of ordinals of cofinality ω_1 is $\aleph_3$-saturated. However this assumption implies that $\Theta^{L(\mathbb{R})} < \omega_2$ and this is inconsistent with the assumption that the nonstationary ideal on ω_1 is $\aleph_2$-saturated.

We discuss this further in Sect. 8.2 (after Theorem 8.8) and again in Sect. 11.

Our first result is due to Shelah. Recall that Devlin and Shelah [22] showed that $2^{\aleph_0} < 2^{\aleph_1}$ is equivalent to the following *weak diamond* property:[47]

> For all $F : 2^{<\omega_1} \to 2$ there is a function $g : \omega_1 \to 2$ such that for all $f : \omega_1 \to 2$ the set $\{\alpha : g(\alpha) = F(f\restriction\alpha)\}$ is stationary.

5.57 Theorem (Shelah [102]). *Suppose that weak diamond holds. Then the nonstationary ideal on ω_1 is not $\aleph_1$-dense.*

Proof. Let $\langle A_\alpha : \alpha < \omega_1\rangle$ be a collection of stationary sets such that $\{[A_\alpha]_I : \alpha < \omega_1\}$ is dense in $P(\omega_1)/I$ where I is the nonstationary ideal on ω_1. Given a function $f : \delta \to 2$ define $F(f)$ as follows:

$$F(f) = \begin{cases} 1 & \text{if } \delta \notin \bigcup\{A_\alpha : f(\alpha) = 1\}, \\ 0 & \text{if } \delta \in \bigcup\{A_\alpha : f(\alpha) = 1\}. \end{cases}$$

Suppose that g is as in the definition of weak diamond. Let $B = \{\alpha : g(\alpha) = 1\}$. Then B must be stationary. Let $f : \omega_1 \to 2$ be defined by setting $f(\alpha) = 1$ iff $A_\alpha \subseteq_I B$. Then $[\triangledown\{A_\alpha : f(\alpha) = 1\}]_I = [B]_I$. Let C be a closed and unbounded set such that $C \cap \triangledown\{A_\alpha : f(\alpha) = 1\} = C \cap \{\beta : \text{for some } \alpha < \beta, \beta \in A_\alpha \text{ and } f(\alpha) = 1\} = C \cap B$.

Suppose now that $\delta \in C$ and $F(f\restriction\delta) = g(\delta)$. Then $F(f\restriction\delta) = 1$ iff $\delta \notin C \cap \triangledown\{A_\alpha : f(\alpha) = 1\}$ iff $\delta \notin B$ iff $g(\delta) = 0$, a contradiction. ⊣

5.58 Corollary. *Suppose that the nonstationary ideal on ω_1 is $\aleph_1$-dense. Then $2^{\aleph_0} = 2^{\aleph_1}$; in particular,* CH *fails.*

We now show Woodin's remarkable theorem that $\underset{\sim}{\delta}^1_2 = \omega_2$ if the nonstationary ideal on ω_1 is saturated and there is a measurable cardinal.

We need some facts about indiscernibles. For general information we direct the reader to [63]. Suppose that N is a countable, transitive structure in a countable language that satisfies ZFC and has Skolem functions. Suppose further that $\langle i_n : i \in \omega\rangle \subseteq \mathrm{On}^N$ is a sequence of indiscernibles for N such that

[46] See Corollary 6.11.
[47] See Example 3.23.

$N = \mathrm{Sk}^N(\langle i_n : n \in \omega\rangle)$. Let $\Gamma(\langle i_n : n \in \omega\rangle)$ be the theory of $\langle N, \langle i_n : n \in \omega\rangle\rangle$. Suppose that $\gamma \geq \omega$ is an ordinal and define N' to be the *stretch* of N by adding γ indiscernibles to N. This is the Ehrenfeucht-Mostowski model constructed by adding new constant symbols $\langle c_\alpha : \alpha < \gamma\rangle$ to our language and using Γ as a "blueprint". If Γ is "remarkable", then every such N' is well-founded and we identify it with its transitive collapse. In this case N is an initial segment of N'.

The following lemma is standard:

5.59 Lemma. *Suppose that $\mathfrak{A}$ is a transitive structure of cardinality κ, where κ is a measurable cardinal. Let U be a normal ultrafilter on κ and suppose that $X \in U$ is a set of indiscernibles for $\mathfrak{A}$. Let $\{j_n : n \in \omega\} \subseteq X$ and N be the transitive model isomorphic to $\mathrm{Sk}^{\mathfrak{A}}(\{j_n : n \in \omega\})$. Then the theory $\langle N, \langle j_n : n \in \omega\rangle\rangle$ is remarkable.*

We say that N is *remarkable* if it is generated by indiscernibles over a remarkable blueprint. We will use remarkable structures for iterations:

5.60 Lemma. *Suppose that N is a remarkable structure and $I \in N$ is a precipitous ideal on a set $Z \in N$. Let μ be any ordinal.*[48] *Then any generic iteration of N by I of length μ is well-founded.*

Proof. Let $\gamma > \mu$ be an ordinal. Let N' be the stretch of N by adding γ indiscernibles. Let

$$\{\langle N_\alpha : \alpha \leq \mu\rangle, \langle j_{\alpha,\alpha'} : \alpha < \alpha' \leq \mu\rangle, \langle G_\alpha : \alpha < \mu\rangle\}$$

be a generic iteration of N. Then one shows by induction on δ that there is an iteration

$$\left\{\langle N'_\alpha : \alpha \leq \delta\rangle, \langle j'_{\alpha,\alpha'} : \alpha < \alpha' \leq \delta\rangle, \langle G'_\alpha : \alpha < \delta\rangle\right\}$$

with the properties that for all $\alpha < \alpha' \leq \delta$:

1. $N'_0 = N'$,
2. N_α is an initial segment of N'_α,
3. $j'_{\alpha,\alpha'} \restriction N_\alpha = j_{\alpha,\alpha'}$,
4. for all $w \in N$, $j'_{0,\delta}(w) = j_{0,\delta}(w)$, and
5. $G'_\alpha = G_\alpha$ for all $\alpha < \delta$.

By Theorem 4.47, we see that N'_μ is well-founded. Since N_μ is an initial segment of N'_μ we see that N_μ is well-founded. ⊣

[48] We note that $\mu > \mathrm{On}^N$ is allowed.

We now fake some descriptive set theory:

5.61 Lemma. *Let δ be a countable ordinal. Suppose that N is countable and $N \models \mathrm{ZFC}$ + "I is a precipitous ideal". Then $R = \{x : x$ is a linear ordering coding On^M where M is the result of a generic iteration of N by I of length $\delta\}$ is a $\mathbf{\Sigma}^1_1$ set.*

Proof. We first remark that the statement "M_0 is a code for a generic ultrapower of M_1 by G" is Σ^1_1 in reals coding M_0 and M_1 and G. Fix real numbers $\tilde{N}$, $\tilde{\delta}$ coding N and δ.

We then see that $x \in R$ iff $\exists \langle N_i : i < \tilde{\delta}\rangle, \langle j_{i,i'} : i < i' \in \tilde{\delta}\rangle, \langle G_i : i \in \tilde{\delta}\rangle$, M such that:

1. $N_0 = N$,
2. for all i, N_{i+1} is the generic ultrapower of N_i by G_i and $j_{i,i+1}$ is the canonical ultrapower embedding of N_i to N_{i+1},
3. for all $i < i'$, $j_{i,i'} : N_i \to N_{i'}$ and the $j_{i,i'}$'s commute,
4. for limit i', $N_i = \varinjlim \langle N_i : i < i'\rangle$ by the embeddings $\langle j_{i,k} : i < k < i'\rangle$,
5. the maps $j_{i,i'}$ are the canonical maps into the direct limit,
6. $M = \varinjlim \langle N_i : i \in \delta\rangle$ by the maps $\langle j_{i,i'} : i < i' < \delta\rangle$, and
7. x is isomorphic to On^M.

⊣

We get the following immediate corollaries:

5.62 Corollary. *Let δ be a countable ordinal. Suppose that N is countable and $N \models \mathrm{ZFC}$ + "I is a precipitous ideal" and every countable generic iteration of N by I is well-founded. Then for every $\delta < \omega_1$ there is a $\beta(\delta) < \omega_1$ such that the order type of the ordinals in a generic iteration of N of length δ is less than $\beta(\delta)$.*

Proof. Since N is iterable, the set R above is a $\mathbf{\Sigma}^1_1$ subset of $\mathcal{WO}$, the set of reals coding well-orderings, and hence bounded. ⊣

5.63 Corollary. *Suppose that $V \subseteq W$ are transitive models of* ZFC*, and $N \in V$ is countable and $N \models \mathrm{ZFC}$ + "I is a precipitous ideal". Suppose that $V \models \delta, \gamma$ are countable ordinals. Then the statement "there is a generic iteration M of N of length δ where the order type of $\mathrm{On}^M = \gamma$" is absolute between V and W.*

We now apply these ideas to prove:

5.64 Theorem (Woodin [126]). *Suppose that the nonstationary ideal on ω_1 is $\aleph_2$-saturated and there is a measurable cardinal. Then $\underset{\sim}{\delta}^1_2 = \omega_2$.*

As a coarse consequence of the hypotheses of Theorem 5.64, $\Theta^{L(\mathbb{R})} > \omega_2$ and CH fails.

Proof. We will use the characterization:

$$\underset{\sim}{\delta}^1_2 = \sup\{(\kappa^+)^{L(x)} : x \in \mathbb{R}\}$$

where $\kappa = \omega_1^V$.

Let $\alpha < \omega_2$ be an ordinal. We will find a real number we will call $\tilde{N}$ such that $(\kappa^+)^{L(\tilde{N})} \geq \alpha$. Let $\mathfrak{A} = \langle H(\mu), \in, \Delta, \alpha\rangle$, where μ is a measurable cardinal. Let I be a remarkable set of indiscernibles for $\mathfrak{A}$, and N be the model $\mathrm{Sk}^{\mathfrak{A}}(\{i_n : n \in \omega\})$, where $\{i_n : n \in \omega\}$ are the first ω elements of I. By Lemma 5.60, we see that any generic iteration of N by the nonstationary ideal on ω_1 is well-founded.

Let N_0 be the transitive collapse of N and $j_0 : N_0 \to \mathfrak{A}$ be the inverse of the collapse map.

Claim. There is an iteration $\langle N_\gamma : \gamma \leq \omega_1\rangle$ of N_0 of length ω_1 such that $\mathrm{On}^{N_{\omega_1}} > \alpha$.

Proof of Claim. Inductively define models N_γ and embeddings $j_\gamma : N_\gamma \to \mathfrak{A}$. Suppose that we are given N_γ, j_γ. By Example 3.47, if M_γ is the image of N_γ under j_γ, and $\delta_\gamma = M_\gamma \cap \omega_1$, then $U(j_\gamma, \delta_\gamma)$ is generic over N_γ. Let $N_{\gamma+1}$ be the transitive collapse of the ultrapower of N_γ by $G = U(j_\gamma, \delta_\gamma)$. Define $j_{\gamma+1} : N_{\gamma+1} \to \mathfrak{A}$ by $j_{\gamma+1}([f]_G) = j_\gamma(f)(\delta_\gamma)$. At limit stages γ we take direct limits of the N_η with the j_η for $\eta < \gamma$.

It is easy to check inductively that $M_{\gamma+1} = \mathrm{Sk}^{\mathfrak{A}}(M_\gamma \cup \{\delta_\gamma\})$. In particular, $M_{\omega_1} \supseteq \omega_1$. Since $M_{\omega_1} \prec \mathfrak{A}$, $\alpha \subseteq M_{\omega_1}$ and hence the order type of $\mathrm{On}^{M_{\omega_1}} > \alpha$, and hence the order type of $\mathrm{On}^{N_{\omega_1}} > \alpha$. This establishes the claim. $\dashv$

Let $\tilde{N}$ be a real number coding N. We show that $(\kappa^+)^{L(\tilde{N})} > \alpha$, where $\kappa = \omega_1^V$. Let G be generic for $\mathrm{Col}(\omega, \kappa)$ over $L(\tilde{N})$. Apply Corollary 5.62 in $L(\tilde{N})[G]$ with $\delta = \kappa$, to see that there is a $\beta(\kappa) < \omega_1^{L(\tilde{N})[G]}$ such that all iterations of N of length κ in $L(\tilde{N})[G]$ have ordinals bounded by $\beta(\kappa)$. By Corollary 5.63, and the previous claim we see that $\alpha < \beta(\kappa) < \omega_1^{L(\tilde{N})[G]}$. Since G is generic for $\mathrm{Col}(\omega, \kappa)$, $\omega_1^{L(\tilde{N})[G]} = (\kappa^+)^{L(\tilde{N})}$, so $\alpha < (\kappa^+)^{L(\tilde{N})}$, as desired. $\dashv$

6. Some Limitations

In this section we discuss some limitations on the types of ideals that can exist. These limitations affect all three of the parameters determining the nature of the generic embeddings:

- where the cardinals go,

- the closure of the ultrapower (in particular, the saturation of the ideal), and
- the nature of the quotient algebra of the ideal.

We note that Burke found a limitation on the closure of the generic ultrapower when forcing with a tower of ideals that appears in a different section as Proposition 9.48.

6.1. Soft Limitations

For this section we let $j : V \to M$ be a generic elementary embedding and let κ be the critical point of j. The following facts are straightforward:

6.1 Proposition. *κ is regular in V. If $2^\lambda < \kappa$ and $M^\lambda \cap V[G] \subseteq M$ then $P(\lambda) \cap V[G] = P(\lambda) \cap V$.*

Note however the last conclusion cannot be strengthened to say that $V^\lambda \cap V[G] \subseteq V$. In Sect. 9, there are examples of stationary tower forcings that induce elementary embeddings with critical point $\aleph_{\omega+1}$ (and GCH holds). Hence the forcing adds new ω-sequences to $\aleph_\omega$ even though the critical point of the generic embedding is above $2^{\aleph_0}$.

6.2 Proposition. *Suppose that $\lambda < \delta$ are cardinals such that:*

1. *$\eta^{<\lambda} < \kappa$ for all cardinals $\eta < \kappa$,*
2. *$\delta^{<\lambda} > \delta$, and*
3. *$P(\delta^+)^V \subseteq M$.*

Then $j(\kappa) \neq \delta^+$.

From Proposition 6.2 we see, for example, that CH implies that there is no normal, fine, precipitous ideal on $[\aleph_{\omega+1}]^{\omega_2}$. We see this by setting $\kappa = \omega_2$, $\lambda = \omega_1$ and $\delta = \aleph_\omega$.

A weak version of the next result was proved by Ulam [123] using Ulam matrices and improved by Baumgartner, Taylor and Wagon [8].

6.3 Proposition. *Suppose that κ is not a weakly Mahlo cardinal of high degree. Then there is no κ-saturated ideal I on any set Z that has completeness κ.*

Proof. To see this note that if $j : V \to M$ is the generic embedding from a κ-complete, κ-saturated ideal on Z, then:

1. $\mathrm{crit}(j) = \kappa$,
2. $M^\kappa \cap V[G] \subseteq M$, and
3. κ is regular in M.

If $\kappa = \delta^+$ in V then $M \models \delta^+ = j(\kappa) > \kappa$ and hence κ is not a cardinal in M, contradicting κ-saturation. Thus κ must be a regular limit cardinal. Let C be a closed unbounded set in κ. Then $j(C)$ is unbounded in κ and hence $M \models \kappa \in j(C)$. Thus by reflection, C contains a regular cardinal and so κ is Mahlo. Clearly this argument can be used to show that κ is also highly Mahlo. ⊣

We note that one ingredient in the proof is the fact that if $j : V \to M$ is a generic elementary embedding in $V[G]$ with critical point κ where κ is a successor cardinal in V, then κ is not a cardinal in M.

Recall the definition of the weakly compact filter from Example 3.28. From Proposition 6.1 we can easily see:

6.4 Proposition. *Let κ be a weakly compact cardinal. Then the weakly compact filter on κ is not κ-saturated.*

Proof. Toward a contradiction, assume that κ is the least weakly compact cardinal where the weakly compact ideal is κ-saturated.

Let F be the weakly compact filter, and I be the dual ideal. Let $G \subseteq P(\kappa)/I$ be generic and $j : V \to M$ be the generic embedding. Since I is κ-saturated and κ-complete, $M^\kappa \cap V[G] \subseteq M$.

We first claim that the forcing $P(\kappa)/I$ is (κ, ∞)-distributive. Since the critical point of j is κ, $j \restriction V_\kappa$ is the identity. Since κ is inaccessible and M is closed under κ-sequences from $V[G]$, this implies that $P(\kappa)/I$ adds no new bounded subsets of κ.

If $P(\kappa)/I$ is not (κ, ∞) distributive, let τ be a term for a new function from γ into V for some $\gamma < \kappa$. Let $\langle \mathcal{A}_\alpha : \alpha < \gamma \rangle$ be a sequence of maximal antichains such that each $p \in \mathcal{A}_\alpha$ decides the value of $\tau(\alpha)$. Then each $\mathcal{A}_\alpha$ has cardinality less than κ. Let $\mu = \sup\{|\mathcal{A}_\alpha| : \alpha < \gamma\}$. In V choose a sequence of injections $i_\alpha : \mathcal{A}_\alpha \to \mu$. If G is generic, then the sequence $\langle G \cap \mathcal{A}_\alpha : \alpha < \gamma \rangle$ determines τ. However the sequence $\langle i_\alpha(G \cap A_\alpha) : \alpha < \gamma \rangle$ is a bounded sequence in κ, hence it lies in V. But then the sequence $\langle G \cap \mathcal{A}_\alpha : \alpha < \gamma \rangle$, and hence τ also lie in V, a contradiction.

We now claim that there is a new subset of κ in $V[G]$. If not, then $P(\kappa)^{V[G]} = P(\kappa)^V = P(\kappa)^M$. Hence, κ is weakly compact in M and has the same weakly compact filter.

Since κ is weakly compact the product of two κ-c.c. partial orderings is still a κ-c.c. partial ordering. So $P(\kappa)/I \times P(\kappa)/I$ is κ-c.c. Hence I is still κ-saturated in M. But $M \models$ "$j(\kappa)$ is the least weakly compact cardinal where the weakly compact filter is saturated", a contradiction.

Thus $P(\kappa)/I$ is κ-c.c., (κ, ∞)-distributive and adds a new subset to κ. Let $\dot{\tau}$ be a term for a new subset of κ. Let $\mathcal{B}$ be the complete Boolean subalgebra generated by $\{\|\alpha \in \tau\| : \alpha < \kappa\}$. Then $\mathcal{B}$ is a Suslin algebra, contradicting the weak compactness of κ. ⊣

In recent unpublished work Hellsten has shown that it is consistent for the weakly compact ideal on a weakly compact cardinal κ to be κ^+-saturated.

6.2. The "Kunen Argument"

Let $j : V \to M$ be an elementary embedding and let $\kappa_0 = \mathrm{crit}(j)$, $\kappa_{n+1} = j(\kappa_n)$ and $\kappa_\omega = \sup_n \kappa_n$. Then $j(\kappa_\omega) = \kappa_\omega$ and for all $\alpha < \mathrm{crit}(j)$, $j(\kappa_\omega^{+\alpha}) = (\kappa_\omega^{+\alpha})^M$.

Kunen [78] showed that it is inconsistent for there to be a V-definable elementary embedding $j : V \to M$ such that $V_{\kappa_\omega+1} \subseteq M$ or even an elementary embedding $j : V_{\kappa_\omega+2} \to V_{\kappa_\omega+2}$. Kunen's proof uses the construction of an "ω-Jónsson algebra" on κ_ω due to Hajnal and Erdős [27].

As such, Kunen's argument does not immediately generalize to the case where j is not definable in V. For example, if $\mathbb{P}$ is the partial ordering producing a generic embedding j, then $\mathbb{P}$ might destroy ω-Jónsson algebras. Nonetheless, his general technique is quite relevant.

We begin by reminding the reader of a basic definition. An algebra on a cardinal λ with no proper elementary substructure of cardinality λ is called a *Jónsson algebra*. A cardinal λ is called *Jónsson* if there is no Jónsson algebra on λ. Equivalently, every algebra on λ has a proper elementary substructure of cardinality λ.

At the heart of the Kunen technique is the result shown in Sect. 5 that if $\mathfrak{A}$ is an algebra on a cardinal λ then $j``\lambda \prec j(\mathfrak{A})$. In particular, if we have an elementary embedding $j$ and a cardinal $\lambda > \mathrm{crit}(j)$ such that $j(\lambda) = \lambda$ and $j``\lambda \in M$, then λ must be a Jónsson cardinal in V. Since results of Woodin, Tryba [122] and others have shown that the successors of regular cardinals are *not* Jónsson we immediately see the following results:

6.5 Theorem. *Let κ be a successor of a regular cardinal. Then there is no normal, fine, precipitous ideal on $[\kappa]^\kappa$.*

Proof. Note that if I is a non-trivial normal, fine, precipitous ideal on $[\kappa]^\kappa$, then for I-almost every $z \in [\kappa]^\kappa$, there is an $\alpha \in \kappa \setminus z$. By normality, for each I-positive set $A \subseteq [\kappa]^\kappa$ there is a $\beta < \kappa$ and an I-positive $B \subseteq A$ such that for all $z \in B$ there is a $\gamma \in \beta \setminus z$.

Hence if $j : V \to M$ is the generic embedding from the ideal I then the critical point of j must be less than κ. Since I concentrates on $[\kappa]^\kappa$, κ is a fixed point of j. Moreover, by normality and fineness, $j``\kappa \in M$. Thus κ is Jónsson, a contradiction. ⊣

The next corollary follows immediately from the existence of a Jónsson algebra on $j``\kappa_\omega^{+2}$.

6.6 Corollary. *There is no generic elementary embedding $j : V \to M$ such that $j``\kappa_\omega^{+2} \in M$ and $(\kappa_\omega^{+2})^M = (\kappa_\omega^{+2})^V$.*

Shelah [105] has shown that many successors of singular cardinals carry Jónsson algebras. In particular this is true for all successors of singulars below the first inaccessible cardinal.[49] As a result, Kunen's theorem follows for all

[49] Actually, much further.

elementary embeddings whose critical point lies below the first inaccessible cardinal.

6.7 Proposition. *Suppose that κ_ω is below the first inaccessible cardinal. Then there is no elementary embedding $j : V \to M$ such that:*

- $(\kappa_\omega^+)^V = (\kappa_\omega^+)^M$, *and*
- $j``(\kappa_\omega^+)^V \in M$.

In particular, there is no normal, fine, precipitous ideal on $[\aleph_{\omega+1}]^{\aleph_{\omega+1}}$.

Of course there are finer versions of this theorem ruling out elementary embeddings of $V_{\kappa_\omega+2}$ into $M_{\kappa_\omega+2}$ when M contains $j``(\kappa_\omega^+)^V$.

Zapletal [130] pointed out that the techniques used in Shelah's theorem about Jónsson algebras on successors of singular cardinals (pcf theory) can be used to directly show Kunen's theorem that there can be no $j : V \to M$ with $V_{\kappa_\omega+1} \subseteq M$. We briefly review the definitions:

6.8 Definition. Let a be a set of regular cardinals, and I an ideal on a. We consider the reduced product $\prod a/I$ as a partial ordering, by giving each $\kappa \in a$ the ordering of "$\in$". A $<_I$-increasing sequence $\langle f_\alpha : \alpha < \nu\rangle$ is a *scale* in $\prod a/I$ iff for all $g \in \prod a$ there is an α such that $g <_I f_\alpha$.

Shelah [105] showed that for all singular cardinals λ there is a cofinal set $a \subseteq \lambda$ of regular cardinals such that there is a scale $\langle f_\alpha : \alpha < \lambda^+\rangle$ in $\prod a/\{\text{bounded sets in } \lambda\}$.

Using this fact we can give Zapletal's proof of Kunen's theorem:

Let $a \subseteq \kappa_\omega$ be a cofinal set of regular cardinals on which there is a scale $\langle f_\alpha : \alpha < \kappa_\omega^+\rangle$. By thinning out if necessary, we can assume that there is at most one element of a between each κ_n and κ_{n+1} and the least element of a is above κ_0. In particular, $j(a) = j``a$. Suppose that $j : V \to M$ is such that $j``\kappa_\omega \in M$. Then we can verify the following claims:

1. $j(\kappa_\omega^+) = \kappa_\omega^+$ and $j``\kappa_\omega^+$ is cofinal in κ_ω^+.
2. $M \models$ "$j(\langle f_\alpha : \alpha < \kappa_\omega^+\rangle)$ is a scale in $\prod j(a)$" and hence for all $g \in \prod j(a) \cap M$ there is an $\alpha < \kappa_\omega^+$ such that $g <_{\text{bounded}} j(f_\alpha)$.
3. For each $\mu \in a$, we have $j``\mu$ is bounded in $j(\mu)$.
4. For each $\alpha, \mu \in a$ we have $j(f_\alpha)(j(\mu)) \in j``\mu$.
5. Let $g \in \prod j(a)$ be defined as $g(j(\mu)) = \sup(j``\mu)$. Then every function in $\langle j(f)_\alpha : \alpha \in \kappa_\omega^+\rangle$ is bounded everywhere by g. Note that $g \in M$ by the assumption on M.
6. This contradicts clause 2.

Several people, including the author, Burke and Matsubara noted that Zapletal's proof gives information about generic elementary embeddings too:

6.9 Theorem. *Let λ be a singular cardinal. Then there is no λ-saturated normal, fine ideal on $[\lambda]^\lambda$. In particular, there is no normal, fine, countably complete, $\aleph_n$-saturated ideal on $[\aleph_\omega]^{\aleph_\omega}$.*

Proof. We follow the same steps as Zapletal's argument: the first two items follow for identical reasons. The third item must be slightly modified. By the closure of M, we know that every $j(\mu)$ for $\mu \in a$ is a cardinal in V. Since the ideal is λ-saturated there is a tail of $\mu \in j(a)$ that remain regular cardinals in $V[G]$. Since $\mu < j(\mu)$, $j``\mu$ must be bounded in $j(\mu)$. The rest of the proof is the same. ⊣

Burke and Matsubara improved this result to eliminate the assumption of normality. The author noted that the proof above works assuming only λ^+-saturation: If I is λ^+-saturated, then it has the disjointing property. Hence, if $j : V \to M$ is the generic embedding, $M^\lambda \cap V[G] \subseteq M$. In particular, for all $\mu \in a$, $j(\mu)$ is regular in $V[G]$, so $j``\mu$ is bounded in μ and the proof works as before.

We end this subsection by remarking that the requirement on M that it share some cardinal structure with V is necessary. The various stationary tower forcings that yield elementary embeddings with many fixed points give examples of elementary embeddings with $j : V \to M$ where M contains $j``\alpha$ for many α much bigger than κ_ω.

6.3. Saturated Ideals and Cofinalities

We now state two theorems that are of use in showing that various ideals cannot be saturated.

6.10 Theorem (Shelah [103]). *Let $V \subseteq W$ be two models of set theory with the same ordinals and suppose that*

$$V \models \kappa \textit{ is a regular cardinal and } \lambda = \kappa^+.$$

If λ is a cardinal in W then

$$W \models \mathrm{cf}(\kappa) = \mathrm{cf}(|\kappa|).$$

We note that the hypotheses of this theorem are satisfied if W is a λ-c.c. forcing extension of V.

For the reader's convenience (and because the proof is so nice) we give the proof of Shelah's theorem.

Proof of Theorem 6.10. Working in V, let $\langle A_\alpha : \alpha < \kappa^+\rangle$ be a sequence of subsets of κ such that the intersection of any pair has cardinality less than κ. Then for all $\gamma < \kappa^+$, there is a function $f_\gamma : \gamma \to \kappa$ such that $\langle A_\alpha \setminus f_\gamma(\alpha) : \alpha < \gamma\rangle$ is a pairwise disjoint sequence of sets.

If κ is a cardinal in W then there is nothing to show. Otherwise suppose that $W \models$"$\mu = |\kappa|$ and $\mathrm{cf}(\kappa) \neq \mathrm{cf}(\mu)$". Let $f \in W$ be a bijection between μ

and κ. Then for all $\alpha < \lambda$ there is a $\delta_\alpha < \mu$ such that $f``\delta_\alpha$ is unbounded in A_α. Since λ is a cardinal in W there is a set $Y \subseteq \lambda$ lying in W having cardinality λ such that for all $\alpha, \beta \in Y$ we have $\delta_\alpha = \delta_\beta$. Let the common value be δ. Choose a $\gamma \in \lambda$ such that $Y \cap \gamma$ has ordertype at least μ. Then $W \models$"$\langle f^{-1}(A_\alpha \setminus f_\gamma(\alpha)) \cap \delta : \alpha \in Y \cap \gamma\rangle$ is a sequence of μ disjoint non-empty subsets of δ". This contradicts the fact that μ is a cardinal in W. $\dashv$

Shelah's theorem gives an immediate corollary for saturated ideals:

6.11 Corollary. *Suppose that I is a κ-complete, κ^+-presaturated ideal on $\kappa = \mu^+$. Then $\{\delta : \mathrm{cf}(\delta) = \mathrm{cf}(\mu)\} \in \breve{I}$.*

Proof. Consider the generic embedding $j : V \to M$. The critical point of j is κ and $M^\kappa \cap V[G] \subseteq M$. Hence $V[G] \models |\kappa| = \mu$. From Theorem 6.10 it follows that $V[G] \models \mathrm{cf}(\kappa) = \mathrm{cf}(\mu)$. The corollary now follows from the results of Sect. 1.5. $\dashv$

In particular, this shows that the nonstationary ideal can never be κ^+-saturated or even presaturated on any successor cardinal larger than ω_1. Theorem 6.10 leaves open the possibility that the nonstationary ideal on ω_2 can be saturated when restricted to the ordinals of cofinality ω_1. As of this writing this is open, although there are closely related results in Sect. 7.

Shelah and Matsubara established a formally similar result for ideals whose quotient is proper in the sense of "proper forcing":

6.12 Proposition (Matsubara and Shelah [94]). *Suppose that $Z \subseteq P(X)$ and I is a normal, fine, κ-complete ideal on Z such that $P(Z)/I$ is proper. If $\rho < \kappa$ is regular, then $\{z : z \cap \kappa \in \mathrm{Cof}({<}\rho) \cap \kappa\} \in I$.*

Proof. If this fails, then there is a regular δ with $\delta^+ < \kappa$ such that $T = \{z : z \cap \kappa \in \mathrm{Cof}(\delta)\} \in I^+$. Partition $\kappa \cap \mathrm{Cof}(\omega)$ into stationary sets $\langle S_\alpha : \alpha < \delta^+\rangle$. Each α of the form $z \cap \kappa$ for $z \in T$ has cofinality δ. Hence there is a closed unbounded set $C \subseteq \alpha$ of order type δ. In particular, there is a $\gamma(\alpha)$ such that $S_{\gamma(\alpha)} \cap \alpha$ is not stationary.

By the κ-completeness of the ideal there is a $\gamma^* < \delta^+$ and a positive set T' such that for all $z \in T'$, $\gamma(z \cap \kappa) = \gamma^*$. Letting $P = \{z \cap \kappa : z \in T'\}$ we see that for all $\alpha \in P$, $S_{\gamma^*} \cap \alpha$ is nonstationary. This contradicts Proposition 5.23. $\dashv$

Cummings generalized Theorem 6.10 to singular cardinals:

6.13 Theorem (Cummings [16]). *Let $V \subseteq W$ be two transitive models of* ZFC *with the same ordinals and suppose that $V \models \lambda = \kappa^+$. Suppose further that for all V-stationary sets $S \subseteq \lambda$, $W \models$ "S is stationary". Then:*

$$W \models \mathrm{cf}(\kappa) = \mathrm{cf}(|\kappa|).$$

Again the hypotheses of this theorem are satisfied if W is a λ-c.c. forcing extension of V.

For general regular κ, Gitik and Shelah were able to prove:

6.14 Theorem (Gitik-Shelah [56]). *If κ is a regular cardinal then for all regular cardinals δ with $\delta^+ < \kappa$, the nonstationary ideal on κ restricted to points of cofinality δ is not κ^+-saturated.*

If κ is the successor of a regular cardinal, this already follows from Corollary 6.11. Hence the substance of this theorem is when:

1. $\kappa = \mu^+$ where μ is singular, or
2. κ is weakly inaccessible.

Proof (Sketch). Towards a contradiction, assume that the nonstationary ideal on κ restricted to points of cofinality δ is κ^+-saturated.

- We take as a fact that for all stationary sets $S \subseteq \kappa \cap \mathrm{Cof}(\delta)$ there is a club guessing sequence consisting of points of high cofinality. Precisely: there is a sequence of sets $\langle S_\alpha : \alpha \in S \rangle$ for all $\alpha \in S$:

  1. $S_\alpha \subseteq \alpha \cap \mathrm{Cof}(>\delta)$, and
  2. S_α unbounded in α

  such that for all closed unbounded sets $C \subseteq \kappa$ the set $\{\alpha : S_\alpha \subseteq C\}$ is stationary in κ.

- We claim that the saturation of the ideal implies that for all S and club guessing sequences $\langle S_\alpha : \alpha \in S \rangle$, there is a stationary $S^* \subseteq S$ such that $\langle S_\alpha : \alpha \in S^* \rangle$ is a *strong club guessing sequence* on S^*. This means that:

  1. S_α is unbounded in α, and
  2. for all closed unbounded sets $C \subseteq \kappa$,

  $$\{\alpha : \text{a tail of } S_\alpha \text{ is a subset of } C\}$$

  is closed unbounded relative to S^*.

  For if this failed, for each $T \subseteq S$ there would be a closed unbounded set $C(T)$ such that $T^* =_{\mathrm{def}} \{\alpha : \text{a tail of } S_\alpha \text{ is a contained in } C(T)\}$ would be stationary and co-stationary in T. We inductively define a sequence $\langle \langle T_\beta, C_\beta \rangle : \beta < \kappa^+ \rangle$. Set $T_0 = S$ and $C_0 = C(S)$. Suppose that we have defined C_β. Let $T_\beta = \{\alpha \in S : S_\alpha \text{ is eventually included in } C_\beta\}$. Given T_β, let $C_{\beta+1} \subseteq C_\beta \cap C(T_\beta)$ be any closed and unbounded set. At limit β choose C_β so that it is eventually included in $\langle C_{\beta'} : \beta' < \beta \rangle$. Then:

  1. $\langle C_\beta : \beta < \kappa^+ \rangle$ is a sequence of closed unbounded sets so that $\beta' < \beta$ implies C_β is eventually included in $C_{\beta'}$,
  2. $T_{\beta+1}$ is a stationary and co-stationary subset of T_β, and
  3. $\langle T_\beta : \beta < \kappa^+ \rangle$ is a decreasing sequence of stationary sets.

But then $\{T_\beta \setminus T_{\beta+1} : \beta < \kappa^+\rangle$ is an antichain with respect to NS_κ, contradicting the κ^+ saturation assumption.

- Again by the saturation of the ideal, we can find a pairwise disjoint collection of such S^* whose union contains a closed unbounded set in κ. Gluing together the guessing sets yields a strong club guessing sequence $\langle S_\alpha : \alpha \in \kappa \cap \mathrm{Cof}(\delta)\rangle$ on $\kappa \cap \mathrm{Cof}(\delta)$.

  Since our original S_α's consisted of points of large cofinality, the sequence continues to have the additional property that for all α,

$$S_\alpha \subseteq \alpha \cap \mathrm{Cof}(>\delta).$$

  Shelah and Gitik called a strong club guessing sequence with this property $\diamondsuit^*_{\mathrm{club}}(\kappa, \delta)$.

- $\diamondsuit^*_{\mathrm{club}}(\kappa, \delta)$ is inconsistent with ZFC. To see this in the case where $\delta > \omega$, build a decreasing sequence of closed unbounded subsets of κ, $\langle E_n : n < \omega\rangle$. Let E_0 be the set of ordinals below κ which are limits of ordinals of cofinality bigger than δ. Suppose that we have defined E_n. Let E_{n+1} be a closed unbounded set witnessing $\diamondsuit^*_{\mathrm{club}}(\kappa, \theta)$ for the collection of limit points of E_n. Without loss of generality assume that E_{n+1} is a subset of the limit points of E_n.

  Let $E = \bigcap E_n$. Let η be the least point of E of cofinality δ. Then for all $n \in \omega$ the limit points of E_n contain a tail of S_η, and δ has uncountable cofinality. Hence E contains a tail of S_η. Let $\beta \in E \cap S_\eta$. Then β has cofinality greater then δ and is a limit point of every E_n. Hence $E \cap \beta$ is closed unbounded in β. But then there is a $\gamma \in E \cap \beta$ of cofinality δ, contradicting the minimality of η.

  The case where $\delta = \omega$ is similar, except that one builds a sequence of E_n's with length ω_1.

$\dashv$

In contrast to this, Foreman and Komjáth [40] jointly established a general result that when $\kappa = \omega_2$ or $\kappa = \aleph_{\omega+1}$ shows that it is consistent for:

1. $\mathrm{NS}_\kappa \restriction S$ is κ^+ saturated for a stationary $S \subseteq \kappa$, and

2. strong club guessing at κ.

This is Theorem 8.14, which is outlined in Sect. 8.2. The resolution of the apparent contradiction between Theorem 8.14 and the proof of Theorem 6.14, is that the cofinality of the ordinals in the strong club guessing sequence in the model for Theorem 8.14 is small. Hence $\diamondsuit^*_{\mathrm{club}}(\kappa, \delta)$ fails.

6.4. Closed Unbounded Subsets of $[\kappa]^\omega$

In this section we present a theorem from [5] that says that every closed unbounded relative to $[\kappa]^\omega$ is large. This stands in marked contrast to the results of Sect. 4.6, where we saw that for exponents other than ω and normal ideals there were usually sets of measure one of small cardinality.[50]

As a corollary of the theorem, we see that $[\kappa]^\omega$ can be split into a large collection of disjoint stationary sets. In particular, the nonstationary ideal on $[\kappa]^\omega$ cannot be $2^{\aleph_0}$-saturated for any regular $\kappa \geq \omega_2$.

Since the partial ordering for adding Cohen reals is c.c.c., it does not make a stationary subset of $[\kappa]^\omega$ into a nonstationary set. Thus, we see that it is consistent that there be stationary subsets of $[\omega_2]^\omega$ of size $\aleph_2$ even with $2^{\aleph_0}$ arbitrarily large.

6.15 Theorem (Baumgartner-Taylor [5]). *Let $\kappa \geq \omega_2$ be regular. Suppose that C is a closed unbounded subset of $P(\kappa)$. Then there is a countable subset $R \subseteq \kappa$ such that $|C \cap [R]^\omega| = 2^{\aleph_0}$.*

Proof. For $\alpha \in \kappa \cap \mathrm{Cof}(\omega)$ choose an increasing cofinal sequence $\vec{\alpha} = \{\alpha(n) : n \in \omega\}$.

Without loss of generality we can assume that there is a function $f : \kappa^{<\omega} \to \kappa$ such that C is the collection of $z \subseteq \kappa$ closed under f. For a set $z \subseteq \kappa$, let $\mathrm{Sk}^f(z)$ be the closure of z under f. We can assume that if $\alpha \in \mathrm{Sk}^f(z)$ then $\vec{\alpha} \subseteq \mathrm{Sk}^f(z)$.

Let Z be the collection of $\alpha < \kappa$ of cofinality ω that are closed under f. For $\vec{\xi} \in [\kappa]^{<\omega}$, let $P_{\vec{\xi}} = \{\alpha \in Z : \vec{\xi} \subseteq \vec{\alpha}\}$.

We note that if $T \subseteq P_{\vec{\xi}}$ is stationary, then there are unboundedly many $\eta < \kappa$ such that $T \cap P_{\vec{\xi}^\frown\eta}$ is stationary. For if there were a bound, then each $\alpha \in T$ above the bound has some n where $\alpha(n)$ is above the bound. For stationarily many α in T, we have the same n, and by a regressive function argument, the same $\alpha(n)$. But this shows that $P_{\vec{\xi}^\frown\alpha(n)} \cap T$ is stationary, a contradiction.

Define by induction a sequence $\langle\langle Z_s, \xi_s\rangle : s \in 2^{<\omega}\rangle$ such that for all $s \in 2^{<\omega}$ and $i \in \{0,1\}$:

1. Z_s is a stationary subset of $P_{\langle \xi_{s\restriction j} : j \leq \mathrm{length}(s)\rangle}$,
2. $Z_{s^\frown i} \subseteq Z_s$,
3. For all $\alpha \in Z_{s^\frown i}$, the ordinal $\xi_{s^\frown(1-i)} \notin \mathrm{Sk}^f(\vec{\alpha})$.

We first show that these conditions imply that if h and g are distinct elements of 2^ω, then $\mathrm{Sk}^f(\{\xi_{h\restriction j} : j \in \omega\})$ is different than $\mathrm{Sk}^f(\{\xi_{g\restriction j} : j \in \omega\})$. Letting $R = \mathrm{Sk}^f(\{\xi_s : s \in 2^{<\omega}\})$, this establishes the theorem.

[50] Assuming the consistency of large cardinals, Baumgartner [4] showed that it is consistent that there is a closed unbounded set whose intersection with $[\kappa]^{\omega_1}$ has cardinality less than κ^{ω_1}.

Let h and g be different elements of 2^ω. Consider the least n such that $h(n) \neq g(n)$. Then $\xi_{h\restriction n+1} \in \mathrm{Sk}^f(\{\xi_{h\restriction j} : j \in \omega\})$. On the other hand, if $\xi_{h\restriction n+1} \in \mathrm{Sk}^f(\{\xi_{g\restriction j} : j \in \omega\})$, then there would be a finite $m \geq n+1$ such that $\xi_{h\restriction n+1} \in \mathrm{Sk}^f(\{\xi_{g\restriction j} : j \in m\})$. If we let $\alpha \in Z_{\langle \xi_{g\restriction j} : j \in m\rangle}$, then $\alpha \in Z_{\langle \xi_{g\restriction j} : j \in n+1\rangle}$ and $\xi_{h\restriction n+1} \in \mathrm{Sk}^f(\vec{\alpha})$, contradicting clause 3.

We are reduced to defining the sequence $\langle\langle Z_s, \xi_s\rangle : s \in 2^{<\omega}\rangle$ satisfying clauses 1–3. Suppose that we have defined Z_s and $\xi_{s\restriction j}$ for $j \leq \mathrm{length}(s)$. Let $\vec{\xi}$ be the sequence $\langle \xi_{s\restriction j} : j \leq \mathrm{length}(s)\rangle$. Let $K \subseteq \kappa$ be unbounded so that for all $\eta \in K$, $P_{\vec{\xi}^\frown \eta} \cap Z_s$ is stationary. Let K' be the first ω_1 many elements of K.

For each $\alpha \in Z_s$, there is an $\eta(\alpha) \in K'$ such that $\eta(\alpha) \notin \mathrm{Sk}^f(\vec{\alpha})$. Hence we can find an unbounded set $K_1 \subseteq K$ and a fixed η_0 such that for all $\zeta \in K_1$ the set of α in $P_{\vec{\xi}^\frown \zeta} \cap Z_s$ with $\eta(\alpha) = \eta_0$ is stationary.

Repeating this argument we can find an $\eta_1 \in K_1$ such that the collection Z_0 of $\alpha \in Z_s \cap P_{\vec{\xi}^\frown \eta_0}$ such that $\eta_1 \notin \mathrm{Sk}^f(\vec{\alpha})$ is stationary.

Let $Z_{s^\frown 0} = Z_0$, $Z_{s^\frown 1} = \{\alpha \in Z_s \cap P_{\vec{\xi}^\frown \eta_1} : \eta_0 \notin \mathrm{Sk}^f(\vec{\alpha})\}$, $\xi_{s^\frown 0} = \eta_0$, and $\xi_{s^\frown 1} = \eta_1$. ⊣

6.16 Corollary. *Let $\kappa \geq \omega_2$ be a cardinal. Every closed unbounded subset relative to $[\kappa]^\omega$ has cardinality $\kappa^{\aleph_0}$.*

Proof. Let C be a closed unbounded subset of $P(\kappa)$. Define a map $f : [\kappa]^\omega \to C$, by sending $x \in [\kappa]^\omega$ to a countable $z \in C$ such that $x \subseteq z$. The map f is at most $2^{\aleph_0}$-to-one. Hence $\kappa^{\aleph_0} = 2^{\aleph_0} \times |C \cap [\kappa]^\omega|$. Since $|C \cap [\kappa]^\omega| \geq 2^{\aleph_0}$, we see that $|C \cap [\kappa]^\omega| = \kappa^{\aleph_0}$. ⊣

We can now see

6.17 Corollary. *Suppose that $\omega_2 \leq \kappa \leq 2^{\aleph_0}$. Then there is a collection of $2^{\aleph_0}$ disjoint stationary subsets of $[\kappa]^\omega$.*

Proof. Let $\langle (A_\alpha, f_\alpha) : \alpha < 2^\omega\rangle$ be an enumeration of the pairs $\langle (A, f)\rangle$ such that $A \in [\kappa]^\omega$, $f : A^{<\omega} \to A$, and there are $2^{\aleph_0}$ distinct subsets of A closed under f. We inductively build continuum many pairwise disjoint sets $\langle S_\beta : \beta < 2^{\aleph_0}\rangle$ such for all β and α, S_β contains some subset of A_α closed under f_α. By Theorem 6.15, this suffices. ⊣

6.5. Uniform Ideals on Ordinals

Our attention has been focused on normal ideals on $Z \subseteq P(X)$, where we can always take X to be a cardinal λ. We frequently use the ordering on λ for reflection arguments using Łoś's Theorem. In many situations it might be convenient to give up normality in order that X have a well-ordering whose length is not a cardinal and have I uniform in the sense of order type rather than cardinality; e.g. all subsets of X of small order type belong to I. The next result says that this is not possible for κ-complete, κ^+-saturated ideals.

6.18 Theorem (Foreman-Hajnal [39]). *Let κ be a successor cardinal. Suppose that I is a κ-complete, κ^+-saturated ideal on an ordinal γ having cardinality κ such that I is uniform in the sense that if $a \subseteq \gamma$ has order type less than γ, then $a \in I$. Then $\gamma = \kappa$.*

Proof. The Milner-Rado Paradox says that every ordinal less than κ^+ can be written as a countable union of subsets of order type less than κ^ω.[51] Hence if γ carries a countably complete, uniform ideal, then $\gamma < \kappa^\omega$. Since γ must be indecomposable, we know $\gamma = \kappa^n$ for some n. Let I be an ideal satisfying the hypothesis of the theorem.

We view the ordinal κ^n as a product of n copies of κ and show that there is a function of the first coordinate in the product which bounds the other coordinates on a set of positive measure for the ideal I. This will contradict the uniformity of I. To reduce to one coordinate we must take some Rudin-Keisler reductions of the usual ultrapower.

Let $\phi : (\gamma, \in) \to \langle \kappa \times \kappa \times \cdots \times \kappa, <_{\text{lex}} \rangle$ be an isomorphism between γ and the product of n copies of κ, where $<_{\text{lex}}$ is the left-to-right lexicographical ordering. The fact that I is uniform implies that if $A \subseteq \gamma$ and $A \notin I$ then $\phi[A]$ contains a κ-splitting tree isomorphic to the n-fold product of κ's. Via the isomorphism ϕ we can regard I as a κ-complete, κ^+ saturated ideal on $\{(\alpha_0, \ldots, \alpha_{n-1}) : \alpha_i \in \kappa\}$ containing all sets that do not have such a tree. For the rest of this proof we will write κ^n for this n-fold product of κ.

Suppose that $\kappa = \mu^+$. Let $G \subseteq P(\kappa^n)/I$ be generic, and $j : V \to M \subseteq V[G]$ be the generic ultrapower. As usual $M^\kappa \cap V[G] \subseteq M$ and $[a]_I \in G$ iff $[\text{id}]^M \in j(a)$, where $\text{id} : \kappa^n \to V$ is the identity function. Let $[\text{id}]_M = (\tilde{\alpha}_0, \tilde{\alpha}_1, \ldots, \tilde{\alpha}_{n-1})$.

We define:

$$H_1 = \{A \subseteq \kappa : A \times \kappa^{n-1} \in G\}.$$

It is easy to verify that $H_1 = \{A \subseteq \kappa : \tilde{\alpha}_0 \in j(A)\}$. Thus H_1 is an ultrafilter and we can construct an ultrapower V^κ/H_1. Define:

$$k_1 : V^\kappa/H_1 \to M$$

by setting $k_1([f]) = j(f)(\tilde{\alpha}_0)$. Then k_1 is well-defined and elementary. Hence V^κ/H_1 is well-founded and we replace it by its transitive collapse N_1 and reconstrue k_1 to have domain N_1.

Denote the ultrapower embedding from V to N_1 by j_1. One can check easily that $j = k_1 \circ j_1$, and that the critical point of j_1 is κ. Moreover, $j_1(\kappa) = (\mu^+)^{N_1}$ and $P(\kappa)^V \subseteq N_1$, so $j_1(\kappa) = (\kappa^+)^V = j(\kappa)$. Thus the critical point of k_1 must be greater than the κ^+ of V.

Let $i : \kappa \to V$ be such that $[i]_{N_1} = \kappa$. Define

$$H_0 = \{A \subseteq \kappa : i^{-1}(A) \in H_1\}.$$

[51] Ordinal exponentiation.

Then $H_0 = \{A \subseteq \kappa : \kappa \in j_1(A)\}$. Repeating the analysis we did for H_1 we see that the ultrapower V^κ/H_0 is well-founded and if N_0 is the transitive collapse, there is an elementary embedding $k_0 : N_0 \to N_1$ given by $k_0([f]_{N_0}) = j_1(f)(\kappa)$. Moreover if j_0 is the ultrapower embedding $j_0 : V \to N_0$, then the critical point of j_0 is κ and the critical point of k_0 is bigger than $(\kappa^+)^V$, and finally $j_1 = k_0 \circ j_0$.

$$\begin{tikzcd} V \arrow[r, "j"] \arrow[d, "j_0"'] \arrow[dr, "j_1"] & M \\ N_0 \arrow[r, "k_0"'] & N_1 \arrow[u, "k_1"'] \end{tikzcd}$$

Since $j(\kappa) = \kappa^+$, we know that $\max\{\tilde{\alpha}_0, \tilde{\alpha}_1, \dots, \tilde{\alpha}_{n-1}\} < \kappa^+$. By the κ^+ saturation of I, there is an $\eta < \kappa^+$ such that

$$\| \max\{\tilde{\alpha}_0, \tilde{\alpha}_1, \dots, \tilde{\alpha}_{n-1}\} < \eta \|_{P(\kappa^n)/I} = 1.$$

Let $f : \kappa \to \kappa$ be in V such that $[f]_{N_0} = \eta$. Since the critical points of k_0 and k_1 are both greater than the κ^+ of V, $k_1 \circ k_0(\eta) = k_0(\eta) = \eta$. Hence, $j_0(f)(\kappa) = \eta$ and thus $j(f)(j(i)(\tilde{\alpha}_0)) = \eta$.

Let $B = \{(\alpha_0, \alpha_1, \dots, \alpha_{n-1}) : \max\{\alpha_0, \dots, \alpha_{n-1}\} < f(i(\alpha_0))\}$. Then $B \in G$, since $\max\{\tilde{\alpha}_0, \tilde{\alpha}_1, \dots, \tilde{\alpha}_{n-1}\} < \eta = j(f)(j(i)(\tilde{\alpha}_0))$. But this is a contradiction, since B does not contain a tree isomorphic to κ^n and hence $B \in I$. ⊣

6.6. Restrictions on the Quotient Algebra

In this section we discuss theorems of Gitik and Shelah about the nature of the quotient algebra of an ideal.

If κ is a successor cardinal then a precipitous κ-complete ideal on κ yields an embedding that has critical point κ. As remarked after Proposition 6.3 this implies that the forcing arising from I must collapse κ. On the other hand, as we shall see in Sect. 7, if κ is a measurable cardinal, $\eta < \kappa$ and $\mathbb{P}$ is an η-c.c. forcing, then in $V^{\mathbb{P}}$ there is a κ-complete, η-c.c. ideal on κ. In particular, adding at least κ Cohen or random reals to a model where κ is measurable gives a highly saturated ideal whose quotient algebra is isomorphic to the algebra for adding more Cohen or random reals.

The question arises, can this algebra actually have small cardinality rather than just small chain condition? More succinctly: What are the possible densities of $P(\kappa)/I$ if I is a κ-complete ideal on κ?

This question was asked classically by Ulam [123] in the context of determining the smallest size of a collection of countably complete measures such that every subset of the real numbers is measurable with respect to one of the measures. The question is clearly natural for cardinals such as $\aleph_1, \aleph_2$, as well as $2^{\aleph_0}$.

Ulam showed that there is no measure that measures every subset of ω_1; i.e. ω_1 is not measurable. Alaoglu and Erdős showed that for every countable collection of measures on $\aleph_1$ there is a set that is not measurable by one of the measures. Ulam asked whether there could be a collection of ω_1 countably complete measures such that every subset of ω_1 is measurable with respect to one of them. If the ideals corresponding to the measures are normal, then Taylor showed (Theorem 4.3) that this is equivalent to the existence of a countably complete, $\aleph_1$-dense ideal.

The next theorem gives a characterization of ideals with very small density in terms of a version of Ulam's property:

6.19 Theorem (Taylor [119]). *Let $\delta < \kappa$ be regular cardinals. Suppose that $\langle \mu_\alpha : \alpha < \delta \rangle$ is a collection of $<\kappa$-additive 0-1 measures over Z such that every subset of Z that is not measure zero with respect to all of them is measure one with respect to one of them. Let I be the κ-complete ideal of subsets of Z that have measure zero with respect to each μ_α. Then $P(Z)/I$ has a dense set of size δ.*

Proof. Note that the second assertion easily implies the first. For if $\{d_\alpha : \alpha \in \delta\}$ is a collection of subsets of Z such that every subset of Z not in I contains some d_α modulo I, then the measures associated to $I \restriction d_\alpha$ measure every subset of Z in the prescribed manner.

For the other direction, suppose that $\langle \mu_\alpha : \alpha \in \delta \rangle$ is a sequence of measures such that every subset of Z not measure zero with respect to all of them is measure one with respect to one of them. Let I_α be the ideal of sets of measure zero for μ_α and $I = \bigcap I_\alpha$. We claim that $P(Z)/I$ has a dense set of size δ.

Clearly $P(Z)/I$ has the δ^+-c.c. For if $\langle A_\gamma : \gamma \in \delta^+ \rangle$ were an antichain, then we would have to have a γ, a β and an α such that A_γ and A_β both are measure one for μ_α. But then $A_\gamma \cap A_\beta \notin I_\alpha \supseteq I$.

Thus for a fixed α, any strictly I-decreasing chain of μ_α-measure one sets has length less than δ^+. Using the additivity of μ_α, for each α we can find a d_α that is measure one for μ_α such that for any a that is measure one for μ_α, $d_\alpha \leq_I a$. Then if $a \in I^+$ is arbitrary, there is an α such that a has measure one for μ_α. Hence $d_\alpha \leq_I a$. Thus $\{d_\alpha : \alpha \in \delta\}$ is a dense set in $P(Z)/I$.[52] $\dashv$

We note that the converse of Theorem 6.19 is easy: if there is a dense set of size δ, then there is a collection of measures satisfying the hypothesis. Thus we have an equivalence to the existence of an ideal with quotient containing a countable dense set.

Since any complete Boolean algebra with a countable dense set is isomorphic to the Boolean algebra for adding a single Cohen real, the question becomes whether there is a κ-complete, uniform ideal on a set Z such that adding a Cohen real adds a generic object for $P(Z)/I$.

[52] Alternatively, we could apply Theorem 4.2, to find sets d_α such that each $I_\alpha = I \restriction d_\alpha$ and the $\{[d_\alpha]_I : \alpha \in \delta\}$ would be dense.

If $|Z|$ is a measurable cardinal and $\breve{I}$ is the dual of a $|Z|$-complete ultrafilter on $|Z|$ then $|P(Z)/I| = 2$. To rule out this trivial case we require our ideal to be *nowhere prime*, i.e. there is no $A \in I^+$ such that $\breve{I}\restriction A$ is an ultrafilter on A.

Tarski showed in a 1962 paper [118] that:

6.20 Theorem. *There is no cardinal $\lambda > 2^{\aleph_0}$ that carries a nowhere prime, countably complete, uniform, $\aleph_0$-dense ideal.*

Krawczyk and Pelc [74] found an extension of this theorem to sets of size continuum:

6.21 Theorem. *The continuum does not carry a countably complete uniform $\aleph_0$-dense ideal.*

Finally Gitik and Shelah [55] finished the problem by showing:

6.22 Theorem. *There is no countably complete, $\aleph_0$-dense, nowhere prime ideal on any set Z.*

Proof. The proof will use two standard facts about Cohen forcing. Let r be V-generic for the Cohen forcing $\mathrm{Add}(\omega)$. Then:

1. $r \notin \bigcup\{M : M$ is a meager set belonging to $V\}$.
2. If $A \subseteq \omega^\omega$ is not meager in V, then A is not meager in $V[r]$.

We now describe a complicated scenario that allows us to state a lemma useful for proving both Theorem 6.22 and Theorem 5.9. The argument proving the lemma is essentially due to Gitik and Shelah, although Woodin saw its relevance to Theorem 5.9 and modified it appropriately. We adapt Woodin's approach to formulate a lemma that works for both theorems. We will give the assumptions forming the hypotheses of the lemma Roman numerals.

I. There are class models $N \subseteq W$ of ZFC with N closed under ω-sequences from W.

II. κ is an N-regular cardinal and $(\kappa^+)^N = (\kappa^+)^W$.

III. There is an ideal $J \in W$ on $P(\kappa)^N$ such that

   (a) J is normal and κ-complete with respect to sequences lying in N.

   (b) $P(\kappa)^N/J$ has a countable dense set in W and hence is forcing equivalent to $\mathrm{Add}(\omega)$, the partial ordering for adding a single Cohen real. We will view $\mathrm{Add}(\omega)$ as the tree $\langle \omega^{<\omega}, \supseteq\rangle$.

   (c) If $H \subseteq P(\kappa)^N/J$ is W-generic, then N^κ/H is well-founded.

Assume for the moment that I–III hold. Let $D \subseteq P(\kappa)^N/J$ be countable and dense with $D \in W$. Since N is closed under ω-sequences, we can find a collection $\langle A_p : p \in \omega^{<\omega}\rangle \in N$ such that:

1. $A_{p\frown i} \subseteq A_p \subseteq \kappa$,
2. $A_{p\frown i} \cap A_{p\frown j} = \emptyset$ for $i \neq j$, and
3. $\{[A_p]_J : p \in \omega^{<\omega}\}$ is dense in $P(\kappa)^N/J$.

We redefine D to be equal to $\{[A_p]_J : p \in \omega^{<\omega}\}$.

The collection of sets $\langle A_p : p \in \omega^{<\omega}\rangle$ determines a canonical bijection between W-generic ultrafilters $H \subseteq P(\kappa)^N/J$ and W-generic reals $r \subseteq \mathrm{Add}(\omega, 1)$. We will write $r(H)$ for the Cohen real associated with H, and if r is a Cohen real we will write $H(r)$ for the associated ultrafilter on $P(\kappa)^N/J$.

Let $H \subseteq P(\kappa)^N/J$ be generic over W. Let $i' : N \to N' \cong N^\kappa/H$ be the ultrapower map, where N' is a transitive model. By the N-normality of J, if $\mathrm{id} : \kappa \to \kappa$ is the identity map then $[\mathrm{id}]^{N'} = \kappa$.

If τ is a $P(\kappa)^N/J$ term in W for an element of N', then we can find a maximal antichain $\mathcal{A} \subseteq D$ and a collection of functions $\{f_a : a \in \mathcal{A}\} \subseteq N$ such that $a \Vdash [f_a]^{N'} = \tau$. Since $\mathcal{A} \subseteq D$, if $a = [A_p]_J$ and $b = [A_q]_J$ are distinct elements of $\mathcal{A}$, then $A_p \cap A_q = \emptyset$. Since N is ω-closed, $\{A_p : [A_p]_J \in \mathcal{A}\}$ and $\{f_{[A_p]} : [A_p]_J \in \mathcal{A}\}$ both belong to N. Define $f = \bigcup_{[A_p]\in\mathcal{A}} f_{[A_p]} \restriction A_p$. Then $1 \Vdash [f]_H = \tau$. Hence to each W-term τ for an element of N' we can associate a function f in N that represents it in N', no matter which generic object is chosen. A similar argument shows that $(N')^\omega \cap W[H] \subseteq N'$.

Since J is κ-complete in N and N is closed under ω-sequences

$$B = \bigcap_{n\in\omega} \bigcup_{|p|=n} A_p \in \breve{J}.$$

For $\xi \in B$, let $r_\xi : \omega \to \omega$ be the unique function such that $\xi \in \bigcap_{n\in\omega} A_{r_\xi \restriction n}$. Then the sequence $\langle r_\xi : \xi \in B\rangle \in N$ and for all W-generic H,

$$i'(\langle r_\xi : \xi \in B\rangle)(\kappa) = r(H).$$

Each $r_\xi \in N$ but $r(H) \notin N$. Hence $\{\xi : \text{there is an } \eta < \xi, r_\xi = r_\eta\} \in J$. By thinning slightly we can assume that $\langle r_\xi : \xi \in B\rangle$ is one-to-one. Modifying the sequence again on a set of measure zero we can assume that

1. $\langle r_\xi : \xi < \kappa\rangle \in N$ is one-to-one,
2. $A_p = \{\xi : r_\xi \in [p]\}$, and
3. $1 \Vdash i'(\langle r_\xi : \xi < \kappa\rangle)(\kappa) = r(H)$.

Suppose that $i'(\langle r_\xi : \xi < \kappa\rangle) = \langle r_\xi^{i'} : \xi < i'(\kappa)\rangle$. Then each $r_\xi^{i'} \in W[r(H)]$ and hence there is an $\mathrm{Add}(\omega)$-term s_ξ in W such that $1 \Vdash s_\xi = r_\xi^{i'}$. Since a Cohen term is a countable object, $s_\xi \in N$. Moreover, any Cohen term $t \in N$ for an element of ω^ω can be canonically viewed as a Borel function $T : \omega^\omega \to \omega^\omega$ that is coded in N. Our final assumption is:

IV. There is a sequence of Cohen terms $\langle t_\alpha : \alpha < \kappa^+\rangle \in N$ such that:

(a) $\{\alpha : 1 \Vdash t_\alpha = s_\alpha\}$ is unbounded in κ^+, and

(b) for all $\alpha < \beta < \kappa^+$, $\{x : T_\alpha(x) = T_\beta(x)\}$ is meager.

6.23 Lemma. *Hypotheses* I, II, III, *and* IV *are jointly inconsistent.*

We begin by reducing Theorem 6.22 to Lemma 6.23. Let $N = W = V$. Let I be a countably complete $\aleph_0$-dense, nowhere prime ideal on any set Z. Force with $P(Z)/I$ and consider the resulting generic elementary embedding $j : V \to N'$. Let κ be the critical point of j. If J is the ideal induced by using κ as the "ideal point" (as in Example 3.37), then J is a uniform, normal, κ-complete ideal, and the countable dense set in $P(Z)/I$ projects to a countable dense set in $P(\kappa)/J$. Thus we can assume without loss of generality that we have a J that is a uniform, normal, κ-complete ideal on a regular cardinal κ and that $P(\kappa)/J$ has a countable dense set.

Let $\langle t_\alpha : \alpha < \kappa^+\rangle = \langle s_\alpha : \alpha < \kappa^+\rangle$. We know that $1 \Vdash t_\alpha \neq t_\beta$ for $\alpha \neq \beta$. Hence $\{x : T_\alpha(x) \neq T_\beta(x)\}$ is meager and $\langle t_\alpha : \alpha < \kappa^+\rangle$ satisfy the hypotheses of the lemma.

We now sketch a proof of the lemma.

Proof (Sketch). Let H be generic for $P(\kappa)^N/J$, $r = r(H)$ and $i' : N \to N'$ the generic ultrapower embedding with N' transitive.

Here are the main points of the proof.

1. For sets of reals that belong to N, meagerness is absolute between N and W.

2. We will make the harmless simplifying assumption that if $1 \Vdash_{\mathrm{Add}(\omega)} t_\alpha^{V[r]} = s_\alpha^{V[r]}$ then $s_\alpha = t_\alpha$.

3. Every Borel set in W has a code that lies in N. If c is a Borel code then $i'(c) = c$. We claim that for each $A \in \breve{J}$ the set $\{r_\xi : \xi \in A\}$ is non-meager inside each basic open interval $[p]$. For otherwise, there would be a meager set X coded in N with $\{r_\xi : \xi \in A_p \cap A\} \subseteq X$. If we take H with $[A_p]_J \in H$ we would see that $r \in i'(X)$, a contradiction.

4. Since Cohen forcing preserves non-meagerness, for $A \in \breve{J}$ and $p \in \omega^{<\omega}$, $\{r_\xi : \xi \in A\} \cap [p]$ is non-meager in N'. Since $i'(A) \cap \kappa = A$ we can use i' and reflection to see that there is a $\xi_0 < \kappa$ such that $\{r_\xi : \xi \in \xi_0 \cap A\}$ is non-meager inside each basic open interval $[p]$.

5. If $\vec{f} = \langle f_\alpha : \alpha < \kappa^+\rangle$ is a sequence of canonical functions representing the ordinals less than κ^+ in the ultrapower[53] then $\vec{f} \in N$. Let $\langle r_\xi^{i'} : \xi < i'(\kappa)\rangle = i'(\langle r_\xi : \xi < \kappa\rangle)$. For $\alpha < \kappa^+$ the function $g_\alpha(\xi) = r_{f_\alpha(\xi)}$ represents $r_\alpha^{i'}$.

[53] As in Proposition 2.34.

6. For $\alpha < \kappa^+$, let $A_\alpha = \{\xi : T_\alpha(r_\xi) = g_\alpha(\xi)\}$. Then the sequence $\langle A_\alpha : \alpha < \kappa^+\rangle$ is definable from the sequences $\langle T_\alpha : \alpha < \kappa^+\rangle$, $\langle r_\xi : \xi < \kappa\rangle$ and $\langle f_\alpha : \alpha < \kappa^+\rangle$. Hence $\langle A_\alpha : \alpha < \kappa^+\rangle \in N$.

7. If $\alpha < \kappa^+$ with $t_\alpha = s_\alpha$ then $r_\alpha^{i'} = T_\alpha(r_\kappa^{i'}) = i'(g_\alpha)(\kappa)$. Hence, $A_\alpha \in \breve{J}$.

8. Working in N, let $\xi(\alpha)$ be the least $\xi < \kappa$ such that

   (a) ξ is closed under f_α, and

   (b) $\{r_\xi : \xi \in A_\alpha \cap \xi(\alpha)\}$ is not meager in any interval $[p]$,

   if such a ξ exists and 0 otherwise. By clauses 4 and 7 if $t_\alpha = s_\alpha$ then $\xi(\alpha)$ is non-zero.

9. In W, there is a set $E \subseteq \{\alpha : t_\alpha = s_\alpha\}$ with size κ^+ and a non-zero $\xi^* < \kappa$ such that for all $\alpha \in E$, $\xi(\alpha) = \xi^*$. Let F be the collection of $\alpha < \kappa^+$ such that $\xi(\alpha) = \xi^*$. Then $F \in N$ and $E \subseteq F$ so $|F| = \kappa^+$.

10. For $\alpha \in F$, $\{r_\xi : \xi < \xi^*$ and $T_\alpha(r_\xi) = r_\eta$ for some $\eta < \xi^*\}$ is non-meager in any interval $[p]$. Note that i' fixes the sequence $\langle r_\xi : \xi < \xi^*\rangle$.

11. Let $\alpha^* \in i'(F)$ with $\alpha^* \notin (i')``\kappa^+$. Let $\langle t_\alpha^{i'} : \alpha < i'(\kappa^+)\rangle$ be the sequence $i'(\langle t_\alpha : \alpha < \kappa^+\rangle)$. Consider the function $T_{\alpha^*}^{i'}$ in N' corresponding to $t_{\alpha^*}^{i'}$. Then $N' \models \{r_\xi : \xi < \xi^*$ and $T_{\alpha^*}^{i'}(r_\xi) = r_\eta$ for some $\eta < \xi^*\}$ is non-meager in any interval $[p]$. Since N' is closed under ω-sequences from $W[r]$, this is true in $W[r]$ as well.

12. Since Cohen forcing is countable, there is a condition p, a non-meager set $B \subseteq \{r_\xi : \xi < \xi^*\}$ and a function $w : B \to \{r_\xi : \xi < \xi^*\}$, such that $p \Vdash^W w = T_{\alpha^*}^{i'} \restriction B$.

13. Let $\tau \in N$ be a Cohen term for the function $T_{\alpha^*}^{i'}$. Working in W, we can view τ as a Borel function $T : \omega^\omega \times \omega^\omega \to \omega^\omega$ such that for a generic r and all $x \in \omega^\omega \cap N[r]$, $T(r, x) = T_{\alpha^*}^{i'}(x)$. Then $p \Vdash^W T_{\alpha^*}^{i'}(r_\eta) = r_\xi$ iff $W \models \{y : T(y, r_\eta) = r_\xi\}$ is comeager in the interval $[p]$. Since T is coded in N and comeagerness is absolute between N and W we can find a non-meager set $B \subseteq \{r_\xi : \xi < \xi^*\}$ and a function w that lies in N such that $p \Vdash^W w = T_{\alpha^*}^{i'} \restriction B$.

14. Note that $i'(B) = B$ and $i'(w) = w$. Consider $\phi(\eta, \gamma, B, w)$ saying:

$$\exists \alpha (\eta < \alpha < \gamma \wedge w = T_\alpha \restriction B).$$

   Let γ be the least ordinal such that $i(\gamma) > \alpha^*$ and $\eta < \gamma$ be arbitrary. Then $N' \models \phi(i'(\eta), i'(\gamma), i'(B), i'(w))$. Using α^* we can reflect twice to find $\alpha < \beta < \gamma$ such that $T_\alpha \restriction B = T_\beta \restriction B = w$. Since B is non-meager this contradicts condition IV.

⊣

Gitik and Shelah's results extend to show that if I is a nowhere prime ideal on a set X then the completeness of I is less than or equal to the density of I. Moreover, there are many forcing notions that are not possible as quotients of κ-complete ideals. These include:

- Any forcing P that has a filtration $\langle P_\alpha \rangle$ into forcings of size less than κ that are neatly embedded in P,[54]
- random real forcing,
- Cohen $*$ random forcing,
- Hechler forcing,
- Miller forcing,
- Sacks forcing.

6.7. Yet Another Result of Kunen

From the Gitik-Shelah limitations on $\aleph_0$-dense ideals, one sees that the strongest consistent ideal property on a cardinal below the first measurable cardinal is that an ideal be $\aleph_1$-dense. Kunen showed the following result which put a limitation on when countably complete ideals can even be $\aleph_2$-saturated.

6.24 Proposition. *There is no uniform, countably complete, $\aleph_2$-saturated ideal on any cardinal between $\aleph_\omega$ and $\aleph_{\omega_1}$.*

We can generalize Kunen's result as follows (see [31] for a complete discussion):

6.25 Definition. Let κ be a regular cardinal. Define $\mathcal{C}_\kappa$ to be the smallest class of ordinals such that:[55]

1. $\kappa \subseteq \mathcal{C}_\kappa$,
2. if $\alpha, \beta \in \mathcal{C}_\kappa$ and $\beta^{+\alpha} \geq \kappa^{+\omega}$ then $\beta^{+\alpha} \in \mathcal{C}_\kappa$, and
3. if $\beta \in \mathcal{C}_\kappa$ and $\beta \geq \kappa$, then every cardinal in the interval $[\beta, \beta^{+\kappa})$ belongs to $\mathcal{C}_\kappa$.

An easy induction shows that for all κ, $[\kappa, \kappa^{+\omega}) \cap \mathcal{C}_\kappa = \emptyset$. The next result generalizes Kunen's proposition:

6.26 Proposition. *Let κ be a successor cardinal. Suppose that λ is a regular cardinal in $\mathcal{C}_\kappa$. Then there is no κ-complete, κ^+-saturated uniform ideal on λ.*

---

[54] An example of such a forcing is the partial ordering for adding κ Cohen reals.
[55] Here we will use $\beta^{+\alpha}$ to mean the αth cardinal successor of β.

In the section on consistency results we will see that this theorem is sharp at the upper end of the interval, and that there is some evidence that it is sharp at the lower end.

Proof. As in the examples in Sect. 4.5, we see that if I is a uniform ideal on λ and $j : V \to M \subseteq V[G]$ is the generic elementary embedding coming from $G \subseteq P(\lambda)/I$, then $j(\lambda) > \lambda$.

6.27 Claim. *Suppose that α is an ordinal in $\mathcal{C}_\kappa$. Then for all κ-complete, κ^+-saturated ideals I on a set Z and all generic $G \subseteq P(Z)/I$, α is fixed by the generic elementary embedding determined by G.*

Proof. We show that the collection of fixed points of such an embedding j are closed under clauses 1–3 of Definition 6.25 of $\mathcal{C}_\kappa$. Let $G \subseteq P(Z)/I$ be generic and $j : V \to M \cong V^Z/G$ be the associated embedding, with M transitive.

Clause 1 is immediate since the ideal is κ-complete.

For clause 2: we remark that every cardinal of $V[G]$ is a cardinal of M. In particular, since the only cardinal collapsed by forcing with $P(Z)/I$ is $(\kappa^+)^V$ we know that for all α, β with $\beta^{+\alpha} \geq \kappa^{+\omega}$,

$$(\beta^{+\alpha})^M \leq (\beta^{+\alpha})^V.$$

Suppose that α, β are fixed points of j and $\beta^{+\alpha} \geq \kappa^{+\omega}$. Then,

$$(\beta^{+\alpha})^V \leq j(\beta^{+\alpha}) = (j(\beta)^{+j(\alpha)})^M = (\beta^{+\alpha})^M \leq (\beta^{+\alpha})^V.$$

For clause 3, note that if $\beta \geq \kappa^{+\omega}$ is a fixed point of j then every cardinal in the interval $[\beta, \kappa^{+\beta})$ is of the form $\beta^{+\alpha}$ for a fixed point α. Clause 3 then follows from the fact that $[\kappa, \kappa^{+\omega}) \cap \mathcal{C}_\kappa = \emptyset$. ⊣

Proposition 6.26 now follows from the fact that $j(\lambda) > \lambda$ and Claim 6.27. ⊣

6.8. The Matsubara-Shioya Theorem

Example 3.1 showed that the ideal of bounded sets on a regular cardinal κ is never precipitous. Matsubara and Shioya's theorem shows the analogous result for the minimal fine ideal on $[\lambda]^{<\kappa}$ where κ is a regular uncountable cardinal. The result is a corollary of an elegant general theorem that was discovered amazingly late in the study of ideals. The contents of this section are very similar to their paper [95].

6.28 Definition. Let I be a countably complete ideal on a set Z such that $P(Z)/I$ is non-atomic. Let

- $\pi(I)$ be the cardinality of the smallest I-positive set, and
- $\gamma(I)$ be the smallest cardinality of a set that generates I by taking finite unions and subsets.

It is an unpublished observation of Johnson that:

1. $\omega \leq \pi(I) \leq \gamma(I)$, and
2. if $\pi(I) = \gamma(I)$, then every I-positive set contains an I-positive set of cardinality $\pi(I)$.

To see the first clause, choose a set $\mathcal{G} \subseteq I$ of cardinality $\gamma(I)$ closed under finite unions that generates I. Then we can find a set $T = \{z_A : A \in \mathcal{G}\}$ such that for all $A \in \mathcal{G}$, $z \in Z \setminus A$. Then $T \notin I$, since otherwise there would be an $A \in \mathcal{G}$ such that $T \subseteq A$.

To see the second clause, fix an I-positive set S. Repeat the previous argument with respect to a generating family $\mathcal{G}'$ for $I \restriction S$ that has cardinality less than or equal to $\gamma(I)$. We get an I-positive $T \subseteq S$ of cardinality less than or equal to $|\mathcal{G}'|$. Since $\pi(I) \leq |T| \leq \gamma(I)$ and $\pi(I) = \gamma(I)$, we see $|T| = \pi(I)$.

6.29 Theorem (Matsubara-Shioya [95]). *If $\pi(I) = \gamma(I)$ then I is nowhere precipitous.*

We defer the proof of Theorem 6.29 until we state and prove some significant corollaries.

Recall from Example 3.1 the bounded ideal on $[\lambda]^{<\kappa}$, $I_{\kappa\lambda}$. We can also describe $I_{\kappa\lambda}$ as the smallest κ-complete, fine ideal on $P(\lambda)$.

6.30 Corollary. *Let $\kappa \leq \lambda$ and κ regular and uncountable. Then $I_{\kappa\lambda}$ is not precipitous.*

The corollary follows from Theorem 6.29 by observing that $\pi(I_{\kappa\lambda}) = \gamma(I_{\kappa\lambda})$ because they are both equal to the smallest cardinality of a subset $\mathcal{A}$ of $[\lambda]^{<\kappa}$ such that every element of $[\lambda]^{<\kappa}$ is covered by a set in $\mathcal{A}$.

Note as well that $\pi(I_{\kappa\lambda})$ has cofinality at least κ. Otherwise, let $\mathcal{A}$ be a covering subset of $[\lambda]^{<\kappa}$ of cardinality $\pi(I_{\kappa\lambda})$. Write $\mathcal{A} = \bigcup_{\alpha<\nu} A_\alpha$ where:

1. $|A_\alpha| < |A_{\alpha'}| < \pi(I_{\kappa\lambda})$ for $\alpha < \alpha'$,
2. each A_α is not a covering set, and
3. $\nu < \kappa$.

Then there is an $a_\alpha \in [\lambda]^{<\kappa}$ such that there is no element $b \in A_\alpha$ with $a_\alpha \subseteq b$. Since $\nu < \kappa$, the cardinality of $a = \bigcup_{\alpha<\nu} a_\alpha$ is less than κ and a is not covered by any element of $\mathcal{A}$, a contradiction.

Let the nonstationary ideal on λ restricted to $[\lambda]^{<\kappa}$ be denoted $\mathrm{NS}_{\kappa\lambda}$. Using the definition from Example 3.2 it is easy to verify that $\gamma(\mathrm{NS}_{\kappa\lambda}) \leq 2^\lambda$.

Moreover, any positive set for $\mathrm{NS}_{\kappa\lambda}$ is positive for $I_{\kappa\lambda}$, and hence $\pi(I_{\kappa\lambda}) \leq \pi(\mathrm{NS}_{\kappa\lambda})$. Thus if λ is singular of cofinality less than κ and $2^\lambda = \lambda^+$ the last three of the following inequalities are actually equalities:

$$\lambda < \pi(I_{\kappa\lambda}) \leq \pi(\mathrm{NS}_{\kappa\lambda}) \leq \gamma(\mathrm{NS}_{\kappa\lambda}) \leq 2^\lambda.$$

Thus we have:

6.31 Corollary. *Suppose that* $\mathrm{cf}(\lambda) < \kappa$ *and* $2^\lambda = \lambda^+$. *Then* $\mathrm{NS}_{\kappa\lambda}$ *is nowhere precipitous. In particular, if* GCH *holds then for all* n, $\mathrm{NS}_{\aleph_n\aleph_\omega}$ *is nowhere precipitous.*

Matsubara and Shioya draw several other corollaries including:

6.32 Corollary.

1. *If* $2^{<\kappa} < \lambda^{<\kappa} = 2^\lambda$ *then* $\mathrm{NS}_{\kappa\lambda}$ *is nowhere precipitous.*
2. *If* $\sup\{\mathrm{cf}(\prod a/U) : a \in [\lambda]^{<\kappa}$ *is a collection of regular cardinals greater than* κ, *and* U *is an ultrafilter on* $a\} = 2^\lambda$, *then* $\mathrm{NS}_{\kappa\lambda}$ *is nowhere precipitous.*
3. *If* $2^{\aleph_0} < \aleph_\omega^{\aleph_0}$ *then* $\mathrm{NS}_{\aleph_n\aleph_\omega}$ *is nowhere precipitous.*

Proof of Theorem 6.29. First note that it suffices to prove the following:

Claim. Let $\kappa = \pi(I) = \gamma(I)$. For all I-positive sets X and one-to-one functions $f : X \to \kappa$ there is an I-positive set $Y \subseteq X$ and a one-to-one function $g : Y \to \kappa$ such that for all $y \in Y$, $g(y) < f(y)$.

To see that the claim suffices, we suppose that $I\restriction A$ is precipitous. We use the claim to build maximal antichains $A_n \subseteq P(Z)/(I\restriction A)$ such that:

- A_{n+1} refines A_n,
- for each $a \in A_n$ we have a one-to-one function $f_a : a \to \kappa$, and
- if $a \in A_{n+1}$, $b \in A_n$ and $a \subseteq b$, then for all $y \in a$, $f_a(y) < f_b(y)$.

Then each sequence of functions $\langle f_a : a \in A_n\rangle$ determines a term for a function $F_n \in V^Z$ such that for all n, $1 \Vdash [F_{n+1}]^{\dot{M}} < [F_n]^{\dot{M}}$, where $\dot{M}$ is a term for the transitive model isomorphic to V^Z/G.

To see the claim: enumerate a generating set for I as $\langle J_\alpha : \alpha < \kappa\rangle$ and inductively choose a $y_\alpha \in X \setminus (J_\alpha \cup f^{-1}(\alpha+1) \cup \{y_\beta : \beta < \alpha\})$. Let $Y = \{y_\alpha : \alpha < \kappa\}$ and $g(y_\alpha) = \alpha$. ⊣

Matsubara and Shelah were able to extend Theorem 6.29 to show:

6.33 Theorem (Matsubara-Shelah [94]). *If* λ *is a strong singular limit cardinal and* $\kappa < \lambda$ *is regular, then* $\mathrm{NS}_{\kappa\lambda}$ *is nowhere precipitous.*

The proof fixes a continuous cofinal sequence $\langle \lambda_\alpha : \alpha \in \mathrm{cf}(\lambda)\rangle$ and uses pcf theory to reduce the issue to those λ_α with $\mathrm{cf}(\lambda_\alpha) < \kappa$. It then uses the proof of Theorem 6.29 to deal with these cardinals individually.

6.9. The Nonstationary Ideal on $[\lambda]^{<\kappa}$

In the previous section we saw that GCH implies that the nonstationary ideal on $[\lambda]^{<\kappa}$ is not precipitous in many cases, such as $[\aleph_\omega]^{<\omega_n}$. In this section we describe a result saying that the nonstationary ideal is never saturated unless $\kappa = \lambda = \omega_1$.

This problem was studied by Burke and Matsubara [14] who made substantial progress on it. The cases they left open were finished by Foreman and Magidor in [44].

6.34 Theorem. *Let κ be a regular cardinal. The nonstationary ideal on $[\lambda]^{<\kappa}$ is not λ^+-saturated unless $\kappa = \lambda = \omega_1$.*

We note that the statement that the nonstationary ideal on ω_1[56] is $\aleph_2$-saturated has a complicated history; see Sect. 8.

Theorem 6.34 is not a local statement. Gitik proved:

6.35 Theorem (Gitik [52]). *Suppose that there is a supercompact cardinal κ. Then there is a generic extension in which κ remains inaccessible and there is a set $S \subseteq \{z \in [\kappa^+]^{<\kappa} : \mathrm{ot}(z) = \mathrm{ot}(z \cap \kappa)^+\}$ such that the nonstationary ideal restricted to S is κ^+-saturated.*[57]

This was later improved by Krueger [75] to show that it is possible to have $\mathrm{NS}\restriction\{z \in [\kappa^+]^{<\kappa} : \mathrm{ot}(z) = \mathrm{ot}(z \cap \kappa)^+\}$ be κ^+-saturated.

Proof of Theorem 6.34. The proof splits into several cases depending on the properties of κ and λ. We discuss the proof in some of the cases and refer the reader to [44] for a complete proof.

Note that if $\kappa = \lambda$ then there is a stationary subset S of $[\lambda]^{<\kappa}$ such that $\mathrm{NS}\restriction S = \mathrm{NS}_\lambda$. For $\kappa = \lambda \neq \omega_1$, Theorem 6.14 implies that $\mathrm{NS}_{\kappa\lambda}$ is not λ^+-saturated. Hence we can assume that $\lambda > \kappa$.

Case 1. λ is a regular cardinal, and κ is a successor cardinal.

Suppose that $\kappa = \mu^+$ for some cardinal μ. Let $\eta = \mathrm{cf}(\mu)$. We claim that the nonstationary ideal on λ restricted to points of cofinality η is not λ^+-saturated.

We can see this from various theorems depending on what type of cardinal λ is. If λ is either the successor of a singular cardinal or weakly inaccessible we use Theorem 6.14. If λ is a successor of a regular cardinal then we use Corollary 6.11.

Let $\{T_\alpha : \alpha < \lambda^+\}$ be an antichain in $P(\lambda)/(\mathrm{NS}\restriction \mathrm{Cof}(\eta))$. Let $S_\alpha = \{N \in [\lambda]^{<\kappa} : \sup(N) \in T_\alpha\}$. Then each S_α is stationary and $\{S_\alpha : \alpha < \lambda^+\}$ forms an antichain in $P([\lambda]^{<\kappa})/\mathrm{NS}_{\kappa\lambda}$.

Case 2. $\kappa = \omega_1$ and $\lambda > \omega_1$.

[56] Or equivalently, the nonstationary ideal on $[\omega_1]^{<\omega_1}$.

[57] An alternate proof was given by Shioya [107].

Significant progress was made in this case by Donder and Matet as well as Shelah who showed the following $\diamondsuit$-principle under various cardinal arithmetic assumptions. The diamond principle was later shown to hold in ZFC by Shelah [106] using techniques similar to those in [44].

6.36 Definition. If $\lambda > \omega_1$ is a cardinal and $S \subseteq [\lambda]^{<\omega_1}$ is stationary, then $\diamondsuit_{\omega_1,\lambda}(S)$ asserts the existence of a sequence $\langle s_a \colon a \in [\lambda]^{<\omega_1}\rangle$ such that for all $A \subseteq \lambda$ the set $\{a \in S \colon s_a = A \cap a\}$ is stationary in $[\lambda]^{<\omega_1}$.

This principle immediately implies that the nonstationary ideal on $[\lambda]^{<\omega_1}$ is not 2^λ-saturated.

The original proof for the case of $\kappa = \omega_1$ is due to Foreman and Magidor [44] who developed the theory of mutually stationary sets:

6.37 Definition. Let K be a set of regular cardinals, and $\mathcal{S} = \langle S_\kappa : \kappa \in K\rangle$ be a sequence of sets such that $S_\kappa \subseteq \kappa$. Then the sequence $\mathcal{S}$ is called *mutually stationary* iff for all algebras $\mathfrak{A}$ on $\sup(K)$, there is an elementary substructure $N \prec \mathfrak{A}$ such that for all $\kappa \in K \cap N$, $\sup(N \cap \kappa) \in S_\kappa$.

Note that if the sequence $\mathcal{S}$ is mutually stationary, then in particular, each S_κ is stationary.

See [44] for the following facts:

1. Mutually stationary sequences remain mutually stationary under finite variations.[58]

2. If K is a collection of measurable cardinals then every sequence of stationary sets is mutually stationary.

3. (Welch) If $f : \omega \to \omega$ is a function that is not eventually constant and $S_n = \omega_n \cap \mathrm{Cof}(\omega_{f(n)})$ defines a mutually stationary sequence, then there is an inner model with a measurable cardinal. A weak converse has been proved by Liu and Shelah [87].

4. In L for all $k > 0$, there is a sequence of stationary sets $\mathcal{S} = \langle S_n : n > k\rangle$ such that $S_n \subseteq \omega_n \cap \mathrm{Cof}(\omega_k)$ is stationary but the sequence $\mathcal{S}$ is *not* mutually stationary.

5. In ZFC, if $\mathcal{S} = \langle S_\kappa : \kappa \in K\rangle$ is a sequence of stationary sets such that each $S_\kappa \subseteq \kappa \cap \mathrm{Cof}(\omega)$, then $\mathcal{S}$ is mutually stationary.

We use property 5, to settle case 2. If λ is regular, then case 2 follows from the first case.

If λ is singular, then we choose a cofinal sequence $\langle \lambda_\alpha : \alpha < \mathrm{cf}(\lambda)\rangle$ such that each λ_α is regular. By a theorem of Solovay (see [63]) we can partition $\lambda_\alpha \cap \mathrm{Cof}(\omega)$ into λ_α disjoint stationary sets $\{S^\alpha_\beta : \beta < \lambda_\alpha\}$.

By property 5, for each function $f \in \prod \lambda_\alpha$, the sequence $\mathcal{S}_f = \langle S^\alpha_{f(\alpha)} : \alpha < \mathrm{cf}(\lambda)\rangle$ is mutually stationary.

[58] Subject to a mild cofinality restriction.

In particular, for each $f \in \prod \lambda_\alpha$ if we let

$$T_f = \{N : \text{ for all } \alpha \in N, \ \sup(N \cap \lambda_\alpha) \in S^\alpha_{f(\alpha)}\},$$

then each T_f is stationary and for $f \neq g, T_f \cap T_g$ is not stationary. Since there are at least λ^+ such f, we get an antichain of cardinality λ^+.

Case 3. $\mathrm{cf}(\lambda) \geq \kappa$ and κ is a successor cardinal, or κ is weakly inaccessible and $\mathrm{cf}(\lambda) > \kappa$.

In this case Burke and Matsubara used Cummings' theorem (Theorem 6.13) to show that the nonstationary ideal on $[\lambda]^{<\kappa}$ is not saturated. For if it were, then forcing with $\mathbb{P} = P([\lambda]^{<\kappa})/\mathrm{NS}_{\kappa\lambda}$ would preserve stationary subsets of λ^+. Hence by Cummings' theorem, if $G \subseteq \mathbb{P}$ is generic then $V[G]$ satisfies "$\mathrm{cf}(\lambda) = \mathrm{cf}(|\lambda|)$". Hence the generic ultrapower M must satisfy "$\mathrm{cf}(\lambda) = \mathrm{cf}(|\lambda|)$" as well.

The following lemma is standard (see [4]):

6.38 Lemma. *Let κ and λ be cardinals with κ regular.*

1. *Suppose that $\mathrm{cf}(\lambda) > \kappa$, and μ, ν are regular cardinals less than κ. Let S_1 be the collection of x in $[\lambda]^{<\kappa}$ such that:*

   (a) $x \cap \kappa \in \kappa$,

   (b) $|x| = |x \cap \kappa|$,

   (c) $\mathrm{cf}(x \cap \kappa) = \mu$, *and*

   (d) $\mathrm{cf}(\sup(x)) = \nu$.

   Then S_1 is stationary.

2. *Suppose that $\kappa = \rho^+ \geq \omega_2$ and $\mathrm{cf}(\lambda) \geq \mathrm{cf}(\rho)$. Let S_2 be the set of x in $[\lambda]^{<\kappa}$ such that:*

   (a) $x \cap \kappa \in \kappa$,

   (b) $|x| = |x \cap \kappa|$, *and*

   (c) $\mathrm{cf}(x \cap \kappa) = \mathrm{cf}(\sup(x)) \neq \mathrm{cf}(\rho)$.

   Then S_2 is stationary.

Assuming the lemma we get an immediate contradiction to Cummings' theorem. If κ is a successor cardinal, we force with $P([\lambda]^{<\kappa})/\mathrm{NS}_{\kappa\lambda}$ below S_2. By Lemma 2.38, we see that in $V[G]$, $|\lambda| = \rho$, but $\mathrm{cf}(\lambda) \neq \mathrm{cf}(\rho)$, a contradiction.

If κ is weakly inaccessible and $\mathrm{cf}(\lambda) > \kappa$, then forcing below S_1 yields a model $V[G]$ satisfying "$|\lambda| = \kappa$" but $\mathrm{cf}(\lambda) \neq \mathrm{cf}(\kappa)$, again contradicting Cummings' theorem.

Case 4. $\mathrm{cf}(\lambda) < \kappa$.

In this case Burke and Matsubara showed that the nonstationary ideal on $[\lambda]^{<\kappa}$ is not λ^+-saturated, but it is shown in [44] that even more is true: the nonstationary ideal on $[\lambda]^{<\kappa}$ is not even λ^{++}-saturated.

By appealing to the Gitik-Shelah theorem one sees that there is a large antichain of stationary sets of approachable ordinals in λ^+ (see [43]). Via Shelah's pcf theory, such a set in the antichain can be used to code a stationary set in $[\lambda]^{<\kappa}$ through comparisons of characteristic functions and elements of a scale.

Case 5. κ is weakly inaccessible and $\mathrm{cf}(\lambda) = \kappa$.

This case is handled with an argument combining Shelah's "trichotomy" theorem in pcf theory with generic ultrapowers. $\dashv$

7. Consistency Results

In this section we discuss some consistency results for ideals. It is a trivial, but significant observation that classical large cardinals are special cases of ideal axioms; namely they are typically equivalent to the existence of normal, fine, prime ideals, or systems of such. One of the main techniques for proving consistency results is to take prime ideals on large cardinals and transform them, via forcing, into ideals on more accessible sets.

Most of these results rely on rather technical arguments involving iterated forcing and master conditions. As a result we will do no more than outline the deeper results. The reader is referred to Cummings' chapter in this Handbook for information about backwards Easton forcing. It is beyond the scope of this chapter to attempt to describe the intricate lore of constructing master conditions.

Trivial Master Conditions

We will use the following lemma which describes the situation where no master condition is needed:

7.1 Lemma. *Suppose that $j : V \to M \subseteq V[G]$ is a generic elementary embedding with critical point κ, where $G \subseteq \mathbb{Q}$ is generic. Let $\mathbb{P} \in V$ be a κ-c.c. partial ordering. Then for all M-generic $\hat{H} \subseteq j(\mathbb{P})$ the filter $H = \{p : j(p) \in \hat{H}\} \subseteq \mathbb{P}$ is V-generic.*

If $H \subseteq \mathbb{P}$ is V-generic then one can force over $V[H]$ to produce a $V[G]$-generic $\hat{H} \subseteq j(\mathbb{P})$ such that j extends to an elementary embedding

$$\hat{j} : V[H] \to M[\hat{H}] \subseteq V[G * \hat{H}].$$

Proof. Let $\hat{H}$ be generic over M. For all maximal antichains $\mathcal{A} \subseteq \mathbb{P}$ lying in V, we know that $|\mathcal{A}| < \kappa$. Hence $j(\mathcal{A}) = j``\mathcal{A}$. Since $\hat{H} \cap j(\mathcal{A}) \neq \emptyset$ there is a $p \in \mathcal{A}$ with $j(p) \in \hat{H}$. Hence $H \cap \mathcal{A} \neq \emptyset$, and so H is generic.

The proof shows that in $V[G]$ the map $j\restriction\mathbb{P}$ sends V-maximal antichains $\mathcal{A}\subseteq\mathbb{P}$ to M-maximal antichains $j(\mathcal{A})\subseteq j(\mathbb{P})$. Hence if we force over $V[G]$ to get a generic H, then there is a further forcing $\mathbb{R}$ to get a $V[G]$ generic $\hat{H}\subseteq j(\mathbb{P})$ with $j``H\subseteq\hat{H}$. This can be summarized by the formula:

$$\mathbb{Q}*j(\mathbb{P})\sim(\mathbb{Q}*\mathbb{P})*\mathbb{R}.$$

Since both $\mathbb{P}$ and $\mathbb{Q}$ lie in V, the product lemma tells us that $\mathbb{Q}*\mathbb{P}\sim\mathbb{Q}\times\mathbb{P}\sim\mathbb{P}*\mathbb{Q}$. Rearranging the terms, we see that if $H\subseteq\mathbb{P}$ is generic, then forcing over $V[H]$ with $\mathbb{Q}*\mathbb{R}$ produces both G and $\hat{H}$ with the property that for all $p\in\mathbb{P}$, $p\in H$ iff $j(p)\in\hat{H}$.

Define a map $\hat{j}$ by setting $\hat{j}(\tau^{V[H]})=j(\tau)^{M[\hat{H}]}$. That $\hat{j}$ is well-defined and elementary follows from the fact that $j``H\subseteq\hat{H}$. ⊣

The Basic Idea

We here avail ourselves of the notation and discussion in Sect. 3, referring to ideal elements, master conditions, $U(j,i)$ and induced ideals, and so forth. For most of the results in this section we will be in the situation described by Example 3.37. We suggest the reader reread that example before proceeding.

Let $\mathbb{Q}$ be a partial order. We extend our notation slightly to write $\mathbb{Q}/H$ for an arbitrary subset $H\subseteq\mathbb{Q}$ to mean the structure with domain $\{q\in\mathbb{Q}:$ for all $h\in H$, q is compatible with $h\}$, and the relation $\leq_{\mathbb{Q}}$. For $p\in\mathbb{Q}$ we write $\mathbb{Q}/p$ for $\mathbb{Q}/\{p\}$.

Hence if $j:V\to M$ is elementary, $\mathbb{P}\in V$ and $G\subseteq\mathbb{P}$, then the conditions in $j(\mathbb{P})/j``G$ that are compatible with a condition $m$ will be written $j(\mathbb{P})/(j``G\cup\{m\})$. If $H\subseteq\mathbb{Q}$ is a finite set, then forcing with the ordering $\mathbb{Q}/H$ is equivalent to forcing with $\{q\in\mathbb{Q}:$ for all $h\in H$, $q\leq_{\mathbb{Q}}h\}$.

If $m\in j(\mathbb{P})$ is a master condition and $\hat{G}\subseteq j(\mathbb{P})/m$ is V-generic, then $\{p:j(p)\in\hat{G}\}\subseteq\mathbb{P}$ is V-generic. Hence there is a $p\in\mathbb{P}$ such that the restriction of j to $\mathbb{P}/p$ is a regular embedding from $\mathbb{P}/p$ to $j(\mathbb{P})/\{p,m\}$.

A typical construction in this section will start with an elementary embedding $j:V\to M$ that has critical point κ and choose an ideal object $i\in M$. We will force with a partial ordering $\mathbb{P}$ and find a master condition $m\in j(\mathbb{P})/j``G$ where $G\subseteq\mathbb{P}$ is generic. If $\hat{G}\subseteq j(\mathbb{P})/(j``G\cup\{m\})$ is generic then we can extend j to $\hat{j}:V[G]\to M[\hat{G}]$. If Z is such that $m\Vdash_{j(\mathbb{P})/j``G} i\in j(Z)$ then, as in Example 3.37 applied to the partial ordering consisting of the collection of conditions in $j(\mathbb{P})/j``G$ that lie below m, we get an ideal $I\subseteq P(Z)$ that depends on $\hat{j},i$ and m for its definition.

Let $\mathcal{B}$ be the completion of $j(\mathbb{P})/(j``G\cup\{m\})$. Then we get an order and antichain preserving embedding:

$$\iota:P(Z)/I\to\mathcal{B}$$

defined by setting $\iota([X])=\|i\in j(X)\|$.

As a consequence, if $\mathcal{B}$ has the γ-c.c. then I is γ-saturated. Moreover if ι maps $P(Z)/I$ onto a dense subset of $\mathcal{B}$ or simply takes maximal antichains to maximal antichains, then the canonical ultrafilter $U(\hat{j}, i)$ defined by setting $X \in U(\hat{j}, i)$ iff $i \in \hat{j}(X)$ is generic for the partial ordering $P(Z)/I$.

Let $k : V^Z/U(\hat{j}, i) \to M$ be defined by setting $k([g]) = j(g)(i)$. Since the diagram:

$$\begin{tikzcd} & V \arrow[dl] \arrow[dr, "\hat{j}"] & \\ V^Z/U(\hat{j}, i) \arrow[rr, "k"'] & & M \end{tikzcd}$$

commutes, we see that $V^Z/U(\hat{j}, i)$ is well-founded. If ι takes maximal antichains to maximal antichains, the ultrafilter $U(\hat{j}, i)$ is generic for $P(Z)/I$. Hence there is a condition $A \in P(Z)/I$ that forces "if $U \subseteq P(Z)/I$ is generic then V^Z/U is well-founded". Thus $I \restriction A$ is precipitous.

If we know that the range of ι is dense in $\mathcal{B}$ then forcing with $P(Z)/I$ is the same as forcing with $j(\mathbb{P})/(j``G \cup \{m\})$. In this case we have an exact description of the quotient algebra of the ideal. In Sect. 7.4 we give a general method for computing the quotient algebras $P(Z)/I$.

7.2 Remark. We note the close connection with proper forcing ideas. The notion of a "generic" condition in proper forcing is exactly the same as what we are calling a "master condition". The difference in context is that proper forcing deals with the specific case that $\kappa = \omega_1$ and the elementary embedding involved comes from reflection, rather than extension.[59] Corollary 7.18 also illustrates the connection.

The next example gives the simplest mechanism for getting saturated ideals.

7.3 Example. Let κ be measurable and $j : V \to M$ be the elementary embedding induced by an ultrapower by a κ-complete ultrafilter U on κ. If $\mathbb{P}$ is the partial ordering for adding Cohen or random reals, then $\mathbb{P}$ has the c.c.c., and hence the empty condition is a master condition. By the remarks above the ideal induced by j using κ as the ideal element is precipitous and has the c.c.c. In particular, it has the disjointing property.

Solovay [111] proved that adding κ random reals to a measurable cardinal makes κ real-valued measurable, i.e. there is a countably complete probability measure defined on all subsets of κ. In this model $\kappa = 2^{\aleph_0}$, and the ideal of null sets for the measure is c.c.c. and hence precipitous.

Note that this example generalizes quite easily to get generically supercompact, and huge elementary embeddings. Namely, if j is λ-supercompact (or huge, with $j(\kappa) = \lambda$) then we choose the ideal element to be $j``\lambda$ and Z to be either $[\lambda]^{<\kappa}$ (or $[\lambda]^{\kappa}$) and argue in exactly the same way to get a normal, fine, countably complete c.c.c. ideal on $[\lambda]^{<\kappa}$ (or $[\lambda]^{\kappa}$).

59 See the discussion around Definition 3.43.

7.1. Precipitous Ideals on Accessible Cardinals

Let κ be a measurable cardinal. Let $j : V \to M$ be the ultrapower of V by a κ-complete ultrafilter U on κ. Let $\mathbb{P} = \mathrm{Col}(\omega, {<}\kappa)$. Let $G \subseteq \mathbb{P}$ be generic. Since $\mathbb{P}$ is κ-c.c., if $H \subseteq j(\mathbb{P})/G$ is an arbitrary generic filter, then j can be extended to $\hat{j} : V[G] \to M[H]$. Hence we can take the empty condition in $j(\mathbb{P})/j``G$ to be a master condition and, working in $V[G]$, define an ideal I as above using $\hat{j}$ and $i = \kappa$ as the ideal element. Then in $V[G]$, I is a precipitous ideal on ω_1. More generally:

7.4 Theorem. *Suppose that κ is a measurable cardinal. If $\nu < \kappa$ is a regular cardinal and $G \subseteq \mathrm{Col}(\nu, {<}\kappa)$ is generic, then there is a precipitous ideal on ν^+ in $V[G]$.*

As a corollary we get the following theorem:

7.5 Corollary (Jech et al. [65]). *Suppose that it is consistent that there is a measurable cardinal. Then it is consistent that there is a precipitous ideal on ω_1.*

Proof of Theorem 7.4. We show that the map ι maps $(P(\kappa)/I)^{V[G]}$ to a dense subset of $j(\mathbb{P})/G$. This suffices, since it shows that the ultrafilter $U(\hat{j}, \kappa)$ is generic for the forcing $P(\kappa)/I$ and as we argued above, the ultrapower $V^\kappa/U(\hat{j}, \kappa)$ embeds into M and hence is well-founded.

Let $p \in j(\mathbb{P})/G$. Then there is a function $f : \kappa \to \mathbb{P}$ lying in V such that $\hat{j}(f)(\kappa) = p$.

Working in $V[G]$, let $X = \{\alpha : f(\alpha) \in G\}$. Then $X \in U(\hat{j}, i)$ iff $\kappa \in \hat{j}(X)$ iff $\hat{j}(f)(\kappa) \in H$. But $j(f)(\kappa) = p$. Hence $\iota(X) = p$, and we have established the theorem. ⊣

With some extra work one can show that the ideal I defined in the proof of Theorem 7.4 is exactly the ideal generated in $V[G]$ by the dual of U.

The argument above is an example of a more general phenomenon explored in the Duality Theorem and a special case, Proposition 7.13. The latter immediately implies:

7.6 Theorem (Laver[60]). *Let κ be a measurable cardinal, and $\nu < \kappa$ be regular. If $G \subseteq \mathrm{Col}(\nu, {<}\kappa)$ is generic, then in $V[G]$ there is a κ-complete, normal, precipitous ideal I such that $P(\kappa)/I$ has a ${<}\nu$-closed dense subset.*

The main point of the argument above is that the set Z and the ideal element i generating the ideal are chosen to be the same as those for the original large cardinal embedding. Thus with minor variations, one can check that if I is a master condition ideal generated by an ideal element $j``\lambda$ over an ultrapower of $V$ by a ultrafilter on $[\lambda]^{<\kappa}$, then $I$ is precipitous and $P([\lambda]^{<\kappa})/I$ is isomorphic to the quotient forcing for $j(\mathbb{P})/(j``G \cup \{m\})$.

---

[60] It is remarked in [50] that this was proved independently by Galvin, Jech and Magidor.

The following example, discovered independently by Laver and the author, and used fruitfully by Laver in [85], partially illustrates the close connection between ideals and proper forcing.

7.7 Example. Let κ be supercompact, and let $G \subseteq \mathrm{Col}(\omega, {<}\kappa)$ be generic. Let $\lambda > \kappa$ be a regular cardinal and $j : V \to M$ be a λ-supercompact embedding. Then for all generic $H \subseteq \mathrm{Col}(\omega, j(\kappa) \setminus \kappa)$ there is an elementary embedding $\hat{j} : V[G] \to M[G, H]$.

Let $\mathbb{P}$ be a proper partial ordering in $V[G]$, and suppose that we take $\lambda \geq (2^{|\mathbb{P}|})^+$. Then in $M[G, H]$:

1. $j(\mathbb{P})$ is proper, and
2. $j``H(\lambda)$ is countable.

So by properness, in $M[G, H]$, there is a "generic" condition m for $j``H(\lambda)$. From the point of view of $V[G]$ the condition m is a master condition for the forcing $\mathbb{P}$ with respect to the embedding j. If $G^* \subseteq \mathbb{P}$ is generic and compatible with m, then in $V[G * G^*]$ there is a precipitous ideal I on $[\lambda]^{<\kappa} = Z$ such that the quotient algebra $P(Z)/I$ is isomorphic to $\mathrm{Col}(\omega, j(\kappa) \setminus \kappa) * j(\mathbb{P})/(j``G^* \cup \{m\})$.

In particular, if there is a single condition m in $j(\mathbb{P})$ below every element of $j``G^*$ then the quotient algebra is isomorphic to the Levy collapse followed by forcing with $j(\mathbb{P})$ below m.

7.2. Strong Master Conditions

In this section we briefly describe the construction of non-trivial master conditions. This topic is covered in depth in Cummings' chapter in the Handbook. The first use of this technique was due to Silver who showed that it was consistent for GCH to fail at a measurable cardinal, provided the existence of a supercompact cardinal is consistent.

In a typical situation, we are given an elementary embedding $j : V \to M$ that is closed under λ-sequences for some cardinal $\lambda \geq \kappa$. We will force with a partial ordering of the form $\mathbb{P} * \mathbb{Q}$ where $\mathbb{P}$ is κ-c.c. and $|\mathbb{Q}| \leq \lambda$. The result will be a generic filter of the form $G * H \subseteq \mathbb{P} * \mathbb{Q}$. To extend the embedding j we must find a generic $\hat{G} * \hat{H} \subseteq j(\mathbb{P} * \mathbb{Q})$ such that for all $(p, \dot{q}) \in \mathbb{P} * \mathbb{Q}$, $(p, \dot{q}) \in G * H$ iff $(j(p), j(\dot{q})) \in \hat{G} * \hat{H}$.

Since $\mathbb{P}$ has the κ-c.c. this is automatic for $p \in \mathbb{P}$ and $G, \hat{G}$. If one can arrange that the generic object $H \subseteq \mathbb{Q}$ lies in $M[\hat{G}]$, then it is frequently possible to construct a condition m such that for all $\dot{q} \in H$, $M[\hat{G}] \models m \leq j(\dot{q})$. Such an m is called a *strong master condition*. Forcing with $j(\hat{\mathbb{Q}})$ below m then gives an $\hat{H}$ with the requisite properties.

H can often be constructed in $V^{j(\mathbb{P})}$ because $\mathbb{P}$ is a sufficiently strong Levy collapse that $\mathbb{Q}$ is embedded in $j(\mathbb{P})/G$. If $j(\mathbb{Q})$ is ${<}\lambda^+$-directed-closed then in $M[G]$ the desired condition m is defined by taking a condition below $\bigcup j``H$.

There are examples when $\bigcup j``H$ is a condition in $j(\mathbb{Q})$ even without $<\lambda^+$-closure due to the geometry of the conditions in $\mathbb{Q}$. This is the reason for forcing with the Silver collapse, rather than the Levy collapse in many models given below.

7.3. Precipitousness is not Preserved Under Projections

In this subsection we outline a result of Laver that illustrates two interesting points: that not every master condition ideal is precipitous and that projection maps do not preserve the property of being precipitous. Gitik has very recently given an example of a precipitous ideal on a regular cardinal whose canonical projection to a normal ideal is not precipitous.

7.8 Theorem (Laver). *Suppose that it is consistent that there to be a supercompact cardinal. Then it is consistent that:*

1. *There is a master condition ideal on ω_1 that is not precipitous.*
2. *There is a precipitous ideal on $[\omega_2]^{<\omega_1}$ whose projection to ω_1 is not precipitous.*

Proof (Sketch). A basic building block for Laver's partial construction is a version of Heckler forcing. It is a partial ordering D designed to add a generic function $f : \omega_1 \to \omega_1$ that dominates every ground model function. Conditions in D are ordered pairs (g, s) where $g : \omega_1 \to \omega_1$ and s is a countable approximation to f. The ordering on D is given by taking (g, s) to be stronger than (h, t) iff g eventually dominates h and $s \supseteq t$. Assuming the CH, this partial ordering is $\aleph_2$-c.c. and countably closed.

Let $j : V \to M$ be a λ-supercompact embedding where $\kappa = \mathrm{crit}(j)$ and $\lambda = \kappa^+$. Let

$$\mathbb{P} = \mathrm{Col}(\omega, <\kappa) * \prod_{\alpha<\lambda}^{\text{ctbl sppt}} D_\alpha,$$

where each D_α is a copy of the partial ordering D defined in $V^{\mathrm{Col}(\omega,<\kappa)}$ and the product is taken with countable supports. It is routine to check that $\mathbb{P}$ has cardinality λ, is λ-c.c. and belongs to M.

- There is a regular embedding $e : \mathbb{P} \to \mathrm{Col}(\omega, <j(\kappa))$ that lies in M such that the restriction of e to $\mathrm{Col}(\omega, <\kappa)$ is the identity map. If $\hat{G} \subseteq \mathrm{Col}(\omega, <j(\kappa))$ is generic over V then in M, we can build a V-generic object $G*H \subseteq \mathrm{Col}(\omega, <\kappa)*\prod_{\alpha<\lambda}^{\text{ctbl sppt}} D_\alpha$. In the model $V[G*H]$ we note that $\kappa = \omega_1$ and $\lambda = \omega_2$.
- By the κ-c.c. of $\mathrm{Col}(\omega, <\kappa)$ there is an extension of j to $j_1 : V[G] \to M[\hat{G}]$, and by the supercompactness of j, $j_1``H \in M[\hat{G}]$. Since $j_1``H$ is countable, we can form the master condition $m = \bigcup j_1``H \in j_1(\prod_{\alpha<\lambda}^{\text{ctbl sppt}} D_\alpha)$. Forcing with $j_1(\prod_{\alpha<\lambda}^{\text{ctbl sppt}} D_\alpha)$ below m we get an $\hat{H}$ and an elementary embedding $\hat{j} : V[G * H] \to M[\hat{G} * \hat{H}]$.

- Arguing as in the discussion before Remark 7.2[61] the ideal J on $[\omega_2]^{<\omega_1}$ induced by $\hat{j}$ and j“λ is precipitous in the model $V[G * H]$. We now show that the projection of this ideal to ω_1 is *not* precipitous. Note that the projected ideal I on ω_1 is the ideal induced by j and $i = \omega_1$.

- Let f_α be the generic function determined by D_α. To show that this ideal is not precipitous it suffices to show that for all $\alpha < \omega_2$ and all I-positive sets X, there is an I-positive set $Y \subseteq X$ and a $\beta < \omega_2$ such that $f_\beta(\delta)$ is less than $f_\alpha(\delta)$ for all $\delta \in Y$. This allows one to construct terms for a decreasing sequence of functions in the generic ultrapower.

- For this latter statement, it suffices to show that for all $X \in I^+$, and all f_α, there is a condition $q \in j(\prod_{\alpha<\lambda}^{\text{ctbl sppt}} D_\alpha)$ below m and a β such that q forces that $\kappa \in \hat{j}(X)$ and $\hat{j}(f_\alpha)(\kappa) > \hat{j}(f_\beta)(\kappa)$.

- Note that each $X \subseteq \omega_1$ in $V[G * H]$ is in $V[G * (H \cap \prod_A^{\text{ctbl sppt}} D_\alpha)]$ for some $A \subseteq (\omega_2)^{V[G*H]}$ of cardinality $\omega_1^{V[G*H]}$. Without loss of generality we can assume that $A = \omega_1^{V[G*H]} = \kappa$.

- All of the conditions involved in deciding $\|\kappa \in j(X)\|$ are in the product of the first $j(\kappa)$ coordinates. Hence, if $\beta \notin \omega_1$, then we can extend the condition m to an m_1 that decides $j(f_\beta)(\kappa)$ to be any value that is above $\sup\{j(g)(\kappa) : g \in \kappa^\kappa \cap V[G]\}$, without affecting the truth value of $\|\kappa \in j(X)\|$.

- Thus we will be done if we can show that for all sets $X \in I^+$ and all $\alpha < \kappa^+$ and all $\theta < j(\kappa)$ there is an extension q of m belonging to $j(\prod_{\alpha<\lambda}^{\text{ctbl sppt}} D_\alpha)$ such that q forces $\kappa \in j(X)$ and $j(f_\alpha)(\kappa) \geq \theta$.

The latter point uses a delicate reflection argument to show that any such bound θ can be taken to be of the form $j(g)(\kappa)$ for some function $g \in \kappa^\kappa \cap V$, and “works” relative to an auxiliary embedding j_κ also determined by a function with domain κ that lies in the ground model. The two embeddings j and j_κ then can be simultaneously extended, but the function $j(f_\alpha)$ eventually dominates g, yielding a contradiction. The reader is referred to [85] for details. $\dashv$

7.4. Computing Quotient Algebras and Preserving Strong Ideals under Generic Extensions

Many generic embeddings are constructed by taking standard large cardinal embeddings and modifying them by forcing. Since the nature of the forcing is one of the three parameters of the strength of a generic embedding, characterizing it is a fundamental problem. Indeed most consistency results about

[61] Or applying Proposition 7.13.

ideals explicitly refer to properties, such as saturation, of the quotient algebras $P(Z)/I$. Thus it is desirable to have a general method for computing exactly what the quotient algebra is.

Such a general method must necessarily be abstract. Formulating it requires a balance between retaining its generality and keeping it concrete enough for actual use in consistency arguments. Three results of this type are given here. Proposition 7.13 is the most concrete and easy to use. It covers many common cases, but does not directly apply in several important arguments. In the author's view, the Duality Theorem (Theorem 7.14) gives the best balance. It is completely general in the case that master conditions exist, is easy to use and has many standard theorems as consequences. Theorem 7.30 and the discussion that follows it give completely general results. At the moment, they have only been applied in fairly exotic situations.

A related topic of current interest is the preservation of various axioms under generic extensions. In the context of generalized large cardinals this can be viewed as calculating the quotient algebra of a generic embedding after forcing. Hence the Duality Theorem has corollaries about the preservation properties of ideals under fairly general circumstances. As corollaries we deduce theorems of Kakuda [66], Baumgartner-Taylor [6], and Laver [83].

We only give a brief tour of the known results. The proofs appear in [30].

Preservation of Normality and a Warm-Up Theorem

We start with some basic remarks about ideals in generic extensions. Let $\mathbb{P}$ be a partial ordering and J an ideal on Z for some $Z \subseteq P(X)$. If $H \subseteq \mathbb{P}$ is generic we will denote the ideal generated by J in $V[H]$ by $\bar{J}$. Thus for $W \subseteq Z$ and $W \in V[H]$ we have $W \in \bar{J}$ iff there is a $Y \in J$ such that $W \subseteq Y$. Note that with this definition it is a triviality that $\bar{J} \cap P(Z)^V = J$. For shorthand, if $\mathbb{P}$ and H are clear from context we will denote $P(Z)^{V[H]}$ by $\overline{P(Z)}$.

The next observation is standard:

7.9 Proposition. *Suppose that J is a κ-complete ideal on Z and $\mathbb{P}$ is a κ-c.c. partial ordering. Then for all generic $H \subseteq \mathbb{P}$, $\bar{J}$ is a κ-complete ideal in $V[H]$. Moreover, if J is also normal then $\bar{J}$ is normal in $V[H]$.*

Prior to a discussion of calculating quotients of the closure of an ideal after forcing, there is the more basic question about whether the closure remains normal. The next result is a general criterion for the preservation of normality of an ideal J under a generic extension. Note the close resemblance to definitions used in proper forcing.

7.10 Lemma. *Suppose that J is a normal, fine, κ-complete ideal on $Z \subseteq P(X)$, $\mathbb{P}$ is a $|X|^+$-c.c. partial ordering and θ is a regular cardinal sufficiently large so that $X, Z, \mathbb{P} \in H(\theta)$. Let $H \subseteq \mathbb{P}$ be generic. Then for $L \in P(Z)^{V[H]}$, the following are equivalent:*

1. *$\bar{J}\restriction L$ is normal, fine and κ-complete.*

2. *For all algebras $\mathfrak{A} \in V[H]$ on $H(\theta)^V$, $\{z \in Z : H$ is generic over $\mathrm{Sk}^{\mathfrak{A}}(z)\}$ is in the dual of $\bar{J}\restriction L$.*[62]

3. *For all algebras $\mathfrak{A} \in V$ on $H(\theta)^V$, $\{z \in Z : H$ is generic over $\mathrm{Sk}^{\mathfrak{A}}(z)\}$ is in the dual of $\bar{J}\restriction L$.*

In the case that we have an ideal J on a set $Z \subseteq P(X)$ and a partial ordering $\mathbb{P}$ that is not $|X|^+$-c.c. Lemma 7.10 can be applied to the nonstationary ideal I on $H(\gamma)$ conditioned[63] on J for some γ such that $\mathbb{P}$ is γ^+-c.c. After forcing with $\mathbb{P}$, the projection of $\bar{I}$ is $\bar{J}$. Thus the question of preservation of the normality of J can be reduced to the question of the preservation of the normality of the conditional nonstationary ideal. In this way, Lemma 7.10 gives an almost complete answer to the question of preservation of normality under forcing.

The following example shows that Lemma 7.10 has content.

7.11 Example. Let U be a supercompact ultrafilter on $[\kappa^+]^{<\kappa}$. Let $J = \breve{U}$ Then J is a 2-saturated, normal, fine ideal on $[\kappa^+]^{<\kappa} = Z \subseteq P(X)$, where $X = \kappa^+$. Let $\mathbb{P} = \mathrm{Col}(\kappa, \kappa^+)$. Then $|\mathbb{P}| \leq |X|$. Let $H \subseteq \mathbb{P}$ be generic. Then in $V[H]$, $\bar{J}$ is κ-complete. However, $\{x : |x \cap \kappa| < |x|\} \in U$, but $\{x : |x \cap \kappa| = |x|\} \in \breve{I}$ for all normal, fine, κ-complete ideals I on Z in $V[H]$. Hence $\bar{J}$ is not normal in $V[H]$.

The next proposition partially describes when forcing with $\mathbb{P}$ preserves maximal antichains in $P(Z)/J$, an approximation to characterizing the forcing $P(Z)^{V^{\mathbb{P}}}/\bar{J}$.

7.12 Proposition. *Suppose that J is a normal, fine, countably complete ideal on $Z \subseteq P(X)$ and $\mathbb{P}$ is a partial ordering such that $1 \Vdash \bar{J}$ is normal. Suppose that either:*

1. *J is $|X|^+$-saturated in V, or*

2. *$|\mathbb{P}| \leq |X|$.*

Then if $\mathcal{A} \subseteq P(Z)/J$ is a maximal antichain in V, then $\mathcal{A} \subseteq P(Z)^{V[H]}/\bar{J}$ is a maximal antichain in $V[H]$. In particular, if $\bar{J}$ is precipitous in $V[H]$, then J is precipitous in V.

Note that this proposition does *not* say that in $V^{\mathbb{P}}$, the identity map from $P(Z)/J$ to $P(Z)^{V^{\mathbb{P}}}/\bar{J}$ is a regular embedding (see Corollary 7.26).

Here is a warm-up for the full Duality Theorem. The warm-up is often easier to apply, though much less general:

[62] Recall that H is generic over $N \prec H(\theta)$ iff for all maximal antichains $\mathcal{A} \in N, H \cap \mathcal{A} \cap N \neq \emptyset$.

[63] See Definition 4.19.

7.13 Proposition. *Suppose that $\mathbb{Q}$ is a partial ordering, and $Z \subseteq P(X)$ is such that for all generic $H \subseteq \mathbb{Q}$ there is a V-normal, V-κ-complete ultrafilter U on $P(Z)^V$ belonging to $V[H]$ such that:*

1. *V^Z/U is well-founded, and*
2. *there are functions $h, Q, \{f_q : q \in \mathbb{Q}\}$ in V such that for all generic $H \subseteq \mathbb{Q}$, if M is the transitive collapse of V^Z/U, then $[Q]^M = \mathbb{Q}$, $[h]^M = H$ and for all $q \in \mathbb{Q}$, $[f_q]^M = q$.*

In V, let $J = \{A \subseteq Z : \|A \in \dot{U}\|_{\mathbb{Q}} = 0\}$. Then J is normal, fine, κ-complete and precipitous and $\mathcal{B}(P(Z)/J) \cong \mathcal{B}(\mathbb{Q})$.

The isomorphism defined in Proposition 7.13 maps $[X] \in P(Z)/J$ to $\|X \in \dot{U}\|_{\mathbb{Q}}$. To see that this maps onto a dense set, let $q \in \mathbb{Q}$. Then $A = \{z : f_q(z) \in h(z)\}$ gets sent to q.

When Master Conditions Exist

For the rest of the subsection we will have a precipitous ideal J on Z for some set Z and a partial ordering $\mathbb{P}$. As usual we will consider a generic $G \subseteq P(Z)/J$ and the associated elementary embedding $j : V \to V^Z/G \cong M \subseteq V[G]$, where M is transitive. We explicitly *include* the case where J is a prime ideal.[64]

We are interested in calculating the quotient algebra of the ideal $\bar{J}$ after forcing with $\mathbb{P}$ provided that it still yields a generic elementary embedding. In most situations this is equivalent to the existence of a master condition m. We now make that equivalence explicit. For the general situation we refer the reader to Theorem 7.30 and the remarks after it.

We will consider the partial ordering $j(\mathbb{P})$ in M and force with it over $V[G]$ to get an $\hat{H}$. If $m \Vdash^{V[G]}_{j(\mathbb{P})} j^{-1}(\hat{H}) \subseteq \mathbb{P}$ is generic, then there is a condition $q \in \mathbb{P}$ such that $q \Vdash^V_{\mathbb{P}}$ "j"$H \cup \{m\}$ can be generically extended to a generic $\hat{H} \subseteq j(\mathbb{P})$". Then j is a regular embedding from $\mathbb{P}/q$ to $j(\mathbb{P})/(m \wedge j(q))$. Replacing the original $\mathbb{P}$ by the conditions in $\mathbb{P}$ below q we can see that $j : \mathbb{P} \to j(\mathbb{P})/m$ is a regular embedding in $V[G]$.

Summarizing: if $\mathbb{P}$ is a partial ordering in V such that for all generic $G \times H \subseteq P(Z)/J \times \mathbb{P}$ there is a $V[G]$-generic $\hat{H}$ such that the embedding $j : V \to M \subseteq V[G]$ induced by the ultrapower can be extended to an embedding:

$$\hat{j} : V[H] \to M[\hat{H}]$$

[64] This is the situation where j is a conventional large cardinal embedding. In this case the "generic" G is trivial.

then there is a condition $\dot{m} \in j(\mathbb{P})$ such that

$$\mathrm{id} \times \dot{j} : P(Z)/J \times \mathbb{P} \to P(Z)/J * j(\mathbb{P})/m,$$

is a regular embedding.[65]

This is exactly the main hypothesis of the next theorem, which is due to the author, and says that forcing with $\mathbb{P} * P(Z)/\bar{J}$ is equivalent to forcing with $P(Z)/J * j(\mathbb{P})$.

The Duality Theorem and Its Consequences

7.14 Theorem (The Duality Theorem; Foreman [30]). *Suppose that there is a condition $\dot{m} \in j(\mathbb{P})$ such that the embedding*

$$\mathrm{id} \times \dot{j} : P(Z)/J \times \mathbb{P} \to P(Z)/J * j(\mathbb{P})/m$$

is a regular embedding. Then there are conditions $p \in P(Z)/J * j(\mathbb{P})$ and $q \in \mathbb{P} * P(Z)/\bar{J}$ such that:

$$(\mathbb{P} * P(Z)/\bar{J})/q \sim (P(Z)/J * j(\mathbb{P}))/p.$$

7.15 Remark. We can make the Duality Theorem more explicit. Under the hypotheses of the Duality Theorem, if $[A] \in P(Z)/J$ is such that $[A] \Vdash_{P(Z)/J} m = [f]$ and $\mathcal{M} \in V^{\mathbb{P}}$ is defined as $\{z \in A : f(z) \in H\}$ (where $H \subseteq \mathbb{P}$ is the generic object), then there is a canonical isomorphism ι witnessing:

$$\mathcal{B}(\mathbb{P} * P(Z)/(\bar{J}\restriction\mathcal{M})) \cong \mathcal{B}(P(Z)/(J\restriction A) * j(\mathbb{P})/m).$$

We now reduce several other theorems to the duality theorem:

7.16 Corollary. *Suppose that J is a precipitous ideal on $Z \subseteq P(X)$ and $\mathbb{P}$ is a partial ordering satisfying the hypotheses of Theorem 7.14. Then for all generic $H \subseteq \mathbb{P}$ there is a set $\mathcal{M}$ such that $\bar{J}\restriction\mathcal{M}$ is precipitous.*

Proof. For $V[H]$-generic $\bar{G} \subseteq P(Z)/(\bar{J}\restriction\mathcal{M})$, we get a generic object $G * \hat{H}$ for $P(Z)/J * j(\mathbb{P})$ such that $j``H \subseteq \hat{H}$. Hence there is an elementary embedding $\hat{j} : V[H] \to M[\hat{H}]$. Moreover $\bar{G} = \{A \subseteq Z : A \in V[H]$ and $[\mathrm{id}]^M \in \hat{j}(A)\}$. In particular, the ultrapower $V^Z/\bar{G}$ (taken in $V[H]$, using functions from $V[H]$) is well-founded for all generic $\bar{G}$. Hence $\bar{J}$ is precipitous. ⊣

A special case of this is the following result that was discovered independently by Magidor:

7.17 Corollary (Kakuda's Theorem [66]). *Suppose that $\mathbb{P}$ is a κ-c.c. partial ordering on κ and that J is a κ-complete precipitous ideal. Then $\bar{J}$ is precipitous in $V^{\mathbb{P}}$.*

---

[65] It is important that $\hat{H}$ is $V[G]$-generic. Without this requirement we cannot argue that m exists.

Proof. This follows immediately, since the condition $\mathbf{1} \in j(\mathbb{P})$ works for m. Hence in the theorem, we need only consider $A = Z$. Moreover, from the definition of $\mathcal{M}$ we see that in this case $\mathcal{M} = Z$. ⊣

From Kakuda's Theorem one easily sees that collapsing a large cardinal κ to be a successor cardinal using κ-c.c. forcing yields precipitous ideals; in particular, Theorem 7.4 follows. Moreover, collapsing a λ-supercompact cardinal to μ^+ yields a precipitous ideal on $[\lambda]^{<\mu^+}$, collapsing a huge cardinal κ to μ^+ yields the existence of a precipitous ideal on $[\lambda]^{\mu^+}$ for some λ and so on. The next corollary implies that the property:

For all sufficiently large λ there is a precipitous ideal on $[\lambda]^{<\omega_1}$

is indestructible by proper forcing (compare with Example 7.7).

7.18 Corollary. *Suppose that I is a normal, fine, precipitous ideal on $[\lambda]^{<\omega_1}$ for some λ, and $\mathbb{P}$ is a proper partial ordering with $2^{|\mathbb{P}|} \leq \lambda$. Then there is a dense collection of sets $A \in P([\lambda]^{<\omega_1})/I$ such that $I{\restriction}A$ precipitous in $V^{\mathbb{P}}$.*

Proof. We claim that $I{\restriction}A$ and $\mathbb{P}$ satisfy the hypotheses of the theorem for a dense collection of A. Without loss of generality we can take I to be on $[X]^{<\omega_1}$, where X is a transitive set with $P(\mathbb{P}) \subseteq X$. Let $G \subseteq P([X]^{<\omega_1})/I$ be generic, and $j : V \to M$ be the generic elementary embedding.

Let θ be a large regular cardinal. We can assume that for each $z \in [X]^{<\omega_1}$ and all conditions $p \in \mathrm{Sk}^{H(\theta)}(z)$ there is a condition m stronger than p that is $\mathrm{Sk}^{H(\theta)}(z)$-generic. Thus in M, there is a condition $m \in j(\mathbb{P})$ that is $\mathrm{Sk}^{H(j(\theta))}(j``X)$-generic. Then $m \Vdash^M$ "for all dense sets $D \in \mathrm{Sk}^{H(j(\theta))}(j``X)$, there is a $p \in \mathrm{Sk}^{H(j(\theta))}(j``X) \cap D \cap \hat{H}$", where $\hat{H}$ is the canonical term for the generic object for $j(\mathbb{P})$ in M. Hence $m \Vdash^{V[G]}$ "$\{p \in \mathbb{P} : j(p) \in \hat{H}\}$ is V-generic".

Let $A \in P([X]^{<\omega_1})/I, f : [X]^{<\omega_1} \to \mathbb{P}$ be such that $A \Vdash [f]^M = m$. Then A and $\mathbb{P}$ satisfy the hypotheses of the theorem. ⊣

The next example shows that it is not a theorem of ZFC that precipitous ideals are preserved under $<\kappa$-directed closed forcing.

7.19 Example. Let U be a κ-complete, normal ultrafilter on κ. Force over the model $L[U]$ with the partial ordering $\mathrm{Add}(\kappa)$ to get a generic G. Then in $V = L[U][G]$, the ideal generated by the dual of U is no longer precipitous. For if it were and we took the generic elementary embedding $j : V \to M \subseteq V[H]$ then $M \models P(\kappa) \subseteq L[j(U)]$. But by the standard theory of $L[U]$, $L[j(U)]$ is an iterate of $L[U]$, and hence $P(\kappa)^{L[j(U)]} = P(\kappa)^{L[U]}$. But $G \in M$, and $G \notin L[U]$ a contradiction.

Another immediate consequence of Theorem 7.14 is:

7.20 Corollary. *Suppose that J is an $|X|^+$-saturated ideal on $Z \subseteq P(X)$ and $\mathbb{P}$ is a partial ordering satisfying the hypotheses of Theorem 7.14. Let $A, f, \mathcal{M}$ be as in Remark 7.15. Then $\bar{J}{\restriction}\mathcal{M}$ is $|X|^+$-saturated in $V^{\mathbb{P}}$ iff $j(\mathbb{P})/m$ is $|X|^+$-c.c. in $V[G]$ for all generic $G \subseteq P(Z)/J$.*

The next corollary is immediate from the previous one, since we do not need m (hence A or $\mathcal{M}$).

7.21 Corollary (Baumgartner-Taylor [6] and Laver independently). *Suppose that J is a κ-complete, κ^+-saturated ideal on κ and $\mathbb{P}$ is κ-c.c. Then $\bar{J}$ is $|\kappa|^+$-c.c. in $V^{\mathbb{P}}$ iff $j(\mathbb{P})$ is κ^+-c.c. in $V[G]$ for all generic $G \subseteq P(\kappa)/J$.*

We give an example of a c.c.c.-destructible saturated ideal on ω_1 in the discussion of Theorem 8.52 and show in Theorem 8.46 that the nonstationary ideal on ω_1 can be a c.c.c.-indestructible $\aleph_2$-saturated ideal.

Another consequence is a generalization of a classical result of Solovay [111] which also follows easily from the Duality Theorem.

7.22 Corollary. *Let $\lambda, \delta < \kappa$ be regular and $\gamma \leq |X|^+$. Suppose that J is a normal, fine, weakly (λ, γ)-saturated, κ-complete ideal on $Z \subseteq P(X)$. Let $\mathbb{P}$ be a partial ordering and $H \subseteq \mathbb{P}$ be generic. If $\mathbb{P}$ is λ-c.c. then in $V[H]$, $\bar{J}$ is weakly (λ, γ)-saturated and $\operatorname{sat}(\bar{J})^{V[H]} \leq \max\{\lambda, \operatorname{sat}(J)^V\}$.*

In particular, if $\mathbb{P}$ is δ-c.c. and J is a η-saturated ideal on κ with $\eta \leq \kappa^+$, J remains η-saturated in $V[H]$.

Proof. Since $\mathbb{P}$ is κ-c.c. the hypotheses of Theorem 7.14 are automatically satisfied. Hence $\mathbb{P} * P(Z)/\bar{J} \sim P(Z)/J * j(\mathbb{P})$. Let $G \subseteq P(Z)/J$ be generic and $j : V \to M$ be the generic ultrapower. Then M is closed under λ-sequences and $j(\lambda) = \lambda$. Hence $j(\mathbb{P})$ is λ-c.c. in $V[G]$. From this we conclude that $\mathbb{P} * P(Z)/\bar{J}$ is weakly (λ, γ)-saturated and has the $\max\{\lambda, \operatorname{sat}(J)^V\}$-c.c. It follows abstractly that $P(Z)/\bar{J}$ has the same properties in $V[H]$ for a generic $H \subseteq \mathbb{P}$. ⊣

The next examples illustrate how the Duality Theorem can be used to calculate quotients of large cardinal ideals after doing some forcing. Many lengthy calculations of quotient algebras such as those that appear in [48] and [41] are also made quite easy by the Duality Theorem.

7.23 Example (Laver). Suppose that κ is a measurable cardinal and U a normal ultrafilter on κ. Let $H \subseteq \operatorname{Col}(\mu, {<}\kappa)$ be generic. Then in $V[H]$, $P(\kappa)/\breve{U}$ contains a dense set isomorphic to $\operatorname{Col}(\mu, {<}j(\kappa))$. In particular, the quotient has a ${<}\mu$-closed dense subset.

Proof. Take $J = \breve{U}$ and $\mathbb{P} = \operatorname{Col}(\mu, {<}\kappa)$ in the theorem. Note that $P(\kappa)/J$ is the trivial, two-element Boolean algebra.

Since $\mathbb{P}$ is κ-c.c. we can take m to be the trivial condition and hence $A = \mathcal{M} = \kappa$. By the theorem, in $V[H]$, $\mathcal{B}(P(Z)/\bar{J}) \cong \mathcal{B}(j(\mathbb{P})/H)$. Since $j(\mathbb{P}) = \operatorname{Col}(\mu, {<}j(\kappa))$ and $j \restriction \operatorname{Col}(\mu, {<}\kappa)$ is the identity, we see that $\mathcal{B}(j(\mathbb{P})/H) \cong \mathcal{B}(\operatorname{Col}(\mu, {<}j(\kappa) \setminus \kappa))$. ⊣

7.24 Example. Let I be a normal, countably complete, $\aleph_1$-dense ideal on ω_1. Let $\mathbb{P}$ be the partial ordering $\operatorname{Add}(\omega, \omega_1)$ for adding ω_1 Cohen subsets of ω with finite conditions. Then in $V^{\mathbb{P}}$, $P(\omega_1)/\bar{I}$ is isomorphic to the partial ordering that collapses ω_1 with finite conditions and then adds ω_2 Cohen subsets of ω with finite conditions.

Proof. To see this we apply duality. Note that $\mathrm{Add}(\omega,\omega_1) * P(\omega_1)/\bar{I}$ is isomorphic to the quotient of $P(\omega_1)/I * \mathrm{Add}(\omega,\omega_2^V) \sim \mathrm{Col}(\omega,\omega_1) * \mathrm{Add}(\omega_1,\omega_2^V)$. If H adds ω_1 Cohen reals then, by duality the ordering $P(\omega_1)/\bar{I}$ is isomorphic to the quotient of $\mathrm{Col}(\omega,\omega_1) * \mathrm{Add}(\omega,\omega_1)/H$ which is isomorphic to $\mathrm{Col}(\omega,\omega_1) * \mathrm{Add}(\omega,\omega_1)$. ⊣

The next example plays an unfortunate role in the discussion of generalized large cardinals as axioms for set theory, as we shall see in Sect. 11.2. It follows immediately since $j(\mathrm{Col}(\omega,{<}\kappa)) = \mathrm{Col}(\omega,{<}\lambda)$ and $\mathrm{Col}(\omega,{<}\lambda)/G \sim \mathrm{Col}(\omega,{<}\lambda)$:

7.25 Example. Suppose that $j : V \to M$ is a huge embedding with critical point κ and $j(\kappa) = \lambda$. Let I be the dual of the huge ultrafilter on $[\lambda]^\kappa$ and $G \subseteq \mathrm{Col}(\omega,{<}\kappa)$ be generic. Then in $V[G]$, λ is inaccessible and:

$$P([\lambda]^\kappa)/I \cong \mathcal{B}(\mathrm{Col}(\omega,{<}\lambda)).$$

Understanding the Embeddings: Master Conditions Must Exist

Suppose that J is a normal, fine ideal on $Z \subseteq P(X)$, and $\bar{J}$ is precipitous in $V[G]$. One can ask:

> Suppose that $\hat{j}$ is a generic elementary embedding coming from a $V[H]$-generic $\bar{G} \subseteq P(Z)^{V[H]}/\bar{J}$. How close is $\hat{j}$ to a generic elementary embedding j arising from a V-generic $G \subseteq P(Z)/J$?

One answer is given by the following corollary:

7.26 Corollary. *Suppose that*

$$\mathrm{id} \times \dot{j} : P(Z)/J \times \mathbb{P} \to P(Z)/J * j(\mathbb{P})/m$$

is a regular embedding. Then there is a J-positive set $A \in V$ and a $\bar{J}$-positive set $L \in V^{\mathbb{P}}$ such that

$$\mathrm{id} : \mathbb{P} \times P(Z)/(J \restriction A) \to \mathbb{P} * P(Z)/(\bar{J} \restriction L)$$

sending $(p, A) \mapsto (p, \check{A})$ is a regular embedding. Moreover, if $\bar{G} \subseteq P(Z)/\bar{J}$ is $V[H]$-generic and G is the V-generic ultrafilter induced by id*, and $\hat{j} : V[H] \to M[\hat{H}]$ and $j : V \to M$ are the two generic ultrapower embeddings then j and $\hat{j}$ agree on V.*

Since there are many examples of consistency results that rely on extending generic elementary embeddings, it is interesting to understand if this can be done using methods besides constructing master conditions. Unfortunately the full force of the Duality Theorem requires master conditions.

Indeed Corollary 7.26 is a near equivalence: the conclusions almost imply the existence of a master condition. From the proof of the duality theorem we can derive more information that yields an exact converse.

7.27 Remark. Under the hypotheses of the Duality Theorem, if $H * \bar{G} \subseteq \mathcal{B}(\mathbb{P} * P(Z)/(\bar{J}\restriction\mathcal{M}))$ is generic, then:

1. $\mathrm{comp}(J\restriction A)^V = \mathrm{comp}(\bar{J}\restriction\mathcal{M})^{V[H]}$,
2. for all $f : Z \to V$ with $f \in V[H]$ there is a $g \in V$ such that $[f]_{\bar{G}} = [g]_{\bar{G}}$, and
3. the isomorphism
$$\iota : \mathcal{B}(\mathbb{P} * P(Z)/(\bar{J}\restriction\mathcal{M})) \cong \mathcal{B}(P(Z)/(J\restriction A) * j(\mathbb{P})/m)$$
is such that if $G \subseteq P(Z)/(J\restriction A)$ is generic, $G^* = \iota^{-1}(G)$ and $\bar{\imath}$ is the induced isomorphism from
$$\{\mathcal{B}(\mathbb{P} * P(Z)/(\bar{J}\restriction\mathcal{M}))\}/G^* \cong \{\mathcal{B}(P(Z)/(J\restriction A) * j(\mathbb{P})/m)\}/G,$$
then $\bar{\iota}\restriction\mathbb{P} = j\restriction\mathbb{P}$ and is a regular embedding from $\mathbb{P}$ to $j(\mathbb{P})/m$ in $V[G]$.

Master conditions must exist if we assume properties 1–3:

7.28 Proposition. *Suppose that $\mathbb{P}$ is a partial ordering, J is a precipitous ideal on Z and there are $A \in P(Z)$, $f : Z \to \mathbb{P}$ and $\mathcal{M} \in P(Z)^{V^{\mathbb{P}}}$ such that 1–3 of Remark 7.27 hold with $m = [f]^M$.*
Then
$$\mathrm{id} \times \dot{j} : P(Z)/J \times \mathbb{P} \to P(Z)/J * j(\mathbb{P})/m$$
is a regular embedding.

When the forcing $\mathbb{P}$ preserves the saturation of J, we can succinctly state a converse to the Duality Theorem.

7.29 Theorem. *Let J be a normal, fine, precipitous ideal on $Z \subseteq P(X)$ and $\mathbb{P}$ a partial ordering. Suppose that:*

1. *$\bar{J}\restriction\mathcal{M}$ is normal and $|X|^+$-saturated in $V^{\mathbb{P}}$,*
2. *for all generic $H * \bar{G} \subseteq \mathbb{P} * P(Z)/(\bar{J}\restriction\mathcal{M})$ and all $f : Z \to V$ in $V[H]$ there is a $g : Z \to \mathbb{P}$ in V such that $[h]_{\bar{G}} = [g]_{\bar{G}}$,*
3. *the identity mapping:*
$$\mathbb{P} \times P(Z)/J \to \mathbb{P} * \overline{P(Z)}/(\bar{J}\restriction\mathcal{M})$$
is a regular embedding, and
4. *for all generic $G \subseteq P(Z)/J$, $j(\mathbb{P})$ is $|X|^+$-saturated in $V[G]$.*

Then there is a condition $\dot{m} \in j(\mathbb{P})$ such that the mapping:
$$\mathrm{id} \times \dot{j} : P(Z)/J \times \mathbb{P} \to P(Z)/J * j(\mathbb{P})/m$$
is a regular embedding.

Generalizations of the Duality Theorem Without Master Conditions

In later sections it will be convenient to use a generalization of the Duality Theorem. We state a version here (and an even more general version in the remarks following it).

7.30 Theorem. *Let J be a precipitous ideal on a set Z and $\mathbb{P}$ be a partial ordering. Let $\dot{F}$ be a $P(Z)/J$-term for a filter on $j(\mathbb{P})$. Suppose that:*

1. $\mathrm{id} \times \dot{j} : P(Z)/J \times \mathbb{P} \to P(Z)/J * j(\mathbb{P})/\dot{F}$ *is a regular embedding,*
2. $\dot{F}$ *is generated by* $\langle \dot{m}_\alpha : \alpha < \gamma \rangle$,
3. $A \in J^+$ *is such that for each* α, $A \Vdash [f_\alpha]_M = \dot{m}_\alpha$, *and*
4. $A \Vdash_{P(Z)/J}$ *if* $\hat{H} \subseteq j(\mathbb{P})/\dot{F}$ *is* $V[G]$*-generic, then* $\hat{H} \subseteq j(\mathbb{P})$ *is generic over* M.[66]

Let $H \subseteq \mathbb{P}$ be generic and $\mathcal{J}_F \in V[H]$ be the ideal generated over $\bar{J}$ by the sets $\mathcal{M}_\alpha = \{z \in A : f_\alpha(z) \notin H\}$. Then there is a canonical isomorphism ι witnessing:

$$\mathcal{B}(\mathbb{P} * P(Z)/\mathcal{J}_F) \cong \mathcal{B}(P(Z)/(J{\restriction}A) * j(\mathbb{P})/\mathcal{F}).$$

We can weaken our assumptions of the generalized duality theorem further. Suppose that:

1. $\dot{F}$ is a $P(Z)/J$-term for a filter on $j(\mathbb{P})$ generated by a collection of terms T,
2. $\mathrm{id} \times \dot{j} : P(Z)/J \times \mathbb{P} \to P(Z)/J * j(\mathbb{P})/\dot{F}$ is a regular embedding, and
3. if $\hat{H} \subseteq j(\mathbb{P})/\dot{F}$ is generic then $\hat{H} \subseteq j(\mathbb{P})$ is generic over M.

Then if $H \subseteq \mathbb{P}$ is generic, there is a minimal ideal $\mathcal{J}_F \in V[H]$ such that for all $A \in J^+$, $\tau \in T$ if $A \Vdash f^\tau_A = \tau$, then $\{z \in A : f^\tau_A(z) \notin H\} \in \mathcal{J}_F$. For this ideal, there is a canonical isomorphism ι witnessing:

$$\mathcal{B}(\mathbb{P} * P(Z)/\mathcal{J}_F) \cong \mathcal{B}(P(Z)/(J{\restriction}A) * j(\mathbb{P})/\mathcal{F}).$$

7.5. Pseudo-Generic Towers

In this section we discuss a technique for showing strong properties of an ideal closely related to a master condition ideal.

In the typical situation where this technique is used, we have a large cardinal embedding $j : V \to M$ and $M^\lambda \subseteq M$. We will force over V to get

[66] Where $G \subseteq P(Z)/J$ is the canonical term for the V-generic filter.

$G * H \subseteq \mathbb{P} * \mathbb{Q}$ and $\hat{G} * \hat{H} \subseteq j(\mathbb{P} * \mathbb{Q})$ and extend the embedding to a

$$\hat{j} : V[G * H] \to M[\hat{G} * \hat{H}].$$

If $j(\mathbb{P})$ is λ-c.c. then $M[\hat{G}]$ is closed under λ-sequences from $V[\hat{G}]$. Suppose now that $j(\mathbb{Q})$ is $<\lambda$-closed over $M[\hat{G}]$. Then, working in $V[\hat{G}]$, for all sets $Z \in V[G * H]$ such that $|P(Z)^{V[G*H]}| \leq \lambda$ and all ultrafilters $U(\hat{j}, i)$ induced by $\hat{j}$ on Z we can build a tower of conditions $\mathcal{T} \subseteq j(\mathbb{Q})$ such that for all $X \in P(Z)^{V[G*H]}$, there is a $p \in \mathcal{T}$ such that $p \parallel$ "$i \in \hat{j}(X)$".

In $V[\hat{G}]$ we define an ultrafilter $\tilde{U}$ on $P(Z)^{V[G*H]}$ by setting $X \in \tilde{U}$ iff there is a $p \in \mathcal{T}$ such that $p \Vdash i \in \hat{j}(X)$. Then $\tilde{U}$ is closed under intersections of $<\kappa$-sequences that lie in $V[G * H]$.

We can phrase this as building the tower $\mathcal{T}$ to be generic for some collection $\mathcal{D}$ of dense sets in $j(\mathbb{Q})$. Such a tower is called *pseudo-generic.*

This is particularly interesting in the case where $i = \eta \in \mathrm{On}$ or $i = j``\mu$ for some ordinal μ. In either of these cases, we can arrange that the tower meets a larger collection of dense sets so that $\tilde{U}$ is closed under diagonal intersections of sequences of sets that lie in $V[G * H]$.

Pseudo-generic tower arguments can be formalized with the following result:

7.31 Lemma (Kunen [79]). *Assume that $\kappa^{<\kappa} = \kappa$. Suppose that $\mathbb{P}$ is a $<\kappa$-closed partial ordering and ϕ is formula in the language of set theory supplemented by an n-ary predicate symbol X. Suppose that $a_1, \ldots, a_n \in H(\kappa)$ and there is a condition $p \in \mathbb{P}$ such that:*

$$p \Vdash \exists X \subseteq H(\kappa)^n, \langle H(\kappa), \in, X\rangle \models \phi(X, a_1, \ldots, a_n).$$

Then $\exists X \subseteq H(\kappa), \langle H(\kappa), \in, X\rangle \models \phi(X, a_1, \ldots, a_n)$.

The proof of this lemma builds a pseudo-generic tower deciding longer and longer initial segments of X for enough dense sets. The cardinal arithmetic assumption guarantees that the list of dense sets to be met is not too large.

7.6. A κ-Saturated Ideal on an Inaccessible Cardinal κ

In this section we prove the following theorem of Kunen:

7.32 Theorem (Kunen [79]). *Let κ be a measurable cardinal. Then there is a partial ordering $\mathbb{P}$ such that for all generic $G \subseteq \mathbb{P}$, $V[G] \models \kappa$ is inaccessible but not weakly compact and there is a κ-complete, κ-saturated ideal on κ.*

Proof. We begin with some preliminaries:

Let λ be a regular cardinal and $\mathcal{T}$ be the collections of sets $(t, <_t)$ with the following properties:

1. $t \subseteq \lambda \times \lambda$, $|t| < \lambda$ and $<_t$ is a tree ordering on t such that the αth level of $<_t$ is $t \cap (\lambda \times \{\alpha\})$,

2. the tree has a "top level", i.e. there is a maximal $\alpha \in \lambda$ such that $t \cap (\lambda \times \{\alpha\}) \neq \emptyset$,
3. every node in the tree at level ν is below at least two nodes at level $\nu + 1$ and some node at the top level of the tree, and
4. for all $\sigma, \tau \in t$ in the same level of $<_t$ there is an automorphism of $(t, <_t)$ sending σ to τ.

For conditions $s, t \in \mathcal{T}$ we define $t \leq_{\mathcal{T}} s$ iff $t \supseteq s$ and $<_t$ is an end extension of $<_s$ and every automorphism of s extends to an automorphism of t. Then $\mathcal{T}$ is ω-closed and $<\lambda$-strategically closed. Further, forcing with $\mathcal{T}$ adds a λ-Suslin tree $\mathbb{T}$ to V.

The following lemma is crucial for Kunen's theorem and is of independent interest:

7.33 Lemma. *Suppose that* $\lambda^{<\lambda} = \lambda$ *and let* $\mathbb{R} = \mathcal{T} * \mathbb{T}$. *Then forcing with* $\mathbb{R}$ *is equivalent to forcing with* $\mathrm{Add}(\lambda)$.

Proof. The Boolean algebra $\mathcal{B}(\mathrm{Add}(\lambda))$ can be characterized as the unique complete Boolean algebra with a dense $<\lambda$-closed subset of cardinality λ. Hence it suffices to show that $\mathcal{T} * \mathbb{T}$ is $<\lambda$-closed and λ-dense.

Let $\mathbb{Q}$ be the partial ordering consisting of pairs (p, b) where $p \in \mathcal{T}$ and b is a branch through the tree of p that includes a node on the top level of p. We let $(q, c) \leq (p, b)$ iff $q \leq_{\mathcal{T}} p$ and c extends b.

A few moments' thought shows that $\mathbb{Q}$ is $<\lambda$-closed and λ-dense, so it suffices to see that forcing with $\mathbb{Q}$ is equivalent to forcing with $\mathcal{T} * \mathbb{T}$.

Let $G \subseteq \mathbb{Q}$ be generic. Then the sequence of first coordinates of conditions in G is a generic filter H for $\mathcal{T}$, and the sequence of second coordinates is a branch through $\mathcal{T}$ of length λ. Since any λ-branch through a λ-Suslin tree is generic, forcing with $\mathbb{Q}$ yields a generic object for $\mathcal{T} * \mathbb{T}$.

The set of conditions D of the form $(p, \check{b}) \in \mathcal{T} * \mathbb{T}$, where $b \in V$ and b has an element on the top level of the tree given by p, is dense in $\mathcal{T} * \mathbb{T}$ and we have seen that the identity embedding from D into $\mathbb{Q}$ is a regular embedding. Since these conditions are dense in $\mathbb{Q}$, the two forcings are equivalent. $\dashv$

Let κ be a measurable cardinal and $j : V \to M$ be the elementary embedding from a normal ultrafilter on κ. Let $\mathbb{P}$ be an iteration of length κ with Easton supports that adds a generic object for $\mathrm{Add}(\alpha)$ at stage α for every inaccessible α and does nothing at other stages. Then $\mathbb{P}$ is κ-c.c. Let G be generic for $\mathbb{P}$ and $H \subseteq \mathrm{Add}(\kappa)^{V[G]}$ be generic.

We claim that κ is measurable in $V[G*H]$. Note that $j(\mathbb{P}) = \mathbb{P}*\mathrm{Add}(\kappa)*\mathbb{R}$, where $\mathbb{R}$ is $<(2^\kappa)^+$-closed. In particular, it is possible to extend $G * H$ to a V-generic object $G * H * K \subseteq j(\mathbb{P})$. Thus in M we can define the master condition $m = \bigcup j``H$ and extend j to a $\hat{j} : V[G * H] \to M[\hat{G} * \hat{H}]$, where $\hat{H} \subseteq \mathrm{Add}(j(\kappa))$ is generic.

By the closure of $\mathbb{R}$, the ultrafilter $U(\hat{j}, \kappa) \in V[G * H]$, and hence κ is measurable in $V[G * H]$.

By Lemma 7.33, we can split $H \sim H_0 * H_1$, where $V[G * H_0]$ has a Suslin tree $\mathbb{T}$ on κ and H_1 is generic for this tree.

The final model is $V' = V[G * H_0]$. In this model we can force with the Suslin tree $\mathbb{T}$ to make κ measurable. If $\dot{\mu}$ is a term for a normal ultrafilter on κ, then $I = \{X \subseteq \kappa : \|X \notin \dot{\mu}\| = 1\}$ is a normal, κ-saturated ideal on κ. This establishes Kunen's theorem. ⊣

7.34 Remark. An application of Proposition 7.13 shows that if I is the ideal defined at the end of the previous proof, then forcing with $P(\kappa)/I$ is equivalent to forcing with the Suslin tree $\mathbb{T}$.

Kunen's result extends to ideals on $[\lambda]^{<\kappa}$ as follows: Let κ be a supercompact cardinal and let $f : \kappa \to \kappa$ be a function such that for all $\lambda > \kappa$ there is an elementary embedding $j : V \to M$ that is λ-supercompact and $j(f)(\kappa) > \lambda$.[67] To get a κ-saturated ideal on $[\lambda]^{<\kappa}$, start with a 2^λ-supercompact elementary embedding j with $j(f)(\kappa) > 2^\lambda$. Modify the previous iteration by only forcing at inaccessibles α that are closed under the function f.

Using the notation above, the partial ordering $\mathbb{R}$ is $<(2^\lambda)^+$-closed, and hence the induced ultrafilter $U(\hat{j}, j``\lambda)$ on $Z = ([\lambda]^{<\kappa})^{V[G*H]}$ lies in $V[G*H]$. The rest of the argument is identical.

7.7. Basic Kunen Technique: κ^+-Saturated Ideals

We saw in Sect. 6 that it was impossible to have a κ-saturated, κ-complete ideal on a successor cardinal κ. In this subsection we describe Kunen's technique for producing an $\aleph_2$-saturated ideal on ω_1.

This technique and its many variations has proved to be the main tool for producing saturated ideals on accessible cardinals, with one notable exception detailed in Sect. 8.

The basic idea behind Kunen's argument is to start with a huge embedding $j : V \to M$ with critical point κ and $j(\kappa) = \lambda$ and collapse κ to be $\aleph_1$ and λ to be $\aleph_2$ by a two stage forcing $\mathbb{P} * \mathbb{S}$. In order to find an induced ideal, we must be able to extend the embedding j in the resulting model. A basic obstacle arises in that the generic object for $\mathbb{S}$ has cardinality λ which is $\aleph_1$ is $M^{j(\mathbb{P})}$. But $\mathbb{S}$ can be at most countably closed and so the master conditions do not need to exist by virtue of the closure alone.[68] In addition to closure, Kunen used the "shape" of the conditions in a partial ordering invented by Silver to show that a master condition exists.

7.35 Definition. Let $\kappa < \lambda$ be regular cardinals and λ inaccessible. The *Silver Collapse* of λ to be κ^+ is the collection of functions p with domain included in $\kappa \times \lambda$ that map into λ and satisfy:

[67] Such a function always exists, see e.g. [82].

[68] In Sect. 7.11 we will see a method of Magidor for circumventing this problem.

1. $|\operatorname{dom}(p)| \leq \kappa$ and there is an $\eta < \kappa$ such that the domain of p is a subset of $\eta \times \lambda$, and
2. for all $(\alpha, \beta) \in \operatorname{dom}(p)$, $p(\alpha, \beta) < \beta$.

The ordering on the conditions in the Silver Collapse is reverse inclusion.

For inaccessible λ, we will denote the Silver collapse of λ to be κ^+ by $\mathbb{S}(\kappa, \lambda)$. It is easily checked that it is λ-c.c., $<\kappa$-closed and makes every ordinal between κ and λ have cardinality κ.

7.36 Theorem (Kunen [79]). *Suppose that $j : V \to M$ is a huge embedding with critical point κ and $j(\kappa) = \lambda$. Then there is a κ-c.c. partial ordering $\mathbb{P}$ such that if $G * H \subseteq \mathbb{P} * \mathbb{S}(\kappa, \lambda)$ is generic then $V[G * H]$ satisfies the statements $\kappa = \omega_1$, $\lambda = \omega_2$ and there is an $\aleph_2$-saturated ideal on ω_1.*

Proof. Kunen's proof starts by building a "highly saturated" κ-c.c. partial ordering $\mathbb{P} \subseteq V_\kappa$.[69] Since there are many variations on Kunen's actual construction, we begin by describing the cogent properties that allow it to be generalized. At the end of the discussion we will give a specific example of this type of construction.

The saturation property desired of $\mathbb{P}$ is that if $\mathbb{Q}$ is a regular subordering of $\mathbb{P}$ of inaccessible cardinality $\alpha < \kappa$, then there is a regular embedding $i : \mathbb{Q} * \mathbb{S}(\alpha, \kappa) \to \mathbb{P}$ extending the identity mapping of $\mathbb{Q}$ into $\mathbb{P}$.

Suppose that we have succeeded in constructing such a $\mathbb{P}$. We let $G \subseteq \mathbb{P}$ be generic over V. By the κ-c.c. of $\mathbb{P}$ we can find a $\hat{G} \subseteq j(\mathbb{P})$ that is $V[G]$-generic and an extension of j to a $j_1 : V[G] \to M[\hat{G}]$. Moreover, $M[\hat{G}]^\lambda \cap V[\hat{G}] \subseteq M[\hat{G}]$.

Note that $j \restriction \mathbb{P}$ is the identity mapping, since $\mathbb{P} \subseteq V_\kappa$. By the κ-c.c. of $\mathbb{P}$, j is a regular embedding, and hence $\mathbb{P}$ is a regular subordering of $j(\mathbb{P})$. Using the definition of $j(\mathbb{P})$, there is a regular embedding i extending j of $\mathbb{P} * \mathbb{S}(\kappa, \lambda)$ into $j(\mathbb{P})$. In $M[\hat{G}]$ we have a generic object $H \subseteq \mathbb{S}(\kappa, \lambda)$ over $V[G]$. Our final model is $V[G * H]$.

We want to extend the embedding j. Let $m = \bigcup j``H$. We claim that $m \in \mathbb{S}(\lambda, j(\lambda))^{M[\hat{G}]}$. Note that m has the right cardinality, namely λ. Moreover, if $p \in H$, then there is an ordinal $\eta < \kappa$ such that the domain of p is a subset of $\eta \times \lambda$. Hence the domain of $j_1(p)$ is a subset of $\eta \times j(\lambda)$. Thus we see that the domain of m is a subset of $\kappa \times j(\lambda)$ and so m has the right shape. It is now easy to verify that m is a condition in $\mathbb{S}(\lambda, j(\lambda))^{M[\hat{G}]}$. Forcing below m in the partial ordering $\mathbb{S}(\lambda, j(\lambda))$ we get a generic $\hat{H}$ and an extension of j to a $\hat{j} : V[G * H] \to M[\hat{G} * \hat{H}]$.

We are now ready to apply the technique of pseudo-generic towers to find an ultrafilter $\tilde{U}$ on $P(\kappa)^{V[G*H]}$ in $V[\hat{G}]$ mimicking the properties of $U(\hat{j}, \kappa)$. In particular the ultrafilter $\tilde{U}$ is normal and κ-complete for sequences of sets that lie in $V[G * H]$.

---

[69] This is a different sense of *saturation* than "chain condition", related to the model-theoretic idea of saturation.

Working in $V[G * H]$, let I be the collection of $X \subseteq \kappa$ such that $\|X \in \tilde{U}\|_{j(\mathbb{P})/(G*H)} = 0$. Then I is normal and κ-complete and since $j(\mathbb{P})/G * H$ is $\lambda = \kappa^+$-c.c. the ideal is κ^+-saturated.

We now give an explicit example of such a construction. $\mathbb{P}$ will be an iteration-with-amalgamation of length κ with finite supports. To get the construction of $\mathbb{P}$ started take $\mathbb{P}_0 = \mathrm{Col}(\omega, <\kappa)$. At a typical α, $\mathbb{P}_\alpha$ will have been defined. There will be a a regular subordering $\mathbb{Q}_\alpha$ of $\mathbb{P}_\alpha$ having cardinality less than or equal to α. Then $\mathbb{P}_{\alpha+1}$ is:

$$\mathbb{P}_{\alpha+1} = \mathbb{P}_\alpha * \mathbb{S}^{\mathbb{Q}_\alpha}(\alpha, \kappa)$$

where this is defined to consist of pairs (p, τ) where $p \in \mathbb{P}_\alpha$ and τ is a $\mathbb{Q}_\alpha$ term for an element of $\mathbb{S}(\alpha, \kappa)^{V^{\mathbb{Q}_\alpha}}$. Since $\mathbb{Q}_\alpha$ is a regular subordering of $\mathbb{P}_\alpha$, the partial ordering $\mathbb{S}(\alpha, \kappa)^{V^{\mathbb{Q}_\alpha}}$ has a canonical realization in $V^{\mathbb{P}_\alpha}$ and the ordering on $\mathbb{P}_{\alpha+1}$ is defined accordingly.[70]

To finish the description, we take a sequence $\langle \mathbb{Q}_\alpha : \alpha < \kappa \rangle$ to be a sequence of partial orderings dovetailed so that every regular subordering of any $\mathbb{P}_\beta$ for $\beta < \kappa$ occurs as $\mathbb{Q}_\alpha$ for cofinally many $\alpha < \kappa$. $\dashv$

Laver remarked that instead of finite supports, Kunen's construction works with countable or Easton supports. In particular, if you start Kunen's construction with $\mathrm{Col}(\omega_1, <\kappa)$ and iterate with countable supports you can get an $\aleph_3$-saturated ideal on ω_2.

Hence, as a corollary of Kunen's techniques, we get:

7.37 Corollary (Laver using [79]). *Suppose that μ is a regular cardinal less than a huge cardinal κ. Then there is a μ-directed closed partial ordering $\mathbb{P}$ such that for all generic $G \subseteq \mathbb{P}$,*

$$V[G] \models \textit{ there is a } \mu^{+2}\textit{-saturated ideal on } \mu^+.$$

As remarked by the author in [48], this proof combined with Proposition 7.13 gives more:

7.38 Corollary. *Suppose that μ is a regular cardinal less than a huge cardinal κ. Then there is a partial ordering $\mathbb{P}$ such that for all generic $G \subseteq \mathbb{P}$,*

$$V[G] \models \textit{ there is a layered ideal on } \mu^+.$$

Proof. The partial ordering $\mathbb{P} = \mathbb{P}_\kappa$ in Kunen's proof is κ-c.c. and $\mathbb{P} \subseteq V_\kappa$. Hence $j : \mathbb{P} \to j(\mathbb{P})$ is a regular embedding and $M \models j(\mathbb{P}) \cap V_\kappa$ is a regular subordering of $j(\mathbb{P})$.

By elementarity we see that there is a stationary $R \subseteq \kappa$ such that for all $\alpha \in R$, $\mathbb{P} \cap V_\alpha$ is a regular subordering of V_κ and $\mathbb{P} \cap V_\alpha$ has the α-c.c. Since M is closed under $<\lambda$-sequences we see that for all $\alpha \in j(R)$, $j(\mathbb{P}) \cap V_\alpha$ is a regular subordering of $j(\mathbb{P})$ and has the α-c.c.

[70] An alternate description of $\mathbb{P}_{\alpha+1}$ is $\mathbb{Q}_\alpha * (\mathbb{P}_\alpha/\mathbb{Q}_\alpha \times S(\alpha, \kappa))$.

Standard arguments then show that if i is the canonical embedding from $\mathbb{P} * \mathbb{S}(\kappa, \lambda)$ into $j(\mathbb{P})$ given in the Kunen construction and $G * H \subseteq \mathbb{P} * \mathbb{S}(\kappa, \lambda)$ is generic, then $V[G * H] \models$

$$\text{for } \alpha \in j(R),\ (j(\mathbb{P})/G * H) \cap V_\alpha \text{ is a regular subordering of } j(\mathbb{P})/G * H.$$

Let $\langle \mathcal{B}_\alpha : \alpha < \lambda \rangle$ be an increasing, continuous sequence of Boolean subalgebras of $\mathcal{B}(j(\mathbb{P})/G * H)$. Then there is a closed unbounded set C of α, for all $\alpha \in C$, $(j(\mathbb{P})/G * H) \cap V_\alpha$ is dense in $\mathcal{B}_\alpha$. In particular, for $\alpha \in C \cap j(R)$, $\mathcal{B}_\alpha$ is a regular subalgebra of $\mathcal{B}$.

Applying Proposition 7.13 to Kunen's ideal I, we see that $P(\kappa)/I$ is isomorphic to $\mathcal{B}$, and hence I is a layered ideal. ⊣

Kunen pointed out that these models also satisfy various Chang's Conjectures: Using the notation of the proof of Kunen's theorem and assuming we are doing Laver's variation, let

$$\hat{j} : V[G * H] \to M[\hat{G} * \hat{H}]$$

be the generic embedding. Suppose further that $V[G * H] \models \kappa = \mu^+$. Let $\mathfrak{A}$ be a structure in a countable language whose domain is $\kappa^+ = \lambda$. Then $j``\lambda$ is the domain of an elementary substructure of $j(\mathfrak{A})$, and $M[\hat{G} * \hat{H}] \models |j``\lambda| = \mu^+$ and $|j``\lambda \cap j(\kappa)| = \mu$. By the elementarity of j,

$$V[G * H] \models \text{there is an elementary substructure of } \mathfrak{A} \text{ of type } (\mu^+, \mu).$$

To summarize, we see that in a model built by the Kunen technique $(\mu^{+2}, \mu^+) \twoheadrightarrow (\mu^+, \mu)$ holds:

7.39 Corollary. *Suppose that μ is a regular cardinal less than a huge cardinal κ. Then for all finite $n > 0$ there is a partial ordering $\mathbb{P}_n$ such that for all generic $G \subseteq \mathbb{P}_n$,*

$$V[G] \models (\aleph_{n+1}, \aleph_n) \twoheadrightarrow (\aleph_n, \aleph_{n-1}).$$

7.8. $(\aleph_2, \aleph_2, \aleph_0)$-Saturated Ideals

In this section we outline Laver's result giving the consistency of the existence of $(\aleph_2, \aleph_2, \aleph_0)$-saturated ideals. Though Woodin constructed an ideal with stronger saturation properties from an almost huge cardinal (Theorem 7.60), Laver's construction retains certain advantages. The primary one is that it does not require passing to an inner model to find an ideal satisfying the desired conditions.

Laver modified the Silver collapse still further to give the "Eastonized" version. Define a set $X \subseteq \sigma \in \mathrm{On}$ to be δ-*Easton* iff for all regular ρ between δ and σ, $|X \cap \rho| < \rho$. Let $\mathbb{L}(\delta, \sigma)$ be the subset of $\prod_{\alpha<\sigma} \mathrm{Col}(\delta, \alpha)$ consisting of those p such that the support of p is a δ-Easton subset of σ and there is a $\xi < \delta$ such that for all $\alpha \in \mathrm{supp}(p)$, $p(\alpha) \subseteq \xi \times \alpha$. Explicitly, $p \in \mathbb{L}(\delta, \sigma)$ iff p is a partial function from $\sigma \times \delta$ to σ such that for all α, ζ we have

$p(\alpha,\zeta) < \alpha$, $\{\alpha : \text{there is a } \zeta, (\alpha,\zeta) \in \mathrm{dom}(p)\}$ is δ-Easton and for some $\xi < \delta$, $\mathrm{dom}(p) \subseteq \sigma \times \xi$.[71]

The ordering of $\mathbb{L}(\delta,\sigma)$ is inclusion. It is routine to check that this partial ordering is $<\delta$-closed, is σ-c.c. for σ Mahlo and collapses σ to be δ^+. If $p \in \mathbb{L}(\delta,\sigma)$ and $\alpha < \sigma$ we let $p\restriction\alpha$ denote the condition $p \cap (\alpha \times \delta \times \alpha)$.

7.40 Theorem (Laver [83]). *Suppose that there is a huge cardinal κ and $\mu < \kappa$ is regular. Then there is a forcing extension in which $\kappa = \mu^+$ and there is a normal κ-complete ideal I on κ that is (κ^+,κ^+,μ)-saturated.*

Proof. Let $j : V \to M$ be the embedding with critical point κ and $j(\kappa) = \lambda$. Following the general Kunen outline we build an iteration-with-amalgamation $\mathbb{P}$ of length κ with μ-Easton supports.[72] Let $\mathbb{P}_0 = \mathbb{L}(\mu,\kappa)$. At stage α, if $V_\alpha \cap \mathbb{P}_\alpha$ is a regular subordering of $\mathbb{P}_\alpha$, then we let $\mathbb{P}_{\alpha+1} = \mathbb{P}_\alpha * \mathbb{L}^{\mathbb{P}_\alpha \cap V_\alpha}(\alpha,\kappa)$. As in the Kunen construction, the αth coordinate in an element of $\mathbb{P}_{\alpha+1}$ is a $\mathbb{P}_\alpha \cap V_\alpha$-term for an element of $\mathbb{L}(\alpha,\kappa)$. Otherwise $\mathbb{P}_{\alpha+1} = \mathbb{P}_\alpha * 1$, where 1 is the trivial partial ordering. We note that at each stage in the iteration we are forcing with terms that lie in some $V^{\mathbb{Q}}$, where $|\mathbb{Q}| < \kappa$.[73]

The main point of this version of the construction is that $\mathbb{P}$ has a particularly strong chain condition property. At each stage of the forcing we are using terms from an extension of V by a small forcing. Hence we see that for all $X \in [\mathbb{P}]^\kappa$ there are arbitrarily large $\beta < \kappa$ and $Y \in [X]^\kappa$ such that the following strong chain condition property holds:

1. The collection $\{\mathrm{supp}(p) : p \in Y\}$ forms a Δ-system with kernel contained in β,
2. if $\alpha \in \beta$ and $\mathbb{P}_{\alpha+1} \neq \mathbb{P}_\alpha * 1$, then $1 \Vdash_{\mathbb{P}_\alpha \cap V_\alpha} \{p(\alpha) : p \in Y\}$ forms a Δ-system with kernel contained in $\beta \times \beta \times \beta$, and
3. if $p, q \in Y$ and $\alpha < \beta$ then $1 \Vdash_{\mathbb{P}_\alpha \cap V_\alpha} p(\alpha)\restriction\beta = q(\alpha)\restriction\beta$.

If β is regular and Y is a collection of conditions that satisfy 1–3, then for any $Z \in [Y]^{<\beta}$ there is a $q \in \mathbb{P}$ such that for all $p \in Z$:

- $q \leq p$,
- for $\alpha < \beta$, $q(\alpha)\restriction\beta = p(\alpha)\restriction\beta$, and
- for $\alpha \geq \beta$ in the support of q there is a unique $p \in Z, q(\alpha) = p(\alpha)$.

Since $\mathbb{P}$ is κ-c.c. and $j\restriction\mathbb{P}$ is the identity map, $\mathbb{P}$ is a regular subordering of $j(\mathbb{P})$. By the interpretation of the construction in M, $\mathbb{P} * \mathbb{L}(\kappa,\lambda)$ is regularly embedded into $j(\mathbb{P})$ via a canonical map i that is the identity on $\mathbb{P}$ and sends

[71] This description is analogous to the description of the Silver collapse with the domains of the conditions "turned sideways" from the domains given in Definition 7.35.

[72] These are supports S with the property that for all regular $\alpha > \mu$, $|S \cap \alpha| < \alpha$.

[73] We are viewing conditions in an iteration to be partial functions defined on their supports. Thus $\mathbb{P} \subseteq V_\kappa$ and $j(\mathbb{P}) \cap V_\kappa = \mathbb{P}$.

terms in $\mathbb{L}(\kappa,\lambda)$ to the κth-coordinate of $j(\mathbb{P})$. If $\hat{G}\subseteq j(\mathbb{P})$ is generic, i gives a V-generic $G*H\subseteq\mathbb{P}*\mathbb{L}(\kappa,\lambda)$. Then $m=\bigcup j``H\in L^{j(\mathbb{P})}(\lambda,j(\lambda))$, and if $\hat{H}$ is generic with $m\in\hat{H}$ we can extend j to $\hat{j}:V[G*H]\to M[\hat{G}*\hat{H}]$. Moreover in this model $\kappa=\mu^+$, and $\lambda=\kappa^+$.

Using a pseudo-generic tower argument, in $V[\hat{G}]$, we can build a $V[G*H]$-normal and κ-complete ultrafilter U on $P(\kappa)^{V[G*H]}$. As usual we can define a normal κ-complete ideal I in $V[G*H]$ by setting $A\in I$ iff $\|A\in U\|_{j(\mathbb{P})/G*H}=0$. It is this ideal I that we claim is (κ^+,κ^+,μ)-saturated.

If not, let $(r,l)\in\mathbb{P}*\mathbb{L}(\kappa,\lambda)$ and $\langle\tau_\alpha:\alpha<\lambda\rangle$ be a sequence of $\mathbb{P}*\mathbb{L}(\kappa,\lambda)$-terms such that $(r,l)\Vdash$ "$\langle\tau_\alpha:\alpha<\lambda\rangle$ is a counterexample to (λ,λ,μ) saturation". Then we can find a sequence of conditions $\langle p_\alpha:\alpha<\lambda\rangle\in j(\mathbb{P})$ such that $p_\alpha\leq i(r,l)$ and $p_\alpha\Vdash_{j(\mathbb{P})}\tau_\alpha\in U$.

Since j is a huge embedding, $j(\mathbb{P})$ has the strong chain condition property mentioned above in V. Applying the strong chain condition we get a $Y\subseteq[\lambda]^\lambda$ and a $\beta\geq\kappa$ satisfying 1–3. We can find an $r_0\in\mathbb{P}$ such that for all $\gamma<\kappa$, $\alpha\in Y$, $p_\alpha(\gamma)\restriction\kappa=r_0(\gamma)$. Moreover, $r_0\Vdash_{\mathbb{L}(\kappa,\lambda)}|\{\alpha\in Y:p_\alpha(\kappa)\in H\}|=\lambda$. Let $Y'=\{\alpha\in Y:p_\alpha(\kappa)\in H\}$. We claim that $\{\tau_\alpha^{V[G*H]}:\alpha\in Y'\}$ is the witness to (λ,λ,μ)-saturation.

Let $(r_1,l_1)\leq(r_0,l)$ be such that $(r_1,l_1)\Vdash_{\mathbb{P}*\mathbb{L}(\kappa,\lambda)}Z\in[Y']^\mu$. Then $Z\in V[G]$. In V, we can find a collection $Z'\in[Y]^{<\kappa}$ such that $r_1\Vdash Z\subseteq Z'$ and for all $\alpha\in Z'$, $r_1\Vdash_{\mathbb{P}}$ "l_1 and $p_\alpha(\kappa)$ are compatible". By 1–3 there is a $q\in j(\mathbb{P})$ such that:

- for $\gamma<\kappa$, $q(\gamma)\restriction\kappa=r_1(\gamma)$,
- $q(\kappa)\leq l_1$, and
- for all $\alpha\in Z'$, $q\leq p_\alpha$.

Then $r_1\Vdash_{j(\mathbb{P})}$ "$q(\kappa)\in\mathbb{L}(\kappa,\lambda)$ and $q(\kappa)\leq l_1$". Thus, $(r_1,q(\kappa))\Vdash_{\mathbb{P}*\mathbb{L}(\kappa,\lambda)}q\in j(\mathbb{P})/G*H$. But for all $\alpha\in Z'$, $q\Vdash_{j(\mathbb{P})}\tau_\alpha\in U$ and thus $q\Vdash_{j(\mathbb{P})}\bigcap_{\alpha\in Z'}\tau_\alpha\in U$. Hence, $V[G*H]\models\bigcap_{\alpha\in Z}\tau_\alpha\notin I$. ⊣

7.9. Chang Ideals with Simple Quotients I

The Kunen technique also allows "skipping cardinals". This useful variant is a component of many proofs. Fix a regular cardinal $\mu<\kappa$ and a successor ordinal $\gamma<\kappa$. We follow the outline of the Kunen proof. We begin by constructing a partial ordering $\mathbb{P}$. This partial ordering will be a κ-stage iteration with $<\mu$-supports. The first stage of $\mathbb{P}$ is $\mathrm{Col}(\mu,<\kappa)$. For regular suborderings $\mathbb{Q}$ of $\mathbb{P}$ that have cardinality $\alpha<\kappa$ we arrange that there is a regular embedding $i:\mathbb{Q}*\mathbb{S}(\alpha^{+\gamma},\kappa)\to\mathbb{P}$ extending the identity mapping of $\mathbb{Q}$ into $\mathbb{P}$. The result is that $\mathbb{P}$ is a κ-c.c. partial ordering that collapses κ to μ^+.

The final forcing is $\mathbb{P}*\mathbb{S}(\kappa^{+\gamma},\lambda)$. This forcing makes $\kappa=\mu^+$ and $\lambda=\kappa^{+\gamma+1}$. As in the original Kunen construction, if $G*H\subseteq\mathbb{P}*\mathbb{S}(\kappa^{+\gamma},\lambda)$ is generic then there is a generic $\hat{G}*\hat{H}$ such that the huge embedding j can be extended to $\hat{j}:V[G*H]\to M[\hat{G}*\hat{H}]$.

If we assume that the original embedding $j : V \to M$ is somewhat stronger than a huge cardinal, namely that $M^{\lambda^{+\gamma}} \subseteq M$, then the Kunen argument for Chang's Conjecture gives more; it shows that for all $\delta \leq \gamma$,

$$(\mu^{+1+\gamma+1+\gamma}, \mu^{1+\gamma+1+\delta}, \mu^{+1+\gamma+1}, \mu^{+1+\gamma}) \twoheadrightarrow (\mu^{+1+\gamma}, \mu^{+1+\delta}, \mu^{+}, \mu)$$

holds in this model. Taking $\gamma = n$ and $\mu = \omega_k$, one gets the following:

7.41 Corollary. *Suppose that there is an elementary embedding $j : V \to M$ with critical point κ such that $M^{j(\kappa)^{+n}} \subseteq M$. Then for each $k \in \omega$ there is a forcing extension in which*

$$(\aleph_{2n+k+2}, \aleph_{n+k+1}) \twoheadrightarrow (\aleph_{n+k+1}, \aleph_k).$$

Taking $\gamma = \omega + 1, \delta = \omega$ and $\mu = \omega$ one sees:

7.42 Corollary. *Suppose that there is an elementary embedding $j : V \to M$ with critical point κ such that $M^{j(\kappa)^{+\omega+1}} \subseteq M$. Then there is a forcing extension in which*

$$(\aleph_{\omega+\omega+1}, \aleph_{\omega+\omega}) \twoheadrightarrow (\aleph_{\omega+1}, \aleph_\omega).$$

Using arguments very similar to Proposition 3.9, we see that in a model W where $(\aleph_{\omega+\omega+1}, \aleph_{\omega+\omega}) \twoheadrightarrow (\aleph_{\omega+1}, \aleph_\omega)$, every algebra $\mathfrak{A}$ on $\aleph_{\omega+\omega+1}$ has an elementary substructure $\mathfrak{B}$ of size $\aleph_{\omega+1}$ with $\aleph_\omega \subseteq \mathfrak{B}$. Starting from this property, Levinski, Magidor and Shelah in [86] showed that if $G \subseteq \mathrm{Col}(\omega, \aleph_\omega)$ is generic over W, then in the resulting model $(\aleph_{\omega+1}, \aleph_\omega) \twoheadrightarrow (\aleph_1, \aleph_0)$.

We note that the "skipping cardinals" technique is very flexible. It is no longer necessary to force with the Silver collapse, as the geometry of the conditions is no longer relevant. Indeed any $\kappa^{+\gamma}$-closed forcing, such as the Levy collapse, works.

Also, there is no need to fix γ. We can use a function $f : \kappa \to \kappa$ and force with $\mathbb{S}(\alpha^{+f(\alpha)}, \kappa)$ in the construction of $\mathbb{P}$. For the final model we force with $\mathbb{P} * \mathbb{S}(\kappa^{j(f)(\kappa)}, \lambda)$. The partial ordering $\mathbb{P}$ need not have fixed supports, but can have Easton or many other types of support.

$\aleph_3$-Dense Ideals on ω_3

Magidor [89] showed how to use the skipping cardinals technique to get ideals with simple quotients on sets of the form $[\lambda]^\kappa$ where there is a gap between λ and κ.

We start with a model of GCH and a huge embedding j and skip γ cardinals, so that our forcing is $\mathbb{P} * \mathbb{S}(\kappa^{+\gamma}, \lambda)$. Let $G * H \subseteq \mathbb{P} * \mathbb{S}(\kappa^{+\gamma}, \lambda)$ be generic and $\hat{G} \subseteq j(\mathbb{P})$ be generic extending i"$G * H$, where i is the regular embedding of $\mathbb{P} * \mathbb{S}(\kappa^{+\gamma}, \lambda)$ into $j(\mathbb{P})$.

By GCH, $|P([\lambda]^\kappa)^{V[G*H]}| = \lambda^+$ in $V[\hat{G}]$. Since $j(\mathbb{S}(\kappa^{+\gamma}, \lambda))$ is λ^+-closed, in $V[\hat{G}]$ we can build a pseudo-generic tower $\mathcal{T} \subseteq j(\mathbb{S}(\kappa^{+\gamma}, \lambda))$ such that for all $A \in P([\lambda]^\kappa)^{V[G*H]}$ there is a $q \in \mathcal{T}$ deciding the statement j"$\lambda \in j(A)$, and for each regressive function $f : [\lambda]^\kappa \to \lambda$ that lies in V there is a $q \in \mathcal{T}$ deciding the value of $j(f)(j$"$\lambda)$.

Let $\tilde{U} \in V[\hat{G}]$ be the ultrafilter on $P([\lambda]^\kappa)^{V[G*H]}$ defined by setting $A \in \tilde{U}$ iff there is a $q \in \mathcal{T}$ such that $q \Vdash j``\lambda \in j(A)$. Then $\tilde{U}$ is $V[G*H]$ κ-complete, fine and normal for functions that lie in $V[G*H]$. Working in $V[G*H]$, let I be the collection of $X \subseteq [\lambda]^\kappa$ such that $\|X \in \tilde{U}\|_{j(\mathbb{P})/(G*H)} = 0$. Applying Proposition 7.13, we conclude that in $V[G*H]$,

$$\mathbb{B}(P([\lambda]^\kappa)/I) \cong \mathbb{B}(\mathbb{P}).$$

In particular, $P([\lambda]^\kappa)/I$ has a dense set of size λ.

From this we conclude:

7.43 Theorem (Magidor [89]). *Suppose that $\mu < \kappa$ are regular, κ is huge, and* GCH *holds. Let $\gamma < \kappa$ be a successor ordinal. Then there is a forcing extension in which $\kappa = \mu^+$, $\lambda = \kappa^{+\gamma+1}$ and there is a normal, fine, κ-complete, λ-dense, λ-saturated ideal on $[\lambda]^\kappa$.*

Magidor's original paper only claimed that the ideal is λ-centered; however the slight additional strength stated is immediate from Proposition 7.13.

This theorem is most striking when μ and γ are small:

7.44 Corollary. *Suppose that there is a huge cardinal and* GCH *holds. Then there is a forcing extension in which there is a normal, fine, countably complete, $\aleph_3$-dense, $\aleph_3$-saturated ideal on $[\omega_3]^{\omega_1}$.*

In particular, by projecting to ω_3 one sees that it is consistent that there is a countably complete, uniform $\aleph_3$-dense ideal on ω_3.

The author notes that a similar projection argument also shows that in Magidor's model, if we make $\kappa = \omega_1$, $\lambda = \omega_3$ as in the previous corollary, then in the resulting model we get a normal, fine, countably complete, $\aleph_3$-saturated ideal on $[\omega_2]^{<\omega_1}$. Similar results hold for general κ and γ.

7.10. Higher Chang's Conjectures and $\aleph_\omega$ Jónsson

In this section we continue the discussion begun in Sect. 5.2. The Kunen technique of extending generic elementary embeddings comes tantalizingly close to showing the consistency of $\aleph_\omega$ being Jónsson. Recall the definition in Sect. 5.2 of the critical sequence $\langle \kappa_n : n \in \omega \rangle$. By the result of Sect. 5.2, if there is a normal, fine, countably complete ideal on $[\kappa_\omega]^{\kappa_\omega}$, then κ_ω is Jónsson. It is natural to attempt to try to force the existence of such an ideal on $\aleph_\omega$ with the κ_n's being a subsequence of the ω_n's.

Indeed it suffices to start with an elementary embedding $j : V \to M$ such that $V_{\kappa_\omega} \subseteq M$, and force to make the κ_n's a subsequence of the ω_n's in such a way that the embedding j can be extended generically. To date this program has limited success:

7.45 Theorem (Foreman [33]). *Suppose that $j : V \to M$ is a 2-huge embedding and $1 \le n_0 < n_1 < n_2$ are elements of ω such that $n_2 - n_1 \ge n_1 - n_0$. Then there is a forcing extension $\mathbb{P} * \mathbb{R} * \mathbb{S}$ such that:*

1. *$\mathbb{P} * \mathbb{R} * \mathbb{S}$ is $<\omega_{n_0-1}$-closed and κ_2-c.c.,*
2. *$\mathbb{S}$ is $<\kappa_1^{+n_2-n_1-1}$-closed in $V^{\mathbb{P}*\mathbb{R}}$,*
3. *In $V^{\mathbb{P}*\mathbb{R}*\mathbb{S}}$, $\kappa_i = \omega_{n_i}$, and*
4. *If $G * H * K \subseteq \mathbb{P} * \mathbb{R} * \mathbb{S}$ is generic then there are $\hat{G} * \hat{H} * \hat{K} \subseteq j(\mathbb{P} * \mathbb{R} * \mathbb{S})$ such that j can be extended to a*

$$\hat{j} : V[G * H * K] \to M[\hat{G} * \hat{H} * \hat{K}].$$

From this we get the following corollaries:

7.46 Corollary. *Suppose that having a 2-huge cardinal is consistent. Then for $1 \leq n_0 < n_1 < n_2$ such that $n_2 - n_1 \geq n_1 - n_0$ it is consistent that*

$$(\aleph_{n_2}, \aleph_{n_1}, \aleph_{n_0}) \twoheadrightarrow (\aleph_{n_1}, \aleph_{n_0}, \aleph_{n_0-1}).$$

Using a standard pseudo-generic tower argument:

7.47 Corollary. *Suppose that having a 2-huge cardinal is consistent. Then for $1 \leq n$ it is consistent that $[\omega_{n+1}]^{\omega_n}$ carries a normal, fine, $\aleph_n$-complete, $\aleph_{n+2}$-saturated ideal.*

The proof of Theorem 7.45 is a quite complicated adaptation of the Kunen technique and beyond the scope of this chapter. An attempt to extend Theorem 7.45 to 3-huge cardinals and beyond runs into serious technical difficulties known as "ghost coordinates". This approach has not been successful to date.

7.11. The Magidor Variation

In this section we present a development of Kunen's technique invented by Magidor. The method allows one to use the Kunen partial ordering at an *almost* huge cardinal κ to produce saturated ideals. Indeed Magidor's method of avoiding the use of master conditions allows the Kunen partial ordering to be simplified. The Levy collapse can be substituted for the Silver collapse, as the function of the Silver collapse was to allow the construction of a master condition. What is lost, however, is the fact that Chang's Conjecture holds in the resulting extensions.

We will use elaborations of Magidor's techniques in Sect. 8.2 where we present forcing constructions making various natural ideals saturated. We present here a version from [40] that we will use for the more demanding situations in Sect. 8.2.

Frequently, given $j : V \to M$, a partial ordering $\mathbb{P}$ and a V-generic $G \subseteq \mathbb{P}$, we will want to extend j to an elementary embedding $\hat{j} : V[G] \to M[H]$. Magidor realized that it is only necessary that H be M-generic, rather than fully V-generic. In some situations this allows us to extend j without having a master condition.

The embedding $j : \mathcal{B}(\mathbb{P}) \to \mathcal{B}^M(j(\mathbb{P}))$ is a Boolean homomorphism. The embedding j can be extended iff there is an M-generic H such that $j``G \subseteq H$. Translating this into the language of Boolean algebras, this is saying that $H$ is disjoint from the ideal $\mathcal{I} = \{q \in \mathcal{B}^M(j(\mathbb{P})) :$ there is a $p \in j``G$ such that $p \wedge q = 0\}$. We can force over V with the partial ordering $\mathcal{B}^M(j(\mathbb{P}))/\mathcal{I}$, and hope that it yields an $H \subseteq \mathcal{B}^M(j(\mathbb{P}))$ that is M-generic. The next lemma is Remark 20 from [40] and gives a sufficient criterion for this to happen.

7.48 Lemma. *Let λ be a regular cardinal. Let $M \subseteq V$ be a model of set theory such that $M^{<\lambda} \subseteq M$. Suppose that $\mathbb{P} \in M$ is a $<\lambda$-closed partial ordering and that $\mathcal{F} \subseteq \mathbb{P}$ is a $<\lambda$-closed filter with dual $\mathcal{I}$ such that every dense set $D \subseteq \mathbb{P}$ lying in M is dense in $\mathbb{P}/\mathcal{I}$. Then $\mathbb{P}/\mathcal{I}$ is a $<\lambda$-closed partial ordering such that forcing with $\mathbb{P}/\mathcal{I}$ adds an M-generic filter H for $\mathbb{P}$ such that $\mathcal{F} \subseteq H$.*

A corollary of this is the following:

7.49 Corollary. *Let λ be a regular cardinal with $\lambda^{<\lambda} = \lambda$. Let $M \subseteq V$ be a model of set theory such that $M^{<\lambda} \subseteq M$. Suppose that $|\eta| = \lambda$ but $M \models$ "η is an inaccessible cardinal". Suppose that $\mathcal{F} \in V$ is a filter on* $\mathrm{Col}(\lambda, <\eta)$ *generated by a decreasing sequence of conditions $\langle m_\alpha : \alpha < \lambda\rangle$ such that for all $\beta < \eta$ there is an m_α such that*

$$\mathcal{F} \restriction \mathrm{Col}(\lambda, <\beta) = \{p \in \mathrm{Col}(\lambda, <\beta) : m_\alpha \leq_{\mathrm{Col}(\lambda,<\eta)} p\}.$$

Let $\mathcal{I}$ be the ideal dual to $\mathcal{F}$. Then forcing with $\mathrm{Col}(\lambda, <\eta)/\mathcal{I}$ *adds an M-generic object H to* $\mathrm{Col}(\lambda, <\eta)$ *with $\mathcal{F} \subseteq H$. Moreover, in V,* $\mathrm{Col}(\lambda, <\eta)/\mathcal{I}$ *is isomorphic to* $\mathrm{Add}(\lambda)$.

This corollary works for any partial ordering $\mathbb{Q} \in M$ of cardinality λ in V such that in V, there is a filtration $\langle \mathbb{Q}_\alpha : \alpha < \lambda\rangle$ of $\mathbb{Q}$ and a V-stationary collection of α such that $\mathbb{Q}_\alpha$ is a regular subordering of $\mathbb{Q}$. In particular, it also applies to the Silver collapse $\mathbb{S}(\lambda, \eta)$.

The following fact about almost huge cardinals is standard. It is proved in [40] among other places:

7.50 Lemma. *Suppose that κ is an almost huge cardinal. Then there is an almost huge embedding $j : V \to M$ with critical point κ, $j(\kappa) = \lambda$, $j``\lambda$ is cofinal in $j(\lambda)$ and $|j(\lambda)| = \lambda$. Moreover, if λ is the least such, then λ is not Mahlo.*

We now can outline:

7.51 Theorem (Magidor). *Suppose that κ is an almost huge cardinal and $\mu < \kappa$ is regular. Then there is a forcing extension in which $\kappa = \mu^+$ and there is a κ-complete, κ^+-saturated ideal on κ.*

Proof. We assume that j satisfies the conclusion of Lemma 7.50. Let $\mathbb{P}$ be the partial ordering constructed by Kunen, and $\mathbb{Q}$ be the Silver collapse $\mathbb{S}(\kappa, \lambda)$

to make λ into κ^+, as constructed in $V^{\mathbb{P}}$. Let $G*H \subseteq \mathbb{P}*\mathbb{Q}$ be generic. As in the Kunen construction, $\mathbb{P}*\mathbb{Q}$ is regularly embedded into $j(\mathbb{P})$ by a canonical map i that is the identity on $\mathbb{P}$ and there is a generic $\hat{G} \subseteq j(\mathbb{P})$ extending $i``(G*H)$. By the κ-c.c., we see that j can be extended to $\hat{j} : V[G] \to M[\hat{G}]$. Moreover, $M[\hat{G}]$ is closed under $<\lambda$-sequences from $V[\hat{G}]$.

For $\alpha < \lambda$, let $m_\alpha = \bigcup\{j(q) : q \in H \cap \mathbb{S}(\kappa,\alpha)\}$ and $\mathcal{F}$ be the filter generated by $\{m_\alpha : \alpha \in \lambda\}$. Applying Corollary 7.49 (for the Silver collapse, as in the remarks following the corollary), we see that we can force with $\mathbb{S}(\lambda, j(\lambda))^M/\mathcal{I}$ over V to get an M-generic filter $\hat{H}$ extending $\mathcal{F}$.

Since $\hat{H} \supseteq \mathcal{F}$, we can extend j to $\hat{j} : V[G*H] \to M[\hat{G}*\hat{H}]$. The rest of the argument goes as before: $\mathbb{S}(\lambda, j(\lambda))^M/\mathcal{I}$ is $<\lambda$-closed, and hence a pseudo-generic tower argument gives us a $V[G*H]$-ultrafilter on κ that is κ-complete, and normal for sequences that lie in $V[G*H]$. This ultrafilter lies in $V[\hat{G}]$, which is a κ-c.c. extension of $V[G*H]$. By Example 3.30, we are done. $\dashv$

7.52 Remark. As in the Kunen construction, the ideal in Magidor's model can be seen to be layered; this is an immediate corollary of Proposition 7.13.

There are several advantages to Magidor's variation. In the Kunen construction, the use of the Silver collapse was important: the conditions had to have the right "shape" for the union of $j``H$ to be an element of $j(\mathbb{Q})$. The Magidor variation does not use $\bigcup j``H$ as a condition; it extends the filter generated by $j``H$. For this one only needs the $<\lambda$-closure of the conditions. Any $<\kappa$-closed partial ordering that collapses λ to κ^+ and has cardinality λ works. In particular, one can do a similar construction where $\mathbb{Q} = \mathrm{Col}(\kappa, <\lambda)$.

If we work a bit harder, we can see that in the Kunen/Magidor situation, it is not necessary to force beyond $j(\mathbb{P})$ to extend the elementary embedding j. Since $|j(\lambda)| = \lambda$, the cardinality of $\mathbb{S}^{M[\hat{G}]}(\lambda, j(\lambda))$ is λ in $V[\hat{G}]$ and $M[\hat{G}]$ has λ-many dense subsets of $S^{M[\hat{G}]}(\lambda, j(\lambda))$. Since $S^{M[\hat{G}]}(\lambda, j(\lambda))$ is $<\lambda$-closed in $V[\hat{G}]$ there is an $M[\hat{G}]$-generic filter $\hat{H} \subseteq S^{M[\hat{G}]}(\lambda, j(\lambda))$ lying in $V[\hat{G}]$. Using Lemma 7.48, this filter can be built to extend $j``H$. Hence in $V[\hat{G}]$ there is a generic elementary embedding $\hat{j} : V[G*H] \to M[\hat{G}*\hat{H}]$.

7.12. More Saturated Ideals

Is it consistent to have a κ^+-saturated ideal if κ is the successor of a singular cardinal? Can every regular cardinal κ carry a κ^+-saturated ideal? Can there be a model where

$$\text{for all } n > m > 0,\ (\aleph_n, \aleph_{n-1}) \twoheadrightarrow (\aleph_m, \aleph_{m-1})?$$

These questions were answered in the paper [34]. We briefly outline the construction that answers these questions.

Let's now analyze key points of Kunen's construction, with the intention of isolating the essential elements. The main goal of the original construction is to have $\mathbb{P} * \mathbb{S}(\kappa, \lambda)$ sit as a regular subordering of $j(\mathbb{P})$. In the construction, the family of Silver collapses could be replaced by any family $\mathcal{Q} = \{\mathbb{Q}(\alpha, \beta)\}$ of uniformly definable partial orderings indexed by ordinals α, β such that $\mathbb{Q}(\alpha, \beta) \subseteq V_\beta$. Then the construction could be arrange so that $\mathbb{P} * \mathbb{Q}(\kappa, \lambda)$ is regularly embedded into $j(\mathbb{P})$.

In our original description of the construction, we diagonalized over *all* small regular suborderings $\mathbb{Q}$ of $\mathbb{P}$ to make sure that $\mathbb{Q} * S(\alpha, \kappa)$ is regularly embedded into $\mathbb{P}$. As we saw in the Laver construction, this is not necessary. Since $\mathbb{P}$ is $j(\mathbb{P}) \cap V_\kappa$, we need only consider $\mathbb{Q}$'s of the form $\mathbb{P} \cap V_\alpha$. Thus at a typical stage α in the iteration, we force with $\mathbb{Q}^{V^{\mathbb{P} \cap V_\alpha}}(\alpha, \kappa)$ just in case $\mathbb{P}_\alpha \cap V_\alpha$ is a regular subordering of $\mathbb{P}_\alpha$. This gives us a partial ordering $\mathbb{P}$ that is definable in the parameter κ. Reflecting the definition, we get another family of partial orderings $\mathbb{P}(\alpha)$ for many $\alpha < \kappa$. Provided that partial orderings in $\mathcal{Q}$ are not too exotic, it is easy to verify that $\mathbb{P}(\alpha) = \mathbb{P} \cap V_\alpha$ for most α.

Summarizing, if one is given a family $\mathcal{Q}$, the construction produces another family of partial orderings $\mathbb{P}(\alpha)$ such that for most $\alpha < \beta$,

- $\mathbb{P}(\alpha)$ is α-c.c. and makes α into a cardinal such as ω_1 or ω_2,
- $\mathbb{P}(\alpha)$ is naturally included in $\mathbb{P}(\beta)$ and is a regular subordering, and
- there is a regular embedding of $\mathbb{P}(\alpha) * \mathbb{Q}(\alpha, \beta)$ into $\mathbb{P}(\beta)$ extending the inclusion of $\mathbb{P}(\alpha)$ into $\mathbb{P}(\beta)$.

Since the construction is "top down" there is no problem iterating it for finitely many cardinals. For example, to do a construction like this for three cardinals one would start with two huge embeddings j_0 and j_1 with the property that $\kappa_0 = \mathrm{crit}(j_0)$ and $j_0(\kappa_0) = \kappa_1$, where $\kappa_1 = \mathrm{crit}(j_1)$. We let $\kappa_2 = j_1(\kappa_1)$.

We can define a family of partial orderings $\mathbb{Q}(\alpha, \beta)$ by doing the Kunen construction with α-closed partial orderings as in the construction showing Corollary 7.37. The inductive construction yields a definable family of partial orderings $\mathbb{Q}(\alpha, \beta)$ defined such that $\mathbb{Q}(\kappa_0, \kappa_2)$ has $\mathbb{Q}(\kappa_0, \kappa_1) * S(\kappa_1, \kappa_2)$ as a regular subordering. Let $\{\mathbb{P}(\alpha)\}$ be the partial orderings anticipating the family of $\mathbb{Q}(\alpha, \beta)$'s.

If we force with $\mathbb{P}(\kappa_0) * \mathbb{Q}(\kappa_0, \kappa_1) * S(\kappa_1, \kappa_2)$, then we get a model where $(\aleph_3, \aleph_2) \twoheadrightarrow (\aleph_2, \aleph_1)$, $(\aleph_2, \aleph_1) \twoheadrightarrow (\aleph_1, \aleph_0)$ and there are saturated ideals on both ω_1 and ω_2.

For a fixed m, similar methods using the Silver collapse at the top and working downwards give the consistency of the statement that:

- for all positive $n < m$ there is an $\aleph_{n+1}$-saturated ideal on ω_n, and
- $(\aleph_{n+1}, \aleph_n) \twoheadrightarrow (\aleph_n, \aleph_{n-1})$.

It requires a new idea to prove the analogous results for an infinite interval of cardinals. This was done in [34], where the author showed how to uniformly construct a family of partial orderings $\mathbb{R}(\vec{\alpha})$ for finite increasing sequences of Mahlo cardinals[74] $\vec{\alpha}$ such that:

- $\mathbb{R}(\alpha,\beta) \subseteq V_\beta$, $\mathbb{R}(\alpha,\beta)$ is $<\alpha$-closed, β-c.c. and collapses β to be the successor of α,
- if $\vec{\alpha} = (\alpha_0, \ldots, \alpha_n)$ and $\beta > \alpha_n$, then $\mathbb{R}(\vec{\alpha}^\frown\beta) = \mathbb{R}(\vec{\alpha}) * \mathbb{R}(\alpha_n, \beta)$,
- if $\vec{\alpha}_0$ and $\vec{\alpha}_1$ are increasing sequences of Mahlo cardinals and β is a Mahlo cardinal where $\max \vec{\alpha}_0 < \beta < \min \vec{\alpha}_1$, then there is a natural embedding of $\mathbb{R}(\vec{\alpha}_0^\frown\beta^\frown\vec{\alpha}_1)$ into $\mathbb{R}(\vec{\alpha}_0^\frown\vec{\alpha}_1)$ and these embeddings commute in the obvious sense, and
- $\mathbb{R}$ has the type of "geometry" that allows master conditions to exist.

If we are given a huge embedding $j_n : V \to M_n$ with critical point κ_n and $j_n(\kappa_n) = \kappa_{n+1}$ and a finite increasing sequence of Mahlo cardinals $\vec{\alpha}$ below κ_n, then there is a natural embedding:

$$i_n : \mathbb{R}(\vec{\alpha}, \kappa_n) * \mathbb{R}(\kappa_n, \kappa_{n+1}) \to \mathbb{R}(\vec{\alpha}, \kappa_{n+1}) = j(\mathbb{R}(\vec{\alpha}, \kappa_n)).$$

Thus if $\hat{G} \subseteq \mathbb{R}(\vec{\alpha}, \kappa_{n+1})$ is generic then it induces a generic $G * H \subseteq \mathbb{R}(\vec{\alpha}, \kappa_n) * \mathbb{R}(\kappa_n, \kappa_{n+1})$, and there is an $m \in \mathbb{R}(\kappa_{n+1}, j_n(\kappa_{n+1}))$ such that

$$M[\hat{G}] \models \text{for all } p \in H,\ m \leq j_n(p).$$

In particular, it is possible to extend the elementary embedding j_n to a

$$\hat{j_n} : V[G * H] \to M[\hat{G} * \hat{H}].$$

This allows us to apply the pseudo-generic tower arguments to conclude that in $V[G*H]$, there is a κ_n-complete, κ_n^+-saturated ideal on κ_n and if the largest element of $\vec{\alpha}$ is α_n, then $(\kappa_{n+1}, \kappa_n) \twoheadrightarrow (\kappa_n, \alpha_n)$.

We need to see that the various $\mathbb{R}(\kappa_n, \kappa_{n+1})$ do not destroy the effects of $\mathbb{R}(\kappa_m, \kappa_{m+1})$ for $m < n$. For this the following lemma was first proved in [34]. It is proved using a pseudo-generic tower argument.

7.53 Lemma. *Suppose that $\mathbb{P}$ is a $<\kappa$-closed partial ordering and $\kappa > \lambda \geq \kappa' > \lambda'$. Let $G \subseteq \mathbb{P}$ be generic. Then*

- *if $(\kappa, \lambda) \twoheadrightarrow (\kappa', \lambda')$ then $V[G] \models (\kappa, \lambda) \twoheadrightarrow (\kappa', \lambda')$, and*
- *if there is a λ-complete, λ^+-saturated ideal on λ then $V[G] \models$ "there is a λ-complete, λ^+-saturated ideal on λ".*

[74] For these purposes, we include ω as a Mahlo cardinal.

Suppose now that we are given a sequence of huge embeddings $\langle j_n : n \in \omega \rangle$ where the critical point of j_n is κ_n and $j_n(\kappa_n) = \kappa_{n+1}$. We have argued that if we take a generic $G_n \subseteq \mathbb{R}(\omega, \kappa_0, \kappa_1, \ldots, \kappa_{n+1})$ then in $V[G_n]$ there is a saturated ideal on ω_{n+1} and $(\aleph_{n+2}, \aleph_{n+1}) \twoheadrightarrow (\aleph_{n+1}, \aleph_n)$. If we force with the inverse limit over $n \in \omega$ of the $\mathbb{R}(\omega, \kappa_0, \kappa_1, \ldots, \kappa_{n+1})$ we will have the conclusion that for all $n \in \omega$ there is a saturated ideal on ω_{n+1} and $(\aleph_{n+2}, \aleph_{n+1}) \twoheadrightarrow (\aleph_{n+1}, \aleph_n)$.

What remains is to outline the construction of the $\mathbb{R}$'s. An important tool for this is the *termspace* partial ordering. This stratagem is due to Laver and was exploited most fruitfully by Abraham [2].

7.54 Definition. Let $\mathbb{P}$ be a partial ordering and $\mathbb{Q}$ be a $\mathbb{P}$-term for a partial ordering. The *termspace* partial ordering $\mathbb{Q}^*$ is defined to be the partial ordering whose domain consists of all $\mathbb{P}$-terms for elements of $\mathbb{Q}$, with the ordering that $\sigma \leq_{\mathbb{Q}^*} \tau$ iff $1 \Vdash_{\mathbb{P}} \sigma \leq \tau$.

We can take the domain of $\mathbb{Q}^*$ to be a set, since there are only a set of equivalence classes of elements of $\mathbb{Q}$ with respect to the relation $\sigma \sim \tau$ iff $1 \Vdash_{\mathbb{P}} \sigma = \tau$. Note also that the termspace partial ordering depends on both $\mathbb{P}$ and $\mathbb{Q}$. It is denoted here by $A(\mathbb{P}, \mathbb{Q})$.

One must prove some basic facts about the termspace partial ordering such as:

1. (Laver) The identity map defines a projection from $\mathbb{P} \times \mathbb{Q}^*$ to $\mathbb{P} * \mathbb{Q}$.

2. (Abraham) If $1 \Vdash$ "$\mathbb{Q}$ is $<\lambda$-closed", then $\mathbb{Q}^*$ is $<\lambda$-closed.

3. (Foreman) $A(\mathbb{P}, A(\mathbb{Q}, \mathbb{R})) \cong A(\mathbb{P} * \mathbb{Q}, \mathbb{R})$ canonically.

4. (Foreman) $A(\mathbb{P}, \prod_{n\in\omega} \mathbb{Q}_n) \cong \prod_{n\in\omega} A(\mathbb{P}, \mathbb{Q}_n)$ canonically.

For regular $\alpha < \beta$ we define the partial orderings $\mathbb{R}(\alpha, \beta)$ by induction on inaccessible β simultaneously in all generic extensions of V. Suppose that we have defined $\mathbb{R}(\alpha, \beta)$ for all pairs $\alpha < \beta$ which lie below λ. We now define $\mathbb{R}(\alpha, \lambda)$.

- If λ is the first inaccessible above α, let $\mathbb{R}(\alpha, \lambda) = \mathbb{S}(\alpha, \lambda)$.

- Otherwise, by induction on $n \in \omega$ we define partial orderings $S^n(\alpha, \lambda)$. We will define this in the ground model. The same definition, relativized appropriately, will allow us to define a partial ordering $S^n(\alpha, \lambda)^{\mathbb{R}(\gamma,\alpha)}$ in a generic extension of V by a partial ordering of the form $\mathbb{R}(\gamma, \alpha)$.

  For $n = 0$, $S^0(\alpha, \lambda) = \mathbb{S}(\alpha, \lambda)$.

  Assume that we have defined $S^n(\delta, \lambda)$ in every extension of V of the form $\mathbb{R}(\gamma, \delta)$ for $\alpha < \delta < \lambda$ and δ inaccessible. Then we let $S^{n+1}(\alpha, \lambda)$ be the product with supports of size α of all the partial orderings $A(\mathbb{R}(\alpha, \delta), S^n(\delta, \lambda))$ as δ ranges over Mahlo cardinals in the interval between α and λ.

We let $\mathbb{R}(\alpha,\lambda)=\prod_{n\in\omega} S^n(\alpha,\lambda)$.

The main point of this construction is the following: if the identity mapping of $\mathbb{R}(\alpha,\delta)$ into $\mathbb{R}(\alpha,\lambda)$ is a regular embedding, then for each n, $A(\mathbb{R}(\alpha,\delta), S^n(\delta,\lambda))$ is a factor in $S^{n+1}(\alpha,\lambda)$. Hence, there is an embedding of $\mathbb{R}(\alpha,\delta)\times\prod_{n\in\omega} A(\mathbb{R}(\alpha,\delta), S^n(\delta,\lambda))$ into $\mathbb{R}(\alpha,\lambda)=\prod_{n\in\omega} S^n(\alpha,\lambda)$ that extends the identity mapping on $\mathbb{R}(\alpha,\delta)$. By property 4 above, we see that $\mathbb{R}(\alpha,\delta)\times A(\mathbb{R}(\alpha,\delta),\prod_{n\in\omega} S^n(\delta,\lambda))$ is canonically embedded in $\mathbb{R}(\alpha,\lambda)$, and hence by property 1 above we see that $\mathbb{R}(\alpha,\delta)*\mathbb{R}(\delta,\lambda)$ is canonically embedded in $\mathbb{R}(\alpha,\lambda)$.

We now discuss the chain conditions satisfied by the $\mathbb{R}(\alpha,\beta)$'s. Let $\alpha<\beta$ be Mahlo cardinals, and $\mathbb{P}$ be an α-c.c. partial ordering. Then one can check that $A(\mathbb{P},\mathbb{S}(\alpha,\beta))$ is isomorphic to a subcollection of the order-preserving maps from $\mathbb{P}$ to $\mathbb{S}(\alpha,\beta)$ ordered by setting $f\le g$ iff there is a dense set $D\subseteq\mathbb{P}$ such that for all $p\in D$, $f(p)\le g(p)$. In particular, the chain condition of $A(\mathbb{P},\mathbb{S}(\alpha,\beta))$ is less than or equal to the chain condition of the product of $|\mathbb{P}|$-copies of $\mathbb{S}(\alpha,\beta)$ ordered coordinatewise. Though the details are quite technical this is the basis for the argument showing:

7.55 Lemma. *For all regular β and all Mahlo λ, $\mathbb{R}(\beta,\lambda)$ is λ-c.c. and has cardinality λ.*

We have outlined the proof of the following theorem:

7.56 Theorem. *Suppose that $\langle j_n : n\in\omega\rangle$ is a sequence of huge embeddings and the critical point of j_n is κ_n and $j_n(\kappa_n)=\kappa_{n+1}$. Then there is a partial ordering $\mathbb{P}$ such that for all generic $G\subseteq\mathbb{P}$, $V[G]$ satisfies:*

1. *for all $n\in\omega$ there is an $\aleph_{n+1}$-complete, $\aleph_{n+2}$-saturated ideal on ω_{n+1}, and*
2. *for all $n\in\omega$, $(\aleph_{n+2},\aleph_{n+1})\twoheadrightarrow(\aleph_{n+1},\aleph_n)$.*

What about the consistency of a κ^+-saturated ideal if κ is the successor of a singular cardinal? This is also answered in [34]. From the machinery we have developed this is not difficult.

Suppose that κ is an indestructibly supercompact cardinal[75] and that there is a huge cardinal μ above κ. We can do the Kunen construction to collapse μ to be κ^+ and arrange that there is a μ^+-saturated ideal I on μ. Then κ is still supercompact so we can follow this by forcing to make κ singular, or even $\aleph_\omega$.

As long as the forcing making κ singular is κ-centered, Corollary 7.21 implies that the ideal I remains μ^+-saturated. Typically, Prikry-type forcings are κ centered even when mixed with collapsing to make κ into $\aleph_\omega$.[76]

[75] That is, κ is supercompact and remains so after any forcing extension via a $<\kappa$-directed closed forcing. Laver [82] showed how to make a supercompact cardinal indestructible, and his construction is given in Cummings's chapter in this Handbook. See also Definition 11.4.
[76] For example, one can use the "projected" version of Magidor forcing collapsing κ to be $\aleph_\omega$ is κ-centered (see [88, 46]).

We have outlined the argument that if we first force the existence of a supercompact κ such that κ^+ carries a κ^{+2}-saturated ideal, and then collapse κ to be $\aleph_\omega$ in the usual way, the resulting model W satisfies the sentence:

$$\aleph_{\omega+1} \text{ carries an } \aleph_{\omega+2}\text{-saturated ideal.}$$

This outline is very general. For example, if κ is supercompact and the nonstationary ideal on $\mu = \kappa^+$ restricted to a particular stationary set is saturated,[77] then after making $\kappa = \aleph_\omega$ in the standard way, the nonstationary ideal on μ restricted to that stationary set is still saturated, and $\mu = \aleph_{\omega+1}$.

Life is not quite so simple if one wants to have all cardinals less than or equal to $\aleph_{\omega+1}$ carry a saturated ideal. We now outline the proof that this is possible and even:

7.57 Theorem (Foreman [34]). *Suppose that there is a huge cardinal. Then there is a model of* ZFC + *"for all regular cardinals κ there is a κ-complete, κ^+-saturated ideal on κ".*

Here is a brief outline of the proof of this theorem. We start with a model of GCH with a λ-supercompact cardinal κ that has some additional properties. If $j : V \to M$ is the λ-supercompact embedding, we will assume that there is a set $X \subseteq \kappa$ such that:

1. $\kappa \in j(X)$,
2. for $\alpha < \beta$ belonging to X there is an almost huge embedding $j_{\alpha,\beta}$ that has critical point α and $j_{\alpha,\beta}(\alpha) = \beta$, and
3. λ is bigger than the first 5 elements of $j(X)$ above κ.

The existence of such a pair κ and λ follows from the assumption of a huge cardinal.

To get the necessary anticipation properties we modify the partial orderings $\mathbb{R}(\alpha, \beta)$ defined in the proof of Theorem 7.56 so that if $\alpha < \alpha'$ are limit elements of X, then $\mathbb{R}(\alpha, \alpha_1) * \mathbb{R}(\alpha_1, \alpha_2) * \mathbb{R}(\alpha_2, \alpha_3) * \mathbb{R}(\alpha_3, \alpha_4) * (\mathrm{Col}(\alpha_4, \alpha') \times \mathbb{R}(\alpha', \alpha'_1))$ is canonically embedded into $\mathbb{R}(\alpha, \alpha_1) * \mathbb{R}(\alpha_1, \alpha_2) * \mathbb{R}(\alpha_2, \alpha_3) * \mathbb{R}(\alpha_3, \alpha'_1)$. This involves essentially the same technique as before.

As is common in "singular cardinals" type constructions, we do a preparatory forcing before we change any cofinalities. For $\alpha \in X$, denote the next four elements of X as $\alpha_1, \alpha_2, \alpha_3$ and α_4. The preparatory forcing in this proof is an Easton iteration of length $\kappa + 1$ where, at a limit stage α of X that lies in X, we will collapse $\alpha_1, \ldots, \alpha_4$ using the partial ordering of the form $\mathbb{R}(\alpha, \alpha_1) * \mathbb{R}(\alpha_1, \alpha_2) * \mathbb{R}(\alpha_2, \alpha_3) * \mathbb{R}(\alpha_3, \alpha_4)$. So, if I is the iteration, then I has Easton supports and $I_{\alpha+1} = I_\alpha * (\mathbb{R}(\alpha, \alpha_1) * \mathbb{R}(\alpha_1, \alpha_2) * \mathbb{R}(\alpha_2, \alpha_3) * \mathbb{R}(\alpha_3, \alpha_4))$. At κ we force with $\mathbb{R}(\kappa, \kappa_1) * \mathbb{R}(\kappa_1, \kappa_2) * \mathbb{R}(\kappa_2, \kappa_3) * \mathbb{R}(\kappa_3, \kappa_4)$. Standard arguments show that after forcing with I, κ remains $2^{2^{2^\kappa}}$-supercompact.

[77] Section 8 establishes the consistency of this.

We use the variant definition of the $\mathbb{R}$'s for the preparatory forcing. This is used to establish the following:

7.58 Lemma. *If V_1 is the resulting model after the preparatory forcing, and $\alpha < \alpha'$ are limit elements of X and $G \subseteq \mathrm{Col}(\alpha_4, \alpha')$ is generic over V_1, then in $V_1[G]$, α'_1 is the successor of α_4 and α_4 carries an α_4-complete, α_4^+-saturated ideal.*

This takes care of the local problem of producing saturated ideals on successor of regular cardinals. In V_1, all limit points α of X have the property that for $i \in \{1, 2, 3\}$, $\alpha_i = \alpha^{+i}$ carries a saturated ideal.

A forcing extension of V_1 yields our next model V_2, which has the properties that:

1. all cardinals below κ and above some fixed κ_0 are elements of X, and

2. all successor cardinals between κ_0 and κ are of the form α_i for some $1 \leq i \leq 4$.

The final model is $V_2[g]$ where $g \subseteq \mathrm{Col}(\omega, \kappa_0)$ is generic. The generic collapse g makes all of the remaining regular cardinals below the first inaccessible be of the form α_i for some $\alpha \in X$ and $1 \leq i \leq 4$, while preserving the saturation of the ideals on all of the cardinals above κ_0. If δ is the first inaccessible cardinal in the final model $V_2[g]$ and W is the collection of sets in $V_2[g]$ of rank less than δ, then W is a model of "every regular cardinal carries a saturated ideal".

The crux of the issue is the forcing to produce V_2 from V_1. This follows the general outline of [46], which in turn, adapted Magidor's techniques of [88] to work with Radin forcing.

There are two relevant partial orderings $\mathbb{P}$ and $\mathbb{P}^\pi$ for producing V_2 from V_1. The model V_2 is the result of forcing with $\mathbb{P}^\pi$ over V_1. The first partial ordering $\mathbb{P}$ uses a supercompact Radin forcing to add a closed unbounded set through $\{z \in [\kappa^{+3}]^{<\kappa} : z \cap \kappa \in X\}$. It also uses Levy collapses to make the successor cardinals of V_2 be successors of elements of X. This forcing preserves the fact that κ is a highly Mahlo cardinal.

Since $\mathbb{P}$ adds a closed unbounded set C in $[\kappa^{+3}]^{<\kappa}$, if $\alpha \in X$ is a limit point of $C^\pi = \{z \cap \kappa : z \in C\}$, then $\mathbb{P}$ adds a closed unbounded set through $(\alpha^+)^V$ of order type the same as the order type of $C^\pi \cap \alpha$.

There will be a projection map from $\pi : \mathbb{P} \to \mathbb{P}^\pi$. The forcing $\mathbb{P}^\pi$ adds the Radin-generic closed unbounded subset $C^\pi \subseteq X \cap \kappa$, while collapsing cardinals. The following are some of the properties of $\mathbb{P}^\pi$:

1. If κ_0 is the first point in C^π, then between κ_0 and κ, every limit cardinal α is an element of C and $C \cap \alpha$ is Radin generic for a Radin forcing involving α.

2. If $\alpha < \beta$ are successive points of C^π, then the forcing $\mathbb{P}^\pi$ factors as $\mathbb{P}^\pi_\alpha \times \mathrm{Col}(\alpha_4, \beta) \times \mathbb{P}^\pi_{>\beta}$, where $\mathbb{P}^\pi_\alpha$ is α-centered, and $\mathbb{P}^\pi_{>\beta}$ adds no new β-sequences.

From the factoring we see that for all $\alpha \in X$ that lie on the Radin sequence, we have preserved the saturated ideals on α_1, α_2 and α_3. Each successor element of X on the Radin sequence is collapsed. So to complete the picture we must see that α_4 carries a saturated ideal.

This follows from our remarks about the preparatory forcing. The factoring properties of $\mathbb{P}^\pi$ imply that the subsets of β_1 in the final model are those in the model after forcing over V_1 to with $\mathbb{P}^\pi_\alpha \times \mathrm{Col}(\alpha_4, \beta)$. The forcing $\mathbb{P}^\pi_\alpha$ is α-centered, so it suffices to see that there is a saturated ideal on α_4 in the model produced over V' by forcing with $\mathrm{Col}(\alpha_4, \beta)$. This is the content of the lemma mentioned in the beginning of the proof.

3. $\mathbb{P}$ and $\mathbb{P}^\pi$ have the relevant Prikry type properties.

4. GCH holds in $V^{\mathbb{P}^\pi}$.

These properties ensure that every regular cardinal α less than the first inaccessible cardinal carries an α^+-saturated ideal. We remark that using the techniques of [41] it is easy to verify that the ideals produced in [34] are more than just α^+-saturated—they are α-centered.

We note that a novel element in the proof of Theorem 7.57 is that the successor points on the Radin sequence are collapsed by the forcing. This makes no difference in the proofs of the relevant Prikry properties, as was pointed out by Woodin.

7.13. Forbidden Intervals

Proposition 6.26 showed that for each successor cardinal κ there is a proper class $\mathcal{C}_\kappa$ consisting of intervals I of cardinals such that no regular cardinal λ in I can carry a uniform κ-complete, κ^+-saturated ideal on λ. Each of these intervals was of the form $[\gamma, \delta)$ where δ had cofinality κ. We now state a consistency result appearing in [31] that shows that the limitations given by these intervals is sharp at the upper ends of each interval.

7.59 Theorem. *Suppose that there is a huge cardinal and* GCH *holds. Then there is a partial ordering $\mathbb{P}$ and an α such that in $V^{\mathbb{P}}_\alpha$:*

1. ZFC *holds,*

2. every regular uncountable cardinal ξ carries a normal, ξ-centered ideal on ξ, and

3. if λ is a singular cardinal of cofinality ξ, then for all ideals I on ξ there is a uniform ideal J on λ^+ such that

(a) $P(\xi)/I \cong P(\lambda^+)/J$,

(b) the completeness of I is equal to the completeness of J, and

(c) if I is normal, then J is weakly normal.

After this section was written, Magidor showed that $\aleph_{\omega_1}$ can carry a uniform, countably complete, $\aleph_2$-saturated ideal, a case not covered by Theorem 7.59.

The conclusions of Theorem 7.59 hold in the model constructed in the proof of Theorem 7.57. We indicate some of the elements one needs to see this.

Let $\kappa_0 < \alpha < \delta$ be a singular cardinal of cofinality ξ in $V[G^\pi]$ and I a uniform ideal ξ. To construct an ideal J on the successor of α with quotient isomorphic $P(\xi)/I$, we force with a sufficiently large part of $\mathbb{P}/\mathbb{P}^\pi$ to get a G which projects to G^π, in which $P(\xi^+)^{V[G^\pi]} = P(\xi^+)^{V[G]}$ and which makes $\mathrm{cf}(\alpha^+) = \xi$. In $V[G]$, we choose a closed unbounded subset $\langle \delta_i : i < \xi \rangle$ of $(\alpha^+)^V =_{\mathrm{def}} \eta$ of order type ξ and "copy" the ideal onto η. The resulting ideal $\bar{J}$ in $V[G]$ has the same completeness as I, and the map $\iota : P(\delta)/\bar{J} \to P(\xi)/I$ defined by $\iota(A) = \{i : \delta_i \in A\}$ defines an isomorphism.

Looking carefully at the forcing used to produce G in $V[G^\pi]$ we see that it is sufficiently homogeneous so that $J =_{\mathrm{def}} (P(\delta)^{V[G^\pi]} \cap \bar{J})$ and the isomorphism ι both lie in $V[G^\pi]$. In particular, we see that J has the same degree of completeness as I does and is weakly normal, if I is normal.

7.14. Dense Ideals on ω_1

In the late 1970's Woodin showed that it is consistent to have a countably complete, $\aleph_1$-dense ideal on ω_1, assuming the consistency of ZF + $\mathrm{AD}_{\mathbb{R}}$ + "Θ is regular". Later Woodin [124] improved this result showing, assuming the consistency of an almost huge cardinal, that the following is consistent: For all $\aleph_2$-c.c. partial orderings $\mathbb{P}$ that collapse $\aleph_1$ and have cardinality at most ω_2, there is a countably complete ideal I on ω_1 such that $P(\omega_1)/I$ has a dense set isomorphic to $\mathbb{P}$.

We present here a special case of this result: that it is consistent to have an $\aleph_1$-dense ideal on ω_1.

7.60 Theorem. *Let j be an almost huge embedding with critical point κ_0 and $j(\kappa_0) = \kappa_1$. Let $C_0 \subseteq \mathrm{Col}(\omega, {<}\kappa_0)$ be generic over V. Let $\mathbb{R}_0 = P(\omega) \cap V[C_0]$ and $V_1 = V(\mathbb{R}_0) \subseteq V[C_0]$. Let $\mathbb{Q} = \mathrm{Add}(\omega_1) * \mathbb{Q}'$ be a κ_1-c.c. partial ordering in V_1 that is countably closed, has cardinality κ_1, and collapses κ_1 to be ω_2. Then for all V_1-generic $G \subseteq \mathbb{Q}$, $V_1[G] \models \mathrm{ZFC} + \diamondsuit_{\omega_1}$ + "There is a normal $\aleph_1$-dense ideal J on ω_1".*

We will use a forcing fact:

7.61 Lemma. *Let $V \subseteq W$ be models of* ZFC. *Suppose that:*

1. *κ is an inaccessible cardinal in V,*
2. *$\kappa = \omega_1^W$, and*
3. *if $r \in \mathbb{R}^W$, then there is a partial ordering $\mathbb{Q} \in V$ with $|\mathbb{Q}| < \kappa$ and a V-generic $H \subseteq \mathbb{Q}$ belonging to W such that $r \in V[H]$.*

Then there is a partial ordering $\mathbb{C}$ in W such that if $U \subseteq \mathbb{C}$ is W-generic there is a V-generic object $H \subseteq \mathrm{Col}(\omega, {<}\kappa)$ lying in $W[U]$ such that $\mathbb{R}^{V[H]} = \mathbb{R}^W$. Moreover, if $H_\alpha \subseteq \mathrm{Col}(\omega, {<}\alpha)$ is generic over V and belongs to W, then H can be taken to extend H_α.

Proof (Sketch). Let $\mathbb{C}$ be the partial ordering in W whose domain consists of V-generic filters $H_\alpha \subseteq \mathrm{Col}(\omega, {<}\alpha)$ for some $\alpha < \kappa$. If H_α and H_β are elements of $\mathbb{C}$, then H_α is a stronger condition than H_β iff $\alpha > \beta$ and $H_\alpha \supseteq H_\beta$.

If H^* is generic for $\mathbb{C}$ over W, then $H = \bigcup H^*$ is generic over V for $\mathrm{Col}(\omega, {<}\kappa)$ and every real in W belongs to $V[H]$. ⊣

Proof of Theorem 7.60. Let $\mathbb{R}_0 = P(\omega) \cap V[C_0]$. Since $\mathrm{Add}(\omega_1)$ adds a well-ordering of $\mathbb{R}$ in a canonical way, we see that any generic $G \subseteq \mathbb{Q}$ can be decomposed into $G_0 * G_1$, and $V_1[G_0] \models \mathrm{ZFC}$.

Let $G \subseteq \mathbb{Q}$ be $V[C_0]$-generic. Let $C \subseteq \mathrm{Col}(\omega, \omega_1)$ be $V[C_0, G]$-generic and $\mathbb{R}_1 = P(\omega) \cap V_1[G * C]$.

We let W be the model $V_1[G_0]$ and construct the partial ordering $\mathbb{C} \in W$ as in Lemma 7.61. In $V_1[G * C]$, the cardinality of $P(\mathbb{C})^W$ is countable, so we can build a W-generic object for $\mathbb{C}$. This in turn yields a V-generic $C_0' \subseteq \mathrm{Col}(\omega, {<}\kappa_0)$ belonging to $V_1[G * C]$ such that $\mathbb{R}^{V[C_0]} = \mathbb{R}^{V[C_0']}$. We can now apply Lemma 7.61 in $V_1[G * C]$ to force a V-generic $C_1 \subseteq \mathrm{Col}(\omega, {<}\kappa_1)$ such that $\mathbb{R}^{V[C_1]} = \mathbb{R}^{V_1[G,C]}$ and C_1 extends C_0'.

Since $\mathrm{Col}(\omega, {<}\kappa_0)$ is κ_0-c.c., j can be extended to a

$$\hat{j} : V[C_0'] \to M[C_1].$$

The restriction of $\hat{j}$ to $V(\mathbb{R}_0)$ is an elementary embedding from $V(\mathbb{R}_0)$ to $M(\mathbb{R}_1)$. If τ is a V-term for an element of $V(\mathbb{R}_0)$ then $\hat{j}(\tau^{V(\mathbb{R}_0)}) = \tau^{M(\mathbb{R}_1)}$. Hence the restriction of $\hat{j}$ to $V(\mathbb{R}_0)$ can be defined in $V_1[G * C]$ independently of C_0' and C_1.[78]

We work in $V_1[G * C]$. For $\kappa_0 < \alpha < \kappa_1$, let $m_\alpha = \hat{j}``(G \cap V_\alpha)$. Then each m_α is in $M(\mathbb{R}_1)$. Let $\langle x_\alpha : \alpha < \kappa_1 \rangle$ be an enumeration of the V_1-terms for elements of $P(\kappa_0) \cap V_1[G]$ such that for a closed unbounded set of α and all $\beta < \alpha \in \kappa_1$, $x_\beta \in V_1[G \cap V_\alpha]$. Note that for $\beta < \kappa_1$, $\langle x_\alpha : \alpha < \beta \rangle$ is in $M(\mathbb{R}_1)$. Let $\blacktriangle$ be a well-ordering of $\hat{j}(\mathbb{Q}')$ in $M(\mathbb{R}_1)^{j(\mathrm{Add}(\omega_1))}$. Define a descending sequence $\langle p_\alpha : \alpha < \kappa_1 \rangle \subseteq \hat{j}(\mathbb{Q})$ such that:

1. for each α and γ, if $x_\alpha \in V_1[G \cap V_\gamma]$, then $p_{\alpha+1} \cap M_{\hat{j}(\gamma)}$ decides $\|\kappa_0 \in \hat{j}(x_\alpha)\|$,
2. if $p_\alpha \in V_{\hat{j}(\gamma)}$, then p_α is compatible with m_γ, and
3. if $p_{\alpha+1} = q_0^\alpha * q_1^\alpha \in \mathrm{Add}(\omega_1) * \mathbb{Q}'$ then $q_0^\alpha \Vdash$ "q_1^α is the $\blacktriangle$-least element of $\mathbb{Q}'$ so that $p_{\alpha+1} < p_\alpha$ and $p_{\alpha+1}$ has q_0^α as its first coordinate and satisfies 1 and 2".

[78] The generic C_0' and C_1 are used to show that the embedding is elementary, not to define the embedding.

Using 3, and the fact that $\langle q_0^\alpha : \alpha < \beta\rangle \in M(\mathbb{R}_1)$, one can check that for all $\beta < \kappa_1$ the sequence $\langle p_\alpha : \alpha < \beta\rangle \in M(\mathbb{R}_1)$.

The sequence $\langle p_\alpha : \alpha < \kappa_1\rangle$ induces an ultrafilter U on $P(\kappa_0) \cap V_1[G]$ that is κ_0-complete for sequences that lie in $V_1[G]$ and belongs to $V_1[G*C]$. Define an ideal J in $V_1[G]$ by putting $x \in J$ iff $\|x \in U\| = 0$, where the Boolean value is taken in $\mathcal{B}(\mathrm{Col}(\omega, \omega_1))$. Equivalently, $x \in \breve{J}$ iff $\|$there is an α, $p_\alpha \Vdash \kappa_0 \in \hat{j}(x)\| = 1$.

To see that J is a normal ideal, let $\langle x_\beta : \beta < \kappa_0\rangle \in V_1[G]$ be a sequence of elements of $\breve{J}$. Then for all β, $\|$for some α, $p_\alpha \Vdash \kappa_0 \in \hat{j}(x_\beta)\| = 1$. Since in $V_1[G * C]$,

1. $\mathrm{cf}(\kappa_1) > \kappa_0$,

2. $\langle p_\alpha : \alpha \in \kappa_1\rangle$ is a descending sequence, and

3. the forcing yielding $V_1[G * C]$ is κ_1-c.c.,

we see that $\|$for some α, $p_\alpha \Vdash \kappa_0 \in \bigcap\{\hat{j}(x_\beta) : \beta < \kappa_0\}\| = 1$. Hence $\|$for some α, $p_\alpha \Vdash \kappa_0 \in \hat{j}(\Delta\{x_\beta\})\| = 1$. Thus $\breve{J}$ is closed under diagonal intersections, so J is normal.

A similar argument shows that the map $x \mapsto \|x \in U\|$ induces a Boolean algebra monomorphism from $P(\kappa_0)/J$ to $B(\mathrm{Col}(\omega, \omega_1))$. Hence, J is $\aleph_2$-saturated. Since J is normal, this map is a regular embedding and thus $P(\kappa_0)/J$ is isomorphic to a regular subalgebra of $B(\mathrm{Col}(\omega, \omega_1))$ that collapses ω_1. Thus J is an $\aleph_1$-dense ideal. ⊣

7.15. The Lower End

Proposition 6.26 showed that for successor cardinal κ there is a proper class of forbidden intervals that contain no cardinals λ with κ-complete, κ^+-saturated ideals. This generalized a result of Kunen for $\kappa = \omega_1$. Theorem 7.59 showed that the cardinal bounds at the upper ends of the forbidden intervals are sharp. At the other ends of the intervals, the situation is much less clear.

We state a theorem which implies the consistency of an $\aleph_1$-dense, countably complete, uniform ideal on ω_2. This is the best result known at this time. We outline the proof of this consistency result. The whole proof is in Foreman [36]. The proof has two parts: the first part is an unexciting, but original, application of the Woodin and Kunen techniques to get ideals on consecutive cardinals. The second part is a method for transferring ideals from κ to κ^+.[79]

We begin with a definition, one that gives a slight strengthening of the notion of "strongly layered ideal".

[79] On the other hand, the transfer result in the second part is completely general. The obstacle to getting $\aleph_1$-dense ideals on ω_n for $n > 2$ is in generalizing the "unexciting" first part.

7.62 Definition. A normal κ^+-complete ideal I on κ^+ is *very strongly layered* iff

$$P(\kappa^+)/I = \bigcup\{B_\alpha : \alpha < \kappa^{+2}\}$$

where:

1. the sequence $\langle B_\alpha : \alpha < \kappa^{+2}\rangle$ is increasing and continuous, and for all α, $|B_\alpha| = \kappa^+$. In other words $\langle B_\alpha : \alpha < \kappa^{+2}\rangle$ is a filtration,

2. there is a dense set $D \subseteq P(\kappa^+)/I$ that is closed under descending $<\kappa$-sequences and finite non-zero meets (i.e. if $\{d_1, \dots, d_n\}$ are in D and $\bigwedge d_i \neq 0$ then $\bigwedge d_i \in D$),

3. if $\alpha \in \kappa^{+2}$ and $\mathrm{cf}(\alpha) = \kappa^+$ or α is a successor ordinal, then B_α is a regular subalgebra of $P(\kappa^+)/I$. Further, there is a commuting family of projection maps $\{\pi_\alpha : \alpha \in \kappa^{+2} \cap (\mathrm{Cof}(\kappa^+) \cup \mathrm{Succ})\}$ such that $\pi_\alpha : D \to (D \cap B_\alpha)$, $\pi_\alpha \restriction (D \cap B_\alpha)$ is the identity, and for $\alpha < \beta$ we have $\pi_\alpha \circ \pi_\beta = \pi_\alpha$, and

4. there is a dense set $D'_0 \subseteq D \cap B_0$ such that $(D'_0, \leq_I)$ is isomorphic to $\mathrm{Col}(\kappa, \kappa^+)$.

Essentially any model with a layered ideal can be turned into a model with a very strongly layered ideal by forcing a closed unbounded set through the appropriate stationary set. The "very" part of the definition holds in all models with strongly layered ideals known to the author.

The first step in the consistency result is to prove the following:

7.63 Theorem. *Let j_0 and j_1 be almost huge embeddings with critical points κ_0 and κ_1 respectively. Suppose that $j_0(\kappa_0) = \kappa_1$ and that $\kappa_2 = j_1(\kappa_1)$ is Mahlo. Let $\mu < \kappa_0$ be regular. Then there is a partial ordering $\mathbb{P}$ such that there is a definable subclass W of $V^{\mathbb{P}}$ satisfying:*

1. $\kappa_0 = \mu^+$,

2. ZFC + GCH + $\diamondsuit_{\mu^+}$ + $\diamondsuit_{\mu^{+2}}(\mathrm{Cof}(\mu^+))$ + $\square_{\mu^{+2}}$*,*

3. there is an μ^+-dense ideal J on μ^+, and

4. there is a very strongly layered ideal I on μ^{+2}.

7.64 Remark. It is not known how to get a successor cardinal κ with a κ-dense ideal on κ and very strongly layered ideals on κ^+ and κ^{+2}. The weaker property that there are three successor consecutive cardinals with strongly layered ideals is also open.

The next theorem is the heart of the consistency result:

7.65 Theorem (Foreman [36]). *Let κ be a regular cardinal with $\kappa^{<\kappa} = \kappa$. Suppose there is a very strongly layered ideal I on κ^+, $\square_{\kappa^+}$, and $\diamondsuit_{\kappa^+}(\mathrm{Cof}(\kappa))$. Then there is a κ-complete uniform ideal $K \supseteq I$ on κ^+ such that*

$$P(\kappa^+)/K \cong P(\kappa)/\{\text{bounded sets}\}.$$

From this one sees:

7.66 Corollary. *Suppose that κ is regular, $\kappa^{<\kappa} = \kappa$ and there is a very strongly layered ideal I on κ^+, $\square_{\kappa^+}$ and $\diamondsuit_{\kappa^+}(\mathrm{Cof}(\kappa))$. Then for all uniform ideals J on κ, there is a uniform ideal K on κ^+ such that:*

$$P(\kappa^+)/K \;\cong\; P(\kappa)/J.$$

Furthermore, the degree of completeness of K equals the degree of completeness of J, and if J is κ^+-saturated then K is weakly normal.

This corollary shows that in the model built in Theorem 7.63 with $\mu = \omega$, there is a weakly normal, countably complete, uniform $\aleph_1$-dense ideal on ω_2. Since the hypotheses of Theorem 7.65 hold in a model where every $\aleph_2$-c.c., ω_1-collapsing Boolean algebra of cardinality at most ω_2 is realized as a quotient of an ideal on ω_1, we see that every such Boolean algebra is realized as a quotient of a weakly normal, countably complete, uniform ideal on ω_2.

7.67 Remark. There can be no analogue of Corollary 7.66 for normal fine ideals on $[\kappa^+]^\kappa$, because of Remark 5.39. If there were, there would simultaneously be an $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$ and an ideal on $[\omega_2]^{\omega_1}$ with quotient isomorphic to $\mathcal{B}(\mathrm{Col}(\omega, {<}\omega_2))$—an impossibility.

We now outline the first step in the proof of Theorem 7.65. This step is easier to describe than the main construction in [36].

The main idea of Theorem 7.65 is to build a surjective homomorphism $h : P(\kappa^+)/I \to P(\kappa)/\{\text{bounded sets}\}$. The ideal K will be the kernel of h, which we must verify is κ-complete. It follows that

$$P(\kappa^+)/K \cong P(\kappa)/\{\text{bounded sets}\}.$$

Fix a strongly layered ideal I, and witnesses $B_\alpha, D, \pi_\alpha, \ldots$ to the strong layering. Let $D_\alpha = D \cap B_\alpha$.

Given a subset of κ^+ we need to "measure" it by a subset of κ. Any function $f : \kappa \to D$ measures each set $x \subseteq \kappa^+$ by yielding the set $A_x = \{i : f(i) \subseteq_I x\}$. Unfortunately this measurement may be ambiguous in that typically $\kappa^+ \setminus A_x \neq A_{\kappa^+ \setminus x}$ (modulo bounded sets). This failure is equivalent to the statement that it is not the case that for all sufficiently large i, either $f(i) \subseteq_I x$ or $f(i) \subseteq_I \kappa^+ \setminus x$.

It is hopeless to unambiguously measure every subset of κ^+ with a single function f. Hence we need a family of functions. Furthermore, the measurements these functions make must agree with each other. This is the motivation for the first three clauses of the following definition. The last clause is a coding device to make the homomorphism surjective. In what follows we will use $\leq$ to mean $\subseteq_I$.

We will construct a matrix of functions:[80]

$$\mathcal{F} = \{f^\delta_\gamma : \gamma < \kappa^+,\ \delta \in \kappa^{+2} \cap (\mathrm{Cof}(\kappa^+) \cup \mathrm{Succ})\}$$

such that for each δ, γ,

$$f^\delta_\gamma : \kappa \to D_\delta.$$

The family of functions $\mathcal{F}$ will satisfy the following four properties:

1. Horizontal Coherence: For $\gamma < \gamma'$, for all but less than κ many i, $f^\delta_\gamma(i) \geq f^\delta_{\gamma'}(i)$.

2. Vertical Coherence: For $\delta < \delta'$ there is an unbounded set of $\gamma < \kappa^+$ such that for all but less than κ many i, $f^\delta_\gamma(i) = \pi_\delta(f^{\delta'}_\gamma(i))$.

3. Genericity: For each $x \subseteq \kappa^+$, with $x \in B_\delta$ there is a $\gamma < \kappa^+$ such that for all but less than κ many i, either $f^\delta_\gamma(i) \leq x$ or $f^\delta_\gamma(i) \wedge x =_I 0$.

   Let $D'_0 \subseteq D_0$ be dense with $D'_0 \cong \mathrm{Col}(\kappa, \kappa^+)$. If f^0_γ takes values in D'_0, then by using this isomorphism we can assume that for all i, $f^0_\gamma(i) \in \mathrm{Col}(\kappa, \kappa^+)$.

4. Coding: Fix an enumeration $P(\kappa) = \{y_\eta : \eta < \kappa^+\}$. For each $\eta < \kappa^+$, there is a γ_η such that for all i, $f^0_{\gamma_\eta}(i) \in D'_0$, and $\gamma_\eta \in \mathrm{ran}(f^0_{\gamma_\eta}(i))$. Further, letting $\beta_\eta(i)$ be the least β such that $f^0_{\gamma_\eta}(i)(\beta) = \gamma_\eta$, then $y_\eta = \{i : \beta_\eta(i) \text{ is a limit ordinal}\}$.

7.68 Remark. The purpose of the vertical coherence condition is to show that the homomorphism h defined in Claim 7.69 below is well-defined. It can be weakened to the following statement:

Weak Vertical Coherence: For all $\delta < \delta'$ and all γ' there is a $\gamma > \gamma'$ such that for sufficiently large i, $f^\delta_\gamma(i) \leq \pi_\delta(f^{\delta'}_{\gamma'}(i))$.

7.69 Claim. *If there is a set of functions $\mathcal{F}$ satisfying the conditions 1–4, there is a surjective homomorphism $h : P(\kappa^+)/I \to P(\kappa)/\{\text{bounded sets}\}$ with a κ-complete kernel.*

Proof. Given the set of functions $\mathcal{F}$ and an $x \subseteq \kappa^+$, we look at the least δ such that $x \in B_\delta$. By genericity there is a $\gamma < \kappa^+$ such that for sufficiently large i, $f^\delta_\gamma(i) \subseteq_I x$ or $f^\delta_\gamma(i) \cap x =_I 0$. Let $A_x = \{i : f^\delta_\gamma(i) \subseteq_I x\}$.

We claim that for all $\delta' > \delta$ and all sufficiently large γ' (depending on δ'), $A_x = \{i : f^{\delta'}_{\gamma'}(i) \subseteq_I x\}$ modulo bounded sets. Namely, fix a δ' and choose

[80] Here, Succ denotes the class of successor ordinals.

a $\gamma' > \gamma$ where for sufficiently large i, $f^{\delta}_{\gamma'}(i) = \pi_\delta(f^{\delta'}_{\gamma'}(i))$. Since $x \in B_\delta$ and π_δ is a projection map, $f^{\delta'}_{\gamma'}(i) \subseteq_I x$ iff $\pi_\delta(f^{\delta'}_{\gamma'}(i)) \subseteq_I x$. Since $\gamma' > \gamma$ for all but less than κ many i, $f^{\delta}_{\gamma'}(i) \subseteq_I x$ iff $f^{\delta}_{\gamma}(i) \subseteq_I x$ and similarly for $\kappa^+ \setminus x$. Hence for sufficiently large i, $f^{\delta}_{\gamma'}(i) \subseteq_I x$ or $f^{\delta}_{\gamma'}(i) \subseteq_I \kappa^+ \setminus x$, and $A_x = \{i : f^{\delta}_{\gamma'}(i) \subseteq_I x\} = \{i : f^{\delta'}_{\gamma'}(i) \subseteq_I x\}$.

Define a function $h : P(\kappa^+) \to P(\kappa)/\{\text{bounded sets}\}$ by setting $h(x) = [A_x]$. Then h is well-defined by the remarks in the previous paragraph. To see that h is a homomorphism, it suffices to show that h preserves complements and intersections. Clearly, for all δ, γ and all x, y,

$$\{i : f^{\delta}_{\gamma}(i) \subseteq_I x \cap y\} = \{i : f^{\delta}_{\gamma}(i) \subseteq x\} \cap \{i : f^{\delta}_{\gamma}(i) \subseteq y\}.$$

Hence $h(x \cap y) = h(x) \cap h(y)$. Let $x \subseteq \kappa^+$. Choose sufficiently large δ, γ such that $h(x) = \{i : f^{\delta}_{\gamma}(i) \subseteq x\}$ and for all sufficiently large i, $f^{\delta}_{\gamma}(i) \subseteq x$ or $f^{\delta}_{\gamma}(i) \cap x =_I 0$. Then

$$h(\kappa^+ \setminus x) = \{i : f^{\delta}_{\gamma}(i) \subseteq_I \kappa^+ \setminus x\} = \{i : f^{\delta}_{\gamma}(i) \cap x =_I 0\} = \kappa \setminus h(x).$$

To see that h is surjective, fix some $[y_\eta] \in P(\kappa)$. By the coding condition 4 on $\mathcal{F}$, there is a γ_η such that for all i, $f^{0}_{\gamma_\eta}(i) \in D'_0$, $\gamma_\eta \in \operatorname{ran}(f^{0}_{\gamma_\eta}(i))$ and $y_\eta = \{i : \text{the least } \beta \text{ with } f^{0}_{\gamma_\eta}(i)(\beta) = \gamma_\eta \text{ is a limit ordinal}\}$. Since a generic ultrafilter for $P(\kappa^+)/I$ canonically induces a generic ultrafilter on D'_0, we have a canonical term $\dot{G}_0$ for a generic object for $\mathrm{Col}(\kappa, \kappa^+)$.

Let $x = \|\text{the least } \beta \text{ with } \dot{G}_0(\beta) = \gamma_\eta \text{ is a limit}\|$ where the Boolean value is taken in the forcing $P(\kappa^+)/I$. Then $x \in B_\delta$, for some δ. Hence $h(x) = [\{i : f^{\delta}_{\gamma}(i) \subseteq_I x\}]$ for all sufficiently large γ.

By the coding condition 4, for all i, $f^{0}_{\gamma_\eta}(i) \in \mathrm{Col}(\kappa, \kappa^+)$ and γ_η is in the range of $f^{0}_{\gamma_\eta}(i)$. Hence $f^{0}_{\gamma_\eta}(i) \subseteq_I x$ iff the least β with $f^{0}_{\gamma_\eta}(i)(\beta) = \gamma_\eta$ is a limit. Otherwise, $f^{0}_{\gamma_\eta}(i) \subseteq_I \kappa^+ \setminus x$.

Hence, by the coding condition, for $\gamma \geq \gamma_\eta$ and sufficiently large i, $f^{0}_{\gamma}(i) \subseteq_I x$ or $f^{0}_{\gamma}(i) \subseteq_I \kappa^+ \setminus x$. Hence we see that for all sufficiently large $\gamma \geq \gamma_\eta$, $f^{\delta}_{\gamma}(i) \subseteq_I x$ iff $f^{0}_{\gamma}(i) \subseteq_I x$, and $h(x) = [\{i : f^{0}_{\gamma_\eta}(i) \subseteq_I x\}]$.

But $f^{0}_{\gamma_\eta}(i) \subseteq_I x$ iff $i \in y_\eta$, by the coding condition. Hence, $h(x) = [y_\eta]$, and we have shown that h is surjective.

Let K be the kernel of h. To see that K is κ-complete, let $\eta^* < \kappa$ and $\{X_\eta : \eta \in \eta^*\} \subseteq K$. Then for all δ, γ and all η, $\{i : f^{\delta}_{\gamma}(i) \subseteq_I X_\eta\} =_{\{\text{bounded sets}\}} 0$. Let δ, γ be so large that for all $\eta \in \eta^*$ and sufficiently large i, $f^{\delta}_{\gamma}(i) \subseteq_I X_\eta$ or $f^{\delta}_{\gamma}(i) \cap X_\eta =_I 0$ and that $h(\bigcup X_\eta) = \{i : f^{\delta}_{\gamma}(i) \subseteq_I \bigcup X_\eta\}$. Then $h(\bigcup X_\eta) = \bigcup\{i : f^{\delta}_{\gamma}(i) \subseteq_I X_\eta\}$ and so has size less than κ. Hence, $\bigcup X_\eta \in K$. $\dashv$

The heart of Theorem 7.65 is the construction of the matrix of functions $\mathcal{F}$. This uses the powerful $\diamondsuit$ techniques forged by Shelah in his papers *Models with second-order properties* I–V (see e.g. [101]). Though the published proof [36] uses square, it is not necessary for the construction.

7.16. Chang-Type Ideals with Simple Quotients II

In this section we see how the technique of the previous section can be used to produce an ideal I on $[\omega_2]^{\omega_1}$ that is normal and fine, and is such that forcing with $P([\omega_2]^{\omega_1})/I$ is equivalent to forcing with an $\aleph_1$-centered partial ordering $\mathbb{P}$ followed by an $<\aleph_2^V$-closed partial ordering; moreover, GCH holds in the model with this ideal. A pseudo-generic tower argument shows that this implies the existence of an $\aleph_1$-centered ideal on ω_1.

Donder [23] pointed out that if there is an $\aleph_1$-centered ideal on ω_1 and CH holds, then one can force an example of a c.c.c.-destructible $\aleph_2$-saturated ideal on ω_1. This follows because there is a well-known forcing for adding $\square_{\omega_1}$ without adding new subsets of ω_1. The relationship between square and c.c.c.-destructibility is discussed in Sect. 8.6.

7.70 Theorem. *Suppose that there is a huge cardinal κ and $\mu < \kappa$ is regular. Then there is a partial ordering $\mathbb{Q}$ such that for all generic $G \subseteq \mathbb{Q}, V[G]$ satisfies* GCH *and the statement: There is a normal fine ideal I on $[\mu^{+2}]^{\mu^+}$, a μ^+-centered partial ordering $\mathbb{P}$ and an $\mathbb{R} \in V^{\mathbb{P}}$ that is $<(\mu^{+2})^V$-closed in $V^{\mathbb{P}}$ such that:*

$$\mathcal{B}(P([\mu^{+2}]^{\mu^+})/I) \cong \mathcal{B}(\mathbb{P} * \mathbb{R}).$$

We also refer the reader to Theorem 5.2 for some consequences of the existence of such an ideal in combinatorics and algebra.

Proof. We now briefly outline the argument for Theorem 7.70. We will use the Kunen technique to build partial orderings $\mathbb{P}(\alpha)$ and $\mathbb{R}(\alpha,\beta)$ such that both are definable from Mahlo α, β and:

1. $\mathbb{P}(\alpha) \subseteq V_\alpha$, $\mathbb{R}(\alpha,\beta) \subseteq V_\beta$ and $\mathbb{P}(\alpha)$ is α-c.c. and $<\mu$-closed, and $\mathbb{R}(\alpha,\beta)$ is $<\alpha$-closed and β-c.c.
2. $\mathbb{P}(\alpha)$ collapses α to be μ^+ and $\mathbb{R}(\alpha,\beta)$ collapses β to be α^+.
3. For $\alpha < \beta$, if the identity map from $\mathbb{P}(\alpha)$ maps to $\mathbb{P}(\beta)$ and is a regular embedding, then $\mathbb{P}(\alpha) * \mathbb{R}(\alpha,\beta)$ is regularly embedded in $\mathbb{P}(\beta)$ by a map $i_{\alpha,\beta}$ extending the identity.
4. Moreover if $G \subseteq \mathbb{P}(\alpha) * \mathbb{R}(\alpha,\beta)$ is generic then in $V[G]$, the quotient forcing $\mathbb{P}(\beta)/i_{\alpha,\beta}$"$G$ is α-centered.
5. $\mathbb{R}(\alpha,\beta)$ has the right "shape" for the existence of master conditions.

Most of the properties on the list above are familiar, the new one being 4.

The conditions on the list guarantee that if $j : V \to M$ is a huge embedding with critical point κ, $j(\kappa) = \lambda$ and one forces with $\mathbb{P}(\kappa) * \mathbb{R}(\kappa,\lambda)$ to get a G then one can generically extend the huge embedding to a $\hat{j} : V[G] \to M[\hat{G}]$. The ideal I will be the ideal induced by $\hat{j}$ and the ideal element j"λ. The ideal has the correct quotient, since $\mathbb{P}(\lambda) * \mathbb{R}(\lambda, j(\lambda))/G$ is κ-centered followed by $<\lambda$-closed forcing. $\dashv$

The centering argument from [41] can be seen to work in the model discussed in Sect. 7.12. In particular, the construction in Theorem 7.57 gives the stronger statement:

7.71 Theorem. *Suppose that there is a huge cardinal. Then there is a model of* ZFC + *"For all regular cardinals κ there is a κ-complete, κ-centered ideal on κ".*

7.17. Destroying Precipitous and Saturated Ideals

We now consider the possibility of completely ridding the universe of ideals with nice embedding properties. Since the existence of generic elementary embeddings implies the existence of inner models with large cardinals, if one starts with a small enough model (such as L) there are no ideals with nice properties. Even this is not completely understood, as it is not known if there are precipitous ideals on successor cardinals in $L[E]$ models.

Here is what is known about forcing over an arbitrary model V to get rid of precipitous and saturated ideals.

Baumgartner [3] described a partial ordering $\mathbb{D}$ for adding a closed unbounded subset of ω_1 with finite conditions. Elements of $\mathbb{D}$ can be viewed as finite collections of disjoint intervals of countable ordinals that are open at the lower end and closed at the upper end. Extension is by taking a bigger collection of intervals. These intervals approximate the complement of a closed unbounded set $D \subseteq \omega_1$ in the extension. The following facts were shown by Baumgartner:

1. $\mathbb{D}$ adds a closed unbounded subset of ω_1 that does not include any closed unbounded set in V, and
2. $\mathbb{D}$ is proper and hence preserves ω_1.

The following result appears in [6] as Theorem 3.5:

7.72 Theorem (Baumgartner-Taylor [6]). *Suppose that $G \subseteq \mathbb{D}$ is generic over V. Then in $V[G]$ there are no $\aleph_2$-saturated ideals on ω_1.*

Assuming GCH, there are analogues of Baumgartner's forcing for each successor cardinal μ^+. These involve forcing with approximations to the complement of the generic closed unbounded set that have size $< \mu$ and satisfy some continuity conditions. The Baumgartner-Taylor argument generalizes directly to show that after forcing over a model of GCH with a forcing of this type, there are no μ^{+2}-saturated ideals on μ^+.

The situation for precipitous ideals is less satisfactory. In [47], the following theorem is shown:

7.73 Theorem. *For all κ with $\kappa^{<\kappa} = \kappa$, there is a forcing $\mathbb{Q}$ that is $<\kappa$-closed, κ^+-c.c such that if I is a normal ideal in V then its normal closure in $V^{\mathbb{Q}}$ is not precipitous.*

By Theorem 7.73 it is consistent with a supercompact cardinal that the nonstationary ideal on ω_1 is not precipitous, but it is not known how to build a model with a supercompact cardinal where there is no precipitous ideal on ω_1. The results of the next section show that the nonstationary ideal on ω_1 is always a pre-precipitous ideal if one assumes the existence of Woodin cardinals.

8. Consistency Results for Natural Ideals

In this section we discuss methods of creating models where various natural ideals yield well-founded generic ultrapowers. These results fall into three categories. The first type are situations where one starts with an induced ideal with strong properties and forces that ideal to be a natural ideal while maintaining the properties of the generic embedding. One way to do this is to shoot closed unbounded sets through sets in the dual of the ideal.

The second type of result begins with a natural ideal and manipulates its antichain structure in such a way so as to make the generic ultrapower have strong properties. A typical method for making an ideal saturated is to iterate collapsing the size of each maximal antichain, while maintaining its maximality.

The third method for making natural ideals have strong properties was pioneered by Steel and Van Wesep [115]. This technique starts with a model of ZF together with some determinacy hypothesis and forces to add choice to construct a model where the NS_{ω_1} is $\aleph_2$-saturated.

8.1. Forcing over Determinacy Models

The first construction of a model of ZFC where NS_{ω_1} is $\aleph_2$-saturated was done by Steel and Van Wesep. Their technique was extremely original in that it started with an inherently choiceless model of $V = L(\mathbb{R})$ and added a well-ordering of the real numbers. If NS_{ω_1} is dual to an ultrafilter in the original model, then one can hope that the forcing for adding Choice is mild enough to preserve its saturation. Their theorem is:

8.1 Theorem (Steel-Van Wesep [115]). *Suppose that V is a model of* ZF + $\mathrm{AD}_{\mathbb{R}}$ + *"Θ is regular". Then there is a forcing extension of* ZFC *in which NS_{ω_1} is $\aleph_2$-saturated.*

Woodin improved their result by weakening the hypothesis to the assumption AD + $V = L(\mathbb{R})$. Later work of Woodin showed that even the following is possible:

8.2 Theorem (Woodin [126]). *Suppose that V is a model of* AD + $V = L(\mathbb{R})$. *Then there is a forcing extension in which NS_{ω_1} is $\aleph_1$-dense.*

Note that Shelah's Corollary 5.58 implies $2^{\aleph_0} = 2^{\aleph_1}$ in this model. In contrast, Woodin was able to show from similar determinacy hypotheses that it is consistent to have CH together with the statement "there is a dense set $D \subseteq P(\omega_1)/\mathrm{NS}_{\omega_1}$ such that for all $S \in D$, $P(S)/\mathrm{NS}_{\omega_1}$ is $\aleph_1$-dense".

Using $\mathbb{P}_{\max}$ and $\mathbb{Q}_{\max}$ techniques, Woodin was able to show many related consistency results. For example, he showed the consistency of strong club guessing together with NS_{ω_1} being $\aleph_2$-saturated. Woodin's $\mathbb{P}_{\max}$ techniques are covered in detail in his book [126], as well as in Larson's chapter in this Handbook.

These results have the peculiar feature that it is not clear from the method that *every* model of ZFC can be included in a model in which NS_{ω_1} has strong saturation properties.

8.2. Making Induced Ideals Natural

These constructions are based on various types of forcing that transform sets in an induced ideal into members of a given natural ideal. For example, in the case of the nonstationary ideal, these partial orderings shoot closed unbounded sets through stationary sets S in the dual of the induced ideal. These make the complement of S nonstationary in the generic extension. For other natural ideals the constructions use other mechanisms, such as forcing sets in the ideals to be meager or adding strong club guessing sequences on sets in the dual filter.

The general outline of this type of argument is to start with a generic elementary embedding $j_0 : V_0 \to M_0$ and let I be the induced ideal from $U(j_0, i)$ for some i. A forcing construction is carried out that makes elements of $\breve{I}$ belong to the dual of the natural ideal. Care must be taken to make sure that the generic embedding j can be extended during the forcing construction. The ability to extend the embedding j implies that the critical point of j remains a regular cardinal after the forcing.

A complication to this outline is that if j_α is the generic embedding after α stages of the iteration, then the induced ideal I_α for $U(j_\alpha, i)$ may properly contain the initial ideal I. Thus the construction involves:

1. A "nice" initial ideal $I = I_0$.

2. An iteration $\langle(\mathbb{R}_\alpha, \dot{\mathbb{Q}}_\alpha) : \alpha < \lambda\rangle$ such that in $V_0^{\mathbb{R}_\alpha}$, the original embedding j can be generically extended to an embedding j_α from $V_0^{\mathbb{R}_\alpha}$ to $M_0^{j(\mathbb{R}_\alpha)/m_\alpha}$ where m_α is a master condition. Moreover, for $\alpha < \beta$ we have $m_\beta \leq m_\alpha$ and $j_\alpha \subseteq j_\beta$.

3. An sequence of ideals $\langle I_\alpha : \alpha < \lambda\rangle$ where I_α is the induced ideal for $U(j_\alpha, i)$. Since the j_α's cohere and the m_α's get stronger with α, we have $I_\alpha \subseteq I_\beta$ for $\alpha < \beta$.

4. For every element S that belongs to some I_α for an $\alpha < \lambda$ there is a β so that $\mathbb{Q}_\beta$ puts S into the natural ideal.

5. $I_\infty =_{\mathrm{def}} \bigcup_{\alpha<\lambda} I_\alpha$ is the natural ideal in $V_0^{\mathbb{R}_\lambda}$.

The final model will be $V_0^{\mathbb{R}_\lambda}$. Typically $j_\infty =_{\mathrm{def}} \varinjlim j_\alpha$ gives a generic embedding from $V_0^{\mathbb{R}_\lambda}$ to $M_0^{j(\mathbb{R}_\lambda)}$ and the induced ideal from $U(j_\infty, i)$ is I_∞. By the last clause 5, I_∞ is the natural ideal.

If the original ideal I has nice properties, e.g. that I is saturated or that I is precipitous and the embedding j was the generic ultrapower of I, then I_∞ can be shown to retain some of these properties.

The Null and Meager Ideals

We first deal with two relatively easy examples, the null ideal and the meager ideal. That the ideal of null sets of a measure can be precipitous follows from the next result due to Solovay [111].

8.3 Theorem. *Suppose that κ is measurable. Then there is a forcing extension in which there is a countably additive $\mu : P([0,1]) \to [0,1]$.*

Since the ideal of μ-null subsets of the reals is necessarily c.c.c. and $\aleph_1$-complete, it is an example of a precipitous ideal. Later work of Kunen showed that this ideal can be taken to extend the ideal of Lebesgue null subsets of the real line. Dow remarked that the ideal of Lebesgue null subsets of the unit interval can never be c.c.c. since there is an uncountable pairwise disjoint collection of sets of outer measure one.

As far as the author knows it is an open question whether it is consistent for the ideal of Lebesgue null subsets of $[0,1]$ to be a precipitous ideal on $P([0,1])$.

The analogous result for the meager ideal is open; however, Komjáth showed the following:

8.4 Theorem (Komjáth [73]). *Suppose that there is a measurable cardinal. Then there is a forcing extension in which there is a non-meager set $A \subseteq \mathbb{R}$ such that $P(A)/\{\text{meager sets}\}$ is c.c.c.*

Proof. We sketch the proof. Let κ be measurable and U a normal ultrafilter on κ. The idea is to make $\breve{U}$ into the meager ideal restricted to a non-meager set. More explicitly, one first adds a sequence of Cohen reals $\langle s_\alpha : \alpha < \kappa\rangle$ and then forces that $S \subseteq \{s_\alpha : \alpha < \kappa\}$ is meager iff there is an $Y \in \breve{U}$ such that $S \subseteq \{s_\alpha : \alpha \in Y\}$.

We start by describing a forcing for making a particular set meager. Fix a set $S \subseteq \omega^\omega$. We let $\mathbb{P}_S$ be the collection of conditions

$$p = \langle \{s_0, \ldots, s_n\}, c, \{U^i_j : i, j \in F\}\rangle$$

where:

1. U^i_j are basic open sets in ω^ω and F is a finite subset of ω,
2. $n \in \omega$ and $\{s_0, \ldots, s_n\} \subseteq S$,

3. $c : \{s_0, \dots, s_n\} \to F$, and
4. $s_m \notin \bigcup_{j \in F} U_j^{c(s_m)}$.

For conditions $p, q \in \mathbb{P}_S$ we say that q is stronger than p if q can be built from p by adding elements of S to $\{s_0, \dots, s_n\}$, extending c and expanding the collection of U_j^i to a larger collection $\{U_j^i : i, j \in F' \supseteq F\}$.

$\mathbb{P}_S$ is $\aleph_1$-Knaster[81] and, as is well-known for such partial orderings, arbitrary products of partial orderings of the form $\mathbb{P}_S$ with finite support are c.c.c. Moreover, if H is generic for $\mathbb{P}_S$ and $\{U_j^i : i, j \in \omega\}$ are the basic open sets appearing in the conditions in H, then for each i, $\bigcup_j U_j^i$ is open dense and $S \cap \bigcap_i \bigcup_j U_j^i = \emptyset$

Komjáth's model is built by starting with a κ-complete, normal ultrafilter U on a measurable cardinal κ and adding κ Cohen reals $A = \langle s_\alpha : \alpha < \kappa \rangle$. The second step is to force with the finite support product $\mathbb{P} = \prod_{S \in I} \mathbb{P}_S$, where $S \in I$ iff $S \subseteq A$ and $\{\alpha : s_\alpha \in S\} \in \breve{U}$.

Fix $G * H$ generic for $\mathrm{Add}(\omega, \kappa) * \mathbb{P}$. Since the two step forcing $\mathrm{Add}(\omega, \kappa) * \mathbb{P}$ is c.c.c. it follows from Kakuda's theorem (Corollary 7.17) that $\breve{U}$ remains a precipitous ideal on $P(\kappa)$ in $V[G * H]$.[82] We will be done if we can show that in $V[G * H]$, for all $Y \subseteq A$, Y is meager iff $\{\alpha : s_\alpha \in Y\} \in \breve{U}$.

One direction of this is clear. If $\{\alpha : s_\alpha \in T\} \in \breve{U}$, then there is an $Y \in V \cap \breve{U}$ such that $\{\alpha : s_\alpha \in T\} \subseteq Y$. If $S = \{s_\alpha : \alpha \in Y\}$ then $\mathbb{P}_S$ is a factor of the forcing and hence S is meager.

Suppose now that $T \subseteq A$ is meager. We show that there is a countable collection $C \subseteq I$, such that $T \subseteq \bigcup C$. This suffices, since $\breve{U}$ is countably complete in $V[G * H]$ and $\{\alpha : s_\alpha \in T\} \subseteq \bigcup_{S \in C} \{\alpha : s_\alpha \in S\}$.

In $V[G * H]$ there is a sequence of basic open sets $\langle O_j^i : i, j \in \omega \rangle$ such that in $V[G * H]$, for all i, $\bigcup_j O_j^i$ is dense and $T \cap \bigcap_i \bigcup_j O_j^i = \emptyset$. Since the forcing $\mathrm{Add}(\omega, \kappa) * \mathbb{P}$ is c.c.c. there is an $\alpha_0 < \kappa$ and a countable subset $C \subseteq I$ such that $\langle O_j^i : i, j \in \omega \rangle$ belongs to

$$V\big[\{s_\alpha : \alpha \in \big(\alpha_0 \cup \bigcup C\big)\}\big]\big[H \cap \textstyle\prod_{S \in C} \mathbb{P}_S\big].$$

If T is not a subset of $\bigcup C$ modulo bounded sets, then we can find a $\beta > \alpha_0$ such that $a_\beta \in T \setminus \bigcup C$. But then a_β is generic over the above model and hence belongs to $\bigcap_i \bigcup_j O_j^i$, a contradiction. ⊣

Nonstationary Ideals

The nonstationary ideals on general $Z \subseteq P(\lambda)$ are somewhat mysterious. We show in Theorem 8.37 that they can be made precipitous by collapsing a large cardinal to be λ^+. Not much is known about their saturation properties, with

[81] That is, any uncountable set of conditions has an uncountable subset of pairwise compatible conditions.
[82] We can say more: by Theorem 7.14, the quotient $P(A)/\{\text{meager sets}\}$ is c.c.c.

one notable exception: Gitik was able to give an example of a model with a large cardinal κ such that the nonstationary ideal on a stationary subset of $[\kappa^+]^{<\kappa}$ is κ^+-saturated.[83]

We turn to the nonstationary ideals on cardinals. In these arguments we shoot closed unbounded sets through sets in the dual of the induced ideal. The partial ordering usually used can be described as follows. If S is a stationary subset of a regular cardinal κ, then $\mathbb{P}_S$ consists of closed bounded subsets of S, ordered by end extension.

Forcing with this partial ordering can be disastrous, not only collapsing κ but many other cardinals as well. Equally problematic, if $\mathcal{C}$ is a collection of stationary sets, then the iterated forcing given by the partial orderings $\mathbb{P}_S$ for $S \in \mathcal{C}$ can collapse cardinals even if each individual $\mathbb{P}_S$ is well-behaved. What prevents the situation from being hopeless in the cases we are interested in is the fact that the collection $\mathcal{C}$ forms a filter that has a nice generic ultrapower.

Two examples of arguments of this form are in Cummings' chapter in this Handbook. One is the following theorem:

8.5 Theorem (Magidor; see [65]). *Suppose that κ is a measurable cardinal. Then there is a forcing extension in which $\kappa = \omega_1$ and NS_{ω_1} is precipitous.*

The situation for creating the precipitousness of nonstationary ideals on arbitrary regular cardinals is simple, provided there are sufficiently many large cardinals in the universe. Theorem 8.37 shows that if μ is regular and $\kappa > \mu$ is supercompact, then NS_μ is precipitous in $V^{\mathrm{Col}(\mu,<\kappa)}$.

Though the large cardinal hypothesis required in the proof of Theorem 8.37 can be reduced to a Woodin cardinal, that assumption is far from optimal. The following theorems of Gitik [51, 54, 53] give exact equiconsistency results:

8.6 Theorem. *The statement "NS_{ω_2} is precipitous" is equiconsistent with the existence of a measurable cardinal of Mitchell order 2.*

More generally:

8.7 Theorem. *If $\mu > \omega_1$, then* CH + *"NS_{μ^+} is precipitous" is equiconsistent with μ^+ being an $(\omega, \mu + 1)$-repeat point for the normal ultrafilters on μ^+ in the core model K.*

8.8 Theorem. *The property "κ is an inaccessible cardinal and NS_κ is precipitous" is equiconsistent with κ having an $(\omega, \kappa + 1)$-repeat point for the normal ultrafilters on κ in the core model K.*

See Cummings' chapter in this Handbook particularly for Theorem 8.6.

The saturation of NS_{ω_1} is a very special situation that is dealt with by manipulating the antichain structure of $P(\omega_1)/\mathrm{NS}_{\omega_1}$. This is covered in Sect. 8.3. It is not known how to make NS_{ω_1} saturated by making an induced ideal become the nonstationary ideal. This may be related to the problem of whether CH + "NS_{ω_1} is $\aleph_2$-saturated" is consistent with ZFC.

[83] See Theorem 6.35.

The saturation of nonstationary ideals on cardinals greater than ω_1 is even more mysterious. If κ is the successor of a singular cardinal or is weakly inaccessible then Theorem 6.14 implies that for all regular $\delta < \kappa$, the ideal $\mathrm{NS}_\kappa \restriction \mathrm{Cof}(\delta)$ is not κ^+-saturated.

At successors of regular cardinals above ω_1 essentially nothing is known. Corollary 6.11 shows that if I is a κ^+-saturated ideal on a successor cardinal $\kappa = \mu^+$ then $\{\alpha < \mu^+ : \mathrm{cf}(\alpha) = \mathrm{cf}(\mu)\} \in \breve{I}$, so the best one can hope for is that NS_κ restricted to $\mathrm{Cof}(\mu)$ is κ^+-saturated. A prominent open problem is whether it is consistent with ZFC to have NS_{ω_2} restricted to $\mathrm{Cof}(\omega_1)$ to be $\aleph_3$-saturated.

In the positive direction, Woodin has proved the strongest known consistency result about the saturation of the nonstationary ideals on cardinals at least ω_2:

8.9 Theorem (Woodin). *Suppose that μ is a regular cardinal and $\kappa > \mu$ is almost huge. Then there is a forcing extension by a $<\mu$-closed partial ordering that satisfies "there is a stationary set $S \subseteq \mu^+$ such that $\mathrm{NS}_{\mu^+} \restriction S$ is μ^{+2}-saturated". If* GCH *holds in the ground model, then* GCH *holds in the extension.*

From Woodin's theorem, one can argue as in [34] that it is consistent for the successor κ of a supercompact cardinal μ to have a stationary set $S \subseteq \kappa$ such that $\mathrm{NS}_\kappa \restriction S$ is κ^+-saturated. As described in the discussion of Theorem 7.57 [34], it is then possible to collapse μ to be e.g. $\aleph_\omega$ while preserving the saturation of the nonstationary ideal restricted to S. As a corollary we get:

8.10 Corollary. *Suppose that μ is a supercompact cardinal and $\kappa > \mu$ is an almost huge cardinal. Then there is a forcing extension that satisfies* GCH + *"there is a stationary subset S of $\aleph_{\omega+1}$ such that the nonstationary ideal on $\aleph_{\omega+1}$ restricted to S is $\aleph_{\omega+2}$-saturated".*

8.11 Remark. As proved in Theorem 5.64, if NS_{ω_1} is $\aleph_2$-saturated and there is a measurable cardinal, then CH fails in a concrete way. It remains a prominent open problem whether it is consistent to have CH together with NS_{ω_1} being $\aleph_2$-saturated.

Since measurable cardinals seem to be an accepted extension of ZFC, this problem does not seem relevant to settling CH, but a solution to it would certainly require new and interesting techniques.

We now give a sketch of a proof of Woodin's theorem. Woodin's original proof has not been published. We outline a subroutine that was used in the proof of Theorem 8.14 and was heavily influenced by Woodin's ideas. We assume the reader is familiar with the Kunen proof of the consistency of an $\aleph_2$-saturated ideal on ω_1 and the Magidor variation of that proof. These appear in Sects. 7.7 and 7.11.

Proof. The proof of Woodin's theorem follows the general outline given at the beginning of Sect. 8 for transforming an induced ideal into a natural ideal. One starts with an almost huge embedding $j : V \to M$ with critical point κ. From the general theory of large cardinals, we can assume that $j(\kappa) = \lambda$ where λ is not Mahlo and that $j``\lambda$ is cofinal in $j(\lambda)$. Let $\mathcal{I}$ be the V-inaccessibles below κ. Then $j(\mathcal{I})$ is NS_λ from the point of view of V.

The first forcing uses the Magidor variation on Kunen's theorem described in Sect. 7.11. This produces a partial ordering of the form $\mathbb{P} * \mathrm{Col}(\kappa, {<}\lambda)$ such that for each generic $G * H \subseteq \mathbb{P} * \mathrm{Col}(\kappa, {<}\lambda)$ there are M-generic $\hat{G} * \hat{H}$ such that j can be extended to a generic

$$j_0 : V[G * H] \to M[\hat{G} * \hat{H}].$$

The partial ordering $\mathbb{P}$ is ${<}\mu$-closed, κ-c.c. and collapses κ to be μ^+.[84]

Let I_0 be the induced ideal from $U(j_0, \kappa)$. Then I_0 is κ^+-saturated. The rest of the forcing is an iteration $\mathbb{R}$ of length λ with supports of size less than κ.

For each $\alpha < \lambda$ we will have a master condition $m_\alpha \in \mathbb{R}_\alpha$ guaranteeing that j can be extended to

$$j_\alpha : V^{\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}_\alpha} \to M^{j(\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}_\alpha)/m_\alpha}.$$

The ideal I_α will be the induced ideal from $U(j_\alpha, \kappa)$. The partial ordering $\mathbb{R}$ adds closed unbounded sets in such a way that the final ideal I_∞ is the nonstationary ideal restricted to the set $\mathcal{I}$ of V-inaccessibles.

There are two issues in constructing $\mathbb{R}$. The first is making sure that there are master conditions m_α so that the intermediate generic embeddings j_α can be constructed. The second is making sure that the partial orderings $j(\mathbb{R}_\alpha)$ are sufficiently closed that the pseudo-generic tower argument can be used to recover an ultrafilter over $V^{\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}}$ in a λ-c.c. extension of $V^{\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}}$.

The first issue is straightforward. Suppose inductively that we have defined m_α and S is a stationary set lying in $\breve{I}_\alpha \cap V^{\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}_\alpha}$. We will shoot a closed unbounded set through $S \cup (\kappa \setminus \mathcal{I})$. This makes S closed unbounded *relative* to $\mathcal{I}$. Since $S \in \breve{I}_\alpha$, for all generic extensions of j to j_α, we know that $\kappa \in j_\alpha(S)$. If $C \subseteq \mathbb{P}_{S \cup (\kappa \setminus \mathcal{I})}$ is generic over $V^{\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}_\alpha}$ and lies in $M^{j(\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}_\alpha)/m_\alpha}$, then $r = C \cup \{\kappa\}$ is a condition in $j_\alpha(\mathbb{P}_{S \cup (\kappa \setminus \mathcal{I})})$ that lies below $j(c)$ for each $c \in C$. If we let $\mathbb{R}_{\alpha+1} = \mathbb{R}_\alpha * \mathbb{P}_{S \cup (\kappa \setminus \mathcal{I})}$, then we can define a master condition for $\mathbb{R}_{\alpha+1}$ by setting $m_{\alpha+1} = m_\alpha^\frown r$.

To summarize, if we iterate shooting closed unbounded sets $\langle C_\alpha : \alpha < \lambda \rangle$ through sets in the duals of each ideal and each initial segment of $\langle C_\alpha : \alpha < \lambda \rangle$ belongs to $M^{j(\mathbb{P}) * \mathrm{Col}(\lambda, <j(\lambda))}$, we can construct a sequence of master conditions $\langle m_\alpha : \alpha < \lambda \rangle$. The $j(\xi)$th coordinate of m_α will be $C_\xi \cup \{\kappa\}$, where C_ξ is the closed unbounded coming from the ξth forcing in $\mathbb{R}$.[85]

---

84 In the notation of the outline given in Sect. 8.2, $V_0 = V[G * H]$ and $M_0 = M[\hat{G} * \hat{H}]$.

85 Very similar arguments are given in Cummings' chapter in this Handbook in the proof of the consistency of "NS_{ω_1} is precipitous".

The second issue is more subtle. Woodin's method relies on the very clever observation that if $\mathbb{P}_S$ is the partial ordering for shooting a closed unbounded subset through S with initial segments and $S \subseteq \kappa$ contains a closed unbounded set then there is a dense subset of $\mathbb{P}_S$ that is $<\kappa$-closed. In particular, assuming $\kappa^{<\kappa} = \kappa$, forcing with $\mathbb{P}_S$ is equivalent to forcing with the partial ordering for adding a Cohen subset of κ.

To illustrate the relevance of this observation, let's consider $\mathbb{R}_0$, the first partial ordering for adding a closed unbounded set. $\mathbb{R}_0$ is defined in $V[G*H]$. A stationary set $S_0 \in \breve{I}$ is chosen. $\mathbb{R}_0$ is defined to be $\mathbb{P}_{S_0 \cup (\kappa \setminus \mathcal{I})}$. Then $j(\mathbb{R}_0)$ is $\mathbb{P}_{j(S_0) \cup (\lambda \setminus j(\mathcal{I}))}$ as defined in $M[\hat{G} * \hat{H}]$. However, from the point of view of V, $\lambda \setminus j(\mathcal{I})$ is closed unbounded. Hence from the point of view of $V[\hat{G}]$ the forcing $(\mathrm{Col}(\lambda, <j(\lambda)) * \mathbb{P}_{j(S_0) \cup (\lambda \setminus j(\mathcal{I}))})^M$ is $<\lambda$-closed. This is sufficient for a pseudo-generic tower argument.

We can now give a summary of Woodin's argument. The partial ordering used will be of the form $\mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}$, where $\mathbb{R}$ is an iteration with $<\kappa$-supports for shooting closed unbounded sets through stationary sets.

The Magidor variation of Kunen's theorem (Sect. 7.11) gives an ideal I_0 that is saturated in $V^{\mathbb{P} * \mathrm{Col}(\kappa, <\lambda)}$ and concentrates on the set $\mathcal{I}$ of ordinals that were inaccessible cardinals in V. Generic elementary embeddings, ideals and master conditions $\langle j_\alpha, I_\alpha, m_\alpha : \alpha < \lambda \rangle$ are defined inductively, with j_0 being the extension of the original almost huge embedding in the Magidor variation.

The αth stage of $\mathbb{R}$ is of the form $\mathbb{P}_{S_\alpha \cup (\kappa \setminus \mathcal{I})}$. Since all of the forcings are of this form, for each $\alpha < \lambda$ the partial ordering $j(\mathrm{Col}(\kappa, <\lambda) * \mathbb{R}_\alpha)$ is $<\lambda$-closed over $V[\hat{G}]$ and hence in $V[\hat{G}]$ it is possible to find filters $\hat{H} * \vec{C}^j_\alpha \subseteq j(\mathrm{Col}(\kappa, <\lambda) * \mathbb{R}_\alpha)$ that are sufficiently generic over M to extend the embeddings to j_α, build $U(j_\alpha, i)$, and determine the ideal I_α. Every set in $\bigcup_{\alpha<\lambda} \breve{I}_\alpha$ occurs on the sequence $\langle S_\alpha : \alpha < \lambda \rangle$.

The final model will be $V[G * H * \vec{C}]$ where $G * H * \vec{C} \subseteq \mathbb{P} * \mathrm{Col}(\kappa, <\lambda) * \mathbb{R}$ is V-generic. By the pseudo-genericity arguments, there is an ultrafilter U that is κ-complete and normal for $V[G * H * \vec{C}]$-sequences that lies in $V[\hat{G}]$ where $\hat{G} \subseteq j(\mathbb{P})$. Since $\hat{G}$ lies in a λ-c.c. forcing extension of $V[G * H * \vec{C}]$ and $\lambda = \kappa^+$ we see that the induced ideal from U is κ^+-c.c. On the other hand the induced ideal for U is $\bigcup_{\alpha<\lambda} I_\alpha$ which has been forced to be the ideal $\mathrm{NS} \restriction \mathcal{I}$. ⊣

8.12 Remark. One can apply Theorem 7.30 to see that Woodin's construction and the Foreman-Komjáth construction below actually yield κ-centered ideals on $\kappa = \mu^+$.

Club Guessing Ideals

Recall the following definitions from Example 3.19: Let $\kappa > \mu$ be regular cardinals and $S \subseteq \kappa \cap \mathrm{Cof}(\mu)$. Let $\langle C_\alpha : \alpha \in S \rangle$ be a sequence such that C_α

is unbounded in α. We define two filters, the *club guessing filter* and the *tail club guessing filter* on S.

Let $D \subseteq \kappa$ be closed unbounded. Let $G(D) = \{\alpha \in S : C_\alpha \subseteq D\}$ and $E(D) = \{\alpha \in S : C_\alpha \subseteq^* D\}$.

1. The club guessing filter on S is the filter generated by the sets $\{G(D) : D$ is closed unbounded$\}$ together with the filter of closed unbounded sets.

2. The tail club guessing filter on S is the filter generated by the sets $\{E(D) : D$ is closed unbounded$\}$ together with the filter of closed unbounded sets.

The sequence $\langle C_\alpha : \alpha \in S\rangle$ is *club guessing* iff the club guessing filter on S is a proper filter, and *tail club guessing* iff the tail club guessing filter on S is a proper filter. A sequence $\langle C_\alpha : \alpha \in S\rangle$ is *strong club guessing* iff the tail club guessing filter is the nonstationary ideal restricted to S.[86]

Club guessing sequences and their associated filters play a vital role in singular cardinal combinatorics and other subjects. They are an interesting class of natural filters and the possible generic embeddings associated with club guessing filters are only beginning to be understood.

Woodin was able to show, using a $\mathbb{P}_{\max}$ variation:

8.13 Theorem. *Assume* $\mathrm{AD}^{L(\mathbb{R})}$. *Then there is a forcing extension of* $L(\mathbb{R})$ *in which* NS_{ω_1} *is* $\aleph_2$*-saturated and there is a strong club guessing sequence* $\langle C_\alpha : \alpha < \omega_1\rangle$.

Independently of this, Foreman and Komjáth were able to extend the Woodin techniques of Theorem 8.9 to show:

8.14 Theorem (Foreman-Komjáth [40]). *Suppose that* κ *is an almost huge cardinal and* $\mu < \kappa$ *is regular. Then there is a partial ordering* $\mathbb{P}$ *such that in* $V^{\mathbb{P}}$ *the following hold:*

1. $\kappa = \mu^+$,

2. *there is a stationary set* $S \subseteq \kappa$ *such that* $\mathrm{NS}_\kappa \restriction S$ *is* κ^+*-saturated, and*

3. *there is a strong club guessing sequence* $\langle x_\alpha : \alpha < \kappa\rangle$.

8.15 Corollary. *Assuming the hypotheses of Theorem 8.14, there is a forcing extension in which* $\kappa = \mu^+$ *and there is a sequence* $\langle x_\alpha : \alpha \in S\rangle$ *for a stationary* $S \subseteq \kappa$ *such that the tail club guessing filter on* μ^+ *determined by* $\langle x_\alpha : \alpha \in S\rangle$ *is* μ^{+2}*-saturated.*

8.16 Corollary. *Let* α *be an ordinal. Assume that there is an almost huge cardinal* κ *bigger than a supercompact cardinal* $\mu > \alpha$. *Then there is a generic extension of* V *in which* $\kappa = \aleph_{\alpha+1}$, *there is a stationary subset* S *of* κ *on*

[86] The concept of a strong club guessing sequence appears in the proof of Theorem 6.14.

which NS_κ *is* κ^+*-saturated and strong club guessing holds. In particular, there is a club guessing sequence* $\langle x_\beta : \beta \in S\rangle$ *such that the tail club guessing ideal determined by sequence is* κ^+*-saturated.*

Corollary 8.16 stands in strange counterpoint to the use of $\diamondsuit^*_{\text{club}}$ in Theorem 6.14 of Gitik and Shelah. A contradiction appears narrowly avoided by noting that the ordinals in the elements x_α of the guessing sequence have small cofinality.

In fact we can prove a slightly stronger theorem than Theorem 8.14. A slight variant of the proof shows that it is consistent to have $\mathrm{NS}_\kappa\restriction S$ be κ^+-saturated, a strong club guessing sequence defined on S and a $\diamondsuit^+(\kappa\setminus S)$-sequence.

In [40] the following forcing is defined that adds a strong club guessing sequence on a stationary set S:

8.17 Definition. Let κ be a regular cardinal and $S \subseteq \kappa$ be stationary. Let $\mathcal{CG}(S)$ be the iteration of length 2^κ with $<\kappa$-supports of the following components:

1. We let $\mathcal{CG}(S)_0$ be the collection of sequences $\langle x_\alpha : \alpha \in S \cap (\beta+1)\rangle$ for some $\beta < \kappa$, where each x_α is closed and unbounded in α. The ordering of $\mathcal{CG}(S)_0$ is by end extension.

2. We use a bookkeeping system that at stage γ will choose an appropriate closed unbounded set $C_\gamma \subseteq \kappa$ with $C_\gamma \in V^{\mathcal{CG}(S)_\gamma}$ and we will let $S_\gamma = \{\alpha : x_\alpha \subseteq^* C_\gamma \text{ or } \alpha \notin S\}$. Then $\mathcal{CG}(S)_{\gamma+1} = \mathcal{CG}(S)_\gamma * \mathbb{P}_{S_\gamma}$ where $\mathbb{P}_{S_\gamma}$ is the partial ordering for shooting a closed unbounded set through S_γ.

3. We arrange our bookkeeping so that every closed unbounded set in $V^{\mathcal{CG}(S)}$ appears as some C_γ for some $\gamma < 2^\kappa$.

Assuming that $\kappa^{<\kappa} = \kappa$, the partial orderings $\mathcal{CG}(S)_\gamma$ are κ^+-c.c. and hence that it is possible to achieve the third clause in the definition of $\mathcal{CG}(S)$. Moreover, there is a dense set of *flat* conditions that form a $<\kappa$-closed subset of $\mathcal{CG}(S)$.

In the proof of Theorem 8.14, the iteration used in $\mathcal{CG}(S)$ is interdigitated with the iteration used in the Woodin construction and with yet another partial ordering, the partial ordering for adding a "fast club" set:

The following partial ordering appeared in Jensen's proof of the consistency of CH + Suslin's Hypothesis (see [21]):

8.18 Definition. Let $\mu > \omega$ be a regular cardinal. Define $\mathcal{FC}(\mu)$ to be the partial ordering consisting of pairs, (s, C) where s is a closed bounded subset of μ and C is a closed unbounded subset of μ. We will say that a condition (s, C) is stronger than a condition (t, D) iff

1. s is an end extension of t,
2. $C \subseteq D$, and
3. $s \setminus t \subseteq D$.

If we assume that $\mu^{<\mu} = \mu$, then this partial ordering is μ^+-c.c. and $<\mu$-closed. If $G \subseteq \mathcal{FC}(\mu)$ is generic and $E = \bigcup\{s : \text{for some } C, (s, C) \in G\}$ then E is a closed unbounded subset of μ. A simple density argument shows that if $C \in V$ is a closed unbounded subset of μ then there is a condition $(t, D) \in G$ with $D \subseteq C$. In particular, $E \setminus \sup(t) \subseteq D$.

We now have the ingredients to describe the construction in Theorem 8.14 informally:

Proof. We start with an almost huge embedding $j : V \to M$ with critical point κ and $j(\kappa) = \lambda$ where λ is not Mahlo in V. The forcing will have three parts $\mathbb{P}*\mathbb{Q}*\mathbb{R}$. The partial ordering $\mathbb{P}$ will make $\kappa = \mu^+$, $\mathbb{Q}$ will make $\lambda = \kappa^+$ and $\mathbb{R}$ will be a "termspace" forcing, that will ultimately be isomorphic to adding Cohen subsets to λ. Since $\mathbb{R}$ does not add subsets of κ, the ideals built during the construction will be on subalgebras of $P(\kappa)^{V^{\mathbb{P}*\mathbb{Q}}}$.

We will initially use the Magidor variation of the Kunen construction and build a model V_0 where $\kappa = \mu^+$ and there is a saturated ideal I_0 on the set of V-inaccessible cardinals $\mathcal{I} \subseteq \kappa$ induced by a generic elementary embedding $\hat{j}$. We then begin an iteration that shoots closed unbounded sets through the sets of measure one for $\breve{I}_0$ relative to the V-inaccessible cardinals. The result will be an increasing series of saturated ideals I_α for $\alpha < \lambda$. We dovetail adding closed unbounded sets to make sure that these ideals all eventually end up being NS_κ restricted to the old inaccessible cardinals. This iteration will be a subiteration of $\mathbb{Q}$.

We have three tasks:

1. making strong club guessing hold on $\kappa \setminus \mathcal{I}$,
2. shooting the closed unbounded sets to make the induced saturated ideal the nonstationary ideal, and
3. making strong club guessing hold on $\mathcal{I}$.

These are accomplished in three different ways. The first two are the result of the comingling of the forcing for adding a strong club guessing sequence on $\kappa \setminus \mathcal{I}$, and the forcing for making the sets that appear in the ideals I_α nonstationary. This describes a partial ordering $\mathbb{Q}$ that creates a club guessing sequence on $\kappa \setminus \mathcal{I}$ and makes the nonstationary ideal restricted to the V-inaccessible cardinals saturated. As is crucial, Woodin's observation is used to see that $j(\mathbb{Q})$, which iterates shooting closed unbounded sets through M-stationary subsets relative to the V-nonstationary set of M-inaccessible cardinals $j(\mathcal{I})$), is $<\lambda$-closed.

The third task uses a completely different technique: during the construction of the first phase $\mathbb{P}$ of the partial ordering we will frequently be adding fast closed sets c_α to α over the model $V^{\mathbb{P}_\alpha \cap V_\alpha}$. The strong club guessing sequence on $\mathcal{I}$ will be $\langle c_\alpha : \alpha \in \mathcal{I}\rangle$.

This plan assumes that the inductive construction of the ideals I_α works. The ideals I_α are defined inductively *after* $\mathbb{P}$ is defined, and hence the $\mathbb{Q}_\alpha$

are defined after $\mathbb{P}$ is defined. The definition uses the fact that we extend the elementary embeddings to $j_\alpha : V^{\mathbb{P}*\mathbb{Q}_\alpha} \to M^{j(\mathbb{P}*\mathbb{Q}_\alpha)/m_\alpha}$. To extend the embeddings we must have $\mathbb{P}*\mathbb{Q}_\alpha$ regularly embedded into $j(\mathbb{P})$. This presents a problem because we do not have a definable way of anticipating in advance what the inductive construction of $\mathbb{Q}_\alpha$ is.

To build $\mathbb{P}$, we must then do at least two things. First, we need to find a universal way of anticipating a large class of iterations that include many coordinates that shoot closed unbounded sets through α in $V^{\mathbb{P}_\alpha \cap V_\alpha}$. Second, we need to add a closed unbounded subset c_α of α that is "fast" over any of these iterations.

This involves axiomatizing the type of iterations we will anticipate. In the terminology of [40], these are the "α-acceptable, canonically μ-closed iterations with V-limits". These iterations are shown to have the property of *near properness*, an iterable condition on partial orderings. We then define a partial ordering that is universal for this type of iteration:

Let $\mu < \alpha$ be regular cardinals. Let $\mathbb{B}(\mu, \alpha, \gamma)$ be the partial ordering:

$$\prod_{\substack{\gamma\text{-copies} \\ \text{bounded height} \\ <\alpha\text{-supports}}} \mathrm{Col}(\mu, \alpha),$$

the product partial ordering on γ copies of $\mathrm{Col}(\mu, \alpha)$ with $<\alpha$ supports restricted to those elements p of the product such that there is a $\beta < \mu$ for all $\xi \in \mathrm{supp}(p)$, $\mathrm{dom}(p(\xi)) \subseteq \beta$.

This partial ordering is universal in the sense that if $\mu < \alpha$ are regular cardinals and $\mathbb{Q}$ is a V-limit iteration of canonically μ-closed, α-acceptable partial orderings that has length γ, then there is a regular embedding:

$$\mathbb{Q} \to \mathbb{B}(\mu, \alpha, \gamma).$$

The partial ordering $\mathbb{P}$ is then defined inductively as a $<\mu$ support iteration with:

$$\mathbb{P}_{\alpha+1} = \mathbb{P}_\alpha * (\mathrm{Col}(\alpha, <\kappa) * \mathbb{B}(\mu, \alpha, \kappa) * \mathcal{F}C(\mu))^W$$

where $W = V^{\mathbb{P}_\alpha \cap V_\alpha}$.

Note that since α has cofinality μ in $W^{\mathrm{Col}(\alpha,<\kappa)*\mathbb{B}(\mu,\alpha,\kappa)}$ and W and $W^{\mathrm{Col}(\alpha,<\kappa)*\mathbb{B}(\mu,\alpha,\kappa)}$ have the same $<\mu$-sequences, the partial ordering $\mathcal{F}C(\mu)^W$ adds a closed unbounded subset of α that is eventually included in every closed unbounded subset of α that lies in $W^{\mathrm{Col}(\alpha,<\kappa)*\mathbb{B}(\mu,\alpha,\kappa)}$.

Then at stage κ,

$$j(\mathbb{P})_{\kappa+1} = j(\mathbb{P}_\kappa) * (\mathrm{Col}(\kappa, j(\kappa)) * \mathbb{B}(\mu, \kappa, \lambda), *\mathcal{F}C(\mu))^{V^{\mathbb{P}}}.$$

The fast closed subset of κ added at this stage is eventually inside every closed unbounded subset of κ in the final model $V^{\mathbb{P}*\mathbb{Q}*\mathbb{R}}$. Hence by reflection the fast closed sets added to α at stage α for α in $\mathcal{I}$ will be a club guessing sequence.

It turns out that the iteration $\mathbb{Q}$ described above has a dense set isomorphic to a V-limit of canonically μ-closed, κ-acceptable partial orderings, no matter how the sequence of ideals I_α eventuate. Hence by the universality, we see

$$\mathbb{P} * \mathbb{Q} \to j(\mathbb{P}).$$

We now face the final obstacle. The partial ordering $j(\mathbb{Q})$ is $<\lambda$-closed, so we can attempt pseudo-generic tower arguments in $j(\mathbb{Q})$. However, the inductive definition of the ideals I_α depend on which tower one chooses, and the towers must be collectively generic.

To illustrate why this is a problem, consider a simple case: To define the ideal I_2 we have to build pseudo-generic towers to the first two coordinates of $j(\mathbb{Q})$. To build I_3 we need to build a third tower on the third coordinate of $j(\mathbb{Q})$. However this tower needs to be pseudo-generic over the decisions made by first two towers, which may not be possible if the first two towers were chosen badly. Even more problematic, at a limit stage δ the sequence of pseudo-generic towers built for iterations of length less than α must be pseudo-generic at α.

In this construction the partial ordering $\mathbb{R}$ is a termspace partial ordering that provides *actual* $M^{j(\mathbb{P})}$-generic objects for the iterations $j(\mathbb{Q})_\alpha$, that allow the embeddings $j_\alpha : V^{\mathbb{P}*\mathbb{Q}_\alpha} \to M^{j(\mathbb{P})*j(\mathbb{Q})_{j(\alpha)}/m_\alpha}$ to be extended and cohere sufficiently to give the definitions of the ideals I_α. The interaction of $\mathbb{R}$ with the other partial orderings and the manner in which it provides generic objects for $j(\mathbb{Q})_{j(\alpha)}$ is beyond the scope of this survey. ⊣

8.3. Making Natural Ideals Have Well-Founded Ultrapowers

In this section we briefly summarize some of the results originating from [47]. We start by giving some criteria for a natural ideal to have interesting generic ultrapowers. These involve the notion of "good" structure as given by Definition 3.43.

8.19 Definition. Let I be an ideal on a set $Z \subseteq P(X)$ and $\mathcal{A} = \{a_\alpha : \alpha < \gamma\} \subseteq P(Z)$ be a maximal antichain relative to I.[87] Suppose that θ is a regular cardinal bigger than 2^Z, and $N \prec H(\theta)$ a good structure for I with $I, Z, \mathcal{A} \in N$. Then N *catches an index for* (or just *catches*) $\mathcal{A}$ iff for some $\alpha \in N$, $N \cap X \in a_\alpha$.

Note that the goodness of N implies that it can catch at most one index for $\mathcal{A}$. "Catching an index" is the first step towards being "self-generic" in the sense of Definition 3.45:

8.20 Proposition. *If N is good then the following are equivalent:*

1. *N catches an index for every antichain that belongs to N.*

[87] Precisely, $\{[a_\alpha]_I : \alpha < \gamma\}$ is a maximal antichain in $P(Z)/I$.

2. N is self-generic.

If every good N catches an index for each maximal antichain that belongs to N and $|Z| \leq |X|$, then I is $|X|^+$-saturated.

Proof. Note that N catches an index for $\mathcal{A}$ iff there is an $a \in \mathcal{A} \cap N$ with $N \cap X \in a$. Let $j : \bar{N} \to N$ be the inverse of the transitive collapse map of N. From the definition, N catches an index for every antichain belonging to N iff for all antichains $\mathcal{A} \in N$,

$$\mathcal{A} \cap U(j, N \cap X) \cap N \neq \emptyset.$$

This latter statement is equivalent to the $\bar{N}$-genericity of $U(j, N \cap X)$ for $(P(Z)/I)^{\bar{N}}$.

The final sentence is a restatement of part 3 of Lemma 3.46. ⊣

The method for making natural ideals be precipitous or have saturation properties is to create situations where there is a stationary set of good N that catch many antichains.

The next proposition gives a criterion for precipitousness in these terms.

8.21 Proposition. *Let $Z \subseteq P(X)$ and $I \subseteq P(Z)$ be an ideal. Suppose that for all $S \in I^+$, and all sequences $\langle \mathcal{A}_n : n \in \omega \rangle$ of maximal antichains below $[S]_I$ there is an*

$$N \prec \langle H((2^{|Z|})^+), \in, \Delta, I, Z, X, \langle \mathcal{A}_n : n \in \omega \rangle \rangle,$$

such that:

1. $N \cap X \in S$, and

2. for all n, N catches an index for the antichain $\mathcal{A}_n$.

Then I is precipitous.

Proof. First note that N is good, since this is part of the definition of catching an index for an antichain. We use Proposition 2.7. Let $\langle \mathcal{A}_n : n \in \omega \rangle$ be a tree of maximal antichains below S. Since N is good, there is a a unique element a_n of $\mathcal{A}_n \cap N$ for which $N \cap Z \in a_n$. Since $\mathcal{A}_{n+1}$ refines $\mathcal{A}_n$, either $a_{n+1} \subseteq_I a_n$ or $a_{n+1} \cap a_n =_I \emptyset$. Since N is good, we must have $a_{n+1} \subseteq_I a_n$. Thus the sequence $\langle a_n : n \in \omega \rangle$ forms a branch through the tree of antichains and $N \cap X \in \bigcap_{n \in \omega} a_n$. ⊣

8.22 Definition. Let $S \subseteq H(\theta)$ be a stationary set. Then S *reflects to a set of size* μ iff there is a set $Y \subseteq H(\theta)$ with $\mu \subseteq Y$ and $|Y| = \mu$ such that $S \cap P(Y)$ is stationary.

If I is a normal, fine, countably complete ideal on $Z \subseteq P(\mu)$, Y is a set of cardinality μ and $S \subseteq P(Y)$, then S corresponds canonically to an element $[\bar{S}]_I$ of $P(Z)/I$. Namely, if one fixes a bijection $f : \mu \to Y$, then $\bar{S} = \{z \in Z : f``z \in S\}$. By the normality of I, $[\bar{S}]_I$ is independent of the choice of f. Hence it is well-defined to say that S is *I-positive* iff $[\bar{S}]_I \neq 0$.

We can generalize Definition 8.22 as follows:

8.23 Definition. Let I be a normal, fine, countably complete ideal on $Z \subseteq P(\mu)$, and $S \subseteq H(\theta)$. Then S *reflects to a set in* I^+ iff there is a set $Y \subseteq H(\theta)$ with $\mu \subseteq Y$ and $|Y| = \mu$ such that $S \cap P(Y)$ is I-positive.

In this language, "S reflects to a set of size μ" is equivalent to saying that S reflects to a positive set with respect to the nonstationary ideal on $P(\mu)$.

In certain circumstances the next proposition yields presaturated ideals.

8.24 Proposition. *Let $Z \subseteq P(\mu)$, $\gamma \leq \mu$ and I be a normal, fine, countably complete uniform ideal on Z. Suppose that for all sequences $\langle \mathcal{A}_\alpha \subseteq P(Z) : \alpha < \gamma \rangle$ of maximal antichains relative to I and $S_0 \in I^+$, if T is the set of $N \prec \langle H((2^{|Z|})^+), \in, \Delta, \{I, S_0\}, \langle \mathcal{A}_\alpha : \alpha \in \gamma \rangle \rangle$ such that:*

1. *$N \cap \mu \in S_0$, and*

2. *for all $\alpha \in N \cap \gamma$, N has an index for the antichain $\mathcal{A}_\alpha$,*

then T reflects to a set in I^+. Then I is weakly (γ^+, μ^+)-saturated.[88]

Proof. Suppose that Y is a set of size μ with $\mu \subseteq Y$ such that $T \cap P(Y)$ is in I^+. Let $f : \mu \to Y$ be a bijection. The set of $M \in P(Y)$ such that M is closed under f and f^{-1} is closed and unbounded. Let T' be the collection of $N \in T \cap P(Y)$ that are closed under f and f^{-1} such that $f^{-1}(N) \in Z$. Then $[\bar{T}]_I = [\bar{T}']_I$. Letting $S = \{N \cap \mu : N \in T'\}$ we see that $S = \bar{T}'$.

Since $S \in I^+$ and $|Y| = \mu$ it suffices to show that for each $\alpha < \gamma$, $\{a \cap S : a \cap S \notin I \text{ and } a \in \mathcal{A}_\alpha \cap Y\}$ is a maximal antichain below S.

Modulo closed unbounded sets, $\bigtriangledown(\mathcal{A}_\alpha \cap Y) \cap S$ is the collection of $z \in S$ such that there is a $\delta \in z$ such that $z \in f(\delta)$ and $f(\delta) \in \mathcal{A}_\alpha$. But this collection is a closed unbounded set relative to S. For if $z \in S$ and $\alpha \in z$, then $N = f``z \in T$. Hence N catches $\mathcal{A}_\alpha$. Thus there is a $\delta \in z$ such that $z \in f(\delta)$ and $f(\delta) \in \mathcal{A}_\alpha$.

Hence, for a closed unbounded set of z, if $z \in S$ then $z \in \bigtriangledown(\mathcal{A}_\alpha \cap Y)$. This implies that $S \leq_I \bigtriangledown(\mathcal{A}_\alpha \cap Y)$. By Theorem 2.24, $\bigtriangledown(\mathcal{A}_\alpha \cap Y)$ is the Boolean sum of $\mathcal{A}_\alpha \cap Y$ in $P(Z)/I$. Hence $\{a \cap S : a \cap S \notin I \text{ and } a \in \mathcal{A}_\alpha \cap Y\}$ is a maximal antichain below S. ⊣

Catching Antichains Using Reflection

We now introduce a technique for modifying an existing natural ideal to make it precipitous. We will follow the original route to these results from

[88] Weak saturation is defined in Definition 4.5.

[47] which use reflection and a supercompact.[89] Woodin [126] discovered how to modify these arguments to work from a Woodin cardinal. His arguments do not use stationary set reflection.

8.25 Lemma. *Suppose that $\theta \gg \mu$ are regular cardinals and I is a normal and fine ideal on $Z \subseteq P(\mu)$. Suppose that $R \subseteq P(H(\theta))$ is a stationary set of good structures such that the projection to $P(\mu)$ of any relatively closed unbounded subset of R belongs to $\breve{I}$ and every stationary subset of R reflects to a set in I^+. Then for each maximal antichain $\mathcal{A} \subseteq P(Z)/I$ and each expansion $\mathfrak{A}$ of $\langle H(\theta), \in, \Delta\rangle$ there is a closed unbounded set C of $N \prec \mathfrak{A}$ such that if:*

(a) $N \in C \cap R$, and

(b) $\mathcal{A} \in N$,

then there is an $N' \prec \mathfrak{A}$ such that:

(A) $N' \in R$,

(B) $N' \cap \mu = N \cap \mu$,

(C) $N \prec N' \prec \mathfrak{A}$, and

(D) N' catches $\mathcal{A}$.

Proof. Suppose not. Then there is a stationary set B of $N \prec \mathfrak{A}$ such that:

(a) $B \subseteq R$,

(b) $\mathcal{A} \in N$ for all $N \in B$,

and such that whenever $N' \prec \mathfrak{A}$ is such that

(A) $N' \in R$,

(B) $N' \cap \mu = N \cap \mu$, and

(C) $N \prec N'$

then N' does not catch $\mathcal{A}$.

Let $Y \subseteq H(\theta)$ with $\mu \subseteq Y$ and $|Y| = \mu$ such that $B \cap P(Y)$ is I-positive. Let $f : \mu \to Y$ be a bijection, and $S = \{z : f``z \cap \mu = z \text{ and } f``z \in T\}$. Then S is I-positive, so there is an $b \in \mathcal{A}$ such that $S \cap b$ is in I^+.

The collection of $M \in R$ such that $M \prec \mathfrak{A}$ and $b, f \in M$ is closed unbounded relative to R. Thus we can find an $N' \prec \mathfrak{A}$ in R with $b, f \in N'$ and $N' \cap \mu \in S \cap b$. Let $N = f``N' \cap \mu$. Then $N \in B$, $N \cap \mu = N' \cap \mu$ and $N \prec N'$, a contradiction. ⊣

[89] Matsubara [93] showed how to interpolate ideal assumptions to get similar results; his arguments use a result similar to Theorem 5.26 that he discovered independently to prove the reflection properties needed to catch antichains.

Reflecting Stationary Sets

The following definition gives a name for a standard idea:

8.26 Definition. Let X be a set, and $Z \subsetneq P(X)$ be stationary. Then Z is *μ-robust* iff for all stationary subsets $S \subseteq Z$ and all $<\mu$-closed partial orderings $\mathbb{P}$, S is stationary in $V^{\mathbb{P}}$.

Abstract forcing arguments easily show that Z is μ-robust iff every stationary subset of Z is preserved under forcing with $\mathrm{Col}(\mu, |Z|)$.

We now give some examples of robust stationary sets.

8.27 Example. Let $X = \mu$ be a cardinal and $Z = \mu$. Since $<\mu$-closed forcing does not destroy stationary subsets of μ, Z is λ-robust for all $\lambda \geq \mu$.

Our next example illustrates the point of robustness. We recall the following definition from [42]. Let $N \subseteq H(\lambda)$. Then N is *internally approachable* (or IA) *of length* β iff there is a sequence $\langle N_\alpha : \alpha < \beta \rangle$ such that:

1. $N = \bigcup_{\alpha<\beta} N_\alpha$,
2. $N_\alpha \subseteq N_\beta$ for $\alpha < \beta$, and
3. for all $\beta' < \beta$, $\langle N_\alpha : \alpha < \beta' \rangle \in N$.

Given an $N \prec \langle H(\lambda), \in, \Delta \rangle$, any two approaching sequences have the same cofinality. If this cofinality is γ we will say that $N \in \mathrm{IA}(\mathrm{Cof}(\gamma))$.

8.28 Example. Let μ be a regular cardinal and let $Z = \{z \in [H(\lambda)]^{<\mu} : z \cap \mu \in \mu$ and z is internally approachable$\}$. Then Z is a maximal μ-robust subset of $\{z \in [H(\lambda)]^{<\mu} : z \cap \mu \in \mu\}$.

This follows from Lemma 2.5 of [42] where it is shown that IA is μ-robust and for all sets $S \subseteq [H(\lambda)]^{<\mu} \cap \{N : N \cap \mu \in \mu\}$ and all V-generic $G \subseteq \mathrm{Col}(\mu, H(\lambda))$,

$$V[G] \models [S]_{\mathrm{NS}} = [S \cap \mathrm{IA}]_{\mathrm{NS}}.$$

We now present a slight generalization of Example 8.28 that covers Chang's Conjecture and clarifies the results in [47] slightly:

8.29 Definition. Suppose that $N \prec H(\theta)$ with $|N| < \mu$. Then N is *μ-weakly approachable* iff there is an increasing continuous sequence $\langle N_\alpha : \alpha < \sup(N \cap \mu) \rangle$ such that:

1. $|N_\alpha| < \mu$ for all α,
2. $N \subseteq \bigcup_{\alpha \in N \cap \mu} N_\alpha$, and
3. for all $\beta \in N \cap \mu$, $\langle N_\alpha : \alpha \in \beta \rangle \in N$.

If $N \in [H(\theta)]^{<\mu}$ and $N \cap \mu \in \mu$, then N is μ-weakly approachable iff N is internally approachable. It is a standard fact (see [47]) that if $\theta > \eta$, $N \prec H(\theta)$ is internally approachable, $\eta \in N$, and $a \in \eta$, then $\mathrm{Sk}^{H(\theta)}(N \cup \{a\})$ is also internally approachable. The following generalization is shown using the same technique:

8.30 Proposition. *Suppose that θ is a regular uncountable cardinal and $\mu < \theta$. Let $N \prec \langle H(\theta), \in, \Delta\rangle$ be a μ-weakly approachable structure and $a \in y$ for some $y \in N$. Then $\mathrm{Sk}^{H(\theta)}(N \cup \{a\})$ is μ-weakly approachable.*

Proof (Sketch). The structure $\langle H(\theta) \in, \Delta\rangle$ has definable Skolem functions. Fix an internally approachable structure $N \prec H(\theta)$ and let $\langle N_\alpha : \alpha \in \gamma\rangle$ be a witness to approachability. For each $x \in N$ the restriction of each of those Skolem functions to x is a member of N. For each α, let N^*_α be the closure of $N_\alpha \cup \{a\}$ under all functions from $H(\theta)$ to $H(\theta)$ that belong to $N_{\alpha+1}$. Then the sequence $\langle N^*_\alpha : \alpha \in \gamma\rangle$ witnesses the fact that $\mathrm{Sk}^{H(\theta)}(N \cup \{a\})$ is weakly approachable. $\dashv$

Weak approachability is intimately tied to robustness. We now describe the relationship.

8.31 Proposition. *Let μ and θ be regular cardinals with $\theta > 2^\mu$. Then any stationary collection $S \subseteq P(H(\theta))$ of μ-weakly approachable structures is μ-robust.*

Proof. Let S be a stationary subset of the μ-weakly approachable subsets of $H(\theta)$ and κ be a cardinal. Suppose that $p \in \mathrm{Col}(\mu, \kappa)$ forces that S is not stationary in $V[G]$, where $G \subseteq \mathrm{Col}(\mu, \kappa)$ is generic. Let $\lambda \gg \max\{|S|, \kappa\}$ be a regular cardinal and $\dot{F}$ be a $\mathrm{Col}(\mu, \kappa)$-term for a function from $H[\theta]^{<\omega}$ to $H(\theta)$ such that $p \Vdash \{N \in [H(\theta)]^{<\mu} : N \text{ is closed under } \dot{F}\} \cap S = \emptyset$. Since S is stationary there is an $N \prec \langle H(\lambda), \in, \Delta, S, \kappa, p, \dot{F}\rangle$ with $|N| < \mu$ such that $N \cap H(\theta) \in S$. Let $\langle N_\alpha : \alpha \in \sup(N \cap \mu)\rangle$ witness the weak approachability of $N \cap H(\theta)$.

Since $\beta \in N$ implies that $\langle N_\alpha : \alpha \in \beta\rangle \in N$, one sees that there is a decreasing sequence of conditions $\langle p_\alpha : \alpha \in \sup(N \cap \mu)\rangle$ below p such that

1. for all $\beta \in N \cap \mu$, $\langle p_\alpha : \alpha < \beta\rangle \in N$, and
2. if $x \in N_\alpha \cap [H(\theta)]^{<\omega}$ and $\alpha < \beta$, then there is a y such that $p_\beta \Vdash \dot{F}(x) = y$.

Since $|N| < \mu$, we see that $q = \bigcup_{\alpha \in N \cap \mu} p_\alpha \in \mathrm{Col}(\mu, \kappa)$. However $q \Vdash$ "$N \cap H(\theta)$ is closed under $\dot{F}$", a contradiction. $\dashv$

We can generalize Lemma 2.5 of [42] with the following remark:

8.32 Remark. Let $S \subseteq [H(\theta)]^{<\mu}$. If $G \subseteq \mathrm{Col}(\mu, |H(\theta)|)$ is generic, then in $V[G]$ there is a closed unbounded set $C \subseteq P(H(\theta)^V)$ such that $S \cap C \subseteq \{N : N \text{ is } \mu\text{-weakly approachable in } V\}$. In particular, in $V[G]$, $[S]_{\mathrm{NS}} = [S \cap \{\text{weakly approachable structures}\}]_{\mathrm{NS}}$.

Proof. View G as a function from μ to $H(\theta)^V$ and let $N_\alpha = G``\alpha$. Let $C = \{N : N \prec \langle H(\theta)^V, \in, \Delta, G\rangle\}$. Then for $N \in C \cap ([H(\theta)]^{<\mu})^V$, the sequence $\langle N_\alpha : \alpha \in \sup(N \cap \mu)\rangle$ witnesses that N is weakly approachable. $\dashv$

We note that if $|H(\mu)| = \mu$ and $\mathfrak{A}$ is an algebra expanding the structure $\langle H(\mu), \in, \Delta\rangle$, then $H(\mu)$ is a union of a continuously increasing sequence of structures $\langle N_\alpha : \alpha < \mu\rangle$ such that

1. $|N_\alpha| < \mu$,
2. for $\beta < \beta'$, $\langle N_\alpha : \alpha < \beta\rangle \in N_{\beta'}$, and
3. $N_\alpha \prec \mathfrak{A}$.

If $M \prec \langle H(\mu), \in, \Delta, \langle N_\alpha : \alpha < \mu\rangle\rangle$ has cardinality less than μ, then M is μ-weakly approachable. Hence, the μ-weakly approachable structures form a closed unbounded set in $[H(\mu)]^{<\mu}$.

Using this and the usual arguments that show that the nonstationary ideals restricted to IA form a tower we see:

8.33 Proposition. *Suppose that $\mu \le \theta < \theta'$ are regular. Then*

1. *The nonstationary ideal on $[H(\theta')]^{<\mu}$ restricted to the μ-weakly approachable structures projects to the nonstationary ideal on $[H(\theta)]^{<\mu}$ restricted to the μ-weakly approachable structures.*
2. *If $|H(\mu)| = \mu$, then the μ-weakly approachable structures form a closed unbounded set in $[H(\mu)]^{<\mu}$.*

8.34 Example (Foreman et al. [47]). Suppose that $(\mu, \rho) \twoheadrightarrow (\mu', \rho')$. Then for all $\theta \ge \mu$, $W = \{N \prec H(\theta) : |N \cap \mu| = \mu'$ and $|N \cap \rho| = \rho'$ and N is μ-weakly approachable$\}$ is stationary. Moreover, if $|H(\mu)| = \mu$ then the projection of $\mathrm{NS}\restriction W$ to an ideal on $P(H(\mu))$ is the Chang ideal on $\{N \prec H(\mu) : |N| = \mu'$ and $|N \cap \rho| = \rho'\}$.

Our use of the notion of robustness is the following lemma.

8.35 Lemma. *Suppose that κ is a supercompact cardinal. Let $\mu < \kappa$ be regular. Let $G \subseteq \mathrm{Col}(\mu, <\kappa)$ be generic. In V[G], if $R \subseteq P(H(\theta))$ is a μ-robust stationary set and $S \subseteq R$ is stationary, then S reflects to a set of size μ.*

Proof. Let $j : V \to M$ be a $|H(\theta)|$-supercompact embedding. Then for all generic $G \subseteq \mathrm{Col}(\mu, <\kappa)$, there is a generic $H \subseteq \mathrm{Col}(\mu, <j(\kappa))$ such that j can be extended to a

$$\hat{j} : V[G] \to M[H].$$

By robustness, $\hat{j}(S) \cap P(\hat{j}``H(\theta))$ is stationary in $V[H]$ and $M[H] \models |\hat{j}``H(\theta)| = \mu$. Hence $M[H] \models$ "there is an $Y \subseteq H(j(\theta))$ with $\mu \subseteq Y$ and $|Y| = \mu$ such that $\hat{j}(S) \cap P(Y)$ is stationary in $P(Y)$". Hence the statement holds in $V[G]$ by elementarity. $\dashv$

Catching Your Tail

We now describe a typical "catch-your-tail" argument. Catching your tail allows one to change "there is a club set of N" in antichain catching lemmas (such as Lemma 8.25) to "for every N". The hypotheses of the next lemma are those of Lemma 8.25, with R being the μ-weakly approachable sets and I being the nonstationary ideal. The improvement on the conclusion of Lemma 8.25 is that instead of saying that there is a closed unbounded set of structures that can be expanded to catch a fixed maximal antichain $\mathcal{A}$, we find a $\mathfrak{B}$ such that for *every* elementary substructure $N \prec \mathfrak{B}$ and *every* maximal antichain $\mathcal{A}$ in N, N can be so extended to catch $\mathcal{A}$.

8.36 Lemma. *Let:*

1. *$\theta \gg \mu$ be regular cardinals,*
2. *R be the set of μ-weakly approachable subsets of $H(\theta)$,*
3. *$\mathfrak{A}$ be a structure expanding $\langle H(\theta), \in, \Delta\rangle$,*
4. *Z be the set of μ-weakly approachable subsets of $H(\mu)$, and*
5. *I be $\mathrm{NS}\restriction Z$.*

Suppose that every stationary subset of R reflects to a stationary set of size μ. Then there is a structure $\mathfrak{B}$ with domain $H(\theta)$ expanding $\langle H(\theta), \in, \Delta, \mu, R\rangle$ and $\mathfrak{A}$ such that for every $N \prec \mathfrak{B}$ with $N \in R$ and for every maximal antichain $\mathcal{A} \subseteq P(Z)/I$ with $\mathcal{A} \in N$ there is an $N' \in R$ with

(A) $N' \cap \mu = N \cap \mu$,

(B) $N \prec N' \prec \mathfrak{B}$, and

(C) N' catches an index for $\mathcal{A}$.

Proof. Let $\theta' \gg \theta$ and $\mathfrak{A}^* = \langle H(\theta'), \in, \Delta, \mathfrak{A}, \{\theta, Z, \mu, R, I\}\rangle$. Let $\langle f_i : i \in \omega\rangle$ be a complete set of Skolem functions for $\mathfrak{A}^*$ closed under composition, where each f_i is definable in $\mathfrak{A}^*$. Let $\mathfrak{B}$ be the expansion of $\mathfrak{A}$ and $\langle H(\theta), \in, \Delta, \mu, R\rangle$ built by adding function symbols for $\langle g_i : i \in \omega\rangle$ where the g_i's are the f_i's restricted to $H(\theta)$. Then any elementary substructure N of $\mathfrak{B}$ is of the form $N^* \cap H(\theta)$ for some $N^* \prec \mathfrak{A}^*$.

Suppose now that $N \prec \mathfrak{B}$ belongs to R and that $\mathcal{A} \in N$ is a maximal antichain. Let N^* be the Skolem hull of N in $\mathfrak{A}^*$. Since $\mathcal{A} \in N^*$ and $\mathfrak{A}$ is definable in $\mathfrak{A}^*$, if C is the closed unbounded set given in the conclusion of Lemma 8.25 applied to $\mathfrak{A}$ and $\mathcal{A}$, then $C \in N^*$. In particular, $N \in C$.

Hence we can find an $M \in R$ with $N \prec M \prec \mathfrak{A}$, $M \cap \mu = N \cap \mu$ and M catches an index for $\mathcal{A}$.

Suppose that a is the index caught by M. Let $N' = \mathrm{Sk}^{\mathfrak{A}}(N \cup \{a\})$. Then $N \prec N' \prec M$ and $N \cap \mu = N' \cap \mu$. Hence N' catches an index for $\mathcal{A}$. By Proposition 8.30, N' is weakly approachable.

It remains to see that $N' \prec \mathfrak{B}$. Every element of $\mathrm{Sk}^{\mathfrak{B}}(N \cup \{a\})$ is of the form $g_i(\vec{x}, a)$ for some $\vec{x} \in [N]^{<\omega}$. Fixing $\vec{x}$, we can view $g_i(\vec{x}, \cdot)$ as a function h from $\mathcal{A}$ to $H(\theta)$. Since this function is definable in $\mathfrak{B}$ from $\vec{x}$ and $N \prec \mathfrak{B}$ it must belong to N. In particular, $h(a) \in \mathrm{Sk}^{\mathfrak{A}}(N \cup \{a\}) = N'$. Thus $g_i(\vec{x}, a) \in N'$, as desired. ⊣

We note that Lemma 8.36 can be reformulated equivalently by having a closed unbounded set D play the role of the structure $\mathfrak{A}$. In this alternate version there is a closed unbounded set $D \subseteq H(\theta)$ replacing $\mathfrak{A}$ in the third clause of the lemma. The conclusion is that there is a structure $\mathfrak{B}$ such that for every weakly approachable structure $N \prec \mathfrak{B}$ in D and every maximal antichain $\mathfrak{A} \in N$ there is a weakly approachable $N' \prec \mathfrak{B}$ belonging to D that catches $\mathcal{A}$ and has the same intersection with μ that N does.

This conclusion can be further reformulated combinatorially by saying for all closed unbounded sets D there is a closed unbounded set $C \subseteq D$ for all weakly approachable $N \in C$ and all maximal antichains $\mathcal{A} \in N$ there is a weakly approachable elementary extension $N' \in C$ catching $\mathcal{A}$ that lies in C. This combinatorial version is close to what is necessary for stationary tower arguments.

The Nonstationary Ideal is Precipitous

Since all $N \prec H(\theta)$ are good for the nonstationary ideal, we immediately deduce:

8.37 Theorem (Foreman et al. [47]). *Suppose that κ is a supercompact cardinal and $\mu < \kappa$ is regular. Suppose that $G \subseteq \mathrm{Col}(\mu, {<}\kappa)$ is generic. Then in $V[G]$ the nonstationary ideal restricted to $[\mu]^{<\mu}$ is precipitous. In particular:*

1. $\mathrm{NS}{\restriction}\mu$ *is precipitous.*

2. $\mathrm{NS}{\restriction}[\mu]^{<\delta}$ *is precipitous for all uncountable regular cardinals δ.*

3. *If $(\mu, \rho) \twoheadrightarrow (\mu', \rho')$ in V for cardinals ρ, μ', ρ' then in $V[G]$, the Chang ideal $\mathrm{CC}((\mu, \rho), (\mu', \rho'))$ is precipitous.*

4. *If $\mu = \eta^+$, where η is a Jónsson cardinal then $\mathrm{NS}{\restriction}\{N \in [H(\mu)]^{<\mu} : |N \cap \eta| = \eta$ and $\eta \nsubseteq N\}$ is precipitous.*

Proof. Let $G \subseteq \mathrm{Col}(\mu, {<}\kappa)$ be generic. We work in $V[G]$. Note that $|H(\mu)| = \mu$ in $V[G]$ so we work with $[H(\mu)]^{<\mu}$.

Let R be the collection of μ-robust subsets of $H((2^\mu)^+)$. Then by Proposition 8.33 the nonstationary ideal on R projects to the nonstationary ideal on $[H(\mu)]^{<\mu}$.

We use Proposition 8.21. Let $\langle \mathcal{A}_n : n \in \omega \rangle$ be a tree of antichains. Choose $N_0 \prec H(\theta)$ such that $N_0 \in R$ and $\langle \mathcal{A}_n : n \in \omega \rangle \in N_0$. Applying Lemma 8.36, we see that we can build a chain $\langle N_n : n \in \omega \rangle$ of elementary substructures of

$H((2^\mu)^+)$ such that N_{n+1} catches $\mathcal{A}_n$ and $N_n \in R$ and $N_n \cap \mu = N_{n+1} \cap \mu$. Let $N = \bigcup_n N_n$. Then $N \cap \mu$ belongs to the projection of R to μ, is good and catches an index for each antichain $\mathcal{A}_n$. ⊣

Saturation of the Nonstationary Ideal

Suppose that κ is supercompact and $G \subseteq \mathrm{Col}(\omega_1, {<}\kappa)$ is generic. We work in $V[G]$, noting that there, for all $\lambda \geq \omega_1$, every stationary subset of $[\lambda]^{<\omega_1}$ reflects to a set of size $\aleph_1$.

Let $\langle \mathcal{A}_n : n \in \omega \rangle$ be a collection of maximal antichains in $P(\omega_1)/\mathrm{NS}_{\omega_1}$ and fix a $\theta \gg \omega_1$. We follow the arguments of Theorem 8.37. Since every countable $N \prec \langle H(\theta), \in, \Delta \rangle$ is internally approachable, if $\mathfrak{A}$ is an expansion of $\langle H(\theta), \in, \Delta, \langle \mathcal{A}_n : n \in \omega \rangle \rangle$ and $N \prec \mathfrak{A}$ then there is a countable $N' \prec \mathfrak{A}$ catching every $\mathcal{A}_n$. Hence the collection S of countable $M \prec \langle H(\theta), \in, \Delta \rangle$ that catch every $\mathcal{A}_n$ is stationary. But then S reflects to a set of size $\aleph_1$. Hence by Proposition 8.24, we see that $P(\omega_1)/\mathrm{NS}_{\omega_1}$ is weakly $(\aleph_1, \aleph_2)$-saturated. In particular, it is presaturated. We have shown:

8.38 Corollary. *Suppose that κ is supercompact and $G \subseteq \mathrm{Col}(\omega_1, {<}\kappa)$ is generic. Then in $V[G]$, CH holds and NS_{ω_1} is presaturated.*

If we want to have NS_{ω_1} $\aleph_2$-saturated, then we need to do more than collapse a large cardinal to be ω_2. We must control the size of maximal antichains.

The most naïve approach would be to take a large maximal antichain $\mathcal{A} = \langle a_\alpha : \alpha < \gamma \rangle$ with $\gamma \geq \omega_2$ in $P(\omega_1)/\mathrm{NS}_{\omega_1}$ and collapse γ to have cardinality ω_1. The problem with this approach is that $\mathcal{A}$ no longer is a maximal antichain after the collapse.

We can make antichains persistently maximal by the following trick. Suppose that $\mathcal{A} \subseteq P(\omega_1)/\mathrm{NS}_{\omega_1}$ is any antichain of size at most $\aleph_1$, and S is $\bigtriangledown\mathcal{A}$. If we force with the partial ordering $\mathbb{P}_S$ for adding a closed unbounded set inside S to get a generic G, then in $V[G]$, $\mathcal{A}$ is a maximal antichain. Moreover $\mathcal{A}$ remains a maximal antichain in any model $W \supseteq V[G]$ with $\omega_1^W = \omega_1^{V[G]}$.

This suggests a strategy of reducing the size of antichains $\mathcal{A} = \langle a_\alpha : \alpha < \gamma \rangle$ by shooting closed unbounded sets through the diagonal union of the first ω_1 elements of $\mathcal{A}$, $\langle a_\alpha : \alpha < \omega_1 \rangle$, and iterating this forcing for all antichains. The problem with this approach, as is typical for iterations that destroy stationary sets, is that ω_1 is collapsed by the iteration.

The solution is to combine the two approaches into a single forcing:

8.39 Definition (Foreman et al. [47]). Suppose that $\mathcal{A} = \langle a_\alpha : \alpha < \gamma \rangle$ is a maximal antichain in $P(\omega_1)/\mathrm{NS}_{\omega_1}$. The *antichain sealing forcing* for $\mathcal{A}$ is $\mathrm{Col}(\omega_1, \gamma) * \mathbb{P}_T$ where T is the diagonal union of $\mathcal{A}$ in $V^{\mathrm{Col}(\omega_1, \gamma)}$.

Iterating this forcing does not, in general, preserve ω_1. However, it is still relatively gentle to V:

8.40 Lemma. *Suppose that $S \subseteq \omega_1$ is a stationary set. Then for all maximal antichains $\mathcal{A} \subseteq P(\omega_1)/\mathrm{NS}_{\omega_1}$, the antichain sealing forcing for $\mathcal{A}$ preserves the stationarity of S.*

Proof. Let $\mathbb{P}$ be the antichain sealing forcing. Suppose that a $\mathbb{P}$-term $\dot{C}$ for a closed unbounded subset of ω_1 and $(p,q) \in \mathbb{P}$ are such that $(p,q) \Vdash \dot{C} \cap S = \emptyset$. Let $a \in \mathcal{A}$ be such that $a \cap S$ is stationary. Let $\theta \gg \omega_1$ and $N \prec \langle H(\theta), \in, \Delta, \mathcal{A}, \{p, a, S, \dot{C}\}\rangle$ be a countable set such that $\delta =_{\mathrm{def}} N \cap \omega_1 \in a \cap S$. Choose a descending sequence $\langle (p_i, q_i) : i \in \omega\rangle \subseteq \mathbb{P} \cap N$ below (p,q) such that for all dense sets $D \subseteq \mathbb{P}$ with $D \in N$ there is an i such that $(p_i, q_i) \in D$. Then $m = (\bigcup_{i\in\omega} p_i, \bigcup_{i\in\omega} q_i \cup \{\delta\}) \in \mathbb{P}$ and is stronger than each (p_i, q_i). Hence m is N generic and forces that δ is a limit point of $\dot{C}$, a contradiction. ⊣

There are models where preserving stationary sets is equivalent to being semiproper:

8.41 Theorem (Foreman et al. [47]). *Suppose that $\mathbb{P}$ is a κ-c.c. partial ordering that preserves stationary subsets of ω_1 and collapses κ to be ω_2. Suppose that there is a λ-supercompact embedding $j : V \to M$ with critical point κ such that $j(\mathbb{P}) \sim \mathbb{P} * \mathrm{Col}(\omega_1, \lambda) * \mathbb{R}$, where $\mathbb{R}$ preserves stationary subsets of ω_1 in $V^{\mathbb{P}*\mathrm{Col}(\omega_1,\lambda)}$. Then for all generic $G \subseteq \mathbb{P}$, and partial orderings $\mathbb{Q} \in V[G]$:*

If $\mathbb{Q}$ preserves stationary subsets of ω_1 and $2^{2^{|\mathbb{Q}|}} < \lambda$, then $\mathbb{Q}$ is semiproper.

Proof (Sketch). Suppose that $G \subseteq \mathbb{P}$ is generic and $\mathbb{Q}$ preserves stationary subsets of ω_1. If $\mathbb{Q}$ is not semiproper, then there is a "bad" stationary set $B \subseteq [H((2^{2^{|\mathbb{Q}|}})^+)]^{<\omega_1}$ and a fixed condition $p \in \mathbb{Q}$ such that for all $N \in B$, $p \in N$ and if $H \subseteq \mathbb{Q}$ is generic with $p \in H$, then $N[H] \cap \omega_1 \neq N \cap \omega_1$.

Let $\lambda = |H((2^{2^{|\mathbb{Q}|}})^+)|$. Choose a λ-supercompact embedding $j : V \to M$ such that $j(\mathbb{P}) \sim \mathbb{P} * \mathrm{Col}(\omega_1, \lambda) * \mathbb{R}$, where $\mathbb{R}$ preserves stationary subsets of ω_1. Let $G * H_0 * H_1 \subseteq \mathbb{P} * \mathrm{Col}(\omega_1, \lambda) * \mathbb{R}$ be a generic object extending G and $\hat{j} : V[G] \to M[G * H_0 * H_1]$ be an elementary embedding extending j.

Since $\mathrm{Col}(\omega_1, \lambda)$ is $<\omega_1$-closed, it preserves the stationarity of B. Let $h : \omega_1 \to H((2^{2^{|\mathbb{Q}|}})^+)$ be a bijection lying in $M[G * H_0]$, and $B' \subseteq \omega_1$ be $\{\alpha : h``\alpha \in B,\ h``\alpha \cap \alpha = \alpha\}$. Then B' is stationary in $V[G * H_0]$ and so in $V[G * H_0 * H_1]$.

Let $H_2 \subseteq j(\mathbb{Q})$ be generic over $M[G * H_0 * H_1]$ with $j(p) \in H_2$. Let N' be a countable elementary substructure of

$$\langle H((2^{2^{j(|\mathbb{Q}|)}})^+)^{M[G*H_0*H_1]}, \in, \Delta, j(\mathbb{Q}), \mathbb{Q}, h, j{\restriction}H((2^{2^{|\mathbb{Q}|}})^+), H_2\rangle$$

such that $\delta =_{\mathrm{def}} N' \cap \omega_1 \in B'$. Let $N_0 = h``\delta$. Then $N_0 = N' \cap H((2^{2^{|\mathbb{Q}|}})^+)^V$ and $N_0 \in B$. Let $N = j(N_0)$. Then $N = j``N_0 \subseteq N'$ and $N \in j(B)$. But $N[H_2] \subseteq N'$, so $\delta \subseteq N \cap \omega_1 \subseteq N[H_2] \cap \omega_1 \subseteq N' \cap \omega_1 = \delta$. Hence $N \in j(B)$ and $N \cap \omega_1 = N[H_2] \cap \omega_1$, a contradiction to the definition of $j(B)$ in M. ⊣

If $\mathbb{P}$ satisfies the hypotheses of Theorem 8.41, then in $V^{\mathbb{P}}$ every antichain sealing forcing is semiproper. An elementary chain argument shows that when this is the case, the partial ordering

$$\mathrm{Col}(\omega_1, 2^{\omega_1}) * \prod_{\substack{\mathcal{A}\in V \\ <\omega_1\text{-supports}}} \mathbb{P}_{T_{\mathcal{A}}}$$

is also semiproper, where the product is taken over all V-maximal antichain $\mathcal{A} \subseteq P(\omega_1)^V/\mathrm{NS}_{\omega_1}$ and $\mathbb{P}_{T_{\mathcal{A}}}$ is the partial ordering for shooting a closed unbounded set through $\triangledown\mathcal{A}$.

The Equivalence of "Semiproper" with "Stationary Set Preserving" in the Case of Antichain Sealing Forcing

Since an important special case of Theorem 8.41 is when $\mathbb{Q}$ is the antichain sealing forcing, we discuss the proof in this special case. Assume that $\mathbb{P}$ satisfies the hypotheses of the theorem.

Let $G \subseteq \mathbb{P}$ be generic and $\mathbb{Q} = \mathrm{Col}(\omega_1, \gamma) * \mathbb{P}_T$ be the antichain sealing forcing for $\mathcal{A}$. We show that $\mathbb{Q}$ is semiproper in $V[G]$. Let $\theta = (2^{2^{|\mathbb{Q}|}})^+$.

The argument for Lemma 8.40 shows that if $N' \prec \langle H(\theta), \in, \Delta, \mathcal{A}\rangle$ catches $\mathcal{A}$, and $(p, q) \in N' \cap \mathbb{Q}$ there is a generic condition $m \le (p, q)$ for N'. If $N \prec N'$ and $N \cap \omega_1 = N' \cap \omega_1$ then m is a semigeneric condition for N.

Thus to see that $\mathbb{Q}$ is semiproper it suffices to show that for each $\mathfrak{A}$ there is a closed unbounded set C relative to $[H(\theta)]^{<\omega_1}$ of $N \prec \mathfrak{A}$ with $\mathcal{A} \in N$ such that there is an $N' \prec \mathfrak{A}$:

(A) $N' \cap \omega_1 = N \cap \omega_1$,

(B) $N \prec N'$, and

(C) N' catches $\mathcal{A}$.

If this fails then there is a structure $\mathfrak{A}$ with domain $H(\theta)$ and a bad stationary set $B \subseteq [H(\theta)]^{<\omega_1}$ such that for all $N \in B$, we have $\mathcal{A} \in N$ and whenever $N' \prec \mathfrak{A}$ is such that

(A) $N' \cap \omega_1 = N \cap \omega_1$, and

(B) $N \prec N'$,

then

(C) N' does not catch $\mathcal{A}$.

By the hypotheses of the theorem we can find a $|H(\theta)|$-supercompact embedding $j : V \to M$ such that $j(\mathbb{P}) \sim \mathbb{P} * \mathrm{Col}(\omega_1, \lambda) * \mathbb{R}$, where $\mathbb{R}$ preserves stationary subsets of ω_1. Let $G * H_0 * H_1 \subseteq \mathbb{P} * \mathrm{Col}(\omega_1, \lambda) * \mathbb{R}$ be a generic object extending G and $\hat{j} : V[G] \to M[G * H_0 * H_1]$ be an elementary embedding extending j.

Since $\mathrm{Col}(\omega_1, |H(\theta)|)$ is $<\omega_1$-closed, it preserves the stationarity of B. Let $h : \omega_1 \to H(\theta)$ be a bijection lying in $M[G * H_0]$, and $B' \subseteq \omega_1$ be $\{\alpha : h``\alpha \in B,\ h``\alpha \cap \alpha = \alpha\}$. Then B' is stationary in $V[G * H_0 * H_1]$. Hence there is a $b \in j(\mathcal{A})$ such that B' is compatible with b.

Let $N' \prec j(\mathfrak{A})$ be such that

1. $N' \cap \omega_1 \in b \cap B'$, and
2. $\{j{\restriction}H(\theta), h, b\} \subseteq N'$.

Let $N_0 = h``\delta$, where $\delta = N' \cap \omega_1$. Then $N_0 \in B$ and $N_0 = N' \cap H(\theta)^V$. Let $N = j(N_0)$. Then $N = j``N_0$ and $N \in j(B)$.

Thus in $M[G * H_0 * H_1]$, N belongs to the bad set $j(B)$. But:

(A) $N' \cap \omega_1 = N \cap \omega_1$,

(B) $N \prec N'$, and

(C) N' catches $j(\mathcal{A})$,

which is a contradiction.

We now outline the argument from [47] that one can force NS_{ω_1} to be $\aleph_2$-saturated, provided one starts with a model with a supercompact cardinal. The actual argument given there was more ambitious: it showed that Martin's Maximum[90] is consistent. The iteration given here is specific to the nonstationary ideal.

Define a semiproper iteration $\mathbb{P} = \mathbb{P}_\kappa$ of length κ with revised countable supports that, at a typical limit stage α, seals a maximal antichain $\mathcal{A}_\alpha \subseteq P(\omega_1)/\mathrm{NS}_{\omega_1}$ lying in $V^{\mathbb{P}_\alpha}$ provided that every antichain sealing forcing lying in $V^{\mathbb{P}_\alpha}$ is semiproper. There are several mechanisms for choosing $\mathcal{A}_\alpha$ that work. We can use a "Laver function" f,[91] and force with $f(\alpha)$ if $f(\alpha)$ is a maximal antichain in $V^{\mathbb{P}_\alpha}$. Equally well, we can generically choose a maximal antichain $\mathcal{A}_\alpha$. Alternately we could simultaneously seal all maximal antichains $\mathcal{A} \subseteq P(\omega_1)/\mathrm{NS}_{\omega_1}$ lying in $V^{\mathbb{P}_\alpha}$ with the forcing described after Theorem 8.41. In the original proof a Laver function was used.

If there is a maximal antichain which for which the sealing forcing is not semiproper, then at stage α the iteration $\mathbb{P}$ forces with $\mathrm{Col}^{\mathbb{P}_\alpha}(\omega_1, (2^{2^{\omega_2}})^+)$. Then $\mathbb{P}$ is κ-c.c., semiproper and collapses κ to be ω_2.

If $\mathbb{Q}$ is an antichain sealing forcing in $V^{\mathbb{P}}$, then $\mathbb{Q}$ is semiproper. For otherwise, $\mathbb{P}$ would satisfy the hypotheses of Theorem 8.41. But the conclusion of the theorem says that "semiproper" and "stationary set preserving" are equivalent, a contradiction.

By reflection, there are many α such that every antichain sealing forcing at stage α is semiproper. Whichever diagonalization method we used to choose

[90] See Theorem 8.48.

[91] That is, a "universal" function available at supercompacts that anticipates all possibilities; see Laver [82].

the forcing at stage α, this iteration has the property that if $\mathcal{A}$ is a maximal antichain in $V^{\mathbb{P}}$ then for some $\alpha < \kappa$,

$$\mathcal{A}_\alpha = \{z \subseteq \omega_1 : z \in V^{\mathbb{P}_\alpha} \text{ and } z \in \mathcal{A}_\alpha\}$$

lies in $V^{\mathbb{P}_\alpha}$ and is a maximal antichain in $(P(\omega_1)/\mathrm{NS}_{\omega_1})^{\mathbb{P}_\alpha}$ and is sealed at stage α. Thus $\mathcal{A} = \mathcal{A}_\alpha$. Since $|\mathcal{A}_\alpha| = \omega_1$ in $V^{\mathbb{P}}$, we see that the NS_{ω_1} is $\aleph_2$-saturated.

We have outlined a proof of the following theorem:

8.42 Theorem. *Suppose that κ is a supercompact cardinal, then there is a κ-c.c. semiproper forcing that makes NS_{ω_1} $\aleph_2$-saturated.*

Unlike iterations for creating general forcing axioms, the antichain sealing forcing does not require a "guessing function", and hence with some modifications to the proof, the large cardinal hypothesis of Theorem 8.42 can be reduced to a Woodin cardinal (see [126]).

Because of the Woodin result Theorem 5.64, we cannot hope that the forcing for making NS_{ω_1} $\aleph_2$-saturated preserves the Continuum Hypothesis. However, we can do something only slightly weaker:

8.43 Definition (Foreman et al. [47]). Let $S \subseteq \omega_1$ be stationary and $\mathcal{A} \subseteq P(\omega_1)/\mathrm{NS}_{\omega_1}\restriction S$ a maximal antichain. The *antichain sealing forcing relative to S* is the partial ordering $\mathrm{Col}(\omega_1, |\mathcal{A}|) * \mathbb{P}_T$ where T is the union of $\omega_1 \setminus S$ and the diagonal union of $\mathcal{A}$ in $V^{\mathrm{Col}(\omega_1,|\mathcal{A}|)}$.

If $G*H \subseteq \mathrm{Col}(\omega_1, |\mathcal{A}|)*\mathbb{P}_T$ is generic over V, then $\mathcal{A}$ is a maximal antichain in $P(\omega_1)/(\mathrm{NS}_{\omega_1}\restriction S)$ in any model $W \supseteq V[G * H]$ such that $\omega_1^V = \omega_1^{V[G*H]}$. Let S_0 be a co-stationary set and $S = \omega_1 \setminus S_0$. Then the antichain sealing forcing relative to S_0 has a property discovered by Shelah [103] known as *S-closure* where $S = \omega_1 \setminus S_0$. If $\mathbb{P}$ is a partial ordering with this property then $\mathbb{P}$ does not add new ω-sequences to V. Moreover, S-closure is preserved under iterations with countable supports.

Hence if we define an iteration with countable supports up to a supercompact cardinal by alternately using the antichain sealing forcing relative to a stationary and co-stationary set S_0 and collapsing ω_2 we construct a model as above in which CH holds and $\mathrm{NS}_{\omega_1}\restriction S_0$ is $\aleph_2$-saturated.

The remarkable thing about this iteration is that it contains $\mathrm{Col}(\omega_1, {<}\kappa)$ as a regular subalgebra. In particular, by Lemma 3.31, we see that if we collapse a supercompact cardinal to be ω_2 using countably closed forcing then there is an $\aleph_2$-saturated ideal on ω_1.

We summarize:

8.44 Theorem (Foreman et al. [47]). *Suppose that κ is a supercompact cardinal. Then:*

1. *If S is a stationary and co-stationary set there is a semiproper forcing that does not add new ω-sequences and makes $\mathrm{NS}_{\omega_1}\restriction S$ $\aleph_2$-saturated. In particular, if CH holds in V then it holds in the extension.*

2. *In $V^{\mathrm{Col}(\omega_1,<\kappa)}$, there is an $\aleph_2$-saturated ideal on ω_1.*

We note that Todorčević [121] later explicitly described the saturated ideal in the second clause above. As with the full nonstationary ideal, modifications of the argument give the same results assuming only that κ is a Woodin cardinal [104].

Recently Ishiu [59, 60] was able to adapt these techniques to show:

8.45 Theorem. *Let κ be a Woodin cardinal. Then:*

1. *If $\mu < \kappa$ is regular and $\mathcal{C} = \langle C_\alpha : \alpha \in S\rangle$ is a club guessing sequence on a stationary set $S \subseteq \mu$, and $G \subseteq \mathrm{Col}(\mu,<\kappa)$ is generic, then in $V[G]$ the club guessing ideal associated with $\mathcal{C}$ is precipitous.*

2. *There is a κ-c.c. partial ordering $\mathbb{P}$ such that if $G \subseteq \mathbb{P}$ is generic then:*

   (a) V and $V[G]$ have the same ω_1,

   (b) in $V[G]$, κ is ω_2, CH *holds, and*

   (c) there is a club guessing sequence $\mathcal{C} = \langle C_\alpha : \alpha \in \omega_1\rangle$ such that the club guessing ideal associated with $\mathcal{C}$ is $\aleph_2$-saturated. Moreover this ideal is not *the nonstationary ideal restricted to a stationary set.*

For this theorem, Ishiu studied towers of ideals that are analogous to the stationary tower, suitably adapted to club guessing situations.

8.4. Martin's Maximum and Related Topics

The results of this section appear in [47]. We begin with an examination of some properties that NS_{ω_1} has when it is $\aleph_2$-saturated. The first result shows that an appropriate version of Chang's Conjecture implies that the nonstationary ideal is c.c.c.-indestructible. This version of Chang's Conjecture is simpler than one given in [6] for preservation of saturated ideals and implies the other version in the special case of the nonstationary ideal. In Sect. 8.6, we give a method of Donder for producing c.c.c.-destructible saturated ideals on ω_1, and discuss a theorem of Shelah that shows that NS_{ω_1} can be c.c.c.-destructible.

8.46 Theorem. *Suppose that for all structures $\mathfrak{A} = \langle \omega_2, f_i, R_j, c_k\rangle_{i,j,k\in\omega}$ and all stationary sets $T \subseteq \omega_1$ there is a $\mathfrak{B} \prec \mathfrak{A}$ with $|\mathfrak{B}| = \omega_1$ and $\mathfrak{B} \cap \omega_1 \in T$. If NS_{ω_1} is $\aleph_2$-saturated and $\mathbb{P}$ is a c.c.c. partial ordering then NS_{ω_1} is $\aleph_2$-saturated in $V^{\mathbb{P}}$.*

Proof. By Corollary 7.21, it suffices to show that for all generic $G \subseteq P(\omega_1)/\mathrm{NS}_{\omega_1}$, if $j : V \to M$ is the generic ultrapower then $j(\mathbb{P})$ is $\aleph_2^V$-c.c. in $V[G]$. If this fails there is a stationary $T \subseteq \omega_1$ and a collection of functions $\langle f_\alpha : \alpha < \omega_2^V\rangle$ such that $f_\alpha : \omega_1 \to \mathbb{P}$ and for all α, β the set $C_{\alpha,\beta} = \{\delta : \delta \notin T$ or $f_\alpha(\delta)$ is incompatible with $f_\beta(\delta)\}$ is closed unbounded.

Let θ be sufficiently large and $\mathfrak{B} \prec \langle H(\theta), \in, \Delta, T, \mathbb{P}, \langle f_\alpha\rangle\rangle$ be such that $|\mathfrak{B}| = \omega_1$ and $\mathfrak{B} \cap \omega_1 =_{\mathrm{def}} \delta \in T$. Then for all distinct α and β in $\mathfrak{B} \cap \omega_2$,

$C_{\alpha,\beta} \in \mathfrak{B}$, and hence $\delta \in C_{\alpha,\beta}$. But then $\{f_\alpha(\delta) : \alpha \in \mathfrak{B} \cap \omega_2\}$ is an uncountable antichain in $\mathbb{P}$, a contradiction. $\dashv$

Under MA, if NS_{ω_1} is $\aleph_2$-saturated, it yields minimal degrees of reals in forcing extensions.

8.47 Theorem. *Suppose that Martin's Axiom holds and* CH *fails. Let I be an $\aleph_2$-saturated ideal on ω_1 and $G \subseteq P(\omega_1)/I$ be generic. Suppose that r is a real in $V[G]$ that does not belong to V. Then $V[r] = V[G]$.*

Proof. Let $j : V \to M$ be the generic ultrapower. Then $r \in M$, so there is a function $f : \omega_1 \to 2^\omega$ lying in V such that $[f]^M = r$. By Lemma 2.37, we can assume that f is one-to-one.

Fix a recursive enumeration $\langle \sigma_n : n \in \omega \rangle$ of $2^{<\omega}$. For $s \in 2^\omega$, let $\mathrm{Seq}(s) = \{n : \text{for some } k,\ s{\restriction}k = \sigma_n\}$. A standard application of MA shows for all $X \subseteq \omega_1$, there is a set $a_X \subseteq \omega$ such that for all $\alpha \in \omega_1$,

$$\alpha \in X \quad \text{iff} \quad |a_X \cap \mathrm{Seq}(f(\alpha))| < \omega.$$

Then $X \in G$ iff $\mathrm{Seq}(r) \cap a_X$ is finite. Hence from r we can recover G. $\dashv$

We note that we only use MA_{ω_1} and that this method of proof works equally well to show in ZFC + MA_{ω_1} that Namba forcing with stationary branching trees yields a minimal degree.

When the Steel-Van Wesep proof of the consistency of ZFC + "NS_{ω_1} is $\aleph_2$-saturated" first appeared, it was not known that large cardinals implied AD (or $\mathrm{AD}_\mathbb{R}$), and hence it was not known that ZFC + "NS_{ω_1} is $\aleph_2$-saturated" was consistent relative to large cardinals. The original proof of the consistency of ZFC + "NS_{ω_1} is $\aleph_2$-saturated" from large cardinals went by proving the consistency of Martin's Maximum. *Martin's Maximum* is a provably strongest forcing axiom and has the following statement:

> Suppose that $\mathbb{P}$ is a partial ordering with the property that every stationary $S \subseteq \omega_1$ remains stationary after forcing with $\mathbb{P}$. Let $\mathcal{D} = \langle D_\alpha : \alpha \in \omega_1 \rangle$ be a sequence of dense subsets of $\mathbb{P}$. Then there is a filter $F \subseteq \mathbb{P}$ such that for all α, $F \cap D_\alpha \neq \emptyset$.

We now show:

8.48 Theorem. *Suppose that Martin's Maximum holds. Then* NS_{ω_1} *is $\aleph_2$-saturated.*

Proof. Let $\mathcal{A} = \langle a_\alpha : \alpha < \gamma \rangle$ be a maximal antichain in $P(\omega_1)/\mathrm{NS}_{\omega_1}$. Let $\mathbb{P}$ be the antichain sealing forcing for $\mathcal{A}$.[92] Then by Lemma 8.40, $\mathbb{P}$ preserves stationary subsets of ω_1.

Recall that $\mathbb{P}$ is $\mathrm{Col}(\omega_1, \gamma) * \mathbb{P}_T$, where $\mathbb{P}_T$ is the partial ordering for shooting a closed unbounded set through $T = \bigtriangledown_G \mathcal{A}$. A dense collection of the

[92] See Definition 8.39.

conditions are of the form (p, q), where $p \in \mathrm{Col}(\omega_1, \gamma)$ and q is a closed bounded subset of ω_1. Let D_α be the dense collection of conditions with α in the domain of p and $\sup(q) > \alpha$.

Let $F \subseteq \mathbb{P}$ be a filter such that $F \cap D_\alpha \neq \emptyset$ for all α. Set $G = \bigcup\{p :$ for some q, $(p, q) \in F\}$, and $C = \bigcup\{q :$ for some p, $(p, q) \in F\}$. Then C is a closed unbounded subset of ω_1 inside $\triangledown\{a_{G(\alpha)} : \alpha \in \omega_1\}$. Hence $\{a_{G(\alpha)} : \alpha \in \omega_1\}$ is a maximal antichain and so $|\gamma| \leq \omega_1$. ⊣

Since c.c.c. forcing preserves stationary subsets of ω_1, Martin's Maximum implies MA_{ω_1}. Moreover, Martin's Maximum implies Strong Chang's Conjecture in a form even stronger than the hypothesis of Theorem 8.46 (see [47]). Hence we get the following corollary.

8.49 Corollary. *Suppose that Martin's Maximum holds. Then* NS_{ω_1} *is c.c.c. indestructibly* $\aleph_2$*-saturated and any real added by forcing with* $P(\omega_1)/\mathrm{NS}_{\omega_1}$ *is a minimal degree over* V*.*

8.5. Shelah's Results on Ulam's Problem

Shelah showed that many of the properties of the Kunen-style saturated ideals can hold for NS_{ω_1}, from significantly weaker hypotheses. In doing so he gave a consistency proof for Ulam's Problem for ω_1[93] from an assumption much weaker than a huge cardinal. His remarkable theorems from [104] are:

8.50 Theorem. *Suppose that there is a regular cardinal* κ *with stationarily many supercompact cardinals below* κ*. Then there is a forcing extension which preserves* ω_1 *and* κ*, and:*

1. $2^{\aleph_0} = 2^{\aleph_1} = \omega_2 = \kappa$,
2. $P(\omega_1)/\mathrm{NS}_{\omega_1}$ *is* $(\aleph_1, \aleph_1)$*-centered, and*
3. $P(\omega_1)/\mathrm{NS}_{\omega_1} \cong \mathcal{B}(\mathrm{Col}(\omega, \omega_1) * \mathrm{Add}(\omega, \omega_2^V))$.

In particular, NS_{ω_1} *is strongly layered.*

Note that the statement that $P(\omega_1)/\mathrm{NS}_{\omega_1}$ is $(\aleph_1, \aleph_1)$-centered is equivalent to the property that there is a collection of countably complete filters $\langle F_\alpha : \alpha < \omega_1\rangle$ such that for every non-stationary set $X \subseteq \omega_1$ there is an α with $X \in F_\alpha$. This implies a positive solution to Ulam's problem for ω_1.

Shelah was able to get similar results holding with CH for the NS_{ω_1} restricted to an arbitrary stationary, co-stationary subset of ω_1:

8.51 Theorem. *Suppose that there is a regular cardinal* κ *such that there are stationarily many supercompact cardinals below* κ *and* $S \subseteq \omega_1$ *is stationary and co-stationary. Then there is a partial ordering that does not add real numbers, preserves* κ *and forces:*

[93] Ulam's problem was introduced in Sect. 6.6. At ω_1 it asks whether it is consistent for there to be a collection $\mathcal{I} = \{I_\alpha : \alpha \in \omega_1\}$ of countably complete ideals such that $P(\omega_1) = \bigcup_{\alpha\in\omega_1}(I_\alpha \cup \breve{I}_\alpha)$.

1. $2^{\aleph_0} = \omega_1$, $2^{\aleph_1} = \omega_2$,
2. $P(\omega_1)/\mathrm{NS}_{\omega_1} \restriction S$ *is* $\aleph_1$*-centered, and*
3. $P(\omega_1)/\mathrm{NS}_{\omega_1} \restriction S \cong \mathcal{B}(\mathrm{Col}(\omega, \omega_1) * \mathrm{Add}(\omega, \omega_2^V))$.

8.6. Saturated Ideals and Square

An important tool for distinguishing between elementary embeddings is their tolerance for square and square-like properties. For example, it is a classical result that square is incompatible with supercompact cardinals. It is not difficult to give similar proofs that square is inconsistent with Chang's Conjectures.[94] This leads to the question of the consistency of square with saturated ideals.

The combinatorial properties of square often make it easier to force other properties. For example, Jensen showed that $\square_{\omega_1}$ implies the existence of a c.c.c. forcing for adding a Kurepa tree on ω_1.

The first results showing the consistency of square with a saturated ideal is due to Donder.

8.52 Proposition (Donder). *If there is a countably complete, $\aleph_1$-dense ideal on ω_1, then there is a forcing extension in which there is an $\aleph_1$-dense ideal on ω_1 and $\square_{\omega_1}$ holds. Moreover, if* CH *holds in the ground model then it holds the extension with $\square_{\omega_1}$.*

Donder's proposition follows from the fact that one can add $\square_{\omega_1}$ with a forcing that adds no subsets of ω_1. As remarked earlier in Sect. 7.16, this also shows that if there is an $\aleph_1$-centered ideal on ω_1 then it remains centered after forcing square in this manner.

Donder further pointed out that if I is an $\aleph_2$-saturated ideal on ω_1, and $\square_{\omega_1}$ holds, then, by Jensen's result and Theorem 5.31, I is c.c.c.-destructible. Hence the existence of an $\aleph_1$-dense ideal implies that one can force the existence of a c.c.c.-destructible $\aleph_2$-saturated ideal on ω_1 in a generic extension.

Historically, these remarks were made around the time that Woodin constructed an $\aleph_1$-dense ideal on ω_1 by forcing over models of determinacy. Forcing over a model with large cardinals to get a c.c.c-destructible saturated ideal on ω_1 was first done with Theorem 7.70.

In Theorems 8.50 and 8.51, published in 1987, Shelah showed that it is consistent to have NS_{ω_1} $\aleph_1$-centered. This immediately gives the following result:

8.53 Theorem (Shelah [104]). *Suppose that there is a regular cardinal κ with stationarily many supercompact cardinals below κ. Then:*

1. *There is a forcing extension in which* NS_{ω_1} $\aleph_1$*-centered and* $\square_{\omega_1}$ *holds.*

---

[94] E.g. Corollary 5.4.

2. *There is a forcing extension in which there is a stationary set S such that $\mathrm{NS}_{\omega_1} \restriction S$ is $\aleph_1$-centered and $\square_{\omega_1}$ and* CH *holds.*

In particular, in these models the saturation of NS_{ω_1} *is c.c.c.-destructible.*

Later, several people, including Foreman/Magidor and Velickovic gave constructions from a supercompact cardinal along the lines of the Martin's Maximum construction of models in which NS_{ω_1} is $\aleph_2$-saturated, and $\square_{\omega_1}$ holds. More recently, Woodin has deduced the consistency of the existence of an $\aleph_1$-dense ideal on ω_1 and the failure of CH from the consistency of $\mathrm{AD}^{L(\mathbb{R})}$. This gives a consistency result for a saturated ideal on ω_1 with $\square_{\omega_1}$ from weaker assumptions, but at the cost of the failure of CH.

On larger cardinals, the model for Theorem 7.71, combined with the distributive version of the partial ordering for adding square, answers the analogous questions:

8.54 Theorem. *Suppose that there is an almost huge cardinal κ and $\mu < \kappa$ is regular. Then there is a forcing extension in which there is a μ^+-centered, μ^+-complete ideal on μ^+ and $\square_{\mu^+}$.*

We note that Chang's Conjecture is preserved by c.c.c. forcing and is inconsistent with the existence of a Kurepa tree.

9. Tower Forcing

In Sect. 4.8, we discussed generic ultrapowers of V associated with forcing with towers of ideals.[95] It was discovered in [47] that if one collapses a supercompact cardinal κ to be ω_2, then there is an $\aleph_2$-saturated ideal I on ω_1. If we let $\mathbb{P}$ be $\mathrm{Col}(\omega, {<}\kappa) * P(\omega_1)/I$, then forcing with $\mathbb{P}$ to get $H * G$ yields a generic elementary embedding $j' : V[H] \to M'$ for some transitive M' isomorphic to $V[H]^{\omega_1}/G$. Restricting j' to V we get a transitive M and an elementary embedding $j : V \to M$. Skipping the intermediate step, forcing with $\mathbb{P}$ yields a generic elementary embedding $j : V \to M$ where:

1. M is transitive,
2. $j(\omega_1) = \kappa$, and
3. $M^\omega \cap V[H] \subseteq M$.

Thus we see that large cardinals imply the existence of generic elementary embeddings with small critical points such as ω_1.

Woodin greatly expanded the technology of [47] by showing that large cardinals imply the existence of many precipitous and presaturated towers of ideals. This first appeared in [125]. The tower forcings have proven extremely useful in that they yield generic elementary embeddings with small critical

[95] The definition of a tower of ideals is given in Definition 4.17.

points and their properties can be established directly from large cardinals. They act as a bridge between large cardinals and descriptive set theory which is concerned with definable properties of small sets.

In this section we prove basic facts about certain examples of towers that have nice ultrapowers. The subject of tower forcings and their consequences is well explored in the books of Woodin [126] and Larson [80], so we barely scratch the surface of the theory. As with single ideals the study splits into two closely related types of towers, induced and natural. We give a brief discussion of induced towers and then focus on a particular type of natural tower, the stationary towers. The latter have proved most useful for applications and have a better developed theory.

Recall that if X and Y have the same cardinality and $f : X \to Y$ is a bijection, then f induces a one-to-one correspondence between ideals on X and ideals on Y. Moreover, for normal ideals this correspondence is independent of the choice of f.[96] For this reason, if $\gamma = |H(\alpha)|$, and we are forcing with towers of ideals of height $\delta > \gamma$, it makes no essential difference whether we view the tower as consisting of ideals on sets of the form $P(\gamma)$ or $P(H(\alpha))$. Woodin uses sets of the form V_α as his base sets. Depending on context we will use the most convenient version. We note that for inaccessible α, $V_\alpha = H(\alpha)$ and $|H(\alpha)| = \alpha$.

Throughout this section we will be assuming:

> δ is a strong limit cardinal, $U \subseteq \delta$ is an unbounded set of cardinals and $\mathcal{T} = \langle I_\alpha \subseteq PP(H(\alpha)) : \alpha \in U\rangle$ is a tower of normal, fine, countably complete ideals.

We will call $\delta = \sup(U)$ the *height* of the tower. For $\alpha < \delta$ we let α^* be the least element of U greater than 2^{2^α}. For all of our towers we get an equivalent forcing partial order if we restrict to a cofinal subset of U. For this reason we can assume that α^* is the least element of U above α. We will use the notation of Sect. 4.8. In particular, we will write $\mathcal{P}_\mathcal{T}$ for the forcing associated with a tower $\mathcal{T}$.

If we have conditions $b, c \in \mathcal{P}_\mathcal{T}$ with $\beta = \operatorname{supp}(b) < \gamma = \operatorname{supp}(c)$, then there is a canonical meet of b and c in $\mathcal{P}_\mathcal{T}$. This is given by $\{z : z \cap H(\beta) \in b$ and $z \cap H(\gamma) \in c\}$. In an abuse of notation we will denote this by $b \cap c$.

If $\alpha \leq \sup(U)$, we define $\mathcal{T}_\alpha = \mathcal{T}\restriction\alpha =_{\text{def}} \langle I_\beta : \beta \in U \cap \alpha\rangle$.

9.1 Definition. We will say that a tower $\mathcal{T}$ of inaccessible height δ is *presaturated* iff forcing with $\mathcal{P}_\mathcal{T}$ preserves the statement "δ is a regular cardinal".

9.2 Proposition. *Suppose that $\mathcal{T}$ is a presaturated tower of inaccessible height δ. Then $\mathcal{T}$ is precipitous. If $G \subseteq \mathcal{P}_\mathcal{T}$ is generic and $j : V \to M$ is the generic ultrapower with M transitive, then $M^{<\delta} \cap V[G] \subseteq M$.*

Proof. By Proposition 4.55, it suffices to show that if $\langle \mathcal{A}_\alpha : \alpha < \gamma\rangle$ is a sequence of maximal antichains of length $\gamma < \delta$, then there is a dense set of

[96] In the language of [18], the correspondence is "natural structure".

conditions $S \in \mathcal{P}_\mathcal{T}$ such that for all $\alpha < \gamma$, $|\{a \in \mathcal{A}_\alpha : a$ is compatible with $S\}| < \delta$.

Define a term for a function $\dot{f} : \gamma \to \delta$ by setting $\dot{f}(\alpha)$ to be the least β such that β is the support of a condition $a \in \mathcal{A}_\alpha \cap G$. Since δ is regular in $V[G]$, there is a dense set $D \subseteq \mathcal{P}_\mathcal{T}$ for all $S \in D$ there is a $\rho < \delta$ such that $S \Vdash$ "$\dot{f}$ is bounded by ρ". If $S \in D$ then for all α, $|\{a \in \mathcal{A}_\alpha : S$ is compatible with $S\}| \leq 2^{2^{|H(\rho)|}}$. ⊣

Using this proposition and Proposition 4.56, we can now describe some typical tower behavior:

9.3 Example. Suppose that

1. $\rho \geq \omega_1$ is a successor cardinal,
2. each I_α is ρ-complete and concentrates on $[H(\alpha)]^{<\rho}$, and
3. $\mathcal{P}_\mathcal{T}$ is weakly (ρ, δ)-saturated.[97]

Then $\mathcal{T}$ is presaturated. If $j : V \to M \subseteq V[G]$ is the elementary embedding arising from a generic $G \subseteq \mathcal{P}_\mathcal{T}$ then $\mathrm{crit}(j) = \rho$, $j(\rho) = \delta$ and $M^{<\delta} \cap V[G] \subseteq M$.

9.1. Induced Towers

This section summarizes some of the results of [42].

Let μ be regular and $\delta > \mu$ be an inaccessible cardinal. Suppose that $\mathbb{Q}$ is a partial ordering collapsing δ to be μ^+. Let $\mu < \gamma < \delta$ with γ a cardinal. If $G \subseteq \mathbb{Q}$ is generic and $f : \mu \to H(\gamma)$ is a bijection in $V[G]$, then for each $S \subseteq [H(\gamma)]^{<\mu}$ we can define $\overline{S} \subseteq \mu$ by setting $\overline{S} = \{\beta\colon f``\beta \in S\}$. Modulo $\mathrm{NS}_\mu$, $\overline{S}$ is independent of the choice of the bijection $f$ and $\{\beta\colon f``\beta \cap \mu = \beta\}$ is closed and unbounded. In $V[G]$, the map $S \mapsto \overline{S}$ is $\subseteq$ order-preserving.

Let I be a normal ideal on μ in $V^\mathbb{Q}$. For $\gamma < \delta$, define an ideal $I_\gamma \subseteq P([H(\gamma)]^{<\mu})$ by putting $S \in I_\gamma$ iff $\|\overline{S} \notin I\|_\mathbb{Q} = 0$. Then I_γ is a normal ideal.

Define $\iota'_\gamma : P([H(\gamma)]^{<\mu}) \to \mathcal{B}(\mathbb{Q}) * P(\mu)/I$ by letting $\iota'_\gamma(S) = \langle \|\bar{S} \notin I\|, [\overline{S}]\rangle$. Then ι'_γ has kernel I_γ and hence induces a well-defined order and antichain preserving map $\iota_\gamma : P([H(\gamma)]^{<\mu})/I_\gamma \to \mathcal{B}(\mathbb{Q}) * P(\mu)/I$.[98]

If $\gamma < \gamma'$ then the restriction of $\iota'_{\gamma'}$ to $P([H(\gamma)]^{<\mu})$ is ι'_γ. Hence $\mathcal{T} = \langle I_\gamma\colon \gamma < \delta\rangle$ is a tower of ideals. The direct limit of the ι_γ's gives an order and antichain preserving map from $\mathcal{P}_\mathcal{T}$ into $\mathcal{B}(\mathbb{Q}) * P(\mu)/I$. Hence if I is δ-saturated, then $\mathcal{P}_\mathcal{T}$ has the δ-c.c.

If $\mathbb{Q}$ is $<\mu$-closed then $\mathbb{Q}$ adds a generic object to $\mathrm{Col}(\mu, |H(\gamma)|)$ for each $\gamma < \delta$. If $S \subseteq [H(\gamma)]^{<\mu}$ and $\overline{S}$ is I-positive then $\overline{S}$ is stationary in μ. By our remarks on robustness around Example 8.32 we see that $S \cap \mathrm{IA}$ is positive and S is equivalent to $S \cap \mathrm{IA}$ modulo I_γ. Moreover I_γ extends the nonstationary

[97] The definition is given in the discussion before Proposition 4.6.
[98] A similar situation is discussed in the paragraphs before Proposition 4.25.

ideal on $[H(\gamma)]^{<\mu}\restriction\mathrm{IA}$. If I is the nonstationary ideal on μ (respectively, the nonstationary ideal on μ restricted to cofinality $\rho<\mu$) then I_γ is exactly the nonstationary ideal on $[H(\gamma)]^{<\mu}\cap\mathrm{IA}$ (respectively the nonstationary ideal on $[H(\gamma)]^{<\mu}\cap\mathrm{IA}(\mathrm{Cof}(\rho))$).

We have outlined:

9.4 Proposition. *Let μ be regular and $\delta>\mu$ be inaccessible. Suppose that $\mathbb{Q}$ is $<\mu$-closed, δ-c.c. and $V^{\mathbb{Q}}\models\delta=\mu^+$. If there is a μ-complete, μ^+-saturated ideal on μ in $V^{\mathbb{Q}}$, then there is a tower $\mathcal{T}$ of normal, μ-complete ideals $\langle I_\gamma:\gamma<\delta\rangle$ on $\langle[H(\gamma)]^{<\mu}\cap\mathrm{IA}:\gamma<\delta\rangle$ such that $\mathcal{P}_{\mathcal{T}}$ has the δ-chain condition.*

From this we get the following corollaries:

9.5 Corollary. *Suppose that ρ is a regular cardinal and $\mu>\rho$ is an almost huge cardinal. Then there is a $<\rho$-closed, μ-c.c. partial ordering $\mathbb{P}$ such that in $V^{\mathbb{P}}$:*

1. *$\mu=\rho^+$, and*
2. *there is an inaccessible cardinal δ and a tower of normal, fine, μ-complete ideals $\mathcal{T}=\langle I_\gamma:\gamma<\delta\rangle$ such that I_γ concentrates on $[H(\gamma)]^{<\mu}\cap\mathrm{IA}$ and $\mathcal{P}_{\mathcal{T}}$ has the δ-chain condition.*

Proof. Let $j:V\to M$ be an almost huge embedding with critical point μ and $j(\mu)=\delta$. The partial ordering $\mathbb{P}$ is the first stage of the Magidor variation on the Kunen construction described in Sect. 7.11. That construction builds a partial ordering $\mathbb{P}*\mathbb{Q}$ such that:

1. $\mathbb{P}$ is $<\rho$-closed and μ-c.c.,
2. $\mathbb{Q}$ is $<\mu$-closed and δ-c.c.,[99] and
3. $V^{\mathbb{P}*\mathbb{Q}}\models\delta=\mu^+$ and there is a μ^+-saturated ideal on μ.

Hence we can apply Proposition 9.4 to conclude that in $V^{\mathbb{P}}$ there is a tower $\mathcal{T}$ as desired. ⊣

From Proposition 9.4 and Theorem 8.44, we also see:

9.6 Corollary. *Suppose that δ is a supercompact cardinal. Then there is a δ-saturated tower $\langle I_\gamma:\gamma<\delta\rangle$ of normal, countably complete ideals on $\langle[H(\gamma)]^{<\omega_1}:\gamma<\delta\rangle$.*

Since the hypothesis of Theorem 8.44 can be weakened to the assumption that δ is a Woodin cardinal the conclusions of Corollary 9.6 follow if we simply assume that δ is Woodin.

We can get information about the stationary tower $\mathcal{T}$ on $\langle[H(\gamma)]^{<\omega_1}:\gamma<\delta\rangle$ as well (see Theorem 4.9 of [42]). In this case the maps ι_γ yield a regular embedding from $\mathcal{P}_{\mathcal{T}}$ into $\mathcal{B}(\mathbb{Q}*P(\omega_1)/\mathrm{NS}_{\omega_1})$.

[99] In fact $\mathbb{Q}$ can be taken to be $\mathrm{Col}(\mu,<\delta)$.

9.7 Theorem. *Let δ be an inaccessible cardinal, $\mathbb{Q} = \mathrm{Col}(\omega_1, {<}\delta)$, and suppose that $V^{\mathbb{Q}} \models \mathrm{NS}_{\omega_1}$ is presaturated. Let $\mathcal{T}$ be the tower of nonstationary ideals restricted to $[H(\gamma)]^{<\omega_1}$ for $\gamma < \delta$. Then $\mathcal{P}_{\mathcal{T}}$ is a regular subalgebra of $\mathbb{Q} * P(\omega_1)/\mathrm{NS}_{\omega_1}$.*

In particular, by Example 9.3, forcing with $\mathcal{P}_{\mathcal{T}}$ preserves δ, the generic ultrapower is well-founded and is closed under ω-sequences from $V[G]$.

Woodin proved much more general results as we see in Sect. 9.3.

9.2. General Techniques

Woodin used the ideas of catching antichains to show that towers of natural ideals have nice generic ultrapowers. We now explore this technology but only sketch the proofs. The books of Woodin [126] and Larson [80] are excellent definitive references containing complete proofs and many applications. The notation and terminology adopted in this section is somewhat different than Woodin's in order to place it in the context of the rest of this chapter. Standard terminology is found in the two books.

Good Structures

In this subsection we discuss *good structures*. The antichain catching ideas from [47] are crucial for showing that certain towers have nice properties. For these arguments to work they require good structures. Most of the theory of stationary tower forcing can be developed for arbitrary towers under assumptions about the existence of good structures. If each ideal I_α has the form $\mathrm{NS}\restriction Z_\alpha$ for some stationary set Z_α, the goodness of a structure $N \prec H((2^{2^\delta})^+)$ is equivalent to having $N \cap H(\alpha) \in Z_\alpha$ for all $\alpha \in N$.[100] Those readers who are only interested in stationary towers can simplify some arguments by taking this as the definition of *goodness*.

9.8 Definition. Let N be a set. Then N is *good for* α iff $\alpha \in N$ and for all $C \in \breve{I}_\alpha \cap N$ we have that $N \cap H(\alpha) \in C$. We will say that N is a *good structure* iff for all $\alpha \in N \cap U$, N is good for α.

Note that if $\alpha < \beta$, $N \cap H(2^\beta) \prec H(2^\beta)$, $\alpha \in N$ and N is good for β, then N is good for α. Proposition 3.44 implies that for each α, I_α-almost all z generate structures that are good for α. Under mild assumptions, we can show that good structures exist.

9.9 Proposition. *Let $\mathcal{T} = \langle I_\alpha : \alpha \in U\rangle$ be a tower of normal, fine, countably complete ideals with height δ. Suppose that there is a normal, fine, countably complete ideal J on $P(H(\delta))$ such that for all $\alpha \in U$, the projection of J to an ideal on $P(H(\alpha))$ is I_α. Then for all $\theta \geq \delta^+$ and all Skolemized structures $\mathfrak{A}$ expanding $\langle H(\theta), \in \Delta, J, \mathcal{T}\rangle$ there is a set $C \in \breve{J}$ for all $z \in C$:*

[100] See Lemma 3.46.

1. $\mathrm{Sk}^{\mathfrak{A}}(z) \cap V_\delta = z$, *and*

2. $\mathrm{Sk}^{\mathfrak{A}}(z)$ *is good.*

Proof. Same as Proposition 3.44. $\dashv$

Catching Antichains

The antichain catching arguments used in [47] were informally referred to as "catching an index for an antichain". Woodin formalized this by calling the method "capturing an antichain". We will slightly abuse terminology by frequently using the word "antichain" for a collection of subsets of $P(H(\alpha))$ for $\alpha \in U$ whose I_α equivalence classes represent an antichain in $\mathcal{P}_{\mathcal{T}}$.

9.10 Definition. Let $\mathcal{A}$ be a collection of subsets of $P(H(\alpha))$ for $\alpha \in U$ that form an antichain in $\mathcal{P}_{\mathcal{T}}$. A structure N *captures* $\mathcal{A}$ *below* α iff N is good for α and there is an $a \in N \cap \mathcal{A}$ such that $\mathrm{supp}(a) < \alpha$ and $N \cap H(\mathrm{supp}(a)) \in a$.

The next two results play the role of Proposition 8.24 for towers.

9.11 Lemma. *Let $\mathcal{A}$ be a maximal antichain. Suppose that $\alpha < \delta$ and $[S] \in \mathcal{P}_{\mathcal{T}}$. If $S \subseteq \{z \in H(\delta) : z$ captures $\mathcal{A}$ below $\alpha\}$, then $\{b \in \mathcal{A} : b$ is compatible with $[S]\} \subseteq \{b : \mathrm{supp}(b) < \alpha\}$.*

Proof. By Lemma 4.49,

$$[\triangledown\{b \in \mathcal{A} : \mathrm{supp}(b) < \alpha\}] = \Sigma\{[b] : b \in \mathcal{A} \text{ and } \mathrm{supp}(b) < \alpha\}.$$

Since the right hand side is less than or equal to $\Sigma\{[b] : \mathrm{supp}(b) < \alpha\}$ and $S \subseteq \triangledown\{b \in \mathcal{A} : \mathrm{supp}(b) < \alpha\}$ we see the lemma. $\dashv$

From this we easily deduce:

9.12 Proposition. *Let $\rho \leq \delta$. Suppose that for all $\gamma < \rho$ and all sequences of maximal antichains $\langle \mathcal{A}_\alpha : \alpha < \gamma\rangle$ there is a dense set of $S \in \mathcal{P}_{\mathcal{T}}$ with an η (depending on S) between γ and δ such that if $N \in S$ and $\alpha \in \gamma \cap N$, then N captures $\mathcal{A}_\alpha$ below η. Then $\mathcal{P}_{\mathcal{T}}$ is weakly (ρ, δ)-saturated.*

9.13 Definition. Let $\mathcal{T}$ be a tower of height δ. Let $\mathcal{A}$ be a maximal antichain in $\mathcal{P}_{\mathcal{T}}$. Then $\mathcal{T}$ *can capture* $\mathcal{A}$ *at* α iff

1. $\mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}$ is a maximal antichain in $\mathcal{P}_{\mathcal{T}_\alpha}$, and
2. whenever:
   (a) γ is between α and δ, $\sigma < \alpha$ and $\mathfrak{A}$ is a structure in a countable language expanding $\langle H(\gamma^*), \in, \Delta\rangle$,

   there is a closed unbounded set of $N \prec \mathfrak{A}$ such that if:

   (b) N is good for γ,

(c) $\{\mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}, \mathcal{T}_\alpha\} \subseteq N$, and

(d) $N^* \prec N$ has cardinality less than α

then there is an $N' \prec \mathfrak{A}$ such that

(A) N' is good for γ,

(B) $N' \cap H(\sigma) = N \cap H(\sigma)$,

(C) $N^* \prec N'$, and

(D) N' captures $\mathcal{A}$ below α.

We will say that $\mathcal{T}$ *captures antichains* iff for all maximal antichains $\mathcal{A}$ there is a stationary set of $\alpha < \delta$ such that $\mathcal{T}$ can capture $\mathcal{A}$ at α.

In all of the arguments we give it suffices to have an unbounded rather than stationary set of α such that $\mathcal{T}$ captures $\mathcal{A}$ at α. Woodin called the property of capturing antichains at α "semiproper at α". The tower $\mathcal{T}$ is typically not semiproper in the sense of the forcing property, so we have shifted terminology in this chapter.

9.14 Remark. If I_α is of the form $\mathrm{NS}\restriction Z_\alpha$, then any $N \in Z_\alpha$ with $N \prec \langle H(\alpha^*), \in, \Delta, I_\alpha \rangle$ is good for α. If $\mathcal{T} = \langle \mathrm{NS}\restriction Z_\alpha : \alpha \in U \rangle$ is a tower, then for $\alpha < \gamma$ in U there is a closed unbounded set C such that for all $z \in C \cap Z_\alpha$ there is an $N \prec \langle H(\gamma^*), \in, \Delta, I_\gamma \rangle$ with $N \cap H(\gamma) \in Z_\gamma$ and $N \cap H(\alpha) = z$. This N is necessarily good for γ.

Thus for towers of this form we can modify Definition 9.13 by taking $\mathfrak{A}$ to be a structure with domain $H(\alpha^*)$ and in clause (b) replace "N is good for γ" by "$N \in Z_{\alpha^*}$".

Catching Your Tail

Next we describe a "catch-your-tail" argument in this context. The point of catching your tail is to turn the quantifier "there is a closed unbounded set of N" in the definition of antichain catching into the quantifier "for every N". This trick is quite familiar in the context of proper forcing.

In a situation where we want to catch antichains, our data will be:

1. a tower $\mathcal{T}$,
2. a maximal antichain $\mathcal{A}$ in $\mathcal{P}_{\mathcal{T}}$ that $\mathcal{T}$ can capture at α,
3. a γ between α and δ,
4. a structure $\mathfrak{A}$ in a countable language expanding $\langle H(\gamma^*), \in, \Delta \rangle$,[101] and
5. the closed unbounded set C posited in clause 2 of Definition 9.13.

[101] Equivalently, we could be given a closed unbounded subset of $H(\gamma^*)$. This discussion parallels the simpler Lemma 8.36.

Let λ be a regular cardinal greater than 2^{γ^*}. Suppose that we are given an arbitrary $M \prec \langle H(\lambda), \in, \Delta\rangle$ such that $\{\alpha, \gamma, \mathfrak{A}, \mathcal{T}_\alpha, \mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}\} \subseteq M$ and M is good for γ. Let $N = M \cap H(\gamma^*)$. Then $N \prec \mathfrak{A}$ and N is good for γ. We note that M has definable Skolem functions.

Let $M^* \prec M$ have cardinality less than α with $\{\alpha, \gamma, \mathcal{T}_\alpha, \mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}\} \subseteq M^*$ Letting $N^* = M^* \cap H(\gamma^*)$, we see that if $f(x, y_0, \ldots, y_n)$ is a definable Skolem function, and $a \in M^*$, then the restricted Skolem function $g : [H(\gamma)]^{n+1} \to H(\gamma^*)$ defined by setting:

$$g(a_1, \ldots, a_n) = \begin{cases} f(a, a_1, \ldots, a_n) & \text{if } f(a, a_1, \ldots, a_n) \in H(\gamma^*), \\ 0 & \text{otherwise,} \end{cases}$$

belongs to N^*.

Applying Definition 9.13 we can find an $N' \prec \mathfrak{A}$ that is good for γ, $N^* \prec N'$, N' has the same intersection with $H(\sigma)$ as N does, and N' captures $\mathcal{A}$ below α.

Now let M' be the Skolem hull of $(N' \cap H(\gamma)) \cup M^*$ in $\langle H(\lambda), \in, \Delta\rangle$. Since each restricted Skolem function of $H(\lambda)$ belongs to N', we see that $M' \cap H(\gamma) = N' \cap H(\gamma)$ and $M' \cap H(\gamma^*) \subseteq N'$. In particular:

(A$'$) M' is good for γ,

(B$'$) $M' \cap H(\sigma) = N \cap H(\sigma)$,

(C$'$) $M^* \prec M'$, and

(D$'$) M' captures $\mathcal{A}$ below α.

Hence we see that by passing from γ^* to λ we can change the quantifier "there is a closed unbounded set of $N \prec \mathfrak{A}$" in Definition 9.13 to "for all sufficiently large λ and all $M \prec \langle H(\lambda), \in, \Delta\rangle$ with $\{\alpha, \gamma, \mathfrak{A}, \mathcal{T}_\alpha, \mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}\} \subseteq M$".

By using standard Skolemization arguments this shows that given the structure $\mathfrak{A}$ in Definition 9.13, we can find an expansion $\mathfrak{A}'$ such that for *every* $N \prec \mathfrak{A}'$ satisfying (b), (c) and (d) there is an N" $\prec \mathfrak{A}'$ satisfying (A)–(D).

Using Antichain Catching

9.15 Theorem. *Suppose that $\mathcal{T}$ is a tower that captures antichains. Then $\mathcal{T}$ is precipitous.*[102]

Proof. We verify the conditions of Proposition 4.52. Suppose that $\langle \mathcal{A}_n : n \in \omega\rangle$ is a tree of maximal antichains below a condition $[X] \in \mathcal{P}_{\mathcal{T}}$. Fix an increasing sequence of ordinals α_n such that $\mathcal{T}$ can capture $\mathcal{A}_n$ at α_n. Let $\gamma \in U \setminus \sup_n \alpha_n$ and $\lambda > 2^{\gamma^*}$. Let $N_0 \prec \langle H(\lambda), \in, \Delta\rangle$ be such that $\{\langle \mathcal{A}_n : n \in \omega\rangle, \langle \alpha_n : n \in \omega\rangle, \mathcal{T}\} \subseteq N_0$ and N_0 is good for γ.

By the remarks on catching your tail, we can build a sequence of structures $\langle N_i : i \in \omega\rangle$ such that:

[102] This is the tower analogue of Theorem 8.37.

1. $N_i \prec \langle H(\lambda), \in, \Delta\rangle$ and is good for γ,
2. $\{\langle \mathcal{A}_n : n \in \omega\rangle, \langle \alpha_n : n \in \omega\rangle, \mathcal{T}\} \in N_i$,
3. N_{i+1} captures $\mathcal{A}_i$ below α_{i+1}, and
4. $N_i \cap H(\alpha_i) = N_{i+1} \cap H(\alpha_i)$.

Then $z_i = N_i \cap H(\alpha_i)$ witnesses the hypothesis of Proposition 4.52. ⊣

We now want to be able to extend this technique to be able to catch antichains in a transfinite sequence. This is not possible in general:

9.16 Example (Foreman and Magidor [42]). Let δ be Woodin. For regular $\alpha < \delta$ let Z_α be the collection of $N \in [H(\alpha)]^{<\omega_2}$ that are internally approachable by a sequence of length ω_1. Then $\langle \mathrm{NS}\restriction Z_\alpha : \alpha \text{ is regular and } \alpha < \delta\rangle$ forms a precipitous tower. Further, if this tower is presaturated then $\Theta^{L(\mathbb{R})} < \omega_2$.

Thus, by Woodin's Theorem 5.64 if NS_{ω_1} is $\aleph_2$-saturated, then this tower is not presaturated.

To build transfinite sequences that catch antichains we need to be able to continue past limit stages. The obstacle in the previous example is that after catching ω many antichains, a model is no longer internally approachable. An extra hypothesis that works is given by the following definition that is idiosyncratic to this chapter.

9.17 Definition. Let $\rho < \delta$ and δ inaccessible. A tower $\mathcal{T} = \langle I_\alpha : \alpha \in U\rangle$ of height δ will be called *ρ-complete* iff for all $\gamma < \rho$ and all increasing sequences $\langle \alpha_i : i < \gamma + 1\rangle$ of elements of U and all regular $\lambda \gg \alpha_\gamma$ and all $u \in H(\lambda)$, if:

1. $\langle N_i : i \in \gamma\rangle$ is a sequence of elementary substructures of $\langle H(\lambda), \in, \Delta, u\rangle$ with
$$\{\langle \alpha_i : i < \gamma + 1\rangle, \langle I_\alpha : \alpha \in U \cap (\alpha_\gamma + 1)\rangle\} \subseteq N_j$$
for all $j < \gamma$,
2. N_i good for α_γ, and
3. $N_i \cap H(\alpha_i) = N_j \cap H(\alpha_i)$ for $i < j < \gamma$,

then there is an $N_\gamma \prec \langle H(\lambda), \in, \Delta, u\rangle$ with $\{\langle \alpha_i : i < \gamma + 1\rangle, \langle I_\alpha : \alpha \in U \cap (\alpha_\gamma + 1)\rangle\} \subseteq N_\gamma$ that is good for α_γ and for all $i < \gamma$, $N_\gamma \cap H(\alpha_i) = N_{\alpha_i} \cap H(\alpha_i)$.

When each $I_\alpha = \mathrm{NS}\restriction Z_\alpha$, we will say that the sequence of stationary sets $\langle Z_\alpha : \alpha \in U\rangle$ is ρ-complete.

By using the catch-your-tail arguments of the previous section, we see that this is equivalent to the statement that any structure $\mathfrak{A}_0$ with domain $H((2^{\alpha_\gamma})^+)$ can be expanded to a structure $\mathfrak{A}$ so that any sequence of elementary substructures $\langle N_i : i < \gamma\rangle$ with:

1. $\{\langle \alpha_i : i < \gamma + 1\rangle, \langle I_\alpha : \alpha \in U \cap (\alpha_\gamma + 1)\rangle\} \subseteq N_j$ for all $j < \gamma$,
2. N_i good for α_γ, and
3. $N_i \cap H(\alpha_i) = N_j \cap H(\alpha_i)$ for $i < j < \gamma$

has a limiting structure $N_\gamma \prec \mathfrak{A}$ containing $\{\langle \alpha_i : i < \gamma + 1\}, \langle I_\alpha : \alpha \in U \cap (\alpha_\gamma + 1)\rangle\}$ that is good for α_γ and such that for all $i < \gamma$, $N_\gamma \cap H(\alpha_i) = N_{\alpha_i} \cap H(\alpha_i)$.

9.18 Example. Let δ be inaccessible, $\kappa < \delta$ regular and $Z_\alpha = [H(\alpha)]^{<\kappa}$. Then the tower $\langle \mathrm{NS}\restriction Z_\alpha : \alpha < \delta\rangle$ is κ-complete.

The next example appears in [42] and its significance is discussed in Example 9.36.

9.19 Example. Suppose that δ is inaccessible, and μ and $\kappa > \mu^+$ are regular cardinals less than δ. For regular $\alpha < \delta$ let $Z_\alpha = \{N \in [H(\alpha)]^{<\kappa} : N \cap \alpha$ is $\leq\mu$-closed$\}$. Then $\langle \mathrm{NS}\restriction Z_\alpha : \alpha$ is regular and $\alpha < \delta\rangle$ is a κ-complete tower of ideals.

The main point of the proof of Example 9.19 is to show that if $\alpha < \beta$ are two regular cardinals bigger than 2^κ and $\mathfrak{A}_0$ is a structure in a countable language with domain $H(\beta)$ then there is an expansion of $\mathfrak{A}_0$ to a fully Skolemized structure $\mathfrak{A}$ in a countable language such that if:

1. $z \subseteq H(\alpha)$,
2. $z \cap \alpha$ is $\leq\mu$-closed, and
3. $\mathrm{Sk}^{\mathfrak{A}}(z) \cap H(\alpha) = z$

then $\mathrm{Sk}^{\mathfrak{A}}(z) \cap \beta$ is $\leq\mu$-closed.

9.20 Theorem. *Let $\mathcal{T} = \langle I_\alpha : \alpha \in U\rangle$ be a tower of normal, fine, countably complete ideals of inaccessible height δ. Suppose that:*

1. $\mathcal{T}$ captures antichains, and

2. $\mathcal{T}$ is ρ-complete.

Then $\mathcal{T}$ is weakly (ρ, δ)-saturated.

Proof. We verify the conditions of Proposition 9.12. Let $\gamma < \rho$, $\langle \mathcal{A}_i : i < \gamma\rangle$ be a sequence of maximal antichains in $\mathcal{T}$ and $[X] \in \mathcal{P}_{\mathcal{T}}$. We need to find an $S \in \mathcal{P}_{\mathcal{T}}$ below $[X]$ and an η such that if $N \in S$ and $i \in \gamma \cap N$, then N captures $\mathcal{A}_i$ below η.

Fix an increasing sequence $\langle \alpha_i : i < \gamma\rangle$ drawn from $U \setminus \max\{\gamma, \mathrm{supp}(X)\}$ such that $\mathcal{T}$ can capture $\mathcal{A}_i$ at α_i. Let $\alpha_\gamma \in U$ be much larger than the supremum of the $\langle \alpha_i : i < \gamma\rangle$, and λ a sufficiently large regular cardinal below δ to witness γ^+-completeness.

We let $\eta = \alpha_\gamma$. Indirectly assume that there is no $S \in I_\eta^+$ below $[X]$ as desired. Then there is a $C \in \breve{I}_\eta$ such that if $N \in C \cap X$ then there is an $i \in \gamma \cap N$ such that N does not capture $\mathcal{A}_i$ below α_i. Hence it suffices to show that there is an $N \prec H(\lambda)$ that is good for α_γ such that $C \in N$ and for all $i \in N \cap \gamma$, N captures $\mathcal{A}_i$ below α_i.

Let $N_0 \prec \langle H(\lambda), \in, \Delta\rangle$ be such that

1. $\{\langle \alpha_i : i < \gamma + 1\rangle, \langle \mathcal{A}_i : i < \gamma\rangle, C, \langle I_\alpha : \alpha \in U \cap (\alpha_\gamma + 1)\rangle\} \subseteq N_0$,
2. N is good for α_γ.

Using completeness at limit stages and antichain capturing at successor stages, build a sequence of structures $\langle N_i : i \in \gamma + 1\rangle$ such that:

1. $N_i \prec \langle H(\lambda), \in, \Delta\rangle$ and
$$\{\langle \alpha_i : i < \gamma + 1\rangle, \langle \mathcal{A}_i : i < \gamma\rangle, C, \langle I_\alpha : \alpha \in U \cap (\alpha_\gamma + 1)\rangle\} \subseteq N_i,$$
2. N_i is good for α_γ,
3. if $i < j < \gamma$, $N_i \cap H(\alpha_i) = N_j \cap H(\alpha_i)$, and
4. if $i \in N_i$, then N_{i+1} captures $\mathcal{A}_i$ below α_i.

Letting $N = N_\gamma$ we get the desired contradiction. $\dashv$

9.3. Natural Towers

Just as for single ideals there are many examples of natural towers. The only type of natural tower whose generic embeddings have been explored extensively are given by the following definition.

9.21 Definition. The tower $\mathcal{T} = \langle I_\alpha : \alpha \in U\rangle$ will be called a *stationary tower* iff there is a sequence of stationary sets $\langle Z_\alpha \subseteq P(H(\alpha)) : \alpha \in U\rangle$ such that $I_\alpha = \mathrm{NS}{\restriction}Z_\alpha$.

We note that the requirement that $\langle \mathrm{NS}{\restriction}Z_\alpha : \alpha \in U\rangle$ forms a tower is sometimes hard to verify as illustrated in Example 9.19. Moreover, Burke's Corollary 4.21 shows that for sufficiently large α_2 any normal ideal on $P(H(\alpha_1))$ is the projection of the nonstationary ideal restricted to a stationary subset of $P(H(\alpha_2))$. In particular, if α_1 is supercompact we can find Z_2 such that the projection of $\mathrm{NS}{\restriction}Z_2$ to $P(H(\alpha_1))$ is a prime ideal dual to a supercompact ultrafilter!

Methods for Proving Antichain Capturing

We now examine the methods for showing that various towers catch antichains. All of the arguments take the same basic form used to prove Theorem 8.41 in the paper [47]. To verify semiproperness in the context of forcing and antichain catching in the context of an ideal or a tower of ideals, we have a model N and a σ and want to add some ordinals to N without changing $N \cap H(\sigma)$. In the case of semiproperness, $\sigma = \omega_1$. In the case of towers, σ is an ordinal above the support of some elements of antichains N already captures.

In Theorem 9.46, we give Burke's examples of towers that are not precipitous. Burke's methods of proof do not restrict the height of the tower in any way. For example, the non-precipitous towers can have supercompact height. In light of Theorem 9.15, Burke's towers cannot capture antichains. However, with a sufficient large cardinal hypothesis every stationary tower forcing does capture antichains.

All of the antichain catching arguments follow the same pattern. By Remark 9.14, we can simplify the definition of antichain catching by working with structures $\mathfrak{A}$ on $H(\alpha^*)$ and replace "good for γ" with "$N \in Z_{\alpha^*}$". We will assume that $\mathcal{T}$ cannot capture an antichain $\mathcal{A}$ and use our large cardinal hypothesis to create a situation with a cardinal α such that:

1. $\mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}$ is a maximal antichain in $\mathcal{P}_{\mathcal{T}_\alpha}$, and
2. there are:

   (a) a $\sigma < \alpha$ and a structure $\mathfrak{A}$ expanding $\langle H(\alpha^*), \in, \Delta\rangle$[103]

   and a "bad" stationary set B of $N \prec \mathfrak{A}$ such that

   (b) $B \subseteq Z_{\alpha^*}$,

   (c) $\{\mathcal{T}_\alpha, \mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}\} \in N$ for all $N \in B$, and

   (d) each $N \in B$ has an $N^* \prec N$ of cardinality less than α

   such that whenever $N' \prec \mathfrak{A}$ is such that

   (A) $N' \in Z_{\alpha^*}$,

   (B) $N \cap H(\sigma) = N' \cap H(\sigma)$, and

   (C) $N^* \prec N'$

   then

   (D) N' does not capture $\mathcal{A}$ below α.

The cardinal α is chosen so that there is an appropriately strong $j : V \to M$ with critical point α. Then $j(\mathcal{A})$ is a maximal antichain up to $j(\alpha)$. The set B determines a condition in the forcing $j(\mathcal{P}_{\mathcal{T}})$ and hence is compatible with some $b \in j(\mathcal{A})$ that can be taken to have support bigger than α^*. A structure $N' \prec j(\mathfrak{A})$ is considered with

[103] We are using Remark 9.14.

1. $N' \cap H(\text{supp}(b)) \in b \cap B$,
2. $b \in N'$, and
3. $N' \in j(Z_{\alpha^*})$.

Such an N' captures $j(\mathcal{A})$.

The strength of the embedding is used to see that we can find an N' with properties 1–3 that is sufficiently closed and belongs to M. Depending on Z_{α^*}, this is done in at least two different ways. For simple sequences $\langle Z_\alpha : \alpha \in U\rangle$, as in what we call "Woodin's towers" below, all that is required is that $b \cap B$ is stationary in V. For this, δ being a Woodin cardinal suffices to generate the required embeddings j. When the sequence of Z_α's is more complicated, as in the towers considered by Burke [11], we need the fact that j witnesses some degree of supercompactness.

Next we will have $N_0 = N' \cap H(\alpha^*)$ and $N = j(N_0)$. Since $N_0 \in B$, there are witnesses N^* and σ. By elementarity $j(N^*)$ and $j(\sigma)$ are witnesses to N being in $j(B)$.

Since $j(\sigma) = \sigma$, $N \cap H(\sigma) = N_0 \cap H(\sigma) = N' \cap H(\sigma)$. Since $|N^*| < \alpha$, $j(N^*) = j``N^*$. We use the closure of N' to argue that $j(N^*) \subseteq N'$. This will be done different ways in different contexts.

Arguing in M, we can now reach our desired contradiction by noting that $N' \prec j(\mathfrak{A})$ and:

(A) $N' \in j(Z_{\alpha^*})$,

(B) $N \cap H(\sigma) = N' \cap H(\sigma)$,

(C) $j(N^*) \prec N'$, and

(D) N' captures $j(\mathcal{A})$ below $j(\alpha)$.

We give the explicit arguments in the next two sections.

Woodin's Towers

Woodin's investigation and application of tower forcing focused on cases where the Z_α were of a simple form such as $[H(\alpha)]^{<\kappa}$ or $P(H(\alpha))$. The towers considered in [42], while concentrating on Z_α whose definitions are not as simple, are also amenable to arguments of the style of this section.

Notation. Woodin introduced the following notation, which has become standard for towers:

1. when each $Z_\alpha = P(H(\alpha))$, the tower is called $\mathbb{P}_{<\delta}$, and
2. when each $Z_\alpha = [H(\alpha)]^{<\omega_1}$, the tower is called $\mathbb{Q}_{<\delta}$.

We will use the following definition of a Woodin cardinal:

9.22 Definition. Let δ be a cardinal. Then δ is *Woodin* iff for every $A \subseteq V_\delta$ and all functions $f : \delta \to \delta$ there is an $\alpha < \delta$ closed under f and an elementary embedding $j : V \to M$ with M transitive such that:

1. $\operatorname{crit}(j) = \alpha$ and M is closed under $<\alpha$-sequences,
2. $j(f)(\alpha) = f(\alpha)$, $V_{f(\alpha)} \subseteq M$, and
3. $j(A) \cap V_{f(\alpha)} = A \cap V_{f(\alpha)}$.

9.23 Theorem (Woodin). *Let δ be a Woodin cardinal and $\mathcal{T}$ the stationary tower $\langle \mathrm{NS}{\restriction} Z_\alpha : \alpha \in \delta\rangle$ where either:*

1. *for all α, $Z_\alpha = P(H(\alpha))$, or*
2. *for all α, $Z_\alpha = [H(\alpha)]^{<\kappa}$ for some regular uncountable cardinal $\kappa < \delta$.*

Then $\mathcal{T}$ captures antichains.

Proof. Suppose that the theorem fails. Let $\mathcal{A}$ be a counterexample. Then there is a closed unbounded set $D \subseteq \delta$ such that for all $\alpha \in D$, $\mathcal{T}$ cannot capture $\mathcal{A}$ at α. If our tower is of the form $Z_\alpha = [H(\alpha)]^{<\kappa}$ we can take the least element of D to be above κ. We can assume without loss of generality that for all $\alpha \in D$,

1. $\mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}$ is a maximal antichain in $\mathcal{P}_{\mathcal{T}_\alpha}$, and
2. there are

   (a) a $\sigma < \alpha$ and a structure $\mathfrak{A}_\alpha$ expanding $\langle H(\alpha^*), \in, \Delta\rangle$

   and a "bad" stationary set B_α of $N \prec \mathfrak{A}_\alpha$ such that

   (b) $B_\alpha \subseteq Z_{\alpha^*}$,
   (c) $\{\mathcal{T}_\alpha, \mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}\} \in N$ for all $N \in B_\alpha$, and
   (d) each $N \in B_\alpha$ has an $N^* \prec N$ of cardinality less than α

   such that if $N' \prec \mathfrak{A}_\alpha$ is such that

   (A) $N' \in Z_{\alpha^*}$,
   (B) $N \cap H(\sigma) = N' \cap H(\sigma)$, and
   (C) $N^* \prec N'$

   then

   (D) N' does not capture $\mathcal{A}$ below α.

Define a function f by setting $f(\alpha)$ to be the least element of D above α if $\alpha \notin D$. For each $\alpha \in D$, let $f(\alpha)$ be some regular β sufficiently large so that:

1. β is above the next inaccessible element of D above α, and
2. there is a $b \in \mathcal{A} \cap V_{f(\alpha)}$ such that $b \cap B_\alpha$ is stationary.

Since δ is Woodin, we can find an $\alpha < \delta$ and an elementary embedding $j : V \to M$ with critical point α such that $\alpha \in D$, $V_{f(\alpha)} \subseteq M$, $j(\mathcal{A}) \cap V_{f(\alpha)} = \mathcal{A} \cap V_{f(\alpha)}$, $j(\mathcal{T}) \cap V_{f(\alpha)} = \mathcal{T} \cap V_{f(\alpha)}$ and M is closed under $<\alpha$-sequences.

Choose a $b \in \mathcal{A} \cap V_{f(\alpha)}$ so that $b \cap B_\alpha$ is stationary in V. We can do this since stationarity is absolute between V and M for bounded subsets of $V_{f(\alpha)}$. We can assume that $\mathrm{supp}(b) > \alpha^*$ and $b \subseteq Z_{\mathrm{supp}(b)}$. Arguing in V, let $\mathfrak{B}$ be a structure in a countable language expanding $j(\mathfrak{A}_\alpha)$ containing constant symbols for $j \restriction H(\alpha^*)$, $\mathfrak{A}_\alpha$ and b. Since $b \cap B_\alpha$ is stationary in V, there is a $z \subseteq H(\mathrm{supp}(b))$ belonging to $b \cap B_\alpha$ such that

$$\mathrm{Sk}^{\mathfrak{B}}(z) \cap H(\mathrm{supp}(b)) = z.$$

Let $N_0 = z \cap H(\alpha^*)$ and $N = j(N_0)$. Since $N_0 \in B_\alpha$, there are witnesses N^* and σ. By elementarity $j(N^*)$ and $j(\sigma)$ are witnesses to N being in $j(B_\alpha)$. Since $|N^*| < \alpha$, $j(N^*) = j``N^* \in M$. Since $\mathrm{Sk}^{\mathfrak{B}}(z)$ is closed under $j \restriction H(\alpha^*)$ and $N^* \subseteq z$ we see that $j(N^*) \subseteq \mathrm{Sk}^{\mathfrak{B}}(z)$. Since $j(\sigma) = \sigma$, $N \cap H(\sigma) = N_0 \cap H(\sigma) = z \cap H(\sigma)$.

Let $N' = \mathrm{Sk}^{j(\mathfrak{A}_\alpha)}(z \cup j(N^*) \cup \{b\})$. Then $N' \subseteq \mathrm{Sk}^{\mathfrak{B}}(z)$. Since z, $j(N^*)$, b and $j(\mathfrak{A}_\alpha)$ belong to M we see that $N' \in M$. Hence

1. $N' \cap \mathrm{supp}(b) = z \in b \cap B_\alpha$,
2. $b \in N'$, and
3. $N' \in j(Z_{\alpha^*})$.[104]

By 1–3, N' captures $j(\mathcal{A})$.

Arguing in M, we can now reach our desired contradiction by noting that $N' \prec j(\mathfrak{A}_\alpha)$ and:

(A) $N' \in j(Z_{\alpha^*})$,

(B) $N \cap H(\sigma) = N' \cap H(\sigma)$,

(C) $j(N^*) \prec N'$, and

(D) N' captures $j(\mathcal{A})$ below $j(\alpha)$.

$\dashv$

9.24 Corollary. *Let δ be a Woodin cardinal. Then the stationary tower forcing is presaturated if either:*

1. $Z_\alpha = P(H(\alpha))$ for all α, or

2. for some successor $\kappa < \delta$, $Z_\alpha = [H(\alpha)]^{<\kappa}$ for all α.

[104] This is automatic in the case of the Woodin's towers, but not for arbitrary stationary towers.

Proof. If $Z_\alpha = P(H(\alpha))$ then the sequence $\langle Z_\alpha\rangle$ is δ-complete. Hence $\mathcal{P}_\mathcal{T}$ is weakly (δ,δ)-saturated.

Suppose that $\kappa = \mu^+$. If $Z_\alpha = [H(\alpha)]^{<\kappa}$, then the sequence $\langle Z_\alpha\rangle$ is $<\kappa$-complete, and hence weakly (κ,δ)-saturated. Let $G \subseteq \mathcal{P}_\mathcal{T}$ be generic and $j : V \to M$ be the generic embedding associated with G. As in Example 9.3, $j(\kappa) \geq \delta$. This implies that $V[G] \models |\delta| \leq \mu^+$. By weak saturation, $V[G] \models |\delta| \geq \mu^+$ and hence δ is a regular a cardinal in $V[G]$. ⊣

Burke's Towers

In [11], Burke considered stationary towers $\mathcal{T} = \langle \mathrm{NS}\restriction Z_\alpha : \alpha \in U \subseteq \delta\rangle$ that were arbitrary save for the restriction that U contained all sufficiently large regular cardinals below δ.

The arguments in his paper yield the somewhat more general result that we prove below. The hypotheses that we impose on the tower to ensure that it captures antichains is that there is a function f that bounds the map sending α to α^* that is sufficiently absolute and that δ is a supercompact cardinal.

9.25 Theorem (Burke [11]). *Let δ be a supercompact cardinal and $\mathcal{T} = \langle \mathrm{NS}\restriction Z_\alpha : \alpha \in U\rangle$ be an arbitrary stationary tower of height δ. Suppose that there is a Σ_2 formula $\phi(x, x', \vec{y})$ and $\vec{p} \in H(\delta)$ such that if we set*

$$f(\alpha) = \alpha' \quad \textit{iff} \quad \phi^V(\alpha, \alpha', \vec{p})$$

then $f : \mathrm{On} \to \mathrm{On}$ and $f\restriction\delta$ bounds the map sending α to α^*, the least element of U above α.[105]

Then $\mathcal{T}$ captures antichains.

Proof. A simple class pigeon-hole argument together with the assumption that ϕ exists yields the following property: There are $\delta^* > 2^\delta$ and a stationary $Z_{\delta^*} \subseteq P(H(\delta^*))$ such that for unboundedly many $\lambda \in \mathrm{On}$ there is a λ-supercompact embedding $j : V \to M$ such that:

1. δ^* is the least element of $j(U)$ above δ, and
2. if we write $j(\langle Z_\alpha : \alpha \in U\rangle) = \langle Z^j_\alpha : \alpha \in j(U)\rangle$, then $Z^j_{\delta^*} = Z_{\delta^*}$.

Let $\mathcal{A}$ be a maximal antichain in $\mathcal{P}_\mathcal{T}$. We show that for every $(2^{\delta^*})^+$-supercompact embedding $j : V \to M$ satisfying 1 and 2, $j(\mathcal{T})$ can catch $j(\mathcal{A})$ at δ. Using a reflection argument we see this implies that there are stationarily many $\alpha < \delta$ such that $\mathcal{T}$ captures $\mathcal{A}$ at α.

Indirectly assume that $\mathcal{A}$ and j are a counterexample. Since $j(\mathcal{A})\restriction\delta = \mathcal{A}$, and $j(\mathcal{T})_\delta = \mathcal{T}$ we see that

---

[105] Given an arbitrary stationary tower $\mathcal{T} = \langle \mathrm{NS}\restriction Z_\alpha : \alpha \in U\rangle$, we can interpolate ideals to make another tower $\mathcal{T}'$ with a U' bounded by the function $\alpha \mapsto (2^{2^\alpha})^+$ such that forcing with $\mathcal{P}_\mathcal{T}$ is equivalent to forcing with $\mathcal{P}_{\mathcal{T}'}$. The resulting tower $\mathcal{T}'$ does not necessarily satisfy the hypotheses of Theorem 9.25, since it may not be a stationary tower.

1. $j(\mathcal{A}) \cap j(\mathcal{T})_\delta$ is a maximal antichain in $\mathcal{P}_{j(\mathcal{T})_\delta}$ and
2. there are

   (a) a $\sigma < \alpha$ and a structure $\mathfrak{A}$ expanding $\langle H(\delta^*), \in, \Delta \rangle$

   and a "bad" stationary set B of $N \prec \mathfrak{A}$ such that

   (b) $B \subseteq Z_{\delta^*}$,
   (c) $\{\mathcal{T}_\delta, \mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\delta}\} \in N$ for all $N \in B$, and
   (d) each $N \in B$ has an $N^* \prec N$ of cardinality less than δ

   such that if $N' \prec \mathfrak{A}$ is such that

   (A) $N' \in Z_{\delta^*}$,
   (B) $N \cap H(\sigma) = N' \cap H(\sigma)$, and
   (C) $N^* \prec N'$

   then

   (D) N' does not capture $j(\mathcal{A})$ below δ.

We note that we can rephrase condition (D) equivalently as:

(E) There is no $a \in N' \cap \mathcal{A}$ with $N' \cap H(\mathrm{supp}(a)) \in a$.

Let $b \in j(\mathcal{A})$ be a condition in M such that $M \models b \cap B$ is stationary. We can assume that $\mathrm{supp}(b) > \delta^*$ and $b \subseteq Z_{\mathrm{supp}(b)}$. In M, choose an N' such that

1. $N' \cap \mathrm{supp}(b) \in B \cap b$,
2. $N' \prec j(\mathfrak{A})$ with $\{j \restriction H(\delta^*), B, b, \mathfrak{A}, \mathcal{T}\} \subseteq N'$, and
3. $N' \in j(Z_{\delta^*})$.

Then $b \in N'$ and $N' \cap \mathrm{supp}(b) \in b$.

Let $N_0 = N' \cap H(\delta^*)$, and $N = j(N_0)$. Let $\sigma < \delta$ and N^* witness $N_0 \in B$. Then $j(\sigma)$ and $j(N^*)$ witness $N \in j(B)$.

Since $|N^*| < \delta$ and $j(N^*) = j``N^*$, and moreover $j(\sigma) = \sigma$. Since $N'$ is closed under $j \restriction H(\delta^*)$ and $N^* \subseteq N'$ we see that $j``N^* \subseteq N'$. Moreover, $N \cap H(\sigma) = N_0 \cap H(\sigma) = N' \cap H(\sigma)$.

We have shown that $N' \prec j(\mathfrak{A})$ and:

(A) $N' \in j(Z_{\delta^*})$,

(B) $N \cap H(\sigma) = N' \cap H(\sigma)$,

(C) $j(N^*) \prec N'$, and

(E) There is an $a \in N' \cap j(\mathcal{A})$ with $N' \cap H(\mathrm{supp}(a)) \in a$.

This contradicts $N \in j(B)$ with witnesses $j(N^*)$ and $j(\sigma)$. ⊣

We now compare the proofs of Woodin's theorem and Burke's theorem. In Woodin's proof the strength of the embedding j is used to see that $b \cap B_\alpha$ is stationary in V. This gives the existence of z and hence of an $N' = \mathrm{Sk}^{\mathfrak{A}}(z \cup j(N^*) \cup \{b\})$ with $N' \cap H(\mathrm{supp}(b)) = z$. For simple sequences $\langle Z_\alpha \rangle$, N' is automatically a member of $j(Z_{\alpha^*})$.

In Burke's situation this may not hold. To find an $N' \in j(Z_{\alpha^*})$, one either needs $j(Z_{\alpha^*})$ to be stationary in V or else have $j \restriction H(\alpha^*) \in M$. For arbitrary sequences, the former possibility requires j to have a degree of hugeness. The latter requires only supercompactness. Hence Burke's hypothesis.

We remark on the use of the function f bounding the growth of U. Without the existence of such a function we cannot focus on particular δ^* and Z_{δ^*}. Unless we fix these in advance, among other problems, we cannot necessarily assume that $j \restriction H(\delta^*) \in M$. The assumption that f exists can be avoided at the cost of assuming that δ is a cardinal larger than a supercompact, as the next theorem shows.

In Burke's paper he asks the whether general stationary tower forcing captures antichains. Woodin proved that with sufficient large cardinal strength, it does. He used the following cardinal:

9.26 Definition. Let δ be a cardinal. Then δ is a *Woodinized supercompact* cardinal iff for every $A \subseteq V_\delta$ and all functions $f : \delta \to \delta$ there is an $\alpha < \delta$ closed under f and an elementary embedding $j : V \to M$ with M transitive such that:

1. $\mathrm{crit}(j) = \alpha$ and M is closed under $|V_{j(f)(\alpha)}|$-sequences,
2. $j(f)(\alpha) = f(\alpha)$, and
3. $j(A) \cap V_{f(\alpha)} = A \cap V_{f(\alpha)}$.

9.27 Remark. The definition can be equivalently reformulated to simply demand that for all $f : \delta \to \delta$ there is an $\alpha < \delta$ closed under f and a $j : V \to M$ with critical point α such that M is closed under $|V_{j(f)(\alpha)}|$-sequences.

These cardinals stand in the same relation to supercompact cardinals as Woodin cardinals stand to hypermeasurable cardinals. Standard large cardinal techniques can be used to check that every almost huge cardinal is a Woodinized supercompact cardinal and has many Woodinized supercompact cardinals below it. Moreover, if δ is a Woodinized supercompact cardinal then there is a stationary set of $\kappa < \delta$ such that

$$(V_\delta, \in) \models \kappa \text{ is supercompact.}$$

9.28 Theorem. *Suppose that δ is a Woodinized supercompact cardinal and $\mathcal{T}$ is a stationary tower of height δ. Then $\mathcal{T}$ captures antichains.*

Proof. Suppose that $\mathcal{T} = \langle \mathrm{NS} \restriction Z_\alpha : \alpha \in U \rangle$ is a stationary tower of height δ. Let $\mathcal{A}$ be an antichain that cannot be caught stationarily often. As in the proof of antichain catching for the Woodin towers, we let $D \subseteq \delta$ be a closed unbounded set such that for $\alpha \in D$ there are $B_\alpha \subseteq Z_{\alpha^*}$ and $\mathfrak{A}_\alpha$ showing that $\mathcal{A}$ cannot be caught at α. As before we can assume that for all $\alpha \in D$, $\mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}$ is a maximal antichain in $\mathcal{A} \cap \mathcal{P}_{\mathcal{T}_\alpha}$. We again define a function f by setting $f(\alpha)$ to be the least element of D above α if $\alpha \notin D$; for each $\alpha \in D$, $f(\alpha)$ is some regular β sufficiently large so that:

1. β is above the next inaccessible element of D above α^*, and
2. there is a $b \in \mathcal{A} \cap V_{f(\alpha)}$ such that $b \cap B_\alpha$ is stationary.

Since δ is Woodinized supercompact, we can find an $\alpha \in D$ and a $j : V \to M$ with critical point α such that:

1. α^* is the least element of $j(U)$ above α,
2. if we write $j(\langle Z_\alpha : \alpha \in U\rangle) = \langle Z^j_\alpha : \alpha \in j(U)\rangle$, then $Z^j_{\alpha^*} = Z_{\alpha^*}$, and
3. M is closed under $2^{2^{\alpha^*}}$ sequences.

The proof now follows the proof of Theorem 9.25, with α playing the role of δ. The strength of the embedding is used to find N' closed under $j{\restriction}H((2^{\alpha^*})^+)$. $\dashv$

9.4. Self-Genericity for Towers

The definition of self-genericity for individual ideals (Definition 3.45) generalizes easily in the context of towers.

9.29 Definition. Let $\mathcal{T}$ be a tower of height δ and $\theta > 2^\delta$ a regular cardinal. Let $M' \prec \langle H(\theta), \in, \Delta, \mathcal{T}\rangle$ be good, M be the transitive collapse of M', $\mathcal{T}^M$ the image in M of $\mathcal{T}$ and j the inverse of the transitive collapse map. Then M' is self-generic iff $\bigcup_{\alpha\in\delta\cap\mathrm{ran}(j)} U(j, M' \cap H(\alpha))$ is generic over M for $\mathcal{P}^M_{\mathcal{T}}$.

As in Proposition 8.20, M' is *self-generic* iff M' captures an index for every maximal antichain $\mathcal{A} \in M'$ below some $\alpha < \delta$.

We remind the reader that if $\mathcal{T}$ is a tower and $\lambda < \delta$ is a strong limit cardinal with $U \cap \lambda$ unbounded in λ, then we can consider the tower $\mathcal{T}_\lambda = \mathcal{T}{\restriction}\lambda$, consisting of $\langle I_\alpha : \alpha \in U \cap \lambda\rangle$. The next proposition gives a sufficient condition for $\mathcal{P}_{\mathcal{T}_\lambda}$ to be a regular subalgebra of $\mathcal{P}_{\mathcal{T}}$. It says that if the collection of N that are self-generic for $\mathcal{T}_\lambda$ is a condition in T, then below that condition $\mathcal{P}_{\mathcal{T}_\lambda}$ is a regular subalgebra of $\mathcal{P}_{\mathcal{T}}$.

9.30 Proposition. *Let $\alpha \in U$ be at least $(2^\lambda)^+$. Let S be the collection of N such that:*

1. *$N \prec \langle H(\alpha), \in, \Delta, \mathcal{T}_\lambda, \dots\rangle$, and*
2. *for all maximal antichains $\mathcal{A} \subseteq \mathcal{P}_{\mathcal{T}_\lambda}$, if $\mathcal{A} \in N$ then N captures $\mathcal{A}$ below λ.*

If $S \in I_\alpha^+$, then there is a condition $R \in \mathcal{P}_{\mathcal{T}_\lambda}$ such that $\mathcal{P}_{\mathcal{T}_\lambda}/R$ is a regular subalgebra of $\mathcal{P}_{\mathcal{T}}/(S \cap R)$.

Proof. Let $G \subseteq \mathcal{P}_{\mathcal{T}}/S$ be generic and $j : V \to V^Z/G$ be the canonical embedding. The proof of the easy part of Proposition 2.34 shows that V^Z/G is well-founded at least up to δ, so we replace it by an isomorphic structure M that is transitive to rank δ. Then $j``H(\lambda)$ is self-generic. Hence $\bigcup_{\alpha \in \delta \cap \mathrm{ran}(j)} U(j, j``H(\alpha))$ is generic for $\mathcal{P}_{\mathcal{T}_\lambda}$ over $H(\lambda^*)^V$. Let $R \in \mathcal{P}_{\mathcal{T}_\lambda}$ force that the generic object for $\mathcal{P}_{\mathcal{T}_\lambda}$ can be extended to a generic $G \subseteq \mathcal{P}_{\mathcal{T}}/S$. Then $\mathcal{P}_{\mathcal{T}_\lambda}/R$ is a regular subalgebra of $\mathcal{P}_{\mathcal{T}}/(S \cap R)$. ⊣

This proposition generalizes easily to a criterion for one tower to be embedded in a different tower.

9.31 Proposition. *Let $\mathcal{T}_1, \mathcal{T}_2$ be towers of height $\delta_1 < \delta_2$. Suppose that there is a condition $B \in \mathcal{T}_2$ that is a subset of $\{N \subseteq H(\theta) : N$ is self-generic for $\mathcal{T}_1\}$ for some $\theta \geq (2^{\delta_1})^+$. Then there is a condition $R \in \mathcal{P}_{\mathcal{T}_1}$ such that $\mathcal{P}_{\mathcal{T}_1}/R$ is a regular subalgebra of $\mathcal{P}_{\mathcal{T}_2}/B \cap R$.*

Proof. Let $G \subseteq \mathcal{P}_{\mathcal{T}_2}$ be generic with $B \in G$. Then $j``H(\theta)$ is self-generic for $\mathcal{T}_1$. In particular, $G \cap \mathcal{P}_{\mathcal{T}_1}$ is generic over V for $\mathcal{P}_{\mathcal{T}_1}$. ⊣

In analogy with Lemma 3.46 for individual ideals we see the following proposition.

9.32 Proposition. *Suppose that $\mathcal{T}$ is a tower of inaccessible height δ. Then the following are equivalent:*

1. *$\mathcal{P}_{\mathcal{T}}$ is δ-c.c., and*
2. *there is a closed unbounded set $D \subseteq \delta$ for all $\alpha \in D$*

$$\{N : N \textit{ is self-generic for } \mathcal{P}_{\mathcal{T}_\alpha}\} \in \breve{I}_{\alpha^*}.$$

Woodin showed the following for $\mathbb{P}_{<\delta}$ and $\mathbb{Q}_{<\delta}$:

9.33 Proposition. *Suppose that $\delta_1 < \delta_2$ are Woodin cardinals, and either:*

1. *$\mathbb{R}_1 = \mathbb{P}_{<\delta_1}$ and $\mathbb{R}_2 = \mathbb{P}_{<\delta_2}$, or*
2. *$\mathbb{R}_1 = \mathbb{Q}_{<\delta_1}$ and $\mathbb{R}_2$ is either $\mathbb{P}_{<\delta_2}$ or $\mathbb{Q}_{<\delta_2}$.*

Then there is an $b \in \mathbb{R}_2$ such that $\mathbb{R}_1$ is a regular subalgebra of $\mathbb{R}_2/b$.

Proof (Sketch). Let S be the set described in Proposition 9.31, and $b = S$ if $\mathbb{R}_1 = \mathbb{P}_{<\delta_1}$ and $\{N \in S : |N| = \omega\}$ if $\mathbb{R}_1 = \mathbb{Q}_{<\delta_1}$. We need to see that b is stationary. This is shown by fixing an arbitrary structure $\mathfrak{A}$ on $H((2^{\delta_1})^+)$ and building a chain $\langle N_i \rangle$ of elementary substructures of $\mathfrak{A}$ together with an increasing sequence of cardinals $\langle \alpha_i \rangle$. The lengths of the sequences are determined by what $\mathbb{R}_1$ is. The sequences will have the properties that:

1. $i < j$ implies $N_j \cap H(\alpha_i) = N_i \cap H(\alpha_i)$,
2. if $\mathcal{A}$ is a maximal antichain in $\mathbb{R}_1$ that belongs to $\mathrm{Sk}^{\mathfrak{A}}(\bigcup_i (N_i \cap H(\alpha_i)))$ then there is an i such that N_{i+1} captures $\mathcal{A}$ below α_i.

Then $\mathrm{Sk}^{\mathfrak{A}}(\bigcup_i (N_i \cap H(\alpha_i)))$ is an elementary substructure of $\mathfrak{A}$ that belongs to S. $\dashv$

Proposition 9.33 can be reformulated in a general context by the use of Definition 9.17. For example using the same technique as the previous sketch, one can show:

9.34 Proposition. *Let $\rho \leq \delta_1 < \delta_2$ regular cardinals with δ_1 and δ_2 inaccessible. Let $\mathcal{T} = \langle I_\alpha : \alpha \in U \rangle$ be a tower of height δ_2 and $A \in \mathcal{P}_{\mathcal{T}}$ be a condition with support at least δ_1^*. Let $\mathcal{S}$ be the tower of height δ_1 determined by projecting $I_{\mathrm{supp}(A)} \restriction A$ to a sequence of ideals on $H(\alpha)$ for $\alpha < \delta_1$. Suppose that*

1. *$\mathcal{T}/A$ is ρ-complete,*
2. *if J is the projection of $I_{\mathrm{supp}(A)} \restriction A$ to an ideal on $H(\delta_1)$, then J concentrates on $[H(\delta_1)]^{<\rho^+}$, and*
3. *$\mathcal{S}$ captures antichains.*

Then there is a condition $B \in \mathcal{T}$ such that $\mathcal{S}$ is a regular subalgebra of $\mathcal{T}/B$.

9.5. Examples of Stationary Tower Forcing

We now consider some examples of stationary tower forcing. Our goal is to give the reader a glimpse of the possibilities inherent in the forcing without exploring the many applications. This is done in the excellent books by Woodin [126] and Larson [80].

9.35 Example (Woodin). Let δ be Woodin and $\mu < \delta$ be a regular uncountable cardinal. For $\mu \leq \alpha < \delta$, let $Z_\alpha = [H(\alpha)]^{<\mu}$ and $\mathcal{T} = \langle \mathrm{NS} \restriction Z_\alpha : \alpha < \delta \rangle$. Then forcing with $\mathcal{P}_{\mathcal{T}}$ yields a generic embedding $j : V \to M$ with $M^{<\delta} \subseteq M$. If η is an ordinal less than δ and $\{z : z \cap \mu \in \mu\}$ and $\{z : \mathrm{cf}(z \cap \eta) = \rho\}$ are in the generic object G, then the critical point of j is μ and in both $V[G]$ and M, the cofinality of η is $j(\rho)$.

In particular, if there are Woodin cardinals then there is a partial ordering that changes the cofinality of $\aleph_{\omega+1}^V$ to $\aleph_n$, while preserving all cardinals less than $\aleph_\omega$. Closely related to this is:

9.36 Example (Foreman and Magidor [42]). Let δ be supercompact and ρ, μ and κ be regular with $\mu^+ \leq \rho < \kappa < \delta$. Let $\eta < \delta$ and $\langle Z_\alpha : \kappa \leq \alpha < \delta \rangle$

be a sequence of stationary sets determining a stationary tower, with Z_α a subset of

$$\{z \in [H(\alpha)]^{<\kappa} : z \cap \kappa \in \kappa,\ z \cap \alpha \text{ is } {<}\mu^+\text{-closed and } \mathrm{cf}(z \cap \eta) = \rho\}.$$

Then in $V[G]$, the critical point of j is κ, the cofinality of η is ρ and for all ordinals ξ, if $\mathrm{cf}(\xi)^{V[G]} \leq \mu$ then $\mathrm{cf}(\xi)^{V[G]} = \mathrm{cf}(\xi)^V$.

If $Z_\alpha = \{z \in [H(\alpha)]^{<\kappa} : z \cap \kappa \in \kappa,\ z \cap \alpha \text{ is } {<}\mu^+\text{-closed and } \mathrm{cf}(z \cap \eta) = \rho\}$, then a Woodin cardinal suffices to draw the same conclusion.

Specializing this example by taking $\kappa = \eta = \aleph_{\omega+1}$, $\mu = \aleph_{16}$, and $\rho = \aleph_{17}$ and assuming the existence of Woodin cardinals we see that there are partial orderings that force $\aleph_{\omega+1}$ to have cofinality $\aleph_{17}$ but preserve all cardinals below $\aleph_\omega$ and the V-cofinality of any cardinal whose cofinality in $V[G]$ is below $\aleph_{17}$.

If a tower preserves cofinalities then the possible fixed points of its generic embedding are restricted. The next result appears in [42], as Proposition 1.5:

9.37 Proposition. *Suppose that $\mathbb{P}$ is δ-presaturated with δ regular, $j : V \to M$ is definable in $V^{\mathbb{P}}$, M is well-founded and $M^{<\delta} \subseteq M$. Suppose that $\alpha < \delta$ is a regular cardinal bigger than the critical point of j and $j(\alpha) = \alpha$. Then $j``\alpha$ is not ω-closed.*

Proof. If $j``\alpha$ is ω-closed, for ordinals below α forcing with $\mathbb{P}$ preserves the properties of having cofinality ω and of having cofinality bigger than ω.[106] Let $\langle S_\gamma : \gamma < \alpha\rangle \in V$ be a partition of $\alpha \cap \mathrm{Cof}(\omega)$ into stationary sets. Each set on the sequence $j(\langle S_\gamma : \gamma < \alpha\rangle)$ is a stationary subset of α in $V[G]$ since $M^{<\delta} \subseteq M$. Let $f : \alpha \cap \mathrm{Cof}(\omega) \to \alpha$ be given by $f(\eta) = \gamma$ iff $\eta \in S_\gamma$. Consider $j``\alpha$. Then $j``\alpha$ is closed under $j(f)$. Since $j``\alpha$ is $\omega$-closed, $j``\alpha$ intersects each set on the list $j(\langle S_\gamma : \gamma < \alpha\rangle)$. Since $j``\alpha$ is closed under $f$, we must have $j``\alpha = \alpha$. But this contradicts $\alpha > \mathrm{crit}(j)$. ⊣

9.38 Corollary. *Suppose that $\mathcal{T}$ is a presaturated tower of height δ such that if $G \subseteq \mathcal{P}_{\mathcal{T}}$ is generic then $\delta \cap \mathrm{Cof}(\omega)^V = \delta \cap \mathrm{Cof}(\omega)^{V[G]}$. Let $j : V \to M$ be the generic embedding from $\mathcal{T}$. Then j has no fixed points whose V-cofinality is between* $\mathrm{crit}(j)$ *and δ.*

The next couple of examples illustrate that if one is willing to change some cardinals to cofinality ω one can have fixed points within the strength of a generic elementary embedding. Note that this is not possible with conventional large cardinal embeddings.[107]

9.39 Example. Let δ be a Woodin cardinal, $G \subseteq \mathbb{P}_{<\delta}$ be generic and $j : V \to M$ be the generic elementary embedding. Then in $V[G]$:

[106] See Proposition 2.32.

[107] The "Kunen Contradiction" implies that if $j : V \to M$ is a large cardinal embedding and λ is a fixed point of j above the critical point of j, then $P(\lambda) \not\subseteq M$.

1. $j(\delta) = \delta$,

2. δ is a regular cardinal and there are unboundedly many measurable $\mu < \delta$ with $j(\mu) = \mu$, and

3. for unboundedly many measurable $\mu \in \delta$ there is a $\gamma < \mu$ and $x \subseteq \gamma$ such that $V_\mu \subseteq L[x]$.

Proof. We first show that the collection of measurable fixed points of j is unbounded in δ. Let $\beta < \mu < \delta$ where μ is measurable and suppose that $S \subseteq P(H(\beta))$ is a stationary set. Standard indiscernibility arguments show that there is a stationary set $T \subseteq P(H(\mu^+))$ such that $T \leq_{\mathbb{P}_{<\delta}} S$, and for all $N \in T$ there is an expansion $\mathfrak{A}$ of $H(\mu^+)$ in a countable language and an unbounded set of indiscernibles $I \subseteq \mu$ such that $N = \mathrm{Sk}^{\mathfrak{A}}((N \cap H(\beta)) \cup I)\}$.

In analogy to Remark 2.27, the function $f : P(H(\mu^+)) \to \mathrm{On}$ given by $f(z) = \mathrm{ot}(z \cap \mu)$ represents μ in every generic ultrapower produced by the tower $\mathcal{T}$. Since for all $N \in T$, $f(N) = \mu$ we see that $T \Vdash \mu = j(\mu)$. Hence the condition T forces in $\mathbb{P}_{<\delta}$ that μ is a measurable fixed point of the generic embedding j.

We have shown that for every $S \in \mathbb{P}_{<\delta}$ and $\beta < \delta$ there is a $T \leq_{\mathbb{P}_{<\delta}} S$ and a $\mu > \beta$ such that T forces that μ is a fixed point of j. Hence, the set of fixed points of j is cofinal in δ.

To see that δ is a fixed point, suppose that $[f]^M$ is an ordinal less than $j(\delta)$ in M. Then f is a function from some $P(H(\alpha))$ into δ, where $\alpha < \delta$. Since $|P(H(\alpha))| < \delta$ and δ is inaccessible, f is bounded in δ by some fixed point of j, call it μ. Thus $[f]^M < j(\mu) = \mu < \delta$, and we see that δ is a fixed point of j.

Since $j(\delta) = \delta$, δ is regular in M. Since $\mathbb{P}_{<\delta}$ is presaturated, M is closed under $<\delta$-sequences, so δ is regular in $V[G]$.

We sketch the last claim. The condition T forces that there is an expansion $\mathfrak{B}$ of $j(H(\mu^+))$ and an unbounded set $J \subseteq \mu$ such that:

1. $j``H(\mu^+) = \mathrm{Sk}^{\mathfrak{B}}(j``H(\beta) \cup J)$, and

2. J is a set of $\mathfrak{B}$ indiscernibles over $j``H(\beta)$.

Let $\gamma = |H(\beta)|$ and $x \subseteq \gamma$ code the structure $\mathrm{Sk}^{\mathfrak{B}}(j``H(\beta))$ together with the "blueprint" of the indiscernibles J. Then $L[x]$ can reconstruct a structure isomorphic to $H(\mu^+)^V$, and hence V_μ. ⊣

9.40 Remark. The only role of γ is clause 3 of Example 9.39 is to work below the condition S. If we start below the trivial condition then we can take $x \subseteq \omega$. Thus we can force to keep any given $\mu < \delta$ measurable and code V_μ by a real.

Stationary tower forcings typically add sequences $\langle \gamma_i : i \in \omega \rangle$ that are V-generic for Prikry forcing through a measurable cardinal $\mu < \delta$. To see this we use an indiscernible argument similar to the one in the previous example.

Let $S \subseteq P(H(\beta))$ be stationary for some $\beta < \delta$. Let $\mu > \beta$ be measurable. We show that the collection of $M^* \prec H((2^{2^\mu})^+)$ such that $M \cap H(\beta) \in S$ and there is a sequence $\langle \gamma_i : i \in \omega\rangle$ in V that is Prikry generic over M^* is stationary.

Let $\mathfrak{A}$ be any structure expanding $\langle H((2^\delta)^+), \in, \Delta, F, \{\beta\}\rangle$, where F is a normal ultrafilter on some $\mu > \beta$. It suffices to find an $M \prec \mathfrak{A}$ such that $M \cap H(\beta) \in S$ and a Prikry sequence through F over M. Let $N \prec \mathfrak{A}$ with $N \cap H(\beta) \in S$. Choose $\gamma_1 \in \bigcap(F \cap N)$. If $N_1 = \mathrm{Sk}^{\mathfrak{A}}(N \cup \{\gamma_1\})$ then $N_1 \cap H(\mu)$ end extends $N \cap H(\mu)$. This process can be repeated to build sequences $\langle N_i : i \in \omega\rangle$ and $\langle \gamma_i : i \in \omega\rangle$ such that $N_i \prec \mathfrak{A}$ and $N_{i+1} \cap H$ end extends $N_i \cap H(\mu)$. If we let $M = \bigcup N_i$ then $M \prec \mathfrak{A}$ and $\langle \gamma_i : i \in \omega\rangle$ is a Prikry sequence through F over M. Moreover $M \cap H(\beta) = N \cap H(\beta) \in S$.

We have sketched:

9.41 Example. Suppose that $\mathcal{P}_\mathcal{T}$ is a stationary tower given by $\langle Z_\alpha : \alpha < \delta\rangle$ where δ is Woodin and either each $Z_\alpha = P(H(\alpha))$ or there is an $\eta \geq \omega_1$ so that each Z_α is of the form $[H(\alpha)]^{<\eta}$. Then for each $S \in \mathcal{P}_\mathcal{T}$, we can find arbitrarily large measurable $\mu < \delta$ for which there are $T \leq_{\mathcal{P}_\mathcal{T}} S$ such that $T \subseteq \{N \prec H((2^{2^\mu})^+) :$ there is a sequence $\langle \gamma_i : i \in \omega\rangle$ Prikry generic over N for a ultrafilter F on $\mu\}$. This T forces that $\mathcal{P}_\mathcal{T}$ adds a Prikry generic sequence over V through a ultrafilter on μ. Thus $\mathcal{P}_\mathcal{T}$ adds Prikry generic sequences to a cofinal set of cardinals below δ.

We remark that this same technique can add "longer" Prikry sequences to μ.

Woodin proved the following theorem about "Σ_2 resurrection":

9.42 Theorem (Woodin; see [80]). *Suppose that there is a proper class of Woodin cardinals. Then for all Σ_2 formulas $\phi(\vec{x})$, all $\vec{a} \in V$, and all partial orderings $\mathbb{P}$ there is a partial ordering $\mathbb{Q} \in V^\mathbb{P}$ such that:*

$$\phi^V(\vec{a}) \quad \textit{implies} \quad \phi^{\mathbb{P}*\mathbb{Q}}(\vec{a}).$$

We illustrate this theorem by giving a special case that shows that if there is a huge cardinal and a proper class of Woodin cardinals then after any forcing $\mathbb{P}$ one can do a further forcing $\mathbb{Q}$ to restore a huge cardinal to the universe.

9.43 Example. Suppose that $j : V \to M$ is a huge embedding with critical point κ and $j(\kappa) = \lambda$. Suppose that $\mathbb{P}$ is a partial ordering and there is a Woodin cardinal bigger than both λ and $|\mathbb{P}|$. Then in $V^\mathbb{P}$ there is a partial ordering $\mathbb{Q}$ such that

$$V^{\mathbb{P}*\mathbb{Q}} \models \text{ there is a huge cardinal.}$$

Proof. Fix a Woodin cardinal $\delta > \max(|\mathbb{P}|, \lambda)$. We first argue that if $H \subseteq \mathbb{P}$ is generic then we can find a partial ordering $\mathbb{Q} \in V[H]$ such that for all $V[H]$-generic $H' \subseteq \mathbb{Q}$, there is a V-generic $G \subseteq \mathbb{P}_{<\delta}$ such that $V[H * H'] = V[G]$.

Let $\mu = |\mathbb{P}|$. We force with the Woodin tower $\mathbb{P}_{<\delta}$ below the condition $S = \{z : |z \cap H(2^{2^\mu})| = \aleph_0\}$ to get a generic object G. This collapses $|2^{2^\mu}|$ to be countable. Hence for each condition $p \in \mathbb{P}$ there is a V-generic object $H \subseteq \mathbb{P}$ with $p \in H$ that belongs to $V[G]$. Applying standard forcing arguments we see that there is a regular embedding

$$e : \mathbb{P} \to \mathcal{B}(\mathbb{P}_{<\delta}/S).$$

The forcing fact highlighted in the introduction shows that for each generic $H \subseteq \mathbb{P}$ there is a partial ordering $\mathbb{Q} \in V[H]$ such that

$$\mathbb{P}_{<\delta}/S \sim \mathbb{P} * \mathbb{Q}.$$

To see that this $\mathbb{Q}$ works, it suffices to show that for all generic $G \subseteq \mathbb{P}_{<\delta}$, there is a huge cardinal in $V[G]$. We showed in Example 9.39 that in $V[G]$ there is a generic elementary embedding $k : V \to M$ where $M^{<\delta} \subseteq M$ and $k(\delta) = \delta$. In particular, M is a model of "there is a huge embedding j' with critical point κ' and $j'(\kappa') < \delta$". Since this huge embedding comes from a normal, fine, ultrafilter U on $[\lambda']^{\kappa'}$, and $P([\lambda']^{\kappa'})^M = P([\lambda']^{\kappa'})^{V[G]}$, we see that κ' is huge in $V[G]$. ⊣

The next result is a very small improvement of a result of Burke's in his [12]:

9.44 Proposition. *Suppose that I is a countably complete ideal on a set Z and suppose that $\delta > |Z|$ is a Woodin cardinal. Then I is pre-precipitous.*[108]

Proof. We need to see that there is a partial ordering $\mathbb{P}$ and a $\mathbb{P}$-term i and an elementary embedding $j : V \to M$ definable in $V^{\mathbb{P}}$ such that $A \in I$ iff $\|i \in j(A)\| = 0$.

We first show Burke's result that using $\mathbb{P}_{<\delta}$ we can force the existence of an ultrafilter $U \supseteq \breve{I}$ such that V^Z/U is well-founded. For some $\alpha > 2^{2^{|Z|}}$ let $S = \{z \subset H(\alpha) : |z \cap 2^{2^{|Z|}}|$ is countable$\}$. Let $G \subseteq \mathbb{P}_{<\delta}$ be generic with $S \in G$. If $j : V \to M \subseteq V[G]$ is the generic ultrapower, then

$$\textstyle\bigcap_{A \in \breve{I}} j(A) \in j(\breve{I}).$$

In particular, $\bigcap_{A \in \breve{I}} j(A) \neq \emptyset$. If we choose $i \in \bigcap_{A \in \breve{I}} j(A)$ then $U(j, i) \supseteq \breve{I}$ and $V^Z/U(j, i)$ is well-founded.

To see the full result, we apply Burke's technique to the ideals $I \restriction B$ for each $B \in I^+$. Choose a maximal antichain $\mathcal{A} \subset \mathbb{P}_{<\delta}$ of size at least $2^{|Z|}$. Partition $\mathcal{A}$ into non-empty sets $\langle \mathcal{A}_B : B \in I^+ \rangle$. Burke's technique gives us a collection of terms i_T for $T \in \mathcal{A}$ such that if $T \in \mathcal{A}_B$, then

$$T \Vdash i_T \in \textstyle\bigcup_{A \in \breve{I}} j(A) \cap j(B).$$

Let i be a term such that for all $T \in \mathcal{A}$, $T \Vdash i = i_T$. Then $B \in I$ iff $\|i \in j(B)\| = 0$. ⊣

[108] The definition of pre-precipitous is given in Definition 3.39.

9.6. A Tower that is not Precipitous

In this subsection we present an example due to Burke [11], of a tower that has height a supercompact cardinal and is not precipitous. This stands in contrast to Theorems 9.25 and 9.28.

The example in Burke's paper uses a hypothesis that is a consequence of a supercompact cardinal and Schimmerling showed holds in some inner models of the form $L[E]$:

9.45 Definition. Let $*(\kappa, \delta)$ be the statement that κ is a regular cardinal, $\delta > \kappa$ is an inaccessible cardinal and there is an increasing sequence of transitive models of ZFC, $\langle N_\xi : \xi < \lambda\rangle$ that belongs to V_δ such that for all $x \in V_\delta$ there is an $a \prec V_\delta$ with $x \in a$, $|a| < \kappa$, and $a \cap \kappa \in \kappa$ and for some $\xi < \lambda$ the transitive collapse of a is a rank initial segment of N_ξ.

9.46 Theorem (Burke [11]). *Suppose that $*(\kappa, \delta)$. Then there is a tower of height δ with critical point κ that is not precipitous.*

Burke noted that if κ is supercompact and $\delta > \kappa$ is inaccessible then the sequence of length one $\langle V_\kappa\rangle$ is a witness to $*(\kappa, \delta)$. Hence he deduces:

9.47 Corollary. *Suppose that κ is supercompact and $\delta > \kappa$ is inaccessible. Then there is a tower of height δ and critical point κ that is not precipitous.*

We start with two preliminary results.

9.48 Proposition. *Suppose that $\mathcal{T}$ is a precipitous tower of height δ where δ is an inaccessible cardinal, $G \subseteq \mathcal{P}_{\mathcal{T}}$ is generic and $j : V \to M$ is the associated elementary embedding. If $j(\delta) > \delta$, then $\mathcal{P}_{\mathcal{T}}$ is not in M.*

Proof. If the proposition fails then we may assume that for all $G \subseteq \mathcal{P}_{\mathcal{T}}$, $j(\delta) > \delta$ and $\mathcal{P}_{\mathcal{T}} \in M$. Let $N = L(V_\delta, \mathcal{T})$. Then N may not be a model of AC, but $\mathcal{P}_{\mathcal{T}}$ belongs to N as do all functions into V_δ with support below δ.

Fix $G \subseteq \mathcal{P}_{\mathcal{T}}$ generic over V, and let $j : V \to M$ be the elementary embedding coming from the ultrapower map. Let $\delta^* = j(\delta)$. Then G is also generic over N. If j_G is the generic ultrapower constructed over N using G, we have $j_G(\delta) \geq \delta^*$. As this can be expressed in the forcing language, there is a $p \in \mathcal{P}_{\mathcal{T}}$ such that $N \models p \Vdash_{\mathcal{P}_{\mathcal{T}}} j_G(\delta) \geq \check{\delta}^*$.

Let $[f]^M = \delta$ and $[g]^M = \mathcal{T}$. Without loss of generality we can assume that:

1. $\mathrm{supp}(f) = \mathrm{supp}(g) = \alpha$ for some $\alpha < \delta$, and
2. for all $a \in H(\alpha)$, $f(a) < \delta$ and $g(a)$ is a tower of height $f(a)$ that belongs to $L(V_{f(a)}, g(a))$.

Since δ is inaccessible, $|{}^{H(f(\alpha))}f(a)| < \delta$ for all $a \in H(\alpha)$. If $G_a \subseteq \mathcal{P}_{g(a)}$ is generic over $L(V_{f(a)}, g(a))$, then $|j_{G_a}(f(a))| \leq |{}^{H(f(\alpha))}f(a)|$. Hence $L(V_{f(a)}, g(a)) \models$"for all generic $G_a \subseteq \mathcal{P}_{g(a)}$, $j_{G_a}(f(a)) < \check{\delta}$".

Passing to M, and using the fact that $N = L(V_{[f]^M}, [g]^M)$ we see that $N \models$"for all generic $G, j_G(\delta) < \check{\delta^*}$". This contradicts the existence of the condition p. ⊣

9.49 Lemma. *Suppose that δ is an inaccessible cardinal, U is an unbounded subset of δ and $\langle Z_\alpha \subseteq P(H(\alpha)) : \alpha \in U\rangle$ is a sequence of stationary sets such that for $\alpha < \beta \in U$, $\mathrm{NS}\restriction Z_\beta$ projects to a superset of $\mathrm{NS}\restriction Z_\alpha$. Then there is a tower $\mathcal{T} = \langle I_\alpha : \alpha \in U\rangle$ such that for all $\alpha \in U$, $Z_\alpha \in \breve{I}_\alpha$.*

Proof. Let $I_{\alpha,\beta}$ be the projection of $\mathrm{NS}\restriction Z_\beta$ to $P(H(\alpha))$. Then the $I_{\alpha,\beta}$ increase with β and hence stabilize in a proper ideal at some $\beta(\alpha) < \delta$. Then $I_\alpha = I_{\alpha,\beta(\alpha)}$ is the desired sequence. ⊣

We now prove Theorem 9.46.

Proof. Assume $*(\kappa, \delta)$ and let $\langle N_\xi : \xi < \lambda\rangle$ be a witness. To follow Burke's proof closely, it is easier to work with V_α's instead of $H(\alpha)$'s. Since δ is inaccessible, there is a closed unbounded set of $\alpha \in \delta$ where $V_\alpha = H(\alpha)$, so this is primarily a notational distinction.

For α a limit ordinal between κ and δ, let $Z_\alpha = \{a \subseteq V_\alpha : |a| < \kappa,\ a \cap \kappa \in \kappa$ and there is a $\xi < \lambda$ such that the transitive collapse of a is a rank initial segment of $N_\xi\}$.

We claim that:

1. each Z_α is stationary, and

2. for $\alpha < \beta$ the projection of $\mathrm{NS}\restriction Z_\beta$ to α is a superset of $\mathrm{NS}\restriction Z_\alpha$.

To see that Z_α is stationary, fix an algebra $\mathfrak{A}$ with domain V_α. Apply $*(\kappa, \delta)$ with $x = \mathfrak{A}$, to find an $a \prec V_\delta$ with $x \in a$ and a ξ such that the transitive collapse of a is a rank initial segment of N_ξ. Then $a \cap V_\alpha \prec \mathfrak{A}$. Further, the transitive collapse of $a \cap V_\alpha$ is a rank initial segment of the transitive collapse of a and hence of N_ξ.

To see the second claim, it suffices to show that the projection of the closed unbounded filter on V_β restricted to Z_β is a superset of the closed unbounded filter on V_α restricted to Z_α. Fix an algebra $\mathfrak{A}$ on V_α. Let $\mathfrak{B}$ be any fully Skolemized structure expanding $(V_\beta, \in, \delta)$ containing a constant symbol whose interpretation is $\mathfrak{A}$. Then any elementary substructure $b \prec \mathfrak{B}$ has $b \cap V_\alpha \prec \mathfrak{A}$. For $b \prec \mathfrak{B}$ with transitive collapse a rank initial segment of N_ξ, we know that the transitive collapse of $b \cap V_\alpha$ is also a rank initial segment of N_ξ. Thus the projection to V_α of those $b \in Z_\beta$ that are elementary substructures of $\mathfrak{B}$ is contained in the collection of elementary substructures of $\mathfrak{A}$ that belong to Z_α.

By Lemma 9.49 we can find a tower $\mathcal{T} = \langle I_\alpha : \alpha \in U\rangle$ such that for all $\alpha \in U$, $Z_\alpha \in \breve{I}_\alpha$.

Indirectly assume that $\mathcal{P}_\mathcal{T}$ is precipitous. Let $G \subseteq \mathcal{P}_\mathcal{T}$ be generic, and let $j : V \to M \subseteq V[G]$ be the generic ultrapower. Note that $j(\kappa) \geq \delta$, so in particular, $j(\delta) > \delta$. We establish our contradiction by showing that $\mathcal{T} \in M$ and hence $\mathcal{P}_{\mathcal{T}} \in M$. Since $\mathcal{T}$ is definable in V_δ from the sequence $\langle N_\xi : \xi < \lambda \rangle$, this is equivalent to showing that $V_\delta \in M$.

Let $\alpha \in U$. Since $Z_\alpha \in \check{I}_\alpha$, we know that the transitive collapse of $j``V_\alpha$ is a rank initial segment of some element of $j(\langle N_\xi : \xi < \lambda \rangle)$. Denote $j(\langle N_\xi : \xi < \lambda \rangle)$ by $\langle N^j_\xi : \xi < j(\lambda) \rangle$. Let $\xi(\alpha)$ be the least ordinal such that V_α is a rank initial segment of $N^j_{\xi(\alpha)}$ and $\gamma = \sup\{\xi(\alpha) + 1 : \alpha < \delta\}$. Note that the map $\alpha \mapsto \xi(\alpha)$ is monotone. In M, let $R = \{x : \mathrm{rank}(x) < \delta$ and $x \in N^j_\xi$ for some $\xi < \gamma\}$.

We claim that $R = V_\delta$. Clearly $V_\delta \subseteq R$. Suppose that $x \in R$. Let $\beta < \delta$ be a limit ordinal such that x has rank less than β and $\xi < \gamma$ be such that $x \in N^j_\xi$. Since the sequence $\langle N^j_\xi : \xi < j(\lambda) \rangle$ is increasing and $\xi < \gamma$, we can assume that $\xi = \xi(\beta')$ for some $\beta' \geq \beta$. Since $V_{\beta'}$ is a rank initial segment of N^j_ξ, we see that $x \in V_\beta$. $\dashv$

10. Consistency Strength of Ideal Assumptions

In this section we describe some progress towards clarifying the relationships between generic ultrapowers and conventional large cardinals. We begin with a brief survey of the results showing that generic embeddings yield fine structural inner models. Relevant information on these results can be found in the chapters by Mitchell, by Schindler and Zeman, and by Steel in this Handbook and in the papers referenced in the text. We shall confine ourselves to telegraphic remarks here. It is important to note as well that there are direct equiconsistency results between ideal assumptions and determinacy hypotheses. For example, Woodin showed that $2^{\aleph_0} = \omega_2$ + "NS_{ω_1} is $\aleph_1$-dense" is equiconsistent with $\mathrm{AD} + V = L(\mathbb{R})$. This type of result is beyond the scope of this chapter.

Some new results that show the existence of very large cardinals are presented. The underlying point of the new results is that knowing the image of just a few sets by the generic ultrapower embedding is sufficient to show that there is a conventional large cardinal in an inner model whose embedding agrees with the generic ultrapower embedding. The proofs of the new results in this section can be found in the forthcoming paper [32].

Throughout this section we will use the notation π_N to be the unique isomorphism between an extensional set N and its transitive collapse.

10.1. Fine Structural Inner Models

We begin by describing conventional theorems using core model theory to build inner models with large cardinals from generic embedding assumptions. As we will see, the gap between the lower bounds on consistency strength provided by core model theory and the upper bounds given by forcing are, in many cases, quite large.

Early work of Kunen was used by Jech and Prikry (see [65]) to show that if U is the dual of a normal, precipitous ideal on some cardinal κ then $L[U] \models U$ is a normal ultrafilter on κ. In particular, this gave one direction of the equiconsistency between real-valued measurable cardinals and (two-valued) measurable cardinals.[109]

As pointed out earlier, in Theorems 8.6, 8.7 and 8.8, work of Gitik [53, 54] showed that having NS_{ω_2} be precipitous is equiconsistent with the existence of a measurable cardinal of Mitchell order 2. More generally, if $\mu > \omega_1$ then CH + "NS_{μ^+} is precipitous" is equiconsistent with μ^+ being an $(\omega, \mu+1)$ repeat point for the normal ultrafilters on μ^+ in the core model K. The property "κ is an inaccessible cardinal and NS_κ is precipitous" is equiconsistent with κ having an $(\omega, \kappa+1)$-repeat point for the normal ultrafilters on κ in K.

For saturated ideals, the situation is less clear. Steel [114] showed that if there is a presaturated ideal on a cardinal κ and a measurable cardinal $\mu > \kappa$, then there is an inner model with a Woodin cardinal.

Steel also showed that if there is a homogeneous presaturated ideal on ω_1 and CH holds, then Projective Determinacy holds. Hence, for all $n \in \omega$ there is an inner model with n Woodin cardinals. This result was superseded by Woodin who showed that CH was not necessary and was able to get inner models with ω-many Woodin cardinals. This is an exact equiconsistency result, as the Steel-Van Wesep ideal (Theorem 8.1) is homogeneous.

Steel and Zoble showed that the assumption "NS_{ω_1} is $\aleph_2$-saturated and every pair of stationary subsets of $\omega_2 \cap \mathrm{Cof}(\omega)$ simultaneously reflect" implies $\mathrm{AD}^{L(\mathbb{R})}$, with the consequent inner model implications. We note that the Steel-Zoble hypotheses follows from many standard propositions such as Martin's Maximum. Somewhat weaker versions of these results appear in Zoble's thesis [131].

We note that for saturated or cardinal preserving ideals above ω_1, there is an enormous gap between the known lower bounds (some number of Woodin cardinals) and the known upper bounds (almost huge cardinals).

There is a similar situation for Chang's Conjecture type properties. The classical Chang's Conjecture $(\aleph_2, \aleph_1) \twoheadrightarrow (\aleph_1, \aleph_0)$ is equiconsistent with the existence of an ω_1-Erdős cardinal, as shown by results of Silver, Baumgartner, Donder and Levinski, among others [70, 24]. For the property $(\aleph_{n+2}, \aleph_{n+1}) \twoheadrightarrow (\aleph_{n+1}, \aleph_n)$ with $n > 0$, the known upper bound on consistency strength is a huge cardinal. A lower bound with $n = 1$ and CH was given by Schindler [99, 100] as a κ with Mitchell order $\kappa^{+\omega}$. For $n \in [2, \omega)$ with $2^{\aleph_{n-1}} = \aleph_n$, Schindler showed that there is an inner model with a strong cardinal. Without the assumptions on cardinal arithmetic, Jensen showed 0-sword exists.

For "gap two" Chang Conjectures the distance between the known lower and upper bounds is even greater, as the best known upper bound is a 2-huge cardinal [33].

[109] The consistency result was proved previously by Solovay [111].

10.2. Getting Very Large Cardinals from Ideal Hypotheses

In this section we discuss various non-standard ways of getting inner models with very large cardinals.

Constructing from Stationary Sets and the Nonstationary Ideal

We begin by illustrating how to construct models with arbitrarily large cardinals by constructing relative to the nonstationary ideal.

Recall the following theorem of Burke (Corollary 4.21):

Theorem. *Suppose that I is a normal, fine, countably complete ideal on a stationary set $Z \subseteq P(X)$. Then for all Y with $|Y| \geq 2^X$, there is a stationary set $A \subseteq P(Y)$ such that I is the projection of the nonstationary ideal on Y restricted to A.*

Suppose that $X = \lambda$ and $Y = \lambda'$ for cardinals λ, λ'. An examination of the argument for Burke's theorem yields the following observation: If $\breve{I}$ is an ultrafilter and U is a normal, fine ultrafilter on $P(\lambda')$ projecting to $\breve{I}$, then $A \in U$. Hence, if U is (say) a supercompact ultrafilter, we can take A to be canonically well-ordered.

The A produced in Burke's theorem can be taken to have many of the properties typical to sets in $\breve{I}$. Arguments from [42] show that if there is a set of measure one C for I such that every element $z \in C$ is ω-closed as a set of ordinals, then we can find an A such that every $N \in A$ is ω-closed as a set of ordinals. Moreover, if I concentrates on sets of size less than κ (resp. equal to κ or greater than κ etc.), then Z can be taken to concentrate on sets of size less than κ (resp. equal to κ or greater than κ).

Many large cardinal properties of a cardinal κ can be defined in terms of the existence of certain kinds of ultrafilters U on a subset of $P(\lambda)$ for $\lambda \geq \kappa$. In attempting to construct a canonical inner model theory for such cardinals, a major obstacle is finding a suitable set of measure one to build into the model. Typically, doing simple *relative constructibility* one finds that $L[U]$ is a very small model and the method fails. Alternatively, one can simply "throw in" a set of measure one $A \in U$, making sure that A is canonically well-ordered. A theorem of Solovay [112] says that if U is a supercompact or strongly compact ultrafilter then A can be taken so that distinct elements of A have different suprema. The cost of the second approach is that the model seems in no way canonical.

Let $A \subseteq [\lambda]^{<\kappa}$ be a set such that the function $\sup : A \to \lambda$ is one-to-one. For β in the range of the sup function, let $a_\beta \in A$ be such that $\sup(a_\beta) = \beta$. Define $A^* \subseteq \lambda \times \lambda$ by setting $(\alpha, \beta) \in A^*$ iff $\alpha \in a_\beta$. Then $A \in L[A^*]$.

From Burke's theorem we get:

10.1 Corollary. *Suppose that κ is $[2^\lambda]^{<\kappa}$-supercompact. Then there is a stationary set $A \subseteq [2^\lambda]^{<\kappa}$ such that $L[\mathrm{NS}{\restriction}[2^\lambda]^{<\kappa}, A^*]$ is a model of* ZFC + *"κ is λ-supercompact".*

We note that there are many stationary sets A that work for Corollary 10.1. One possible definition of such an A is:

$$\{x \in [H((2^\lambda)^+)]^{<\kappa} : x \cap \kappa \in \kappa \text{ and } \mathrm{tc}(x) \subseteq H(\lambda_x)\},$$

where λ_x is the order type of $\lambda \cap x$ and $\mathrm{tc}(x)$ is the transitive closure of x.

Moreover, using arguments similar to Theorem 1.3 of [42], one sees that if U is a supercompact ultrafilter on $[\lambda]^{<\kappa}$ then there is always a stationary set A of good structures in $H((2^\lambda)^+)$ such that the sup function is one-to-one on A. Hence, the assumption of Corollary 10.1 can be reduced to λ-supercompactness. Indeed one sees:

10.2 Corollary. *Let $\kappa < \lambda$ be regular cardinals. Then κ is λ-supercompact iff there is a stationary set $A \subseteq [2^\lambda]^{<\kappa}$ such that the supremum function is one-to-one on A and $L[\mathrm{NS}{\restriction}[2^\lambda]^{<\kappa}, A^*]$ is a model of* ZFC + *"κ is λ-supercompact".*

There is nothing particularly remarkable about supercompact cardinals in the previous arguments. It generalizes easily to essentially any type of very large cardinal such as huge cardinals, n-huge cardinals or towers of n-huge cardinals. In the case of the huge cardinal, to see that the Axiom of Choice holds in the inner model, we note that if U is a huge ultrafilter on $[\lambda]^\kappa$, then there is a set $A \in U$ such that the map $z \mapsto (z \cap \kappa, \sup(z \cap \lambda))$ is a one-to-one map into $\kappa \times \lambda$.[110] Similar tricks for generalizations to larger cardinals such as n-huge cardinals.

Decisive Ideals

Next we give a definition that seems to adequately distinguish between ideals that arise as induced ideals in models built after collapsing large cardinals by forcing and the natural ideals whose generic embeddings are not the traces of large cardinal embeddings in inner models.

10.3 Definition. Let $Z \subseteq P(X)$ and J be an ideal on Z. Let $X' \subseteq X$ and I be the projection of J to an ideal on $P(X')$ via the map $\pi(z) = z \cap X'$. Then J *decides* I iff there is a set $A \in \breve{I}$ and a well-ordering W of A and sets A', W', O' and I' such that for all generic $G \subseteq P(Z)/J$,

1. an initial segment of the ordinals of V^Z/G is well-founded and isomorphic to $(|A'|^+)^V$, and
2. if $j : V \to M$ is the canonical elementary embedding determined by replacing the ultrapower V^Z/G by an isomorphic model M transitive up to $|A'|^+$, then

$$j(A) = A', \qquad j(W) = W', \qquad j``|A| = O', \qquad I' = j(I) \cap P(A')^V.$$

[110] There is even a large set such that the supremum function is one-to-one. This is not necessarily true in the examples we consider later in this section, so we mention the weaker property now.

We will say that J is *decisive* if J decides itself.[111]

Some of the hypotheses in Definition 10.3 are easily satisfied. For example, if J is normal and fine, and $|X| \geq |A'|^+$, then the first clause is automatically satisfied. Moreover, if A has a $\Delta_1^{\mathrm{ZF}^-}$ well-ordering in $H(|A|^+)$ then W and W' automatically exist. Often A has a simple well-ordering given by the properties of the characteristic function of its members.

10.4 Remark. For most induced ideals J produced by collapsing a large cardinal and extending the large cardinal embedding, it is routine to check decisiveness.

The definition can easily be extended to arbitrary generic embeddings, rather than just generic ultrapowers V^Z/G: If $j : V \to M$ is a generic elementary embedding defined in a forcing extension $V^{\mathbb{P}}$ we can ask that M be well-founded up to $|A'|^+$ and that the sets A, A', W', O', I' exist in the inner model M. In this case we say that $\mathbb{P}$ *decides* I.

10.5 Theorem. *Let $\mu \leq \lambda$ be cardinals. Let $\pi : P(\lambda) \to P(\mu)$ be defined by $\pi(z) = z \cap \mu$. Suppose that J is a normal, fine ideal on a set $Z \subseteq P(\lambda)$ that decides a countably complete ideal $I \subseteq P(Z')$ for some $Z' \subseteq P(\mu)$. Suppose that A, W witness the fact that J decides I and W well-orders A as $\langle a_\beta : \beta < \gamma < |A|^+ \rangle$. Let $A^* = \{(\alpha, \beta) : \alpha \in a_\beta\} \subseteq \mu \times \mu$. Then either:*

$$L[A^*, I] \models \check{I} \text{ is an ultrafilter on } A$$

or for some generic $G \subseteq P(Z)/J$

$$L[j(A^*), j(I)] \models j(\check{I}) \text{ is an ultrafilter on } j(A).$$[112]

We can replace clause 1 in the definition of "decisive" by the demand that "if $a = |j(A)|^M$ and $b = (a^+)^M$, then M is well-founded up to b". This change in the hypothesis yields the stronger conclusion that $L[A^*, I] \models \check{I}$ is an ultrafilter.

10.6 Corollary. *Suppose that I is a normal, fine, κ-complete decisive ideal on λ with witnesses A, W. Then:*

1. *If $\alpha < \kappa$ and $A \subseteq [\kappa^{+\alpha}]^{<\kappa}$, then there is an inner model of V with a cardinal μ that is $\mu^{+\alpha}$-supercompact.*

2. *If $A \subseteq [\lambda]^\kappa$, then there is an inner model of V with a huge cardinal.*

3. *If $A \subseteq \{z : \mathrm{ot}(z) = \lambda_1 \text{ and } \mathrm{ot}(z \cap \lambda_1) = \kappa\}$, then there is an inner model of V with a 2-huge cardinal.*

---

111 I.e. if we take π to be the identity map and $I = J$.

112 The two alternatives are not equivalent because M is not necessarily well-founded.

Moreover if I is precipitous then:

4. *If $A \subseteq [\lambda]^{<\kappa}$, then κ is λ-supercompact in an inner model of V.*
5. *If $A \subseteq [\lambda]^{\kappa}$, then κ is huge in an inner model.*
6. *If $A \subseteq \{z : \mathrm{ot}(z) = \lambda_1$ and $\mathrm{ot}(z \cap \lambda_1) = \kappa\}$, then κ is 2-huge in an inner model.*

In particular, the following are equiconsistent:

a. *for $n < m \in \omega$ there is normal, fine, decisive ideal on $[\omega_m]^{\omega_n}$,*

b. *there is a huge cardinal,*

as are:

a. *for $n < m \in \omega$ there is normal, fine, decisive ideal on $[\omega_m]^{<\omega_n}$,*

b. *there is a $\kappa^{+(m-n)}$-supercompact cardinal κ.*

Note that there are obvious analogous corollaries for n-huge cardinals.

In unpublished work, starting from a measurable cardinal, Gitik has given an example of an indecisive κ-complete precipitous ideal on a cardinal κ. Another example of a nowhere decisive ideal is the following.

Start in a model with a Woodin cardinal. Collapse the first Ramsey cardinal to be ω_2 so that $(\aleph_2, \aleph_1) \twoheadrightarrow (\aleph_1, \aleph_0)$. Now collapse a Woodin cardinal to be ω_3. Then Theorem 8.37 shows that the Chang ideal on $[\omega_2]^{\omega_1}$ is precipitous. Were it decisive it would give an inner model with a huge cardinal. However, if the model we start in is the minimal inner model with one Woodin cardinal this is impossible.

Chang's Conjecture and Huge Cardinals

In this section we will use Proposition 3.9 and the definitions of the Chang ideals.

Recall that Lemma 4.34 implies that if $\kappa > \mu$ and there are finitely many cardinals between κ and μ then any ideal I concentrating on $\{N \in P(\kappa) : N \cap \mu \in \mu$ and for all cardinals λ with $\mu \le \lambda \le \kappa$ we have $\mathrm{cf}(N \cap \lambda) > \omega\}$, has a canonically well-ordered set $A \in \breve{I}$ of cardinality κ. Thus any Chang ideal involving cardinals at least as big as ω_1 has a canonically well-ordered set of measure one. Hence clause 2 of the hypotheses of the next theorem is satisfied by most Chang ideals. The clause 1 implies that $|N \cap \kappa_1| = \kappa_0$ and hence clause 1 is a version of the Chang's Conjecture $(\kappa_1, \kappa_0) \twoheadrightarrow (\kappa_0, {<}\kappa_0)$. Clauses 3 and 4 are condensation properties that hold in huge type embeddings.

10.7 Theorem. *Suppose that $\kappa_2 > \kappa_1 > \kappa_0$ are cardinals and there is a regular θ and a stationary set $S \subseteq P(H(\theta))$ and sets $A \subseteq [\kappa_1]^{\kappa_0}$, $A' \subseteq [\kappa_2]^{\kappa_1}$, O', I' such that for all $N \in S$:*

1. *$N \cap \kappa_0 \in \kappa_0$ and $N \cap \kappa_1 \in A$,*

2. *$A, A' \in N$ and $\pi_N(A') = A$, and the map $z \mapsto (z \cap \kappa_0, \sup(z))$ is one-to-one on A,*

3. *$O' \in N$ and $N \cap \kappa_1 = \pi_N(O')$, and*

4. *$I' \in N$ and $\pi_N(I') = (\mathrm{CC}((\kappa_1, \kappa_0), (\kappa_0, {<}\kappa_0))\restriction A) \cap N$.*

Then there is an inner model with a huge cardinal.

Theorem 10.7 is proved using a decisive elementary embedding that has critical point κ_0 and $j(\kappa_0) = \kappa_1$ and $\kappa_2 = j(\kappa_1)$. Since the ideal $I = \mathrm{CC}((\kappa_1, \kappa_0), (\kappa_0, {<}\kappa_0))$ is a definable ideal, we have the fact that $j(I) = \mathrm{CC}((\kappa_2, \kappa_1), (\kappa_1, <\kappa_1))^M$. If we assume the principle $(\kappa_2, \kappa_1, \kappa_0) \twoheadrightarrow (\kappa_1, \kappa_0, {<}\kappa_0)$ then the Chang ideals $\mathrm{CC}((\kappa_2, \kappa_1), (\kappa_1, {<}\kappa_1))$ and $\mathrm{CC}((\kappa_1, \kappa_0), (\kappa_0, {<}\kappa_0))$ are both proper.

With this remark in mind we note that we can replace clause 4 of Theorem 10.7 with the property that all $N \in S$ be *correct*, which we define to be the following condensation property:

10.8 Definition. Let

$$N \prec \langle H(\theta), \in, \{\kappa_2, \kappa_1, \kappa_0\}, \Delta, \{A, A'\}\rangle$$

be a structure such that $\mathrm{ot}(N \cap \kappa_2) = \kappa_1$, $\mathrm{ot}(N \cap \kappa_1) = \kappa_0$, and $|N \cap \kappa_0| < \kappa_0$. We will say that N is *correct* for $\mathrm{CC}((\kappa_1, \kappa_0), (\kappa_0, {<}\kappa_0))\restriction A$ iff whenever $\pi_N : N \to \bar{N}$ is the transitive collapse map, we have

$$\pi_N(\mathrm{CC}((\kappa_2, \kappa_1), (\kappa_1, {<}\kappa_1))\restriction A') = (\mathrm{CC}((\kappa_1, \kappa_0), (\kappa_0, {<}\kappa_0))\restriction A) \cap \bar{N}.$$

To make these results concrete we give a corollary. By choosing $n = 0$, the corollary provides a consistent statement about $H(\omega_4)$ that gives an inner model with a huge cardinal:

10.9 Corollary. *Suppose that $n \in \omega$ and there are $A \subseteq [\omega_{n+2}]^{\omega_{n+1}}$, $A' \subseteq [\omega_{n+3}]^{\omega_{n+2}}$, and $O' \in [\omega_{n+3}]^{\omega_{n+2}}$, such that for all structures $\mathfrak{A}$ expanding the structure $\langle H(\omega_{n+4}), \in, \Delta, \{A, A'\}\rangle$ there is an $N \prec \mathfrak{A}$:*

1. *$|N \cap \omega_{i+1}| = \omega_i$ for $i = n, n+1, n+2$, $\omega_n \subseteq N$, and $N \cap \omega_{n+2} \in A$,*

2. *$\pi_N(A') = A$,*

3. *The map $z \mapsto (z \cap \omega_{n+1}, \sup(z))$ is one-to-one on A,*

4. *$O' \in N$ and $N \cap \omega_{n+2} = \pi_N(O')$, and*

5. *N is correct for $\mathrm{CC}((\omega_{n+2}, \omega_{n+1}), (\omega_{n+1}, {<}\omega_{n+1}))\restriction A$.*

Then there is an inner model with a huge cardinal.

Note that if $n \geq 1$ in the previous two corollaries, then Lemma 4.34 gives a canonically well-ordered set A of measure one for the Chang ideal. This set is the collection of $N \cap \omega_{n+4}$ where $N \prec H(\omega_{n+4})$ is a Chang elementary substructure that has uniform cofinality bigger than ω. The issue in satisfying the hypotheses becomes determining where that set goes.

The following theorem gives a partial converse to Corollary 10.9:

10.10 Theorem. *If there is a 2-huge cardinal, then there is a generic extension satisfying* GCH *and the hypotheses of Corollary* 10.9.

A Martin's Maximum Result

It is a standard fact that if κ is supercompact, $\lambda > \kappa$ is regular, and $\langle S_\alpha : \alpha < \lambda\rangle$ is a partition of $\lambda \cap \mathrm{Cof}(\omega)$ then for all supercompact measures U on $[\lambda]^{<\kappa}$, the collection of $z \in [\lambda]^{<\kappa}$ such that

$$z \cap \kappa \in \kappa \text{ and for all } \alpha \in \lambda,\ \alpha \in z \text{ iff } S_\alpha \cap \sup(z) \text{ is stationary in} \sup(z)$$

belongs to U.

Assuming that $|H(\lambda)| = \lambda$ we can index the partition of $\lambda \cap \mathrm{Cof}(\omega)$ by elements of $H(\lambda)$, $\langle S_x : x \in H(\lambda)\rangle$, and hence we can state that for all supercompact measures U on $[H(\lambda)]^{<\kappa}$, the collection of $z \in [H(\lambda)]^{<\kappa}$ such that:

$$z \cap \kappa \in \kappa \text{ and for all } x \in H(\lambda),\ x \in z \text{ iff } S_x \cap \sup(z) \text{ is stationary in } \sup(z)$$

belongs to U.

By our earlier results, if κ is supercompact we can take a stationary subset of $[2^\lambda]^{<\kappa}$ with this property and construct from it with the nonstationary ideal as a predicate to get a model where κ is λ-supercompact. We note that the next theorem is a variation of Theorem 10 of [47].

10.11 Theorem. *Assume Martin's Maximum. Suppose that $\lambda \geq \omega_2$ and $H \subseteq H(\lambda)$ has cardinality λ and $\lambda \subseteq H$. Let $\langle S_x : x \in H\rangle$ be a partition of $\lambda \cap \mathrm{Cof}(\omega)$. Then there is a stationary subset $A \subseteq [H]^{<\omega_2}$ such that for all $N \in A$:*

$$x \in N \textit{ iff } S_x \textit{ is stationary in } \sup(N \cap \lambda).$$

Let κ be a supercompact cardinal and suppose that $\mathbb{P}$ is some standard iteration for creating a model $V[H]$ that satisfies Martin's Maximum. Using the techniques of Corollary 10.1, we can see that there is a set $A \in U$ where U is a supercompact filter on 2^λ, such that in $V[H]$, $L[\mathrm{NS}{\restriction}[2^\lambda]^{<\omega_2}, A] \models \omega_2^{V[H]}$ is λ-supercompact. This might be construed as evidence that a set A of the form produced in Theorem 10.11 could be used to construct an inner model with a supercompact cardinal. Concretely, assuming Martin's Maximum one can ask whether there is a set $A \subseteq H(\omega_4)$ such that the model $L[A, \mathrm{NS}{\restriction}[\omega_4]^{\omega_2}] \models \mathrm{ZFC} +$ "κ is κ^+-supercompact", where $\kappa = \omega_2^V$?

10.3. Consistency Hierarchies Among Ideals

While it is not known how the consistency strength of saturated n-huge ideals compares to the hierarchies of consistency strength of conventional large cardinals, one can prove that they form a hierarchy of consistency strength among themselves. We give a sample result from [35] (Theorem 15).

10.12 Theorem. *Suppose that κ is a successor of a regular cardinal, $\kappa \geq \omega_2$ and there is a κ-complete, κ^+-saturated (resp. κ-centered, or κ-dense) ideal on $[\kappa^{+n+1}]^{\kappa^{+n}}$ for some $n \in \omega$. There is a transitive set model N of* ZFC *such that $\kappa^{+n} \subseteq N$ and $N \models$ "there is a κ-complete, κ^+-saturated (resp. κ-centered, or κ-dense) ideal on $[\kappa^{+n}]^{\kappa^{+n-1}}$."*

Note that this is a consistency strength hierarchy along one of the three axes determining a generic large cardinal, namely the closure of the generic ultrapower M. It is not known how to find hierarchies that involve different axes. For example the following is a typical open question along these lines:

> Suppose that there is an $\aleph_3$-complete, normal, fine, precipitous ideal on $[\omega_5]^{\omega_4}$ concentrating on the collection of z such that the order type of $z \cap \omega_4$ is ω_3. Is it consistent that there is an $\aleph_4$-saturated ideal on ω_3?

11. Ideals as Axioms

In this section we discuss extending ZFC by asserting the existence of generic elementary embeddings. The attempt is to put the discussion in the context of current ideas about methods for evaluating axiom systems. This necessitates terse and incomplete summaries of these ideas. The author wrote a more complete version of this section in [38], but the mathematical situation has changed somewhat since that article was published.

To be explicit from the outset of the discussion, in the collection of axioms that derive from combinatorial assumptions on ideals, there is an anomaly that does not fit the general pattern: the assertion that NS_{ω_1} is $\aleph_2$-saturated. This assumption, combined with the assertion of conventional large cardinals, implies CH fails and that $P(\omega_1)$ is very close to $L(\mathbb{R})$. This situation, and deep elaborations of the situation, are discussed extensively in Woodin's work [127–129].[113]

One might speculate that the assumption NS_{ω_1} is $\aleph_2$-saturated is less analogous to conventional large cardinals than are the "generalized large cardinal" assumptions described in the next section that are derived from the "three parameters".[114] Some slight support for this view comes from the

[113] See also Dehornoy's discussion [19] of Woodin's work.
[114] It is not known to the author how to state the saturation of the nonstationary ideal on ω_1 in a non-circular way using the three parameters.

fact that it is not known if it is possible that NS_{ω_1} be $\aleph_2$-saturated and also be the induced ideal from a conventional large cardinal.[115]

It also seems worthwhile pointing out again explicitly that there are no known generalizations of the assumption that NS_{ω_1} is $\aleph_2$-saturated to other cardinals. By Corollary 6.11, it is inconsistent that NS_{ω_2} be $\aleph_3$-saturated. If one assumes that "NS_{ω_2} restricted to $\mathrm{Cof}(\omega_1)$ is $\aleph_3$-saturated" (an assumption not known to be consistent relative to large cardinals) then Theorem 5.20 implies that $\Theta^{L(\mathbb{R})} < \omega_2$, and hence NS_{ω_1} is not $\aleph_2$-saturated. Thus the natural generalizations of "NS_{ω_1} is $\aleph_2$-saturated" appear to be either outright inconsistent or inconsistent with the assumption itself.

11.1. Generalized Large Cardinals

As has been heralded throughout this chapter, generic elementary embeddings are rather straightforward generalizations of large cardinals. We now focus and elaborate on the connections.

In [113], essentially all conventional large cardinal assumptions[116] are shown to be equivalent to the assertion of the existence of definable elementary embeddings $j : N \to M$, where N and M are transitive classes. The strength of these assertions is determined by two parameters, or axes:

W: Where j sends the ordinals.

Cl: How big N and M are.

Typically, the more one asserts about what j does to the ordinals and the larger N and M are, the stronger the axiom. A remarkable feature of this collection is a form of convexity: asserting the existence of one such j with suitable parameters does not contradict the assertion of other j's that have strengthened the parameters along a fixed given axis.[117] Moreover, by suitable strengthening along the axis, the axioms form a hierarchy both in outright strength and in consistency strength.

Generic large cardinals are straightforward generalizations of large cardinals in that they assert the existence of elementary embeddings of N to M; however, these elementary embeddings are only required to exist in generic extensions of the universe V. As such they introduce a third parameter of potential strength: the nature of the forcing. Thus the three parameters are now:

W: Where j sends the ordinals.

Cl: How big N and M are.

F: The nature of the forcing.

---

[115] Explicitly: It is not known how to force over an arbitrary model containing a conventional large cardinal, such as a huge cardinal, and make the nonstationary ideal on ω_1 both be $\aleph_2$-saturated and be the induced ideal from the large cardinal embedding.

[116] In consistency strength there is a cofinal collection of large cardinals of this form.

[117] Subject of course to the Kunen limitations.

As an informal working definition, we take a "generalized large cardinal axiom" to mean an axiom whose statement posits an elementary embedding or system of elementary embeddings by specifying where ordinals go, the closure of N and M, and the isomorphism type of the Boolean algebra used to force the generic embedding.[118]

By adjusting the parameters "W", "Cl" and "F", one gets a cofinal set of generalized large cardinal axioms. These are often studied by fixing one of the parameters and taking the "level set" determined by that parameter. For example, one studies $\aleph_1$-dense ideals on:

$$\omega_1,\ \omega_2,\ [\omega_2]^{\omega_1}, \ldots .$$

In Sect. 6, we showed that one cannot adjust these parameters arbitrarily: there are limitations analogous to the "Kunen contradiction" for large cardinals, as well as limitations on the additional parameter of which forcing can yield elementary embeddings with a given amount of closure.

11.2. Flies in the Ointment

The assertion of a collection Σ of axioms has as a meta-assumption the assertion that Σ is consistent.

Conventional large cardinal axioms have a well-ordered spine that give a cofinal collection of assumptions that are believed to be consistent. Since this collection of axioms is linearly ordered, a finite set of axioms that are individually consistent are mutually consistent. This is not the case with generalized large cardinals, due to the additional axis "F".

Most, although not all, consistency results for generalized large cardinal properties show the consistency of an ideal with a particular property on a particular cardinal. Since the generalized large cardinals are not linearly ordered in strength this leaves open the possibility of mutual inconsistency.

This possibility is unfortunately realized,[119] though examples of this type are remarkably rare at the time of writing.[120] The only example known involves the partition relation

$$\binom{\omega_2}{\omega_1} \to \binom{\omega}{\omega_1}_2 .$$

Namely, as discussed in Remark 5.39, if there is a huge cardinal then there is a forcing extension in which there is an $(\aleph_2, \aleph_2, \aleph_0)$-saturated ideal [83] and another one in which there is an ideal $[\lambda]^{\omega_1}$ with quotient isomorphic to

[118] This mechanism appears to define away the anomaly of NS_{ω_1}.

[119] See Corollary 5.38.

[120] As this chapter went to press Woodin discovered more mutually inconsistent generalized large cardinal axioms. At this very moment, it is not known if there is a mutually inconsistent pair of axioms that are the result of varying the parameters along just one of the axes "W", "Cl" or "F".

$\mathrm{Col}(\omega, {<}\lambda)$. The former implies the partition relation and the latter implies its failure.

This same example shows that some particularly attractive sounding axioms are inconsistent. For example, it is not consistent to have the assumption:

> For all $\aleph_2$-c.c. Boolean algebras $\mathbb{B}$ of cardinality less than or equal to 2^{ω_2} that collapse ω_1, there is a normal fine ideal I on $[\omega_2]^{\omega_1}$ such that $P([\omega_2]^{\omega_1})/I \cong \mathbb{B}$.

While the counterexample to mutual consistency is certainly very troubling, it may not be fatal to the program of looking to generalized large cardinals for true extensions of ZFC. The general "picture" given by the axioms is remarkably coherent; conventional large cardinals actually imply the existence of generalized large cardinal embeddings with small critical points and the "mutual inconsistency phenomenon" seems rare. At the moment the question "which generalized large cardinals are true" seems to be narrower, more focussed and less arbitrary than the broader question "which combinatorial and cardinal arithmetic statements are true".

It is also a possibility, albeit somewhat unlikely in the author's opinion, that the axiom "there is a countably complete, normal, fine, $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$" is inconsistent.[121] The axiom collection "for all $n \in \omega \setminus \{0\}$ there is a countably complete, normal, fine $\aleph_1$-dense ideal on $[\omega_{n+1}]^{\omega_n}$" together with the assertions that the ω_n's are generically supercompact answer many classical set theoretic questions. While this or any particular theory may be inconsistent, it does not negate the more general point that generalized large cardinals provide a well-motivated and systematic framework for the development of new axioms that are effective in settling classical independent questions. This framework fits well into traditional Gödelian ideas of axiom development: reflection and generalization. In the author's opinion, the question is not *whether* generalized large cardinals are relevant, but *which* generalized large cardinal axioms are true.

Defining the boundaries of the region of consistency for generalized large cardinals is likely to be a topic of research for some time. The two facets of this research consist in proving relative consistency results for generalized large cardinals from conventional large cardinal axioms and further exploring limitations on what axioms one can consistently assert.

It is certain that there are imaginative versions of these axioms that still have not been considered; moreover these will have interesting and far-reaching consequences. In the course of exploring the possibilities for these axioms it is inconceivable that there will not be more limitations discovered on what generic large cardinals can exist. This should not be viewed as a disaster. Indeed it can be argued that the axiomaticians are being too cautious if they rarely consider axioms that turn out to be inconsistent.

---

[121] This property is not known to be consistent relative to conventional large cardinals.

11.3. First-Order Statements in the Language of ZFC

A boundary condition for extending the axioms of ZFC is that the extensions be able to be expressed in a language compatible with the first-order language expressing ZFC. This condition is imposed for the same epistemically convenient reasons that first-order logic is used to state the axioms of ZFC.

A priori, a statement of the form "there is an elementary embedding $j : V \to M, \ldots$" is not a statement in the first-order language of ZFC. It asserts the existence of a proper class, it appears to require truth predicates and so forth. As generalized large cardinals appear to assert as well the existence of virtual sets in a proper extension of the universe, the situation appears even more critical.

In [113] for example, this obstacle was overcome for conventional large cardinals by finding first-order statements in the language of set theory that were provably equivalent by metamathematical methods to the intended second-order axiom. For example, the assertion that κ is supercompact is equivalent to the assertion that for all $\lambda \geq \kappa$ there is a normal, fine, κ-complete ultrafilter on $[\lambda]^{<\kappa}$.

The language of ideals, together with the mechanics of forcing provide the same kind of vehicle for stating generalized large cardinal axioms in the language of set theory. Assuming the existence of a proper class of Woodin cardinals, Burke's Proposition 9.44 shows that every countably complete ideal is pre-precipitous. More directly: the existence of an elementary embedding $j : V \to M \subseteq V[G]$ where $G \subseteq \mathbb{P}$ is generic and $j``\lambda \in M$ is easily seen to be equivalent to the existence of a $\mathbb{P}$-term for an ultrafilter $\dot{U} \subseteq P(P(\lambda))^V$ that is normal for regressive functions in V and fine and is such that there is no descending ω-sequence of U-equivalence classes of functions from V. The idea of an *induced ideal* allows us to restate this combinatorially as a normal, fine, precipitous ideal I on $P(\lambda)$ such that the quotient algebra $P(P(\lambda))/I$ inherits some of the properties of the original partial ordering $\mathbb{P}$. Finally, moving along the "F" axis in the direction of greater strength, the saturation properties of ideals play exactly the same role for generalized large cardinals as ultrafilters do for conventional large cardinals.

11.4. Some Examples of Axioms

In this subsection we name some examples of axioms. Many of the axioms have strong consequences but have not, as yet, been shown to be consistent from conventional large cardinals.

11.1 Definition. A cardinal $\kappa = \mu^+$ is *minimally generically n-huge* iff there is a normal, fine, κ-complete ideal I such that $P([\kappa^{+n}]^{\kappa^{+n-1}})/I$ has a dense set isomorphic to $\mathrm{Col}(\mu, \kappa)$.

The "n-huge" is there because if $j : V \to M \subseteq V[G]$ is the generic embedding, then $M^{j^n(\kappa)} \cap V[G] \subseteq M$. The quotient algebra $\mathrm{Col}(\mu, \kappa)$ is in many ways the simplest quotient, hence "minimal".[122]

11.2 Definition. A successor cardinal $\kappa = \mu^+$, where μ is regular, is *generically supercompact* iff for all $\lambda > \kappa$, and all generic $G \subseteq \mathrm{Col}(\mu, \lambda)$, there is a generic elementary embedding $j : V \to M \subseteq V[G]$ with critical point κ such that $j(\kappa) > \lambda$, $j``\lambda \in M$, and $\lambda > \sup(j``\lambda)$.

Again the name comes from the closure of the embedding and the quotient algebra is asked to be simple.

11.3 Definition. The *Axiom of Resemblance* is the statement that for all regular $\kappa < \lambda$, $n \in \omega$, there is a generic elementary embedding $j : V \to M$ such that $j(\kappa^{+i}) = \lambda^{+i}$ for all $i < n$ and $j``\kappa^{+n} \in M$.

This axiom suggests that the regular cardinals are in some weak sense, indiscernible. It suffices to show many instances of Chang's Conjecture and thus, to transfer instances of GCH from cardinal to cardinal.

The author would be remiss if he did not mention the particularly interesting, if slightly technical axiom "indestructible generic supercompactness". This axiom was discussed by Cummings in [17]:

11.4 Definition. Let μ be a regular cardinal and $\kappa = \mu^+$. Then κ is *indestructibly generically supercompact* iff for all $<\kappa$-directed closed partial orderings $\mathbb{R}$ and all generic $G \subseteq \mathbb{R}$, regular $\lambda > \kappa$, there is a $\tilde{\mathbb{R}} \in V[G]$ that is μ-closed such that if $H \subseteq \tilde{\mathbb{R}}$ is $V[G]$ generic, then there is a

$$j : V[G] \to M \subseteq V[G * H]$$

with:

1. $\mathrm{crit}(j) = \kappa$,
2. $j(\kappa) > \lambda$,
3. $j``\lambda \in M$,
4. $\sup(j``\lambda) < j(\lambda)$, and
5. $M \models \mathrm{cf}(\lambda) = \mu$.

This axiom holds when an indestructible supercompact cardinal[123] is collapsed to be the successor of μ. It plays an important role in the interplay between generalized large cardinal axioms and combinatorial properties of successors of singular cardinals.

---

[122] As this article went to press, Woodin showed that it is inconsistent to have ω_1 minimally generically 3-huge, and simultaneously for ω_3 to be minimally generically 1-huge.

[123] That is, κ is supercompact and remains so after any forcing extension via a $<\kappa$-directed closed forcing. Laver [82] showed how to make a supercompact cardinal indestructible, and his construction is given in Cummings's chapter in this Handbook. We applied this concept after Theorem 8.42.

11.5. Coherence of Theories, Hierarchies of Strength and Predictions

The coherence and predictive value of axioms has been considered relevant to the evaluation of axioms by several commentators, notably Gödel [57] and Martin [92].

Predictions

The notion of prediction used here requires some explication.[124] Given a sequence of axiom systems $\Sigma_0 \subseteq \Sigma_1 \subseteq \Sigma_2 \cdots$, the predictive capacity of the sequence can mean at least two things:

A. There are consequences σ of Σ_i are that are proved first (temporally) by some Σ_j with $j > i$, or perhaps have significantly easier proofs in Σ_j than in Σ_i.

B. There is mathematical structure uncovered in the study of Σ_j that has analogues in the theory Σ_i for $i < j$.

While these are necessarily vague and perhaps artificial formulations, some observations can be made. The most trivial remark is that the collections of axioms systems we are studying are often not linearly ordered by inclusion. For coherent collections of axiom systems, the theories do form a directed system. For the purposes of calibration of strength, it seems to this author that it suffices to have a directed collection of axiom systems that has a linearly ordered cofinal subcollection.

A more difficult problem is that both of these criteria are sociological in nature; the order of discovery of consequences structure depends heavily on human events that can proceed in arbitrary and capricious ways. This is particularly evident if, as is usually in axiomatic discussions, the theories Σ_i with small i have a much longer history of historical study than the Σ_j for large j. Concrete examples of this are when Σ_0 may be the theory of Peano Arithmetic, second-order number theory, or ZFC.

Perhaps the most challenging problem is weighing the significance of purported examples of "predictions". It is clearly possible to create artificial "predictions" by concocting consequences of Σ_0 that no previous investigator would have bothered to look at. A type of prediction with perhaps more weight is that many families of axioms, including generalized large cardinals, are determined by varying parameters in a fixed conceptual framework. The axioms with larger/stronger parameters can then be said to "predict" in some sense the axioms with smaller/weaker parameters.

A less artificial kind of prediction is when Σ_{i+1} "predicts" the consistency of Σ_i. Indeed the linearity of the consistency hierarchy for conventional large

[124] The exposition given here is due the author. This terse account does not reflect the views of Martin or Gödel.

cardinals has often been held to be one of its main attributes, particularly in regard to the calibration of strength of properties independent of ZFC.

In the case of generalized large cardinals, issues of consistency strength are largely open, except for the weakest of the cardinals. There are however examples of these hierarchies among the stronger axioms. A notable example of this is Theorem 10.12, where it is shown that the consistency of generically n-huge cardinals follows from the existence of generically $(n+1)$-huge cardinals. The author suspects that many more such results can be proved with sufficient effort and attention.

We now turn to "predictions" in the more commonly used meaning. An oft-cited example of such a "prediction" made by large cardinals involves the structural feature of the subsets of the real numbers known as the Wadge hierarchy. This hierarchy of complexity of sets of real numbers was first shown to have the correct structure using large cardinals [92]. This correctly predicted the analogous structure for Borel sets of reals, which is a theorem of ZFC.

There are such examples in the realm of generalized large cardinals as well. The first proof of Silver's theorem that "if GCH holds below $\aleph_{\omega_1}$ then it holds at $\aleph_{\omega_1}$" was given by Magidor, under the assumption that there was a precipitous ideal on ω_1.[125] Indeed the proof assuming the existence of a precipitous ideal is so short and elegant we give it here:

> Let $\alpha = \omega_1^V$, $\kappa = \aleph_{\omega_1}^V$. Let I be a precipitous ideal on ω_1. Then $|P(\omega_1)| < \aleph_\omega$ so forcing with $P(\omega_1)/I$ preserves all cardinals above $\aleph_\omega$. Let G be generic, and $j : V \to M \subseteq V[G]$ be the generic elementary embedding.
>
> For all $f \in (\kappa^{\omega_1})^V$, $j(f)\restriction\alpha \in M$. Hence $V[G] \models |\kappa^\alpha|^M \geq |\kappa^\alpha|^V$. Since $V[G] \models \alpha < \omega_1$ and $\kappa < \aleph_{\omega_1}$, we know $V[G] \models |\kappa^\alpha|^V \leq \kappa^+$. Since $(\kappa^+)^{V[G]} = (\kappa^+)^V$ we must have $V \models |\kappa^\alpha| \leq \kappa^+$.

This example appears to satisfy the criterion for a Gödel-style prediction: the result was proved first under the assumption of the existence of a precipitous ideal on ω_1, and then in ZFC. The proof, assuming the existence of a precipitous ideal is elegant and much shorter than the ZFC proof.

An example that carries perhaps less weight as it is internal to the theory of generalized large cardinals is the postulate that there is a normal, fine, $\aleph_n$-complete, $\aleph_\omega$-saturated ideal on $[\aleph_\omega]^{\aleph_\omega}$. In [35] there is an argument of Woodin that the existence of such an ideal implies $2^{\aleph_0} \geq \omega_n$. Indeed, if ω_1 is generically n-huge with quotient $\mathrm{Col}(\omega, \omega_1)$, then there can be no such ideal.

---

125 The author relates this anecdote from personal interaction with Magidor, who stated that this proof preceded Silver's [109] by several weeks. Other contemporary accounts state that the initial assumption was the existence of a non-regular ultrafilter on ω_1 rather than a precipitous ideal. Indeed the key combinatorial element was a result of Kanamori that there is a "least" function $f : \omega_1 \to \omega_1$ relative to a non-regular ultrafilter; i.e. a non-regular ultrafilter is incompressible. Silver credits Kanamori and Magidor in his paper.

Viewing this as a prediction, it can be argued that Theorem 6.9,[126] which shows in ZFC that there are no such ideals, is confirmation of the prediction.

The author points out that there are numerous cases in this chapter where he was able to show consequences of rather strong ideal axioms[127] that Woodin was later able to show from weaker assumptions. These are also "predictions", though not of ZFC results. Indeed Theorem 5.42, a very early result showing that all sets in $L(\mathbb{R})$ are Lebesgue measurable, preceded the result that "CH together with the existence of an $\aleph_1$-dense ideal on ω_1 implies $\mathrm{AD}^{L(\mathbb{R})}$" by more than 10 years.

Gradations of Consequence

A more subtle type coherence comes in the form of *gradations of consequence.* This idea is that among a coherent family of axioms indexed by a parameter, stronger axioms should prove genuinely stronger natural consequences. This is a strange kind of "prediction", but it has the advantage that it is not related to accidents of mathematical history. Here are some examples from generalized large cardinals.

In Example 5.7, it is shown that if there is an $\aleph_2$-complete ideal I on ω_2 such that $P(\omega_2)/I$ has a dense countably closed subset, then CH holds. In a universe with ambient large cardinals, Theorem 5.20 shows that an $\aleph_2$-complete ideal I on ω_2 that has the weaker property that it concentrates on the approachable ordinals and that $P(\omega_2)/I$ is reasonable, has the weaker consequence that $\Theta^{L(\mathbb{R})} < \omega_2$.

In Theorem 5.9, Woodin showed that if there is a uniform, countably complete $\aleph_1$-dense ideal on ω_2, then CH holds. It follows from Theorem 7.14 that if you add at least ω_2 Cohen reals to a model where there is an $\aleph_1$-dense ideal on ω_2, one gets a model with an $\aleph_2$-saturated ideal on ω_2. Since CH fails in the resulting model, the axiom that there is an $\aleph_1$-dense ideal on ω_2 is strictly stronger than the axiom that there is an $\aleph_2$-saturated ideal on ω_2. Theorem 5.21 shows that the weaker axiom still proves a vestige of CH. It shows that if there is a uniform, countably complete, $\aleph_2$-saturated ideal on ω_2, then $\Theta < \omega_2$. Thus a weaker axiom has a weaker consequence.

Another example of "gradation of consequences" has to do with partition properties. In Sect. 5.6, it is shown that as one passes from normal, κ-complete

1. prime,
2. κ-dense,
3. $(\kappa^+, \kappa^+, \kappa)$-saturated

ideals, one gets the partition properties:

[126] Proved several years later.

[127] Such as CH or the existence of Suslin trees from $\aleph_1$-dense ideals on $[\omega_2]^{\omega_1}$.

1. $\kappa^+ \to (\rho)^2_m$ for all $\rho < \Omega(\kappa)$,
2. $\kappa^+ \to (\kappa^2 + 1)^2_2$,
3. $\kappa^+ \to (\kappa \times 2 + 1)^2_2$,

respectively. While these results have not been shown to be optimal, they nonetheless exhibit the kind of coherence expected from genuine axiom systems.

Methodological Predictions

We mention very briefly yet another possible type of "prediction". The use of "prediction" by Gödel or Martin usually is taken as a prediction of results; e.g. a number-theoretic fact proved using infinitary tools that is verified by a proof in Peano Arithmetic. One can also see predictions in light of methods developed using strong assumptions that can be specialized and applied with weaker assumptions. The fact that the strong assumptions suggested methods that were fruitful in weaker theory could be construed as a kind of inductive evidence for the stronger theory. The Axiom of Determinacy has this type of flavor: it can be specialized to $L(\mathbb{R})$, or (in ZFC) to Borel sets.

This type of "prediction" has occurred in more subtle ways with generic elementary embeddings. In [35] it was first shown that the existence of an $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$ implies that every set in $L(\mathbb{R})$ is Lebesgue measurable, has the property of Baire and the partition property holds in $L(\mathbb{R})$. Later work [47] showed that supercompact large cardinals imply the existence of generic large cardinals sufficiently strong to show the same consequences. Woodin later showed that the existence of sufficiently many Woodin cardinals suffices to show the existence of the generic embeddings needed to prove the same results.

This may be interpreted as follows: the method of generic elementary embeddings can be adapted from their use with the very strong assumption of the existence of an $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$, to more standard contexts of conventional large cardinals and still have some of the same consequences.

Thus: from generic large cardinals one shows certain consequences; these consequences can then be shown to follow from conventional large cardinals using the vehicle of generic large cardinals.

11.6. A Final Relevant Issue

Many authors who propose axioms claim that their axioms are, in some sense, "maximality principles". Unlike other heuristics for the development of axioms (such as reflection, or elementary embedding principles) the notion of a "maximality principle" does not seem sufficiently precise to allow general agreement on what qualifies. For some, CH limits how many reals there are. For others, the failure of CH limits what subsets of ω_1 exist.

The situation is complicated by the existence of models M and N satisfying ZFC such that:

1. M and N have the same cardinals,
2. M and N have the same real numbers,
3. CH holds in M and fails in N.

Of course, M and N differ on $P(\omega_1)$.

A very weak related concept might be the following: ϕ is *not limiting* if any model containing sufficiently large cardinals has a forcing extension in which ϕ is true. Ideas like this have been informally discussed in set theory for some time. Indeed Woodin's work on the Ω-conjecture deals, in part, with exactly these issues. The author conjectures that most generalized large cardinal axioms are not limiting.

11.7. Conclusion

Generalized large cardinal axioms form a natural family of assumptions that are very similar in nature to conventional large cardinals. There are problematic aspects to this generalization due to examples of mutually contradictory ideal assumptions. Nonetheless, even among the contradictory examples, there is a general picture that settles most important examples of independent statements in set theory.

The arguments involving intuitive or aesthetic judgments and prediction or confirmation that have been advanced for large cardinals seem to apply as well to generalized large cardinals; there does not seem to be an abstract conceptual basis to distinguish between the narrower family of axioms and its generalization. Indeed large cardinals[128] *imply* the existence of generic elementary embeddings with small critical points such as ω_1.

The theory is currently immature and it is expected that there will be many surprises before the story is completely told. The author speculates that this avenue is likely to eventually provide reasonable solutions to many of the puzzles of independence in set theory.

12. Open Questions

Some open problems are given in this section. They are organized roughly in the order that material is presented in the paper, rather than in any order of significance. They range from technical questions that the author was curious about to questions that may be fundamental set theoretic problems. None of the problems are guaranteed to be hard or deep. The theory is so underdeveloped that virtually all theorems contain hypotheses whose necessity has not been validated by appropriate examples. The emphasis has been

[128] Via the mechanism of stationary tower forcing.

on enumerating novel problems rather than restating well-known problems such as the question of the consistency of the property: "$\aleph_\omega$ is Jonsson". The reader can thus be trusted to create his or her own problems.

1. What is the consistency strength of "Every function $f : \omega_n \to \omega_n$ is bounded by a canonical function modulo the (strongly) nonstationary ideal on $P(\omega_n)$"? What if we only require that every function is bounded by the nonstationary ideal restricted to ω_n? The nonstationary ideal restricted to $\omega_n \cap \mathrm{Cof}(\omega_{n-1})$?

2. Is there an example of a $Z \subseteq P(X)$ and a normal, fine, countably complete ideal on Z that is $|Z|^+$-saturated, but not $|X|^+$-saturated?

3. What can one say about P-, Q-, and selective ideals on $[\lambda]^{<\kappa}$ or $[\lambda]^\kappa$? (See Proposition 2.7.)

4. In spite of the close ties with the nonstationary ideal, proper forcing and Hungarian combinatorics, almost nothing is known about the various Chang's Conjectures. The most basic consistency results are open, for example, it is not known if it is consistent that $(\aleph_4, \aleph_1) \twoheadrightarrow (\aleph_3, \aleph_0)$. Assuming that $2^{\aleph_0} < \aleph_\omega$, Silver showed that the cardinal $\aleph_\omega$ is Jónsson iff there is an infinite subsequence $\langle \kappa_n : n \in \omega\rangle$ of the $\aleph_n$'s such that the infinitary Chang conjecture of the form $(\dots, \kappa_n, \kappa_{n-1}, \dots, \kappa_1) \rightarrow$ $\rightarrow (\dots, \kappa_{n-1}, \kappa_{n-2}, \dots, \kappa_0)$ holds. It is not known how to get such a sequence of length 4.

5. Essentially equivalent questions are whether there can be countably complete, normal, fine, precipitous ideals on $[\omega_n]^{\omega_m}$. The positive sets for such ideals determine instances of Chang's Conjecture.

6. Is it consistent that there is a normal, fine, countably complete ideal on $[\aleph_{\omega+1}]^{\omega_n}$ for $n \geq 2$? The existence of such an ideal is equivalent to the statement that $(\aleph_{\omega+1}, \aleph_\omega) \twoheadrightarrow (\aleph_n, \aleph_{n-1})$. Cummings has made some progress on this problem in a negative direction.

7. Are any global Chang's Conjecture type properties consistent? For example is it consistent that for all successor μ and all regular $\kappa < \mu$ one has $(\mu^+, \mu) \twoheadrightarrow (\kappa^+, \kappa)$?

8. Is every κ-complete, cardinal preserving ideal on a regular cardinal κ precipitous? One could also consider a generalization of this to normal, fine, countably complete ideals on κ. (Note that this is known under GCH and various other assumptions.)

9. Does the existence of a precipitous ideal on ω_1 imply the existence of a normal precipitous ideal on ω_1? For arbitrary κ? For ideals on $P(X)$?

10. As noted in the text there are very interesting consequences when a natural ideal has nice generic embeddings. For most natural ideals, the

possible generic ultrapower properties have not been explored. We note here just some of the possible questions.

Can I be precipitous when I is:

(a) The ideal of null sets for Lebesgue measure and $Z = P(\mathbb{R})$?
(b) The ideal of meager sets and $Z = P(\mathbb{R})$?
(c) $I[\lambda]$ for a regular cardinal $\lambda \geq \omega_2$?
(d) $I_d(\lambda, \kappa)$ (see Example 3.17)?
(e) the weak diamond ideal on ω_1?
(f) any of the uniformization ideals?

Some of these ideals are known not to be saturated, but others are not. However, other results are possible. For example, the algebra $P(\mathbb{R})/\{\text{null sets}\}$ is never saturated. It seems possible that it could be densely often c.c.c. Similar possibilities exist for the meager ideal. The saturation possibilities of the weak diamond and uniformization ideals are not known.

11. The author conjectures that for all normal, $\aleph_2$-complete, $\aleph_3$-saturated ideals J on ω_2:

    (a) $I_d(\omega_2, \omega_1) \subseteq J$, and
    (b) $I[\omega_2] \nsubseteq J$ for such a J.

    In particular, there is a set in $I[\omega_2] \cap \breve{J}$. These remarks are not intended to be special to ω_2: suppose that I is a normal, κ-complete, κ^+-saturated ideal on κ. Is there a set $A \in I[\kappa]$ that belongs to $\breve{I}$?

12. Another conjecture in the same spirit is that a normal, fine, ideal I on $P(Z)$ with $Z \subseteq H(\theta)$ that is $|Z|^+$-saturated and $\mathrm{comp}(I) = \omega_2$ must concentrate on $\mathrm{IA}(\mathrm{Cof}(\omega_1))$.[129] This may be the correct generalization of Shelah's theorem that a saturated ideal on ω_2 must concentrate on $\mathrm{Cof}(\omega_1)$. In this problem ω_2 can be replaced by any μ^+ and ω_1 by μ for any regular cardinal μ.

13. Suppose that J is an ideal on $Z \subseteq P(\kappa^{+(n+1)})$, and I is the projected ideal on the projection of Z to $Z' \subseteq P(\kappa^{+n})$. Suppose that the canonical homomorphism from $P(Z')/I$ to $P(Z)/J$ is a regular embedding. Is I $\kappa^{+(n+1)}$-saturated?

14. Is "presaturation" closed under projections?

15. Can there be countably complete, $\aleph_1$-dense, uniform ideals on ω_n for $n > 2$? What are the possible quotient algebras of uniform, countably complete ideals on ω_n?

[129] $\mathrm{IA}(\mathrm{Cof}(\omega_1))$ is the class of internally approachable structures of cofinality ω_1.

16. Is it consistent that there is a uniform ultrafilter on ω_3 such that ω^{ω_3}/U has cardinality ω_3? Is it consistent that there is a uniform ultrafilter U on $\aleph_{\omega+1}$ such that $\omega^{\aleph_{\omega+1}}/U$ has cardinality $\aleph_{\omega+1}$? Give a characterization of the possible cardinalities of ultrapowers.

17. Using the techniques of [36], the previous question could be answered by showing that sufficiently long sequences of consecutive cardinals can carry very strongly layered ideals. A typical question here is whether it is consistent to have an $\aleph_1$-dense ideal on ω_1 and strongly layered ideals on ω_2 and ω_3. A closely related question is whether it is consistent to have three consecutive cardinals carry very strongly layered ideals.

18. Can there be a cardinal $\kappa = \mu^+ \geq \omega_2$ such that the nonstationary ideal on κ restricted to $\mathrm{Cof}(\mu)$ is κ^+-saturated? Is it consistent for the nonstationary ideal on ω_2 restricted to $\mathrm{Cof}(\omega_1)$ to be $\aleph_3$-saturated?

19. Is there a large cardinal axiom such that forcing over an arbitrary model of that axiom makes an induced ideal be the nonstationary ideal on ω_1 and simultaneously $\aleph_2$-saturated in the generic extension?

20. Conjecture: If every ω_n carries a very strongly layered ideal, then $\aleph_\omega$ is Jónsson.

21. Is it consistent for there to be a countably complete, normal, fine, $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$? $[\omega_n]^{\omega_{n-1}}$? These questions are particularly relevant as these ideal properties are a “fly in the ointment” for generalized large cardinal axioms.

22. Find other hierarchies of consistency strength among ideal axioms similar to those described in Theorem 10.12. What are the relations among the various “axes” of the three parameters?

    As a sample of this kind of problem one might ask: from the assumption that there is an $\aleph_3$-complete, normal, fine precipitous ideal on $[\omega_5]^{\omega_4}$ concentrating on the collection of z such that the order type of $z \cap \omega_4$ is ω_3, can one show that it is consistent that there is an $\aleph_4$-saturated ideal on ω_3?

23. Given an example of a model of set theory with an ideal I on $P(Z)$ with $Z \subseteq P(X)$, and a set Y with $|Y| > |Z|$ such that the closed unbounded filter on $PP(Y)$ conditioned on I is not the nonstationary ideal restricted to a single set.

24. Which ideal assumptions imply the existence of Suslin trees on ω_2?

25. We note that if I is a normal, κ-complete, κ^+-saturated ideal on κ, then there is no $\diamondsuit(I)$ sequence (i.e. a $\diamondsuit$-sequence that guesses every subset of κ on an I-positive set). However, the following is open: Does CH together with the existence a normal, countably complete, $\aleph_1$-dense,

ideal on ω_1 imply $\diamondsuit_{\omega_1}$? Is there an ideal assumption on ω_2 that implies $\diamondsuit_{\omega_2}(\mathrm{Cof}(\omega_1))$? Does the existence of a normal, fine, countably complete $\aleph_1$-dense ideal on $[\omega_2]^{\omega_1}$ imply $\diamondsuit_{\omega_1}$?

26. Give a direct proof of $\mathrm{AD}^{L(\mathbb{R})}$ from ideal hypotheses.

27. Does the existence of an $\aleph_2$-complete, $\aleph_2$-dense ideal on ω_3 imply that $2^{\omega_1} = \omega_2$?

28. Does some generic supercompactness property of all of the ω_n's imply that $\aleph_{\omega+1} \in I[\aleph_{\omega+1}]$? (or even just full stationary set reflection?)

29. (From [55]) Can there be a non-trivial generic elementary embedding in a forcing extension by a Boolean algebra that is countably generated and proper?

30. (From [55]) Can there be a κ complete ideal on κ, that whose quotient is isomorphic to a forcing of size κ and is α-c.c. for some $\alpha < \kappa$?

31. Can there be a normal $\aleph_2$-complete ideal $I \subseteq P(\omega_2)$ that is $\aleph_3$-saturated in every $\aleph_2$-c.c. forcing extension? Other κ?

32. Can there be a normal, fine, κ-complete, κ-saturated ideal on $[\lambda]^\kappa$ for a non-huge κ? For a non-measurable κ?

33. Can the weakly compact filter on a cardinal κ be κ^+-saturated?

34. Recall the definition of the "forbidden intervals" $\mathcal{C}_\kappa$ (see Definition 6.25). Is there a model of set theory such that for all regular uncountable cardinals κ and all $\lambda \notin \mathcal{C}_\kappa$, there is a κ-complete, uniform, κ^+-saturated ideal on λ? (See Proposition 6.26 and Theorem 7.59.)

35. While the nonstationary ideal on $[\lambda]^{<\kappa}$ cannot be λ^+-saturated, the local saturation properties are relatively unexplored, the results of Gitik and Krueger being the only positive consistency results.

36. There are many open problems about mutually stationary sequences of sets. Probably the easiest to state is: Is there a mutually stationary sequence of sets $\langle S_n \subseteq \omega_n : n \in \omega \setminus k\rangle$ such that whenever $S_n = T_n^0 \cup T_n^1$ with T_n^0 and T_n^1 disjoint, either $\langle T_n^0 : n \in \omega \setminus k\rangle$ or $\langle T_n^1 : n \in \omega \setminus k\rangle$ is not mutually stationary?

37. Explore the properties of natural towers different from the usual stationary towers. Typical problems might be: give an example of a model with an inaccessible cardinal δ such that a stationary tower of height δ concentrating on $\mathrm{IA}(\mathrm{Cof}(\omega_1))$ is presaturated. Give an example of a tower generated by club guessing ideals that is presaturated.

38. Is it consistent to have CH and NS_{ω_1} is $\aleph_2$-saturated?

39. (Woodin) Does the existence of a countably complete $\aleph_1$-dense ideal on ω_1 imply that the continuum is less than ω_3? (If so, combined with Corollary 5.58, it shows that if NS_{ω_1} is $\aleph_1$-dense then $2^{\aleph_0} = \omega_2$.) Does the existence of an $\aleph_1$-dense ideal on ω_1 and the failure of CH imply that $\underset{\sim}{\delta}^1_2 > \omega_2$?

40. Is it consistent with large cardinals that $\Theta^{L(\mathbb{R})} > \omega_3$?

41. Generalize Theorem 7.72. Is it true in ZFC that there is a forcing $\mathbb{Q}$ such that for all generic $G \subseteq \mathbb{Q}$, there is no saturated ideal on ω_3? $\aleph_{\omega+1}$?

42. (Jech) Suppose that there is a supercompact cardinal. Is there a precipitous ideal on ω_1? Any successor cardinal?

43. Is it true in an "$L[E]$ model" model for some large cardinal that there is a precipitous ideal on a successor cardinal?

44. Suppose that J is an ideal on $Z \subseteq P(X)$, that $\mathbb{P}$ is a $|X|^+$-c.c. partial ordering, and that $\bar{J}$ is a $|X|^+$-saturated, normal, fine ideal in $V^{\mathbb{P}}$. Is it true that there are $A \in J^+$ and $L \in \bar{J}^+$ such that

$$\mathrm{id} : \mathbb{P} \times P(Z)/(J{\restriction}A) \to \mathbb{P} * \overline{P(Z)}/(\bar{J}{\restriction}L)$$

is a regular embedding? Note that $\bar{J}$ is precipitous.

45. Assume Martin's Maximum. Is there a set $A \subseteq \omega_4$ such that the model $L[A, \mathrm{NS}{\restriction}[\omega_4]^{\omega_2}] \models \kappa$ is κ^+-supercompact, where $\kappa = \omega_2^V$?

46. Is it consistent to have the stationary tower forcing up to an inaccessible concentrating on $\mathrm{IA}(\mathrm{Cof}({>}\omega_1))$ presaturated? (This is shown consistent from quite exotic large cardinal assumptions in [42]. The example given in Proposition 9.4 of an induced saturated tower concentrates on $\mathrm{IA}(\mathrm{Cof}({>}\omega))$.)

47. Is there a cardinal δ so large that it implies there are two presaturated towers $\mathcal{T}_0$, and $\mathcal{T}_1$ such that:

    (a) If j_i is the elementary embedding induced by $\mathcal{T}_i$, then $\mathrm{crit}(j_0) = \omega_4$ and $\mathrm{crit}(j_1) = \omega_3$.

    (b) The forcing for $\mathcal{T}_0$ can be regularly embedded into the forcing for $\mathcal{T}_1$?

    If there is such a cardinal, then Theorem 3.14 of [42] implies that $\Theta^{L(\mathbb{R})} < \omega_3$. Weaker conditions for $\Theta^{L(\mathbb{R})} < \omega_3$ exist as well [42].

48. Is there a cardinal δ so large that it implies there is an inaccessible κ and two towers $\mathcal{T}_0, \mathcal{T}_1$ yielding generic objects G_0, G_1 and embeddings j_0, j_1 with the property that:

(a) $j_0(\omega_1) = j_1(\omega_1) = \kappa$,

(b) Every real in $V[G_i]$ is generic over V by a forcing of size less than κ, and

(c) $j_0(\omega_3) \neq j_1(\omega_3)$?

If so, again $\Theta^{L(\mathbb{R})} < \omega_3$.

1. Introduction

Cardinal arithmetic is the study of rules and properties of arithmetic operations mainly on infinite cardinal numbers. Since sums and products are trivial in the sense that

$$m + n = m \cdot n = \max\{m, n\}$$

holds for infinite cardinals, cardinal arithmetic refers mainly to exponentiation m^n. If M is a set of cardinality m and $[M]^n$ is the collection of all subsets of M of cardinality n, then m^n is equal to the cardinality of $[M]^n$. Thus exponentiation is intimately connected with the power set operation and hence lies at the heart of set theory. Classical and basic properties of cardinal arithmetic can be found, for example, in the Levy [12] and Jech [8] textbooks (the latter contains more advanced material). The aim of this introduction is to mention some elementary results and to put our chapter in its context—not to give a historical introduction to the subject of cardinal arithmetic, for which the reader is referred to these textbooks, to [7], and to [9] for a more general perspective.

A theorem of Zermelo generalizing a result of J. König says that if $\langle \kappa_i \mid i \in I\rangle$ and $\langle \lambda_i \mid i \in I\rangle$ are sequences of cardinals such that $\kappa_i < \lambda_i$ holds for every $i \in I$, then

$$\textstyle\sum_{i\in I}\kappa_i < \prod_{i\in I}\lambda_i.$$

A theorem of Bukovský and of Hechler says that if μ is a singular cardinal and the values 2^γ for cardinals $\gamma < \mu$ stabilize, then $2^\mu = 2^{\gamma_0}$, where $\gamma_0 < \mu$ is such that $2^{\gamma_0} = 2^\gamma$ for all $\gamma_0 \le \gamma < \mu$.

Building on earlier results (of Hausdorff, Tarski, Bernstein and others) Bukovský (1965) and Jech show how cardinal exponentiation can be computed from the gimel function (which takes κ to $\kappa^{\mathrm{cf}(\kappa)}$). Applications of Solovay and Easton of the forcing method of Cohen (1963) show that for regular cardinals κ there is no restriction on 2^κ except that which follows from the Zermelo-König theorem, namely that $\mathrm{cf}(2^\kappa) > \kappa$ (see [8, Chap. 3] for details). Thus the question about the possible values of $\kappa^{\mathrm{cf}(\kappa)}$ is most interesting from our point of view when κ is a singular cardinal. It was evident that it is much harder to apply the forcing method to singular cardinals. Involving large cardinals, work of Prikry and of Silver showed that it is possible for a strong limit singular cardinal μ to satisfy $2^\mu > \mu^+$ in some generic extension. Using large cardinals Magidor proved the consistency of $\aleph_\omega$ being the first cardinal κ for which $2^\kappa > \kappa^+$ holds. For a long time it was believed that large cardinal and more complex applications of the forcing method should yield greater flexibility for values of the power set of singular cardinals. A first indication that there are possible limitations was the theorem of Silver (1974): If κ is a singular cardinal with uncountable cofinality and if $2^\delta = \delta^+$ for all cardinals $\delta < \kappa$, then $2^\kappa = \kappa^+$. This result paved the way for further investigations by Galvin and Hajnal (1975). A representative result of their work is the following: If $\aleph_\delta$ is a strong limit singular cardinal with uncountable cofinality, then

$$2^{\aleph_\delta} < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}.$$

For example, if $\aleph_{\omega_1}$ is a strong limit cardinal, then

$$2^{\aleph_{\omega_1}} < \aleph_{(2^{\aleph_1})^+}.$$

The method of proof of these results relied in an essential way on the assumption that $\mathrm{cf}(\delta) > \aleph_0$. Shelah (1978) was able to prove similar results for singular cardinals with countable cofinality. For example, if $\aleph_\omega$ is a strong limit cardinal, then

$$2^{\aleph_\omega} < \aleph_{(2^{\aleph_0})^+}. \tag{14.1}$$

In a series of papers culminating in his book [15], Shelah developed a powerful theory with many applications, pcf theory, which changed our view of cardinal arithmetic. A remarkable result of this theory is the following. If $\aleph_\omega$ is a strong limit cardinal then

$$2^{\aleph_\omega} < \aleph_{\omega_4}. \tag{14.2}$$

If $2^{\aleph_0} \leq \aleph_2$, then (14.1) is a better bound than (14.2), but in general, since $(2^{\aleph_0})^+$ can be arbitrarily high, ω_4 seems to be a firmer bound.

The major definition in pcf theory is the set $\mathrm{pcf}(A)$ of possible cofinalities defined for every set A of regular cardinals, as the collection of all cofinalities of ultraproducts $\prod A/D$ with ultrafilters D over A. This basic and rather simple definition appears in many places and is the basis of a very fruitful investigation. It is a basic definition also in the sense that while the power set can be easily changed by forcing, it is very hard to change $\mathrm{pcf}(A)$.

Our aim in this chapter is to give a self-contained development of pcf theory and to present some of its important applications to cardinal arithmetic. Unless stated otherwise, all theorems and results in this chapter are due to Shelah.

The fullest development of pcf theory is in Shelah's book [15], and the interested reader can access newer articles (and the survey paper "Analytical Guide") in the archive maintained at Rutgers University.

In addition to this material, we have profited from expository papers (Burke-Magidor [2], Jech [7], and unpublished notes by Hajnal), and in particular a recently published book [6] which is very detailed, complete and carefully written.

The authors thank Maxim R. Burke, Matt Foreman, Stefan Geschke, Peter Komjáth, John Krueger, Klaas Pieter Hart, Donald Monk, and Martin Weese for valuable corrections and improvements of earlier versions.

2. Elementary Definitions

An *ideal* over a set A is a collection $I \subseteq \mathcal{P}(A)$ such that (1) I is closed under subsets, that is, $X \in I$ and $Y \subseteq X$ implies $Y \in I$, and (2) I is closed under finite unions, that is, $X_1, X_2 \in I$ imply $X_1 \cup X_2 \in I$ (and thus the union of any finite sequence of members of I is in I). If $A \notin I$, then I is said to be *proper*. We do not require that ideals be proper (see the definition of $J_{<\lambda}$ in Sect. 3.1).

The dual notion, that of a filter, is also used in this chapter. A collection $F \subseteq \mathcal{P}(A)$ is a *filter* over A if (1) F is closed under supersets, that is, $X \in F$ and $X \subseteq Y \subseteq A$ imply $Y \in F$, and (2) F is closed under finite intersections. However, usually a filter is proper, that is $\emptyset \notin F$.

If I is an ideal over A, then $I^* = \{X \subseteq A \mid A \setminus X \in I\}$ is its *dual* filter. Sets belonging to an ideal are intuitively "small" or "null", whereas those of a filter are "big" or "of measure one". If I is an ideal over A, then subsets of A not in I are called "positive", and the collection of positive sets is denoted I^+.

$$I^+ = \{X \subseteq A \mid X \notin I\}.$$

On denotes the class of ordinals and Reg denotes the class of regular cardinals.

We shall deal in this section with functions from a fixed, infinite set A into the ordinals. The class of these ordinal functions is denoted On^A. If $f, g \in \mathrm{On}^A$, then $f \leq g$ means that $f(a) \leq g(a)$ for all $a \in A$, and similarly $f < g$ means that $f(a) < g(a)$ for all $a \in A$ (this is called the everywhere dominance ordering).

If $F \subseteq \mathrm{On}^A$ is a set, then the supremum function $h = \sup F$ is defined on A by

$$h(a) = \sup\{f(a) \mid f \in F\}.$$

If $f, g \in \mathrm{On}^A$, then we define

$$<(f, g) = \{a \in A \mid f(a) < g(a)\},$$

and similarly

$$\leq(f, g) = \{a \in A \mid f(a) \leq g(a)\}.$$

and

$$=(f, g) = \{a \in A \mid f(a) = g(a)\}.$$

If I is an ideal over A, then we define a relation $\leq_I$ over On^A by

$$f \leq_I g \quad \text{iff} \quad \{a \in A \mid g(a) < f(a)\} \in I.$$

In general, for any relation R on the ordinals, we define R_I over On^A by

$$f \; R_I \; g \quad \text{iff} \quad \{a \in A \mid \neg(f(a) \; R \; g(a))\} \in I.$$

That is, the set of exceptions to the relation is null. In this way $<_I$ and $=_I$ are defined over On^A. We remark that $\leq_I$ is weaker than "$<_I$ or $=_I$". Note that $\leq_I$ is a quasi-ordering, and that $<_I$ is irreflexive (if I is a proper ideal) and transitive.

The notations $X \subseteq_I Y$ and $X =_I Y$ are also used for subsets $X, Y \subseteq A$, with the obvious meaning. For example, $X \subseteq_I Y$ iff $X \setminus Y \in I$.

For a filter F over A, the dual definitions $f <_F g$, $f \leq_F g$ etc. will be used as well. For example, $f <_F g$ means that $\{a \in A \mid f(a) < g(a)\} \in F$. If F is the dual of an ideal I, then $<_F$ and $<_I$ are the same relation of course.

Products of Sets

Suppose that A is an index set and $S = \langle S(a) \mid a \in A\rangle$ is a sequence of non-empty sets of ordinals. Then the product, denoted $\prod S$ or $\prod_{a\in A} S(a)$, is defined as

$$\prod S = \{f \mid f \in \mathrm{On}^A \text{ and } \forall a \in A\ f(a) \in S_a\}.$$

In particular, if $h : A \to \mathrm{On}$ is any ordinal function defined on A, then $\prod h$ (or $\prod_{a\in A} h(a)$) denotes the set of all ordinal functions f defined on A such that $f(a) \in h(a)$ for all $a \in A$.

If A is a set of cardinals, then $\prod A$ (or $\prod_{a\in A} a$) denotes the set of all ordinal functions f defined on A such that $f(a) \in a$ for all $a \in A$. That is, $\prod A$ is $\prod h$ where $h(a) = a$ is the identity function on A.

For an ideal I over A, the relations $<_I$, $\leq_I$, and $=_I$ are defined on $\prod h$, and the reduced product $\prod h/I$ consisting of all $=_I$ equivalence classes is obtained. If $g \in \mathrm{On}^A$, then we may write (somewhat informally) $g \in \prod h/I$ rather than $[g] \in \prod h/I$, that is $\prod h/I$ is considered as a class of functions rather than equivalence classes.

For a filter F over A, the reduced product $\prod h/F$ is defined in a similar way.

A sequence of functions $f = \langle f_\xi \mid \xi < \lambda\rangle$ in $\prod A$ is said to be *$<_I$-increasing* if $\xi_1 < \xi_2$ implies that $f_{\xi_1} <_I f_{\xi_2}$. For typographical reasons we also say that f is I-increasing, or "increasing modulo I" instead of $<_I$-increasing. A sequence is a function, and if f_ξ denotes a value of that function then the sequence itself is denoted f, not $\bar{f}$ or F.

Partial Orderings

We say that $(P, \leq_P)$ is a *quasi-ordering* iff $\leq_P$ is a reflexive and transitive relation on P. A *strict* partial ordering is a transitive and irreflexive relation $<_P$ on P. In this chapter we consider both the quasi-ordering $\leq_I$ and the strict partial ordering $<_I$, defined on ordinal-valued functions. A typical example is $P = \prod h$ with the orderings $<_I$ and $\leq_I$ where $h \in \mathrm{On}^A$ is such that $h(a) > 0$ is a limit ordinal for every $a \in A$. Thus every function in P is $<_I$ bounded by another function there (for every $f \in \prod h$, $f <_I f + 1$, where $f + 1$ is the function taking a to $f(a) + 1$). So our setting is a structure $(P, <_P, \leq_P)$ where $<_P$ is a strict partial ordering, and $\leq_P$ is a quasi-ordering. The following properties of $(P, <_P, \leq_P)$ are obvious for our typical example:

P1. $a <_P b$ or $a = b$ implies $a \leq_P b$, but this implication is not necessarily reversible.

P2. If $a <_P b \leq_P c$ or $a \leq_P b <_P c$, then $a <_P c$.

P3. There is no $<_P$ maximal member: for every $p \in P$ there exists some $p' \in P$ with $p <_P p'$.

The following definitions apply whenever P is a set or a class, $<_P$ is a strict partial ordering, and $\leq_P$ a quasi-ordering on P.

A collection $B \subseteq P$ is said to be *cofinal* in P iff for all $x \in P$ there is some $y \in B$ with $x \leq_P y$. B is $<_P$*-cofinal* if $\forall x \in P \exists y \in B(x <_P y)$. If B is cofinal and $p \in P$, then we can first find $p' \in P$ such that $p <_P p'$ (by property P3 above) and then find $y \in B$ such that $p' \leq_P y$. Then $p <_P y$. Thus we can replace $\leq_P$ with $<_P$ in the definition of "cofinal". The *cofinality*, $\mathrm{cf}(P, \leq_P)$, of the partial ordering is the smallest cardinality of a cofinal subset. (Again $\mathrm{cf}(P, <_P)$ is similarly defined and these two cardinals are equal if properties P1–P3 above hold.) This cardinal need not be regular, if the ordering is not total (linear). We say that $(P, <_P)$ has "true" cofinality if it has a totally ordered subset $B \subseteq P$ that is cofinal. In this case the cofinality of B itself, and hence of P, is a regular cardinal. Observe that if $(P, <_P)$ has a linear cofinal subset whose order-type is a regular cardinal λ, then λ is the cofinality of P (because no cofinal subset of P is of smaller cardinality, even if non-linear subsets are considered). When $(P, <_P)$ has true cofinality, we write

$$\mathrm{tcf}(P, <_P) = \lambda$$

(or just $\mathrm{tcf}(P) = \lambda$ with the $<_P$ understood) to express both the fact that a totally ordered cofinal set exists, and that λ is the minimal cardinality of such a cofinal set.

In cases (when P3 above is not assumed) that $(P, \leq_P)$ has a greatest element, then the cofinality of P is defined to be 1 and its true cofinality is also 1, but since we assume that there are no $<_P$ maximal elements the cofinality and true cofinality (when it exists) are always infinite cardinals.

The following observation was made by Pouzet. For any infinite cardinal λ, $\mathrm{tcf}(P, <_P) = \lambda$ if and only if the following conditions hold:

1. $(P, <_P)$ has a cofinal set of size λ.

2. $(P, <_P)$ is λ-directed: any set $X \subseteq P$ of size $< \lambda$ has an upper bound in $(P, <_P)$.

It follows that if $\mathrm{tcf}(P, <_P) = \lambda$ and $G \subseteq P$ is any cofinal subset, then $\mathrm{tcf}(G) = \lambda$ as well.

A sequence $\langle p_\xi \mid \xi < \lambda \rangle$ of members of P is defined to be *persistently cofinal* iff

$$\forall h \in P \; \exists \xi_0 < \lambda \; \forall \xi \; (\xi_0 \leq \xi < \lambda \implies h <_P p_\xi). \tag{14.3}$$

Clearly every $<_P$-increasing and cofinal sequence is persistently cofinal. If $\langle p_\xi \mid \xi < \lambda\rangle$ is persistently cofinal and $p_\xi \leq_P p'_\xi$ for every $\xi < \lambda$, then $\langle p'_\xi \mid \xi < \lambda\rangle$ is persistently cofinal as well.

If $(P, \leq_P)$ is a quasi-ordering and $X \subseteq P$, then an *upper bound* of X is some $a \in P$ such that $x \leq_P a$ for all $x \in X$. If a is an upper bound of X and $a \leq_P a'$ for every upper bound $a' \in P$ of X, then we say that a is a *least upper bound* of X. We say that an upper bound a of X is a *minimal upper bound* if there is no upper bound a' of X such that $a' \leq_P a \wedge \neg(a \leq_P a')$.

Suppose that $(P, <_P, \leq_P)$ is as above and $X \subseteq P$ is such that for every $x \in X$ there is an $x' \in X$ with $x <_P x'$ (for example X is an increasing sequence in $<_P$). Then $a \in P$ is an *exact upper bound* of X iff

1. a is a least upper bound of X, and
2. X is cofinal in $\{p \in P \mid p <_P a\}$. Namely $p <_P a$ implies $\exists x \in X$ $(p \leq_P x)$.

Exercises are natural places to stop and think, but it is not an absolute requirement to solve them on first encounter. In fact, they often become easy with later material.

2.1 Exercise. Let $\lambda > |A|$ be a regular cardinal, and $f = \langle f_\xi \mid \xi < \lambda\rangle$ an increasing sequence of functions in On^A in the $<$ ordering (of everywhere dominance). Then f has an exact upper bound h and $\mathrm{cf}(h(a)) = \lambda$ for every $a \in A$. In fact sup f is the required upper bound.

We repeat the definitions given above, for $(\mathrm{On}^A, <_I, \leq_I)$ where I is a proper ideal over A. So, if $F \subseteq \mathrm{On}^A$ then

$$h \in \mathrm{On}^A \text{ is an upper bound of } F \quad \text{iff} \quad f \leq_I h \text{ for every } f \in F.$$

A function h is a least upper bound of F if it is an upper bound and $h \leq_I h'$ for every upper bound $h' \in \mathrm{On}^A$ of F. Here, the notions of least upper bound and minimal upper bound coincide.

If $h \in \mathrm{On}^A$ and $h(a) = 0$ for some $a \in A$, then $\prod h = \emptyset$. So, to avoid triviality $h(a) > 0$ is assumed for all $a \in A$, whenever the expression $\prod h$ is used. Hence if I is an ideal over A then every $g \in \mathrm{On}^A$ such that $g <_I h$ is $=_I$ equivalent to some function in $\prod h$. In fact, we shall usually consider reduced products $\prod h/I$ for functions h such that $h(a) > 0$ is always a limit ordinal, and hence every function in $\prod h$ is $<$-bounded (everywhere dominated) by some function in $\prod h$.

Suppose that F is a (non-empty) set of functions in On^A such that for every $f \in F$ there exists some $f' \in F$ with $f <_I f'$. Then $h \in \mathrm{On}^A$ is an exact upper bound of F if h is a least upper bound of F and for every $g <_I h$ there is some $f \in F$ with $g <_I f$ (namely F is cofinal in the lower $<_I$ cone determined by h). Actually it is not necessary to require that h is a least upper bound of F since this follows from the assumptions that h is an upper bound of F and F is cofinal in $\prod h/I$. Thus if $F \subseteq \prod h/I$ then h is an exact upper bound of F iff F is cofinal in $\prod h/I$.

If h is an exact upper bound of F and $A_0 \in I^+$ then $h \restriction A_0$ is an exact upper bound of $\langle f \restriction A_0 \mid f \in F \rangle$ with respect to the proper ideal $I \cap \mathcal{P}(A_0)$.

If h is an exact upper bound of F with respect to some ideal I over A and $J \supseteq I$ is a larger ideal over A, then h is an exact upper bound of F modulo J as well.

The definition of "true cofinality" of a reduced product is so important for pcf theory that we restate it for this case.

2.2 Definition. We say that $\mathrm{tcf}(\prod h/I) = \lambda$ iff λ is a regular cardinal and there exists a $<_I$-increasing sequence $f = \langle f_\xi \mid \xi < \lambda \rangle$ in $\prod h$ that is cofinal in $\prod h/I$.

Projections

We shall often encounter the following situation.

1. A is a non-empty set of indices, and $S = \langle S(a) \mid a \in A \rangle$ is a sequence of sets of ordinals. The sup_of_S function is defined on A by taking $a \in A$ to $\sup S(a)$.

2. An ordinal function $f \in \mathrm{On}^A$ is given that is bounded by the sup_of_S, namely $f(a) < \sup S(a)$ for every $a \in A$.

Then we define the *projection* of f onto $\prod S$, denoted $\mathrm{proj}(f, S)$, as the function $f^+ \in \prod S$ defined by

$$f^+(a) = \min(S(a) \setminus f(a)).$$

So $f^+(a) = f(a)$ in case $f(a) \in S(a)$, and otherwise $f^+(a)$ is the least ordinal in $S(a)$ above $f(a)$. (There is such an ordinal by our assumption.) It is clear that f^+ is the least function in $\prod S$ that bounds f, and that $f_1 \leq f_2$ implies $f_1^+ \leq f_2^+$.

We shall apply projections in the presence of an ideal I over A. If $f \in \mathrm{On}^A$ is any function, not necessarily bounded by sup_of_S, we define $f^+ = \mathrm{proj}(f, S)$ as follows. For $a \in A$ such that $f(a) < \sup S(a)$, we define $f^+(a) = \min(S(a) \setminus f(a))$ as before, and for $a \in A$ such that $f(a) \geq \sup S(a)$ we define $f^+(a) = 0$. Clearly, $f_1 =_I f_2$ implies that $f_1^+ =_I f_2^+$. It follows, in case $f <_I \sup S$, that f^+ is the $\leq_I$-least function in $\prod_{a \in A} S(a)$ that $\leq_I$-bounds f, up to $=_I$ equivalence.

Given an ideal I over a set A and an ordinal function $h \in \mathrm{On}^A$, we are interested in the existence and value of the true cofinality of $\prod h/I$. Our first step is to reduce this question to ultraproducts of regular cardinals, and we can proceed as follows. Choose for every $a \in A$ a cofinal set $S(a) \subseteq h(a)$ of order-type $\mathrm{cf}(h(a))$. By our assumption that $h(a) > 0$ is always a limit, non-zero ordinal, the order-type of $S(a)$ is a regular infinite cardinal. Then the collections $\prod h$ and $\prod_{a\in A} S(a)$ are cofinally equivalent. That is for every $f \in \prod h$ there is a $g \in \prod S$ with $f \leq g$ (namely it projection), and vice versa.

Next, $\prod_{a\in A} S(a)$ is isomorphic to $\prod_{a\in A} |S(a)| = \prod_{a\in A} \mathrm{cf}(h(a))$. This is also the case when an ideal I over A is introduced and the relation $\leq_I$ is considered. Then $\prod h/I$ has the same cofinality and true cofinality as $\prod_{a\in A} \mathrm{cf}(h(a))/I$. Hence it suffices to consider reduced products $\prod_{a\in A} k(a)/I$ of functions k such that $k(a)$ are infinite regular cardinals. As the following lemma shows, in some cases we may even take k to be one-to-one. Recall that Reg denotes the class of regular cardinals.

2.3 Lemma. *Suppose that $c : A \to \mathrm{Reg}$ is a function and $B = \{c(a) \mid a \in A\}$ is its range. Suppose I is any ideal over A, and J is its Rudin-Keisler projection on B defined by*

$$X \in J \quad \textit{iff} \quad X \subseteq B \textit{ and } c^{-1}X \in I,$$

where $c^{-1}X = \{a \in A \mid c(a) \in X\}$. Then there is an order-preserving isomorphism $h : \prod B/J \to \prod_{a\in A} c(a)/I$ defined by $h([e]_J) = [e \circ c]_I$ for every $e \in \prod B$. If $|A| < \min B$, then

$$\mathrm{tcf}\big(\textstyle\prod B/J\big) = \mathrm{tcf}\big(\textstyle\prod_{a\in A} c(a)/I\big) \tag{14.4}$$

in the sense that existence of the true cofinality for one of $\prod B/J$ and $\prod c/I$ implies existence for the other poset as well, and these cofinalities are equal.

Proof. For every $e \in \prod B$ define $\bar{e} \in \prod c$ by $\bar{e}(a) = e(c(a))$. That is, $\bar{e} = e \circ c$. Then $e_1 =_J e_2$ iff $\bar{e}_1 =_I \bar{e}_2$, and $e_1 <_J e_2$ iff $\bar{e}_1 <_I \bar{e}_2$. Thus $h([e]_J) = \bar{e}/I$ induces an isomorphism from $\prod B/J$ into $\prod c/I$. Hence $\mathrm{tcf}(\prod B/J)$ is the same as the true cofinality of

$$G = \big\{h([e]_J) \mid e \in \textstyle\prod B\big\}$$

in $<_I$. If $|A| < \min B$, then G will be shown to be cofinal in $\prod c/I$ and this implies (14.4). (In general, if G is any cofinal subset of a partial ordering $(P, <_P)$, then G and P have the same true cofinality.)

Now G is cofinal in $\prod c/I$, because any $g \in \prod c$ is bounded by $\bar{f}$ where $f \in \prod B$ is defined by

$$f(b) = \sup\{g(a) \mid a \in A \text{ and } c(a) = b\}.$$

The fact that $|A| < b$ is used here to deduce that this supremum is below the regular cardinal $b \in B$, and hence that $f \in \prod B$. Since $\bar{f}/I \in G$, G is cofinal in $\prod c$. ⊣

To see how this lemma is applied, suppose that λ is a regular cardinal and $f = \langle f_\xi \mid \xi < \lambda\rangle$ is a $<_I$ increasing sequence of functions $f_\xi \in \mathrm{On}^A$. Then (as we have said) $h \in \mathrm{On}^A$ is an exact upper bound of f iff f is cofinal in $\prod h/I$. In this case it follows that $\mathrm{tcf}(\prod h/I) = \lambda$ and hence that the true cofinality of $\prod_{a\in A} \mathrm{cf}(h(a))$ is λ. Let $B = \{\mathrm{cf}(h(a)) \mid a \in A\}$ be the set of cofinalities of the range of h. The preceding lemma shows that λ is the true cofinality of a reduced product of B, if $|A| < \mathrm{cf}(h(a))$ for every $a \in A$.

2.1. Existence of Exact Upper Bounds

An important piece of pcf theory is the determination of conditions that ensure the existence of exact upper bounds. Recall that an exact upper bound of a $<_I$-increasing sequence $\langle f_\xi \mid \xi < \lambda \rangle$ of functions in On^A is a function $g \in \mathrm{On}^A$ that bounds every f_ξ in the $\leq_I$ relation and satisfies the additional requirement that if $d <_I g$ then $d <_I f_\xi$ for some $\xi < \lambda$. The following and Definition 2.8 are central in our presentation of pcf theory.

2.4 Definition (Strongly increasing). Suppose that I is an ideal over A and $f = \langle f_\xi \mid \xi \in L \rangle$ is a $<_I$-increasing sequence of functions $f_\xi \in \mathrm{On}^A$, where L is a set of ordinals. Then f is said to be *strongly increasing* if there are sets $Z_\xi \in I$, for $\xi \in L$, such that whenever $\xi_1 < \xi_2$ are in L

$$a \in A \setminus (Z_{\xi_1} \cup Z_{\xi_2}) \quad \Longrightarrow \quad f_{\xi_1}(a) < f_{\xi_2}(a).$$

2.5 Exercise. An even stronger property would be to require that there are sets $Z_\xi \in I$ for $\xi \in L$ such that whenever $\xi_1 < \xi_2$

$$a \in A \setminus Z_{\xi_2} \to f_{\xi_1}(a) < f_{\xi_2}(a).$$

Prove that a sequence $f = \langle f_\xi \mid \xi \in L \rangle$ satisfies this stronger property iff for every $\xi \in L$

$$\sup\{f_\alpha + 1 \mid \alpha \in L \cap \xi\} \leq_I f_\xi. \tag{14.5}$$

(Recall that $f + 1$ is the function that takes x to $f(x) + 1$.)

2.6 Exercise. Let I be an ideal over A, $\lambda > |A|$ be a regular cardinal, and $f = \langle f_\xi \mid \xi < \lambda \rangle$ be a $<_I$ increasing sequence of functions in On^A. Then the following conditions are equivalent:

1. f contains a strongly increasing subsequence of length λ.
2. f has an exact upper bound h such that $\mathrm{cf}(h(a)) = \lambda$ for (I-almost) all $a \in A$.
3. f is cofinally equivalent to some $<$ (i.e. everywhere) increasing sequence of length λ.

Hint. If f (or a subsequence) is strongly increasing, let $Z_\xi \in I$ be the null sets associated with f_ξ and define

$$h(a) = \sup\{f_\xi(a) \mid a \notin Z_\xi\}.$$

Prove that h is an exact upper bound as required to prove that 1 implies 2.

Since $|A| < \lambda$, it is obvious that 2 implies 3. (For every $a \in A$ choose a cofinal subset of $h(a)$ of order-type λ, and let d_ξ be the "flat" function which assigns to $d_\xi(a)$ the ξth point in the $h(a)$ cofinal subset.)

To prove that 3 implies 1, use the following lemma.

2.7 Lemma (The Sandwich Argument). *Suppose that $d = \langle d_\xi \mid \xi \in \lambda\rangle$ is strongly increasing and $f_\xi \in \mathrm{On}^A$ is such that*

$$d_\xi <_I f_\xi \leq_I d_{\xi+1} \quad \textit{for every } \xi \in \lambda.$$

Then $\langle f_\xi \mid \xi \in \lambda\rangle$ is also strongly increasing.

Proof. Let $Z_\xi \in I$ be the sets that affirm that the sequence d is strongly increasing. For every f_ξ, sandwiched between d_ξ and $d_{\xi+1}$, there exists a $W_\xi \in I$ such that

$$d_\xi(a) < f_\xi(a) \leq d_{\xi+1}(a) \quad \text{for all } a \in A \setminus W_\xi.$$

Define $Z^\xi = W_\xi \cup Z_\xi \cup Z_{\xi+1}$. Then $Z^\xi \in I$, and if $\xi_1 < \xi_2$ then for every $a \in A \setminus (Z^{\xi_1} \cup Z^{\xi_2})$

$$f_{\xi_1}(a) \leq d_{\xi_1+1}(a) \leq d_{\xi_2}(a) < f_{\xi_2}(a).$$

⊣

2.8 Definition. Suppose that I is an ideal over a set A, λ is a regular cardinal, and $f = \langle f_\xi \mid \xi \in \lambda\rangle$ is a $<_I$-increasing sequence of functions $f_\xi \in \mathrm{On}^A$. For any regular cardinal κ such that $\kappa \leq \lambda$ the following crucial property of κ (and f etc.) is denoted $(*)_\kappa$:

$(*)_\kappa$ Whenever $X \subseteq \lambda$ is unbounded, then for some $X_0 \subseteq X$ of order-type κ, $\langle f_\xi \mid \xi \in X_0\rangle$ is strongly increasing.

Thus $(*)_\kappa$ is a kind of partition relation, saying that any unbounded subsequence $\langle f_\xi \mid \xi \in X\rangle$ contains a strongly increasing subsequence of length κ. Clearly $(*)_\kappa$ implies $(*)_{\kappa'}$ for all regular $\kappa' < \kappa$.

2.9 Exercise.

1. Assume $\kappa < \lambda$. Prove that $(*)_\kappa$ holds iff the set of ordinals $\delta \in \lambda$ with $\mathrm{cf}(\delta) = \kappa$ and such that $\langle f_\xi \mid \xi \in X_0\rangle$ is strongly increasing for some unbounded set $X_0 \subseteq \delta$ is stationary in λ.

2. Use the Erdős-Rado Theorem $(2^\kappa)^+ \to (\kappa^+)^2_\kappa$ to prove that if $\lambda \geq (2^{|A|})^+$ and f is a $<_I$ increasing sequence of functions as above, of length λ, then $(*)_{|A|^+}$ holds.

Hint for 2. For $i < j$, if there exists some $a \in A$ such that $f_i(a) > f_j(a)$, then define $c(i,j) = a$ for such an a. Otherwise define $c(i,j) = -1$. The homogeneous set must be of color -1, and $(*)_{|A|^+}$ can be derived by taking a subsequence.

We shall give (in Lemma 2.19) conditions that ensure property $(*)_\kappa$ (without any assumptions on 2^κ), but meanwhile the following lemma and theorem explain the main use of $(*)_\kappa$.

2.10 Definition (Bounding projection). Suppose that I is an ideal over A, λ is a regular cardinal, and $f = \langle f_\xi \mid \xi < \lambda \rangle$ is a $<_I$-increasing sequence of functions in On^A. Let $\kappa \le \lambda$ be any regular cardinal. We say that f has the *bounding projection property* for κ if whenever $S = \langle S(a) \mid a \in A \rangle$ with $S(a) \subseteq \mathrm{On}$ and $|S(a)| < \kappa$ is such that the sequence f is $<_I$-bounded by the function sup_of_S, then there exists a $\xi < \lambda$ such that $f^+_\xi = \mathrm{proj}(f_\xi, \langle S(a) \mid a \in A \rangle)$ is an upper bound of f in the $<_I$ relation. (Recall that sup_of_$S(a) = \sup S(a)$ for all $a \in A$.)

2.11 Exercise.

1. If $f = \langle f_\xi \mid \xi < \lambda \rangle$ has the bounding projection property for κ and $f' = \langle f'_\xi \mid \xi < \lambda \rangle$ is such that $f'_\xi =_I f_\xi$ for every ξ, then f' too has the bounding projection property for κ.

2. A seemingly weaker property results if we require that the sup_of_S map $<$-bounds (i.e. everywhere) each f_ξ. Prove that these two definitions are equivalent.

2.12 Lemma (The Bounding Projection Lemma). *Suppose that I is an ideal over A, $\lambda > |A|$ is a regular cardinal, and $f = \langle f_\xi \mid \xi < \lambda \rangle$ is a $<_I$-increasing sequence satisfying $(*)_\kappa$ for a regular cardinal κ such that $|A| < \kappa \le \lambda$. Then f satisfies the bounding projection property for κ.*

Later on, we shall see that $(*)_\kappa$ is, in fact, *equivalent* to the bounding projection property for κ (see Theorem 2.15 for an exact formulation).

Proof. Suppose that the lemma is false and S is a counter-example, and we shall obtain a contradiction. By changing each f_ξ on an I set, we do not spoil the $(*)_\kappa$ property, and we may assume that $f_\xi(a) < \sup S(a)$ for all $a \in A$. Then define

$$f^+_\xi = \mathrm{proj}(f_\xi, \langle S(a) \mid a \in A \rangle).$$

Since f^+_ξ is not a $<_I$-upper bound, there exists a $\xi' < \lambda$ such that $\le(f^+_\xi, f_{\xi'}) \in I^+$. That is, $f^+_\xi(a) \le f_{\xi'}(a)$ for an I-positive set of a. Hence $<(f^+_\xi, f_{\xi''}) \in I^+$ for every ξ'' above ξ'. This enables the definition of an unbounded set $X \subseteq \lambda$ such that

$$\text{if } \xi, \xi' \in X \text{ and } \xi < \xi' \quad \text{then } <(f^+_\xi, f_{\xi'}) \in I^+.$$

Since $(*)_\kappa$ holds, there exists a set $X_0 \subseteq X$ of order-type κ such that $\langle f_\xi \mid \xi \in X_0 \rangle$ is strongly increasing. Let $Z_\xi \in I$ for $\xi \in X_0$ be as in the definition of strong increase (2.4).

For every $\xi \in X_0$ let $\xi' = \min(X_0 \setminus (\xi + 1))$ be the successor of ξ in X_0, and pick

$$a_\xi \in <(f^+_\xi, f_{\xi'}) \setminus (Z_\xi \cup Z_{\xi'}).$$

As $\kappa > |A|$, we may find a single $a \in A$ such that $a = a_\xi$ for a subset X_1 of X_0 of cardinality κ. Now for $\xi_1 < \xi_2$ in X_1

$$f^+_{\xi_1}(a) < f_{\xi'_1}(a) \le f_{\xi_2}(a) \le f^+_{\xi_2}(a).$$

(The first inequality is a consequence of $a_{\xi_1} \in <(f^+_{\xi_1}, f_{\xi'_1})$, the second follows from $\xi'_1 \leq \xi_2$ and the fact that

$$a = a_{\xi_1} = a_{\xi_2} \in A \setminus (Z_{\xi'_1} \cup Z_{\xi_2}),$$

and the third inequality is obvious from the definition of $f^+_{\xi_2}$.)

But now $f^+_\xi(a) \in S(a)$ turns out to be strictly increasing with $\xi \in X_1$, which is absurd since $|S(a)| < \kappa$. ⊣

2.13 Theorem (Exact Upper Bounds). *Suppose that I is an ideal over A, $\lambda > |A|^+$ is a regular cardinal, and $f = \langle f_\xi \mid \xi \in \lambda\rangle$ is a $<_I$-increasing sequence of functions in On^A that satisfies the bounding projection property for $|A|^+$. Then f has an exact upper bound.*

Proof. Assume the $|A|^+$ bounding projection property for a sequence f that is $<_I$-increasing of length a regular cardinal $\lambda > |A|^+$. We shall prove first that there exists a minimal upper bound to f, and then prove that this bound is necessarily an exact upper bound. Seeking a contradiction, suppose that f has no minimal upper bound. So for every $h \in \mathrm{On}^A$, if h is an upper bound to the sequence f then it is not a minimal upper bound, and there is another upper bound $h' \in \mathrm{On}^A$ to f such that $h' \leq h$ and $<(h', h) \in I^+$.

We shall define by induction on $\alpha < |A|^+$ a sequence $S^\alpha = \langle S^\alpha(a) \mid a \in A\rangle$ of sets of ordinals satisfying $|S^\alpha(a)| \leq |A|$, and such that:

1. The sequence of functions f is bounded by the map $a \mapsto \sup S^\alpha(a)$. So, the projections can always be defined.

2. The sets $S^\alpha(a)$ are increasing with α: if $\alpha < \beta$ then $S^\alpha(a) \subseteq S^\beta(a)$ for every $a \in A$. For a limit ordinal δ, $S^\delta(a) = \bigcup_{\alpha<\delta} S^\alpha(a)$.

To define S^0, we pick a function h_0 that bounds f and define $S^0(a) = \{h_0(a)\}$.

Suppose that $S^\alpha = \langle S^\alpha(a) \mid a \in A\rangle$ has been defined. Since the bounding projection property for $|A|^+$ holds and the cardinality of $S^\alpha(a)$ is $\leq |A|$, there exists some $\xi = \xi(\alpha) < \lambda$ such that $h_\alpha = \mathrm{proj}(f_\xi, S^\alpha)$ is an upper bound of f. It follows for every ξ' satisfying $\xi \leq \xi' < \lambda$ that $h_\alpha =_I \mathrm{proj}(f_{\xi'}, S^\alpha)$.

Since h_α is not a minimal upper bound, there exists an upper bound u to the sequence f such that $u \leq h_\alpha$ and

$$<(u, h_\alpha) \in I^+.$$

Define $S^{\alpha+1}(a) = S^\alpha(a) \cup \{u(a)\}$. Then $\mathrm{proj}(f_\xi, S^{\alpha+1}) =_I u$ for all $\xi(\alpha) \leq \xi < \lambda$.

Now let $\xi < \lambda$ be a fixed ordinal greater than every $\xi(\alpha)$ for $\alpha < |A|^+$ (recall that λ is a regular cardinal above $|A|^+$). Consider the functions $H_\alpha = \mathrm{proj}(f_\xi, S^\alpha)$ for $\alpha < |A|^+$. Since f_ξ is above $f_{\xi(\alpha)}$, $H_\alpha =_I h_\alpha$. Thus $<(H_{\alpha+1}, H_\alpha) \in I^+$. Since $\alpha_1 < \alpha_2 < |A|^+$ implies that $S^{\alpha_1}(a) \subseteq S^{\alpha_2}(a)$ for all $a \in A$, the sequence of projections $\langle H_\alpha \mid \alpha < |A|^+\rangle$ thus obtained satisfies the following property:

$$\text{If } \alpha_1 < \alpha_2 < |A|^+, \quad \text{then } H_{\alpha_2} \leq H_{\alpha_1} \text{ and } <(H_{\alpha_2}, H_{\alpha_1}) \in I^+.$$

Yet this is impossible and leads immediately to a contradiction. For every $\alpha < |A|^+$ pick some $a \in A$ such that $H_{\alpha+1}(a) < H_\alpha(a)$. Then the same fixed $a \in A$ is picked for an unbounded set of indices $\alpha \in |A|^+$. Yet as the functions H_α are $\leq$-decreasing, this yields an infinite strictly descending sequence of ordinals! ⊣

Now that the existence of a minimal upper-bound is established, the following lemma concludes the theorem.

2.14 Lemma. *Suppose that I is an ideal over A, λ is a regular cardinal, and $f = \langle f_\xi \mid \xi \in \lambda\rangle$ is a $<_I$-increasing sequence of functions in* On^A *that satisfies the bounding projection property for $\kappa = 3$. Let h be a minimal upper bound of f. Then h is an exact upper bound.*

Proof. Assume that f satisfies the bounding projection property for 3, and h is a minimal upper bound of f. Suppose that $g \in \mathrm{On}^A$ is such that $g <_I h$. We must find f_ξ in the sequence f with $g <_I f_\xi$. For simplicity, and without loss of generality, we can assume that $g(a) < h(a)$ for all $a \in A$.

Define $S(a) = \{g(a), h(a)\}$ for every $a \in A$. The bounding projection property implies the existence of $\xi < \lambda$ for which $f_\xi^+ = \mathrm{proj}(f_\xi, \langle S(a) \mid a \in A\rangle)$ is an upper bound of the sequence f. We shall prove that $g <_I f_\xi$ as required. Observe that

$$f_\xi^+ =_I h \tag{14.6}$$

or else $f_\xi^+(a) = g(a) < h(a)$ for an I-positive set of a's in A. But then f_ξ^+ is an upper-bound of f that is smaller than the minimal upper bound h on an I-positive set of indices, and this is impossible. Hence (14.6). Yet, for every a such that $f_\xi^+(a) = h(a)$, $g(a) < f_\xi(a)$ follows from the fact that $g(a) \in S(a)$. Thus $g <_I f_\xi$. This proves the lemma. ⊣

The Bounding Projection Lemma 2.12 and the Exact Upper Bounds Theorem 2.13 show together that a $<_I$-increasing sequence of length a regular cardinal $\lambda > |A|^+$ and which satisfies $(*)_{|A|^+}$ has necessarily an exact upper bound h. As we shall see in the following theorem it can be deduced that

$$\forall a \in A \ \ \mathrm{cf}(h(a)) \geq |A|^+.$$

2.15 Theorem. *Suppose that I is an ideal over A, $\lambda > |A|^+$ is a regular cardinal, and $f = \langle f_\xi \mid \xi \in \lambda\rangle$ is a $<_I$-increasing sequence of functions in* On^A*. Then for every regular cardinal κ such that $|A|^+ \leq \kappa \leq \lambda$ the following are equivalent.*

1. *$(*)_\kappa$ holds for f.*
2. *f satisfies the bounding projection property for κ.*

3. *The sequence f has an exact upper bound g for which*

$$\{a \in A \mid \mathrm{cf}(g(a)) < \kappa\} \in I.$$

Proof. Let κ be a regular cardinal such that $|A|^+ \leq \kappa \leq \lambda$. Implication $1 \implies 2$ was proved in Lemma 2.12, and so we next establish $2 \implies 3$.

Since f satisfies the bounding projection property for some cardinal that is $\geq |A|^+$, it satisfies the bounding projection property for $|A|^+$. Theorem 2.13 above implies that f has an exact upper bound g. This exact upper bound is determined up to $=_I$, and we may assume that $g(a)$ is never 0 or a successor ordinal (recall that the sequence f is $<_I$-increasing).

Suppose that $P = \{a \in A \mid \mathrm{cf}(g(a)) < \kappa\} \in I^+$, in contradiction to 3. Choose, for every $a \in P$, $S(a) \subseteq g(a)$ cofinal in $g(a)$ and such that order-type$(S(a)) < \kappa$. For $a \in A \setminus P$ define $S(a) = \{g(a)\}$. Then the bounding projection property for κ gives some $\xi < \lambda$ such that the projection

$$f^+_\xi = \mathrm{proj}(f_\xi, \langle S(a) \mid a \in A\rangle)$$

is an upper bound of f in $\prod_{a\in A} S(a)$. But this is impossible since $f^+_\xi \restriction P < g\restriction P$ (everywhere on P) is in contradiction to our assumption that g is the $\leq_I$-minimal upper bound of f.

We now proceed with $3 \implies 1$. Suppose that g is an exact upper bound for f such that $\mathrm{cf}(g(a)) \geq \kappa$ for all $a \in A$ (change g on a null set if necessary). Choose $S(a) \subseteq g(a)$ cofinal in $g(a)$, closed, and with order-type $\mathrm{cf}(g(a))$. So order-type$(S(a)) \geq \kappa$. We prove that $(*)_\kappa$ holds. Assuming that $X \subseteq \lambda$ is unbounded, we shall find $X_0 \subseteq X$ of order-type κ over which f is strongly increasing. For this we intend to define by induction on $\alpha < \kappa$ a function $h_\alpha \in \prod_{a\in A} S(a) = \prod S$ and an index $\xi(\alpha) \in X$ such that

1. $h_\alpha <_I f_{\xi(\alpha)} <_I h_{\alpha+1}$.
2. The sequence $\langle h_\alpha \mid \alpha < \kappa\rangle$ is $<$ increasing (increasing everywhere). And hence it is certainly strongly increasing.

Then the Sandwich Argument (Lemma 2.7) will show that $\{f_{\xi(\alpha)} \mid \alpha < \kappa\}$ is strongly increasing.

The functions h_α are defined as follows.

1. $h_0 \in \prod_{a\in A} S(a)$ is any function.
2. If $\delta < \kappa$ is a limit ordinal, then define

   $$h_\delta = \sup\{h_\alpha \mid \alpha < \delta\}.$$

   That is

   $$h_\delta(a) = \bigcup\{h_\alpha(a) \mid \alpha < \delta\}$$

   for every $a \in A$. Since each $S(a)$ has regular order-type $\geq \kappa$, and as $\delta < \kappa$, clearly $h_\delta \in \prod_{a\in A} S(a)$.

3. If $h_\alpha \in \prod_{a\in A} S(a)$ is defined then it is bounded by g (since $S(a) \subseteq g(a)$) and hence (as g is an exact upper bound) $h_\alpha <_I f_\xi$ for some $\xi \in X$, which we denote $\xi(\alpha)$. Now let $f^+_{\xi(\alpha)} = \mathrm{proj}(f_{\xi(\alpha)}, S)$ be the projection function, and define $h_{\alpha+1} \in \prod S$ so that $h_{\alpha+1} > \sup\{h_\alpha, f^+_{\xi(\alpha)}\}$.

Thus $h_{\alpha+1} > h_\alpha$ and since $f_{\xi(\alpha)} \leq_I f^+_{\xi(\alpha)}$ we have

$$h_\alpha <_I f_{\xi(\alpha)} <_I h_{\alpha+1}, \quad \text{for every } \alpha. \tag{14.7}$$

Hence

$$X_0 = \{\xi(\alpha) \mid \alpha \in \kappa\} \subseteq X$$

is an increasing enumeration, and it is an evidence for $(*)_\kappa$ (by the Sandwich Argument (Lemma 2.7) and since $\langle h_\alpha \mid \alpha < \kappa\rangle$ is strongly increasing). $\dashv$

We shall give in Lemma 2.19 below a useful condition on f from which $(*)_\kappa$ follows. But first we need a combinatorial theorem.

2.16 Definition. If $S \subseteq \lambda$ is a stationary set, then a *club guessing sequence* is a sequence $\langle C_\delta \mid \delta \in S\rangle$, where each $C_\delta \subseteq \delta$ is closed unbounded in δ, such that for every closed unbounded $D \subseteq \lambda$ there exists some $\delta \in S$ with $C_\delta \subseteq D$.

We shall use the notation $S^\lambda_\kappa = \{\delta \in \lambda \mid \mathrm{cf}(\delta) = \kappa\}$. Clearly for regular infinite cardinals $\kappa < \lambda$, S^λ_κ is stationary in λ.

2.17 Theorem (Club Guessing). *For every regular cardinal κ, if λ is a cardinal such that $\mathrm{cf}(\lambda) \geq \kappa^{++}$, then any stationary set $S \subseteq S^\lambda_\kappa$ has a club-guessing sequence $\langle C_\delta \mid \delta \in S\rangle$ (such that $C_\delta \subseteq \delta$ is closed unbounded of order-type κ).*

Proof. We shall prove this for uncountable κ's, though the theorem holds for $\kappa = \aleph_0$ as well.

Let $S \subseteq S^\lambda_\kappa$ be any stationary set. Fix a sequence $C = \langle C_\delta \mid \delta \in S\rangle$ such that $C_\delta \subseteq \delta$ is closed unbounded of order type κ, for every $\delta \in S$. If $E \subseteq \lambda$ is any closed unbounded set, define

$$C|E = \langle C_\delta \cap E \mid \delta \in S \cap E'\rangle.$$

Here $E' = \{\delta \in E \mid E\cap\delta \text{ is unbounded in } \delta\}$ is the set of accumulation points of E. Clearly $E' \subseteq E$ is closed unbounded. The sequence $C|E$ is defined on $S \cap E'$ in order to ensure that $C_\delta \cap E$ is closed unbounded in δ.

We claim that for some closed unbounded set $E \subseteq \lambda$, $C|E$ is club-guessing. (The theorem demands a sequence defined on *every* $\delta \in S$, but this is trivially obtained once a guessing sequence is defined on a closed unbounded set intersected with S.)

To prove this claim, assume that it is false, and for every closed unbounded set $E \subseteq \lambda$ there is some closed unbounded set $D_E \subseteq \lambda$ not guessed by $C|E$. That is, for every $\delta \in S \cap E'$

$$C_\delta \cap E \not\subseteq D_E.$$

So we can define a decreasing (under inclusion) sequence of closed unbounded sets $E^\alpha \subseteq \lambda$ for $\alpha < \kappa^+$ by induction on α as follows.

1. $E^0 = \lambda$.

2. If $\gamma < \kappa^+$ is a limit ordinal, and E^α for $\alpha < \gamma$ are already defined, let $E^\gamma = \bigcap\{E^\alpha \mid \alpha < \gamma\}$. Clearly $E^\gamma \subseteq \lambda$ is closed unbounded.

3. If E^α is defined, then $E^{\alpha+1} = (E^\alpha \cap D_{E^\alpha})'$. So for every $\delta \in S \cap E^{\alpha+1}$, $C_\delta \cap E^\alpha \nsubseteq E^{\alpha+1}$.

Let $E = \bigcap\{E^\alpha \mid \alpha < \kappa^+\}$. Again $E \subseteq \lambda$ is closed unbounded because $\operatorname{cf}(\lambda) > \kappa^+$.

Now we get the contradiction. Take any $\delta \in S \cap E$. There exists some $\alpha < \kappa^+$ such that $C_\delta \cap E = C_\delta \cap E^\alpha$ (since the sets E^α are decreasing in $\subseteq$ and C_δ has cardinality κ). So $C_\delta \cap E^\alpha = C_\delta \cap E^{\alpha'}$ for every $\alpha' > \alpha$, and in particular for $\alpha' = \alpha + 1$. But as $\delta \in S \cap E^{\alpha+1}$, $C_\delta \cap E^\alpha \nsubseteq E^{\alpha+1}$. ⊣

2.18 Exercise.

1. Club guessing is a relative of the diamond principle which gives much stronger guessing properties. For example, prove that $\diamondsuit^+_{\omega_2}$ implies a sequence $\langle C_\delta \mid \delta \in S^{\omega_2}_{\omega_1}\rangle$ with C_δ closed unbounded in δ such that, for every closed unbounded set $E \subseteq \omega_2$, there exists a closed unbounded set $D \subseteq \omega_2$ such that for every $\delta \in S^{\omega_2}_{\omega_1} \cap D$, C_δ is almost contained in E (i.e. except a bounded set). Prove that it is not possible to have full guessing at a closed unbounded set. That is, it is not possible to require that $C_\delta \subseteq E$ for every $\delta \in S^{\omega_2}_{\omega_1} \cap D$.

2. Prove the club-guessing theorem for $\kappa = \aleph_0$ as well.

Hint. For $S \subseteq S^\lambda_{\aleph_0}$ fix $C = \langle C_\delta \mid \delta \in S\rangle$ where each C_δ is an ω-sequence unbounded in δ. For every closed unbounded set $E \subseteq \lambda$ define the "gluing to E" sequence $C|E = \langle C^*_\delta \mid \delta \in S \cap E^*\rangle$ by

$$C^*_\delta(n) = \max(E \cap (C_\delta(n) + 1)).$$

Try to prove that for some club $E \subseteq \lambda$, $C|E$ is club guessing. Have enough patience for ω_1 trials.

Club guessing is used in the following lemma which produces sequences that satisfy $(*)_\kappa$.

2.19 Lemma. *Suppose that*

1. *I is a proper ideal over A.*

2. *κ and λ are regular cardinals such that $\kappa^{++} < \lambda$.*

3. *$f = \langle f_\xi \mid \xi < \lambda\rangle$ is a sequence of length λ of functions in On^A that is $<_I$-increasing and satisfies the following requirement: For every $\delta < \lambda$ with $\operatorname{cf}(\delta) = \kappa^{++}$, there is a closed unbounded set $E_\delta \subseteq \delta$ such that for some $\delta' \geq \delta$ in λ*

$$\sup\{f_\alpha \mid \alpha \in E_\delta\} <_I f_{\delta'}. \tag{14.8}$$

Then $(*)_\kappa$ holds for f.

Proof. Let $S = S^{\kappa^{++}}_\kappa$ be the stationary subset of κ^{++} consisting of all ordinals with cofinality κ. Fix a club-guessing sequence on S: $\langle C_\alpha \mid \alpha \in S\rangle$. So for every $\alpha \in S$, $C_\alpha \subseteq \alpha$ is closed unbounded, of order-type κ, and for every closed unbounded set $C \subseteq \kappa^{++}$ there is a $\delta \in S$ such that $C_\delta \subseteq C$.

Now let $U \subseteq \lambda$ be an unbounded set, and we shall find an $X_0 \subseteq U$ of order-type κ such that $\langle f_\xi \mid \xi \in X_0\rangle$ is strongly increasing. For this we first define an increasing and continuous sequence $\langle \xi(i) \mid i < \kappa^{++}\rangle \subseteq \lambda$ of order-type κ^{++} by the following recursive procedure.

We start with an arbitrary $\xi(0)$. For i limit, $\xi(i) = \sup\{\xi(k) \mid k < i\}$.

Suppose for some $i < \kappa^{++}$ that $\{\xi(k) \mid k \leq i\}$ has been defined.

For every $\alpha \in S$ define

$$h_\alpha = \sup\{f_{\xi(k)} \mid k \leq i \wedge k \in C_\alpha\}. \tag{14.9}$$

Then ask: is there an ordinal $\sigma > \xi(i)$ below λ such that $h_\alpha <_I f_\sigma$? If the answer is positive, let σ_α be the least such $\sigma < \lambda$, and, if negative, let σ_α be $\xi(i) + 1$.

Since $\lambda > \kappa^{++}$ is regular, we can define

$$\xi(i+1) > \sup\{\sigma_\alpha \mid \alpha \in S\} \quad \text{with } \xi(i+1) \in U.$$

It follows, in case the answer for h_α is positive, that

$$h_\alpha <_I f_{\xi(i+1)}.$$

Finally $D = \{\xi(k) \mid k \in \kappa^{++}\}$ is closed and has order-type κ^{++}. Let $\delta = \sup D$. Then D is closed unbounded in $\delta < \lambda$, and $\mathrm{cf}(\delta) = \kappa^{++}$. By assumption there is a closed unbounded set $E_\delta \subseteq \delta$ such that (14.8) holds. Thus for some $f_{\delta'}$

$$\sup\{f_\xi \mid \xi \in E_\delta\} <_I f_{\delta'}. \tag{14.10}$$

Observe that $D \cap E_\delta$ is closed unbounded in δ, and thus $C = \{i \in \kappa^{++} \mid \xi(i) \in E_\delta\}$ is closed unbounded. Hence for some $\alpha \in S$, $C_\alpha \subseteq C$. So (14.10) implies that

$$\sup\{f_{\xi(i)} \mid i \in C_\alpha\} <_I f_{\delta'}. \tag{14.11}$$

Let $N_\alpha \subseteq C_\alpha$ be the set of non-accumulation points of C_α, that is those $i \in C_\alpha$ for which $C_\alpha \cap i$ is bounded in i. We shall prove that $\{f_{\xi(i)} \mid i \in N_\alpha\}$ is strongly increasing. Since $\xi(i+1) \in U$ for every i, the sandwich argument (2.7) gives a strongly increasing subsequence of $\{f_\alpha \mid \alpha \in U\}$ of order-type κ.

Claim. *For every $i < j$ both in C_α*

$$\sup\{f_{\xi(k)} \mid k \leq i \wedge k \in C_\alpha\} <_I f_{\xi(j)}. \tag{14.12}$$

Proof of Claim. Recall how $f_{\xi(i+1)}$ was defined. We considered (14.9) and asked if h_α is $<_I$ dominated by some f_σ. The answer was positive, since $f_{\delta'}$ is such a bound. Hence the claim and the lemma follow. $\dashv$

2.20 Exercise. Let κ and λ be regular cardinals with $\kappa^{++} < \lambda$, and let F be any function with $\mathrm{dom}(F) \subseteq [\lambda]^{<\kappa}$ and such that $F(X) \in \lambda$ for $X \in \mathrm{dom}(F)$. Suppose that for every $\delta \in S^\lambda_{\kappa^{++}}$ there exists a closed unbounded set $E_\delta \subseteq \delta$ such that $[E_\delta]^{<\kappa} \subseteq \mathrm{dom}(F)$. Then the following set S is stationary: the set of all ordinal $\alpha \in S^\lambda_\kappa$ for which there exists a closed unbounded set $D \subseteq \alpha$ with the property that, for any $a < b$ both in D, $F(\{d \in D \mid d \leq a\}) < b$.

A typical application of Lemma 2.19 is the following.

2.21 Theorem. *Suppose that I is a proper ideal over a set of regular cardinals A, and λ is a regular cardinal such that $\prod A/I$ is λ-directed. If $\langle g_\xi \mid \xi < \lambda\rangle$ is any sequence in $\prod A$, then there exists a $<_I$-increasing sequence $f = \langle f_\xi \mid \xi < \lambda\rangle$ of length λ in $\prod A/I$, such that $g_\xi < f_{\xi+1}$ for every $\xi < \lambda$ and $(*)_\kappa$ holds for f for every regular cardinal κ such that $\kappa^{++} < \lambda$ and $\{a \in A \mid a \leq \kappa^{++}\} \in I$. Hence if $\kappa = |A|^+$ is such a cardinal, then by Theorem 2.15 and the fact that $(*)_\kappa$ holds, we have an exact upper bound g to the sequence f so that $\{a \in A \mid \mathrm{cf}(g(a)) < \kappa\} \in I$.*

Proof. We shall define a $<_I$-increasing sequence $\langle f_\xi \mid \xi < \lambda\rangle$ in $\prod A/I$ as follows. At successor stages, if f_ξ is defined, let $f_{\xi+1}$ be any function in $\prod A$ that $<$-extends f_ξ and g_ξ.

1. At limit stages $\delta < \lambda$ there are two cases. In the first $\mathrm{cf}(\delta) = \kappa^{++}$ where κ is regular and $\{a \in A \mid a \leq \kappa^{++}\} \in I$. Then fix some $E_\delta \subseteq \delta$ closed unbounded and of order-type $\mathrm{cf}(\delta)$, and define

$$f_\delta = \sup\{f_i \mid i \in E_\delta\}.$$

   Then $f_\delta(a) < a$ when $a > \kappa^{++}$, and thus $f_\delta \in \prod A/I$ since $\{a \in A \mid a \leq \kappa^{++}\} \in I$.

2. If $\delta < \lambda$, but case 1 above does not hold, let $f_\delta \in \prod A$ be any $\leq_I$ upper bound of $\langle f_\xi \mid \xi < \delta\rangle$ guaranteed by the λ-directedness assumption.

Now Lemma 2.19 implies that $(*)_\kappa$ holds for every regular cardinal κ of the required form. $\dashv$

In the following, we shall apply Lemma 2.19 (or rather its consequence Theorem 2.21 above) and obtain an important representation of successors of singular cardinals with uncountable cofinality. But first we introduce a notation.

2.22 Notation. Let X be a set of cardinals, then

$$X^{(+)} = \{\alpha^+ \mid \alpha \in X\}$$

denotes the set of successors of cardinals in X.

2.23 Theorem (Representation of μ^+ as True Cofinality). *Suppose that μ is a singular cardinal with uncountable cofinality. Then there exists a closed unbounded set $C \subseteq \mu$ such that*

$$\mu^+ = \mathrm{tcf}\big(\prod C^{(+)}/J^{bd}\big)$$

where J^{bd} is the ideal of bounded subsets of $C^{(+)}$.

Proof. Let $C_0 \subseteq \mu$ be any closed unbounded set of limit cardinals such that $|C_0| = \mathrm{cf}(\mu)$ and all cardinals in C_0 are above $\mathrm{cf}(\mu)$. Clearly all cardinals in C_0 that are limit points of C_0 are singular cardinals, and hence we can assume that C_0 consists only of singular cardinals.

Observe that $\prod C_0^{(+)}/J^{bd}$ is μ-directed, and in fact is μ^+-directed since μ is a singular cardinal. Indeed, suppose that $F \subseteq \prod C_0^{(+)}$ has cardinality $< \mu$ and define $h(a)$ by $h(a) = \sup\{f(a) \mid f \in F\}$ for every $a \in C_0^{(+)}$ above $|F|$ (so that $h(a) \in a$), and $h(a)$ is arbitrarily defined on smaller a's. This proves that every subset of $\prod C_0^{(+)}$ of cardinality $< \mu$ is bounded in $<_{J^{bd}}$. But then it follows that subsets of $\prod C_0^{(+)}$ of cardinality μ are also bounded: decompose any such subset $F = \bigcup_{\alpha<\mathrm{cf}(\mu)} F_\alpha$ where each F_α has cardinality $< \mu$, then bound each F_α, and finally bound the sequence of bounds.

Thus $\prod C_0^{(+)}/J^{bd}$ is μ^+-directed and we may construct a J^{bd} increasing sequence $f = \langle f_\xi \mid \xi < \mu^+\rangle$ in $\prod C_0^{(+)}$ such that $(*)_\kappa$ holds for every regular cardinal $\kappa < \mu$ (apply Theorem 2.21 in its simpler form in which there is no need to extend a given sequence g).

Theorem 2.15 implies that f has an exact upper bound $h : C_0^{(+)} \to \mathrm{On}$ such that

$$\{a \in C_0^{(+)} \mid \mathrm{cf}(h(a)) < \kappa\} \in J^{bd} \tag{14.13}$$

for every regular $\kappa < \mu$. We may assume that $h(a) \le a$ for every $a \in C_0^{(+)}$, since the identity function is clearly an upper bound to f.

2.24 Claim. *The set $\{\alpha \in C_0 \mid h(\alpha^+) = \alpha^+\}$ contains a closed unbounded set.*

Proof of Claim. Suppose toward a contradiction that for some stationary set $S \subseteq C_0$, $h(\alpha^+) < \alpha^+$ for every $\alpha \in S$. Since all cardinals of C_0 are singular, $\mathrm{cf}(h(\alpha^+)) < \alpha$ for every $\alpha \in S$. Hence (by Fodor's theorem) $\mathrm{cf}(h(\alpha^+))$ is bounded by some $\kappa < \mu$ on a stationary subset of α in S. But this is in contradiction to (14.13) above.

Thus we have proved the existence of a closed unbounded set $C \subseteq C_0$ such that $h(\alpha^+) = \alpha^+$ for every $\alpha \in C$. We claim that $\mu^+ = \mathrm{tcf}(\prod C^{(+)}/J^{bd})$. But this is clear since $h\restriction C^{(+)}$, which is the identity function, is an exact upper bound to the sequence $\langle f_\xi\restriction C^{(+)} \mid \xi < \mu^+\rangle$ which is J^{bd} increasing and of length μ^+. This ends the proof of the claim and Theorem 2.23. ⊣

A somewhat stronger form of this theorem is in Exercise 4.17.

2.25 Exercise. Prove the following representation theorem for μ^+ in case $\mathrm{cf}(\mu) = \aleph_0$.

2.26 Theorem. *If μ is a singular cardinal of countable cofinality then for some unbounded set $D \subseteq \mu$ (of order-type ω) of regular cardinals*

$$\mu^+ = \mathrm{tcf}\big(\textstyle\prod D/J^{bd}\big)$$

where J^{bd} is the ideal of bounded subsets of D. For example, there exists a set $B \subseteq \{\aleph_n \mid n < \omega\}$ such that $\mathrm{tcf}(\prod B/J^{bd}) = \aleph_{\omega+1}$.

Hint. Let C_0 be any ω sequence converging to μ, consisting of regular cardinals. Repeat the proof above and define $D = \{\mathrm{cf}(h(a)) \mid a \in C_0\}$. Then use Lemma 2.3.

The theory of exact upper bounds, which is the basis of pcf theory, can be developed in various ways. For example [10] presents Shelah's Trichotomy Theorem, and extends it to further analyze the set of flat points. Suitably interpreted, Theorem 2.15 is equivalent to Theorem 18 of [10]. The following exercise establishes the connection between the trichotomy and the bounding projection property.

2.27 Exercise (The Trichotomy Theorem). Suppose that $\lambda > |A|^+$ is a regular cardinal, and $f = \langle f_\xi \mid \xi < \lambda\rangle$ is a $<_I$ increasing sequence. Consider the following properties of f and a regular cardinal κ such that $|A| < \kappa \leq \lambda$:

Bad$_\kappa$ There are sets of ordinals $S(a)$ for $a \in A$ such that $|S(a)| < \kappa$ and sup_of_S $<_I$-dominates f, and there is an ultrafilter D over A, extending the dual of I, such that for every $\alpha < \lambda$, $f^+_\alpha <_D f_\beta$ for some $\beta < \lambda$ (where $f^+_\alpha = \mathrm{proj}(f_\alpha, S)$).

Ugly There exists a function $g \in \mathrm{On}^A$ such that, forming $t_\alpha = \{a \in A \mid g(a) < f_\alpha(a)\}$, the sequence $\langle t_\alpha \mid \alpha < \lambda\rangle$ which we know to be $\subseteq_I$ increasing does not stabilize modulo I. That is, for every α there is some $\beta > \alpha$ in λ such that $t_\beta \setminus t_\alpha \in I^+$.

Good$_\kappa$ There exists an exact upper bound g to the sequence f such that $\mathrm{cf}(g(a)) \geq \kappa$ for every $a \in A$.

Prove that the bounding projection property for κ is equivalent to $\neg$**Bad**$_\kappa$ $\wedge$ $\neg$**Ugly**. Hence the Trichotomy Theorem which says that if neither **Bad**$_\kappa$ nor **Ugly**, then **Good**$_\kappa$.

2.28 Exercise ([15] Lemma 0.D, Chap. V). If λ is a regular cardinal with $\forall\mu < \lambda\ \mu^{|A|} < \lambda$ and $f_\alpha \in \mathrm{On}^A$ for $\alpha < \lambda$, then for some unbounded $E \subseteq \lambda$, for all $\alpha < \beta$ both in E, $f_\alpha \leq f_\beta$ and $\{a \in A \mid f_\alpha(a) = f_\beta(a)\}$ does not depend on α, β in E.

Hence, if I is an ideal over A and $f_\alpha <_I f_\beta$ for all $\alpha < \beta$, then $(*)_\lambda$ holds.

Hint. For $a \in A$ fix some $\gamma_a > \sup\{f_\alpha(a) \mid \alpha \in \lambda\}$. For $\alpha < \lambda$, $a \in A$, define $s^\alpha(a) = \{f_\beta(a) \mid \beta < \alpha\} \cup \{\gamma_a\}$. Define $g_\alpha = \mathrm{proj}(f_\alpha, s^\alpha)$. Let $T = \{\delta < \lambda \mid \mathrm{cf}(\delta) = |A|^+\}$. For $\alpha \in T$ there exists a $\mu_\alpha < \alpha$ such that $g_\alpha = \mathrm{proj}(f_\alpha, s^{\mu_\alpha})$. By Fodor's theorem we may assume $\mu = \mu_\alpha$ is fixed on a stationary set $T' \subseteq T$. Moreover, since s^μ has cardinality $|\mu|$ and $|\mu|^{|A|} < \lambda$, we may assume that $g_\alpha = g$ is fixed for $\alpha \in T'' \subseteq T'$, stationary.

2.2. Application: Silver's Theorem

One form of Silver's Theorem says that if κ is a singular cardinal of uncountable cofinality such that $2^\delta = \delta^+$ for a stationary set of δ's in κ, then $2^\kappa = \kappa^+$. A slightly more general form is the following

2.29 Theorem (Silver [18]). *Let κ be a singular cardinal with uncountable cofinality: $\aleph_0 < \mathrm{cf}(\kappa) < \kappa$. Suppose that there exists a stationary set of cardinals $S \subseteq \kappa$ such that, for every $\delta \in S$, $\delta^{\mathrm{cf}(\kappa)} = \delta^+$. Then*

$$\kappa^{\mathrm{cf}(\kappa)} = \kappa^+$$

as well.

Proof. Assume that $S \subseteq \kappa$, of order-type $\mathrm{cf}(\kappa)$, is a stationary set of cardinals such that for every $\delta \in S$

$$\delta^{\mathrm{cf}(\kappa)} = \delta^+.$$

We have established the existence of a closed unbounded subset $C \subseteq \kappa$ with $\kappa^+ = \mathrm{tcf}(\prod C^{(+)}/J^{bd})$. So, by taking $S \cap C$ for S, we may conclude that $\prod S^{(+)}/J_{bd}$ has true cofinality κ^+ and let $f = \langle f_\xi \mid \xi \in \kappa^+\rangle$ be J^{bd} increasing and cofinal there.

Since $\lambda^{\mathrm{cf}(\kappa)} = \lambda^+$ for all $\lambda \in S$, there exists an encoding of all pairs $\langle \lambda, X\rangle$ where $X \in [\lambda]^{\mathrm{cf}(\kappa)}$ by ordinals in λ^+. Hence we can encode each $X \in [\kappa]^{\mathrm{cf}(\kappa)}$ by a function $h_X \in \prod S^{(+)}$, where $h_X(\lambda^+)$ gives the code of $X \cap \lambda$. Thus, if $X \neq Y$ then h_X and h_Y are eventually disjoint. Since each h_X is J^{bd} dominated by some f_ξ for $\xi \in \kappa^+$, the following lemma concludes the proof of our theorem.

2.30 Lemma. *For every function $g \in \prod S^{(+)}$, the collection*

$$F = \{X \in [\kappa]^{\mathrm{cf}(\kappa)} \mid h_X <_{J^{bd}} g\}$$

has cardinality $\leq \kappa$.

Proof. Suppose that, on the contrary, $|F| \geq \kappa^+$. For each $\delta \in S$ fix an enumeration of $g(\delta^+) \in \delta^+$ that has order-type $\leq \delta$. Using this enumeration, $h_X(\delta^+)$ is "viewed" as an ordinal in δ, denoted $k_X(\delta)$ whenever $h_X(\delta^+) < g(\delta^+)$. Thus for every $X \in F$, h_X is translated into a pressing down function defined on a final segment of S.

By Fodor's theorem, for some stationary set $S_X \subseteq S$, k_X is bounded on S_X, say by $\delta_X < \kappa$. Now the number of subsets of S is bounded by $2^{\mathrm{cf}(\kappa)} < \kappa$, and hence there exists a subset $F_0 \subseteq F$ of cardinality κ^+, a fixed stationary set S_0, and a fixed cardinal $\delta_0 \in S$ such that $S_X = S_0$ and $\delta_X = \delta_0$ for every X in F_0. Moreover the translation function taking $\delta \in S_0$ to that ordinal in δ_0 that indirectly encodes $X \cap \delta$ can also be assumed to be independent of $X \in F_0$, since there are at most $\delta_0^{\mathrm{cf}(\kappa)} = \delta_0^+$ such functions. Yet this is absurd because the translation function of h_X completely determines $X = \bigcup\{X \cap \delta \mid \delta \in S_0\}$. This is a contradiction which proves the lemma and the theorem. $\dashv$

2.31 Exercise. Show that the following form of Silver's Theorem is equivalent to Theorem 2.29 (cf. [8]). Let κ be a singular cardinal with uncountable cofinality: $\aleph_0 < \mathrm{cf}(\kappa) < \kappa$. Suppose that $\lambda^{\mathrm{cf}(\kappa)} < \kappa$ for all $\lambda < \kappa$, and there exists a stationary set of cardinals $S \subseteq \kappa$ such that, for every $\delta \in S$, $\delta^{\mathrm{cf}(\delta)} = \delta^+$. Then

$$\kappa^{\mathrm{cf}(\kappa)} = \kappa^+$$

as well.

2.32 Exercise. The proof given by Baumgartner and Prikry (in [1]) to Silver's Theorem simplifies the original proof, and is actually simpler than the proof given here which serves to illustrate some of the pcf concepts. In addition the Baumgartner-Prikry proof relies on very elementary notions. The following exercises describes that proof. Assume that κ is a singular cardinal with uncountable cofinality.

1. If $S \subseteq \kappa$ is a stationary set such that $\delta^{\mathrm{cf}(\kappa)} = \delta^+$ for $\delta \in S$, define on $\prod S^{(+)}$ a relation R by $f\ R\ g$ iff $\{\alpha \in S \mid f(\alpha^+) < g(\alpha^+)\}$ is stationary. Prove that for every g the cardinality of $R^{-1}g = \{X \in \kappa^{\mathrm{cf}(\kappa)} \mid h_X\ R\ g\}$ is $\leq \kappa$.

2. Prove that for every $f, g \in \prod S^{(+)}$ that are eventually different either $f\ R\ g$ or $g\ R\ f$. Take any collection $X_i \in [\kappa]^{\mathrm{cf}(\kappa)}$, $i < \kappa^+$, of different subsets and consider $H = \bigcup_{i \in \kappa^+} R^{-1} h_{X_i}$. If $\kappa^{\mathrm{cf}(\kappa)} > \kappa^+$ there must be some $g \notin H$, and hence $h_{X_i}\ R\ g$ for every $i < \kappa^+$. This is a contradiction.

2.3. Application: A Covering Theorem

In this subsection V denotes the universe of all sets, and U a transitive subclass containing all ordinals and satisfying the axioms of ZFC. (See, for example, Levy [12] for the meaning of statements concerning classes.) If X and Y are sets of ordinals in V and U (respectively) and $X \subseteq Y$, then we say that Y *covers* X.

The *countable covering property* of U (or between U and V) is the statement that any countable set of ordinals X is covered by some countable set of ordinals Y in U (that is, Y is in U, and Y is countable in V). Similarly, for any cardinal κ, the $\leq \kappa$ covering property is that any set of cardinals X of cardinality $\leq \kappa$ is covered by some set in U that has cardinality $\leq \kappa$ in V.

If the $\leq \kappa$ covering property holds for every cardinal κ, then we say that the *full covering property* holds for U: every set of ordinals X is covered by some set Y in U such that X and Y are equinumerous in V. The following theorem gives conditions by which the full covering property can be deduced from the countable covering property.

2.33 Theorem (Magidor). *Suppose U is a transitive class containing all ordinals and satisfying all the* ZFC *axioms. Moreover, assume that*

1. GCH *holds in U,*
2. *U and the universe V have the same cardinals, and moreover every regular cardinal in U remains regular in V.*

Then the countable covering property for U implies the full covering property.

Proof. Observe first that if U and V have the same regular cardinals, they have the same cardinals and $\mathrm{cf}^U(\kappa) = \mathrm{cf}^V(\kappa)$ for every ordinal. Also, for every set $X \in U$, $|X|^U = |X|^V$. We prove by induction on $\lambda \in \mathrm{On}$ that every $X \subseteq \lambda$ is covered by some Y in U of the same V cardinality. Of course if X is bounded in λ then the inductive assumption applies, and hence we can consider only sets that are unbounded in λ.

If λ is not a cardinal, let $|\lambda|$ be its cardinality. So $|\lambda| < \lambda < \lambda^+$ in U as well since V and U have the same cardinals. Since λ and $|\lambda|$ are equinumerous in U, the inductive assumption for $|\lambda|$ implies that any subset of λ can be covered by a set in U of the same cardinality.

So we assume that λ is a cardinal. If it is a regular cardinal, then any unbounded $X \subseteq \lambda$ is covered by λ itself. Hence we are left with the case that λ is a singular cardinal, in V and hence in U since both universes have the same regular/singular predicate. Again, if $X \subseteq \lambda$ has cardinality λ then λ itself is a covering as required, and hence we may assume that $|X| < \lambda$.

Assume first that $\mathrm{cf}(\lambda) = \omega$. Then $\mathrm{cf}^U(\lambda) = \omega$ as well. Suppose that an unbounded set $X \subseteq \lambda$ of cardinality $< \lambda$ is given. Take in U an increasing cofinal in λ sequence $\langle \lambda_i \mid i \in \omega \rangle$. Since $2^{<\lambda} = \lambda$ is assumed in U, there exists in U an enumeration of length λ of all *bounded* subsets of λ of cardinality $\leq |X|$. Now consider the sequence $X \cap \lambda_i$, $i \in \omega$ (where X is the set to be covered) and cover first each $X \cap \lambda_i$ by some $Y_i \in U$ with $|Y_i| = |X \cap \lambda_i|$. Then define $\alpha_i \in \lambda$ to be the ordinal that encodes Y_i in U, and form the countable set $A = \{\alpha_i \mid i \in \omega\}$ of ordinals that encode X. This countable set A can be covered by some countable set A' in U, and we can define in U a cover

$$Y = \bigcup \{E \subseteq \lambda_i \mid \ E \text{ is encoded by some ordinal in } A' \text{ and } |E| \leq |X|\}.$$

Clearly $X \subseteq Y$ and $|Y| = |X|$.

Finally suppose that λ is a singular cardinal with uncountable cofinality, and it is here that the theory developed so far is employed. Since V and U have the same regular cardinals, $\mathrm{cf}^U(\lambda) = \mathrm{cf}(\lambda)$.

We work for a while in U and apply the Representation Theorem 2.23 to λ. In fact, we must analyze the proof and use the construction rather than the theorem. Recall that we took an arbitrary closed unbounded set $C_0 \subseteq \lambda$ consisting of singular cardinals such that $|C_0| = \mathrm{cf}(\lambda) < \min C_0$. Then we constructed a J^{bd} increasing sequence $f = \langle f_\xi \mid \xi < \lambda^+ \rangle$ in $\prod C_0^{(+)}$ such that for all limit ordinals $\delta < \lambda^+$ a closed unbounded set $E_\delta \subseteq \delta$ was chosen with $|E_\delta| = \mathrm{cf}(\delta) < \lambda$ and then

$$f_\delta =_{J^{bd}} \sup\{f_i \mid i \in E_\delta\}$$

was defined. All of this is done in U, but now we pass to V and deduce that $(*)_\kappa$ holds for every regular $\kappa < \lambda$ (by Lemma 2.19). Hence f has an exact upper bound h such that $\{a \in C_0^{(+)} \mid \mathrm{cf}(h(a)) < \kappa\} \in J^{bd}$ for every $\kappa < \lambda$. Now the argument of Claim 2.24 applies, and there exists (in V) a closed unbounded set $C \subseteq C_0$ such that $\{f_\xi \restriction C^{(+)} \mid \xi < \lambda^+\}$ is cofinal in $\prod C^{(+)}/J^{bd}$.

We continue now the proof that any set $X \subseteq \lambda$ of cardinality $\lambda_0 < \lambda$ can be covered in U by a set of the same cardinality. Since X is unbounded in λ, $\lambda_0 \geq \mathrm{cf}(\lambda)$. For every $\alpha \in C_0$ cover $X \cap \alpha$ by some $Y_\alpha \in U$ (a subset of α) of cardinality $\leq \lambda_0$. We assume in U an enumeration of length α^+ of all subsets of α of size $\leq \lambda_0$. There is an index $< \alpha^+$ that encodes Y_α in U. The function d taking $\alpha^+ \in C_0^{(+)}$ to that coding ordinal is defined in V and is bounded by some $f_\xi \in U$. Namely $d \restriction C^{(+)} <_{J^{bd}} f_\xi \restriction C^{(+)}$. In U, choose for every $\alpha \in C_0$ a function $g_\alpha : f_\xi(\alpha^+) \to \alpha$ that is one-to-one. Then in V look at the values $g_\alpha(d(\alpha^+)) < \alpha$, and find a stationary set $S \subseteq C$ on which these values are bounded, say by κ. The set $\{g_\alpha(d(\alpha)) \mid \alpha \in S\} \subseteq \kappa$ can be covered by some set Y in U that has the same cardinality (namely $\mathrm{cf}(\lambda)$). Now look in U at the set $\bigcup_{\alpha \in C_0} g_\alpha^{-1} Y$. Every index in $g_\alpha^{-1} Y$ represents a subset of α of cardinality $\leq \lambda_0$, and hence this yields a cover of X of cardinality λ_0. $\dashv$

2.34 Exercise. There is actually no need to start with countable covering in order to deduce covering for all higher cardinals. The following generalization is left as an exercise.

2.35 Theorem. *Assume as in Theorem 2.33 that $U \subseteq V$ have the same regular cardinals, and* GCH *holds in U. Let λ_0 be any cardinal such that every countable set of ordinals is covered by some set in U of cardinality $\leq \lambda_0$. Then any set of ordinals X is covered by some set in U of cardinality $|X| + \lambda_0$.*

3. Basic Properties of the pcf Function

For any set A of regular uncountable cardinals define

$$\mathrm{pcf}(A) = \{\lambda \mid \text{for some ultrafilter } U \text{ over } A,\ \lambda = \mathrm{cf}(\textstyle\prod A/U)\}.$$

Some easily verifiable properties:

1. If $\lambda = \mathrm{tcf}(\prod A/F)$ for some filter F over A, then $\lambda \in \mathrm{pcf}(A)$. (For any ultrafilter U that extends F, $\lambda = \mathrm{tcf}(\prod A/U)$.)

2. $A \subseteq \mathrm{pcf}(A)$. For every $a \in A$ we can take the principal ultrafilter over A concentrating on $\{a\}$.

3. $A \subseteq B$ implies $\mathrm{pcf}(A) \subseteq \mathrm{pcf}(B)$. Because every ultrafilter D over A can be extended to D' over B, and the ultraproducts $\prod A/D$ and $\prod B/D'$ are the same.

4. For any sets A and B, $\mathrm{pcf}(A \cup B) = \mathrm{pcf}(A) \cup \mathrm{pcf}(B)$. Indeed, if $\lambda \in \mathrm{pcf}(A \cup B)$, and D is an ultrafilter over $A \cup B$ with ultraproduct of cofinality λ, then either $A \in D$ or $B \in D$ (or both) and hence $\lambda \in \mathrm{pcf}(A)$ or $\lambda \in \mathrm{pcf}(B)$. For the other direction use the previous item.

We say that A is an *interval of regular cardinals* if for some cardinals $\alpha < \beta$, A is the set of all regular cardinals κ such that $\alpha \leq \kappa < \beta$. This term is slightly misleading because one may misinterpret it as saying that all cardinals between α and β are regular.

3.1 Theorem (The "No Holes" Argument). *Assume that A is an interval of regular cardinals satisfying $|A| < \min A$, and λ is a regular cardinal with $\sup A < \lambda$. Let I be a proper ideal over A such that $\prod A/I$ is λ-directed. Then $\lambda \in \mathrm{pcf}(A)$.*

Proof. We may assume that every proper initial segment of A is in I (or else substitute for A its first initial segment that is not in I). It now follows that A is infinite and unbounded (without a maximum).

Theorem 2.21 gives an $<_I$-increasing sequence $f = \langle f_\xi \mid \xi \in \lambda\rangle$ in $\prod A/I$ that satisfies $(*)_\kappa$ for every regular cardinal κ in A (and thus for smaller cardinals of course). In particular $(*)_{|A|^+}$ holds, and f has an exact upper bound $h \in \mathrm{On}^A$ such that

$$\{a \in A \mid \mathrm{cf}(h(a)) < \kappa\} \in I \tag{14.14}$$

for every $\kappa \in A$ (this by Theorem 2.15). Since the identity function $\mathrm{id} : A \to A$ taking a to a is clearly an upper bound of f, $h(a) \leq a$ for I-almost all $a \in A$. Yet (14.14) implies that

$$\{a \in A \mid \mathrm{cf}(h(a)) < \min A\} \in I,$$

and hence we have $\min(A) \leq \mathrm{cf}(h(a)) \leq a$ for I-almost all $a \in A$. Changing h on a null set, we may assume for simplicity that this holds for every $a \in A$, namely that

$$\mathrm{cf}(h(a)) \in A \quad \text{for all } a \in A$$

(as A is an interval of regular cardinals). Since the sequence f has length λ, $\prod h/I$ has true cofinality λ. Consequently $\prod_{a \in A} \mathrm{cf}(h(a))/I$ has true cofinality λ as well. Since $|A| < \min A$, Lemma 2.3 gives a proper ideal J on

$B = \{\mathrm{cf}(h(a)) \mid a \in A\} \subseteq A$, such that $\prod B/J$ has true cofinality λ as well. So $\lambda \in \mathrm{pcf}(A)$. We note in addition that J is the Rudin-Keisler projection obtained via $\mathrm{cf} \circ h$, and hence (14.14) implies for every $\kappa < \sup A$ that $B \cap \kappa \in J$. $\dashv$

Upon examination of the proof, the reader will notice that the following slightly stronger formulation of the theorem can be obtained. In this formulation the requirement that A is an interval is relaxed.

3.2 Theorem. *Assume that A is a set of regular cardinals such that $|A| < \min A$, and λ is a regular cardinal such that $\sup A < \lambda$. Suppose that I is a proper ideal over A containing all proper initial segments of A and such that $\prod A/I$ is λ-directed. Then $\lambda \in \mathrm{pcf}(A')$ for some set A' of regular cardinals such that*

1. *$A' \subseteq [\min A, \sup A)$, and A' is cofinal in $\sup A$.*
2. *$|A'| \leq |A|$.*

In fact, λ is the true cofinality of $\prod A'/J$ for an ideal J over A' that contains all bounded subsets of A'.

Proof. Follow the previous proof and let A' be the set $\{\mathrm{cf}(h(a)) \mid a \in A\}$. $\dashv$

3.3 Notation. The property $|A| < \min A$ assumed for the set of regular cardinals appearing in the theorem is so pervasive in the pcf theory that it ought to be given a name. Following [6] we say that a set of regular cardinals A is *progressive* if $|A| < \min A$.

3.1. The Ideal $J_{<\lambda}$

Let A be a set of regular cardinals. For any cardinal λ define

$$J_{<\lambda}[A] = \{X \subseteq A \mid \mathrm{pcf}(X) \subseteq \lambda\}.$$

In plain words, $X \in J_{<\lambda}[A]$ iff for every ultrafilter D over A such that $X \in D$, $\mathrm{cf}(\prod A/D) < \lambda$. That is, X "forces" the cofinalities of its ultraproducts to be below λ.

Clearly $J_{<\lambda}[A]$ is an ideal over A, but it is not necessarily a proper ideal since $A \in J_{<\lambda}[A]$ is possible. However, if $\lambda \in \mathrm{pcf}(A)$, then $J_{<\lambda}[A]$ *is* proper ($A \notin J_{<\lambda}[A]$, or else $\mathrm{pcf}(A) \subseteq \lambda$ shows that $\lambda \notin \mathrm{pcf}(A)$). When the identity of A is obvious from the context, we write $J_{<\lambda}$ instead of $J_{<\lambda}[A]$. Note that if $A \subseteq B$ then $J_{<\lambda}[A] = J_{<\lambda}[B] \cap \mathcal{P}(A)$.

Let $J^*_{<\lambda}[A]$ be the dual filter over A. Then

$$J^*_{<\lambda}[A] = \bigcap\bigl\{D \mid D \text{ is an ultrafilter and } \mathrm{cf}(\textstyle\prod A/D) \geq \lambda\bigr\}.$$

3.4 Theorem (λ-directedness). *Suppose that A is a progressive set of regular cardinals. Then for every cardinal λ, $\prod A/J_{<\lambda}[A]$ is λ-directed: any set of fewer than λ functions is bounded in $\prod A/J_{<\lambda}[A]$.*

Proof. The theorem holds trivially if $A \in J_{<\lambda}[A]$, since $|\prod A/J_{<\lambda}| = 1$ in this case. So we assume that $J_{<\lambda}$ is a proper ideal over A. Let $\kappa_0 = \min A$ be the first cardinal of A, and κ_1, κ_2 be the second, third etc. cardinals of A. The case $\lambda \le \kappa_n$ for n finite is quite obvious: if $\lambda = \kappa_n$ then $J_{<\lambda} = \mathcal{P}(\{\kappa_0, \dots, \kappa_{n-1}\})$ and for every family $F \subseteq \prod A$ of cardinality $< \lambda$, $\sup F \in \prod A$, because $(\sup F)(a) = \bigcup\{f(a) \mid f \in F\} < a$, since $|F| < \lambda \le a$ for every $a \notin \{\kappa_0, \dots, \kappa_{n-1}\}$). So we can certainly assume that $\lambda > \kappa_n$ for all $n \in \omega$, and hence that $\{\kappa_n\} \in J_{<\lambda}$.

Since any null subset of A can be removed without changing the structure of $\prod A/J_{<\lambda}$, we may assume that $|A|^+, |A|^{++}, |A|^{+3} \notin A$. That is we can assume that

$$|A|^{+3} < \min A < \lambda.$$

We shall prove by induction on $\lambda_0 < \lambda$ that $\prod A/J_{<\lambda}$ is λ_0^+-directed: for every $F = \{f_i \mid i \in \lambda_0\} \subseteq \prod A$ a family of functions of cardinality λ_0, F has an upper bound in $\prod A/J_{<\lambda}$. The case $\lambda_0 < \min A$ is obvious as we saw.

So let $F = \{f_i \mid i \in \lambda_0\} \subseteq \prod A$ be a subset of $\prod A$ where $\lambda_0 < \lambda$ and assume that $\prod A/J_{<\lambda}$ is λ_0-directed. Our aim is to bound F in $\prod A/J_{<\lambda}$.

In case λ_0 is singular, we take $\langle \alpha_i \mid i < \mathrm{cf}(\lambda_0)\rangle$ increasing and cofinal in λ_0, and obtain $g_i \in \prod A$ for every $i < \mathrm{cf}(\lambda_0)$ that bounds $\{f_\xi \mid \xi < \alpha_i\}$. Then we apply the inductive assumption again to the sequence $\{g_i \mid i < \mathrm{cf}(\lambda_0)\}$, and obtain a bound to F.

Thus λ_0 is assumed to be a regular cardinal above $|A|^{+3}$. We shall replace F by a $<_{J_{<\lambda}}$-increasing sequence that satisfies $(*)_\kappa$ for $\kappa = |A|^+$. That is, using Theorem 2.21 we define a $<_{J_{<\lambda}}$-increasing sequence $\langle f'_\xi \mid \xi < \lambda_0\rangle$ satisfying $(*)_\kappa$ and such that $f_i \le f'_i$.

Hence we can assume that the sequence $f = \langle f_i \mid i < \lambda_0\rangle$ that we want to dominate satisfies $(*)_{|A|^+}$ and thus has an exact upper bound $g \in \mathrm{On}^A$ in $<_{J_{<\lambda}[A]}$ (by Theorem 2.15).

Since the identity function taking $a \in A$ to a is an upper bound of our sequence f, we may assume that $g(a) \le a$ for all $a \in A$ (by possibly changing g on a null set). We intend to prove that $B = \{a \in A \mid g(a) = a\} \in J_{<\lambda}[A]$, and thus that $g =_{J_{<\lambda}} g'$ for some $g' \in \prod A$ which will show that g bounds f in $\prod A/J_{<\lambda}[A]$.

Assume toward a contradiction that $B \notin J_{<\lambda}[A]$. Then (by definition of $J_{<\lambda}$) there is an ultrafilter D over A such that $B \in D$ and $\mathrm{cf}(\prod A/D) \ge \lambda$. Clearly $D \cap J_{<\lambda} = \emptyset$, or else $\mathrm{cf}(\prod A/D) < \lambda$. The sequence f of length $\lambda_0 < \lambda$ is necessarily bounded in $\prod A/D$ and we let $h \in \prod A/D$ be such a bound. So $h(a) < g(a)$ for every $a \in B$ (since $g(a) = a$ for $a \in B$). Hence (by definition of an exact upper bound) there is some f_i in f such that $h \restriction B <_{J_{<\lambda}[A]} f_i \restriction B$. But this would imply $h <_D f_i$, which contradicts the definition of h as an upper bound. ⊣

3.5 Corollary. *Suppose that A is a progressive set of regular cardinals. Then for every ultrafilter D over A*

$$\mathrm{cf}\big(\textstyle\prod A/D\big) < \lambda \quad \textit{iff} \quad J_{<\lambda}[A] \cap D \neq \emptyset.$$

Hence $\mathrm{cf}(\prod A/D) = \lambda$ *iff* $J_{<\lambda^+} \cap D \neq \emptyset$ *and* $J_{<\lambda} \cap D = \emptyset$. *Namely,* $\mathrm{cf}(\prod A/D) = \lambda$ *iff* λ^+ *is the first cardinal* μ *such that* $J_{<\mu} \cap D \neq \emptyset$.

Proof. If $J_{<\lambda}[A] \cap D \neq \emptyset$ and $X \in J_{<\lambda}[A] \cap D$, then by definition of $X \in J_{<\lambda}$

$$\mathrm{cf}\big(\textstyle\prod A/D\big) < \lambda.$$

On the other hand, if $J_{<\lambda} \cap D = \emptyset$, then the above theorem stating that $\prod A/J_{<\lambda}$ is λ-directed gives that $\prod A/D$ is λ-directed as well. Thus $\mathrm{cf}(\prod A/D) < \lambda$ is impossible in this case. The additional conclusion of the corollary is easily derived. ⊣

This corollary allows us to investigate the relationship between $J_{<\lambda}[A]$ and $J_{<\lambda^+}[A]$. By definition $X \in J_{<\lambda^+}[A]$ iff $X \subseteq A$ and for every ultrafilter D over A containing X, $\mathrm{cf}(\prod A/D) \leq \lambda$. For this reason, $J_{<\lambda^+}[A]$ is also denoted $J_{\leq\lambda}[A]$.

If $\lambda \notin \mathrm{pcf}(A)$, for example when λ is singular, then $J_{<\lambda} = J_{\leq\lambda}$. However, if $\lambda \in \mathrm{pcf}(A)$ then $J_{<\lambda} \subset J_{\leq\lambda}$ (where $\subset$ is the strict inclusion relation). Indeed, if D is an ultrafilter over A such that $\mathrm{cf}(\prod A/D) = \lambda$, then by Corollary 3.5 applied to λ^+, $J_{\leq\lambda} \cap D \neq \emptyset$, and certainly $J_{<\lambda} \cap D = \emptyset$. This argument shows that there is a one-to-one mapping from $\mathrm{pcf}(A)$ into $\mathcal{P}(A)$. Namely choosing $X_\lambda \in J_{\leq\lambda} \setminus J_{<\lambda}$ for every $\lambda \in \mathrm{pcf}(A)$. Thus we have the following theorem which is not evident from the definition of pcf.

3.6 Theorem. *If* A *is a progressive set of regular cardinals, then*

$$|\,\mathrm{pcf}(A)| \leq |\mathcal{P}(A)|.$$

Another consequence of Theorem 3.4 is that $\max \mathrm{pcf}(A)$ exists.

3.7 Corollary (max pcf). *If* A *is a progressive set of regular cardinals, then the set* $\mathrm{pcf}(A)$ *contains a maximal cardinal.*

Proof. Observe that if $\lambda_1 < \lambda_2$ are cardinals, then $J_{<\lambda_1}[A] \subseteq J_{<\lambda_2}[A]$. Define

$$I = \bigcup\{J_{<\lambda}[A] \mid \lambda \in \mathrm{pcf}(A)\}.$$

For every $\lambda \in \mathrm{pcf}(A)$ $J_{<\lambda}[A]$ is a proper ideal on A, and hence I (being the union of a chain of proper ideals) is also a proper ideal.

Since I is a proper ideal it can be extended to a maximal proper ideal, and we let E be any ultrafilter over A and disjoint to I. Let $\mu = \mathrm{cf}(\prod A/E)$. Since E is disjoint to I, it is disjoint to every $J_{<\lambda}[A]$ for $\lambda \in \mathrm{pcf}(A)$, and hence $\mathrm{cf}(\prod A/E) \geq \lambda$ by the previous corollary. That is $\mu = \mathrm{cf}(\prod A/E) = \max \mathrm{pcf}(A)$. As an important consequence we note that $\mu = \sup \mathrm{pcf}(A) = \max \mathrm{pcf}(A)$ is a regular cardinal (since it is in $\mathrm{pcf}(A)$). ⊣

3.8 Exercise. If λ is a limit cardinal then

$$J_{<\lambda}[A] = \textstyle\bigcup_{\theta<\lambda} J_{<\theta}[A].$$

Another way of writing this statement is that for every cardinal λ (not necessarily limit)

$$J_{<\lambda}[A] = \bigcup_{\theta<\lambda} J_{<\theta^+}[A] = \bigcup_{\theta<\lambda} J_{\leq\theta}[A].$$

The no holes argument has the following consequence.

3.9 Theorem. *Suppose that A is a progressive interval of regular cardinals. Then* $\mathrm{pcf}(A)$ *is again an interval of regular cardinals.*

Proof. We may assume that A is infinite, as the finite case is clear. We may also assume that A has no last cardinal (and deduce the general theorem in a short argument). Let $\lambda_0 = \max \mathrm{pcf}(A)$. We must show that every regular cardinal in the interval $[\min A, \lambda_0]$ is in $\mathrm{pcf}(A)$. Say $\mu = \sup A$. Since $\mu \notin A$ (A has no maximum), μ is a singular cardinal (because A is progressive). Since $A \subseteq \mathrm{pcf}(A)$ and A is an interval of regular cardinals, the substantial part of the proof is in showing that any regular cardinal in $(\mu, \lambda_0]$ is in $\mathrm{pcf}(A)$. But if λ is a regular cardinal and $\mu < \lambda \leq \lambda_0$, then $J_{<\lambda}$ is a proper ideal (since $\lambda \leq \max \mathrm{pcf}(A)$). By Theorem 3.4, $\prod A/J_{<\lambda}$ is λ-directed. Hence Theorem 3.1 applies, and $\lambda \in \mathrm{pcf}(A)$. ⊣

We can get some information even when A is not progressive.

3.10 Definition. Suppose that A is a set of regular cardinals and $\kappa < \min A$ is a cardinal. We define

$$\mathrm{pcf}_\kappa(A) = \bigcup\{\mathrm{pcf}(X) \mid X \subseteq A \text{ and } |X| = \kappa\}.$$

That is, $\mathrm{pcf}_\kappa(A)$ is the collection of all cofinalities of ultraproducts of A over ultrafilters that concentrate on subsets of A of power κ (or less).

Similarly to the previous theorem stating that $\mathrm{pcf}(A)$ of a progressive interval A is again an interval of regular cardinals, we have the following.

3.11 Theorem. *If A is an interval of regular cardinals, and $\kappa < \min A$, then* $\mathrm{pcf}_\kappa(A)$ *is an interval of regular cardinals.*

Proof. Define $\lambda_0 = \sup \mathrm{pcf}_\kappa(A)$, and let λ be a regular cardinal such that $\min A < \lambda < \lambda_0$. Then for some $X \subseteq A$ such that $|X| = \kappa$, $\lambda \leq \max \mathrm{pcf}(X)$. Hence $J_{<\lambda}[X]$ is proper, and we may assume that every initial segment of X is in $J_{<\lambda}$. As X *is* progressive, $\prod X/J_{<\lambda}$ is λ-directed, Theorem 3.2 can be applied, and it yields that $\lambda \in \mathrm{pcf}(X')$ for some $X' \subseteq A$ of cardinality $\leq |X|$. Thus $\lambda \in \mathrm{pcf}_\kappa(A)$. ⊣

Yet another consequence of the λ-directedness of $\prod A/J_{<\lambda}$ is the following

3.12 Theorem. *Suppose that A is a progressive set of regular cardinals and* $B \subseteq \mathrm{pcf}(A)$ *is also progressive. Then*

$$\mathrm{pcf}(B) \subseteq \mathrm{pcf}(A).$$

Hence if $\mathrm{pcf}(A)$ *is progressive, then* $\mathrm{pcf}(\mathrm{pcf}(A)) = \mathrm{pcf}(A)$.

Proof. Suppose that $\mu \in \mathrm{pcf}(B)$, and let E be an ultrafilter over B such that

$$\mu = \mathrm{cf}\big(\textstyle\prod_{b\in B} b/E\big). \tag{14.15}$$

For every $b \in B$ fix an ultrafilter D_b over A such that

$$b = \mathrm{cf}\big(\textstyle\prod A/D_b\big).$$

Define an ultrafilter D over A by

$$X \in D \quad \text{iff} \quad \{b \in B \mid X \in D_b\} \in E. \tag{14.16}$$

We shall prove that $\mu = \mathrm{cf}(\prod A/D)$, and hence that $\mu \in \mathrm{pcf}(A)$.

Consider (14.15). If, for every $b \in B$, $(b', <_{b'})$ is an ordering that has true cofinality b, then $\mu = \mathrm{cf}(\prod_{b\in B} b'/E)$ as well. Hence

$$\mu = \mathrm{cf}\big(\textstyle\prod_{b\in B}\big(\prod A/D_b\big)/E\big). \tag{14.17}$$

It remains to implement this iterated ultraproduct as an ultraproduct of A over D. For this aim consider the Cartesian product $B \times A$ and the ultrafilter P defined on $B \times A$ by

$$H \in P \quad \text{iff} \quad \{b \in B \mid \{a \in A \mid \langle b, a\rangle \in H\} \in D_b\} \in E.$$

For any pair $\langle b, a\rangle$ let $r(\langle b, a\rangle) = a$ be its right projection. The reader should prove the following isomorphism

3.13 Claim. $\prod_{\langle b,a\rangle\in B\times A} r(\langle b, a\rangle)/P \cong \prod_{b\in B}(\prod A/D_b)/E$.

Thus μ (an arbitrary cardinal in $\mathrm{pcf}(B)$) is the cofinality of the ultraproduct $\prod_{\langle b,a\rangle\in B\times A} r(\langle b, a\rangle)/P$. But the projection map $r : B \times A \to A$, shows that the ultrafilter D defined in (14.16) is the Rudin-Keisler projection of P, and we are almost in the situation of Lemma 2.3, which concludes that $\mu = \mathrm{cf}(\prod A/D)$. However Lemma 2.3 cannot be used verbatim because $|B \times A| < \min A$ is not assumed. All we know is that $|B| < \min B$. Recall (Lemma 2.3) that we had a map from $\prod A$ into $\prod_{\langle b,a\rangle\in B\times A} r(\langle b, a\rangle)$ carrying $h \in \prod A$ to $\bar{h} \in \prod_{\langle b,a\rangle\in B\times A} r(\langle b, a\rangle)$ defined by

$$\bar{h}(\langle b, a\rangle) = h(a).$$

We have proved that this map induces an isomorphism denoted L of $\prod A/D$ into $\prod_{\langle b,a\rangle\in B\times A} r(\langle b, a\rangle)$, but the problem is to prove that the image of L is cofinal there. Let $\lambda = \min B$. We have assumed that $|B| < \lambda$, and we shall use the fact that the reduced product modulo $J_{<\lambda}[A]$ is λ-directed as follows. Given any $g \in \prod_{\langle b,a\rangle\in B\times A} r(\langle b, a\rangle)$ define for every $b \in B$ the map $g_b \in \prod A$ by

$$g_b(a) = g(b, a).$$

Then $\{g_b \mid b \in B\}$ is bounded in $\prod A/J_{<\lambda}[A]$ by some function $h \in \prod A$, and we thus have that $g_b <_{J_{<\lambda}[A]} h$ for every $b \in B$. Hence

$$g_b <_{D_b} h$$

since $J_{<\lambda} \cap D_b = \emptyset$ (because $\mathrm{cf}(\prod A/D_b) = b$ and $\lambda \leq b$). So $g <_P \bar{h}$ is concluded. $\dashv$

4. Generators for $J_{<\lambda}$

A very useful property of the $J_{<\lambda}$ ideals is that for every cardinal $\lambda \in \mathrm{pcf}(A)$ there is a set $B_\lambda \subseteq A$ such that

$$J_{<\lambda^+}[A] = J_{<\lambda}[A] + B_\lambda$$

which means that the ideal $J_{<\lambda^+}[A]$ is generated by the sets in $J_{<\lambda}[A] \cup \{B_\lambda\}$. That is, for every $X \subseteq A$, $X \in J_{<\lambda^+}$ iff $X \setminus B_\lambda \in J_{<\lambda}$. So B_λ is a maximal set in $J_{\leq\lambda}[A]$ in the sense that if $B_\lambda \subseteq C \in J_{\leq\lambda}$ then $C \setminus B_\lambda \in J_{<\lambda}$. The property that $J_{\leq\lambda}[A]$ is generated from $J_{<\lambda}[A]$ by the addition of a single set is called *normality*.

Normality of $\lambda \in \mathrm{pcf}(A)$ is obtained by means of a universal sequence for λ, and these sequences are studied first.

4.1 Definition. Suppose that $\lambda \in \mathrm{pcf}(A)$. A sequence $f = \langle f_\xi \mid \xi < \lambda\rangle$ of functions in $\prod A$, increasing in $<_{J_{<\lambda}}$, is a *universal* sequence for λ if and only if for every ultrafilter D over A such that $\lambda = \mathrm{cf}(\prod A/D)$, f is cofinal in $\prod A/D$.

4.2 Theorem (Universally Cofinal Sequences). *Suppose that A is a progressive set of regular cardinals. Then every $\lambda \in \mathrm{pcf}(A)$ has a universal sequence.*

Proof. The proof is obvious in the case $\lambda = \min A$. (The functions f_ξ defined by $f_\xi(a) = \xi$ will do.) Therefore we shall assume that $|A|^+ < \min A < \lambda$.

Suppose that there is no universal sequence for λ. This means that for every $<_{J_{<\lambda}}$-increasing sequence $f = \langle f_\xi \mid \xi < \lambda\rangle$ there is an ultrafilter D over A such that $\mathrm{cf}(\prod A/D) = \lambda$ but f is bounded in $\prod A/D$.

The proof is typical in that it makes $|A|^+$ steps and obtains a contradiction from the continuous failure at every step.

So for each $\alpha < |A|^+$ we shall define a $<_{J_{<\lambda}}$-increasing sequence $f^\alpha = \langle f^\alpha_\xi \mid \xi < \lambda\rangle$ in $\prod A$, and assume that no f^α is universal. The definition is by recursion on $\alpha < |A|^+$ and the fact that $\prod A/J_{<\lambda}$ is λ-directed is used in this construction.

If we visualize the functions f^α_ξ as lying on a matrix $\langle \xi, \alpha\rangle \in \lambda \times |A|^+$, then in each column α the functions f^α_ξ are $<_{J_{<\lambda}}$ increasing with ξ, and in each row ξ the functions f^α_ξ are $\leq$ increasing with α.

To begin with $f^0 = \langle f^0_\xi \mid \xi < \lambda\rangle$ is an arbitrary $<_{J_{<\lambda}}$-increasing sequence in $\prod A/J_{<\lambda}$ of length λ.

At limit stages $\delta < |A|^+$ we define $f^\delta = \langle f^\delta_\xi \mid \xi < \lambda \rangle$ by induction on $\xi < \lambda$ so that for every $\xi < \lambda$

1. $f^\delta_i <_{J_{<\lambda}} f^\delta_\xi$ for $i < \xi$.

2. $\sup\{f^\alpha_\xi \mid \alpha < \delta\} \leq f^\delta_\xi$.

Suppose now that f^α is defined. Since it is not universal, there exists an ultrafilter D_α over A such that

1. $\mathrm{cf}(\prod A/D_\alpha) = \lambda$, and

2. the sequence f^α is bounded in $<_{D_\alpha}$.

So we can choose an $f^{\alpha+1}_0$ that bounds the sequence f^α in $<_{D_\alpha}$. The sequence $f^{\alpha+1}_i$ for $0 < i < \lambda$ is defined recursively by requiring that

1. $f^{\alpha+1}$ is $<_{J_{<\lambda}}$-increasing and cofinal in $\prod A/D_\alpha$, and

2. $f^{\alpha+1}_i \geq f^\alpha_i$ (everywhere) for every $i < \lambda$.

To sum up, we have constructed $<_{J_{<\lambda}}$-increasing sequences f^α, each of length λ, and ultrafilters D_α over A, for $\alpha < |A|^+$ so that:

1. for every $i < \lambda$, $\langle f^\alpha_i \mid \alpha < |A|^+ \rangle$ is increasing in $\leq$ (i.e. for $\alpha_1 < \alpha_2 < |A|^+$, $f^{\alpha_1}_i(a) \leq f^{\alpha_2}_i(a)$ for every a).

2. $f^\alpha = \langle f^\alpha_\xi \mid \xi < \lambda \rangle$ is bounded in $\prod A/D_\alpha$ by $f^{\alpha+1}_0$.

3. $f^{\alpha+1}$ is cofinal in $\prod A/D_\alpha$.

Now let $h = \sup\{f^\alpha_0 \mid \alpha < |A|^+\}$. Then $h \in \prod A$, because $|A|^+ < \min A$. Find for every $\alpha < |A|^+$ an index $i_\alpha < \lambda$ such that $h <_{D_\alpha} f^{\alpha+1}_{i_\alpha}$. This is possible since $f^{\alpha+1}$ is cofinal in $\prod A/D_\alpha$. Now pick an ordinal $i < \lambda$ such that $i > i_\alpha$ for every $\alpha < |A|^+$. This is possible since $\lambda > |A|^+$ is regular. So $h <_{D_\alpha} f^{\alpha+1}_i$ for every $\alpha < |A|^+$.

Define

$$A^\alpha = \leq(h, f^\alpha_i).$$

The sets $A^\alpha \subseteq A$ are increasing with α, that is $A^\alpha \subseteq A^\beta$ for $\alpha < \beta < |A|^+$ (since $f^\alpha_i \leq f^\beta_i$).

The contradiction is obtained when we show that $A^\alpha \subset A^{\alpha+1}$ (strict inclusion) for every $\alpha < |A|^+$ (and contrast this with $A^\alpha \subseteq A$). For this, observe the following two statements.

1. $A^\alpha \notin D_\alpha$, because $f^\alpha_i <_{D_\alpha} f^{\alpha+1}_0 \leq h$.

2. $A^{\alpha+1} \in D_\alpha$, because $h <_{D_\alpha} f^{\alpha+1}_i$.

$\dashv$

If $\lambda \in \text{pcf}(A)$ and D is an ultrafilter over A such that $\text{cf}(\prod A/D) = \lambda$, then $A \cap (\lambda + 1) \in D$ because otherwise $\{a \in A \mid a > \lambda\} \in D$ and then $\text{cf}(\prod A/D) > \lambda$. Thus, if $\langle f_\xi \mid \xi \in \lambda\rangle$ is a universal sequence for λ, we may assume that $f_\xi(a) = \xi$ for all $a \in A \setminus \lambda$.

4.3 Exercise. If $\lambda = \max \text{pcf}(A)$, then any universal sequence for λ is cofinal in $\prod A/J_{<\lambda}$.

Universal sequences can be used to prove the following

4.4 Theorem. *For every progressive set A of regular cardinals,*

$$\text{cf}\big(\prod A, <\big) = \max \text{pcf}(A).$$

Hence $\text{cf}(\prod A, <)$ *is a regular cardinal.*

Proof. The partial ordering $<$ in this theorem refers to the everywhere dominance relation on $\prod A$. The required equality is obtained by first proving $\geq$ and then $\leq$.

Suppose that $\lambda = \max \text{pcf}(A)$, and D is an ultrafilter over A such that $\lambda = \text{cf}(\prod A/D)$. Then $<_D$ extends $<$ on $\prod A$. That is, for $f, g \in \prod A$, $f < g$ implies $f <_D g$. This shows that any cofinal set in $(\prod A, <)$ is also cofinal in $(\prod A, <_D)$, and hence that $\text{cf}(\prod A, <) \geq \text{cf}(\prod A, <_D) = \lambda$.

Now we must exhibit a cofinal subset of $(\prod A, <)$ of cardinality λ in order to conclude the proof.

Fix for every $\mu \in \text{pcf}(A)$ a universal sequence $f^\mu = \langle f^\mu_i \mid i < \mu\rangle$ for μ. Let F be the set of all functions of the form

$$\sup\{f^{\mu_1}_{i_1}, f^{\mu_2}_{i_2}, \ldots, f^{\mu_n}_{i_n}\}$$

where $\mu_1, \mu_2, \ldots, \mu_n$ is a finite sequence of cardinals in $\text{pcf}(A)$ (with possible repetitions) and $i_k < \mu_k$ are arbitrary indices. (Recall the definition of $\sup\{g_1, \ldots, g_n\}$: at every $a \in A$ it returns $\max\{g_1(a), \ldots, g_n(a)\}$). Clearly $|F| = \lambda$.

4.5 Claim. *F is cofinal in* $(\prod A, <)$.

Proof of Claim. Let $g \in \prod A$ be any function there. Consider the following collection of subsets of A:

$$I = \{>(f, g) \mid f \in F\}.$$

(Recall that $>(f, g) = \{a \in A \mid f(a) > g(a)\}$.) This collection is closed under unions, that is

$$>(f_1, g) \cup >(f_2, g) = >(\sup\{f_1, f_2\}, g).$$

If $A \in I$, namely if $>(f, g) = A$ for some $f \in F$, then evidently $g < f$ as required. But otherwise we obtain a contradiction by extending I to a proper maximal ideal J, and considering $\mu = \text{cf}(\prod A/J)$. Then f^μ, the universal sequence for μ, is cofinal in $\prod A/J$, and at the same time it is $\leq_J$ bounded by g since $f \leq_I g$ for all $f \in F$. Yet this is obviously impossible, and thus the theorem is proved. $\dashv$

If $f' = \langle f'_\xi \mid \xi < \lambda \rangle$ is universal sequence for λ, and if $f = \langle f_\xi \mid \xi < \lambda \rangle$ is another sequence in $\prod A$, $<_{J_{<\lambda}}$-increasing and dominating f' (for all $\xi' < \lambda$ there is a $\xi < \lambda$ such that $f'_{\xi'} \leq_{J_{<\lambda}} f_\xi$) then clearly f is also universal for λ. Hence we can use Theorem 2.21 and deduce the following

4.6 Lemma. *Suppose that A is a progressive set of regular cardinals, and $\lambda \in \mathrm{pcf}(A)$. Let μ be the least ordinal such that $A \cap \mu \notin J_{<\lambda}[A]$. Then there is a universal sequence for λ that satisfies $(*)_\kappa$ with respect to $J_{<\lambda}[A]$ for every regular cardinal κ such that $\kappa < \mu$, and in particular for $\kappa = |A|^+$.*

Proof. Observe first that $\mu \leq \lambda + 1$. (Let D be an ultrafilter over A such that $\lambda = \mathrm{cf}(\prod A/D)$. Then $A \cap (\lambda + 1) \in D$, or else $\{a \in A \mid a > \lambda\} \in D$ and then $\mathrm{cf}(\prod A/D) > \lambda$. Thus $\lambda \in \mathrm{pcf}(A \cap (\lambda + 1))$.) Observe also that $\mu = \lambda$ is impossible, since λ is regular and $A \cap \lambda$ is necessarily bounded in λ as $|A| < \min A \leq \lambda$. The case $\mu = \lambda + 1$ is rather trivial: $\lambda \in A$ and $J_{<\lambda}[A] = \mathcal{P}(A \cap \lambda)$. In this case the functions defined by $f_\xi(a) = \xi$ for all $a \in A \setminus \lambda$ are as required (and $(*)_\lambda$ holds). So we assume that $\mu < \lambda$ and $A \cap \mu$ is unbounded in μ.

Let $\langle f'_\xi \mid \xi < \lambda \rangle$ be any universal sequence for λ. Theorem 2.21 can be applied to this sequence and to $I = J_{<\lambda}$. This gives a sequence $f_\xi \in \prod A$ that dominates f'_ξ and that satisfies $(*)_\kappa$ for every regular cardinal κ such that $\kappa^{++} < \lambda$ and $\{a \in A \mid a \leq \kappa^{++}\} \in I$. Thus $(*)_\kappa$ holds for every regular $\kappa < \mu$. ⊣

We intend to prove next the existence of a generating set for $J_{<\lambda^+}$. For this we need first the following characterization of generators for $J_{<\lambda^+}$.

4.7 Lemma. *Suppose that A is a progressive set of regular cardinals and $B \subseteq A$. Then*

$$J_{<\lambda^+}[A] = J_{<\lambda}[A] + B \tag{14.18}$$

if and only if

$$B \in J_{<\lambda^+}[A] \quad \textit{and} \tag{14.19}$$

$$\begin{aligned} &\textit{If } D \textit{ is any ultrafilter over } A \textit{ with } \mathrm{cf}(\textstyle\prod A/D) = \lambda \\ &\quad \textit{then } B \in D. \end{aligned} \tag{14.20}$$

Proof. Assume first that (14.18) holds. Then (14.19) is obvious. We prove (14.20). If D is any ultrafilter over A with $\mathrm{cf}(\prod A/D) = \lambda$, then $D \cap J_{<\lambda^+}[A] \neq \emptyset$, and if $X \in D \cap J_{<\lambda^+}[A]$ is any set in the intersection then (14.18) implies that $X \setminus B \in J_{<\lambda}[A]$. Since $D \cap J_{<\lambda} = \emptyset$, $B \in D$ follows.

Now assume that (14.19) and (14.20) hold, and we prove that $J_{<\lambda^+}[A] = J_{<\lambda}[A] + B$.

Since $B \in J_{<\lambda^+}[A]$, $J_{<\lambda^+}[A] \supseteq J_{<\lambda}[A] + B$.

To prove $J_{<\lambda^+}[A] \subseteq J_{<\lambda}[A] + B$ assume $X \in J_{<\lambda^+}[A]$ and prove that $X \setminus B \in J_{<\lambda}$ as follows. Let D be any ultrafilter over A such that $X \setminus B \in D$. Since $X \in J_{<\lambda^+}$, $\mathrm{cf}(\prod A/D) < \lambda^+$. But $\mathrm{cf}(\prod A/D) = \lambda$ is impossible as $B \notin D$ and we assume (14.20). Hence $\mathrm{cf}(\prod A/D) < \lambda$. ⊣

4.8 Theorem (Normality). *If A is a progressive set of regular cardinals, then every cardinal $\lambda \in \mathrm{pcf}(A)$ is normal: there exists a set $B_\lambda \subseteq A$ such that*

$$J_{<\lambda^+}[A] = J_{<\lambda}[A] + B_\lambda.$$

Proof. By Lemma 4.6, there exists a universal sequence $f = \langle f_\xi \mid \xi < \lambda\rangle$ for λ that satisfies $(*)_{|A|^+}$. Hence f has an exact upper bound h in $\mathrm{On}^A / J_{<\lambda}$. Since the identity function is an upper bound of f, we can assume that $h(a) \leq a$ for every $a \in A$. Now define

$$B = \{a \in A \mid h(a) = a\}.$$

We are going to prove that B satisfies the two properties (14.19) and (14.20) which concludes the theorem and shows that B is a generator for $J_{<\lambda^+}$. We first prove that $B \in J_{<\lambda^+}[A]$. If D is any ultrafilter over A containing B then

$$\mathrm{cf}\big(\prod A/D\big) \leq \lambda \tag{14.21}$$

is deduced in two steps. If $D \cap J_{<\lambda} \neq \emptyset$, then the strict inequality of (14.21) holds by definition of $J_{<\lambda}$. But if $D \cap J_{<\lambda} = \emptyset$, then h remains the exact upper bound of the $<_D$ increasing sequence f in $<_D$ (just because D extends the dual filter of $J_{<\lambda}$). So $\mathrm{cf}(\prod h/D) = \lambda$. As h is $=_D$ equivalent to the identity function over A, $\prod A/D$ has cofinality λ.

To prove (14.20), suppose that D is an ultrafilter over A and $\mathrm{cf}(\prod A/D) = \lambda$. If $B \notin D$ then $\{a \in A \mid h(a) < a\} \in D$, and thus $[h]_D$ (the $=_D$-equivalence class of h) is in $\prod A/D$. Yet $D \cap J_{<\lambda}[A] = \emptyset$ (or else $\mathrm{cf}(\prod A/D) < \lambda$), and this implies that $f_\xi <_D h$ for every $\xi < \lambda$ (because $f_\xi <_{J_{<\lambda}} h$). So f is *not* cofinal in $\prod A/D$, in contradiction to f being a universal sequence for λ. ⊣

The generator set B_λ is not uniquely determined, but if B_1 and B_2 are two generators (they both satisfy 14.18), then the symmetric difference $B_1 \triangle B_2$ is in $J_{<\lambda}[A]$. So generators *are* uniquely determined modulo $J_{<\lambda}$, and we can use a "generic" notation.

4.9 Notation. For a progressive set of regular cardinals A and for any cardinal $\lambda \in \mathrm{pcf}(A)$, $B_\lambda[A]$ denotes a subset $B \subseteq A$ such that (14.19) and (14.20) hold, or equivalently

$$J_{<\lambda^+}[A] = J_{<\lambda}[A] + B. \tag{14.22}$$

We also use the expression "B is a $B_\lambda[A]$ set" if (14.22) holds for B. We often write B_λ instead of $B_\lambda[A]$, when the identity of A is obvious.

The sequence $\langle B_\lambda[A] \mid \lambda \in \mathrm{pcf}(A)\rangle$ is called a "generating sequence" for A, because the ideal $J_{<\lambda}$ is generated by the collection $\{B_{\lambda_0} \mid \lambda_0 < \lambda\}$ (see Corollary 4.12). It is convenient to write $B_\lambda = \emptyset$ when $\lambda \notin \mathrm{pcf}(A)$.

The following conclusion will be needed later on.

4.10 Lemma. *Suppose that A is a progressive set of regular cardinals. If $A_0 \subseteq A$ and $\lambda \in \mathrm{pcf}(A_0)$, then $B_\lambda[A_0] =_{J_{<\lambda}[A_0]} A_0 \cap B_\lambda[A]$. (This justifies our inclination to write B_λ instead of $B_\lambda[A_0]$.)*

Proof. We prove (14.19) and (14.20) for $A_0 \cap B_\lambda[A]$. Clearly $A_0 \cap B_\lambda[A] \in J_{\leq\lambda}[A_0]$. If D_0 is any ultrafilter over A_0 such that $\mathrm{cf}(\prod A_0/D_0) = \lambda$, then $A_0 \cap B_\lambda[A] \in D_0$ can be argued as followed. Assume $A_0 \setminus B_\lambda[A] \in D_0$, and extend D_0 to an ultrafilter over A, still denoted D_0. Then $\mathrm{cf}(\prod A/D_0) = \lambda$ and $B_\lambda[A] \notin D_0$ is in contradiction to (14.20). ⊣

For a progressive set A with $\lambda = \max\mathrm{pcf}(A)$ and B a $B_\lambda[A]$ set, we have by (14.20) that

$$A \setminus B \in J_{<\lambda} \tag{14.23}$$

since $A \in J_{<\lambda^+}[A]$. Hence we can take $B_{\max\mathrm{pcf}(A)} = A$.

We will conclude that the ideal $J_{<\lambda}[A]$ is (finitely) generated by the sets $\{B_\mu[A] \mid \mu < \lambda\}$ using the following "compactness" theorem, which says that any set $X \in J_{<\lambda}$ is covered by a finite collection of B_μ's for $\mu < \lambda$.

4.11 Theorem (Compactness). *Suppose that A is a progressive set of regular cardinals and $\langle B_\lambda \mid \lambda \in \mathrm{pcf}(A)\rangle$ is a generating sequence for A. Then for any $X \subseteq A$*

$$X \subseteq B_{\lambda_1} \cup B_{\lambda_2} \cup \cdots \cup B_{\lambda_n}$$

for some finite set $\{\lambda_1, \ldots, \lambda_n\} \subseteq \mathrm{pcf}(X)$.

Proof. This can be proved by induction on $\lambda = \max\mathrm{pcf}(X)$, since $X \setminus B_\lambda \in J_{<\lambda}$ and so $\max\mathrm{pcf}(X \setminus B_\lambda) < \lambda$. ⊣

4.12 Corollary. *If A is a progressive set of regular cardinals, then for every cardinal λ and every set $X \subseteq A$, $X \in J_{<\lambda}[A]$ iff X is included in a finite union of sets from $\{B_{\lambda'} \mid \lambda' < \lambda\}$.*

Observe that $\lambda \notin \mathrm{pcf}(A \setminus B_\lambda[A])$. For let D_0 be any ultrafilter over $A_0 = A \setminus B_\lambda[A]$. Extend D_0 to an ultrafilter D over A. Since $\prod A_0/D_0$ is isomorphic to $\prod A/D$, it suffices to prove that $\mathrm{cf}(\prod A/D) \neq \lambda$. But since A_0 is disjoint to $B_\lambda[A]$, $B_\lambda[A] \notin D$. So (14.20) implies this, and we have obtained the following result. A set $B \in J_{<\lambda^+}[A]$ is a B_λ set if and only if $\lambda \notin \mathrm{pcf}(A \setminus B)$.

If $\lambda \in \mathrm{pcf}(A)$ and $f = \langle f_\xi \mid \xi < \lambda\rangle$ is a universal sequence for λ, then the definition of $B_\lambda[A] = \{a \in A \mid h(a) = a\}$, where h is an exact upper bound of f, shows that $\langle f_\xi \restriction B_\lambda \mid \xi < \lambda\rangle$ is cofinal in $\prod B_\lambda/J_{<\lambda}$. This result is sufficiently interesting to be isolated as a theorem (and we give a somewhat different proof).

4.13 Theorem. *If A is a progressive set of regular cardinals and $\lambda \in \mathrm{pcf}(A)$, then for some set $B \subseteq A$ we have $\mathrm{tcf}(\prod B/J_{<\lambda}[B]) = \lambda$. In fact, any universal sequence for λ is cofinal in $\prod B_\lambda/J_{<\lambda}$ and thus shows that*

$$\mathrm{tcf}\big(\textstyle\prod B_\lambda/J_{<\lambda}\big) = \lambda. \tag{14.24}$$

Proof. We know that there exists a universal sequence for λ and that there exists a generating set B_λ. We will prove that any universal sequence $f = \langle f_\xi \mid \xi < \lambda\rangle$ for λ is cofinal in $\prod B_\lambda / J_{<\lambda}$. That is, if $h \in \prod B_\lambda$ is any function then

$$\leq(f_\xi \restriction B_\lambda, h) \in J_{<\lambda} \quad \text{for some } \xi < \lambda.$$

Otherwise the sets $\leq(f_\xi \restriction B_\lambda, h)$ are positive and decreasing with $\xi < \lambda$ (mod $J_{<\lambda}$). Hence there is a filter over B_λ containing them all and extending the dual filter of $J_{<\lambda}[B_\lambda]$. Extending this filter to an ultrafilter D over A, $D \cap J_{<\lambda}[A] = \emptyset$ and the ultraproduct $\prod A/D$ has cofinality λ (as $B_\lambda \in D$ and $D \cap J_{<\lambda} = \emptyset$). In this ultrapower h bounds all functions in f, in contradiction to the assumption that f is universally cofinal. Thus the restriction to $B_\lambda[A]$ of any universal sequence for λ is cofinal in $\prod B_\lambda / J_{<\lambda}$. ⊣

In particular, (14.24) shows (again) that $\lambda = \max \operatorname{pcf}(B_\lambda)$ whenever $\lambda \in \operatorname{pcf}(A)$. We have, more generally, the following characterization.

4.14 Lemma. *The following are equivalent for every filter F over a progressive set of regular cardinals A and for every cardinal λ.*

1. $\operatorname{tcf}(\prod A/F) = \lambda$.
2. *$B_\lambda \in F$, and F contains the dual filter of $J_{<\lambda}[A]$.*
3. *$\operatorname{cf}(\prod A/D) = \lambda$ for every ultrafilter D that extends F.*

In particular we get for every ultrafilter D that

$$\operatorname{cf}\big(\prod A/D\big) = \lambda \quad \textit{iff} \quad B_\lambda \in D \textit{ and } D \cap J_{<\lambda} = \emptyset. \tag{14.25}$$

Equivalently,

$$\operatorname{cf}\big(\prod A/D\big) = \lambda \quad \textit{iff} \quad \lambda \textit{ is the least cardinal such that } B_\lambda \in D. \tag{14.26}$$

Proof. Fix a filter F and a cardinal λ. $1 \implies 3$ is obvious. Assume 3 and we prove 2. Since $\operatorname{cf}(\prod A/D) = \lambda$ for every ultrafilter D that extends F, $B_\lambda \in D$ for every such ultrafilter (by (14.20)). Hence $B_\lambda \in F$. It is clear that F contains the dual filter of $J_{<\lambda}$, or else an extension of F can be found that intersects $J_{<\lambda}$ and thus has an ultraproduct with cofinality below λ.

Assume now 2, and then the fact already proved that $\operatorname{tcf}(\prod B_\lambda / J_{<\lambda}) = \lambda$ shows that $\operatorname{tcf}(\prod A/F) = \lambda$ (as $\prod A/F$ and $\prod B_\lambda/F$ are isomorphic, since $B_\lambda \in F$).

In particular, if D is an ultrafilter over A, then $D \cap J_{<\lambda} = \emptyset$ iff the dual filter of $J_{<\lambda}$ is contained in D. So the equivalence of 1 and 2 of the lemma establishes (14.25). ⊣

4.15 Exercise.

1. If D is an ultrafilter over a progressive set A, and λ is the least cardinal such that $B_\lambda \in D$, then $\lambda = \operatorname{cf}(\prod A/D)$.

2. Suppose that A is a progressive set of regular cardinals and $E = \mathrm{pcf}(A)$ is also progressive. Then

$$\mathrm{pcf}(B_\lambda[A]) =_{J_{<\lambda}[E]} B_\lambda[\mathrm{pcf}(A)].$$

(Use Theorem 3.12.)

4.16 Exercise. If A is a progressive set of regular cardinals, then for every cardinal λ, $\lambda = \max \mathrm{pcf}(A)$ iff $\lambda = \mathrm{tcf}(\prod A/J_{<\lambda})$ iff $\lambda = \mathrm{cf}(\prod A/J_{<\lambda})$.

In Theorem 2.23 we have proved for μ, a singular cardinal with uncountable cofinality, that $\mu^+ = \mathrm{tcf}(\prod C^{(+)}/J^{bd})$ for some closed unbounded set of cardinals $C \subseteq \mu$. Since $J_{<\mu} = J_{<\mu^+} \subseteq J^{bd}$, an apparently stronger claim is obtained by asserting $\mathrm{tcf}(\prod C^{(+)}/J_{<\mu}[C^{(+)}]) = \mu^+$.

4.17 Exercise (The Representation Theorem). If μ is a singular cardinal with uncountable cofinality, then for some closed unbounded set of cardinals $C \subseteq \mu$, $\mathrm{tcf}(\prod C^{(+)}/J_{<\mu}[C^{(+)}]) = \mu^+$. Thus $\mu^+ = \max \mathrm{pcf}(C^{(+)})$.

Hint. Let $C_0 \subseteq \mu$ be a closed unbounded set of limit cardinals such that $\mu^+ = \mathrm{tcf}(\prod C_0^{(+)}/J^{bd})$. Then define $C \subseteq C_0$ so that $C^{(+)} = B_{\mu^+}[C_0^{(+)}]$. Prove that $C_0 \setminus C$ is bounded in μ. Then use Theorem 4.13.

4.18 Exercise. For any filter F over a progressive set A of regular cardinals, define

$$\mathrm{pcf}_F(A) = \{\mathrm{cf}(\textstyle\prod A/D) \mid D \text{ an ultrafilter over } A \text{ that extends } F\}.$$

1. Prove that $\max \mathrm{pcf}_F(A)$ exists.

   Hint. Look at the minimal λ such that $F \cap J_{\leq\lambda} \neq \emptyset$.

2. Deduce that $\mathrm{cf}(\prod A/F) = \max \mathrm{pcf}_F(A)$, so that the cofinality of this partial ordering is a regular cardinal.

3. If $B \subseteq \mathrm{pcf}_F(A)$ is progressive, then $\mathrm{pcf}(B) \subseteq \mathrm{pcf}_F(A)$.

4. Suppose that A is a progressive *interval* of regular cardinals, and let F be the filter of co-bounded subsets of A ($X \in F$ iff $A \setminus X$ is bounded in A). Then $\mathrm{pcf}_F(A)$ is an interval of regular cardinals.

5. The Cofinality of $[\mu]^\kappa$

Some of the most important applications of pcf theory will be described in this section. For example, we will prove that $\aleph_\omega^{\aleph_0} < \aleph_{(2^{\aleph_0})^+}$. For this result we investigate obedient universal sequences and their relationship with characteristic functions of elementary substructures. Some of the theorems about obedient sequences proved and used in this section will be applied in the following section to "elevated" sequences. These sequences are not obedient, but they share enough properties with the obedient sequences to enable uniform proofs. This explains our desire to deal here with the shared properties (14.32) and (14.33) rather than with obedient sequences.

As usual, A is a progressive set of regular cardinals. Recall how $B_\lambda[A]$ was obtained. First a universal sequence $\langle f_\xi \mid \xi < \lambda\rangle$ for λ was defined which satisfied $(*)_{|A|^+}$, then an exact upper bound h was constructed, and finally the set $B_\lambda = \{a \in A \mid h(a) = a\}$ was shown to generate $J_{<\lambda^+}[A]$ over $J_{<\lambda}[A]$. Once this is done, we have greater flexibility in tuning-up B_λ by using elementary substructures, and we therefore say first a few words about these structures.

5.1. Elementary Substructures

Elementary substructures are extensively used in pcf theory and its applications, and in this section we study some basic properties of their characteristic functions.

Let Ψ be a "sufficiently large" cardinal, and H_Ψ be the $\in$-structure whose universe is the collection H_Ψ of all sets hereditarily of cardinality less than Ψ (which means having transitive closure of size $< \Psi$). The expression "sufficiently large" depends on the context and means that Ψ is regular and is sufficiently large to include in H_Ψ all sets that were discussed so far. We also add to the structure H_Ψ a well-ordering $<^*$ of its universe. We shall seldom mention $<^*$ explicitly, but it allows us to assume that the objects we talk about are uniquely determined.

For the rest of this section κ denotes a regular cardinal such that $|A| < \kappa < \min A$.

5.1 Definition. An increasing and continuous chain of length λ of elementary substructures of H_Ψ is a sequence $\langle M_i \mid i < \lambda\rangle$ such that

1. Each M_i is an elementary substructure of H_Ψ,
2. $i_1 < i_2 < \lambda$ implies that $M_{i_1} \subseteq M_{i_2}$, and
3. for every limit ordinal $\delta < \lambda$, $M_\delta = \bigcup_{i<\delta} M_i$ (this is continuity).

We say in this chapter that an elementary substructure $M \prec H_\Psi$ is "κ-presentable" if and only if $M = \bigcup_{i<\kappa} M_i$ where $\langle M_i \mid i < \kappa\rangle$ is an increasing and continuous chain of length κ such that

1. M has cardinality κ and $\kappa + 1 \subseteq M$.
2. For every $i < \kappa$, $M_i \in M_{i+1}$. (Thus $M_i \in M_j$ for $i < j$.)

We do not make any assumption on the cardinality of M_i for $i < \kappa$, which may be κ or smaller than κ.

In order to define a κ-presentable elementary substructure define, recursively, the approaching structures M_α, and observe that each M_α (and even the sequence $\langle M_\alpha \mid \alpha \leq \beta \rangle$) is an element of H_Ψ and thus can be incorporated in $M_{\beta+1} \prec H_\Psi$.

We shall use the following observation. Let $\bar{M}_\alpha$ denote the ordinal closure of $M_\alpha \cap \mathrm{On}$. That is $\gamma \in \bar{M}_\alpha$ iff $\gamma \in M_\alpha \cap \mathrm{On}$ or γ is a limit of ordinals in M_α. Since $M_\alpha \in M_{\alpha+1}$ and $M_\alpha \subseteq M_{\alpha+1}$, $\bar{M}_\alpha \in M_{\alpha+1}$, and $\bar{M}_\alpha \subseteq M_{\alpha+1}$.

For any structure N, we let Ch_N be the "characteristic function" of N. That is, the function defined on any regular cardinal μ such that $\|N\| < \mu$ by

$$\mathrm{Ch}_N(\mu) = \sup(N \cap \mu).$$

Then $\mathrm{Ch}_N(\mu) \in \mu$ since μ is regular and N is of smaller cardinality.

A very useful fact that we are going to prove is that if M is κ-presentable, then for cardinals $\kappa \leq \lambda < \mu$, $M \cap \mu$ can be reconstructed from $M \cap \lambda$ and the characteristic function of M restricted to the successor cardinals in the interval $(\lambda, \mu]$. We shall use the following form of this fact.

5.2 Theorem. *Suppose that M and N are elementary substructures of H_Ψ. Let $\kappa < \mu$ be any cardinals (κ is always regular uncountable).*

1. *If $M \cap \kappa \subseteq N \cap \kappa$, and, for every successor cardinal $\alpha^+ \in M \cap \mu + 1$,*

$$\sup(M \cap \alpha^+) = \sup(M \cap N \cap \alpha^+), \tag{14.27}$$

   then $M \cap \mu \subseteq N \cap \mu$.

2. *Therefore, if M and N are both κ-presentable and for every successor cardinal $\alpha^+ \in \mu + 1$*

$$\sup(M \cap \alpha^+) = \sup(N \cap \alpha^+), \tag{14.28}$$

   then $M \cap \mu = N \cap \mu$.

Proof. This is a bootstrapping argument. We prove by induction on δ, a cardinal in the interval $[\kappa, \mu]$, that $M \cap \delta \subseteq N \cap \delta$. For $\delta = \kappa$ this is an assumption. If δ is a limit cardinal, then $M \cap \delta \subseteq N \cap \delta$ is an immediate application of the inductive assumption that $M \cap \delta' \subseteq N \cap \delta'$ for every cardinal δ' in the interval $[\kappa, \delta)$. Assume now that $M \cap \delta \subseteq N \cap \delta$, and we shall argue for $M \cap \delta^+ \subseteq N \cap \delta^+$. If $\delta^+ \notin M$, then M contains no ordinals from the interval $[\delta, \delta^+]$ and the claim is obvious. So assume that $\delta^+ \in M$. (And hence $\delta^+ \in N$ since $[\delta, \delta^+] \cap N \neq \emptyset$.) Let $\gamma = \sup(M \cap \delta^+) = \sup(M \cap N \cap \delta^+)$. Now if $\alpha \in M \cap \gamma$, then there exists some $\beta \in M \cap N \cap \gamma$ such that $\alpha < \beta$. Consider the structure $(H_\Psi, \in, <^*)$ of which M and N are elementary substructures, and pick an injection $f : \beta \to \delta$ that is minimal with respect to the well-ordering $<^*$ of H_Ψ. Then $f \in M \cap N$ because f is definable from the parameter β. Since $\alpha \in M$, $f(\alpha) \in M$, and hence $f(\alpha) \in N$. But then, applying f^{-1} in N, we get $\alpha \in N$. Thus $M \cap \beta \subseteq N \cap \beta$.

For the second part of the theorem, let $M = \bigcup_{\xi<\kappa} M_\xi$ and $N = \bigcup_{\xi<\kappa} N_\xi$ be presentations for M and N. Observe that $M \cap \kappa = N \cap \kappa = \kappa$. Let α^+ be any successor cardinal in the interval $(\kappa, \mu]$. We assume that $\gamma = \mathrm{Ch}_M(\alpha^+) = \mathrm{Ch}_N(\alpha^+)$. We claim that there is a subset of $M \cap N$ that is closed and unbounded in γ. Indeed, the approaching substructures M_ξ provide a closed unbounded sequence $\langle \sup(M_\xi \cap \alpha^+) \mid \xi \in \kappa\rangle$ which is cofinal in γ. Likewise, N contains a closed unbounded sequence of order-type κ cofinal in γ. The intersection of these closed unbounded sets is as required. Hence $\sup(M \cap \alpha^+) = \sup(N \cap \alpha^+) = \sup(M \cap N \cap \alpha^+)$ holds and $M \cap \mu = N \cap \mu$ is obtained by the first part of the theorem. ⊣

Recall that a sequence of functions in $\prod A$ is universal for λ if it is $J_{<\lambda}$ increasing and cofinal in $\prod A/D$ whenever $\mathrm{cf}(\prod A/D) = \lambda$. Recall also (14.3) that a sequence $\langle p_\xi \mid \xi < \lambda\rangle$ of members of a partial ordering $(P, <_P)$ is persistently cofinal iff every member of P is dominated by all members of the sequence with a sufficiently large index.

5.3 Definition. We say that a sequence $\langle f_\xi \mid \xi < \lambda\rangle$ of functions in $\prod A$ is *persistently cofinal for* λ if their restrictions to B_λ form a persistently cofinal sequence in $\prod B_\lambda/J_{<\lambda}$. Namely if for every $h \in \prod A$ there exists a $\xi_0 < \lambda$ such that

$$h \restriction B_\lambda <_{J_{<\lambda}} f_\xi \restriction B_\lambda$$

for all $\xi_0 \le \xi < \lambda$ (where $B_\lambda = B_\lambda[A]$).

For example, if $\langle f_\xi \mid \xi < \lambda\rangle$ is universal for λ then it is persistently cofinal (see Theorem 4.13), and if the functions F_ξ are such that $f_\xi \le_{J_{<\lambda}} F_\xi$ for all $\xi < \lambda$, then $\langle F_\xi \mid \xi < \lambda\rangle$ is also persistently cofinal, although it is not necessarily $J_{<\lambda}$ increasing. Clearly, an arbitrary λ sequence in $\prod A$ is universal for λ iff it is $J_{<\lambda}$ increasing and persistently cofinal.

A basic observation which is used later to define the transitive generators is the following.

5.4 Lemma. *Suppose that the progressive set A and the cardinal $\lambda \in \mathrm{pcf}(A)$ belong to an elementary substructure $N \prec H_\Psi$ so that $N = \bigcup_{\alpha<\kappa} N_\alpha$ where $|A| < \kappa < \min A$ is a regular cardinal, $|N| = \kappa$, $\kappa+1 \subseteq N$, and $\langle N_\alpha \mid \alpha < \kappa\rangle$ is an increasing chain of elementary substructures of H_Ψ. If a sequence of functions $f = \langle f_\xi \mid \xi < \lambda\rangle \in N$, with $f_\xi \in \prod A$, is persistently cofinal for λ, then for every $\xi \ge \sup(N \cap \lambda)$*

$$\le(\mathrm{Ch}_N, f_\xi) = \{a \in A \mid \mathrm{Ch}_N(a) \le f_\xi(a)\} \text{ is a } B_\lambda[A] \text{ set.} \tag{14.29}$$

Proof. We first make some preliminary observations. Since $\kappa < \min A$, we have that $\mathrm{Ch}_N \restriction A \in \prod A$. Since $A, \lambda \in N = \bigcup_{\alpha<\kappa} N_\alpha$, we may as well assume that $A, \lambda, f \in N_0$ (or else re-enumerate the structures). Since $|A| < \kappa$ and $\kappa \subseteq N$, $A \subseteq N$ and we can assume that $A \subseteq N_0$. Since Ψ is sufficiently large, all the pcf theory involved in defining $B_\lambda[A]$ etc. can be done in H_Ψ and hence in N_0. We may assume again that a generating set $B = B_\lambda[A]$ is in N_0. Suppose that $\xi \ge \sup(N \cap \lambda)$. To prove (14.29) we need two inclusions:

1. $\mathrm{Ch}_N \restriction B \leq_{J_{<\lambda}} f_\xi \restriction B$, which shows that $B \subseteq_{J_{<\lambda}} \leq(\mathrm{Ch}_N, f_\xi)$.
2. $\leq(\mathrm{Ch}_N, f_\xi) \cap (A \setminus B) \in J_{<\lambda}$, which shows that $\leq(\mathrm{Ch}_N, f_\xi) \subseteq_{J_{<\lambda}} B$.

We prove 1. For every $a \in A$, if $f_\xi(a) < \mathrm{Ch}_N(a)$ then there exists an index $\alpha = \alpha(a) < \kappa$ such that $f_\xi(a) < \mathrm{Ch}_{N_\alpha}(a)$. Since $|A| < \kappa$ there exists a single index $\alpha < \kappa$ such that, for every $a \in A$, $f_\xi(a) < \mathrm{Ch}_N(a)$ implies that $f_\xi(a) < \mathrm{Ch}_{N_\alpha}(a)$. Hence for every $a \in A$

$$f_\xi(a) < \mathrm{Ch}_N(a) \quad \text{iff} \quad f_\xi(a) < \mathrm{Ch}_{N_\alpha}(a). \tag{14.30}$$

But the sequence f is persistently cofinal in $\prod B/J_{<\lambda}$, and hence $h\restriction B <_{J_{<\lambda}} f_\xi \restriction B$ for every $h \in N \cap \prod A$, because $\xi \geq \sup(N \cap \lambda)$. In particular, for $h = \mathrm{Ch}_{N_\alpha} \in N$, we get

$$\mathrm{Ch}_{N_\alpha} \restriction B \leq_{J_{<\lambda}} f_\xi \restriction B \quad (\text{in fact } <_{J_{<\lambda}}).$$

That is, $\{b \in B \mid f_\xi(b) < \mathrm{Ch}_{N_\alpha}(b)\} \in J_{<\lambda}$. Hence, by (14.30), $\{b \in B \mid f_\xi(b) < \mathrm{Ch}_N(b)\} \in J_{<\lambda}$. Thus

$$\mathrm{Ch}_N \restriction B \leq_{J_{<\lambda}} f_\xi \restriction B.$$

This proves 1.

Now we prove 2. That is

$$\{a \in A \setminus B \mid \mathrm{Ch}_N(a) \leq f_\xi(a)\} \in J_{<\lambda}. \tag{14.31}$$

As $\lambda \notin \mathrm{pcf}(A \setminus B)$, $J_{<\lambda}[A \setminus B] = J_{<\lambda^+}[A \setminus B]$ and hence $\prod(A \setminus B)/J_{<\lambda}$ is λ^+-directed, and f (with functions restricted to $A \setminus B$) has an upper bound. Since $f \in N$, we have this upper bound in N. Let $h \in N \cap \prod(A \setminus B)$ be an upper bound in $<_{J_{<\lambda}}$ of the sequence f restricted to $A \setminus B$. Then

$$f_\xi \restriction (A \setminus B) <_{J_{<\lambda}} h < \mathrm{Ch}_N \restriction (A \setminus B).$$

But this is exactly (14.31). $\dashv$

5.2. Minimally Obedient Sequences

Suppose that δ is a limit ordinal and $f = \langle f_\xi \mid \xi < \delta \rangle$ is a sequence of functions $f_\xi \in \prod A$, where A is a set of regular cardinals and $|A| < \mathrm{cf}(\delta) < \min A$ holds. For every closed unbounded set $E \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ let

$$h_E = \sup\{f_\xi \mid \xi \in E\}.$$

That is, $h_E(a) = \sup\{f_\xi(a) \mid \xi \in E\}$. Since $\mathrm{cf}(\delta) < \min A$, $h_E \in \prod A$. We say that h_E is the "supremum along E of the sequence f". Observe that if $E_1 \subseteq E_2$ then $h_{E_1} \leq h_{E_2}$. The following lemma says that among all functions obtained as suprema along closed unbounded subsets of δ there is a minimal one in the $\leq$ ordering.

5.5 Lemma. *Let δ and f be as above (so $|A| < \mathrm{cf}(\delta) < \min A$ and f is a sequence of length δ of functions in $\prod A$). There is a closed unbounded set $C \subseteq \delta$ of order-type* $\mathrm{cf}(\delta)$ *such that*

$$h_C(a) \leq h_E(a)$$

for every $a \in A$ and $E \subseteq \delta$ closed and unbounded of order-type $\mathrm{cf}(\delta)$.

Proof. Assume that there is no such closed unbounded set $C \subseteq \delta$ as required. We construct a decreasing sequence $\langle E_\alpha \mid \alpha < |A|^+\rangle$ of closed unbounded subsets of δ of order-type $\mathrm{cf}(\delta)$ such that for every $\alpha < |A|^+$, $h_{E_\alpha} \not\leq h_{E_{\alpha+1}}$. (Since $|A| < \mathrm{cf}(\delta)$, at limit stages of the construction we may take the intersection of the clubs so far constructed.) Then find a single $a \in A$ such that $h_{E_\alpha}(a) > h_{E_{\alpha+1}}(a)$ for an unbounded set of indices α. Yet this is obviously impossible. ⊣

In applications of this lemma, an ideal J over A is assumed and the sequence $\langle f_\xi \mid \xi < \delta\rangle$ is $<_J$-increasing. In that case, the minimal function $f_C = \sup\{f_\xi \mid \xi \in C\}$ $\leq$-bounds each f_ξ, for $\xi \in C$, and hence $\leq_J$-bounds all f_ξ's for $\xi < \delta$. This function f_C is called "minimal club-obedient bound of $\langle f_\xi \mid \xi < \delta\rangle$".

5.6 Definition (Minimally obedient universal sequence). Suppose that λ is in $\mathrm{pcf}(A)$ and $f = \langle f_\xi \mid \xi < \lambda\rangle$ is a universal sequence for λ. Let κ be a fixed regular cardinal such that $|A| < \kappa < \min A$. We say that f is *minimally obedient (at cofinality κ)* if for every $\delta < \lambda$ such that $\mathrm{cf}(\delta) = \kappa$, f_δ is the minimal club-obedient bound of $\langle f_\xi \mid \xi < \delta\rangle$.

The universal sequence f is said to be *minimally obedient* if $|A|^+ < \min A$ and it is minimally obedient for every regular κ such that $|A| < \kappa < \min A$.

Suppose that $|A|^+ < \min A$ and $\lambda \in \mathrm{pcf}(A)$. In order to arrange a minimally obedient universal sequence for λ, start with an arbitrary universal sequence $\langle f^0_\xi \mid \xi < \lambda\rangle$ and define the functions f_ξ by induction on $\xi < \lambda$ such that:

1. $f_0 = f^0_0$, and $f_{\xi+1}$ is such that
$$\max\{f_\xi, f^0_\xi\} < f_{\xi+1}.$$
2. At limit stages $\delta < \lambda$ with $\mathrm{cf}(\delta) = \kappa$ and such that $|A| < \kappa < \min A$ let f_δ be the minimal club-obedient bound of $\langle f_\xi \mid \xi < \delta\rangle$.
3. At limit stages $\delta < \lambda$ with $\mathrm{cf}(\delta)$ not of that form use the fact that $\prod A/J_{<\lambda}$ is λ-directed to define f_δ as a $<_{J_{<\lambda}}$ bound of $\langle f_\xi \mid \xi < \delta\rangle$.

Minimally obedient sequences will be used in conjunction with κ-presentable elementary substructures.

5.7 Lemma. *Let A be a progressive set of regular cardinals, and κ be a regular cardinal such that $|A| < \kappa < \min A$. Suppose that*

1. *$\lambda \in \mathrm{pcf}(A)$,*

2. *$f = \langle f_\xi \mid \xi < \lambda \rangle$ is a minimally obedient at cofinality κ, universal sequence for λ, and*

3. *$N \prec H_\Psi$ (for Ψ sufficiently large) is an elementary, κ-presentable substructure of H_Ψ such that $\lambda, f, A \in N$. (So $A \subseteq N$.)*

Let $\bar{N}$ denote the ordinal closure of $N \cap \mathrm{On}$, that is, the set of ordinals that are in N or that are limit of ordinals in N. Then for every $\gamma \in (\bar{N} \cap \lambda) \setminus N$ there is a closed unbounded set $C \subseteq \gamma \cap N$ (of order-type κ) such that $f_\gamma = \sup\{f_\xi \mid \xi \in C\}$ and thus

$$f_\gamma(a) \in \bar{N} \cap a \quad \text{for every } a \in A.$$

In particular, for $\gamma = \mathrm{Ch}_N(\lambda)$, $\gamma \in \bar{N} \setminus N$, and $f_\gamma = \sup\{f_\xi \mid \xi \in C\}$ for a closed unbounded set $C \subseteq N \cap \gamma$ such that

1. *each f_ξ is in N, and*

2. *for every $h \in N \cap \prod A$*

$$h \restriction B_\lambda[A] <_{J_{<\lambda}} f_\xi \restriction B_\lambda[A]$$

for some $\xi \in C$.

Proof. Since N is κ-presentable, $N = \bigcup_{\alpha<\kappa} N_\alpha$ is the union of an increasing and continuous chain such that $N_\alpha \in N_{\alpha+1}$. It follows for every $\gamma \in \bar{N}$, that either $\gamma \in N$ or $\mathrm{cf}(\gamma) = \kappa$. Indeed, if $\gamma \in \bar{N} \setminus N$, then γ is a limit point of ordinals in N and yet γ is not a limit point of ordinals in any N_α (or else $\gamma \in \bar{N}_\alpha \subseteq N$). Hence $\sup(N_\alpha \cap \gamma) < \gamma$ and

$$E = \{\sup(N_\alpha \cap \gamma) \mid \alpha < \kappa\}$$

is closed unbounded in γ and of order-type κ. Thus $\mathrm{cf}(\gamma) = \kappa$. Observe that $E \subseteq N$, because $N_\alpha \in N$ implies that $\bar{N}_\alpha \subseteq N$ and in particular $\sup(N_\alpha \cap \gamma) \in N$.

Now take $\gamma \in (\bar{N} \cap \lambda) \setminus N$ and consider $f_\gamma(a)$ for $a \in A$. Since $\mathrm{cf}(\gamma) = \kappa$, f_γ is the minimal club-obedient bound of $\langle f_\xi \mid \xi < \gamma \rangle$, and there is thus a closed unbounded set $C \subseteq \gamma$ such that $f_\gamma = f_C$. It follows from the minimality of f_C that $f_C = f_{C \cap E}$ and we may thus assume at the outset that $C \subseteq N$. So $f_\gamma = f_C = \sup\{f_\xi \mid \xi \in C\}$ is the supremum of a set of functions that are all in N. (As $C \subseteq N$ implies that $f_\xi \in N$ for $\xi \in C$.) This shows that $f_\gamma(a) \in \bar{N}$ for every $a \in A$.

In particular, if $\gamma = \mathrm{Ch}_N(\lambda)$, then $\gamma < \lambda$ because $\kappa < \lambda$ and N has cardinality κ. So $\gamma \in \bar{N} \setminus N$. Item 2 is a consequence of the fact that f is a universal sequence (see Theorem 4.13) and that C is unbounded in $N \cap \lambda$. ⊣

The conclusions of Lemmas 5.4 and 5.7 will be given names (14.32) and (14.33) so that we can easily refer to these properties in the future. Let A be a progressive set of regular cardinals and suppose that κ is a regular cardinal such that $|A| < \kappa < \min A$. Suppose that $\lambda \in \mathrm{pcf}(A)$, and $f = \langle f_\xi \mid \xi \in \lambda\rangle$ is a sequence of functions in $\prod A$. We shall refer to the following two properties of a κ-presentable $N \prec H_\Psi$ and a sequence $f = \langle f_\xi \mid \xi < \lambda\rangle$ such that $f \in N$.

$$\boxed{\begin{array}{l}\text{If } \gamma = \mathrm{Ch}_N(\lambda), \text{ then} \\ \qquad\qquad \{a \in A \mid \mathrm{Ch}_N(a) \le f_\gamma(a)\} \\ \text{is a } B_\lambda[A] \text{ set.}\end{array}} \tag{14.32}$$

$$\boxed{\begin{array}{l}\text{If } \gamma = \mathrm{Ch}_N(\lambda), \text{ then} \\ \quad 1.\ f_\gamma \le \mathrm{Ch}_N. \\ \quad 2.\ \text{For every } h \in N \cap \prod A \text{ there exists some } d \in \\ \qquad N \cap \prod A \text{ such that} \\ \qquad\qquad h{\restriction}B <_{J_{<\lambda}} d{\restriction}B \text{ and } d \le f_\gamma, \\ \qquad \text{where } B = B_\lambda[A].\end{array}} \tag{14.33}$$

We have seen that any persistently cofinal sequence for λ satisfies (14.32) (this is Lemma 5.4), and that any minimally obedient universal sequence satisfies (14.33) as well (by Lemma 5.7).

Suppose that f is a sequence of length λ and $N \prec H_\Psi$ is κ-presentable and such that $f \in N$ (so $A, \lambda \in N$). Suppose that both (14.32) and (14.33) hold. If $\gamma = \mathrm{Ch}_N(\lambda)$, then $f_\gamma \le \mathrm{Ch}_N$ by (14.33), and hence

$$\{a \in A \mid \mathrm{Ch}_N(a) = f_\gamma(a)\} \tag{14.34}$$

is a $B_\lambda[A]$ set by (14.32). We shall use this observation in the following.

5.8 Lemma. *Suppose that A is a progressive set of regular cardinals and κ is a regular cardinal such that $|A| < \kappa < \min A$. Suppose that $\lambda_0 \in \mathrm{pcf}(A)$ and $f^{\lambda_0} = \langle f^{\lambda_0}_\xi \mid \xi < \lambda_0\rangle$ is a sequence of functions in $\prod A$. Let $N \prec H_\Psi$ be a κ-presentable elementary substructure (Ψ is a sufficiently large cardinal) such that $A, \lambda_0, f^{\lambda_0} \in N$. Suppose that N and $f^{\lambda_0} \in N$ satisfy properties (14.32) and (14.33) for $\lambda = \lambda_0$. Put $\gamma_0 = \mathrm{Ch}_N(\lambda_0)$ and define*

$$b_{\lambda_0} = \{a \in A \mid \mathrm{Ch}_N(a) = f^{\lambda_0}_{\gamma_0}(a)\}.$$

Then the following hold.

1. b_{λ_0} *is a* $B_{\lambda_0}[A]$ *set, namely*

$$J_{\leq\lambda_0}[A] = J_{<\lambda_0}[A] + b_{\lambda_0}.$$

2. There exists a set $b'_{\lambda_0} \subseteq b_{\lambda_0}$ *such that*

(a) $b'_{\lambda_0} \in N$.

(b) $b_{\lambda_0} \setminus b'_{\lambda_0} \in J_{<\lambda_0}[A]$ *(hence* b'_{λ_0} *is also a* B_{λ_0} *set).*

Proof. Note that since $f^{\lambda_0}_{\gamma_0} \leq \mathrm{Ch}_N$, $b_{\lambda_0} = \{a \in A \mid \mathrm{Ch}_N(a) \leq f^{\lambda_0}_{\gamma_0}(a)\}$. We have already observed in the paragraph preceding the lemma that 1 holds.

We prove 2. As the definition of b_{λ_0} involves N and $f^{\lambda_0}_{\gamma_0}$, we do not expect that $b_{\lambda_0} \in N$. However we shall find an inner approximation b'_{λ_0} of b_{λ_0} that lies in N. If $a \in A$ and $f^{\lambda_0}_{\gamma_0}(a) < \mathrm{Ch}_N(a)$, then there exists some $\alpha < \kappa$ such that $f^{\lambda_0}_{\gamma_0}(a) < \mathrm{Ch}_{N_\alpha}(a)$ (because $N = \bigcup_{\alpha<\kappa} N_\alpha$). Since $|A| < \kappa$, there is a sufficiently large $\alpha < \kappa$ such that

$$f^{\lambda_0}_{\gamma_0}(a) < \mathrm{Ch}_N(a) \quad \text{iff} \quad f^{\lambda_0}_{\gamma_0}(a) < \mathrm{Ch}_{N_\alpha}(a)$$

holds for every $a \in A$. Or equivalently (by negating both sides)

$$a \in b_{\lambda_0} \quad \text{iff} \quad \mathrm{Ch}_{N_\alpha}(a) \leq f^{\lambda_0}_{\gamma_0}(a).$$

That is, we have replaced the parameter N with N_α in the definition of b_{λ_0}, but γ_0 is still a parameter not in N.

Since f^{λ_0} satisfies (14.33), there exists (for $h = \mathrm{Ch}_{N_\alpha}$) some function $d \in N$ such that

1. $\mathrm{Ch}_{N_\alpha} \restriction B_{\lambda_0} <_{J_{<\lambda_0}} d \restriction B_{\lambda_0}$ and
2. $d \leq f^{\lambda_0}_{\gamma_0}$.

Define

$$b'_{\lambda_0} = \{a \in A \mid \mathrm{Ch}_{N_\alpha}(a) \leq d(a)\}.$$

Now all parameters are in N and clearly $b'_{\lambda_0} \in N$. Property 1 above implies that for almost all $a \in B_{\lambda_0}$, $\mathrm{Ch}_{N_\alpha}(a) < d(a)$ (i.e. except on a $J_{<\lambda_0}$ set). Hence $B_{\lambda_0} \subseteq_{J_{<\lambda_0}} b'_{\lambda_0}$. Property 2 implies that $b'_{\lambda_0} \subseteq b_{\lambda_0}$. $\dashv$

Suppose that for every $\lambda \in \mathrm{pcf}(A)$ we attach a certain $B_\lambda[A]$ set b^*_λ. Then the Compactness Theorem 4.11 gives a finite set $\lambda_0, \ldots, \lambda_{n-1}$ of $\mathrm{pcf}(A)$ cardinals such that $A = b^*_{\lambda_0} \cup \cdots \cup b^*_{\lambda_{n-1}}$. Now let $N \prec H_\Psi$ be such that $A \in N$ and assume that the sets b^*_λ are chosen in N for each $\lambda \in \mathrm{pcf}(A) \cap N$. Then the covering cardinals $\lambda_0, \ldots, \lambda_{n-1}$ can be found in N, even when the map $\lambda \mapsto b^*_\lambda$ is not in N. To prove that, we define a descending sequence of cardinals $\lambda_0 > \cdots > \lambda_i$ by induction on i, starting with $\lambda_0 = \max \mathrm{pcf}(A)$, so that the following two conditions hold.

1. $\lambda_i \in N$.
2. If $A_k = A \setminus (b^*_0 \cup \cdots \cup b^*_{k-1}) \neq \emptyset$, then $\lambda_k = \max \mathrm{pcf}(A_k)$.

Since $b^*_0, \ldots, b^*_{k-1}$ are in N, $A_k \in N$ as well, and hence $\lambda_k \in N$ (whenever $A_k \neq \emptyset$ and λ_k is defined). It follows from Lemmas 4.14 and 4.10 that $\lambda_0 > \lambda_1 > \cdots > \lambda_k$. Hence, for some k, $A_k = \emptyset$, and then $A = b^*_0 \cup \cdots \cup b^*_{k-1}$.

Here is a main result saying that the number of characteristic functions $\mathrm{Ch}_N \restriction A$ is bounded by $\max \mathrm{pcf}(A)$.

5.9 Corollary. *Suppose that A is a progressive set of regular cardinals, κ is a regular cardinal such that $|A| < \kappa < \min A$, and N with $A \in N$ is a κ-presentable elementary substructure $N \prec H_\Psi$ and containing, for every $\lambda \in N \cap \mathrm{pcf}(A)$, a sequence $f^\lambda = \langle f^\lambda_\xi \mid \xi < \lambda\rangle$ that satisfies properties (14.32) and (14.33). Then there are cardinals $\lambda_0 > \lambda_1 > \cdots > \lambda_n$ in $N \cap \mathrm{pcf}(A)$ such that*

$$\mathrm{Ch}_N \restriction A = \sup\{f^{\lambda_0}_{\gamma_0}, \ldots, f^{\lambda_n}_{\gamma_n}\}, \tag{14.35}$$

where $\gamma_i = \mathrm{Ch}_N(\lambda_i)$.

Proof. We employ Lemma 5.8, which assigns $B_\lambda[A]$ sets, $b'_\lambda \in N$, for every $\lambda \in \mathrm{pcf}(A) \cap N$, so that

$$b'_\lambda \subseteq \{a \in A \mid \mathrm{Ch}_N(a) = f^\lambda_{\mathrm{Ch}_N(\lambda)}(a)\}. \tag{14.36}$$

By the inductive covering procedure explained above, for some $\lambda_0, \ldots, \lambda_{n-1}$ in $\mathrm{pcf}(A) \cap N$

$$A = b'_{\lambda_0} \cup \cdots \cup b'_{\lambda_{n-1}}.$$

Since property (14.33) ensures that $f^\lambda_{\mathrm{Ch}_N(\lambda)} \leq \mathrm{Ch}_N$, (14.36) implies that (14.35) holds. ⊣

Application: The Cofinality of $([\mu]^\kappa, \subseteq)$

For cardinals $\kappa \leq \mu$, let $[\mu]^\kappa$ denote the collection of all subsets of μ of size κ. Under the inclusion relation $\subseteq$ this collection is a partial ordering, and we denote its cofinality by $\mathrm{cf}([\mu]^\kappa, \subseteq)$. Likewise, $[\mu]^{<\kappa}$ is the collection of all subsets of μ of cardinality less than κ. For example, if μ is a regular cardinal then the collection of all proper initial segments of μ is cofinal in $[\mu]^{<\mu}$.

One reason for the importance of studying $\mathrm{cf}([\mu]^\kappa, \subseteq)$ is the relationship

$$|[\mu]^\kappa| = \mathrm{cf}([\mu]^\kappa, \subseteq) \cdot 2^\kappa \tag{14.37}$$

and its applications to cardinal arithmetic (which we shall see). The proof of (14.37) is quite simple. Suppose that $\mathrm{cf}([\mu]^\kappa, \subseteq) = \lambda$ and let $Y = \{Y_i \in [\mu]^\kappa \mid i < \lambda\}$ be cofinal. A one-to-one map from $[\mu]^\kappa$ to $Y \times 2^\kappa$ can be defined as follows. For every $E \in [\mu]^\kappa$ find some $E \subseteq Y_i$. Since Y_i has cardinality κ, E is isomorphic to some subset S of κ, and then we map E to $\langle Y_i, S\rangle$.

We record some relatively simple facts about cofinalities of $[\mu]^\kappa$.

5.10 Lemma. *For any cardinal μ:*

1. *If $\kappa_1 < \kappa_2$ then*

$$\mathrm{cf}([\mu]^{\kappa_1}, \subseteq) \leq \mathrm{cf}([\mu]^{\kappa_2}, \subseteq) \cdot \mathrm{cf}([\kappa_2]^{\kappa_1}, \subseteq).$$

2. *If $\mu_1 < \mu_2$ then* $\mathrm{cf}([\mu_1]^\kappa, \subseteq) \leq \mathrm{cf}([\mu_2]^\kappa, \subseteq)$.

3. *Suppose that $\kappa \leq \mu$ and $E \subseteq [\mu]^\kappa$ is cofinal. Then there exists a cofinal set in $([\mu^+]^\kappa, \subseteq)$ of cardinality $|E| \cdot \mu^+$.*

Proof. We prove the third item. For every $\mu \leq \gamma < \mu^+$ let f_γ be a bijection from γ to μ. Then the collection of all sets of the form $f_\gamma^{-1}X$, where $X \in E$, is cofinal and of cardinality $|E| \cdot \mu^+$. ⊣

A consequence (which can be proved by induction) is that for every $n < \omega$, $\mathrm{cf}([\aleph_n]^{\aleph_0}, \subseteq) = \aleph_n$.

The first application of pcf theory to the subset cofinality question is the following:

5.11 Theorem. *Suppose that μ is a singular cardinal, and $\kappa < \mu$ is an infinite cardinal such that the interval A of regular cardinals in (κ, μ) has size $\leq \kappa$. Then*

$$\mathrm{cf}([\mu]^\kappa, \subseteq) = \max \mathrm{pcf}(A).$$

Proof. Let μ and κ be as in the theorem. Define

$$A = \{\gamma \mid \gamma \text{ is a regular cardinal and } \kappa < \gamma < \mu\}.$$

We assume that $|A| \leq \kappa$, so that A is a progressive interval of regular cardinals. To prove the theorem, we first prove the easier inequality $\geq$. Let $\{X_i \mid i \in I\} \subseteq [\mu]^\kappa$ be cofinal and of cardinality $\mathrm{cf}([\mu]^\kappa, \subseteq)$. Define $h_i = \mathrm{Ch}_{X_i} \restriction A$. That is, $h_i(a) = \sup(X_i \cap a)$ for $a \in A$. Then $\{h_i \mid i \in I\}$ is cofinal in $(\prod A, <)$. (Since for every $f \in \prod A$ the range of f is a subset of μ of size $\leq |A| \leq \kappa$, and is hence covered by some X_i. So $f \leq h_i$.) But we know that the cofinality of $(\prod A, <)$ is $\max \mathrm{pcf}(A)$, and hence $|I| \geq \max \mathrm{pcf}(A)$.

Now we prove the $\leq$ inequality. We assume first that $|A| < \kappa$ and prove the $\leq$ inequality for this case. Then we can obtain the $|A| = \kappa$ case by applying the first case to κ^+ (instead of κ) and using

$$\mathrm{cf}([\mu]^\kappa, \subseteq) \leq \mathrm{cf}([\mu]^{\kappa^+}, \subseteq) \cdot \kappa^+.$$

So assume that $|A| < \kappa$ (and hence κ is uncountable). We plan to present a cofinal subset of $[\mu]^\kappa$ of cardinality $\max \mathrm{pcf}(A)$. Fix for every $\rho \in \mathrm{pcf}(A)$ a minimally obedient (at cofinality κ) universal sequence for ρ, and let $f = \{f^\rho \mid \rho \in \mathrm{pcf}(A)\}$ be the resulting array of sequences. In fact, we let f be the minimal such array in the well-ordering $<^*$ of H_Ψ, so that $f \in M$ for every $M \prec H_\Psi$ such that $A \in M$. Let $\mathcal{M}$ be the collection of all substructures $M \prec$

H_Ψ that are κ-presentable and such that $A \in M$ (so $A \subseteq M$). We know that (14.32) and (14.33) hold. Consider the collection $F = \{M \cap \mu \mid M \in \mathcal{M}\}$. This collection is clearly cofinal in $[\mu]^\kappa$, since for any set $X \in [\mu]^\kappa$ a structure $M \in \mathcal{M}$ can be defined so that $X \subseteq M$ (or even $X \in M$). We shall prove that $|F| \leq \max \operatorname{pcf}(A)$. We know (by Corollary 5.9) that for every $M \in \mathcal{M}$, $\mathrm{Ch}_M \restriction A$ is the supremum of a finite number of functions taken from the array $\{f^\rho \mid \rho \in \operatorname{pcf}(A)\}$, which contains $\max \operatorname{pcf}(A)$ functions. Hence it suffices to prove that whenever $M, N \in \mathcal{M}$ are such that $\mathrm{Ch}_M \restriction A = \mathrm{Ch}_N \restriction A$, then $M \cap \mu = N \cap \mu$. But this is exactly Theorem 5.2. ⊣

The theorem just proved (Theorem 5.11) has important consequences for cardinal arithmetic which we shall explore now. Look, for example, at $\mu = \aleph_\omega$, $\kappa = \aleph_0$, and $A = \{\aleph_n \mid 1 < n < \omega\}$. Then

$$\operatorname{cf}([\aleph_\omega]^{\aleph_0}, \subseteq) = \max \operatorname{pcf}(A).$$

So $\aleph_\omega^{\aleph_0} = (\max \operatorname{pcf}(A)) + 2^{\aleph_0}$. If $\aleph_\omega$ is a strong limit cardinal then $[\aleph_\omega]^\omega$ has cardinality $2^{\aleph_\omega}$, and this cardinal turns out to be regular since it is $\max \operatorname{pcf}(A)$. Similarly, for every $n < \omega$, $\operatorname{cf}([\aleph_\omega, \subseteq]^{\aleph_n}, \subseteq) = \max \operatorname{pcf}(A)$. Hence

$$\operatorname{cf}([\aleph_\omega]^{\aleph_n}, \subseteq) = \operatorname{cf}([\aleph_\omega]^{\aleph_m}, \subseteq)$$

for every $n, m < \omega$.

Since A is an interval of regular cardinals, $\operatorname{pcf}(A)$ is also an interval of regular cardinals (Theorem 3.9) containing all regular cardinals from $\aleph_2$ to $\max \operatorname{pcf}(A)$. Hence if we write $\max \operatorname{pcf}(A) = \aleph_\alpha$, then $|\alpha| = |\operatorname{pcf}(A)|$ follows. Yet $|\operatorname{pcf}(A)| \leq 2^{\aleph_0}$ (Theorem 3.6). Thus $\operatorname{cf}([\aleph_\omega]^{\aleph_0}, \subseteq) = \aleph_\alpha$ for an $\alpha < (2^{\aleph_0})^+$. Thus we have proved the following theorem.

5.12 Theorem. $\operatorname{cf}([\aleph_\omega]^{\aleph_0}, \subseteq) < \aleph_{(2^{\aleph_0})^+}$.

An immediate conclusion is

5.13 Theorem. $\aleph_\omega^{\aleph_0} < \aleph_{(2^{\aleph_0})^+}$.

Proof. If $2^{\aleph_0} > \aleph_\omega$ (equality is impossible by Zermelo-König theorem) then $\aleph_\omega^{\aleph_0} = 2^{\aleph_0}$, and then $2^{\aleph_0} \leq \aleph_{2^{\aleph_0}}$ implies the theorem as a triviality. So we assume that $2^{\aleph_0} < \aleph_\omega$.

Suppose that $\aleph_\alpha = \operatorname{cf}([\aleph_\omega]^{\aleph_0}, \subseteq)$. We have proved in the preceding theorem that $\alpha < (2^{\aleph_0})^+$. Let $\{X_i \mid i < \aleph_\alpha\} \subseteq [\aleph_\omega]^{\aleph_0}$ be cofinal. So $[\aleph_\omega]^{\aleph_0} \subseteq \bigcup\{\mathcal{P}(X_i) \mid i < \aleph_\alpha\}$. Hence $|[\aleph_\omega]^{\aleph_0}| \leq 2^{\aleph_0} \cdot \aleph_\alpha = \aleph_\alpha < \aleph_{(2^{\aleph_0})^+}$. ⊣

We want to generalize this theorem to arbitrary singular cardinals $\aleph_\delta$ such that $\delta < \aleph_\delta$. A straightforward generalization gives the following which we leave as an exercise: If δ is a limit ordinal such that $\delta < \aleph_\delta$, then

$$\operatorname{cf}([\aleph_\delta]^{|\delta|}, \subseteq) < \aleph_{(2^{|\delta|})^+}$$

and hence

$$\aleph_\delta^{|\delta|} < \aleph_{(2^{|\delta|})^+}.$$

We shall describe now a tighter bound: $\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$.

As in the proof for bounding $\aleph_\omega^{\aleph_0}$, which consists in first evaluating the cofinality of $([\aleph_\omega]^{\aleph_0}, \subseteq)$, here too we first investigate cardinalities of covering sets. For cardinals $\mu \geq \tau$ a *cover* for $[\mu]^{<\tau}$ is a collection $\mathcal{C}$ of subsets of μ such that for every $X \in [\mu]^{<\tau}$ there exists a $Y \in \mathcal{C}$ with $X \subseteq Y$. For cardinals $\mu \geq \theta \geq \tau$, $\mathrm{cov}(\mu, \theta, \tau)$ is the least cardinality of a cover for $[\mu]^{<\tau}$ consisting of sets taken from $[\mu]^{<\theta}$. So $\mathrm{cov}(\mu, \theta, \tau)$ measures how many sets, each of cardinality $< \theta$, are needed to cover every subset of μ of cardinality $< \tau$. For example, $\mathrm{cf}([\mu]^\kappa, \subseteq) = \mathrm{cov}(\mu, \kappa^+, \kappa^+)$. We shall prove the following.

5.14 Theorem. *Suppose that μ is a singular cardinal, and $\kappa < \mu$ a regular cardinal. Let A be the set of all regular cardinals in the interval $[\kappa^{++}, \mu)$. If $|A| \leq \kappa$, then*

$$\mathrm{cov}(\mu, \kappa^+, \mathrm{cf}(\mu)^+) = \sup \mathrm{pcf}_{\mathrm{cf}(\mu)}(A).$$

(See Definition 3.10 for $\mathrm{pcf}_{\mathrm{cf}(\mu)}(A)$*.)*

Before proving this theorem, let's see how it can be employed.

5.15 Corollary. *Suppose that δ is a limit ordinal such that $\delta < \aleph_\delta$. Then*

$$\mathrm{cov}(\aleph_\delta, |\delta|^+, \mathrm{cf}(\delta)^+) < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$$

and hence

$$\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}.$$

Proof. Suppose that δ is a limit ordinal such that $\delta < \aleph_\delta$. Let $\mu = \aleph_\delta$, and $\kappa = |\delta|^+$. Define A as the set of all regular cardinals in the interval $(\kappa^{++}, \mu]$. So $|A| \leq |\delta|$. By Theorem 5.14, there exists a collection $\{X_i \mid i \in I\}$, where $X_i \in [\mu]^\kappa$ and $|I| = \sup \mathrm{pcf}_{\mathrm{cf}(\mu)}(A)$, such that for every $Z \in [\aleph_\delta]^{\mathrm{cf}(\mu)}$, $Z \subseteq X_i$ for some $i \in I$. Yet, by Theorem 3.11, $\mathrm{pcf}_{\mathrm{cf}(\mu)}(A)$ is also an interval of regular cardinals, containing all regular cardinals in the interval $[\kappa^{++}, \aleph_\alpha)$ where $\aleph_\alpha = \sup \mathrm{pcf}_{\mathrm{cf}(\mu)}(A)$. Now $|\mathrm{pcf}_{\mathrm{cf}(\mu)}(A)| \leq |[A]^{\mathrm{cf}(\mu)}| \cdot 2^{\mathrm{cf}(\mu)} \leq |\delta|^{\mathrm{cf}(\mu)}$. It follows (see the proof in the following paragraph) that $\alpha < (|\delta|^{\mathrm{cf}(\mu)})^+$. That is, $|I| < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$ (as $\mathrm{cf}(\mu) = \mathrm{cf}(\delta)$). Hence $|[\aleph_\delta]^{\mathrm{cf}(\delta)}| < \kappa^{\mathrm{cf}(\delta)} \cdot \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$. Thus $\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$ as required.

We prove that $\alpha < (|\delta|^{\mathrm{cf}(\mu)})^+$. Since $\delta < |\delta|^+ \leq (|\delta|^{\mathrm{cf}(\mu)})^+$, it follows that the interval $(\aleph_\delta, \aleph_{(|\delta|^{\mathrm{cf}(\mu)})^+})$ contains $(|\delta|^{\mathrm{cf}(\mu)})^+$ regular cardinals. But the interval of regular cardinals in $(\aleph_\delta, \aleph_\alpha)$ is included in $\mathrm{pcf}_{\mathrm{cf}(\mu)}(A)$ and contains $\leq |\delta|^{\mathrm{cf}(\mu)}$ regular cardinals. Hence $\alpha < (|\delta|^{\mathrm{cf}(\mu)})^+$. $\dashv$

Proof of Theorem 5.14. Let $\kappa < \mu$ and $|A| \leq \kappa$ be as in the theorem. Since A is cofinal in μ and $|A| \leq \kappa$, $\mathrm{cf}(\mu) \leq \kappa$. Let $\rho = \mathrm{cf}(\mu)$ be the cofinality of μ. We shall prove that $\mathrm{cov}(\mu, \kappa^+, \rho^+) = \sup \mathrm{pcf}_\rho(A)$.

For the $\geq$ inequality, we must prove that $\mathrm{cov}(\mu, \kappa^+, \rho^+) \geq \lambda$ for every $\lambda \in \mathrm{pcf}_\rho(A)$. That is, if $A_0 \subseteq A$ is of cardinality ρ we want to prove that $\mathrm{cov}(\mu, \kappa^+, \rho^+) \geq \max \mathrm{pcf}(A_0)$. So let $\{X_i \mid i \in I\}$ be a covering of $[\mu]^{\mathrm{cf}(\mu)}$ with sets X_i of cardinality $\leq \kappa$. For each X_i define $h_i = \mathrm{Ch}_{X_i} \restriction A_0$. Then $\{h_i \mid i \in I\}$ is cofinal in $(\prod A_0, <)$, and hence $|I| \geq \max \mathrm{pcf}(A_0)$.

For the $\leq$ inequality, we must provide a covering set for $\mathrm{cov}(\mu, \kappa^+, \rho^+)$ of cardinality $\sup \mathrm{pcf}_\rho(A)$.

For every $\lambda \in \mathrm{pcf}_\rho(A)$, $\lambda \in \mathrm{pcf}(A)$ as well, and we fix a minimally obedient at cofinality ρ^+ sequence $f^\lambda = \langle f^\lambda_\xi \mid \xi < \lambda \rangle$ of functions in $\prod A$ that is universal for λ.

For every $\alpha < \mu$ such that $\mathrm{cf}(\alpha) = \rho^+$, let $E_\alpha \subseteq \alpha$ be a closed unbounded subset of α of order-type ρ^+.

Define $\mathcal{F}$ as the collection of all functions of the form $\sup\{f^{\lambda_1}_{\alpha_1}, \ldots, f^{\lambda_n}_{\alpha_n}\}$ where $\lambda_i \in \mathrm{pcf}_\rho(A)$ and $\alpha_i < \lambda_i$. Clearly $\mathcal{F}$ has cardinality $\sup \mathrm{pcf}_\rho(A)$. For $f \in \mathcal{F}$ let

$$E(f) = \bigcup \{E_{f(a)} \mid a \in A \text{ and } \mathrm{cf}(f(a)) = \rho^+\}.$$

Then the cardinality of $E(f)$ is at most κ^+. Let

$$K(f) = \mathrm{Skolem}(E(f) \cup \kappa^+) \prec H_\Psi$$

be the Skolem hull (closure) of $E(f) \cup \kappa^+$. We remind the reader that the structure H_Ψ includes a class well-ordering $<^*$ of all sets, and hence there is a countable set of Skolem functions for H_Ψ so that $X \prec H_\Psi$ iff X is closed under all of these Skolem functions. The cardinality of $K(f)$ is κ^+.

Clearly $\mathcal{K} = \{K(f) \mid f \in \mathcal{F}\}$ has cardinality $\leq \sup \mathrm{pcf}_\rho(A)$. Our aim now is to show that

$$\mathcal{K} \text{ covers } [\mu]^{\mathrm{cf}(\mu)}.$$

Since $\mathrm{cf}([\kappa^+]^\kappa, \subseteq) = \kappa^+$, this yields that

$$\mathrm{cov}(\mu, \kappa^+, \mathrm{cf}(\mu)^+) = \sup \mathrm{pcf}_{\mathrm{cf}(\mu)}(A).$$

Let $Z \subseteq \mu$ be of size $\rho = \mathrm{cf}(\mu)$. Define $\langle M_i \mid i < \rho^+ \rangle$ an increasing and continuous chain of elementary substructures $M_i \prec H_\Psi$, each of cardinality ρ, such that $A, Z \in M_0$, $M_i \in M_{i+1}$, and $Z \subseteq M_0$. Let $M = \bigcup_{i<\rho^+} M_i$ be the resulting ρ^+-presentable structure.

For every $a \in A \cap M$ (and in fact for every $a \in A$), $\mathrm{Ch}_M(a)$ has cofinality ρ^+. Indeed $\langle \mathrm{Ch}_{M_i}(a) \mid i < \rho^+ \rangle$ is increasing, continuous and with limit $\mathrm{Ch}_M(a)$. There is another closed unbounded sequence in $\mathrm{Ch}_M(a)$ which interests us, namely $E_{\mathrm{Ch}_M(a)}$, and we consider the intersection of these two closed unbounded sets. So there exists a closed unbounded set $D_a \subseteq \rho^+$ such that for every $i \in D_a$

$$\mathrm{Ch}_{M_i}(a) \in E_{\mathrm{Ch}_M(a)}. \tag{14.38}$$

For every $i < \rho^+$, M_i has cardinality ρ and hence $D(i) = \bigcap \{D_a \mid a \in A \cap M_i\}$ is closed unbounded in ρ^+. Form the diagonal intersection $D =$

$\{j \in \rho^+ \mid \forall i < j(j \in D(i))\}$. Fix any $j_0 \in D'$ (a limit point of D). For every $a \in A \cap M_{j_0}$ there exists some $j_1 < j_0$ such that $a \in A \cap M_{j_1}$. If $j_1 < i \le j_0$ and $i \in D$, then $i \in D(j_1)$ and hence $i \in D_a$. So $\mathrm{Ch}_{M_i}(a) \in E_{\mathrm{Ch}_M(a)}$. Thus $\langle \mathrm{Ch}_{M_i}(a) \mid j_1 < i < j_0 \wedge i \in D\rangle$ is a sequence of ordinals in $M_{j_0} \cap E_{\mathrm{Ch}_M(a)}$ that tends to $\mathrm{Ch}_{M_{j_0}}(a)$ (whenever $j_0 \in D'$ and $a \in A \cap M_{j_0}$).

Define $A_0 = A \cap M_{j_0}$. Then $A_0 \in [A]^{\mathrm{cf}(\mu)}$, and $A_0 \in M$. We plan to apply Corollary 5.9 to A_0, ρ^+ and M (substituting A, κ, and N there). For every $\lambda \in \mathrm{pcf}(A_0)$, $\lambda \in \mathrm{pcf}_{\mathrm{cf}(\mu)}(A)$ and the sequence $\langle f^\lambda_\xi \restriction A_0 \mid \xi < \lambda\rangle$ is, in M, universal for λ and minimally obedient at ρ^+. Hence, by Corollary 5.9,

$$\mathrm{Ch}_M \restriction A_0 = f \restriction A_0 \quad \text{for some } f \in \mathcal{F}. \tag{14.39}$$

Since $Z \subseteq M_{j_0}$, the following proves that $Z \subseteq K(f)$.

Claim. *$M_{j_0} \cap \mu \subseteq K(f)$.*

By Lemma 5.2, this is a consequence of the following

5.16 Lemma. *For every successor cardinal $\sigma^+ \in M_{j_0} \cap \mu$*

$$\sup(M_{j_0} \cap \sigma^+) = \sup(M_{j_0} \cap K(f) \cap \sigma^+).$$

Proof. Assume that $\sigma^+ \in M_{j_0} \cap \mu$. If $\sigma^+ \le \kappa^+$, then $\kappa^+ \subseteq K(f)$ implies the lemma immediately. So assume that $\sigma^+ > \kappa^+$, and hence that $\sigma^+ \in A \cap M_{j_0} = A_0$. Now (14.39) implies that $\mathrm{Ch}_M(\sigma^+) = f(\sigma^+) = \alpha$. Hence $\mathrm{cf}(\alpha) = \rho^+$ and $E_\alpha \subseteq E(f) \subseteq K(f)$. The sequence $\langle \mathrm{Ch}_{M_i}(\sigma^+) \mid j_1 < i < j_0 \wedge i \in D\rangle$ is unbounded in $\mathrm{Ch}_{M_{j_0}}(\sigma^+)$, as we have observed above, and thus shows that the lemma is correct. ⊣

This completes the proof of Theorem 5.14. ⊣

5.17 Exercise.

1. Let μ, κ, and A be as in Theorem 5.14. Suppose that $|A| \le \kappa$. Prove that
$$\mathrm{cov}(\mu, \kappa^+, \aleph_1) = \sup \mathrm{pcf}_{\aleph_0}(A).$$
Conclude that if $\delta < \aleph_\delta$ is a limit ordinal, then
$$\aleph_\delta^{\aleph_0} < \aleph_{(|\delta|^{\aleph_0})^+}.$$
Hint. By induction on μ.

2. Suppose that δ is a limit ordinal such that for every cardinal $\mu < \delta$ $\mu^{\aleph_0} < \delta$. Then $\aleph_\delta$ satisfies the same property, namely for every $\mu < \aleph_\delta$, $\mu^{\aleph_0} < \aleph_\delta$.

   Hint. Without loss of generality, $\delta < \aleph_\delta$. Prove that $\mu^{\aleph_0} < \aleph_\delta$ by induction on $\mu < \aleph_\delta$.

6. Elevations and Transitive Generators

Given a progressive set A of regular cardinals, we have proved the existence of generating sets $B_\lambda = B_\lambda[A]$. Suppose that N is such that $A \subseteq N \subseteq \mathrm{pcf}(A)$ and $B = \langle B_\lambda \mid \lambda \in N \rangle$ is a generating sequence (defined only for λ in N). Then B is said to be *smooth* (or transitive) if for every $\lambda \in N$ and $\theta \in B_\lambda$, $B_\theta \subseteq B_\lambda$.

This definition is trivial when $B_\theta = \{\theta\}$ (that is when $\theta \notin \mathrm{pcf}(A \cap \theta)$). However, we shall be interested in A's for which $\theta \in \mathrm{pcf}(A \cap \theta)$ is possible for $\theta \in A$. The reason for considering subsets N of $\mathrm{pcf}(A)$ in this definition, rather than the whole $\mathrm{pcf}(A)$ (which would be most desirable) is that we only know how to prove the existence of smooth sequences for sets N of cardinality $\min A$.

Our aim is to obtain transitive generators; they will be useful in proving, for example, that for every progressive interval of regular cardinals A, $|\mathrm{pcf}(A)| < |A|^{+4}$. However, there is still some material to cover beforehand.

Fix a progressive set A of regular cardinals and let κ be a regular cardinal such that $|A| < \kappa < \min A$. For every $\lambda \in \mathrm{pcf}(A)$ let $f^\lambda = \langle f^\lambda_\xi \mid \xi < \lambda \rangle$ be a universal sequence for λ which is minimally obedient (at cofinality κ). It is convenient to assume that for $a \in A \setminus \lambda$, $f^\lambda_\xi(a) = \xi$. The *elevation* of the array $\langle f^\lambda \mid \lambda \in \mathrm{pcf}(A) \rangle$ is another array $\langle F^\lambda \mid \lambda \in \mathrm{pcf}(A) \rangle$ of persistently cofinal sequences defined below, and which will be shown to satisfy properties (14.32) and (14.33).

For every finite, decreasing sequence $\lambda_0 > \lambda_1 > \cdots > \lambda_n$ of cardinals such that $\lambda_0 \in \mathrm{pcf}(A)$ and $\lambda_{i+1} \in A \cap \lambda_i$ for $i < n$, and for every ordinal $\gamma_0 \in \lambda_0$, define a sequence $\gamma_1 \in \lambda_1, \ldots, \gamma_n \in \lambda_n$ by

$$\gamma_{i+1} = f^{\lambda_i}_{\gamma_i}(\lambda_{i+1}). \tag{14.40}$$

So $\gamma_1 = f^{\lambda_0}_{\gamma_0}(\lambda_1)$, $\gamma_2 = f^{\lambda_1}_{\gamma_1}(\lambda_2)$, etc. until $\gamma_n = f^{\lambda_{n-1}}_{\gamma_{n-1}}(\lambda_n)$. Now define the elevation function $\mathrm{El}_{\lambda_0,\ldots,\lambda_n}$ on λ_0 by

$$\mathrm{El}_{\lambda_0,\ldots,\lambda_n}(\gamma_0) = \gamma_n.$$

We say that the last value obtained, γ_n, is reached from $f^{\lambda_0}_{\gamma_0}$ via the descending sequence $\lambda_0 > \lambda_1 > \cdots > \lambda_n$.

Fix a cardinal $\lambda_0 \in \mathrm{pcf}(A)$. We want to define the elevated sequence F^{λ_0}, first on $A \cap \lambda_0$. Given any $\lambda \in A \cap \lambda_0$, let $F_{\lambda_0,\lambda}$ be the set of all finite, descending sequences $\langle \lambda_0 > \lambda_1 > \cdots > \lambda_n \rangle$ leading from λ_0 to $\lambda_n = \lambda$, such that λ_i for $i > 0$ are all in A. For every $\gamma_0 \in \lambda_0$ we ask whether there is a maximal value among

$$\{\mathrm{El}_{\lambda_0,\ldots,\lambda_n}(\gamma_0) \mid \langle \lambda_0, \ldots, \lambda_n \rangle \in F_{\lambda_0,\lambda}\}.$$

If this set contains a maximum, let $F^{\lambda_0}_{\gamma_0}(\lambda)$ be that maximum, and otherwise put $F^{\lambda_0}_{\gamma_0}(\lambda) = f^{\lambda_0}_{\gamma_0}(\lambda)$. In case $\lambda \in A$ and $\lambda \geq \lambda_0$, define $F^{\lambda_0}_{\gamma_0}(\lambda) = \gamma_0$. So $F^{\lambda_0} = \langle F^{\lambda_0}_\gamma \mid \gamma < \lambda_0 \rangle$ with $F^{\lambda_0}_\gamma \in \prod A$ is defined.

The elevated array $\langle F^{\lambda_0} \mid \lambda_0 \in \mathrm{pcf}(A)\rangle$ thus defined will give the required transitive generating sequence. Observe first that

$$f^{\lambda_0}_\gamma \leq F^{\lambda_0}_\gamma \quad \text{for every } \gamma < \lambda_0.$$

This is so because $\mathrm{El}_{\lambda_0,\lambda}(\gamma_0) = f^{\lambda_0}_{\gamma_0}(\lambda)$ for every $\lambda \in A \cap \lambda_0$; so that this original value is among the values considered for maximum. Hence

$$F^{\lambda_0} \text{ is persistently cofinal for } \lambda_0.$$

This shows that Lemma 5.4 can be applied and property (14.32) holds whenever $F^\lambda \in N$ (and N is κ-presentable).

Another observation concerns any κ-presentable elementary substructure $N \prec H_\Psi$ such that $A, \langle f^\lambda \mid \lambda \in \mathrm{pcf}(A)\rangle \in N$. Being definable, the elevated array is also in N. Even though each f^λ is assumed to be minimally obedient, the elevated sequence F^λ is not anymore club-obedient. We have however the following consequence of Lemma 5.7.

6.1 Lemma. *If $\lambda_0 \in \mathrm{pcf}(A) \cap N$ and $\gamma_0 = \mathrm{Ch}_N(\lambda_0)$, then for every $\lambda \in A \cap \lambda_0$, $F^{\lambda_0}_{\gamma_0}(\lambda) \in \bar{N} \cap \lambda$ (where $\bar{N}$ is the ordinal closure of N). Thus the elevated sequence F^{λ_0} satisfies (14.33). Namely,*

1. *$F^{\lambda_0}_{\gamma_0}(\lambda) \leq \mathrm{Ch}_N(\lambda)$ for every $\lambda \in A$, and*
2. *for every $h \in N \cap \prod A$ there exists some $d \in N \cap \prod A$ such that*

$$h{\restriction}B <_{J_{<\lambda_0}} d{\restriction}B \quad \textit{and} \quad d \leq F^{\lambda_0}_{\gamma_0}$$

where $B = B_{\lambda_0}[A]$.

Proof. Observe first that $A \subseteq N$, $\lambda \in N$, and $F_{\lambda_0,\lambda} \subseteq N$. Consider any $\langle \lambda_0, \ldots, \lambda_n\rangle \in F_{\lambda_0,\lambda}$ and the ordinals γ_i defined by (14.40). It follows from Lemma 5.7 that $\gamma_i \in \bar{N}$. If $\gamma_i \in N$ then obviously $\gamma_{i+1} = f^{\lambda_i}_{\gamma_i}(\lambda_{i+1}) \in N$. If, however, $\gamma_i \in \bar{N} \setminus N$, then Lemma 5.7 yields that $f^{\lambda_i}_{\gamma_i}(a) \in \bar{N}$ for every $a \in A$, and in particular $\gamma_{i+1} \in \bar{N}$. Thus $\mathrm{El}_{\lambda_0,\ldots,\lambda_n}(\gamma_0) \in \bar{N}$ and hence $F^{\lambda_0}_{\gamma_0}(\lambda) \in \bar{N} \cap \lambda$.

Thus (14.33)(1) holds for F^{λ_0}. Since $f^{\lambda_0} \leq F^{\lambda_0}$, where f^{λ_0} is universal and minimally obedient at κ, (14.33)(2) holds as well. ⊣

6.2 Lemma. *Let A, f, and N be as in the previous lemma. Suppose that $\lambda_0 \in \mathrm{pcf}(A) \cap N$, $\gamma_0 = \mathrm{Ch}_N(\lambda_0)$ and $\lambda \in A \cap \lambda_0$.*

1. *If for some descending sequence $\lambda_0 > \cdots > \lambda_n = \lambda$ in $F_{\lambda_0,\lambda}$*

$$\mathrm{El}_{\lambda_0,\ldots,\lambda_n}(\gamma_0) = \mathrm{Ch}_N(\lambda).$$

Then $\mathrm{Ch}_N(\lambda)$ is the maximal value in $\{\mathrm{El}_{\bar{\lambda}}(\gamma_0) \mid \bar{\lambda} \in F_{\lambda_0,\lambda}\}$ and hence

$$\mathrm{Ch}_N(\lambda) = F^{\lambda_0}_{\gamma_0}(\lambda).$$

2. *Suppose that*

$$F^{\lambda_0}_{\gamma_0}(\lambda) = \gamma.$$

For any $a \in A \cap \lambda$, *if*

$$F^{\lambda}_{\gamma}(a) = \mathrm{Ch}_N(a),$$

then

$$F^{\lambda_0}_{\gamma_0}(a) = \mathrm{Ch}_N(a)$$

as well.

Proof. Item 1 says that if some descending sequence leading from λ_0 to λ reaches $\mathrm{Ch}_N(\lambda)$, then no sequence reaches a higher value. But this is clear from Lemma 6.1 since $\mathrm{Ch}_N(\lambda)$ is the maximal possible value.

Item 2 uses item 1. It says that if γ can be reached from $f^{\lambda_0}_{\gamma_0}$ by a finite descending sequence leading to λ, and if there is another sequence leading from λ to a, so that $\mathrm{Ch}_N(a)$ can be reached from f^{λ}_{γ}, then $\mathrm{Ch}_N(a)$ can be reached already from $f^{\lambda_0}_{\gamma_0}$ via the concatenation of these descending sequences (and no higher value can be reached—by 1). $\dashv$

Now we can get our transitive generating sequence.

6.3 Theorem (Transitive Generators). *Suppose that A is a progressive set of regular cardinals, and $|A| < \kappa < \min A$ is a regular cardinal. Let $\langle f^\lambda \mid \lambda \in \mathrm{pcf}(A)\rangle$ be an array of minimally obedient (at cofinality κ) universal sequences. Let $N \prec H_\Psi$ be an elementary substructure that is κ-presentable and such that $A, \langle f^\lambda \mid \lambda \in \mathrm{pcf}(A)\rangle \in N$. Let $\langle F^\lambda \mid \lambda \in \mathrm{pcf}(A)\rangle$ be the derived elevated array. For every $\lambda_0 \in \mathrm{pcf}(A) \cap N$ put $\gamma_0 = Ch_N(\lambda_0)$ and define*

$$b_{\lambda_0} = \{a \in A \mid \mathrm{Ch}_N(a) = F^{\lambda_0}_{\gamma_0}(a)\}.$$

then the following hold:

1. *Every b_{λ_0} is a $B_{\lambda_0}[A]$ set, namely*

$$J_{\leq\lambda_0}[A] = J_{<\lambda_0}[A] + b_{\lambda_0}.$$

2. *There exists sets $b'_{\lambda_0} \subseteq b_{\lambda_0}$, for $\lambda_0 \in \mathrm{pcf}(A) \cap N$, such that*

   (a) $b_{\lambda_0} \setminus b'_{\lambda_0} \in J_{<\lambda_0}[A]$.

   (b) $b'_{\lambda_0} \in N$ (but the sequence $\langle b'_{\lambda_0} \mid \lambda_0 \in \mathrm{pcf}(A) \cap N\rangle$ is not claimed to be in N).

3. *The collection $\langle b_\lambda \mid \lambda \in \mathrm{pcf}(A) \cap N\rangle$ is transitive; which means that if $\lambda_1 \in b_\lambda$ then $b_{\lambda_1} \subseteq b_\lambda$.*

Proof. The elevated sequence F^{λ_0} satisfies properties (14.32) (because it is persistently cofinal) and (14.33) (as shown in Lemma 6.1). Thus items 1 and 2 of our lemma follow from Lemma 5.8. Observe that $b_{\lambda_0} \subseteq \lambda_0 + 1$, since $B_{\lambda_0} \in J_{<\lambda_0^+}$.

Transitivity (item 3) relies on Lemma 6.2. Suppose that $\lambda_0 \in \mathrm{pcf}(A) \cap N$ and $\lambda_1 \in b_{\lambda_0}$. This means

$$\mathrm{Ch}_N(\lambda_1) = F^{\lambda_0}_{\gamma_0}(\lambda_1)$$

where $\gamma_0 = \mathrm{Ch}_N(\lambda_0)$. Say $\mathrm{Ch}_N(\lambda_1) = \gamma_1$. We have to show that $b_{\lambda_1} \subset b_{\lambda_0}$ in this case. So assume that $a \in b_{\lambda_1}$. This means

$$\mathrm{Ch}_N(a) = F^{\lambda_1}_{\gamma_1}(a).$$

Now Lemma 6.2(2) applies and yields

$$F^{\lambda_0}_{\gamma_0}(a) = \mathrm{Ch}_N(a)$$

which gives $a \in b_{\lambda_0}$. ⊣

Localization

Localization is the following property of the pcf function which will be proved in this subsection.

> If A is a progressive set of regular cardinals and $B \subseteq \mathrm{pcf}(A)$ is also progressive, then for every $\lambda \in \mathrm{pcf}(B)$ there exists a $B_0 \subseteq B$ such that $|B_0| \leq |A|$ and $\lambda \in \mathrm{pcf}(B_0)$.

The localization property implies that there exists no $B \subseteq \mathrm{pcf}(A)$ with $|B| = |A|^+$ and such that $b > \max \mathrm{pcf}(B \cap b)$ for every $b \in B$. For indeed if there were such a B it would be progressive, and if we define $\lambda = \max \mathrm{pcf}(B)$, then λ is not in the pcf of any proper initial segment of B. In fact, $\lambda > \max \mathrm{pcf}(B_0)$ for any proper initial segment B_0 of B. It is this conclusion, the simplest case of localization, which is proved first.

6.4 Theorem. *Assume that A is a progressive set of regular cardinals. Then there is no set $B \subseteq \mathrm{pcf}(A)$ such that $|B| = |A|^+$, and, for every $b \in B$, $b > \max \mathrm{pcf}(B \cap b)$.*

Proof. Assume on the contrary that A is as in the theorem and yet, for some $B \subseteq \mathrm{pcf}(A)$ of cardinality $|A|^+$, $b > \max \mathrm{pcf}(B \cap b)$ for every $b \in B$. Since A is progressive $|A| < \min A$, and in case $|A|^+ \in A$ we may remove the first cardinal of A and assume that $|A|^+ < \min A$. The set $E = A \cup B$ of cardinality $|A|^+$ thus satisfies $|E| < \min E$ and the Transitive Generators Theorem 6.3 can be applied to E.

Find a κ-presentable elementary substructure, $N \prec H_\Psi$, that contains A and B where $\kappa = |E|$. Let $\langle b_\lambda \mid \lambda \in \mathrm{pcf}(E) \cap N \rangle$ be the set of transitive generators (subsets of E) as guaranteed by Theorem 6.3. Let $b'_\lambda \in N$ be such that $b'_\lambda \subseteq b_\lambda$ and $b_\lambda \setminus b'_\lambda \in J_{<\lambda}$.

Since $|A| < |B|$ we can find an initial segment $B_0 \subseteq B$ of cardinality $|A|$ such that if an arbitrary $a \in A$ is in some b_β, $\beta \in B$, then it is already in some b_β with $\beta \in B_0$. Namely

$$\forall a \in A[(\exists \beta \in B) a \in b_\beta \implies (\exists \beta \in B_0) a \in b_\beta]. \tag{14.41}$$

Let $\beta_0 = \min(B \setminus B_0)$. So $B_0 = B \cap \beta_0$ and $B_0 \in N$.

Claim. *There exists a finite descending sequence of cardinals $\lambda_0 > \cdots > \lambda_n$ in $N \cap \mathrm{pcf}(B_0)$ such that*

$$B_0 \subseteq b_{\lambda_0} \cup \cdots \cup b_{\lambda_n}. \tag{14.42}$$

Proof. In fact we shall find a finite sequence $\lambda_0, \ldots, \lambda_n \in N \cap \mathrm{pcf}(B_0)$ such that $B_0 \subseteq b'_{\lambda_0} \cup \cdots \cup b'_{\lambda_n}$. The proof is the same as that of Theorem 4.11, but one must be a little bit more careful to ensure that the pcf index-cardinals are in N.

So let $\lambda_0 = \max \mathrm{pcf}(B_0)$. Clearly $\lambda_0 \in N$ and hence $b'_{\lambda_0} \in N$. So $B_1 = B_0 \setminus b'_{\lambda_0} \in N$, and $\lambda_1 = \max \mathrm{pcf}(B_1) \in N \cap \lambda_0$. Next define $B_2 = B_1 \setminus b'_{\lambda_1}$ etc. The point is that we have $B_i \in N$ since $b'_{\lambda_{i-1}} \in N$, and we must stop with $B_{n+1} = \emptyset$ after a finite number of steps since $\lambda_0 > \lambda_1 > \cdots$. Since $b'_{\lambda_i} \subseteq b_{\lambda_i}$, (14.42) holds. $\dashv$

The following claim will bring the desired contradiction and thus prove the theorem. Recall that $\beta_0 = \min(B \setminus B_0)$ and thus $\beta_0 > \max \mathrm{pcf}(B_0) \geq \lambda_0, \ldots, \lambda_n$. Since $\beta_0 \in \mathrm{pcf}(A)$, $\beta_0 \in \mathrm{pcf}(b_{\beta_0} \cap A)$ (or else $\beta_0 \in \mathrm{pcf}(A \setminus b_{\beta_0})$ which is impossible by Lemma 4.14). Yet the following inclusion shows that this is impossible.

6.5 Claim. $b_{\beta_0} \cap A \subseteq b_{\lambda_0} \cup \cdots \cup b_{\lambda_n}$.

Proof. Consider any cardinal $a \in b_{\beta_0} \cap A$. Then

$$a \in b_\beta$$

for some $\beta \in B_0$ (by 14.41). As $B_0 \subseteq b_{\lambda_0} \cup \cdots \cup b_{\lambda_n}$, $\beta \in b_{\lambda_i}$ for some $0 \leq i \leq n$. But transitivity implies

$$b_\beta \subseteq b_{\lambda_i}$$

and hence

$$a \in b_{\lambda_i}$$

as required. This claim shows that $\max \mathrm{pcf}(b_{\beta_0} \cap A) < \beta_0$, and yet $\beta_0 \in \mathrm{pcf}(b_{\beta_0} \cap A)$ which is a contradiction! $\dashv$

Thus Theorem 6.4 is proved. $\dashv$

Now we pass to the general case and prove the localization theorem.

6.6 Theorem (Localization). *Suppose that A is a progressive set of regular cardinals. If $B \subseteq \operatorname{pcf}(A)$ is also progressive, then for every $\lambda \in \operatorname{pcf}(B)$ there exists a $B_0 \subseteq B$ with $|B_0| \leq |A|$ and such that $\lambda \in \operatorname{pcf}(B_0)$.*

Proof. We prove by induction on λ that for every A and B as in the theorem the conclusion holds for λ. Replacing B with $B_\lambda[B]$, we may assume that $\lambda = \max \operatorname{pcf}(B)$.

6.7 Claim. *We may assume that the set $\lambda \cap \operatorname{pcf}(B)$ has no maximal cardinal.*

Proof. Suppose on the contrary the existence of some $\lambda_0 = \max(\lambda \cap \operatorname{pcf}(B))$. It is easy to remove λ_0 by defining

$$B_1 = B \setminus B_{\lambda_0}[B].$$

Then $\lambda \in \operatorname{pcf}(B_1)$ still holds since $B_{\lambda_0} \in J_{<\lambda}$. We can now replace B with B_1, and repeat, if necessary, this procedure a finite number of times until the claim holds (for some B_k which is renamed B). ⊣

We shall find now a set $C \subseteq \lambda \cap \operatorname{pcf}(B)$ of cardinality $\leq |A|$ such that $\lambda \in \operatorname{pcf}(C)$. Such C is necessarily progressive. Together with the inductive hypothesis this will conclude the proof; because for every $\gamma \in C$ we can pick $B(\gamma) \subseteq B$ of cardinality $\leq |A|$ and such that $\gamma \in \operatorname{pcf} B(\gamma)$, and then define $B_0 = \bigcup_{\gamma \in C} B(\gamma)$. Since $C \subseteq \operatorname{pcf}(B_0)$, $\lambda \in \operatorname{pcf}(B_0)$ will then follow from $\lambda \in \operatorname{pcf}(C)$ (by Theorem 3.12). So the following is the last piece of the proof.

6.8 Claim. *There exists a set $C \subseteq \lambda \cap \operatorname{pcf}(B)$ of cardinality $\leq |A|$ and such that $\lambda \in \operatorname{pcf}(C)$.*

Proof. Assume no such C exists. We shall construct a sequence $\langle \gamma_i \mid i \in |A|^+ \rangle$ of cardinals in $\operatorname{pcf}(B)$ such that

$$\gamma_i > \max \operatorname{pcf}\{\gamma_j \mid j < i\}.$$

This will contradict Theorem 6.4.

So suppose that $C = \{\gamma_j \mid j < i\}$ have been defined. Then

$$\lambda > \max \operatorname{pcf}(C).$$

Indeed $\lambda = \max \operatorname{pcf}(C)$ is impossible by our assumption that no such C exists, and $\lambda < \max \operatorname{pcf}(C)$ is impossible since $\operatorname{pcf}(C) \subseteq \operatorname{pcf}(B)$ and $\lambda = \max \operatorname{pcf}(B)$. We can find now $\gamma_i \in \operatorname{pcf}(B)$ above $\max \operatorname{pcf}(C)$ (recall that $\operatorname{pcf}(B)$ has no maximum below λ). ⊣

The proof of the theorem is complete. ⊣

7. Size Limitation on pcf of Intervals

This relatively short section is devoted to a theorem which occupies a central place in pcf theory and to a famous application:

$$\aleph_\omega^{\aleph_0} < \max\{(2^{\aleph_0})^+, \aleph_{\omega_4}\}.$$

The reader will notice that many of the ingredients developed so far appear in its proof. We know that for any A progressive set of regular cardinals the cardinality of $\mathrm{pcf}(A)$ does not exceed $2^{|A|}$, and it is an open question whether $|\,\mathrm{pcf}(A)| \le |A|$ or not. At present the following theorem with its enigmatic appearance of the number four is the best result.

7.1 Theorem. *Let A be an interval of regular cardinals such that $|A| < \min A$. Then*

$$|\,\mathrm{pcf}(A)| < |A|^{+4}.$$

Proof. Suppose that A is as in the theorem a progressive interval of regular cardinals, but $|\,\mathrm{pcf}(A)| \ge |A|^{+4}$. Say $|A| = \rho$. The following proof provides a sequence B of length ρ^+ of cardinals in $\mathrm{pcf}(A)$ such that each cardinal $b \in B$ is above $\max\mathrm{pcf}(B \cap b)$. This, of course, will be in contradiction to Theorem 6.4.

Let $S = S^{\rho^{+3}}_{\rho^+}$ be the set of ordinals in ρ^{+3} that have cofinality ρ^+. Choose a club guessing sequence $\langle C_k \mid k \in S\rangle$. So for every closed unbounded set $E \subseteq \rho^{+3}$ there exists some $k \in S$ such that $C_k \subseteq E$.

Consider the cardinal $\sup A$, and let σ be that ordinal such that $\aleph_\sigma = \sup A$. Since $\mathrm{pcf}(A)$ is an interval of regular cardinals (by Theorem 3.9), and since we assume that $\mathrm{pcf}(A)$ has cardinality at least ρ^{+4}, any regular cardinal in $\{\aleph_{\sigma+\alpha} \mid \alpha < \rho^{+4}\}$ is in $\mathrm{pcf}(A)$.

We intend to define a closed set $D \subseteq \rho^{+4}$ of order-type ρ^{+3}, $D = \{\alpha_i \mid i < \rho^{+3}\}$, and the impossible sequence of length ρ^+, B, will be a subset of $\{\aleph^+_{\sigma+\alpha} \mid \alpha \in D\}$. The definition of the ordinal α_i is by induction on $i < \rho^{+3}$.

1. For $i = 0$, $\alpha_0 = 0$.

2. If $i < \rho^{+3}$ is a limit ordinal, then $\alpha_i = \sup\{\alpha_j \mid j < i\}$.

3. Suppose that $\{\alpha_j \mid j \le i\}$ has been defined for some $i < \rho^{+3}$, and we shall define α_{i+1}. Consider $i + 1 \subset \rho^{+3}$ as an isomorphic copy of $\{\alpha_j \mid j \le i\}$. For every $k \in S$ look at the set $C_k \cap (i + 1)$ and define the set of cardinals $e_k = \{\aleph_{\sigma+\alpha_j} \mid j \in C_k \cap (i + 1)\}$. Then the set of successors $e_k^{(+)} = \{\gamma^+ \mid \gamma \in e_k\}$ is a set of regular cardinals, and we ask whether $\max\mathrm{pcf}(e_k^{(+)}) < \aleph_{\sigma+\rho^{+4}}$ or not. There are ρ^{+3} such questions, and therefore we can define $\alpha_{i+1} < \rho^{+4}$ so that $\alpha_i < \alpha_{i+1}$ and the following holds. For every $k \in S$, if $\max\mathrm{pcf}(e_k^{(+)}) < \aleph_{\sigma+\rho^{+4}}$, then $\max\mathrm{pcf}(e_k^{(+)}) < \aleph_{\sigma+\alpha_{i+1}}$.

So $D = \{\alpha_i \mid i < \rho^{+3}\}$ is defined. Let $\delta = \sup D$. Then $\mu = \aleph_{\sigma+\delta}$ is a singular cardinal of uncountable cofinality (that is, of cofinality ρ^{+3}). The Representation Theorem (Exercise 4.17) can be applied now. So there exists a closed unbounded set $C \subseteq D$ such that

$$\mu^+ = \max \mathrm{pcf}(\{\aleph^+_{\sigma+\alpha} \mid \alpha \in C\}). \tag{14.43}$$

The closed unbounded set D is isomorphic to ρ^{+3}, and C is transformed under this isomorphism to a closed unbounded set $E \subseteq \rho^{+3}$. That is

$$E = \{i \in \rho^{+3} \mid \alpha_i \in C\}.$$

By the club-guessing property, there exists a $k \in S$ such that $C_k \subseteq E$. If C'_k denotes the non-accumulation points of C_k, we claim that $B = \{\aleph^+_{\sigma+\alpha_j} \mid j \in C'_k\}$ has the (impossible) property excluded by Theorem 6.4. Since the order-type of C_k is ρ^+, that of C'_k is also ρ^+. It suffices to prove for every $i \in C_k$ that

$$\max \mathrm{pcf}(\{\aleph^+_{\sigma+\alpha_j} \mid j \in C_k \cap (i+1)\}) < \aleph_{\sigma+\alpha_{i+1}}. \tag{14.44}$$

Consider the definition of α_{i+1}. The set $e_k = \{\aleph_{\sigma+\alpha_j} \mid j \in C_k \cap (i+1)\}$ was defined, and since $e_k^{(+)} \subseteq \{\aleph^+_{\sigma+\alpha} \mid \alpha \in C\}$, (14.43) implies that $\max \mathrm{pcf}(e_k^{(+)}) \leq \mu^+$. So the answer to the question for e_k was "yes", and as a result (14.44) holds. ⊣

This theorem leads to surprising applications. Consider for example $A = \{\aleph_n \mid n \in \omega\}$. Then $\mathrm{cf}([\aleph_\omega]^{\aleph_0}, \subseteq) = \max \mathrm{pcf}(A)$ by Theorem 5.11. But $\mathrm{pcf}(A)$ is an interval of regular cardinals of size $< \aleph_4$. Hence if we write $\max \mathrm{pcf}(A) = \aleph_\alpha$, then $\alpha < \omega_4$. Thus

$$\mathrm{cf}([\aleph_\omega]^{\aleph_0}, \subseteq) < \aleph_{\omega_4}.$$

This result holds even if $2^{\aleph_0}$ is larger than $\aleph_{\omega_4}$. It follows now immediately that if $2^{\aleph_0} < \aleph_\omega$ then $\aleph_\omega^{\aleph_0} < \aleph_{\omega_4}$. Shelah emphasizes that the former result (concerning the cofinality of $[\aleph_\omega]^{\aleph_0}$) is more basic, and hence one should ask questions concerning cofinalities rather than cardinalities, if one wants to get (absolute) answers.

Generalizing this, we have:

7.2 Theorem. *If $\aleph_\delta$ is a singular cardinal such that $\delta < \aleph_\delta$ then*

$$\mathrm{cf}([\aleph_\delta]^{|\delta|}, \subseteq) < \aleph_{(|\delta|^{+4})}.$$

Proof. Write $|\delta| = \kappa$. Then $\kappa < \aleph_\delta$ and if A is the interval of regular cardinals in $(\kappa, \aleph_\delta)$ then $|A| \leq |\delta| = \kappa$ and A is a progressive set. Theorem 5.11 applies with $\mu = \aleph_\delta$ and it yields

$$\mathrm{cf}([\aleph_\delta]^\kappa, \subseteq) = \max \mathrm{pcf}(A).$$

But A is an interval of regular cardinals, and hence $|\mathrm{pcf}(A)| < |A|^{+4}$, by Theorem 7.1. This implies that $\max \mathrm{pcf}(A) < \aleph_{\delta+(|A|^{+4})} \leq \aleph_{|\delta|^{+4}}$. Hence $\mathrm{cf}([\aleph_\delta]^\kappa, \subseteq) < \aleph_{(|\delta|^{+4})}$. ⊣

We are now able to deduce the following application to cardinal arithmetic.

7.3 Theorem. *Suppose that δ is a limit ordinal and $|\delta|^{\mathrm{cf}(\delta)} < \aleph_\delta$. Then*

$$\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{+4})}.$$

Proof. Since $|\delta|^{\mathrm{cf}(\delta)} < \aleph_\delta$, $\delta < \aleph_\delta$. It follows from the cofinality theorem above that

$$\aleph_\delta^{\mathrm{cf}(\delta)} \leq |\delta|^{\mathrm{cf}(\delta)} \cdot \mathrm{cf}([\aleph_\delta]^{|\delta|}, \subseteq) < \aleph_\delta \cdot \aleph_{(|\delta|^{+4})}. \tag{14.45}$$

⊣

8. Revised GCH

The Generalized Continuum Hypothesis (GCH) saying that $2^\kappa = \kappa^+$ for every (infinite) cardinal κ is readily seen to be equivalent to the statement that for every two regular cardinals $\kappa < \lambda$ we have $\lambda^\kappa = \lambda$. In [17] Shelah considers a "revised power set" operation $\lambda^{[\kappa]}$ defined as follows:

$$\lambda^{[\kappa]} = \min\bigl\{|\mathcal{P}| \mid \mathcal{P} \subseteq [\lambda]^{\leq\kappa} \text{ and } \forall u \in [\lambda]^\kappa \exists \mathcal{P}_0 \subseteq \mathcal{P}\bigl(|\mathcal{P}_0| < \kappa \wedge u = \bigcup \mathcal{P}_0\bigr)\bigr\}.$$

An inductive proof shows that GCH is equivalent to the statement that for all regular cardinals $\kappa < \lambda$, $\lambda^{[\kappa]} = \lambda$. The "revised" GCH theorem says that for "many" pairs of regular cardinals we have $\lambda^{[\kappa]} = \lambda$.

8.1 Theorem (Shelah's Revised GCH). *If θ is a strong limit uncountable cardinal, then for every $\lambda \geq \theta$, for some $\kappa_0 < \theta$, for every $\kappa_0 \leq \kappa < \theta$*

$$\lambda^{[\kappa]} = \lambda.$$

The proof that we give here is adopted from a later article [14] of Shelah, and it relies on two notions that we have to investigate first, $\mathrm{pcf}_{\sigma\text{-com}}(A)$ and $T_D(f)$.

8.2 Definition. Let $\lambda > \theta \geq \sigma = \mathrm{cf}(\sigma)$ be cardinals.

1. We say that $\mathcal{P} \subseteq [\lambda]^{\leq\theta}$ is a $(<\sigma)$-*base* for $[\lambda]^{\leq\theta}$ if every $u \in [\lambda]^{\leq\theta}$ is the union of fewer than σ members of $\mathcal{P}$. That is, for some $\mathcal{P}_0 \subseteq \mathcal{P}$, $|\mathcal{P}_0| < \sigma$, and $u = \bigcup \mathcal{P}_0$.

2. We define $\lambda^{[\sigma,\theta]} = \min\{|\mathcal{P}| \mid \mathcal{P} \subseteq [\lambda]^{\leq\theta}$ is a $(<\sigma)$-base for $[\lambda]^{\leq\theta}\}$. Another notation for $\lambda^{[\sigma,\theta]}$ is $\lambda^{[\sigma,\leq\theta]}$. We have $\lambda^{[\sigma]} = \lambda^{[\sigma,\sigma]}$. In a similar fashion define $\lambda^{[\sigma,<\theta]}$. It is the minimal cardinality of a set $\mathcal{P} \subseteq [\lambda]^{<\theta}$ so that every $u \in [\lambda]^{<\theta}$ is a union of fewer than σ members of $\mathcal{P}$.

3. We say that $\mathcal{P} \subseteq [\lambda]^\theta$ is $(<\sigma)$-*cofinal* in $[\lambda]^\theta$ if every $u \in [\lambda]^\theta$ is included in the union of fewer than σ members of $\mathcal{P}$. That is, for some $\mathcal{P}_0 \subseteq \mathcal{P}$, $|\mathcal{P}_0| < \sigma$, and $u \subseteq \bigcup \mathcal{P}_0$.

4. We define $\lambda^{\langle\sigma,\theta\rangle} = \min\{|\mathcal{P}| \mid \mathcal{P} \subseteq [\lambda]^\theta$ is $({<}\sigma)$-cofinal in $[\lambda]^\theta\}$. Define $\lambda^{\langle\sigma\rangle} = \lambda^{\langle\sigma,\sigma\rangle}$.

For a regular infinite cardinal σ and a set A of regular cardinals define

$$\mathrm{pcf}_{\sigma\text{-com}}(A) = \bigl\{\mathrm{tcf}\bigl(\textstyle\prod A/F\bigr) \mid F \text{ is a } \sigma\text{-complete filter over } A \text{ and } \mathrm{tcf}\bigl(\textstyle\prod A/F\bigr) \text{ exists}\bigr\}. \quad (14.46)$$

(A filter is σ-complete if it is closed under the intersections of less than σ members of the filter.)

Clearly, $A \subseteq \mathrm{pcf}_{\sigma\text{-com}}(A) \subseteq \mathrm{pcf}(A)$.

Define $J^{\sigma\text{-com}}_{<\lambda}[A] \subseteq \mathcal{P}(A)$ by the formula $X \in J^{\sigma\text{-com}}_{<\lambda}[A]$ iff $X \subseteq A$ and whenever F is a σ-complete filter over A with $X \in F$ and such that $\mathrm{tcf}(\prod A/F)$ exists, then $\mathrm{tcf}(\prod A/F) < \lambda$. Equivalently,

$$J^{\sigma\text{-com}}_{<\lambda}[A] = \{X \subseteq A \mid \mathrm{pcf}_{\sigma\text{-com}}(X) \subseteq \lambda\}.$$

Clearly, $J_{<\lambda}[A] \subseteq J^{\sigma\text{-com}}_{<\lambda}[A]$.

8.3 Lemma. *$J^{\sigma\text{-com}}_{<\lambda}[A]$ is a σ-complete ideal.*

Proof. Suppose that $X_i \in J^{\sigma\text{-com}}_{<\lambda}[A]$ for every $i < \sigma^*$ where $\sigma^* < \sigma$. We prove that $X = \bigcup_{i<\sigma^*} X_i \in J^{\sigma\text{-com}}_{<\lambda}[A]$. So let F be a σ-complete filter over A containing X and such that $\mathrm{tcf}(\prod A/F) = \tau$ exists. We must show that $\tau < \lambda$. Assume that F is proper (the cofinality of a reduced product by a improper filter is 1). For every $i < \sigma^*$ consider the filter $F + X_i$ (defined as the collection of all subsets of A that contain a set of the form $A \cap X_i$ for $A \in F$). If for some $i < \sigma^*$, $F_i = F + X_i$ is proper, then it is a σ-complete filter containing X_i and such that $\mathrm{tcf}(\prod A/F_i) = \tau$ (extending the filter F will not change the cofinality of the existing reduced product). But as $X_i \in J^{\sigma\text{-com}}_{<\lambda}[A]$, we get $\tau < \lambda$.

If, for every $i < \sigma^*$, $F + X_i$ is improper, then $X \setminus X_i \in F$. Hence the intersection of these sets which is the empty set is in F, and thus F is improper. ⊣

8.4 Lemma. *Suppose that A is a progressive set of regular cardinals and $\lambda = \max \mathrm{pcf}(A)$. Then $X \in J^{\sigma\text{-com}}_{<\lambda}[A]$ iff X is a union of fewer than σ members of $J_{<\lambda}[A]$. That is, $J^{\sigma\text{-com}}_{<\lambda}[A]$ is the σ-completion of $J_{<\lambda}[A]$.*

Proof. Let J be the σ-completion of $J_{<\lambda}[A]$. It is the collection of all sets that are union of fewer than σ members of $J_{<\lambda}[A]$. By the previous lemma, $J^{\sigma\text{-com}}_{<\lambda}[A]$ is σ-complete, and hence it contains J. It remains to prove that $J^{\sigma\text{-com}}_{<\lambda}[A] \subseteq J$. So no assumptions on A were needed in this direction.

Assume for a contradiction that $X \in J^{\sigma\text{-com}}_{<\lambda}[A] \setminus J$. Then $J + (A \setminus X)$, the ideal generated by J and $A \setminus X$, is proper. It is easily seen to be a σ-complete ideal. Let F be the dual filter of that ideal. Then F is σ-complete and $X \in F$. Hence the cofinality of $\prod A/F$ is smaller than λ.

Since $\lambda = \max \mathrm{pcf}(A)$, there are f_ζ for $\zeta < \lambda$ that are increasing and cofinal in $\prod A/J_{<\lambda}[A]$ (Exercise 4.3, or Theorem 4.13). But this sequence is also increasing and cofinal in $\prod A/F$, and this is an obvious contradiction. $\dashv$

We now strengthen the lemma by removing the assumption that $\lambda = \max \mathrm{pcf}(A)$.

8.5 Theorem. *Let A be a progressive set of regular cardinals, and σ a regular cardinal. Then $J^{\sigma\text{-com}}_{<\lambda}[A]$ is the σ-completion of $J_{<\lambda}[A]$.*

Proof. We prove by induction on μ that for every progressive set A of regular cardinals with $\mu = \max \mathrm{pcf}(A)$, for all cardinals λ and σ (regular), $J^{\sigma\text{-com}}_{<\lambda}[A]$ is the σ-completion of $J_{<\lambda}[A]$.

We know already that $J_{<\lambda}[A] \subseteq J^{\sigma\text{-com}}_{<\lambda}[A]$ and that $J^{\sigma\text{-com}}_{<\lambda}[A]$ is σ-complete. It remains to prove that any $X \in J^{\sigma\text{-com}}_{<\lambda}[A]$ is a union of fewer than σ sets from $J_{<\lambda}[A]$. If $\mu < \lambda$ then $X \in J_{<\lambda}[A]$ and this case is uninteresting. In case $\lambda \leq \mu$, $X \in J^{\sigma\text{-com}}_{<\mu}[A]$. So by the previous lemma, X is a union of less than σ sets from $J_{<\mu}[A]$. But the inductive assumption can be applied to each one of these sets, and the lemma follows since σ is regular. $\dashv$

Another characterization of the ideal $J^{\sigma\text{-com}}_{<\lambda}[A]$ is provided by the following theorem dealing with the cofinality of product of cardinals under the $<$ relation: $f < g$ iff for every $a \in \mathrm{dom}(f)$, $f(a) < g(a)$.

We know (Theorem 4.4) that $X \in J_{<\lambda}[A]$ iff $\mathrm{cf}(\prod X) < \lambda$. For a similar characterization of $J^{\sigma\text{-com}}_{<\lambda}[A]$ we need the following definition. Let σ be a regular cardinal and X a set of regular cardinals. If $\mathcal{F} \subseteq \prod X$, we say that $\mathcal{F}$ is ($<\sigma$)-cofinal iff for every $f \in \prod X$ there is a set $\mathcal{F}_0 \subseteq \mathcal{F}$ with $|\mathcal{F}_0| < \sigma$ and such that $f < \sup \mathcal{F}_0$. In other words, the functions formed by taking the supremum of fewer than σ functions from $\mathcal{F}$ form a cofinal set in $\prod X$. The ($<\sigma$)-cofinality of $\prod X$ is the smallest cardinality of a ($<\sigma$)-cofinal subset. It makes sense to assume that $\sigma \leq \min X$ when inquiring about the ($<\sigma$)-cofinality of X.

8.6 Theorem. *Suppose that A is a progressive set of regular cardinals, $\sigma \leq \min A$ is a regular cardinal, and $\sigma \leq \mathrm{cf}(\lambda)$. Define*

$$J = \big\{B \subseteq A \mid B = \emptyset \text{ or } \textstyle\prod B \text{ has } (<\sigma)\text{-cofinality } < \lambda\big\}.$$

Then $J = J^{\sigma\text{-com}}_{<\lambda}[A]$.

Proof. We first prove that $J \subseteq J^{\sigma\text{-com}}_{<\lambda}[A]$. Suppose $B \in J$ and let D be a σ-complete filter over A containing B and such that $\mathrm{tcf}(\prod A/D)$ exists and is equal to $\lambda' \geq \lambda$. This will lead to a contradiction, thereby proving that $B \in J^{\sigma\text{-com}}_{<\lambda}[A]$. Since $\mathrm{tcf}(\prod A/D) = \lambda'$, λ' is a regular cardinal and there is an increasing sequence S in $\prod A/D$ of length λ' that is cofinal in $\prod A/D$. By definition of $B \in J$, there is a set $\mathcal{F} \subseteq \prod B$ of cardinality $< \lambda$ that is ($<\sigma$)-cofinal. For every $f \in \mathcal{F}$ there is a function $s \in S$ such that $f <_D s$ (f is defined on B and s on A, but as $B \in D$, this makes sense). Since λ'

is regular and bigger than $|\mathcal{F}|$, there is a single $s \in S$ such that $f <_D s$ for every $f \in \mathcal{F}$. Since $\mathcal{F}$ is $({<}\sigma)$-cofinal, $s <_D \sup \mathcal{F}_0$ for some $\mathcal{F}_0 \subseteq \mathcal{F}$ of size $< \sigma$. But as D is σ-complete, and $f <_D s$ for every $f \in \mathcal{F}_0$, $\sup \mathcal{F}_0 \leq_D s$ as well. This is a contradiction, and thus $J \subseteq J^{\sigma\text{-com}}_{<\lambda}[A]$.

Clearly $J_{<\lambda}[A] \subseteq J$ (by Theorem 4.4). If we prove that J is σ-complete then $J^{\sigma\text{-com}}_{<\lambda}[A] \subseteq J$ follows from the previous theorem.

So let $\sigma^* < \sigma$ and $X_i \in J$ for $i < \sigma^*$ be given. We shall prove that $X = \bigcup_{i<\sigma^*} X_i \in J$. For every $i < \sigma^*$ we have a $({<}\sigma)$-cofinal set $P_i \subseteq \prod X_i$ of cardinality $< \lambda$. Then $P = \bigcup_{i<\sigma^*} P_i$ has cardinality $< \lambda$ because $\sigma \leq \mathrm{cf}(\lambda)$. The domain of each function in P_i is X_i, but we can extend it arbitrarily on X and then P can be considered as a subset of $\prod X$. Clearly P is $({<}\sigma)$-cofinal. ⊣

We shall apply this theorem to $J^{\sigma\text{-com}}_{\leq\lambda}[A]$ rather than $J^{\sigma\text{-com}}_{<\lambda}[A]$. That is, replacing λ with λ^+ in the theorem, we get the following corollary in which $\sigma \leq \mathrm{cf}\,\lambda$ is no longer required.

8.7 Corollary. *Suppose that A is a progressive set of regular cardinals, $\sigma \leq \min A$ is a regular cardinal, and $\sigma \leq \lambda$. Define*

$$J = \big\{B \subseteq A \mid B = \emptyset \textit{ or } \textstyle\prod B \textit{ has } ({<}\sigma)\textit{-cofinality } \leq \lambda\big\}.$$

Then $J = J^{\sigma\text{-com}}_{\leq\lambda}[A]$.

8.8 Theorem. *Suppose that:*

1. *$\lambda > \theta > \sigma > \aleph_0$ are given, where θ and σ are regular cardinals, and $2^{<\theta} \leq \lambda$.*
2. *For every $A \subseteq \mathrm{Reg} \cap \lambda \setminus \theta$, if $|A| < \theta$ then $A \in J^{\sigma\text{-com}}_{\leq\lambda}[A]$.*

Then $\lambda = \lambda^{[\sigma,<\theta]}$.

Proof. Fix χ sufficiently large, and let $M \prec H_\chi$ be an elementary substructure of cardinality λ and such that $\lambda + 1 \subseteq M$. We shall prove the following claim which yields the theorem:

$$M \cap [\lambda]^{<\theta} \text{ is a } ({<}\,\sigma)\text{-base for } [\lambda]^{<\theta}.$$

For this, we need the following lemma.

8.9 Lemma. *With the same assumptions of the theorem and on M, let $g : \kappa \to \lambda$ and $f : \kappa \to \lambda + 1$ be given with $\kappa < \theta$, $f \in M$, and such that $\forall a \in \kappa\ g(a) \leq f(a)$. Then there is a collection $\Phi \subseteq M$ of functions from κ to λ such that the following hold:*

1. *$|\Phi| < \sigma$.*
2. *For every $p \in \Phi$, $g \leq p \leq f$ (that is, for all $a \in \kappa$, $g(a) \leq p(a) \leq f(a)$).*

3. For every $a \in \kappa$, if $g(a) < f(a)$, then for some $p \in \Phi$ $g(a) \leq p(a) < f(a)$.

Proof. Think of f as an "approximation from above" in M to the function g (which is not in M, or else the theorem is trivial). The set Φ is not required to be a member of M, and each function of Φ (if different from f) is a better approximation that lies in M. For each $a \in \kappa$, if $f(a)$ is not the best approximation, then Φ contains a function that gets a better value at a.

Fix in M a sequence $\langle C_\delta \mid \delta \leq \lambda, \delta \in \lim \lambda \rangle$ such that $C_\delta \subseteq \delta$ is unbounded in δ and of order-type $\mathrm{cf}(\delta)$.

Define the following subsets of κ:

$$
\begin{aligned}
E_0 &= \{a < \kappa \mid g(a) = f(a)\} \\
E_1 &= \{a < \kappa \mid g(a) < f(a),\ f(a) \text{ is a successor ordinal}\} \\
E_2 &= \{a < \kappa \mid g(a) < f(a), f(a) \text{ is a limit and } \mathrm{cf}(f(a)) < \theta\} \\
E_3 &= \kappa \setminus (E_0 \cup E_1 \cup E_2).
\end{aligned}
$$

Since $2^{<\theta} \leq \lambda$, any bounded subset of θ is in M. So each E_ℓ is in M. We define h on κ as follows. For $a \in E_0$, $h(a) = f(a)$. For $a \in E_1$, $h(a)+1 = f(a)$. For $a \in \kappa \setminus (E_0 \cup E_1)$, $h(a) = \min C_{f(a)} \setminus g(a)$.

Obviously $h{\restriction}E_0 \cup E_1 \in M$. We prove that $h{\restriction}E_2 \in M$ as well. By definition $h{\restriction}E_2$ is a function in $\prod_{\delta \in E_2} C_{f(\delta)}$. But θ is regular, and since $|E_2| < \theta$ and $\mathrm{cf}(f(\delta)) < \theta$, there is a bound below θ on the values of $\{\mathrm{cf}(f(a)) \mid a \in E_2\}$, and hence $|\prod_{\delta \in E_2} C_{f(\delta)}| \leq 2^{<\theta} \leq \lambda$.

So $\prod_{\delta \in E_2} C_{f(\delta)} \subseteq M$, and hence $h{\restriction}E_2 \in M$.

There is no reason to assume that $h{\restriction}E_3$ is in M, but we shall find a set Φ of size $< \sigma$ as required by the lemma. Define $A = \{\mathrm{cf}(f(a)) \mid a \in E_3\}$. Then $A \subseteq \lambda + 1 \setminus \theta$ is a set of regular cardinals of size $\leq \kappa$, and so $A \in J^{\sigma\text{-com}}_{\leq\lambda}[A]$. There is by Corollary 8.7 a family $\mathcal{F}$ of size $\leq \lambda$ that is $({<}\sigma)$-cofinal in $\prod A$. Since $A \in M$ we can have $\mathcal{F} \in M$ and $\mathcal{F} \subseteq M$. Since $\kappa < \min A$ and $A \subseteq \mathrm{Reg}$, $\mathcal{F}$ yields a family of functions, $\mathcal{F}' \subseteq \prod_{\delta \in E_3} C_{f(\delta)} = P$ that is $({<}\sigma)$-cofinal in P. As $h{\restriction}E_3 \in P$, there is a set $\mathcal{F}_0 \subseteq \mathcal{F}'$ of size $< \sigma$ such that $h{\restriction}E_3 < \sup \mathcal{F}_0$. If $e \in \mathcal{F}_0$, then $e(\delta) < f(\delta)$ but $e(\delta) < g(\delta)$ is possible. So we correct each $e \in \mathcal{F}_0$ and define:

$$
e'(\delta) = \begin{cases} e(\delta) & \text{if } g(\delta) \leq e(\delta), \\ f(\delta) & \text{otherwise.} \end{cases}
$$

Then $e' \in M$ because $e, f \in M$ and every subset of κ is in M. The collection $\{h{\restriction}(E_0 \cup E_1 \cup E_2)^\frown e' \mid e \in \mathcal{F}_0\}$ is as required, and the lemma is proved. $\dashv$

We continue now with the proof of the theorem. So let $u \in [\lambda]^{<\theta}$ be given and we shall find a subset of $M \cap [\lambda]^{<\theta}$ of cardinality $< \sigma$ whose union is u. Let $\kappa = |u| < \theta$ be the cardinality of u and take an enumeration $g : \kappa \to u$. We shall define by induction on $n \in \omega$ a set Φ_n of functions from κ to λ such that the following holds.

1. Let $f_0 : \kappa \to \lambda + 1$ be defined by $f_0(a) = \lambda$. Then $\Phi_0 = \{f_0\}$.

2. For every n, $\Phi_n \subseteq M$ and $|\Phi_n| < \sigma$. If $f \in \Phi_n$ then $g \leq f$.

3. For every $f \in \Phi_n$ and $a \in \kappa$ such that $g(a) < f(a)$ there exists a $p \in \Phi_{n+1}$ such that $g(a) \leq p(a) < f(a)$.

This is easily obtained by the lemma.

Let $\Phi = \bigcup_{n<\omega} \Phi_n$. Then $|\Phi| < \sigma$. For any $f \in \Phi$, the set

$$E(f) = \{f(a) \mid a \in \kappa \text{ and } f(a) = g(a)\}$$

is in M (because f is, and any subset of κ). We have $u = \bigcup\{E(f) \mid f \in \Phi\}$ because if $x \in u$ then $x = g(a)$ for some $a \in \kappa$, and $g(a) < f_0(a)$. There exists a sequence $f_n \in \Phi_n$ so that if $g(a) < f_n(a)$ then $f_{n+1}(a) < f_n(a)$. And necessarily for some n $g(a) = f_n(a)$. So $a \in E(f_n)$. This ends the proof of Theorem 8.8. $\dashv$

The following corollary shows that the theorem above can also be applied when $\mathrm{cf}(\theta) < \sigma$.

8.10 Corollary. *Suppose that:*

1. $\lambda > \theta > \sigma = \mathrm{cf}(\sigma) > \aleph_0$ are given, where $\mathrm{cf}(\theta) < \sigma$ and $2^{<\theta} \leq \lambda$.

2. For every $A \subseteq \mathrm{Reg} \cap \lambda + 1 \setminus \theta$, if $|A| < \theta$ then $A \in J^{\sigma\text{-com}}_{\leq\lambda}[A]$.

Then $\lambda = \lambda^{[\sigma, \leq\theta]}$.

Proof. Fix a sequence $\langle \theta_i \mid i < \mathrm{cf}(\theta)\rangle$ of regular cardinals that is cofinal in θ and such that $\sigma < \theta_i$ for all i. We claim for every $i < \mathrm{cf}(\theta)$ that the assumptions of Theorem 8.8 hold for $\lambda > \theta_i > \sigma$, and hence $\lambda = \lambda^{[\sigma,<\theta_i]}$ follows. But this clearly implies that $\lambda = \lambda^{[\sigma,\leq\theta]}$.

For the claim, we must prove that if $\theta' < \theta$ is regular then for every $A \subseteq \mathrm{Reg} \cap \lambda + 1 \setminus \theta'$, if $|A| < \theta'$ then $A \in J^{\sigma\text{-com}}_{\leq\lambda}[A]$. Suppose for a contradiction that this is not the case, and for some σ-complete filter D over $A \subset \mathrm{Reg} \cap \lambda + 1 \setminus \theta'$ we have $\mathrm{tcf}(\prod A/D) = \lambda_0 > \lambda$. We may assume that $A \subseteq \theta$, that is, we may assume that $A \cap \theta \in D$, or else $A \setminus \theta$ is not D-null and then it can be added to D without changing the true cofinality of the reduced product, which contradicts the assumptions of the theorem.

If for every $i < \mathrm{cf}(\theta)$ $A \setminus \theta_i \in D$, then by the σ-completeness of D and the fact that $\mathrm{cf}(\theta) < \sigma$, we get a contradiction. So for some i $A \cap \theta_i$ is not D-null. But then $D' = D + A \cap \theta_i$ is σ-complete and it follows that the true cofinality of $\prod A/D'$ remains λ_0. Yet this is impossible since $(\theta_i)^{|A\cap\theta_i|} \leq 2^{<\theta} \leq \lambda$. $\dashv$

8.1. $T_D(f)$

Let J be an ideal over a cardinal κ. We recall some definitions. The collection of J-positive sets is denoted J^+. The corresponding dual filter is denoted J^*. If R is a relation, if f and g are functions defined on κ, then we define $f\ R_J\ g$ if and only if $\{i \in \kappa \mid f(i)\ R\ g(i)\} \in J^*$. We also write $f\ R_{J^+}\ g$ for $\{i \in \kappa \mid f(i)\ R\ g(i)\} \notin J$. That is, $f(i)\ R\ g(i)$ occurs positively.

Thus $f \neq_J g$ means that $\{i \in \kappa \mid f(i) = g(i)\} \in J$, and $f =_{J^+} g$ means that $\neg f \neq_J g$.

Let κ be a cardinal and D a filter over κ. Consider the $<_D$ ordering on On^κ. For $f \in \mathrm{On}^\kappa$, $\prod_{i<\kappa} f(i)$ is denoted $\prod f$, and $\prod_{i<\kappa} f(i)/D$ is denoted $\prod f/D$. (We consider only functions f such that $f(i) > 0$ for $i \in \kappa$.)

For $\mathcal{F} \subseteq \prod f$, we say that $\mathcal{F}$ is a set of pairwise "D-different" functions, if for every distinct $f_1, f_2 \in \mathcal{F}$ we have $f_1 \neq_D f_2$. For any $f \in \mathrm{On}^\kappa$, define

$$T_D(f) = \sup\bigl\{|\mathcal{F}| \mid \mathcal{F} \subseteq \textstyle\prod f \text{ is a set of pairwise } D\text{-different functions}\bigr\}.$$

(Shelah investigated several different definitions, and this cardinal is denoted T_D^0 in [14].)

8.11 Theorem. *Suppose that D is a filter over κ, $f \in \mathrm{On}^\kappa$ and $T_D(f) = \lambda$. If $2^\kappa < \lambda$ then the supremum in the definition of $T_D(f)$ is attained. In fact, if $2^\kappa < \lambda$ and $\mathcal{F} \subseteq \prod f$ is any maximal family of pairwise D-different functions, then $|\mathcal{F}| = \lambda$.*

Proof. Suppose on the contrary that $\mathcal{F} \subseteq \prod f$ is maximal but $|\mathcal{F}| < \lambda$. Let $\mathcal{G} \subseteq \prod f$ be a collection of pairwise D-different functions such that

$$|\mathcal{G}| > |\mathcal{F}| + 2^\kappa. \tag{14.47}$$

For every $g \in \mathcal{G}$ we can find $f = f(g) \in \mathcal{F}$ such that $X(g) = \{i \in \kappa \mid f(i) = g(i)\}$ is not D-null. As (14.47), there are two distinct functions g_1 and g_2 in $\mathcal{G}$ such that $f(g_1) = f(g_2)$ and $X(g_1) = X(g_2)$. But this implies that g_1 and g_2 agree on a non-null set which is a contradiction to the assumption that the functions in $\mathcal{G}$ are pairwise D-different. ⊣

An obvious observation which turns out to be crucial is the following.

8.12 Lemma. *If $\mathrm{tcf}(\prod f/D)$ exists, then $T_D(f) \geq \mathrm{tcf}(\prod f/D)$.*

Proof. If $\mathrm{tcf}(\prod f/D) = \lambda$, then there exists a $<_D$ increasing sequence of length λ, and hence a set of cardinality λ of pairwise D-different functions. ⊣

Assume now that σ is a regular uncountable cardinal, and D is a σ-complete filter over κ. Then $\prod f/D$ is well-founded. This is used in the following.

8.13 Lemma. *Suppose that σ is a regular uncountable cardinal and D is a σ-complete filter over κ. Suppose $f \in \mathrm{On}^\kappa$ and $T_D(f) \geq \lambda$ where $2^\kappa < \lambda$. Then for some $g \leq_D f$ we have $T_D(g) = \lambda$.*

Proof. Let $g \leq_D f$ be minimal in the $\leq_D$ ordering such that $T_D(g) \geq \lambda$. Suppose for a contradiction that $T_D(g) > \lambda$. There is a set $\{f_\alpha \mid \alpha < \lambda^+\}$ of pairwise D-different functions in $\prod g$. For $\alpha < \lambda^+$ define

$$u_\alpha = \{\beta < \lambda^+ \mid f_\beta <_D f_\alpha\}.$$

If, for some α, $|u_\alpha| \geq \lambda$, then u_α proves that $T_D(f_\alpha) \geq \lambda$ in contradiction to the minimality of g. Hence $|u_\alpha| < \lambda$ for every $\alpha < \lambda^+$.

But now we can apply the Free Mapping theorem of Hajnal and obtain $F \subseteq \lambda^+$, of cardinality λ^+ such that $\alpha \notin u_\beta$ (and $\beta \notin u_\alpha$) for every $\alpha \neq \beta$ in F. (The argument in short is the following. First, we can find $\lambda_0 < \lambda$ such that $|u_\alpha| = \lambda_0$ for unboundedly many $\alpha < \lambda^+$. Re-enumerating, we may assume $|u_\alpha| = \lambda_0$ for every α. On those $\alpha < \lambda^+$ with cofinality λ_0^+ we bound $u_\alpha \cap \alpha$ in α, and use Fodor's lemma.)

Hence there are $f_\alpha \in \mathrm{On}^\kappa$ for $\alpha < (2^\kappa)^+$ such that $f_\alpha \not\leq_D f_\beta$ whenever $\alpha \neq \beta$. But this is impossible in view of the Erdős-Rado partition theorem $(2^\kappa)^+ \to (\kappa^+)^2_\kappa$. Indeed, for $\alpha < \beta < \kappa^+$ define $h(\alpha, \beta)$ as some $i < \kappa$ such that $f_\beta(i) < f_\alpha(i)$. Then h has no infinite homogeneous set, which contradicts the theorem. Thus $T_D(g) = \lambda$.

Observe that since $2^\kappa < \lambda$, $L = \{a \in \kappa \mid g(a) \in \lim\}$ is not null in D, and hence we may assume without loss of generality that it is in D. (Or else let $h <_D g$ be such that $g(a) = h(a) + 1$ for every $a \notin L$, and $h(a) = g(a)$ on L. Let f_α, for $\alpha < \lambda$, exemplify $T_D(g) = \lambda$. By minimality of g, there are λ functions f_α that are equal to h on a positive subset of $\kappa \setminus L$. Since $2^\kappa < \lambda$, two such functions are equal on a positive set, which is impossible.) ⊣

The following is one of the two main arguments used in the proof of the revised GCH theorem.

8.14 Theorem. *Assume that $\lambda > \theta \geq \sigma = \mathrm{cf}(\sigma) > \kappa$ are cardinals such that:*

1. *$\theta^\kappa = \theta$.*
2. *If $\tau < \sigma$ then $\tau^\kappa < \sigma$.*
3. *J is an ideal on κ.*
4. *There is a sequence $\bar{\lambda} = \langle \lambda_i \mid i < \kappa \rangle$, $\lambda_i < \lambda$, such that*
   (a) $T_J(\bar{\lambda}) = \lambda$,
   (b) $\lambda_i^{\langle \sigma, \theta \rangle} = \lambda_i$ for every $i < \kappa$.

Then $\lambda^{\langle \sigma, \theta \rangle} = \lambda$. (If we also assume $2^\theta \leq \lambda$, then evidently $\lambda^{[\sigma, \theta]} = \lambda$.)

Proof. In the proof, we actually weaken the requirement $T_J(\bar{\lambda}) = \lambda$ to the following conjunction.

1. There are $f_\alpha \in \prod_{i<\kappa} \lambda_i$, for $\alpha < \lambda$, such that $\alpha \neq \beta \longrightarrow f_\alpha \neq_J f_\beta$.

2. There are $g_\alpha \in \prod_{i<\kappa} \lambda_i$, for $\alpha < \lambda$, such that for every $f \in \prod_{i<\kappa} \lambda_i$ there exists $\alpha < \kappa$ with $f =_{J^+} g_\alpha$.

Fix a sequence of pairwise D-different functions $f_\alpha \in \prod_{i<\kappa} \lambda_i$, for $\alpha < \lambda$, as in 1 above.

For every $i < \kappa$ we assume $\lambda_i^{\langle \sigma,\theta \rangle} = \lambda_i$, so there exists a family $\mathcal{P}_i \subseteq [\lambda_i]^\theta$ of cardinality λ_i that is $({<}\sigma)$-cofinal in $[\lambda_i]^\theta$.

Since $|\mathcal{P}_i| = \lambda_i$, $\prod_{i\in\kappa} \mathcal{P}_i$ is isomorphic to $\prod_{i<\kappa} \lambda_i$. So there is (by 2 above) a family $\{g_\alpha \mid \alpha < \lambda\} \subseteq \prod_{i\in\kappa} \mathcal{P}_i$ such that for every $g \in \prod_{i\in\kappa} \mathcal{P}_i$ there is $\alpha < \lambda$ with $g =_{J^+} g_\alpha$.

For every $g \in \prod_{i\in\kappa} \mathcal{P}_i$ and $A \in J^+$, let $g{\restriction}A$ be the restriction of g to A, and $\prod g{\restriction}A$ is $\prod_{i\in A} g(i)$. We define

$$\mathcal{F}(g{\restriction}A) = \{\zeta \in \lambda \mid \forall i \in A\ f_\zeta(i) \in g(i)\}.$$

In other words, $\mathcal{F}(g{\restriction}A)$ is the set of $\zeta \in \lambda$ such that $f_\zeta{\restriction}A \in \prod g{\restriction}A$. Observe that if $A \subseteq B \subseteq \kappa$, then $\mathcal{F}(g{\restriction}A) \supseteq \mathcal{F}(g{\restriction}B)$.

8.15 Claim. *For every $g \in \prod_{i\in\kappa} \mathcal{P}_i$ and $A \in J^+$, $|\mathcal{F}(g{\restriction}A)| \leq \theta$.*

Since $g(i) \in \mathcal{P}_i \subseteq [\lambda_i]^\theta$, $|\prod_{i\in A} g(i)| \leq \theta^\kappa = \theta$. So, if $|\mathcal{F}(g{\restriction}A)| > \theta$, we would have $\zeta \neq \zeta'$ in λ with $f_\zeta{\restriction}A = f_{\zeta'}{\restriction}A$. But as $A \in J^+$, this contradicts $f_\zeta \neq_J f_{\zeta'}$ and proves the claim.

8.16 Claim. *Every $u \in [\lambda]^\theta$ is included in a union of fewer than σ sets of the form $\mathcal{F}(g_\alpha{\restriction}A)$. That is, the collection $\mathcal{F} = \{\mathcal{F}(g_\alpha{\restriction}A) \mid \alpha < \lambda, A \in J^+\}$ is $({<}\sigma)$-cofinal in $[\lambda]^\theta$.*

Observe first that as $|\mathcal{F}| \leq \lambda \cdot 2^\kappa = \lambda$, this claim proves the theorem.

Given $u \in [\lambda]^\theta$ define for every $i < \kappa$

$$u_i = \{f_\alpha(i) \mid \alpha \in u\}.$$

Then $u_i \in [\lambda_i]^{\leq\theta}$ and hence there is a $\mathcal{P}_i^u \subseteq \mathcal{P}_i$ with $|\mathcal{P}_i^u| < \sigma$ and such that $u_i \subseteq \bigcup \mathcal{P}_i^u$. Since σ is regular, some $\tau < \sigma$ bounds all the cardinals $\sigma_i = |\mathcal{P}_i^u|$, and, as $\tau^\kappa < \sigma$, we have that $|\prod_{i\in\kappa} \sigma_i| < \sigma$. So

$$\mathcal{G} = \textstyle\prod_{i\in\kappa} \mathcal{P}_i^u$$

is a subset of $\prod_{i\in\kappa} \mathcal{P}_i$ of size $< \sigma$. The following two lemmas finish the proof of our claim.

8.17 Lemma. $u \subseteq \bigcup\{\mathcal{F}(g) \mid g \in \mathcal{G}\}$.

Proof. If $\zeta \in u$ then $f_\zeta(i) \in u_i$ for every $i \in \kappa$. Thus $f_\zeta(i) \in \bigcup \mathcal{P}_i^u$ for every $i < \kappa$, and we can find $g \in \mathcal{G}$ such that $f_\zeta(i) \in g(i)$ for all $i < \kappa$. Namely, $\zeta \in \mathcal{F}(g)$ as required. ⊣

8.18 Lemma. *For every $g \in \mathcal{G}$ there is an $\alpha < \lambda$ and $A \in J^+$ such that $\mathcal{F}(g) \subseteq \mathcal{F}(g_\alpha{\restriction}A)$. Thus as $|\mathcal{G}| < \sigma$, u is contained in the union of fewer than σ sets of the form $\mathcal{F}(g_\alpha{\restriction}A)$.*

Proof. For every $g \in \mathcal{G}$ there is some $\alpha < \lambda$ such that $g =_{J^+} g_\alpha$. That is, for some $A \in J^+$, $g \restriction A = g_\alpha \restriction A$. We already observed that $\mathcal{F}(g) \subseteq \mathcal{F}(g \restriction A)$, and hence the lemma follows. So Theorem 8.14 is proved. ⊣

We shall use a variant of Theorem 8.14 in which the assumption $\theta^\kappa = \theta$ is replaced with the assumption that θ is a strong limit cardinal with $\mathrm{cf}(\theta) < \sigma$.

8.19 Corollary. *Assume that $\lambda > \theta > \sigma = \mathrm{cf}(\sigma) > \kappa$ are cardinals such that:*

1. *θ is a strong limit cardinal and $\mathrm{cf}(\theta) < \sigma$.*
2. *If $\tau < \sigma$ then $\tau^\kappa < \sigma$.*
3. *J is an ideal on κ.*
4. *There is a sequence $\bar{\lambda} = \langle \lambda_i \mid i < \kappa \rangle$, $\lambda_i < \lambda$, such that*
   (a) $T_J(\bar{\lambda}) = \lambda$,
   (b) $\lambda_i^{\langle \sigma, \theta \rangle} = \lambda_i$ for every $i < \kappa$.

Then $\lambda^{\langle \sigma, \theta \rangle} = \lambda$.

Proof. Fix a cofinal in θ sequence $\langle \theta_\epsilon \mid \epsilon < \mathrm{cf}(\theta) \rangle$ such that $\theta_\epsilon^\kappa = \theta_\epsilon$ and $\sigma < \theta_\epsilon$ for every ϵ. (Start with any cofinal sequence, and replace θ_ϵ with $(\theta_\epsilon)^\kappa$ if necessary.)

Consider any $\epsilon < \mathrm{cf}(\theta)$. Observe that for every $i < \kappa$ we have $\lambda_i = \lambda_i^{[\sigma, \theta_\epsilon]}$. This follows immediately from the assumptions that θ is a strong limit cardinal with $\mathrm{cf}(\theta) < \sigma$, and such that $\lambda_i = \lambda_i^{\langle \sigma, \theta \rangle}$. Hence Theorem 8.14 is applicable (with θ_ϵ in the role of θ) and $\lambda = \lambda^{\langle \sigma, \theta_\epsilon \rangle}$. Since this holds for every $\epsilon < \mathrm{cf}(\theta)$, we get $\lambda = \lambda^{\langle \sigma, \theta \rangle}$. ⊣

8.2. Proof of the Revised GCH

We prove the following form of the revised GCH.

8.20 Theorem. *If θ is a strong limit singular cardinal, then for every $\lambda \geq \theta$, for some $\sigma < \theta$,*

$$\lambda = \lambda^{[\sigma, \theta]}.$$

Proof. Let $\sigma_0 = (\mathrm{cf}\,\theta)^+$.

The theorem is proved by induction on λ. For $\lambda = \theta$, $\lambda = \lambda^{[\sigma_0, \theta]}$, and the family of all bounded subsets of θ is an evidence for this equality. (Any subset of θ is a union of $\mathrm{cf}(\theta)$ bounded subsets.)

We note for clarification that the induction can easily proceed in case $\mathrm{cf}(\lambda) \neq \mathrm{cf}(\theta)$, and so we may assume that $\mathrm{cf}(\lambda) = \mathrm{cf}(\theta)$. However, we shall not make any use of this in the following proof.

Case 1: For every $A \subseteq \mathrm{Reg} \cap \lambda \setminus \theta$, if $|A| < \theta$ then $A \in J^{\sigma_0\text{-com}}_{\leq\lambda}[A]$.

In this case the inductive assumption is dispensable and Corollary 8.10 yields immediately that $\lambda = \lambda^{[\sigma_0, \leq\theta]}$.

Case 2: Not Case 1.

$$\text{For some } A \subseteq \mathrm{Reg} \cap \lambda \setminus \theta \text{ with } |A| < \theta,\ A \notin J^{\sigma_0\text{-com}}_{\leq\lambda}[A].$$

Hence there is a σ_0-complete filter D over A, where $|A| = \kappa < \theta$, such that $\mathrm{tcf}(\prod A/D) > \lambda$. Say $f : \kappa \to A$ enumerates A. By Lemma 8.12, $T_D(f) \geq \mathrm{tcf}(\prod A/D) > \lambda$. By Lemma 8.13, there exists a $g \leq f$ defined over κ so that $T_D(g) = \lambda$.

We claim that $\{i < \kappa \mid g(i) \geq \theta\} \in D$. If not, then $\{i < \kappa \mid g(i) < \theta\}$ is D-positive. But since $\mathrm{cf}(\theta) < \sigma_0$ and D is σ_0-complete, there is a $\theta' < \theta$ so that $X = \{i < \kappa \mid g(i) < \theta'\}$ is D-positive. Hence $T_D(g \restriction X) = \lambda$. But this is impossible since θ is strong limit and $(\theta')^\kappa < \theta$.

So we can assume now that for every $i < \kappa$, $g(i) \geq \theta$. Hence by the inductive assumption there is a $\sigma(i) < \theta$ such that

$$g(i) = g(i)^{[\sigma(i),\theta]}. \tag{14.48}$$

Since $\mathrm{cf}(\theta) < \sigma_0$ and D is σ_0-complete, there is σ, such that $\kappa, \sigma_0 < \sigma < \theta$ and $\{i < \kappa \mid \sigma(i) < \sigma\}$ is D-positive. For notational simplicity we assume that $\sigma(i) < \sigma$ for all $i < \kappa$. Take $\sigma_1 = (\sigma^\kappa)^+$. Now apply Corollary 8.19 to $\lambda > \theta > \sigma_1 > \kappa$. This yields $\lambda^{\langle\sigma_1,\theta\rangle} = \lambda$, but since θ is a strong limit cardinal with $\mathrm{cf}(\theta) < \sigma_1$ we obtain $\lambda^{[\sigma_1,\theta]} = \lambda$.

$\dashv$

We note that Theorem 8.1 did not make the assumption that θ is a singular cardinal, but Theorem 8.20 did. To see how Theorem 8.1 can be derived from Theorem 8.20, we argue as follows in case θ is a regular uncountable strong limit cardinal. There is a stationary set $S \subseteq \theta$ of strong limit singular cardinals. So if $\lambda \geq \theta$, then Theorem 8.20 applies to each $\theta' \in S$, and $\lambda = \lambda^{[\sigma(\theta'),\theta']}$ follows for some $\sigma(\theta') < \theta'$. By Fodor's theorem, there is a fixed $\sigma < \theta$ such that $\sigma = \sigma(\theta')$ for a stationary set of cardinals $\theta' \in S$. This gives $\lambda = \lambda^{[\sigma,<\theta]}$. So obviously for every $\sigma \leq \kappa < \theta$, we get $\lambda = \lambda^{[\kappa]}$.

8.3. Applications of the Revised GCH

Two applications are given here, the first to the existence of diamond sequences and the second to cellularity of Boolean algebras. Both use the following immediate corollary of the revised GCH theorem.

$$\text{If } \alpha \geq \beth_\omega \text{ then for some regular uncountable } \sigma < \beth_\omega \text{ there is a collection } P_\alpha \subseteq [\alpha]^\sigma \text{ where } |P_\alpha| = |\alpha| \text{ and such that for each } x \in [\alpha]^\sigma, \text{ for some } p \in P_\alpha,\ p \subseteq x. \tag{14.49}$$

To begin this section we recall that for a stationary set $S \subseteq \lambda^+$, $\diamondsuit^-_{\lambda^+}(S)$ is the following diamond statement: there is a sequence $\langle S_\alpha \mid \alpha \in S\rangle$ where $S_\alpha \subseteq \mathcal{P}(\alpha)$, $|S_\alpha| \leq \lambda$, and for every $A \subseteq \lambda^+$, $\{\alpha \in S \mid A \cap \alpha \in S_\alpha\}$ is a stationary set. If $|S_\alpha| = 1$, that is essentially $S_\alpha \subseteq \alpha$, then the sequence is the usual diamond sequence on S, and the resulting statement is the classical diamond $\diamondsuit_{\lambda^+}(S)$. An intriguing theorem of Kunen's (see [11]) states that $\diamondsuit^-_{\lambda^+}(S)$ is equivalent to $\diamondsuit_{\lambda^+}(S)$. (Somewhat more generally, this holds for an arbitrary regular cardinal μ not necessarily a successor cardinal, where $\diamondsuit^-_\mu(S)$ is the diamond statement obtained by restricting S_α to have cardinality not greater than that of α.) When $S = \lambda^+$, we write $\diamondsuit^-_{\lambda^+}$ instead of $\diamondsuit^-_{\lambda^+}(S)$ etc.

A beautiful argument of Gregory [4] proves that if $2^\lambda = \lambda^+$ and $\lambda^{\aleph_0} = \lambda$, then $\diamondsuit^-_{\lambda^+}(S^{\lambda^+}_\omega)$ where $S^{\lambda^+}_\omega$ is the stationary set of ordinals in λ^+ of cofinality ω. (There are stronger formulations, but this suffices to demonstrate the application we have in mind.) To prove this theorem, let $\{X_i \mid i < \lambda^+\}$ be an enumeration of all bounded subsets of λ^+. For every $\alpha < \lambda^+$ define S_α as the collection of all subsets of α that are formed by taking countable unions of sets from $\{X_i \mid i < \alpha\}$. Since $|\alpha|^{\aleph_0} \leq \lambda$, $|S_\alpha| \leq \lambda$. Now, if $A \subseteq \lambda^+$ is given, then the set, C, of $\alpha < \lambda^+$ for which $\forall \zeta < \alpha\ \exists i < \alpha\ (A \cap \zeta = X_i)$ is closed unbounded in λ^+. If $\alpha \in C$ and $\mathrm{cf}(\alpha) = \omega$ then $A \cap \alpha \in S_\alpha$. Applying Kunen's theorem, we can obtain $\diamondsuit_{\lambda^+}(S^{\lambda^+}_\omega)$.

The revised GCH enables in many cases a stronger theorem in which $\lambda^{\aleph_0} = \lambda$ is not required.

8.21 Theorem. *If $\lambda \geq \beth_\omega$ and $2^\lambda = \lambda^+$, then $\diamondsuit^-_{\lambda^+}$ holds. (Hence $\diamondsuit_{\lambda^+}$ is in fact equivalent to $2^\lambda = \lambda^+$ for every $\lambda \geq \beth_\omega$.)*

Proof. As before, let $\{X_i \mid i < \lambda^+\}$ enumerate all bounded subsets of λ^+. $\beth_\omega$ is the first strong limit cardinal, and the revised GCH theorem applies to $\lambda \geq \beth_\omega$. So there is a $\sigma < \beth_\omega$ such that (14.49) holds for some family $P \subseteq [\lambda]^\sigma$.

For every α in the interval $[\lambda, \lambda^+)$, $|\alpha| = \lambda$ and hence P can be transformed into a family $P_\alpha \subseteq [\alpha]^\sigma$ such that (14.49) holds (same σ for all α's). Now we define S_α as the collection of all subsets of α obtained as unions of the form $\bigcup\{X_i \mid i \in B\}$ where $B \in P_\alpha$. So $|S_\alpha| \leq \lambda$.

The argument to prove that $\langle S_i \mid i < \lambda^+\rangle$ is a diamond sequence is now familiar. Let $A \subseteq \lambda^+$ be any set. There is a closed unbounded $C \subseteq \lambda^+$ as before so that for $\alpha \in C$ and $\zeta < \alpha$ there is $i < \alpha$ such that $A \cap \zeta = X_i$. Now pick any $\alpha \in C$ such that $\mathrm{cf}(\alpha) = \sigma$. Pick an increasing sequence $\langle \alpha_\epsilon \mid \epsilon < \sigma\rangle$ cofinal in α, and for each $\epsilon < \kappa$ find $i(\epsilon) < \alpha$ such that $A \cap \alpha_\epsilon = X_{i(\epsilon)}$. Define $u = \{i(\epsilon) \mid \epsilon < \sigma\}$. Observe that if $K \subseteq \sigma$ is any unbounded subset of σ then $\bigcup\{X_{i(\epsilon)} \mid \epsilon \in K\} = A \cap \alpha$. For some $B \in P_\alpha$, $i(\epsilon) \in B$ for unboundedly many $\epsilon < \sigma$. Hence $A \cap \alpha = \bigcup\{X_i \mid i \in B\} \in S_\alpha$. $\dashv$

This kind of result about sufficiently large λ was first seen in this context. Very recently, Shelah [13] has, through a short and ingenious proof having aspects of club guessing, improved the result by weakening the hypothesis

$\lambda \geq \beth_\omega$ to $\lambda \geq \aleph_1$. It had been well known that CH + $\neg\diamondsuit_{\omega_1}$ is consistent by a result of Jensen. Thus, a long story has come to a surprising yet fitting conclusion, that except for the single and focal case $\lambda = \omega$, $\diamondsuit_{\lambda^+}$ is actually equivalent to just the cardinal hypothesis $2^\lambda = \lambda^+$.

We now begin the second application.

8.22 Definition. A subset X of a Boolean algebra is *μ-linked* iff there is a function $h : X \to \mu$ such that $x \wedge y \neq 0_B$ whenever $h(x) = h(y)$.

Our aim is to prove the following theorem from [16]. (For background and motivation and additional results consult [16] and [5].)

8.23 Theorem. *Assume that $\mu = \mu^{<\beth_\omega}$. If B is a c.c.c. Boolean algebra of cardinality $\leq 2^\mu$, then B is μ-linked.*

The proof which follows is an example of an induction that relies on the revised GCH. Since B satisfies the countable chain condition, its completion has cardinality $\leq |B|^{\aleph_0} \leq 2^\mu$, and so we can assume that B is a complete Boolean algebra (and when we prove that it is μ-linked then the original algebra which is embedded in its completion is also μ-linked).

We prove by induction on λ, a cardinal such that $\mu \leq \lambda \leq 2^\mu$, that any subset of B of cardinality λ is μ-linked. This is obvious for $\lambda = \mu$, or when $\mathrm{cf}(\lambda) \leq \mu$ (and the inductive claim holds for smaller cardinals), and so we may assume that $\mathrm{cf}(\lambda) > \mu$. There are several ingredients in the proof of this theorem, and so it is postponed until the required preparations are made.

8.24 Definition. Let C be a Boolean algebra, and $D \subseteq C$ a subalgebra. For any $x \in C$ let $F_x = \{d \in D \mid x \leq d\}$ be the filter generated by x. For a cardinal θ the following property is denoted $(**)_\theta$ (for the pair D and C):

$(**)_\theta$ For every $x \in C$ there is an $F \subseteq F_x$ of cardinality $\leq \theta$ such that for every $b \in F_x$ there is an $a \in F$ such that $a \leq b$.

In other words, F_x is generated by a subset of cardinality $\leq \theta$.

8.25 Lemma. *Let θ, μ, and κ be cardinals such that $\theta, \mu \leq \kappa$. Suppose that C is a Boolean algebra with a decomposition $C = \bigcup_{\alpha<\kappa} C_\alpha$, where the sequence of Boolean subalgebras C_α is increasing and continuous (for limit δ, $C_\delta = \bigcup_{i<\delta} C_i$). Assume the following:*

1. *$C_0 = \emptyset$.*
2. *Each C_α is μ-linked.*
3. *Property $(**)_\theta$ holds for each of the pairs C_α, C.*

Let χ be a sufficiently large cardinal and consider the structure H_χ (with some well ordering of its universe, and with C and its decomposition as constants). Suppose that M_1 and M_2 are two elementary substructures of H_χ that are isomorphic with an isomorphism $g : M_1 \to M_2$ that is the identity *on* $\kappa \cap M_1 \cap M_2$*. Suppose in addition that* $\theta \subseteq M_1 \cap M_2$*, and that* $M_1 \cap \mu = M_2 \cap \mu$*.*

Then for every non-zero $x \in M_1 \cap C$*,*

$$x \wedge g(x) \neq 0_C.$$

Proof. The rank of an element $c \in C$ is the least ordinal τ such that $c \in C_\tau$. Since $C_0 = \emptyset$, the rank of c is a successor ordinal (below κ) such that $c \in C_{\alpha+1} \setminus C_\alpha$. Take $x \in M_1$ of minimal rank $\alpha + 1$ such that $x \wedge g(x) = 0_C$ and we shall obtain a contradiction.

Case 1. $\alpha \in M_1 \cap M_2$. So $g(\alpha) = \alpha$. Let $h : C_{\alpha+1} \to \mu$ be the least function (in the well-ordering of H_χ) given by the assumption that $C_{\alpha+1}$ is μ-linked. So $h \in M_1 \cap M_2$, and since h is definable from α we have $g(h) = h$ (as $g(\alpha) = \alpha$). Say $h(x) = \eta \in \mu$. As $M_1 \cap \mu = M_2 \cap \mu$, we have $g(h(x)) = g(\eta) = \eta$. But $g(h(x)) = g(h)(g(x)) = h(g(x))$. So $h(g(x)) = \eta$, and hence $h(x) = h(g(x))$ which implies that x and $g(x)$ have non-zero meet in C.

Case 2. $\alpha \in M_1 \setminus M_2$, and hence $\alpha \neq g(\alpha)$ and $g(\alpha) \in M_2 \setminus M_1$. Suppose that $g(\alpha) < \alpha$ (case $g(\alpha) > \alpha$ is symmetric). Say $g(x) = y$, and $g(\alpha) = \beta$. Then $\beta + 1$ is the rank of y. Let $\alpha_1 \leq \alpha$ be the least ordinal in M_1 that is strictly above β. Since $\beta + 1 \leq \alpha_1$,

$$y \in C_{\alpha_1}.$$

Let $F_x \subseteq C_{\alpha_1}$ be the filter generated by x. Property $(**)_\theta$ of the pair C_{α_1} and C implies the existence of $F \subseteq F_x$ of cardinality $\leq \theta$ that generates F_x. As x and y are disjoint, the complement, $-y$, of y is in F_x (since it is in C_{α_1}) and hence there is an $a \in F$ that is disjoint from y. Since α_1 and x are in M_1, we have F_x and F in M_1 as well. But as θ is included in M_1, $F \subseteq M_1$ and hence $a \in M_1$ follows. The rank of a is $\alpha_2 + 1 \leq \alpha_1$. The minimality of α_1 implies that $\alpha_2 < \beta$ (equality is impossible because β is not in M_1). But now we can apply a similar argument to F_y (for the pair C_β, C) and discover $b \in C_\beta \cap M_2$ that is disjoint to a. Say $u \in M_1$ is such that $g(u) = b$. Then $u \in C_\alpha$ and hence $x_0 = u \wedge a$ is in C_α. Since $b \in F_y$, $u \in F_x$, and hence x_0 is in F_x too. In particular, $x_0 \neq 0_C$. But $g(x_0) = b \wedge g(a)$ and x_0 is disjoint to $b \wedge g(a)$ because already a is disjoint to b. So x_0 is disjoint to $g(x_0)$, in contradiction to the minimality of the rank of x. ⊣

Here is a lemma which is an immediate consequence of the Engelking-Karlowicz theorem [3]; we state it for reference and will return to its proof later on.

8.26 Lemma. *If* $\mu^\theta = \mu$ *then there is a map* $\tau : [2^\mu]^\theta \to \mu$ *such that if* $\tau(M_1) = \tau(M_2)$ *then* M_1 *and* M_2 *have the same order-type (as subsets of the ordinal* 2^μ*) and the order isomorphism* $g : M_1 \to M_2$ *is the identity on* $M_1 \cap M_2$*.*

8.27 Corollary. *Suppose that $\theta < \mu < \kappa \leq 2^\mu$ are cardinals such that $\mu^\theta = \mu$. Let C be a Boolean algebra of cardinality $\leq 2^\mu$, and suppose that $C = \bigcup_{\alpha<\kappa} C_\alpha$ where the C_α form an increasing and continuous sequence of subalgebras such that: $C_0 = \emptyset$, each C_α is μ-linked, and $(**)_\theta$ holds for each pair C_α, C. Then C is μ-linked.*

Proof. Let χ be sufficiently large and H_χ be the structure of sets of cardinality hereditarily less than χ, with a well-ordering of the universe and C as a constant. For every $a \in C$ find $M(a) \prec H_\chi$ of cardinality θ and such that $\theta \subseteq M(a)$. With each $M = M(a)$ we associate the following three parameters.

1. $M \cap \mu \in [\mu]^\theta$. So there are μ such parameters.

2. $\tau(M \cap 2^\mu)$, where $\tau : [2^\mu]^\theta \to \mu$ is the map from the lemma above.

3. The isomorphism type of $M(a)$ (with a as a parameter). Since $2^\theta \leq \mu$ there are $\leq \mu$ such types.

The map taking $a \in C$ to the three parameters associated with $M(a)$ proves that C is μ-linked. For if $M(a)$ and $M(b)$ have the same parameters then $a \wedge b \neq 0_C$ by the following argument. Let $g : M(a) \to M(b)$ be the isomorphism given by item 3. Then $g(a) = b$, and we plan to apply Lemma 8.25. This is possible because (1) $\tau(M(a) \cap 2^\mu) = \tau(M(b) \cap 2^\mu)$ implies that g is the identity on $2^\mu \cap M(a) \cap M(b)$, (2) $\theta \subseteq M(a) \cap M(b)$ by assumption, and (3) $M(a) \cap \mu = M(b) \cap \mu$ because this is the first of the three parameters. ⊣

We continue the inductive proof of Theorem 8.23. Recall that $\lambda \leq 2^\mu$, B is a complete c.c.c. Boolean algebra of cardinality $\leq 2^\mu$, and every subset of B of cardinality $< \lambda$ is μ-linked. Our aim is to prove that any $X \subseteq B$ of cardinality λ is μ-linked. We intend to use Corollary 8.27, and we must find a $C \subseteq B$ with $X \subseteq C$ and such that the premises of Corollary 8.27 hold.

For every α such that $\beth_\omega \leq \alpha < \lambda$ we have a regular uncountable cardinal $\sigma(\alpha) < \beth_\omega$ and a family $P_\alpha \subseteq [\alpha]^{\sigma(\alpha)}$ such that (14.49) holds. Since $\mathrm{cf}(\lambda) \neq \omega$ (in fact $\mathrm{cf}(\lambda) > \mu$) there is an unbounded set $E \subseteq \lambda$ such that for some fixed σ we have $\sigma = \sigma(\alpha)$ for every $\alpha \in E$. The symbols E and σ retain this meaning throughout the proof. We define $\theta = 2^{<\sigma}$.

8.28 Lemma. *Let $\chi > 2^\mu$ be sufficiently large. Suppose that δ is an ordinal and $\langle M_i \prec H_\chi \mid i < \delta \rangle$ is such that:*

1. $\mathrm{cf}(\delta) > \sigma$.

2. $B, E \in M_0$ *and* $\beth_\omega \subseteq M_0$.

3. $M_i \subseteq M_j$ *for* $i < j$ *and* $M_i \in M_{i+1}$.

4. $|M_i| < \lambda$, *and* $M_i \cap \lambda \in \lambda$.

Then for $M = \bigcup_{i<\delta} M_i$ and $B_0 = B \cap M$, $(**)_{2^{<\sigma}}$ holds for the pair B_0 and B.

Proof. Given $x \in B$ consider $F_x \subseteq B_0$, the filter of members of B_0 that are greater than x. We want to find a $F \subseteq F_x$ of cardinality $\leq \theta = 2^{<\sigma}$ that generates F_x. We choose $a_\zeta \in F_x$ for $\zeta < \sigma$ by the following inductive procedure. Suppose that $A_\zeta = \{a_\epsilon \mid \epsilon < \zeta\}$ is already chosen. Let $G_\zeta = \{\wedge Z \mid Z \subseteq A_\zeta \text{ and } Z \in M\}$. So G_ζ is the collection of all elements of B that can be formed by taking meets of subsets of A_ζ that happen to be in M. Clearly $A_\zeta \subseteq G_\zeta \subseteq F_x$. Since $|A_\zeta| < \sigma$, $|G_\zeta| \leq 2^{<\sigma}$. If there exists $a \in F_x$ not covering any $b \in G_\zeta$, then let a_ζ be such a. If there is no such a, then the procedure stops and $F = G_\zeta$ is as required. We shall prove that the construction cannot proceed for every $\zeta < \sigma$. Suppose it does, and consider $A = \{a_\zeta \mid \zeta < \sigma\}$. Since $\mathrm{cf}(\delta) > \sigma$ there is an $i < \delta$ with $A \subseteq M_i$. As $|M_i| < \lambda$ there is, already in M_{i+1} an ordinal $\alpha \in E$ such that $|M_i| < \alpha$. So $\alpha + 1 \subseteq M_{i+1}$ and hence also $P_\alpha \subseteq M_{i+1}$ (where $P_\alpha \subseteq [\alpha]^\sigma$ satisfies (14.49)). Viewing the universe of M_i as a copy of an ordinal $< \alpha$, the set A is a subset of α of cardinality σ, and we have some $p \in P_\alpha$ such that $p \subseteq A$. Since $\beth_\omega \subset M_{i+1}$, each subset of p is also in M_{i+1}. It follows that for every $a_\zeta \in p$, $A_\zeta \cap p \in M$ and hence $a_\zeta \not\geq \wedge(A_\zeta \cap p)$. Thus $\wedge(A_\zeta \cap p) - a_\zeta \neq 0_B$ is a sequence of σ pairwise disjoint members of B, which contradicts the c.c.c. since σ is uncountable. ⊣

We can complete now the proof of Theorem 8.23. We are assuming that $\lambda \leq 2^\mu$, $\mathrm{cf}(\lambda) > \mu$, $\mu^{<\beth_\omega} = \mu$, and every subset of B of cardinality smaller than λ is μ-linked. A set $X \subseteq B$ of cardinality λ is given, which we want to show is μ-linked. Pick χ sufficiently large and define $M_i \prec H_\chi$, for $i < \mathrm{cf}(\lambda) = \kappa$, such that

1. M_i is increasing and continuous with i. $|M_i| < \lambda$, $\lambda \cap M_i \in \lambda$, and $M_i \in M_{i+1}$.
2. $B, X \in M_0$, $\mu + 1 \subseteq M_0$, $\beth_\omega \subseteq M_0$, and $X \subseteq M = \bigcup_{i<\kappa} M_i$.

We shall prove that $B \cap M$ is μ-linked, and hence that X is μ-linked. For any set R of ordinals, let $\mathrm{nacc}(R)$ denotes those $\alpha \in R$ that are not accumulation points of R (for some $\beta < \alpha$ $R \cap (\beta, \alpha) = \emptyset$).

Let $R \subseteq \kappa$ be a closed unbounded set such that every $\alpha \in \mathrm{nacc}(R)$ is a limit ordinal with $\mathrm{cf}(\alpha) > \sigma$. Then, for $\delta \in \mathrm{nacc}(R)$, Lemma 8.28 applies to the sequence $\langle M_i \mid i < \delta\rangle$ and hence the pair $B \cap M_\delta$, B satisfies $(**)_\theta$ ($\theta = 2^{<\sigma}$). But, then it follows that $(**)_\theta$ holds for *every* $\delta \in R$ for the pair $B \cap M_\delta$, B. Because if $\mathrm{cf}(\delta) > \sigma$ then the lemma applies, and if $\mathrm{cf}(\delta) \leq \sigma$ then δ is a limit of $\leq \sigma$ non-accumulation points of R, and hence $(**)_\theta$ holds for $B \cap M_\delta$ by accumulating $\leq \sigma$ sets, each of cardinality $\leq \theta$.

Now let $\langle \rho_i \mid i < \kappa\rangle$ be an increasing and continuous enumeration of R, and define $C_i = B \cap M_{\rho_i}$, $C = B \cap M$. Then Corollary 8.27 applies with $\theta = 2^{<\sigma}$ and yields that $B \cap M$ is μ-linked. This proves Theorem 8.23.

For completeness we review the theorem of Engelking and Karlowicz that was used in the proof.

8.29 Theorem (Engelking and Karlowicz [3]). *Assume that θ and μ are cardinals such that $\mu^\theta = \mu$. Then there are functions $f_\xi : 2^\mu \to \mu$, for $\xi < \mu$, such that if $A \subseteq 2^\mu$, $|A| \leq \theta$, and $f : A \to \mu$, then there is a $\xi < \mu$ such that $f \subseteq f_\xi$.*

Proof. It is convenient for the proof to see 2^μ as the set of functions from μ to 2. A "template" is a triple (D, S, F) where $D \in [\mu]^\theta$, $S \subseteq 2^D$ and $|S| \leq \theta$ (S is a set of functions from D to 2), and $F : S \to \mu$. The number of possible templates is μ.

For any template $T = (D, S, F)$ we define f_T on 2^μ. If $\alpha \in 2^\mu$ and $\alpha \restriction D \in S$, then we define $f_T(\alpha) = F(\alpha \restriction D)$ (if $\alpha \restriction D \notin S$ then $f_T(\alpha)$ is any value).

Given any $A \subseteq 2^\mu$, $|A| \leq \theta$, and $f : A \to \mu$, find $D \in [\mu]^\theta$ such that $\alpha_1 \restriction D \neq \alpha_2 \restriction D$ whenever $\alpha_1 \neq \alpha_2$ are in A. $S = \{a \restriction D \mid a \in A\}$. For every $s \in S$ there is a unique $a \in A$ such that $s = a \restriction D$ and we define $F(s) = f(a)$. Then $f \subseteq f_T$. ⊣

We can prove now Lemma 8.26. Clearly the map assigning to each $X \in [2^\mu]^\theta$ its order-type (in θ^+) ensures that two sets are isomorphic if they have the same value. The problem is to ensure that two isomorphic sets have an isomorphism that is the identity on their intersection. Given $X \in [2^\mu]^\theta$, let f_X be the collapsing map which assigns to each $x \in X$ the order-type of $x \cap X$. Then there is some $\xi < \mu$ such that $f_X \subseteq f_\xi$ (by the Engelking-Karlowicz theorem). Let's color X with ξ (say the first one). Now if X and Y in $[2^\mu]^\theta$ have the same order-type and the same color ξ, then the isomorphism of X onto Y is the identity on $X \cap Y$ since it is equal to $g_2^{-1} \circ g_1$ where $g_1 = f_\xi \restriction X$ and $g_2 = f_\xi \restriction Y$.

1. Introduction

1.1. Three Problems

The regular cardinals are divided into three classes—those that are themselves successors of regular cardinals, those that are limit cardinals, and those that are successors of singular cardinals. This chapter is concerned with the peculiar nature of the cardinals in the last of these classes, a nature that combines aspects of the other two classes in surprising ways, and whose investigation involves almost all the tools of modern set theory.

Our chapter begins with a brief discussion of three examples, chosen to illustrate some of the difficulties encountered when working with successors of singular cardinals. In each case, we consider a question concerning regular cardinals whose solution is quite easy to obtain for each $\aleph_n$ $(n < \omega)$ but whose resolution at $\aleph_{\omega+1}$ touches on much deeper issues. This shows us how the strange nature of successors of singular cardinals makes itself felt at the first place possible.

The Cofinality of $[\omega_{\omega+1}]^{\aleph_0}$

Our first example involves the cofinality of $[\omega_{\omega+1}]^{\aleph_0}$—the collection of all countable subsets of $\omega_{\omega+1}$. Recall that the cofinality of $[\kappa]^{\aleph_0}$ is defined to be the minimum cardinality of a family $\mathcal{C} \subseteq [\kappa]^{\aleph_0}$ with the property that every countable subset of κ is covered by a member of $\mathcal{C}$. The cofinality of $[\omega_1]^{\aleph_0}$ is trivially equal to $\aleph_1$ (let $\mathcal{C}$ be the collection of initial segments of ω_1), and a simple induction establishes that the cofinality of $[\omega_n]^{\aleph_0}$ is $\aleph_n$ for $n < \omega$. This leads us to the natural question: What can be said about the cofinality of $[\omega_{\omega+1}]^{\aleph_0}$?

We see immediately that our induction will not work, and the reason why is clear—the answer depends on the cofinality of $[\omega_\omega]^{\aleph_0}$, and this is something that ZFC does not decide. Problems concerning cardinal arithmetic in the neighborhood of a singular cardinal are beyond the scope of this chapter—for more information, we refer to the reader to the chapter by Gitik [38] and that by Abraham and Magidor [1] in this Handbook.

Reflection of Stationary Sets

Our next example is a problem considered in Jech's chapter [49] in this Handbook which will be treated at length in our chapter—the problem of *stationary reflection*. Let us recall the relevant definitions.

1.1 Definition. Suppose that λ is an uncountable regular cardinal, and let S be a stationary subset of λ.

1. Given $\alpha < \lambda$, say that S *reflects at* α if α has uncountable cofinality and $S \cap \alpha$ is a stationary subset of α.
2. S *reflects* if there is some $\alpha < \lambda$ such that S reflects at α.
3. If $S \subseteq \lambda$ is stationary, then $\mathrm{Refl}(S)$ means that every stationary subset of S reflects.

1.2 Definition. If $\kappa < \lambda$ are regular cardinals, then we define

$$S^\lambda_\kappa := \{\delta < \lambda : \mathrm{cf}(\delta) = \kappa\}.$$

Variations of this notation (along the lines of $S^\lambda_{\leq\kappa}$) should be given the obvious interpretation.

If κ is a regular cardinal, then every ordinal less than κ^+ has a closed unbounded subset consisting of ordinals of cofinality less than κ. This implies immediately that $S^{\kappa^+}_\kappa$ does not reflect, so successors of regular cardinals (in particular, the cardinals $\aleph_n$ for $n < \omega$) always have non-reflecting stationary subsets. However, this simple argument says nothing about $\aleph_{\omega+1}$ (or other successors of singular cardinals) and so we are led at once to the question of whether or not $\aleph_{\omega+1}$ has a non-reflecting stationary subset.

The answer to this question is a typical one. If the universe is sufficiently "L-like", then an argument of Jensen establishes that $\mathrm{Refl}(\aleph_{\omega+1})$ fails. On the other hand, granted the existence of infinitely many supercompact cardinals (which of course, implies that the universe is far from being "L-like"), a construction of Magidor [62] provides a model in which every stationary subset of $\aleph_{\omega+1}$ reflects.

Is $\aleph_{\omega+1}$ a Jónsson cardinal?

The last problem we consider in this introductory section is motivated by a question from the partition calculus, in particular, on whether or not a very weak version of Ramsey's Theorem can hold for colorings of the finite subsets of a given cardinal.

1.3 Definition. A cardinal λ is a *Jónsson cardinal* if for every function $F : [\lambda]^{<\omega} \to \lambda$, there is a set $H \subseteq \lambda$ of size λ such that the range of $F \restriction [H]^{<\omega}$ is a proper subset of λ.

Note that if we consider the function $f : [\omega]^{<\omega} \to \omega$ given by

$$f(s) = |s|,$$

we see that $\aleph_0$ is certainly not a Jónsson cardinal, and next claim establishes that none of the cardinals $\aleph_n$ for $n < \omega$ are either.

1.4 Claim. *If κ is not a Jónsson cardinal, then neither is κ^+.*

Proof. Assume κ is not a Jónsson cardinal, and let $F : [\kappa]^{<\omega} \to \kappa$ attest to this fact. Given an ordinal α with $\kappa \leq \alpha < \kappa^+$, we may combine F together with a bijection between α and κ to build a function

$$F_\alpha : [\alpha]^{<\omega} \to \alpha$$

with the property that for any $A \subseteq \alpha$ of cardinality κ and any $\beta < \alpha$, there is an $s \in [A]^{<\omega}$ such that $F_\alpha(s) = \beta$.

Define a function $G : [\kappa^+]^{<\omega} \to \kappa^+$ by pasting together the functions F_α in a straightforward way—given $\alpha_0 < \cdots < \alpha_n < \kappa^+$, define

$$G(\{\alpha_0, \ldots, \alpha_n\}) := \begin{cases} 0 & \text{if } \alpha_n < \kappa, \text{ and} \\ F_{\alpha_n}(\{\alpha_0, \ldots, \alpha_{n-1}\}) & \text{if } \kappa \leq \alpha_n < \kappa^+. \end{cases}$$

We claim now that the function G shows that κ^+ is not a Jónsson cardinal. To see this, suppose that $A \subseteq \kappa^+$ has cardinality κ^+ and let an ordinal $\beta < \kappa^+$ be given. We produce an $s \in [A]^{<\omega}$ such that $G(s) = \beta$ as follows:

First, locate an $\alpha \in A$ such that $\beta < \alpha$ and $|A \cap \alpha| = \kappa$; it is clear that such an α exists and $\alpha \geq \kappa$. Using the salient property of F_α, we can choose $t \in [A \cap \alpha]^{<\omega}$ such that $F_\alpha(t) = \beta$. If we define $s := t \cup \{\alpha\}$, then $x \in [A]^{<\omega}$ and the definition of G implies $G(s) = \beta$, as required. ⊣

The situation at $\aleph_{\omega+1}$ seems to require a different idea, however, because the question of whether $\aleph_\omega$ can be a Jónsson cardinal is still unresolved. If there is a Jónsson cardinal, then $0^\#$ exists by an argument of Kunen. (See Sect. 18 of [51]. It was known much earlier that Jónsson cardinals imply $V \neq L$ [54].) Thus, if $V = L$ we know that $\aleph_{\omega+1}$ is not a Jónsson cardinal for the simple reason that there are no Jónsson cardinals at all. On the other hand, a theorem of Rowbottom [72] establishes that Ramsey cardinals are Jónsson cardinals. Thus Jónsson cardinals are consistent relative to the existence of moderately-sized large cardinals and so we cannot get a cheap answer regarding $\aleph_{\omega+1}$.

We will discuss this question in more detail in the final section of this chapter, but we point out that in the particular case of $\aleph_{\omega+1}$, Shelah's pcf theory provides us with an answer—$\aleph_{\omega+1}$ is *not* a Jónsson cardinal (see Theorem 5.7), but his methods do not generalize to arbitrary successors of singular cardinals. In particular, the question of whether or not it is possible for the successor of a singular cardinal to be a Jónsson cardinal is still open, and this is still an active area of research in set theory.

One can summarize the situation in all three of the preceding examples quite succinctly—if the universe is sufficiently "L-like", then successors of singular cardinals behave much like successors of regular cardinals, but in the presence of sufficiently large cardinals, one can sometimes find quite different behavior. As we shall see, these opposing forces are typified by the non-reflection implicit in $\square$-sequences and the abundant reflection supplied by large cardinals, and their interplay gives this area of set theory its special character.

1.2. Conventions and Notation

Elementary Submodels

Elementary submodels will be one of our main tools. Our conventions are standard—we assume χ is some ambient regular cardinal much larger than any cardinals under discussion, and by $H(\chi)$ we mean the collection of all sets whose transitive closure has cardinality less than χ. It is well known that $\langle H(\chi), \in\rangle$ is a model of all axioms of ZFC except perhaps for the power set axiom; for all intents and purposes we can pretend that all relevant set theory is done inside of $H(\chi)$. The book [46] contains a gentle development of elementary submodels of $H(\chi)$ in the context of cardinal arithmetic and pcf theory.

Throughout this chapter, $\mathfrak{A}$ will denote some expansion of the structure $\langle H(\chi), \in, <_\chi\rangle$ by at most countably many functions, constants, and relations. Note that we will indulge in a bit of sloppiness by sometimes referring to elementary submodels of $H(\chi)$, and sometimes referring to elementary submodels of $\mathfrak{A}$—both phrases are used to mean exactly the same thing. The symbol $<_\chi$ denotes some fixed well-ordering of $H(\chi)$; we include such a well-ordering in our structure because it gives us canonical Skolem functions. In more detail, for each formula $\varphi(v_0, \ldots, v_n)$ of the language of $\mathfrak{A}$, we can define an n-ary function f_φ with domain $H(\chi)$ by letting $f_\varphi(x_1, \ldots, x_n)$ be the $<_\chi$-least $x \in H(\chi)$ such that $\mathfrak{A} \models \varphi[x, x_1, \ldots, x_n]$ if such an x exists, and setting $f_\varphi(x_1, \ldots, x_n) = 0$ otherwise. We obtain the set of *Skolem terms* for $\mathfrak{A}$ by closing the collection of Skolem functions under composition. The following definition establishes our notational convention.

1.5 Definition. Let $B \subseteq H(\chi)$. Then $\mathrm{Sk}^{\mathfrak{A}}(B)$ denotes the Skolem hull of B in the structure $\mathfrak{A}$. More precisely,

$$\mathrm{Sk}^{\mathfrak{A}}(B) = \{\tau(b_0, \ldots, b_n) : \tau \text{ a Skolem term for } \mathfrak{A}, \text{ and } b_0, \ldots, b_n \in B\}.$$

The Tarski criterion tells us that $\mathrm{Sk}^{\mathfrak{A}}(B)$ is an elementary substructure of $\mathfrak{A}$, and it is the smallest such structure containing every element of B. The following technical lemma (due to Baumgartner [6]) captures a fact about Skolem hulls that is incredibly useful in our context.

1.6 Lemma. *Assume that $M \prec \mathfrak{A}$ and let $\theta \in M$ be a cardinal. If we define $N = \mathrm{Sk}^{\mathfrak{A}}(M \cup \theta)$, then for all regular cardinals $\sigma \in M \setminus \theta^+$,*

$$\sup(M \cap \sigma) = \sup(N \cap \sigma).$$

Proof. Suppose that $\alpha \in N \cap \sigma$; we must produce a $\beta > \alpha$ in $M \cap \sigma$. Since $\alpha \in N$, there is a Skolem term τ and parameters $\alpha_0, \ldots, \alpha_i, \beta_0, \ldots, \beta_j$ such that $\alpha = \tau(\alpha_0, \dots, \alpha_i, \beta_0, \dots, \beta_j)$, where each α_ℓ is less than θ and each β_ℓ is an element of $M \setminus \theta$. We define a function F with domain $[\theta]^{i+1}$ by

$$F(x_0, \dots, x_i) = \begin{cases} \tau(x_0, \dots, x_i, \beta_0, \dots, \beta_k) & \text{if this is an ordinal less than } \sigma \\ 0 & \text{otherwise.} \end{cases}$$

The function F is an element of M as it is definable from parameters in M and so $\beta := \sup(\mathrm{ran}(F))$ is in M as well. Since σ is a regular cardinal, it is clear that $\beta < \sigma$. Now $\alpha \in \mathrm{ran}(F)$ and therefore $\alpha < \beta$ as required. $\dashv$

We will also make great use of sequences of elementary submodels, and the concept captured by the following definition (first explicitly formulated in [36]) will have a prominent role.

1.7 Definition. Let γ be a limit ordinal, and let $\mathfrak{A}$ be as above. An *internally approachable* (IA) *chain of substructures of* $\mathfrak{A}$ *of length* γ is a continuous and increasing sequence of elementary substructures of $\mathfrak{A}$ such that $\langle M_j : j \le i \rangle \in M_{i+1}$ for all $i < \gamma$.

We remark that in circumstances of the preceding definition that for $j < i < \gamma$ we have $i \subseteq M_i$ and $M_j \in M_i$. The following definition isolates one class of IA chains that appears in almost every section of this work. The terminology goes back to Shelah's original investigations in [83].

1.8 Definition. Let λ be a regular cardinal. A λ-*approximating sequence* is an IA chain of substructures $\langle M_i : i < \lambda \rangle$ of length λ such that $\lambda \in M_0$, and for each $\alpha < \lambda$ we have $|M_\alpha| < \lambda$ and $M_\alpha \cap \lambda$ is an initial segment of λ. A λ-approximating sequence is said to be *over* x if $x \in \bigcup_{\alpha<\lambda} M_\alpha$.

The following proposition is simple to prove, but it captures another property of elementary submodels that is used in almost every part of this chapter.

1.9 Proposition. *Let λ be a cardinal, and suppose that M is an elementary submodel of $H(\chi)$ for which $M \cap \lambda$ is an initial segment of λ. If $A \in M$ satisfies $|A| < \lambda$, then $A \subseteq M$.*

Proof. Since $A \in M$, so is the cardinality of A. Since $|A| < \lambda$ and $M \cap \lambda$ is an initial segment of λ, it follows that $|A| \subseteq M$. The model M must contain a bijection b mapping $|A|$ onto A. Given $a \in A$, there is an $\alpha < |A|$ such that $a = b(\alpha)$. Since both b and α are in M, we conclude that a is as well. $\dashv$

For a typical example of how the above proposition is used, consider the case where $\lambda = \mu^+$ for μ a strong limit singular cardinal. If $A \in M$ is of cardinality less than μ, then it follows that every subset of A is also in M. This sort of argument is used without comment throughout the sequel, so it seemed worthwhile to call the reader's attention to it here in the beginning.

λ-Filtration Sequences

Suppose now that $\lambda = \mu^+$, where μ is a singular cardinal. Many combinatorial arguments make use of the fact that every $\alpha < \lambda$ is the union of $\mathrm{cf}(\mu)$ sets of size less than μ. The following definition gives us a systematic way of speaking of this.

1.10 Definition. Suppose that $\lambda = \mu^+$ for μ singular. A matrix

$$\bar{b} = \langle b_{\alpha,i} : \alpha < \lambda, i < \mathrm{cf}(\mu)\rangle$$

of subsets of λ is a λ-*filtration sequence* if for each $\alpha < \lambda$,

1. $b_{\alpha,i} \subseteq \alpha$,
2. the sequence $\langle b_{\alpha,i} : i < \mathrm{cf}(\mu)\rangle$ is continuous and increasing, and
3. $\alpha = \bigcup_{i<\mathrm{cf}(\mu)} b_{\alpha,i}$.

We note that with each λ-filtration sequence $\bar{b}$ we may associate a natural coloring of the pairs from λ, namely

$$d(\beta, \alpha) = \min\{i < \mathrm{cf}(\mu) : \beta \in b_{\alpha,i}\}.$$

On the other hand, if we are given a function $d : [\lambda]^2 \to \mathrm{cf}(\mu)$, then we can construct a λ-filtration sequence by defining

$$b_{\alpha,i} = \{\beta < \alpha : d(\beta, \alpha) < i\}$$

It is straightforward to build λ-filtration sequences that satisfy additional requirements. For example, if we fix an increasing sequence of regular cardinals $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ cofinal in μ, then an easy inductive argument lets us define a λ-filtration sequence with the additional properties that

$$|b_{\alpha,i}| \le \mu_i,$$

and

$$\beta \in b_{\alpha,i} \quad \Longrightarrow \quad b_{\beta,i} \subseteq b_{\alpha,i}.$$

pcf Theory

Our notation concerning pcf theory is fairly consistent with that presented in the chapter by Abraham and Magidor [1] in this Handbook. We take a moment to recall the most important definitions and establish our conventions.

1.11 Definition. Let $(P, \le)$ be a partially ordered set, and let θ be a cardinal. We say that $(P, \le)$ is θ-*directed* if every subset $A \subseteq P$ of cardinality less than θ has an upper bound, that is, there is a $p \in P$ such that $q \le p$ for all $q \in A$. The *cofinality of* $(P, \le)$ (denoted $\mathrm{cf}(P)$ when $\le$ is understood) is the least cardinal θ for which there is a family $A \subseteq P$ of cardinality θ such that for all $p \in P$, there is a $q \in A$ such that $p \le q$.

1.12 Definition. Let I be an ideal on some index set X, and let R be some relation on the class of ordinals On. Given functions f and g mapping X to On, we define

$$fR_Ig \iff \{x \in X : \neg(f(x)Rg(x))\} \in I. \tag{15.1}$$

In particular, we have

$$f <_I g \iff \{x \in X : g(x) \leq f(x)\} \in I, \tag{15.2}$$

and

$$f \leq_I g \iff \{x \in X : g(x) < f(x)\} \in I. \tag{15.3}$$

Note that in general "$f \leq_I g$" is *not* the same as "either $f <_I g$ or $f =_I g$", but the equivalence holds if I is a maximal ideal.

In some situations, we will work with the filter dual to the ideal I, so for example if D is an ultrafilter on X we may say $<_D$ instead of $<_I$ for I the ideal dual to D.

It is quite natural to consider least upper bounds in this context, and the following definition translates this concept into our framework.

1.13 Definition. A function f is a *$\leq_I$-least upper bound for $\langle f_i : i < \alpha\rangle$* if

1. f is a $<_I$-upper bound for $\langle f_i : i < \alpha\rangle$, and
2. if $\{x \in X : g(x) < f(x)\} \notin I$, then there is an $i < \alpha$ such that $\{x \in X : g(x) < f_i(x)\} \notin I$.

There is also a strengthening of "least upper bound" that is a crucial ingredient in many proofs.

1.14 Definition. A $<_I$-increasing sequence of functions $\langle f_i : i < \alpha\rangle$ has a *$<_I$-exact upper bound* (or *$<_I$-eub*) if there is a function $f \in {}^X\mathsf{On}$ such that

1. f is a $<_I$-upper bound for $\langle f_i : i < \alpha\rangle$, and
2. for all $g <_I f$, there is an i for which $g <_I f_i$.

If there is no opportunity for confusion, we may omit explicitly mentioning the order $<_I$.

In general a given sequence need not have an exact upper bound, but if one exists then it is unique up to equivalence modulo the ideal I. We also remark that a $<_I$-exact upper bound is also a $<_I$-least upper bound, but the converse is not true in general.

1.15 Definition. Let I be an ideal on κ, and let $\langle \mu_i : i < \kappa\rangle$ be an increasing sequence of regular cardinals. We say that $(\prod_{i<\kappa} \mu_i, <_I)$ has *true cofinality* θ, or

$$\operatorname{tcf}\left(\prod_{i<\kappa}\mu_i, <_I\right) = \theta$$

if θ is regular and there is a $<_I$-increasing sequence $\langle f_\alpha : \alpha < \theta\rangle$ in $\prod_{i<\mathrm{cf}(\mu)} \mu_i$ such that

$$\big(\forall g \in \textstyle\prod_{i<\kappa}\mu_i\big)(\exists\alpha < \theta)[g <_I f_\alpha].$$

Note that not every structure of the form $(\prod_{i<\kappa} \mu_i, <_I)$ has a true cofinality, but this problem disappears if I is dual to an ultrafilter.

Of course, it is only a cosmetic change to move from products of the form $\prod_{i<\kappa} \mu_i$ to products of the form $\prod A$ for A a set of regular cardinals. This small change in emphasis moves us into pcf theory.

1.16 Definition. A set A of regular cardinals is *progressive* if $|A| < \min(A)$. If A is a progressive set of regular cardinals, then $\mathrm{pcf}(A)$ is the set of all cardinals θ for which there is an ultrafilter D on A such that

$$\mathrm{cf}\big(\textstyle\prod A/D\big) = \theta.$$

If λ is a cardinal and A is a progressive set of regular cardinals, then $J_{<\lambda}[A]$ is the collection of all $B \subseteq A$ such that

$$\mathrm{cf}\big(\textstyle\prod A/D\big) < \lambda \quad \text{for every ultrafilter } D \text{ on } A \text{ containing } B.$$

The name *progressive* comes originally from [46], and seems well on its way to standard usage.

1.17 Fact. Let A be a progressive set of regular cardinals.

1. $J_{<\lambda}[A]$ is an ideal (not necessarily proper) on A.

2. $\mathrm{pcf}(A)$ has a maximal element, $\max\mathrm{pcf}(A)$. It is the least λ such that $A \in J_{<\lambda^+}[A]$.

3. If $\lambda \in \mathrm{pcf}(A)$, then there is a single set $B_\lambda[A] \subseteq A$ (called a *generator for* λ) such that
$$J_{<\lambda^+}[A] = J_{<\lambda}[A] + B_\lambda[A],$$
that is, the ideal $J_{<\lambda^+}[A]$ is generated by $J_{<\lambda}[A]$ together with the set $B_\lambda[A]$. The set $B_\lambda[A]$ is unique modulo the ideal $J_{<\lambda}[A]$.

4. If $\lambda \in \mathrm{pcf}(A)$, then
$$\mathrm{tcf}\big(\textstyle\prod B_\lambda[A], <_{J_{<\lambda}[A]}\big) = \lambda.$$
In particular, $\mathrm{tcf}(\prod B_\lambda[A], <_{J_{<\lambda}[A]})$ is defined. Of course, the same statement holds if we replace $B_\lambda[A]$ by any member of $J_{<\lambda^+}[A] \setminus J_{<\lambda}[A]$.

The preceding gathers together several results of Shelah, and it encapsulates most of what we will be using from pcf theory. The chapter [1] is a good reference for these results, and [46, 55, 10], and [89] provide a selection of external sources for the material.

One topic not covered in [1] is the pseudopower $\mathrm{pp}(\mu)$ of a singular cardinal. A few of the theorems we prove later are most naturally stated in terms of the pseudopower function, so we recall the definition. Readers interested in a more comprehensive study of pseudopowers should consult [46, Chap. 9] for the preliminaries, and [89] for an exhaustive analysis.

1.18 Definition. Suppose that μ is a singular cardinal, and let $\mathrm{PP}(\mu)$ be the set of all cardinals of the form $\mathrm{cf}(\prod A/D)$, where A is a set of regular cardinals cofinal in μ of order-type $\mathrm{cf}(\mu)$ and D is an ultrafilter on A disjoint to the ideal $J^{\mathrm{bd}}[A]$ of bounded subsets of A. We define the *pseudopower of* μ (denoted $\mathrm{pp}(\mu)$) by the formula

$$\mathrm{pp}(\mu) = \sup(\mathrm{PP}(\mu)). \tag{15.4}$$

Our use of $\mathrm{pp}(\mu)$ is limited in that we are almost exclusively concerned with the statement $\mathrm{pp}(\mu) = \mu^+$ and its negation. With this in mind, it seems reasonable to include the following proposition, which is really just a restatement of the definitions involved.

1.19 Proposition. *Let μ be a singular cardinal. Then the following statements are equivalent:*

1. $\mathrm{pp}(\mu) > \mu^+$.
2. *There is an increasing sequence $\vec{\mu} = \langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ of regular cardinals with limit μ for which*

   $$\left(\prod_{i<\mathrm{cf}(\mu)} \mu_i, <^*\right) \quad \textit{is } \mu^{++}\textit{-directed,}$$

   where $<^*$ abbreviates $<_I$ for I the ideal of bounded subsets of $\mathrm{cf}(\mu)$.

Proof. Assume $\mathrm{pp}(\mu) > \mu^+$. Let θ be the least cardinal greater than μ^+ for which there are A and D as in Definition 1.18 with $\mathrm{cf}(\prod A/D) = \theta$. Since θ is in $\mathrm{pcf}(A)$, we know that there is a generator $B = B_\theta[A]$ corresponding to θ. Since $B \in D$, it must be the case that B is an unbounded subset of A, and we also know

$$\mathrm{tcf}\left(\prod B/J_{<\theta}[A]\right) = \theta.$$

It follows that $(\prod B, <_{J_{<\theta}[A]})$ is θ-directed, hence μ^{++}-directed. If B_0 is a subset of B in $J_{<\theta}[A]$, then B_0 must be bounded in B—otherwise, any ultrafilter on B_0 disjoint to the ideal of bounded sets would contradict the choice of θ. Thus, it follows that

$$\left(\prod B, <_{J^{\mathrm{bd}}[B]}\right) \quad \text{is } \mu^{++}\text{-directed.}$$

If we enumerate B as $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$, then

$$\left(\prod_{i<\mathrm{cf}(\mu)} \mu_i, <^*\right) \quad \text{is } \mu^{++}\text{-directed,}$$

as required.

For the other direction, we note that $A = \{\mu_i : i < \mathrm{cf}(\mu)\}$ is a set of cardinals as in Definition 1.18. If D is any ultrafilter on A disjoint to the ideal of bounded sets, then clearly

$$\mathrm{cf}\big(\prod A/D\big) \geq \mu^+,$$

but since $\prod A/J^{\mathrm{bd}}[A]$ is μ^{++}-directed and $J^{\mathrm{bd}}[A] \cap D = \emptyset$, we know

$$\mathrm{cf}\big(\prod A/D\big) \neq \mu^+.$$

Since $\mathrm{cf}(\prod A/D) \in \mathrm{PP}(\mu)$, we conclude $\mathrm{pp}(\mu) > \mu^+$. $\dashv$

Large Cardinals

Large cardinals make several appearances in this chapter. Our notation is consistent with that of Kanamori's book [53]. We assume that the reader is familiar with the definitions of the most common large cardinals (Mahlo, measurable, supercompact, etc.), as well as with the idea of an elementary embedding. However, there are many equivalent characterizations of some of the cardinals, so we will take a moment to fix the definitions which we shall use.

1.20 Definition.

1. A cardinal κ is *strongly compact* if for any set S, every κ-complete filter over S can be extended to a κ-complete ultrafilter over S.
2. A cardinal κ is *γ-supercompact* (for $\gamma \geq \kappa$) if there is an elementary embedding $j : V \to M$ such that
   (a) $\mathrm{crit}(j) = \kappa$,
   (b) $\gamma < j(\kappa)$, and
   (c) M is closed under sequences of length $\leq \gamma$.

   We will refer to an embedding j with the above properties as a *γ-supercompact embedding.*
3. A cardinal κ is *supercompact* if it is γ-supercompact for all $\gamma \geq \kappa$.

In most cases, we use only a few basic properties of γ-supercompact embeddings. In particular, if we have reason to use a γ-supercompact embedding $j : V \to M$ (with $\kappa = \mathrm{crit}(j)$), then our primary concern tends to be the function $j \restriction \gamma$ and the ordinal

$$\rho := \sup\{j(\alpha) : \alpha < \gamma\}.$$

We note that ρ is an ordinal of cofinality $\mathrm{cf}(\gamma)$, and that $\{j(\alpha) : \alpha < \gamma\}$ is a $<\kappa$-closed unbounded subset of η. Furthermore, since M is closed under sequences of length $\leq \gamma$, the set $\{j(\alpha) : \alpha < \gamma\}$ is an element of M.

It is well-known that strongly compact cardinals can be characterized in many different ways (see [53, Sect. 22] or [51, Chap. 20]). In particular, they can be characterized in terms of elementary embeddings in such a way that it becomes clear that a supercompact cardinal must be strongly compact. The following result taken from [95] gives the characterization.

1.21 Proposition. *A cardinal κ is strongly compact if and only if for every $\gamma \geq \kappa$ there is an elementary embedding $j : V \to M$ such that*

1. $\mathrm{crit}(j) = \kappa$,
2. $\gamma < j(\kappa)$, *and*
3. *for every $X \subseteq M$ with $|X| \leq \gamma$, there is a $Y \in M$ such that $X \subseteq Y$ and $M \models |Y| < j(\kappa)$.*

If we require the above only for a specific $\gamma \geq \kappa$, then κ is said to be γ-strongly compact.

Forcing

In order to keep our chapter to manageable length, we have chosen to keep our use of forcing to a minimum; in the few places we do use it, our notation is standard, that is, as one finds in [51] or [59]. We follow the convention that $p \leq q$ means "p extends q".

By far the most important notion of forcing we use is the Levy collapse, so we take a moment to collect notation.

1.22 Definition. $\mathrm{Col}(\kappa, \lambda)$ is the cardinal collapse to make λ have cardinality κ, i.e. a condition is a partial function from κ into λ with domain of cardinality less than κ, and $p \leq q$ if and only if $q \subseteq p$. $\mathrm{Col}(\kappa, {<}\lambda)$ is the Levy collapse to make all cardinals in $[\kappa, \lambda)$ have cardinality κ. Here a condition p is a partial function from $\lambda \times \kappa$ into λ with $|\operatorname{dom}(p)| < \kappa$, $p(0, i) = 0$, and $p(\alpha, i) < \alpha$ for $\alpha \neq \emptyset$.

Remarks

Finally, I am going to drop the authorial "we" for the remainder of the introduction so that I can comment a bit on the chapter. There were of course two major decisions to make—what should be the scope of the chapter, and for whom should it be written.

The first of these questions was by far the most difficult for me to answer because the assigned topic touches every aspect of set theory. The second question was easier—I decided early on that I would attempt to write the type of survey that I wish had been available when I first started learning about the topic.

The chapter consists of five major divisions, of which the first is taken up with introductory material. The second division is an exposition of Magidor's proof of the consistency of $\mathrm{Refl}(\aleph_{\omega+1})$; I chose this as my starting point because stationary reflection is a major theme in the chapter, and his proof can be used to motivate the idea of approachability and $I[\lambda]$.

The next division deals extensively with $I[\lambda]$ and some of its applications. The section is quite long, and deliberately so, because much of the material covered is scattered through papers of Shelah going back almost three decades. I thought it worthwhile to gather it together in a single place since the lack of such a resource caused considerable aggravation when I was first learning the material. Most of the material in that section is based on notes I took in the Jerusalem Logic Seminar during lectures by Shelah in the summer of 1998 [90].

The fourth division of the paper is primarily based on more recent work of Cummings, Foreman, and Magidor. In contrast to the $I[\lambda]$ material, most of the results in this portion of the paper have appeared in papers where the exposition is masterful—in particular, the papers [36, 16], and [65] are highly recommended. In addition, Cummings has recently written a survey on the same subject [14]—we have benefited immensely from his paper, and in several places we reference his paper for proofs that we have not included in the current chapter.

The final major division of the paper concerns Jónsson cardinals and club guessing, and is for the most part independent of the other parts of the chapter. I chose to include this material for the same reason I devoted so much time to the development of $I[\lambda]$—it is a very interesting topic, but the basic results are scattered through several difficult papers and in Shelah's book [89].

In summary, the chapter could easily have been three times as long as it is, and I reluctantly left out much that is interesting. It is my hope that the level of exposition is sufficient that any set-theorist with a casual interest in the topic can catch a glimpse of the major ideas, and that those people interested in "really learning" the material will receive enough background and guidance for a comfortable transition to current literature.

Finally, a few words of thanks are in order. I would like to thank Matt Foreman and James Cummings for patiently answering my queries as I wrote the chapter. Thanks are due as well to Aki Kanamori and an anonymous referee for many helpful remarks, while Andres Caicedo read through the entire chapter carefully and did yeoman's work rooting out misstatements and typographical errors. The chapter is a much stronger work thanks to their contributions.

2. On Stationary Reflection

We now turn to the question of stationary reflection, mentioned briefly in the first subsection of the introduction. First, we use stationary reflection as a lens to study an important phenomenon in set theory—the tension between

$\Box$-like principles and large cardinals. We then briefly investigate indecomposable ultrafilters and their influence on stationary reflection before plunging into Magidor's proof [62] that $\mathrm{Refl}(\aleph_{\omega+1})$ is consistent relative to the existence of infinitely many supercompact cardinals. This proof occupies the last three subsections of this part of the chapter, and some of the issues that arise therein will lead us to topics considered in later sections.

2.1. Squares and Supercompact Cardinals

In the first part of the introduction, we pointed out that it is quite easy to see that $\mathrm{Refl}(\kappa^+)$ fails whenever κ is a regular cardinal. In particular, if κ is regular then the set $S^{\kappa^+}_\kappa$ is a stationary subset of κ^+ that does not reflect. On the other hand, $\mathrm{Refl}(\kappa)$ holds if κ is weakly compact—this is an easy corollary to the Hanf-Scott characterization [45] of weakly compact cardinals as precisely the Π^1_1-indescribable cardinals. Jech's chapter [49] in this Handbook contains further discussion and references for stationary reflection in the context of successors of regular cardinals and "small" large cardinals. None of this, however, sheds any light on how successors of singular cardinals behave with respect to stationary reflection, and it is to this subject we now turn. Our treatment begins with the $\Box$ principle of Jensen [52].

We affirm some notation for the chapter: For a set X of ordinals, $\mathrm{ot}(X)$ denotes its order-type; $\mathrm{acc}(X)$ denotes the set of accumulation (i.e. limit) points of X other than $\sup(X)$; and $\mathrm{nacc}(X)$ denotes $X \setminus \mathrm{acc}(X)$.

2.1 Definition. Let κ be an uncountable cardinal. A $\Box_\kappa$*-sequence* is a sequence $\langle C_\alpha : \alpha < \kappa^+\rangle$ such that for all $\alpha < \kappa^+$,

1. C_α is closed and unbounded in α,
2. $\mathrm{ot}(C_\alpha) \le \kappa$, and
3. if β is a limit point of C_α, then $C_\beta = C_\alpha \cap \beta$.

$\Box_\kappa$ is the assertion that there is such a sequence.

It is not difficult to prove that $\Box_\kappa$ is equivalent to the *prima facie* stronger principle in which condition (2) is replaced by

$$\mathrm{cf}(\alpha) < \kappa \quad \Longrightarrow \quad \mathrm{ot}(C_\alpha) < \kappa. \tag{15.5}$$

Given a $\Box_\kappa$-sequence $\langle C_\alpha : \alpha < \kappa^+\rangle$, we can construct a $\Box_\kappa$-sequence satisfying (15.5) by fixing a closed unbounded subset C of κ of order-type $\mathrm{cf}(\kappa)$, and replacing each C_α with

$$\{\beta \in C_\alpha : \mathrm{ot}(C_\alpha \cap \beta) \in C\}$$

whenever $\mathrm{ot}(C_\alpha)$ is in $\mathrm{acc}(C) \cup \{\kappa\}$.

Jensen [52] proved that $\Box_\kappa$ holds for all κ in the constructible universe L. Note as well that $\Box_\kappa$ is quite persistent—if $\Box_\kappa$ holds for some cardinal in a model of set theory W, then it will continue to hold in any extension of W in which κ and κ^+ are preserved. These two facts lead us to the following well-known corollary of Jensen's Covering Lemma.

2.2 Theorem. *If $0^\#$ does not exist, then $\square_\mu$ holds for all singular cardinals μ.*

Proof. Let μ be a singular cardinal in V, and assume $0^\#$ does not exist. It suffices to prove that $(\mu^+)^L = \mu^+$, as a $\square_\mu$-sequence from L will then serve to witness that $\square_\mu$ continues to hold in V.

Suppose that $\theta = (\mu^+)^L$, and assume by way of contradiction that $\theta < \mu^+$. It must be the case that $|\theta| = \mu$ and hence $\mathrm{cf}(\theta) < \mu$. Now let X be a cofinal subset of θ of cardinality $\mathrm{cf}(\theta)$. By the Covering Lemma, there is a set $Y \in L$ such that $X \subseteq Y$ and $|Y| \leq |X| + \aleph_1 < \mu = |\theta|$. But since the set Y is cofinal in θ and θ is regular in L, it must be the case that $|Y| = |\theta|$, and we have a contradiction. Thus, $(\mu^+)^L = \mu^+$ and consequently $\square_\mu$ must hold as well. $\dashv$

The failure of $\square_\mu$ for singular μ is not an easy thing to arrange—we have just seen that it necessarily involves large cardinals, and further research has shown that the large cardinals needed are quite large indeed:

2.3 Theorem (Steel [96]). *If there is a singular strong limit cardinal μ for which $\square_\mu$ fails, $L(\mathbb{R})$ determinacy holds and hence there is an inner model with infinitely many Woodin cardinals.*

We cannot hope to treat the relationship between squares and inner models of set theory in this chapter, but we do point out that this is a reason why large cardinals are always in the background when one considers successors of singular cardinals. We send a reader looking for more information on this topic to the chapters by Welch and by Schimmerling in this Handbook. We now leave inner models and turn to combinatorial consequences of $\square_\kappa$.

A $\square_\kappa$-sequence is a prototypical example of a "non-compact" object of size κ^+—if $\langle C_\alpha : \alpha < \kappa^+\rangle$ is such a sequence, then there is no closed unbounded $C \subseteq \kappa^+$ such that $C \cap \alpha = C_\alpha$ for all $\alpha \in \mathrm{acc}(C)$. Much of the strength of $\square_\kappa$ lies in the fact that it is useful for constructing other non-compact objects of size κ^+. In particular, non-reflecting stationary sets are a natural example of such objects, and the following well-known argument (credited to Magidor in [5] and to Jensen in [51]) shows us that they are quite abundant in the presence of squares.

2.4 Theorem. *Suppose that $\square_\kappa$ holds for a given uncountable cardinal κ. Then* $\mathrm{Refl}(S)$ *fails for every stationary $S \subseteq \kappa^+$.*

Proof. Let S be a stationary subset of κ^+, and suppose that $\langle C_\alpha : \alpha < \kappa^+\rangle$ is a $\square_\kappa$-sequence. For each limit ordinal $\alpha < \kappa^+$, let $f(\alpha) = \mathrm{ot}(C_\alpha)$. Clearly this is a regressive function on $S \setminus \kappa + 1$, and so we can find a stationary $T \subseteq S$ on which f is constant.

For $\alpha < \kappa^+$ of uncountable cofinality and $\beta \in \operatorname{acc}(C_\alpha)$, we have

$$f(\beta) = \operatorname{ot}(C_\beta) = \operatorname{ot}(C_\alpha \cap \beta).$$

Thus the function f is one-to-one on $\operatorname{acc}(C_\alpha)$, hence $|T \cap \operatorname{acc}(C_\alpha)| \leq 1$. This immediately implies that $T \cap \alpha$ is not stationary in α and therefore T is a non-reflecting stationary subset of S. ⊣

This is only one example of the ways in which a $\square_\kappa$-sequence can be used to construct non-compact objects of size κ^+. Jensen's original paper [52] uses such sequences together with the Generalized Continuum Hypothesis to construct κ^+-Souslin trees for every uncountable κ. Devlin's book [19] contains a nice exposition of this result, and Todorčević's chapter [98] in this Handbook contains other examples of applications of square in combinatorial set theory.

In light of Theorem 2.4 and Theorem 2.3, it is natural to ask about the effect that large cardinals have on the problem of stationary reflection. We begin with an argument of Solovay that forms part of the background for Magidor's paper [62].

2.5 Theorem. *Suppose that κ is a supercompact cardinal, and $\lambda > \kappa$ is regular. Then* $\operatorname{Refl}(S)$ *holds for every stationary subset of $S^\lambda_{<\kappa}$.*

Proof. Let $S \subseteq S^\lambda_{<\kappa}$, and let j be a λ-supercompact embedding with critical point κ. Let $\rho = \sup\{j(\alpha) : \alpha < \lambda\}$, and note that since

$$M \models \operatorname{cf}(\rho) = \lambda < \rho \quad \text{and} \quad j(\lambda) \text{ is regular},$$

it follows that $\rho < j(\lambda)$.

Thus, if we can show

$$M \models j(S) \cap \rho \text{ is stationary in } \rho \tag{15.6}$$

then the elementarity of j allows us to conclude that $S \cap \alpha$ is stationary in α for some $\alpha < \lambda$. We actually achieve a bit more than (15.6); we show that $j(S) \cap \rho$ is a stationary subset of ρ even in the larger universe V.

Let $C \subseteq \rho$ be closed and unbounded, and consider $D := j^{-1}[C]$. Since $\kappa = \operatorname{crit}(j)$, it follows easily that D is $<\kappa$-club in λ. Since S is a stationary subset of $S^\lambda_{<\kappa}$, we can find $\xi \in D \cap S$. Clearly $j(\xi) \in j(S) \cap C$, so (15.6) follows. ⊣

A few remarks are in order here. First, we note that the above proof only serves to prove that S reflects at an ordinal θ whose cofinality is less than κ. This result is sharp, as we shall see later in Corollary 4.9.

Second, we note that essentially the same proof shows us that given a sequence $\langle S_i : i < \epsilon\rangle$ such that $\epsilon < \kappa$ and each S_i is a stationary subset of $S^\lambda_{<\kappa}$, there is an ordinal $\theta \in S^\lambda_{<\kappa}$ with $S_i \cap \theta$ stationary for all $i < \epsilon$.

Finally, we have the following corollary (also due to Solovay) which gives us our first examples of singular cardinals μ for which $\operatorname{Refl}(\mu^+)$ holds.

2.6 Corollary. *Let μ be a singular limit of supercompact cardinals. Then every stationary subset of μ^+ reflects.*

Proof. Since μ is singular, any stationary subset of μ^+ contains a stationary subset of some fixed cofinality $\theta < \mu$. There is a supercompact cardinal κ with $\theta < \kappa < \mu^+$ and the result follows immediately from Theorem 2.5. $\dashv$

2.2. Reflection and Indecomposable Ultrafilters

The paper [95] credits Gregory with the observation that the conclusion of Theorem 2.5 still holds even if κ is only strongly compact. This is fairly easy to see—essentially the same proof works because of Proposition 1.21. However, the proof given in [95] applies in many more situations, as it establishes a relationship between stationary reflection and indecomposable ultrafilters. In this subsection we examine this line of reasoning.

The following definition is due to Keisler, though Prikry's [71] seems to be the first place where it appears in the literature.

2.7 Definition. Let $\mathcal{U}$ be a uniform ultrafilter on a set A, and let τ be a cardinal. We say that $\mathcal{U}$ is *τ-decomposable* if there is a sequence $\langle A_i : i < \tau \rangle$ of sets such that

$$A = \bigcup_{i<\tau} A_i$$

but

$$\bigcup_{i\in B} A_i \notin \mathcal{U} \quad \text{for each } B \in [\tau]^{<\tau}.$$

We say that $\mathcal{U}$ is *τ-indecomposable* if it is not τ-decomposable. The ultrafilter $\mathcal{U}$ is *indecomposable* if it is τ-indecomposable for all τ with $\aleph_0 < \tau < |A|$.

Indecomposability can be viewed as a weak form of completeness. This is made clear by the following elementary proposition from [71], which connects indecomposability of filters with the closely related notion of descendingly complete filters first studied in [11, 60], and [71].

2.8 Proposition. *If τ is a regular cardinal and $\mathcal{U}$ is a uniform ultrafilter on some cardinal κ, then $\mathcal{U}$ is τ-indecomposable if and only if $\mathcal{U}$ is closed under decreasing intersections of length τ.*

The reason we bring up this topic is that there is a connection between indecomposable ultrafilters and stationary reflection, and the following theorem of Silver and Prikry [71] makes this clear.

2.9 Theorem. *If $\kappa < \lambda$ are regular cardinals and there is a uniform κ-indecomposable ultrafilter on λ, then* $\mathrm{Refl}(S^\lambda_\kappa)$ *holds.*

Before we give the proof, we point out a couple of corollaries illustrating how strongly compact cardinals serve just as well as supercompact cardinals with regard to the reflection results presented in the previous subsection.

2.10 Corollary. *Suppose that κ is strongly compact. Then* $\mathrm{Refl}(S^\lambda_\theta)$ *holds for all regular cardinals θ and λ with $\theta < \kappa < \lambda$.*

Proof. This is easy given our previous work. Since κ is strongly compact, there is a uniform κ-complete ultrafilter on λ. Such an ultrafilter is trivially θ-indecomposable for $\theta < \kappa$, and so we apply Theorem 2.9 to get the conclusion. ⊣

2.11 Corollary. *Let μ be a singular cardinal that is a limit of compact cardinals. Then every stationary subset of μ^+ reflects.*

To prove Theorem 2.9, we rely on an argument attributed by the authors of [95] to an anonymous referee.

2.12 Lemma. *Suppose that S is a non-reflecting (not necessarily stationary) subset of S^λ_κ for some regular $\kappa < \lambda$, and that for each $\delta \in S$, A_δ is a cofinal subset of δ of order-type κ. Then for each $\alpha < \lambda$, there is a regressive function F_α with domain $S \cap \alpha$ such that the family $\{A_\delta \setminus F_\alpha(\delta) : \delta \in S \cap \alpha\}$ is disjoint. In plain terms, for each $\alpha < \lambda$ the family $\{A_\delta : \delta \in S \cap \alpha\}$ can be made pairwise disjoint by removing a bounded set from each A_δ.*

Proof. The proof is by induction on α, with the cases where $\alpha = 0$ or $\alpha = \beta+1$ for $\beta \notin S$ being straightforward.

If α is a limit ordinal, then we choose a closed unbounded $C \subseteq \alpha$ disjoint to S. Thus, every $\delta \in S \cap \alpha$ will fall into an interval of the form (γ, ϵ) where γ and ϵ are consecutive members of C. It is straightforward to check that if we define

$$F_\alpha(\delta) = \max\{F_\epsilon(\delta), \gamma\},$$

then everything works as it should.

The only other troublesome case is when $\alpha = \delta + 1$ for some $\delta \in S$. In this case, we use the fact that A_δ has order-type κ, as this means that for $\gamma \in S \cap \delta$, the set $A_\gamma \cap A_\delta$ is bounded below γ. So we may define

$$F_\alpha(\gamma) = \max\{F_\delta(\gamma), \sup(A_\delta \cap A_\gamma)\}$$

for $\gamma \in S \cap \delta$, and let $F_\alpha(\delta) = 0$. ⊣

The preceding lemma has some importance in general topology, for it is a crucial ingredient in Fleissner's proof [29, 30] of the necessity of large cardinals in Nyikos' celebrated result [70] (assuming the existence of a strongly compact cardinal) that consistently all normal Moore spaces are metrizable.

In the next lemma, we show that uniform κ-indecomposable ultrafilters allow us to patch together the functions F_α from the previous lemma in order to obtain a single function that works simultaneously for all A_δ.

2.13 Lemma. *Let $\kappa < \lambda$ be regular cardinals, and assume $\mathcal{U}$ is a uniform κ-indecomposable ultrafilter on λ. If we are given a family $\{A_\alpha : \alpha < \lambda\}$ of sets, each of order-type κ, with the property that for each $\beta < \lambda$ there is a function F_β with domain β such that*

1. *$F_\beta(\alpha)$ is a proper initial segment of A_α, and*

2. *the family $\{A_\alpha \setminus F_\beta(\alpha) : \alpha < \beta\}$ is disjoint,*

then in fact there is a function F with domain λ such that

1. *$F(\alpha)$ is a proper initial segment of A_α, and*

2. *the family $\{A_\alpha \setminus F(\alpha) : \alpha < \lambda\}$ is disjoint.*

Proof. Fix $\alpha < \lambda$. For each $\epsilon < \kappa$, let B^α_ϵ consist of all those $\beta < \lambda$ for which $F_\beta(\alpha)$ is contained in the first epsilon elements of A_α, that is,

$$B^\alpha_\epsilon := \{\beta < \lambda : \mathrm{ot}(F_\beta(\alpha)) < \epsilon\}.$$

Since the sequence $\langle B^\alpha_\epsilon : \epsilon < \kappa\rangle$ is increasing with union $\lambda \setminus \alpha$, the κ-indecomposability of $\mathcal{U}$ tells us there is an $\epsilon(\alpha) < \kappa$ such that

$$B^\alpha_{\epsilon(\alpha)} \in \mathcal{U}.$$

Now let us define $F(\alpha)$ to be the first $\epsilon(\alpha)$ elements of A_α. We claim that the collection $\{A_\alpha : \backslash F(\alpha) : \alpha < \lambda\}$ is pairwise disjoint.

To see this, suppose that $\alpha < \gamma < \lambda$. Both of the sets $B^\alpha_{\epsilon(\alpha)}$ and $B^\gamma_{\epsilon(\gamma)}$ are in $\mathcal{U}$, so we can find β in their intersection. By the definition of F_β, we know

$$(A_\alpha \setminus F_\beta(\alpha)) \cap (A_\gamma \setminus F_\beta(\gamma)) = \emptyset,$$

and since $F_\beta(\alpha) \subseteq F(\alpha)$ and $F_\beta(\gamma) \subseteq F(\gamma)$, the result follows. ⊣

We are now ready to give the proof of Theorem 2.9.

Proof of Theorem 2.9. Let $\mathcal{U}$ be a uniform κ-indecomposable ultrafilter on λ, and assume by way of contradiction that S is a non-reflecting stationary subset of S^λ_κ. For each $\delta \in S$, we choose a cofinal A_δ of order-type κ, and note that by Lemma 2.12, the family $\{A_\delta : \delta \in S\}$ satisfies the assumptions of Lemma 2.13. Since S is stationary, the function provided by Lemma 2.13 must be constant on some stationary $T \subseteq S$, say with value β. We can assume that $\beta < \min(T)$, and so the sets of the form $A_\delta \setminus \beta$ for $\delta \in T$ are non-empty and pairwise disjoint. However, A_δ is a subset of δ, and so any choice function for this collection contradicts Fodor's Theorem. ⊣

Theorem 2.9 shows us that the existence of indecomposable uniform ultrafilters at the successor of a singular cardinal has high consistency strength, for such ultrafilters are incompatible with $\square$. However, Ben-David and Magidor [7] were able to produce a model in which $\aleph_{\omega+1}$ carries a uniform indecomposable ultrafilter by starting with a supercompact cardinal.

2.14 Theorem (Ben-David and Magidor [7]). *Let V be a model of* ZFC *with a cardinal κ that is κ^+-supercompact. Then there is a forcing extension V' of V such that*

1. $V' \models \kappa = \aleph_\omega$ and $\kappa^+ = \aleph_{\omega+1}$, and

2. in V', $\aleph_{\omega+1}$ carries an indecomposable ultrafilter.

In particular, in their model every stationary subset of $\aleph_{\omega+1}$ made up of ordinals of uncountable cofinality must reflect. This "near miss" brings us to Magidor's construction of a model in which *every* stationary subset of $\aleph_{\omega+1}$ reflects.

2.3. Reflection at $\aleph_{\omega+1}$—Introduction

2.15 Theorem (Magidor [62]). *If the existence of infinitely many supercompact cardinals is consistent, then it is consistent to assume that every stationary subset of $\aleph_{\omega+1}$ reflects.*

Let $\langle \kappa_n : n < \omega \rangle$ be an increasing sequence of supercompact cardinals. Define $\mu = \sup_{n<\omega} \kappa_n$ and $\lambda = \mu^+$. Corollary 2.6 tells us that every stationary subset of λ reflects, and our strategy to transfer this down to $\aleph_{\omega+1}$ is a natural one—we define a notion of forcing $\mathbb{P}$ so that in the generic extension $V[G_\omega]$, κ_n becomes $\aleph_{n+1}$, μ becomes $\aleph_\omega$, and λ becomes $\aleph_{\omega+1}$.

This is done in a straightforward fashion, with the iteration $\langle \mathbb{P}_n, \dot{\mathbb{Q}}_n : n < \omega \rangle$ defined by setting

$$\mathbb{P}_0 = \mathrm{Col}(\omega, {<}\kappa_0)$$

and

$$V^{\mathbb{P}_n} \models \dot{\mathbb{Q}}_n = \mathrm{Col}(\kappa_n, {<}\kappa_{n+1}).$$

We let $\mathbb{P}_\omega$ be the inverse limit of this iteration.

Each κ_n is inaccessible so it follows easily that $\mathbb{P}_n$ satisfies the κ_n-chain condition. Note as well that for each n, we can factor $\mathbb{P}_\omega$ as $\mathbb{P}_n * \mathbb{P}^n$ where $\mathbb{P}^n$ is κ_n-closed. Thus, every sequence of ordinals of length less than κ_n added by forcing with $\mathbb{P}_\omega$ must lie in the initial generic extension obtained by forcing with $\mathbb{P}_n$. From this, we conclude that after forcing with $\mathbb{P}_\omega$, each κ_n has been collapsed to $\aleph_{n+1}$, μ has become $\aleph_\omega$, and λ has become $\aleph_{\omega+1}$.

The supercompactness of each κ_n survives in a vestigial way—in the terminology of [31], each κ_n is *generically supercompact*. We give a more precise description of this below.

Let $G \subseteq \mathbb{P}_\omega$ be generic, and let θ be a regular cardinal larger than κ_n. In $V[G]$, there is an $\aleph_n$-closed notion of forcing $\mathbb{R}$ such that if H is a $V[G]$-generic subset of $\mathbb{R}$, then in the extension $V[G * H]$ there is an elementary embedding $j : V[G] \to M \subseteq V[G * H]$ (for some transitive M) satisfying

1. $\mathrm{crit}(j) = \kappa_n$,

2. $j \restriction \theta \in M$, and

3. $j(\kappa_n) > \theta$.

Thus, in a sense the $\aleph_n$-closed forcing $\mathbb{R}$ resurrects the θ-supercompactness of κ_n and the corresponding elementary embedding is called a *generic elementary embedding.* Rather than digressing into the topic of forcing and large cardinals, we will use the preceding fact as a so-called black box. We refer the reader to Magidor's original paper [62] or Cummings' [13] for more details.

We proceed by trying to imitate the proof of Theorem 2.5 using a generic elementary embedding instead of an honest-to-goodness one. In $V[G]$, suppose that S is a stationary subset of $\lambda = \aleph_{\omega+1}$ consisting of ordinals of cofinality $\aleph_n$ for some $n < \omega$. By the generic supercompactness of $\aleph_{n+2} = \kappa_{n+1}$, there is an $\aleph_{n+1}$-closed notion of forcing $\mathbb{R}$ such that, letting $H \subseteq \mathbb{R}$ be $V[G]$-generic, in the model $V[G][H]$ we can find a transitive M and elementary $j : V[G] \to M$ satisfying

- $\mathrm{crit}(j) = \kappa_{n+1} = \aleph_{n+2}$,
- $j \restriction \lambda \in M$, and
- $j(\kappa_{n+1}) > \lambda$.

Just as in the proof of Theorem 2.5, one can argue

$$\rho := \sup\{j(\alpha) : \alpha < \lambda\} < j(\lambda), \tag{15.7}$$

but we run into a problem trying to show

$$M \models j(S) \cap \rho \text{ is stationary in } \rho. \tag{15.8}$$

The difficulty arises because we need to know that S remains stationary in $V[G * H]$. The question of whether this must be so will occupy us in the next subsection.

2.4. κ^+-closed Forcing and Stationary Subsets of S^λ_κ

Our investigations in the preceding subsection have led us to the following question:

> Suppose that $\kappa < \lambda$ are regular cardinals, and let S be a stationary subset of S^λ_κ, and let $\mathbb{P}$ be a κ^+-closed notion of forcing. Is the stationarity of S preserved when forcing with $\mathbb{P}$?

If $\lambda = \kappa^+$, then the answer is an easy "yes"—a simple argument establishes that λ-closed forcing preserves all stationary subsets of λ. Thus, for example, $\aleph_1$-closed forcing preserves the stationary of subsets of $\aleph_1$. However, in this case, a little more work establishes a much stronger result due to Baumgartner [5].

2.16 Proposition. *Let λ be an uncountable regular cardinal, and let $\mathbb{P}$ be an $\aleph_1$-closed notion of forcing. Then every stationary subset of $S^\lambda_{\aleph_0}$ remains stationary in the $\mathbb{P}$-generic extension.*

Proof. Suppose that $\mathbb{P}$ is $\aleph_1$-closed, and suppose that $S \subseteq S^\lambda_{\aleph_0}$ is stationary. Let $\dot{C}$ be a $\mathbb{P}$-name such that

$$V^{\mathbb{P}} \models \dot{C} \text{ is a closed unbounded subset of } \lambda.$$

We show that the set of conditions in $\mathbb{P}$ which force $S \cap \dot{C}$ to be non-empty is dense in $\mathbb{P}$. Toward this end, let $p \in \mathbb{P}$ be arbitrary.

Since S is stationary, we can find a model $M \prec H(\chi)$ containing everything relevant such that $M \cap \lambda$ is some ordinal $\delta \in S$. Let $\langle \alpha_n : n < \omega \rangle$ be increasing and cofinal in δ. By induction on $n < \omega$, we choose a sequence $\langle p_n : n < \omega \rangle$ as follows:

Let $p_0 = p$. Given p_n, let p_{n+1} be the $<_\chi$-least extension of p_n in $\mathbb{P}$ that decides a value for $\min(\dot{C} \setminus \alpha_n)$, say

$$p_{n+1} \Vdash \min(\dot{C} \setminus \alpha_n) = \delta_n \tag{15.9}$$

for some $\delta_n < \lambda$.

Note that p_{n+1} is definable in $H(\chi)$ from p_n and parameters in M. Thus an easy induction shows that each p_n is an element of M, and it follows that each δ_n is in M as well. The sequence $\langle \delta_n : n < \omega \rangle$ is non-decreasing, and the range is cofinal in δ. Since $\mathbb{P}$ is $\aleph_1$-closed, the sequence $\langle p_n : n < \omega \rangle$ has a lower bound q, and q forces δ to be an accumulation point of $\dot{C}$, hence

$$q \Vdash \delta \in S \cap \dot{C}, \tag{15.10}$$

as required. $\dashv$

Now what goes wrong when we replace $S^\lambda_{\aleph_0}$ with S^λ_κ for κ uncountable? Suppose that S is a stationary subset of S^λ_κ (with κ an uncountable regular cardinal) and let $\mathbb{P}$ be a κ^+-closed notion of forcing. Suppose that $\dot{C}$ is a $\mathbb{P}$-name for a closed unbounded subset of λ, and let p be a condition in $\mathbb{P}$. We can certainly find $M \prec H(\chi)$ containing everything relevant such that $M \cap \lambda$ is some ordinal $\delta \in S$. We can also fix an increasing sequence $\langle a_\alpha : \alpha < \kappa \rangle$ cofinal in δ. Just as before, we define a decreasing sequence of conditions $\langle p_\alpha : \alpha < \kappa \rangle$ so that $p_0 = p$ and

$$p_{\alpha+1} \Vdash \min(\dot{C} \setminus a_\alpha) = \delta_\alpha \tag{15.11}$$

for some $\delta_\alpha < \lambda$. The problem arises in that we cannot guarantee that $\delta = \sup\{\delta_\alpha : \alpha < \kappa\}$—in the earlier construction we were always assured that $\delta_n < \delta$ because $p_{n+1} \in M$. In our current situation, this need not happen. Consider what happens at stage ω—in order to keep the construction going inside M, we need to know that $\langle p_\alpha : \alpha < \omega \rangle \in M$, and we do not know this unless it happens that $\langle a_\alpha : \alpha < \omega \rangle \in M$. In order for our proof to generalize, we need to be able to choose the sequence $\langle a_\alpha : \alpha < \kappa \rangle$ in such a way that every initial segment lies in M. This will be possible under mild cardinal arithmetic assumptions—for example, in certain circumstances we can arrange for M to be closed under sequences of length less than κ—but it need not happen in general. We will deal with the question of when such a sequence $\langle a_\alpha : \alpha < \kappa\rangle$ exists a bit later on, but for now we will be content with the following *ad hoc* definitions and theorem implicit in [83]:

2.17 Definition. Let $\kappa < \lambda$ be regular cardinals, and let S be a stationary subset of S^λ_κ.

1. We say that S is κ^+*-closed indestructible* if for every κ^+-closed notion of forcing $\mathbb{P}$,
$$V^{\mathbb{P}} \models S \text{ is a stationary subset of } \lambda. \tag{15.12}$$
2. S is said to satisfy the κ^+*-closed indestructibility condition* if for every $x \in H(\chi)$, there are $M \prec H(\chi)$, $\delta \in S$, and cofinal $A \subseteq \delta$ such that
   - $x \in M$,
   - $M \cap \lambda = \delta$,
   - $\mathrm{ot}(A) = \mathrm{cf}(\delta) = \kappa$, and
   - every initial segment of A is in M.

2.18 Theorem. *Let κ and λ be regular cardinals, with $\kappa^+ < \lambda$. A stationary $S \subseteq S^\lambda_\kappa$ satisfies the κ^+-closed indestructibility condition if and only if S is κ^+-closed indestructible.*

Proof. If S satisfies the κ^+-closed indestructibility condition, then the argument that S is actually κ^+-closed indestructible is a simple modification of that given in Proposition 2.16. We leave this to the reader, and concentrate on the other direction. Our first step is an easy lemma.

2.19 Lemma. *Let $\kappa < \lambda$ be regular. A stationary $S \subseteq S^\lambda_\kappa$ satisfies the κ^+-indestructibility condition if and only if it satisfies the weaker version where instead of* $\mathrm{ot}(A) = \kappa$ *we demand only that* $\mathrm{ot}(A) < \delta$*.*

Proof. Note that the only difference between the two conditions is that we have weakened the demands on $A \subseteq \delta$. Suppose that we are given M, δ, and $A = \langle a_\alpha : \alpha < \mathrm{ot}(A)\rangle$ satisfying the weaker requirements.

Since $\mathrm{ot}(A) < \delta$, it follows that $\mathrm{ot}(A) \in M$. Since $\mathrm{cf}(\mathrm{ot}(A)) = \kappa$, we can find an increasing function $f : \kappa \to \mathrm{ot}(A)$ in M with range cofinal in $\mathrm{ot}(A)$. Clearly $\langle a_{f(\alpha)} : \alpha < \kappa\rangle$ is cofinal in δ and of order-type κ. To finish, note that every initial segment of $\langle a_{f(\alpha)} : \alpha < \kappa\rangle$ is in M because each such segment is definable from f and an initial segment of A. $\dashv$

To finish the proof of Theorem 2.18, we assume that $S \subseteq S^\lambda_\kappa$ does not satisfy the κ^+-indestructibility condition and we show that there is a κ^+-closed notion of forcing $\mathbb{P}$ that destroys the stationarity of S.

By assumption, there is a large regular χ and an $x \in H(\chi)$ so that whenever $M \prec H(\chi)$ is chosen with $x \in M$ and $M \cap \lambda = \delta \in S$, there is no cofinal $A \subseteq \delta$ of order-type κ with every initial segment of A in M.

Temporarily assume that $\lambda = \lambda^{<\lambda}$, and let $\bar{A} = \langle A_\alpha : \alpha < \lambda\rangle$ enumerate $[\lambda]^{<\lambda}$ so that every set in $[\lambda]^{<\lambda}$ appears unboundedly often.

A forcing condition p is an increasing continuous function such that

- $\mathrm{dom}(p)$ is an initial segment of κ^+,
- $\mathrm{ran}(p) \subseteq \lambda \setminus \kappa^+$, and
- for all $\alpha \in \mathrm{nacc}(\mathrm{dom}(p))$, $\{p(\beta) : \beta < \alpha\} = A_{p(\alpha)}$.

A condition q *extends* p if and only if p is an initial segment of q.

It should be clear that $\mathbb{P}$ is κ^+-closed. An easy density argument establishes that forcing with $\mathbb{P}$ adjoins a function $f : \kappa^+ \to \lambda$ with range cofinal in λ. Since $\mathbb{P}$ is κ^+-closed, we can conclude that in the generic extension λ is an ordinal of cofinality κ^+.

Let G be a generic subset of $\mathbb{P}$, and step into the model $V[G]$. As mentioned before, the generic object is essentially an increasing function $f : \kappa^+ \to \lambda$. Let us define $C := \mathrm{acc}(\mathrm{ran}(f))$, and let $\dot{C}$ be a $\mathbb{P}$-name for C. It is clear

$$V^{\mathbb{P}} \models \dot{C} \text{ is closed and unbounded in } \lambda. \tag{15.13}$$

Back in the ground model, let $E \subseteq \lambda$ consist of all $\delta < \lambda$ for which there is an $M \prec H(\chi)$ with $\{x, \lambda, \mathbb{P}, \dot{C}, S, \bar{A}\} \in M$ and $M \cap \lambda = \delta$. Since E contains a closed unbounded subset of λ, it suffices to prove

$$V[G] \models S \cap E \cap \dot{C} = \emptyset. \tag{15.14}$$

If this fails, then we can find a condition $p \in \mathbb{P}$ and ordinal $\delta < \lambda$ such that

$$p \Vdash \delta \in S \cap \dot{C} \cap E. \tag{15.15}$$

Since δ must actually be an element of $S \cap E$, in the ground model we can find a model $M \prec H(\chi)$ confirming δ's membership in E.

Since p forces δ to be in $\dot{C}$, there must be a $\theta \leq \mathrm{dom}(p)$ such that $B := \{p(\alpha) : \alpha < \theta\}$ is cofinal in δ—otherwise, we could extend p to a condition forcing that δ is not in $\dot{C}$. Since $\theta < \kappa^+$, we certainly know $\mathrm{ot}(B) < \delta$. For $\alpha < \theta$, we have $p(\alpha) < \delta$ hence $p(\alpha) \in M$. Since $\bar{A} \in M$, we conclude that $A_{p(\alpha)} \in M$. But $A_{p(\alpha)} = B \cap \alpha$, and thus every initial segment of B lies in the model M. This contradicts our assumption that S does not satisfy the κ^+-closed indestructibility condition.

Our requirement that $\lambda = \lambda^{<\lambda}$ in the above discussion is not an obstacle, as we can first force with the λ-closed notion of forcing $\mathrm{Col}(\lambda, \lambda^{<\lambda})$, and in this extension define $\mathbb{P}$ as above. The composition of these two notions of forcing will destroy the stationarity of S. ⊣

The following lemma gives us a slightly more general condition guaranteeing that a stationary set satisfies the κ^+-indestructibility criterion, at least in the presence of some cardinal arithmetic considerations. We will make use of this in the next subsection.

2.20 Lemma. *Suppose that $\kappa < \lambda$ are regular cardinals with $\lambda = \mu^+$ for a strong limit singular μ. A stationary $S \subseteq S^\lambda_\kappa$ satisfies the κ^+-indestructibility condition if and only if for every $x \in H(\chi)$, there are $M \prec H(\chi)$, $\delta \in S$, and cofinal $A \subseteq \delta$ such that*

- $x \in M$,
- $M \cap \lambda = \delta$,
- $\mathrm{ot}(A) < \delta$, *and*
- *every initial segment of A is covered by a set in $M \cap [\lambda]^{<\mu}$.*

Proof. Let M, δ, and A be as above. Without loss of generality, each of μ, κ, and λ is in M, and so $\mu \subseteq M$. Given $\beta < \delta$, our hypotheses give us a set $B \in M \cap [\lambda]^{<\mu}$ such that $A \cap \beta \subseteq B$. We assume μ is a strong limit, so $2^{|B|} < \mu$. In M, there is a function f mapping $2^{|B|}$ onto the power set of B, and since $2^{|B|} \subseteq M$, it follows that $\mathcal{P}(B) \subseteq M$ as well. In particular, $A \cap \beta \in M$. $\dashv$

As a final remark, we note that the restriction to $\kappa^+ < \lambda$ in the results of this subsection is reasonable, as λ-closed forcing preserves all stationary subsets of λ. This said, we return now to Magidor's proof.

2.5. Reflection at $\aleph_{\omega+1}$—Conclusion

Our goal is this subsection is to finish the proof that in the model from Sect. 2.3, every stationary subset of $\aleph_{\omega+1}$ reflects. The main point is to verify that in $V[G_\omega]$, every stationary subset of $\aleph_{\omega+1}$ satisfies the appropriate version of the indestructibility condition from Definition 2.17.

Recall that in the ground model we are given the following:

- $\langle \kappa_n : n < \omega \rangle$ is an increasing sequence of supercompact cardinals
- $\mu = \sup_{n<\omega} \kappa_n$, and
- $\lambda = \mu^+$.

Our notion of forcing $\mathbb{P}_\omega$ collapses each κ_n to $\aleph_{n+1}$, makes $\mu = \aleph_\omega$, and makes $\lambda = \aleph_{\omega+1}$. We had no occasion to mention it before, but it is clear that $\aleph_\omega$ is a strong limit cardinal in the generic extension—this is important for us because we will be using Lemma 2.20.

Goal: In the model $V[G_\omega]$, if S is a stationary subset of $S^{\aleph_{\omega+1}}_{\aleph_n}$ then S satisfies the $\aleph_{n+1}$-indestructibility condition.

We will reach our goal in a roundabout fashion. Back in the ground model, let us fix a λ-filtration system $\langle b_{\alpha,i} : \alpha < \lambda, i < \omega \rangle$ with $|b_{\alpha,i}| \leq \kappa_i$. Let d be the associated coloring of $[\lambda]^2$, that is,

$$d(\beta, \alpha) = \text{least } i \text{ such that } \beta \in b_{\alpha,i}$$

It is clear that $d : [\lambda]^2 \to \omega$, and the following lemma of Shelah establishes a crucial property of d in $V[G_\omega]$.

2.21 Proposition. *In $V[G_\omega]$, if $\delta \in \lambda \setminus \mu$ is a limit ordinal of uncountable cofinality, then there is an unbounded $H_\delta \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ that is homogeneous for the coloring d.*

Proof. Suppose that in $V[G_\omega]$, $\delta < \aleph_{\omega+1}$ has uncountable cofinality and $|\delta| = \aleph_\omega$. Back in the ground model, there is an $n < \omega$ such that

$$V \models \kappa_n \le \mathrm{cf}(\delta) < \kappa_{n+1}. \tag{15.16}$$

Since κ_n is supercompact, there is a κ_n-complete ultrafilter $\mathcal{U}$ on δ containing all co-bounded subsets of δ. In particular, $\mathcal{U}$ is countably complete so that for each $\beta < \delta$, there is a unique $i(\beta) < \omega$ such that

$$B_\beta := \{\alpha \in (\beta, \delta) : d(\beta, \alpha) = i(\beta)\} \in \mathcal{U}. \tag{15.17}$$

2.22 Claim. *In $V[G_\omega]$, if $\langle \beta_\zeta : \zeta < \xi \rangle$ is a sequence of ordinals less than δ of length less than κ_n, then $\bigcap_{\zeta<\xi} B_{\beta_\zeta}$ contains a set from $\mathcal{U}$.*

Proof. Note that this is not automatic—in $V[G_\omega]$ the filter generated by $\mathcal{U}$ need not be κ_n-complete. We note, however, that $\langle \beta_\zeta : \zeta < \xi \rangle$ already lies in the P_n-generic extension $V[G_n]$, and hence the sequence $\langle B_{\beta_\zeta} : \zeta < \xi \rangle$ is in $V[G_n]$ as well. Since P_n satisfies the κ_n-chain condition, it follows that in $V[G_n]$ the filter on δ generated by $\mathcal{U}$ is still κ_n-complete and the conclusion is immediate. ⊣

We are now ready to construct the required H_δ in $V[G_\omega]$. We define a sequence $\langle \beta_\xi : \xi < \kappa_n \rangle$ by induction on ξ. To start, let $\beta_0 < \delta$ be arbitrary. Given $\langle \beta_\zeta : \zeta < \xi \rangle$, define

$$\beta_\xi := \text{least member of } \textstyle\bigcap_{\zeta<\xi} B_{\beta_\zeta} \text{ greater than } \alpha_\xi. \tag{15.18}$$

Note that $\bigcap_{\zeta<\xi} B_{\beta_\zeta}$ contains a set from $\mathcal{U}$ by Claim 2.22, and so a suitable β_ξ can always be defined.

It is clear that $\langle \beta_\xi : \xi < \kappa_n \rangle$ is cofinal in δ, and the sequence is constructed so that for $\zeta < \xi < \kappa_n$ the value of $d(\beta_\zeta, \beta_\xi)$ depends only on β_ζ. Since $\kappa_n = \aleph_{n+1}$ is uncountable, there is an unbounded $H_\delta \subseteq \{\beta_\xi : \xi < \kappa_n\}$ such that $d \restriction [H_\delta]^2$ is constant, and the proof of Proposition 2.21 is complete. ⊣

Our next task is to relate Proposition 2.21 to the problem of preserving stationary sets in forcing conditions. Suppose that $n < \omega$ is given, and let $S \subseteq S^{\aleph_{\omega+1}}_{\aleph_n}$ be stationary. If $n = 0$, then S automatically remains stationary in an $\aleph_1$-closed forcing extension, so assume $n > 0$. In $V[G_\omega]$, let $x \in H(\chi)$ be given and fix a model $M \prec H(\chi)^{V[G_\omega]}$ such that

- $\{x, S, \langle b_{\alpha,i} : i < \omega, \alpha < \lambda\rangle\} \in M$, and
- $M \cap \lambda = \delta \in S$.

By Proposition 2.21, there is an unbounded $H \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ homogeneous for the coloring c, say $c \restriction [H]^2$ is constant with value i. Given $\beta \in H$, it follows that

$$H \cap \beta \subseteq b_{\beta,i}. \tag{15.19}$$

Now $b_{\beta,i} \in M \cap [\aleph_{\omega+1}]^{<\aleph_\omega}$, and since $\aleph_\omega$ is a strong limit cardinal in $V[G_\omega]$, we apply Lemma 2.20 and conclude that S satisfies the $\aleph_{n+1}$-closed indestructibility condition. By our comments at the end of Sect. 2.3, it follows that in $V[G_\omega]$ every stationary subset of $\aleph_{\omega+1}$ reflects.

3. On $I[\lambda]$

The goal of this section is to re-examine issues surrounding the somewhat *ad hoc* notion of the "κ^+-closed indestructibility condition" (Definition 2.17). The investigation will lead us to several important concepts, with $I[\lambda]$ and approachability being the most prominent. We will develop the theory of $I[\lambda]$ in some detail in order to demonstrate its importance for combinatorial set theory. All unattributed results in this section are due to Shelah, although in some cases the theorems as stated may only be implicit in his work.

Let us begin our discussion by recalling the definition of the κ^+-closed indestructibility condition. Let $\kappa < \lambda$ be regular, and let χ be a sufficiently large regular cardinal. A stationary $S \subseteq S^\lambda_\kappa$ satisfies the κ^+-closed indestructibility condition if and only if for any $x \in H(\chi)$, there is a model $M \prec H(\chi)$ such that

- $x \in M$,
- $M \cap \lambda$ is an ordinal $\delta \in S$, and
- there is a cofinal $A \subseteq \delta$ of order-type κ, all of whose initial segments lie in M.

One way to look at this is that the set A is built from initial segments that are simpler (in some vague way) than δ. If it happens that $\lambda = \lambda^{<\lambda}$, then we can give a precise meaning to "simpler", as illustrated by the following proposition.

3.1 Proposition. *Assume $\lambda = \lambda^{<\lambda}$, and fix an enumeration $\bar{a}$ of $[\lambda]^{<\lambda}$ in order-type λ. A set $S \subseteq S^\lambda_\kappa$ satisfies the κ^+-indestructibility condition if and only if there are stationarily many $\delta \in S$ for which there is a cofinal $A_\delta \subseteq \delta$ of order-type κ with every initial segment of A_δ enumerated prior to stage δ.*

Proof. First, assume that S satisfies the indestructibility condition. Let χ be a sufficiently large regular cardinal, and suppose that we are given $x \in H(\chi)$ and a closed unbounded $C \subseteq \lambda$. By Definition 2.17, we know there is a model $M \prec H(\chi)$ such that

- $\{x, \bar{a}, C\} \in M$,
- $M \cap \lambda = \delta \in S$, and
- there is a cofinal $A \subseteq \delta$ of order-type κ with every initial segment lying in M.

Since $C \in M$, we know $\delta \in S \cap C$. Since $\bar{a} \in M$ and $M \cap \lambda = \delta$, we know that $\langle a_\alpha : \alpha < \delta\rangle$ enumerates $M \cap [\lambda]^{<\lambda}$. In particular, since every initial segment of A lies in $M \cap [\lambda]^{<\lambda}$, we have that each such initial segment is enumerated by $\bar{a}$ before stage δ.

For the other direction, assume we are given a sufficiently large regular χ and $x \in H(\chi)$. Let $\langle M_\alpha : \alpha < \lambda\rangle$ be a λ-approximating sequence over $\{x, \kappa, S, \bar{a}\}$. The set of δ with $M_\delta \cap \lambda = \delta$ is closed and unbounded, so we can find such $\delta \in S$ for which a suitable A_δ exists. Since every initial segment of A_δ is enumerated by $\bar{a}$ before stage δ, it follows immediately that every initial segment of A_δ lies in M_δ, as required. $\dashv$

Note that if $\lambda = \mu^+$ for μ singular, $\kappa < \lambda$ is regular, and $\lambda = \lambda^{<\lambda}$, then there is a set $S \subseteq S^\lambda_\kappa$ such that a set $T \subseteq S^\lambda_\kappa$ satisfies the κ^+-closed indestructibility condition if and only if $T \cap S$ is stationary. Why? Simply fix an enumeration $\langle a_\alpha : \alpha < \lambda\rangle$ of $[\lambda]^{<\lambda}$ and let S be the set of all $\delta \in S^\lambda_\kappa$ for which there is a cofinal $A_\delta \subseteq \delta$ of order-type κ with every initial segment of A_δ enumerated before stage δ. In addition, the set S is unique modulo the nonstationary ideal, because if $\langle b_\alpha : \alpha < \lambda\rangle$ is any other enumeration of $[\lambda]^{<\lambda}$ then the set of δ for which $\{a_\alpha : \alpha < \delta\} = \{b_\alpha : \alpha < \delta\}$ is closed and unbounded in λ.

We will not make use of the above observation, but we shall be looking at similar results throughout this section.

3.1. The Ideal $I[\lambda]$

The ideas introduced in the preceding discussion still make sense even without the assumption that $\lambda = \lambda^{<\lambda}$—all that is required is a suitable enumeration $\bar{a}$.

3.2 Definition. Let $\bar{a} = \langle a_\alpha : \alpha < \lambda\rangle$ be a sequence of bounded subsets of λ. A limit ordinal $\delta < \lambda$ is said to be *approachable with respect to the sequence* $\bar{a}$ if there is an unbounded $A \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that every initial segment of A is enumerated by $\bar{a}$ before stage δ, that is,

$$\{A \cap \beta : \beta < \delta\} \subseteq \{a_\beta : \beta < \delta\}. \tag{15.20}$$

Now comes the surprising part—the concept isolated in the preceding definition turns out to be incredibly useful in combinatorial set theory, and most of our time in the current section will be spent supporting this thesis. Our first task is to take Definition 3.2 and use it to define an ideal of subsets of λ.

3.3 Definition. A set $S \subseteq \lambda$ *is in* $I[\lambda]$ if and only if there is a sequence $\bar{a} = \langle a_\alpha : \alpha < \lambda \rangle$ of bounded subsets of λ and a closed unbounded $C \subseteq \lambda$ such that every $\delta \in S \cap C$ is singular and approachable with respect to the sequence $\bar{a}$.

With the preceding definition, we have isolated the most important concept in this section of the chapter. Our first task is to prove that $I[\lambda]$ is in fact an ideal of subsets of λ.

3.4 Proposition. *For λ a regular cardinal, the collection $I[\lambda]$ is a (possibly improper) normal ideal on λ.*

Proof. We verify that $I[\lambda]$ is closed under diagonal unions; the rest of the proof is quite trivial. Suppose that we are given a sequence $\langle S_i : i < \lambda \rangle$ of elements of $I[\lambda]$. For each $i < \lambda$, there are a corresponding enumeration $\bar{a}_i$ and closed unbounded E_i witnessing $S_i \in I[\lambda]$. Using a pairing function, we can fold all of the enumerations $\bar{a}_i = \langle a^i_\alpha : \alpha < \lambda \rangle$ into a single enumeration $\bar{a} = \langle a_\alpha : \alpha < \lambda \rangle$ for which there is a closed unbounded $E^* \subseteq \lambda$ such that for $\delta \in E^*$ and $i < \delta$, we have

$$\{a^i_\alpha : \alpha < \delta\} \subseteq \{a_\beta : \beta < \delta\}. \tag{15.21}$$

Let $E := E^* \cap \triangle_{i<\lambda} E_i$. We claim that $\bar{a}$ and E serve as witnesses to the membership of $S := \triangledown_{i<\lambda} S_i$ in $I[\lambda]$.

Suppose now that $\delta \in E \cap S$. By the definition of diagonal union, there is an $i < \delta$ such that $\delta \in S_i$. By definition of diagonal intersection, we know that $\delta \in E_i$ as well. Thus, there is an unbounded $A \subseteq \delta$ of order-type $\operatorname{cf}(\delta)$ such that every initial segment of A is enumerated by $\bar{a}_i$ before stage δ. Since $\delta \in E^*$, we know that every initial segment of A is enumerated by $\bar{a}$ before stage δ as well, and the proof is finished. ⊣

It is not true that $I[\lambda]$ must be a *proper* ideal on λ. In fact, we shall see that the assumption that $I[\lambda]$ is not a proper ideal is a combinatorial statement of some power. Before dealing with such matters, we will invest a little time in deriving some equivalent formulations of the ideal $I[\lambda]$. We begin with an observation that will be used throughout this section.

3.5 Definition. Let $\mathfrak{M} = \langle M_i : i < \lambda \rangle$ be a λ-approximating sequence. We define $S[\mathfrak{M}]$ to be the set of $\delta < \lambda$ such that δ is singular, $M_\delta \cap \lambda = \delta$, and there is a cofinal $a \subseteq \delta$ of order-type $\operatorname{cf}(\delta)$ with the property that every (proper) initial segment of a is in M_δ.

3.6 Theorem. *$I[\lambda]$ is the ideal on λ generated by the nonstationary sets together with all sets of the form $S[\mathfrak{M}]$ with $\mathfrak{M}$ a λ-approximating sequence.*

Proof. It is not difficult to prove that $S[\mathfrak{M}]$ is in $I[\lambda]$—if we enumerate $[\lambda]^{<\lambda} \cap \bigcup_{i<\lambda} M_i$ as $\bar{a} = \langle a_\alpha : \alpha < \lambda \rangle$ and let E be the closed unbounded set of $\delta < \lambda$ for which $\delta = M_\delta \cap \lambda$ and $\langle a_\alpha : \alpha < \delta \rangle$ enumerates $M_\delta \cap [\lambda]^{<\lambda}$, then each $\delta \in S[\mathfrak{M}] \cap E$ is approachable with respect to $\bar{a}$.

Conversely, suppose that $S \in I[\lambda]$ and $\mathfrak{M}$ is a λ-approximating sequence over S. We claim $S[\mathfrak{M}]$ contains almost all members of S. To see this, note that M_0 will contain an enumeration $\bar{a} = \langle a_\alpha : \alpha < \lambda \rangle$ and a closed unbounded $C \subseteq \lambda$ such that each element of $S \cap C$ is approachable with respect to $\bar{a}$. We claim now that any $\delta \in S$ satisfying $M_\delta \cap \lambda = \delta$ must be in $S[\mathfrak{M}]$. This is quite easy, as any such δ must be in C as well, and $a_\alpha \in M_\delta$ for each $\alpha < \delta$. $\dashv$

We remark that the above proof establishes something slightly stronger than what is claimed in the theorem—a minor adjustment shows us that a set S is in $I[\lambda]$ if and only if there is a λ-approximating sequence $\mathfrak{M}$ with $S \setminus S[\mathfrak{M}]$ nonstationary.

Theorem 3.6 is the characterization of $I[\lambda]$ that we tend to use in the sequel, but the following characterization due to Shelah [88] is also of interest because of its similarity to square sequences.

3.7 Theorem (Shelah [88]). *Let λ be a regular cardinal. Then the following two conditions are equivalent for a set $S \subseteq \lambda$:*

1. *$S \in I[\lambda]$.*
2. *There is a sequence $\langle C_\alpha : \alpha < \lambda \rangle$ and a closed unbounded $E \subseteq \lambda$ such that*
   - *(a) C_α is a closed (but not necessarily unbounded) subset of α,*
   - *(b) if $\beta \in \mathrm{nacc}(C_\alpha)$ then $C_\beta = C_\alpha \cap \beta$, and*
   - *(c) if $\delta \in E \cap S$ then δ is singular, and C_δ is a closed unbounded subset of δ of order-type $\mathrm{cf}(\delta)$.*

Proof. The proof that (2) implies (1) is by far the easier direction, so we dispose of it first. Assume that S satisfies (2), and let $\mathfrak{M} = \langle M_\alpha : \alpha < \lambda \rangle$ be a λ-approximating sequence over $\{S, \bar{C}, E\}$. We claim that if $\delta \in S \cap E$ and $M_\delta \cap \lambda = \delta$, then C_δ will attest to δ's membership in $S[\mathfrak{M}]$.

The proof is elementary, but it is worthwhile to pursue it in order to further understand the relationship between $I[\lambda]$ and squares. Given such a δ, we need to verify that each (proper) initial segment of C_δ lies in M_δ, so fix $\zeta < \delta$. Let β be the least member of C_δ greater than ζ (so $\beta \in \mathrm{nacc}(C_\delta)$). Then $C_\beta = C_\delta \cap \beta$ hence $C_\delta \cap \beta \in M_\delta$. We are almost done—if it happens that $C_\delta \cap \beta$ is not $C_\delta \cap \zeta$, then it can only be because $\zeta \in C_\delta$. But then

$$C_\delta \cap \zeta = C_\delta \cap \beta \setminus \{\zeta\} \in M_\delta \tag{15.22}$$

as required. Since $S \setminus S[\mathfrak{M}]$ is nonstationary, we conclude $S \in I[\lambda]$.

The journey from (1) to (2) will also make use of λ-approximating sequences. Suppose that $S \in I[\lambda]$, and let $\mathfrak{M} = \langle M_\alpha : \alpha < \lambda \rangle$ be a fixed λ-approximating sequence with $S \in M_0$. It suffices to define a sequence $\langle A_\alpha : \alpha < \lambda \rangle$ with the following properties:

- $A_\alpha \subseteq \alpha$, and if $A_\alpha \neq \emptyset$ then A_α consists entirely of successor ordinals,
- if $\beta \in A_\alpha$, then $A_\beta = A_\alpha \cap \beta$, and
- if $\delta \in S[\mathfrak{M}]$, then A_δ is unbounded in δ of order-type $\mathrm{cf}(\delta)$.

If we can accomplish this, then letting C_α equal the closure of A_α in α gives us a sequence $\langle C_\alpha : \alpha < \lambda\rangle$ with all the requisite properties. The following *ad hoc* definition isolates a key aspect of the construction.

3.8 Definition. A set $x \in [\lambda]^{<\lambda}$ is said to be an $\mathfrak{M}$-*candidate* if for all $\zeta \in x$, there is an $\alpha < \lambda$ such that $x \cap \zeta \in M_\alpha$, and, letting

$$\alpha_\zeta := \text{least } \alpha < \kappa \text{ with } x \cap \zeta \in M_\alpha,$$

the sequence $\langle \alpha_\zeta : \zeta \in x\rangle$ is strictly increasing.

For each $\alpha < \lambda$, let us define

$$P_\alpha := M_\alpha \cap \mathcal{P}(\alpha),$$

and

$$\delta_\alpha := M_\alpha \cap \lambda.$$

Given $\alpha < \lambda$, fix a function F_α mapping $P_\alpha \times \delta_\alpha$ in a one-to-one manner into the set of successor ordinals between δ_α and $\delta_{\alpha+1}$. Note that this is always possible because $M_\alpha \in M_{\alpha+1}$ and hence $\delta_{\alpha+1}$ is much larger than δ_α. We construct the sequence $\langle A_\alpha : \alpha < \lambda\rangle$ using the following recipe:

Case 1. α a successor ordinal.

If $\alpha \in M_0$, then define $A_\alpha = \emptyset$. Otherwise, there is a unique $i < \lambda$ such that $\delta_i < \alpha < \delta_{i+1}$. We now ask the following question:

> Is there a candidate $x \in M_i$ and a regular cardinal $\beta < \min(x)$ such that $\alpha = F_i(x, \beta)$ and $|x| \leq \beta$?

If no such x and β exist, then we set $A_\alpha = \emptyset$. If on the other hand we do find such x and β, then they must be unique and so we can define

$$A_\alpha = \{F_{\alpha_\zeta}(x \cap \zeta, \beta) : \zeta \in x\}, \tag{15.23}$$

where α_ζ is as in Definition 3.8 for our particular x.

Case 2. α is a limit ordinal.

If $M_\alpha \cap \lambda$ is not equal to α, we let $A_\alpha = \emptyset$. Otherwise, we ask the question:

> Is there a candidate $x \in M_{\alpha+1}$ with x cofinal in α such that $\mathrm{ot}(x) = \mathrm{cf}(\alpha) < \min(x)$?

If no such x exists, we define $A_\alpha = \emptyset$. Otherwise, we choose such an x and define

$$A_\alpha = \{F_{\alpha_\zeta}(x \cap \zeta, \mathrm{cf}(\alpha)) : \zeta \in x\}. \tag{15.24}$$

It is worth remarking that the set A_α will be cofinal in α of order-type $\mathrm{cf}(\alpha)$, as the fact that x is a candidate from $M_{\alpha+1}$ implies $\alpha_\zeta < \alpha$ for all $\zeta \in x$. We use this remark in the proof of Claim 3.10.

The rest of the proof consists in verifying that the sequence $\langle A_\alpha : \alpha < \lambda\rangle$ we constructed above has all the required properties.

3.9 Claim. *If $\alpha < \lambda$ and $\gamma \in A_\alpha$ then $A_\gamma = A_\alpha \cap \gamma$.*

Proof. Our assumptions imply $A_\alpha \neq \emptyset$, and so there exist a candidate x and a regular cardinal β such that $\beta < \min(x)$, $|x| \leq \beta$, and

$$A_\alpha = \{F_{\alpha_\zeta}(x \cap \zeta, \beta) : \zeta \in x\}.$$

Now fix $\zeta^* \in x$ such that

$$\gamma = F_{\alpha_{\zeta^*}}(x \cap \zeta^*, \beta).$$

The ordinal γ is a successor ordinal, and thus A_γ is defined by the procedure outlined in the first case in the construction. Clearly γ cannot be in M_0, and when we ask the question associated with Case 1, the answer is "yes" with $x \cap \zeta^*$ and β serving as the unique witnesses. Thus,

$$A_\gamma = \{F_{\alpha_\zeta}(x \cap \zeta) : \zeta \in x \cap \zeta^*\} = A_\alpha \cap \delta_{\alpha_{\zeta^*}} = A_\alpha \cap \gamma,$$

as required. $\dashv$

3.10 Claim. *If $\delta \in S[\mathfrak{M}]$, then A_δ is cofinal in δ with order-type* $\mathrm{cf}(\delta)$.

Proof. We note that this follows easily provided we can establish that the answer to the question asked in Case 2 is "yes", as the set A_δ produced will have the required properties.

From the definition of $S[\mathfrak{M}]$, it follows that δ is singular and there is a cofinal $a \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ with the property that every initial segment of a is in M_δ. The proof of this claim consists of an argument that a can be "thinned out" so that it becomes a candidate of the required sort. The problem is that we cannot just throw away elements of a willy-nilly because we need to preserve that fact that all proper initial segments are in M_δ. The argument given below is not difficult, but we include it for completeness.

We start by noting that we *are* allowed to throw away initial segments of a—closure properties of elementary submodels (and the fact that each $M_i \cap \lambda$ is an initial segment of λ) tells us that the resulting tail of a has the property that all initial segments lie in M_δ. Thus without loss of generality $\mathrm{ot}(a) < \min(a)$.

Let $\kappa = \mathrm{ot}(a) = \mathrm{cf}(\delta)$; we define an increasing sequence of elements of a by the following recursion:

Construction

Given $\langle x_j : j < i\rangle$, we ask if $\langle x_j : j < i\rangle$ is in M_δ. If not, the construction terminates; if so, we define

$$\alpha_i = \text{least } \gamma < \delta \text{ such that } \langle x_j : j < i\rangle \in M_\gamma \tag{15.25}$$

and define

$$x_i = \text{least element of } a \text{ that is not in } M_{\alpha_i}. \tag{15.26}$$

We claim that our construction will not terminate until stage κ. To see this, suppose by way of contradiction that it terminates at stage $i < \kappa$. Since κ is regular, there is a $\zeta \in a$ such that $\{x_j : j < i\} \subseteq a \cap \zeta$. Furthermore, $\sup\{\alpha_j : j < i\} < \delta$. Thus we can find a $\gamma < \delta$ such that M_γ contains ζ, $a \cap \zeta$, and $\sup\{\alpha_j : j < i\}$. Now we can reconstruct $\langle x_j : j < i\rangle$ inside of the model M_γ, so $\langle x_j : j < i\rangle \in M_\delta$ and we have contradicted the fact that our construction was forced to terminate at stage i. Note that since a is cofinal in δ, we will always be able to find an x_i as in (15.26).

Clearly the sequence $\langle x_i : i < \kappa\rangle$ is increasing and cofinal in a. Furthermore, the above argument shows that every initial segment of $\langle x_i : i < \kappa\rangle$ lies in M_δ. Taken with (15.26), this means that

$$x := \{x_i : i < \kappa\} \text{ is a candidate.} \tag{15.27}$$

To finish the proof of Claim 3.10, we note that the construction of x can be carried out inside the model $M_{\delta+1}$, so without loss of generality x itself is in $M_{\delta+1}$. Thus, the answer to the question asked in Case 2 of the construction of $\langle A_\alpha : \alpha < \lambda\rangle$ is "yes", and therefore A_δ is cofinal in δ of order-type $\mathrm{cf}(\delta)$. $\dashv$

This completes the proof of Theorem 3.7. $\dashv$

We close this section with one more characterization of $I[\lambda]$, this time due to Foreman and Magidor. This characterization will be used in Sect. 3.6 when we show that scales exist.

3.11 Theorem. *Let $\mathfrak{M} = \langle M_i : i < \lambda\rangle$ be a λ-approximating sequence over S. Then $\delta \in S[\mathfrak{M}]$ if and only if we can find an IA chain $\langle N_\alpha : \alpha < \mathrm{cf}(\delta)\rangle$ with $|N_\alpha| < \mathrm{cf}(\delta)$ for each $\alpha < \mathrm{cf}(\delta)$, and, letting $N = \bigcup_{\alpha<\mathrm{cf}(\delta)} N_\alpha$, such that*

1. $\sup(N \cap \lambda) = \delta$,
2. *$M_i \in N$ for unboundedly many $i < \delta$, and*
3. *$N \subseteq M_\delta$.*

Proof. Let $\langle \delta_i : i < \mathrm{cf}(\delta)\rangle$ be a sequence affirming that δ is a member $S[\mathfrak{M}]$. By thinning out this sequence along the lines of what we did in the proof of Claim 3.10, we may assume

$$\langle \delta_j : j \le i\rangle \in M_{\delta_{i+1}}.$$

Let $x_i = \langle M_{\delta_j} : j \leq i\rangle$ and note that $x_i \in M_{\delta_{i+1}}$. We define

$$N_i = \mathrm{Sk}^{\mathfrak{A}}(\{x_j : j < i\}).$$

N_i can be computed in $M_{\delta_{i+1}}$ from the parameter M_{δ_i}, and so

$$\langle N_j : j \leq i\rangle \in N_{i+1}.$$

The rest follows easily as well. ⊣

3.2. The Approachability Property

In this section, we turn our attention to applications of the ideal $I[\lambda]$. For simplicity, we restrict ourselves to the situation of $\lambda = \mu^+$ for μ a singular cardinal. Our investigation begins with isolating the following combinatorial principle:

3.12 Definition. Let μ be a singular cardinal. We say that *the Approachability Property holds at* μ (abbreviated by AP_μ) if the ideal $I[\mu^+]$ is improper, that is, if μ^+ itself is a member of $I[\mu^+]$.

The ideal $I[\lambda]$ is normal, so clearly AP_μ holds if and only if $I[\lambda]$ contains a closed unbounded subset of λ.

3.13 Theorem. *For singular μ, AP_μ follows from $\square_\mu$.*

Proof. Let $\lambda = \mu^+$, let $\bar{C} = \langle C_\alpha : \alpha < \lambda\rangle$ be a $\square_\mu$-sequence, and let $\mathfrak{M} = \langle M_i : i < \lambda\rangle$ be a λ-approximating sequence over $\bar{C}$. We show that $S[\mathfrak{M}]$ contains the closed unbounded set of all $\delta < \lambda$ for which $M_\delta \cap \lambda = \delta$.

Suppose now that $M_\delta \cap \lambda = \delta$. Then C_δ is a closed unbounded subset of δ, $\mathrm{ot}(C_\delta) < \delta$, and

$$\alpha \in \mathrm{acc}(C_\delta) \quad \Longrightarrow \quad C_\alpha = C_\delta \cap \alpha.$$

If $\alpha < \delta$, then C_α is an element of M_δ; from this, it follows easily that every initial segment of C_δ must be in M_δ. This is not quite enough to conclude that $\delta \in S[\mathfrak{M}]$ because it need not be the case that $\mathrm{ot}(C_\delta) = \mathrm{cf}(\delta)$, but if this happens an argument like that of Lemma 2.19 will yield a set A with the properties necessary to witness δ's membership in $S[\mathfrak{M}]$. ⊣

An examination of Theorem 3.7 gives us a good idea of the relationship between $\square_\mu$ and AP_μ. If α is a limit point of C_δ and we are dealing with a $\square_\mu$-sequence, then we know $C_\delta \cap \alpha = C_\alpha$, but in the case of AP_μ, we need to know *the next element of C_δ beyond α* in order to determine $C_\delta \cap \alpha$—if $\beta = \min(C_\delta \setminus \alpha + 1)$, then

$$C_\beta = (C_\delta \cap \alpha) \cup \{\alpha\}.$$

This is reminiscent of the difference between $\diamondsuit$ and CH—both of these axioms involve enumerations, but the stronger axiom has a bit of "promptness" built into it.

3.14 Definition. Let μ be a singular cardinal. An AP_μ*-sequence* is a sequence $\bar{C} = \langle C_\alpha : \alpha < \mu^+\rangle$ such that

1. C_α is a closed (not necessarily unbounded) subset of α,
2. $|C_\alpha| < \mu$, and
3. for a closed unbounded set of $\delta < \mu^+$,
   (a) C_δ is a closed unbounded subset of δ,
   (b) $\mathrm{ot}(C_\delta) = \mathrm{cf}(\delta)$, and
   (c) for all $\beta < \delta$, $C_\beta \cap \delta \in \{C_\alpha : \alpha < \delta\}$.

The reader may find the above definition a little surprising because on the face of it we have weakened considerably the conclusion of Theorem 3.7. However, it is not hard to prove that AP_μ holds if and only if there is an AP_μ-sequence, and the above definition has the advantage of being already ensconced in the literature.

We turn now to the task of demonstrating the utility of AP_μ, at least in the case where μ is a strong limit singular cardinal. For the example we have in mind, it is useful to recast AP_μ as a statement about elementary submodels of $H(\chi)$. The following definition from [4] gives us the terminology needed to state the result.

3.15 Definition. Let τ be a regular cardinal, and let M be an elementary submodel of $H(\chi)$ for some sufficiently large regular χ.

1. M is τ*-closed* if $[M]^{<\tau} \subseteq M$.
2. M is *weakly* τ*-closed* if for every $I \in [M]^\tau$, there exists a $J \in [I]^\tau$ such that $[J]^{<\tau} \subseteq M$.

The following theorem is a reformulation of one of the main results of [4], but the argument we use has appeared several times in the literature (see Remark 13.11 of Todorčević's chapter [98] in this Handbook).

3.16 Theorem. *Let $\lambda = \mu^+$ for μ a strong limit singular cardinal. Then AP_μ holds if and only if for every $x \in H(\chi)$, there is a λ-approximating sequence $\mathfrak{M} = \langle M_\alpha : \alpha < \lambda\rangle$ over x such that M_δ is weakly τ-closed for all regular cardinals $\tau < \mu$ and for all $\delta < \lambda$ satisfying $M_\delta \cap \lambda = \delta$.*

Proof. Let $\bar{C} = \langle C_\alpha : \alpha < \lambda\rangle$ and E be as in the definition of AP_μ. Set $\kappa = \mathrm{cf}(\mu)$, and let $\langle \mu_i : i < \kappa\rangle$ be an increasing sequence of regular cardinals, cofinal in μ, such that $2^{\mu_i} < \mu_{i+1}$.

We build a matrix $\langle M^i_\alpha : \alpha < \lambda, i < \kappa\rangle$ of elementary submodels of $H(\chi)$ such that (letting $M_\alpha := \bigcup_{i<\kappa} M^i_\alpha$)

1. $\langle M_\alpha : \alpha < \lambda\rangle$ is a λ-approximating sequence over $\{x, \bar{C}, E\}$,
2. $|M^i_\alpha| = \mu_i$,

3. $M^i_\alpha \subseteq M^j_\alpha$ for $i < j$,
4. $\mu_{i+1} \cup \mathcal{P}(M^i_{\alpha+1}) \subseteq M^{i+1}_{\alpha+1}$, and
5. for each i, $\mathcal{P}(\bigcup_{\beta\in C_\alpha} M^i_\beta) \subseteq M_{\alpha+1}$.

The construction is straightforward; we note with regard to condition (5) that

$$\left|\mathcal{P}\left(P\bigcup\nolimits_{\beta\in C_\alpha} M^i_\beta\right)\right| \leq 2^{|C_\alpha|+\mu_i} < \mu,$$

and so $\mathcal{P}(\bigcup_{\beta\in C_\alpha} M^i_\beta)$ can be "swallowed" by $M^j_{\alpha+1}$ for some $j < \kappa$.

Now assume $\tau = \mathrm{cf}(\tau) < \mu$. We show first that if $\alpha = \beta + 1$, then M_α is weakly τ-closed. Assume $A \subseteq M_\alpha$ is of cardinality τ. If $\tau = \kappa$, then every member of $[A]^{<\tau}$ is a subset of $M^i_{\alpha+1}$ for some $i < \kappa$, and therefore

$$[A]^{<\tau} \subseteq M_{\alpha+1}$$

by (4). If on the other hand $\tau \neq \kappa$, then there is an $i < \kappa$ such that

$$|A \cap M^i_{\alpha+1}| = \tau,$$

and then

$$[A \cap M^i_{\alpha+1}]^{<\tau} \subseteq M^{i+1}_{\alpha+1} \subseteq M_{\alpha+1},$$

again by (4).

Now suppose that $\delta = M_\delta \cap \lambda$, and let $A \in [M_\delta]^\tau$. If $\mathrm{cf}(\delta) \neq \tau$ then there is an $\alpha < \delta$ such that

$$|A \cap M_{\alpha+1}| = \tau$$

and we can then take advantage of the fact that $M_{\alpha+1}$ is weakly τ-closed. Thus we may assume that $\tau = \mathrm{cf}(\delta)$. If $\tau = \mathrm{cf}(\delta) = \kappa$, then $[A]^{<\tau} \subseteq M_\delta$ as any bounded subset of A is a subset of M^i_δ for some $i < \kappa$. Thus, our one remaining case is when $\tau = \mathrm{cf}(\delta) \neq \kappa$.

Since $M_\delta = \bigcup_{i<\kappa}\bigcup_{\alpha\in C_\delta} M^i_\alpha$, there is an $i < \kappa$ for which

$$B := A \cap \bigcup\nolimits_{\alpha\in C_\delta} M^i_\alpha$$

has cardinality τ. We will finish the proof by showing that $[B]^{<\tau} \subseteq M_\delta$. To see this, suppose that $K \in [B]^{<\tau}$. Since $\mathrm{ot}(C_\delta) = \mathrm{cf}(\delta) = \tau$, there is an $\alpha \in C_\delta$ such that

$$K \subseteq \bigcup\nolimits_{\beta\in C_\delta\cap\alpha} M^i_\beta.$$

Since $\delta \in E$, there is a $\gamma < \delta$ such that $C_\delta \cap \alpha = C_\gamma$. But condition (5) of our construction guarantees that $K \in M_{\gamma+1} \subseteq M_\delta$. This finishes the proof that M_δ is weakly τ-closed whenever τ is a regular cardinal less than μ and $M_\delta \cap \lambda = \delta$.

The other direction of the theorem is easily established—if $\mathfrak{M}$ is any λ-approximating sequence satisfying the assumptions given, then $S[\mathfrak{M}]$ contains the closed unbounded set of δ for which $M_\delta \cap \lambda = \delta$. $\dashv$

The application we give here of AP_μ is reminiscent of Lemma 2.13—we obtain the same conclusion from different hypotheses. Again, the following theorem is taken from [4].

3.17 Theorem. *Let $\lambda = \mu^+$ for μ a singular strong limit cardinal, and assume AP_μ holds. Suppose that for some $\sigma < \mu$ we are given a family*

$$\mathcal{A} = \langle A_\alpha : \alpha < \lambda \rangle$$

of sets from $[\lambda]^{\sigma^+}$ satisfying the following two conditions:

1. *For all $\beta < \lambda$, there is a function $F_\beta : \beta \to [\lambda]^\sigma$ such that*

$$\langle A_\alpha \setminus F_\beta(\alpha) : \alpha < \beta \rangle \text{ is disjoint.} \tag{15.28}$$

2. *For all $Z \in [\lambda]^\sigma$, $|\{\alpha < \lambda : Z \subseteq A_\alpha\}| \leq \mu$.*

Then there exists a function $F : \lambda \to [\lambda]^\sigma$ such that

$$\langle A_\alpha \setminus F(\alpha) : \alpha < \lambda \rangle \text{ is disjoint.} \tag{15.29}$$

Proof. By Theorem 3.16, there is a λ-approximating sequence $\mathfrak{M} = \langle M_\alpha : \alpha < \lambda \rangle$ over $\mathcal{A}$ with the property that M_δ is weakly τ-closed for all regular $\tau < \mu$ whenever $M_\delta \cap \lambda = \delta$.

We claim that if $M_\delta \cap \lambda = \delta$ and $\alpha \geq \delta$, then it must be the case that

$$|A_\alpha \cap \delta| \leq \sigma. \tag{15.30}$$

To see this, suppose that it fails for δ and α. Clearly we may choose $J \subseteq A_\alpha \cap \delta$ of cardinality σ^+. Since M_δ is weakly σ^+-closed, we may assume that $[J]^\sigma \subseteq M_\delta$. Therefore, there is a set $Z \in M_\delta$ of cardinality σ such that $Z \subseteq A_\alpha$.

Since $\alpha \geq \delta$, it follows that for each $\beta \in M_\delta \cap \lambda$, we know

$$H(\chi) \models (\exists \gamma > \beta)[Z \subseteq A_\gamma],$$

hence

$$M_\delta \models (\exists \gamma > \beta)[Z \subseteq A_\gamma].$$

The preceding holds for all $\beta \in M_\delta \cap \lambda$, and so

$$M_\delta \models (\forall \beta < \lambda)(\exists \gamma > \beta)[Z \subseteq A_\gamma].$$

Another application of elementarity tells us

$$H(\chi) \models (\forall \beta < \lambda)(\exists \gamma > \beta)[Z \subseteq A_\gamma],$$

and this contradicts the second assumption we made about $\mathcal{A}$.

Now let $\langle \delta_i : i < \lambda \rangle$ enumerate the closed unbounded set E of δ for which M_δ is weakly σ^+-closed. We define the function $F : \lambda \to [\lambda]^\sigma$ by induction.

We begin by defining $F \restriction \delta_0$ by

$$F(\alpha) = F_{\delta_0}(\alpha),$$

where F_{δ_0} is the function from (15.28) for $\beta = \delta_0$. Next, given $i < \lambda$, we assume that $F \restriction \delta_i$ has already been defined. If $\delta_i \leq \alpha < \delta_{i+1}$, we define

$$F(\alpha) = F_{\delta_{i+1}}(\alpha) \cup (A_\alpha \cap \delta_i).$$

Note that $F(\alpha)$ has cardinality σ, and since E is closed unbounded in λ, our recipe defines $F(\alpha)$ for each $\alpha < \lambda$.

Does F work? All that remains to be shown is that

$$(A_\alpha \setminus F(\alpha)) \cap (A_\beta \setminus F(\beta)) = \emptyset \tag{15.31}$$

for $\alpha < \beta < \lambda$. If there is an i such that $\delta_i \leq \alpha < \beta < \delta_{i+1}$, then (15.31) holds because

$$A_\gamma \setminus F(\gamma) \subseteq A_\gamma \setminus F_{\delta_i}(\gamma)$$

for all $\gamma < \delta_i$. Otherwise, there is an i such that $\alpha < \delta_i \leq \beta$. In this case, note that $A_\alpha \subseteq M_{\delta_i}$ because $M_{\delta_i} \cap \lambda = \delta_i$, $A_\alpha \in M_{\delta_i}$, and $|A_\alpha| = \sigma^+ < \mu$. Thus, (15.31) holds

$$A_\alpha \cap A_\beta \setminus F(\beta) = \emptyset.$$

$\dashv$

The reader may wonder if it is necessary for the family $\mathcal{A}$ to satisfy condition (2) in order for the conclusion to hold. To see that it cannot simply be dropped, let us assume that μ is a singular cardinal for which $\square_\mu$ (and hence AP_μ) holds. Given $\sigma < \mu$, we can apply Theorem 2.4 to find a nonreflecting stationary $S \subseteq \mu^+$ consisting of ordinals of cofinality σ^+. If for each $\delta \in S$ we choose a cofinal A_δ of order-type σ^+, then by Lemma 2.12 the family $\mathcal{A} = \langle A_\delta : \delta \in S \rangle$ satisfies the first assumption of Theorem 3.17, but clearly the conclusion of Theorem 3.17 cannot hold just as in the proof of Theorem 2.9. These issues are studied in much greater detail in [4], as well as in joint work of Hajnal, Juhász, and Shelah [44, 43].

3.3. The Extent of $I[\lambda]$

This section is dedicated to analyzing the extent of the ideal $I[\lambda]$. In particular, we show that the ideal $I[\lambda]$ is quite large—it contains many stationary sets. In the other direction, we show that although $I[\lambda]$ contains stationary sets, if $\mathrm{cf}(\mu) < \kappa < \mu$ for some supercompact cardinal κ then AP_μ fails.

3.18 Theorem. *Suppose that $\kappa^+ < \sigma < \lambda$ for regular cardinals κ, σ, and λ. There is a set $S \subseteq S^\lambda_\kappa$ in $I[\lambda]$ such that $S \cap \theta$ is stationary in θ for stationarily many $\theta \in S^\lambda_\sigma$. In particular, $I[\lambda]$ contains a stationary subset of S^λ_κ.*

Proof. Since $\kappa^+ < \sigma$, one of the basic results of club guessing (see Theorem 2.17 and Exercise 2.18 in the chapter [1]) tells us that there is a sequence $\bar{C} = \langle C_\eta : \eta \in S^\sigma_\kappa \rangle$ such that

- C_η is club in η of order-type κ, and
- for every club $E \subseteq \sigma$, the set of $\eta \in S^\sigma_\kappa$ with $C_\eta \subseteq E$ is stationary.

Let $\mathfrak{M} = \langle M_i : i < \lambda \rangle$ be a λ-approximating sequence over $\{\kappa, \sigma, \bar{C}\}$, and let $S = S[\mathfrak{M}] \cap S^\lambda_\kappa$. We know that S is in $I[\lambda]$, so we need to prove that the set of $\theta \in S^\lambda_\sigma$ for which $S \cap \theta$ is stationary in θ is stationary.

Assume by way of contradiction that this is not true. We can then build an IA chain $\mathfrak{N} = \langle N_i : i < \sigma \rangle$ of elementary submodels of $H(\chi)$ such that

- $|N_i| = \sigma$,
- $\{\kappa, \sigma, S, \bar{C}, \mathfrak{M}\} \in N_0$, and
- $S \cap \theta$ is nonstationary in $\theta := \sup_{i<\sigma}(N_i \cap \lambda)$.

Let $\theta_i = \sup(N_i \cap \lambda)$ for $i < \sigma$. The sequence $\langle \theta_i : i < \sigma \rangle$ is increasing, continuous, and $\langle \theta_j : j \leq i \rangle \in N_{i+1}$ for all $i < \sigma$.

Inside the model $M_{\theta+1}$, we fix a strictly increasing a continuous function g mapping σ onto a closed unbounded subset of θ. Since σ is uncountable, we know the set

$$E := \{i < \sigma : g(i) = \theta_i\}$$

is closed and unbounded in σ. Our goal is to prove that $\theta_\eta \in S[\mathfrak{M}]$ for all $\eta \in S^\sigma_\kappa$ with $C_\eta \subseteq E$. Since the set of such η is a stationary subset of σ, this contradicts the assumption that $S \cap \theta$ is a nonstationary subset of θ.

Thus, let $\eta < \sigma$ be such that $C_\eta \subseteq E$ and for each $\zeta < \theta$ let g_ζ denote the function $g \restriction (C_\eta \cap \zeta)$. It suffices to prove that g_ζ is in M_{θ_η} for all $\zeta < \eta$, as the range of $g \restriction C_\eta$ will then witness that θ_η is a member of $S[\mathfrak{M}]$.

Given $\zeta < \theta_\eta$, we know that g_ζ is in $M_{\theta+1}$ and thus the statement

$$(\exists \alpha < \lambda)[g_\zeta \in M_\alpha] \tag{15.32}$$

holds in $H(\chi)$.

The function g_ζ is definable from ζ, C_η, and a proper initial segment of $\langle N_i : i < \theta_\eta \rangle$, and so there must be an $i_0 < \theta_\eta$ with $g_\zeta \in N_{i_0}$. Now $\mathfrak{M} \in N_{i_0}$, and hence the statement (15.32) must hold in N_{i_0} as well because of elementarity.

In particular, g_ζ must be in M_α for some $\alpha \in N_{i_0} \cap \lambda$. But clearly such an α satisfies

$$\alpha < \sup(N_{i_0} \cap \lambda) < \theta_\eta,$$

and therefore g_ζ is in M_{θ_η} too, as required. $\dashv$

3.19 Corollary. *If $\lambda = \mu^+$ for μ singular and $\kappa < \mu$ is a regular cardinal, then $I[\lambda]$ contains a stationary subset of S^λ_κ.*

Why do we restrict to successors of singular cardinals in the preceding corollary? The answer is that much more is known in the case where $\lambda = \kappa^+$ for κ regular. Later in the chapter (see Corollary 4.6), we show that if κ is regular, then $S^{\kappa^+}_{<\kappa} \in I[\kappa^+]$. Mitchell [69] has announced that it is consistent that no stationary subset of $S^{\aleph_2}_{\aleph_1}$ is in $I[\aleph_2]$. (His argument is outlined in the paper [68].)

We have seen that $I[\lambda]$ contains many large sets, but the next result of Shelah [83] shows that supercompact cardinals impose limits on how big $I[\lambda]$ can be.

3.20 Theorem. *If κ is a supercompact cardinal, the* AP_μ *fails for all singular cardinals μ with* $\mathrm{cf}(\mu) < \kappa < \mu$.

Proof. Assume by way of contradiction that AP_μ holds, and let $\bar{C}$ and E be as in Definition 3.12. By a classical result of Solovay [94], we know that $\theta^{<\kappa} = \theta$ for all regular $\theta > \kappa$.

This means that we can enumerate $[\lambda]^{<\kappa}$ in a one-to-one fashion as $\bar{x} = \langle x_\alpha : \alpha < \lambda\rangle$. Moreover, it follows that $\theta^{<\kappa} \leq \theta + \kappa < \mu$ for all regular $\theta < \mu$ and so there is a function $F : \lambda \to \lambda$ with the property that for all $\alpha < \lambda$,

$$\gamma \leq \alpha \quad \Longrightarrow \quad [C_\gamma]^{<\kappa} \subseteq \{x_\beta : \beta < F(\alpha)\}. \tag{15.33}$$

Let $j : V \to M$ be a λ-supercompact embedding with $\kappa = \mathrm{crit}(j)$. Define

$$\begin{aligned} j(\bar{C}) &= \langle C^j_\alpha : \alpha < j(\lambda)\rangle, \\ j(\bar{x}) &= \langle x^j_\alpha : \alpha < j(\lambda)\rangle, \quad \text{and} \\ \rho &= \sup\{j(\alpha) : \alpha < \lambda\}. \end{aligned}$$

The set $\{j(\alpha) : \alpha < \lambda\}$ is a $<\kappa$-closed subset of ρ, and since C^j_ρ is a club subset of ρ, it follows that

$$D := \{\alpha < \lambda : j(\alpha) \in C^j_\rho\}$$

is a $<\kappa$-closed unbounded subset of λ. Choose $\delta < \lambda$ for which $|D \cap \delta| = \mu$. Since $j(\bar{C})$ is a $\mathrm{AP}_{j(\mu)}$ sequence in M, there is a $\gamma < \rho$ such that

$$C^j_\rho \cap j(\delta) = C^j_\gamma,$$

and we can find $\epsilon < \lambda$ such that $\gamma < j(\epsilon)$. Finally, let us define

$$\mathcal{A} = [j``(D \cap \delta)]^{<\kappa} \subseteq [C^j_\rho \cap j(\delta)]^{<\kappa} = [C^j_\gamma]^{<\kappa}.$$

By the definition of F, we know

$$x \in \mathcal{A} \quad \Longrightarrow \quad x = x^j_\xi \text{ for some } \xi < j(F)(j(\epsilon)) = j(F(\epsilon)). \tag{15.34}$$

However, every element x of $\mathcal{A}$ is also of the form $j(y)$ for some $y \in [D \cap \delta]^{<\kappa}$ and therefore there is a unique $\zeta < \lambda$ such that

$$x = j(x_\zeta) = x^j_{j(\zeta)}. \tag{15.35}$$

From (15.34), an application of elementarity allows us to conclude that the ζ from (15.35) must be less than $F(\epsilon)$. Thus, there is a one-to-one mapping from $\mathcal{A}$ to $F(\epsilon)$ given by

$$x \mapsto \text{ the unique } \zeta < F(\epsilon) \text{ with } x = j(x_\zeta).$$

This is a contradiction, as $|A| = \mu^{<\kappa} = \lambda$, while $F(\epsilon) < \lambda$. $\dashv$

The above argument can easily be modified to prove that if κ is supercompact and $\mathrm{cf}(\mu) < \kappa < \mu$, there is a singular $\theta < \kappa$ with $\mathrm{cf}(\theta) = \mathrm{cf}(\mu)$ such that $S^{\mu^+}_{\theta^+} \notin I[\mu^+]$.

3.4. Weak Approachability and $\mathrm{AP}_{\aleph_\omega}$

What about the situation at $\aleph_{\omega+1}$? Can we (assuming the existence of large cardinals) force the failure of $\mathrm{AP}_{\aleph_\omega}$? The answer is affirmative, and even though the proof is not difficult (we give it at the end of the next section), it will give us an opportunity to re-connect $I[\lambda]$ with some of the ideas used in the proof of Theorem 2.15. The reader may recall that we utilized λ-filtration sequences in order to establish that certain stationary sets were indestructible by nice forcings. Our goal in this section is to deepen our understanding of this connection. The results in this section are all due to Shelah, and most are formulations of ideas and results from [83] and [90].

3.21 Definition. Let $\lambda = \mu^+$ for μ singular, and let $\bar{a} = \langle a_\alpha : \alpha < \lambda\rangle$ be a sequence of elements of $[\lambda]^{<\mu}$. A limit ordinal $\delta < \lambda$ is said to be *weakly approachable with respect to the sequence* $\bar{a}$ if there is an unbounded $A \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that every initial segment of A is covered by a_β for some $\beta < \delta$, that is, if $\alpha < \delta$ then there is a $\beta < \delta$ such that $A \cap \alpha \subseteq a_\beta$.

The use of the adverb *weakly* should not be surprising, as the above is really a weakening of Definition 3.2. There is a slight discrepancy between the two definitions, as Definition 3.2 uses enumerations of elements of $[\lambda]^{<\lambda}$ instead of $[\lambda]^{<\mu}$, but this difference is irrelevant to the question of deciding whether an ordinal is approachable or not, because the initial segments that must appear in the enumeration in Definition 3.2 are all of size less than μ.

3.22 Definition. Assume $\lambda = \mu^+$ for μ singular. A set $S \subseteq \lambda$ *is in* $I[\lambda;\mu]$ if and only if there is a sequence $\bar{a} = \langle a_\alpha : \alpha < \lambda\rangle$ of elements of $[\lambda]^{<\mu}$ and a closed unbounded $C \subseteq \lambda$ such that every $\delta \in S \cap C$ is singular and weakly approachable with respect to the sequence $\bar{a}$.

The proof that $I[\lambda;\mu]$ is a normal ideal is no different from the corresponding proof for $I[\lambda]$. In fact, the ideals are quite closely related—it should be clear that $I[\lambda] \subseteq I[\lambda;\mu]$, while the following proposition tells us that in many situations the ideals actually coincide (compare with Lemma 2.20, for example).

3.23 Proposition. *Suppose that $\lambda = \mu^+$ where μ is a strong limit singular cardinal. Then $I[\lambda] = I[\lambda; \mu]$.*

Proof. It is clear that $I[\lambda] \subseteq I[\lambda; \mu]$, so assume $S \in I[\lambda; \mu]$ with $\bar{a}$ and E the corresponding parameters. Let $\mathfrak{M} = \langle M_\alpha : \alpha < \lambda \rangle$ be a λ-approximating sequence over $\{\bar{a}, E\}$; we show that any $\delta \in S$ satisfying $M_\delta \cap \lambda = \delta$ is in fact in $S[\mathfrak{M}]$. Since $I[\lambda]$ is a normal ideal and $S[\mathfrak{M}] \in I[\lambda]$, this suffices.

Given such a δ, there exists a cofinal $A \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that every initial segment of A is covered by a_α for some $\alpha < \delta$. So fix $\beta < \delta$, and fix $\alpha < \delta$ such that

$$A \cap \beta \subseteq a_\alpha.$$

Since $\alpha < \delta$ and $\bar{a} \in M_\delta$, it follows that both a_α and $\mathcal{P}(a_\alpha)$ are in M_δ. Since $|a_\alpha| < \mu$ and μ is a strong limit, we know $|\mathcal{P}(a_\alpha)| < \mu$ as well. Since $M_\delta \cap \lambda = \delta$, we conclude

$$\mathcal{P}(a_\alpha) \subseteq M_\delta,$$

and therefore $A \cap \beta \in M_\delta$. Thus, $\delta \in S[\mathfrak{M}]$ as required. $\dashv$

We now bring in yet another notion of approachability—this one is tied to colorings associated with certain λ-filtration sequences, and we have already seen it in disguise in Sect. 2.5. The following notation is due to Shelah [83].

3.24 Definition. Let $\lambda = \mu^+$ for μ singular. A function $d : [\lambda]^2 \to \mathrm{cf}(\mu)$ is said to be *normal* if

$$i < \mathrm{cf}(\mu) \quad \Longrightarrow \quad \sup_{\alpha<\lambda} |\{\beta < \alpha : d(\beta, \alpha) < i\}| < \mu. \tag{15.36}$$

The function d is *transitive* if

$$\alpha < \beta < \gamma < \lambda \quad \Longrightarrow \quad d(\alpha, \gamma) \leq \max\{d(\alpha, \beta), d(\beta, \gamma)\}. \tag{15.37}$$

We note here that a normal transitive coloring $d : [\mu^+]^2 \to \mathrm{cf}(\mu)$ is essentially a λ-filtration sequence $\bar{b} = \langle b_{\alpha,i} : \alpha < \lambda, i < \mathrm{cf}(\mu) \rangle$ with nice properties—if we define

$$b_{\alpha,i} = \{\beta < \alpha : d(\beta, \alpha) \leq i\},$$

then the normality condition on d corresponds to

$$\sup\{|b_{\alpha,i}| : \alpha < \lambda\} < \mu \quad \text{for all } i < \mathrm{cf}(\mu), \tag{15.38}$$

while transitivity translates as

$$\beta \in b_{\alpha,i} \quad \Longrightarrow \quad b_{\beta,i} \subseteq b_{\alpha,i}. \tag{15.39}$$

As noted after Definition 1.10, it is straightforward to build such λ-filtration sequences, and hence there are plenty of normal transitive colorings defined on λ.

3.25 Definition. Suppose that $d : [\mu^+]^2 \to \mathrm{cf}(\mu)$ is a normal transitive function, where μ is a singular cardinal. A limit ordinal $\delta < \mu^+$ is *d-approachable* if there is a cofinal $A \subseteq \delta$ such that for every $\alpha \in A$,

$$\sup\{d(\beta,\alpha) : \beta \in A \cap \alpha\} < \mathrm{cf}(\mu).$$

3.26 Proposition. *Let μ and d be as in the preceding definition, and suppose that $\delta < \mu^+$.*

1. *If $\mathrm{cf}(\delta) \leq \mathrm{cf}(\mu)$, then δ is d-approachable.*
2. *If δ is d-approachable and $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$, then there is a cofinal $H \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that*

$$|\operatorname{ran} d \restriction [H]^2| < \mathrm{cf}(\mu).$$

Proof. The first statement is obvious from cardinality considerations. For the second statement, let $A \subseteq \delta$ be as in the definition of d-approachability. Without loss of generality, $\mathrm{ot}(A) = \mathrm{cf}(\delta)$, as shrinking A causes no harm. For $\alpha \in A$, let

$$i_\alpha = \sup\{d(\beta,\alpha) : \beta \in A \cap \alpha\}.$$

Our choice of A implies $i_\alpha < \mathrm{cf}(\mu)$. Since $\mathrm{cf}(\mu) \neq \mathrm{cf}(\delta)$, there is an $i < \mathrm{cf}(\mu)$ for which

$$H := \{\alpha \in A : i_\alpha \leq i\}$$

is unbounded in δ. Clearly H has the required properties. ⊣

3.27 Corollary. *Let d and μ be as in the previous proposition. An ordinal $\delta < \mu^+$ is d-approachable if and only if $\mathrm{cf}(\delta) \leq \mathrm{cf}(\mu)$ or there is a cofinal $H \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ and $i < \mathrm{cf}(\mu)$ such that*

$$\beta < \alpha \text{ in } H \quad \Longrightarrow \quad d(\beta,\alpha) \leq i.$$

The next theorem establishes the connection between the two concepts we have been considering in this section.

3.28 Theorem. *Let $\lambda = \mu^+$ for μ singular. Then the following two conditions are equivalent for a set $S \subseteq \lambda$:*

1. *$S \in I[\lambda;\mu]$.*
2. *There is a normal transitive $d : [\lambda]^2 \to \mathrm{cf}(\mu)$ and a closed unbounded $E^* \subseteq \lambda$ such that all $\delta \in E^* \cap S$ are d-approachable.*

Proof. Assume first that condition (2) holds for S, as witnessed by d and E^*. Any ordinal $\alpha < \lambda$ has a unique representation as $\gamma + i$ where γ is divisible by $\mathrm{cf}(\mu)$ and $i < \mathrm{cf}(\mu)$. With this in mind, we define

$$a_{\gamma+i} = \{\beta < \gamma : d(\beta, \gamma + j) \leq i \text{ for some } j \leq i\}, \tag{15.40}$$

where γ is divisible by $\mathrm{cf}(\mu)$ and $i < \mathrm{cf}(\mu)$. Note that the normality condition on d guarantees that $|a_\alpha| < \mu$ for all α, and so our construction generates an enumeration $\bar{a} = \langle a_\alpha : \alpha < \lambda \rangle$ of sets from $[\lambda]^{<\mu}$. Now let E be the closed and unbounded subset of E^* made up of those elements that are limits of ordinals divisible by $\mathrm{cf}(\mu)$. We claim that any $\delta \in E \cap S$ is weakly approachable with respect to $\bar{a}$.

Given $\delta \in E \cap S$, we know that δ is d-approachable, so there is a cofinal $A \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that for all $\alpha \in A$,

$$\sup\{d(\beta, \alpha) : \beta \in A \cap \alpha\} < \mathrm{cf}(\mu).$$

Any unbounded subset of A also enjoys this property, so without loss of generality if $\beta < \alpha$ in A, then there is an ordinal γ such that

- $\beta < \gamma \leq \alpha$, and
- γ is divisible by $\mathrm{cf}(\mu)$.

Given $\alpha \in A$, there is a unique ordinal γ such that

- γ is divisible by $\mathrm{cf}(\mu)$, and
- $\alpha = \gamma + j$ for some $j < \mathrm{cf}(\mu)$.

Furthermore, we know

- $A \cap \alpha \subseteq \gamma$, and
- $i_\alpha := \sup\{d(\beta, \alpha) : \beta \in A \cap \alpha\} < \mathrm{cf}(\mu)$.

If we define $i = i_\alpha + j$ (so $\gamma + i < \delta$) then it is straightforward to verify

$$A \cap \alpha \subseteq a_{\gamma+i},$$

and we are done.

Now what about the other direction? Assume that there is a closed unbounded E and an enumeration $\bar{a} = \langle a_\alpha : \alpha < \lambda \rangle$ of elements of $[\lambda]^{<\mu}$ such that each $\delta \in E \cap S$ is weakly approachable with respect to $\bar{a}$.

Let $\langle \mu_i : i < \mathrm{cf}(\mu) \rangle$ be an increasing sequence of regular cardinals cofinal in μ. A straightforward construction will give us a λ-filtration system $\bar{b}$ such that

- $|b_{\alpha,i}| \leq \mu_i$
- $\beta \in b_{\alpha,i} \implies b_{\beta,i} \subseteq b_{\alpha,i}$, and
- $|a_\alpha| \leq \mu_i \implies a_\alpha \cap \alpha \subseteq b_{\alpha,i}$.

Let d be the coloring

$$d(\beta, \alpha) = \min\{i : \beta \in b_{\alpha,i}\}; \tag{15.41}$$

it is easily check that d is normal and transitive.

Let us assume that δ is weakly approachable with respect to $\bar{a}$, as shown by the set $A \subseteq \delta$. Let $\langle \alpha_\epsilon : \epsilon < \mathrm{cf}(\delta) \rangle$ be the increasing enumeration of A. By our assumption on A, for each $\epsilon < \mathrm{cf}(\delta)$ there is a $\beta_\epsilon < \delta$ such that

$$\{\alpha_\xi : \xi < \epsilon\} \subseteq a_{\beta_\epsilon} \cap \beta_\epsilon.$$

By thinning out A as necessary, we may assume that for all $\epsilon < \mathrm{cf}(\delta)$,

$$\sup\{\alpha_\xi : \xi < \epsilon\} < \beta_\epsilon < \alpha_\epsilon.$$

By Corollary 3.27, we may assume $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$. Thus, for some $i < \mathrm{cf}(\mu)$, the set

$$B := \{\epsilon < \mathrm{cf}(\delta) : d(\beta_\epsilon, \alpha_\epsilon) \leq i \text{ and } |a_{\beta_\epsilon}| < \mu_i\}$$

is unbounded in $\mathrm{cf}(\delta)$.

Next we define $H := \{\beta_\epsilon : \epsilon \in B\}$. Note that the set H is cofinal in δ, and if $\epsilon_1 < \epsilon_2$ are in B, then $\beta_{\epsilon_1} < \alpha_{\epsilon_1} < \beta_{\epsilon_2}$. This implies

$$d(\beta_{\epsilon_1}, \beta_{\epsilon_2}) \leq \max\{d(\beta_{\epsilon_1}, \alpha_{\epsilon_1}), d(\alpha_{\epsilon_1}, \beta_{\epsilon_2})\} \leq i,$$

and so δ is d-approachable. $\dashv$

Using this characterization of $I[\lambda; \mu]$, we can quickly deduce some corollaries concerning $I[\lambda]$.

3.29 Corollary. *If $\lambda = \mu^+$ for μ a strong limit singular cardinal, then $S^\lambda_{\leq \mathrm{cf}(\mu)} \in I[\lambda]$.*

Proof. This is immediate, since it is clear from Theorem 3.28 that $S^\lambda_{\leq \mathrm{cf}(\mu)}$ is in $I[\lambda; \mu]$. $\dashv$

3.30 Corollary. $\mathrm{AP}_{\aleph_\omega}$ *holds in the model from Theorem 2.15. In particular,* $\mathrm{AP}_{\aleph_\omega}$ *does not imply $\square_{\aleph_\omega}$, nor does it imply the existence of a non-reflecting stationary subset of $\aleph_{\omega+1}$.*

Proof. This follows from Proposition 2.21, as without loss of generality, the λ-filtration system used in the proof satisfies the requirements necessary for the coloring d to be normal and transitive. $\dashv$

We shall see later (Corollary 3.41 in the next subsection) that $\mathrm{Refl}(\aleph_{\omega+1})$ implies $\mathrm{AP}_{\aleph_\omega}$, so the above corollary is not simply an artifact of Magidor's construction.

3.5. The Structure of $I[\lambda]$

In the introduction to this part of the chapter, we pointed out that in certain circumstances the question of whether or not a stationary set satisfies the κ^+-indestructibility condition can be reduced to checking whether it has stationary intersection with a certain special subset of S^λ_κ. The result we prove next can be viewed as a version of this phenomenon—the ideal $I[\lambda]$ very often has a simple structure. As in the last subsection, all results presented here are due to Shelah.

3.31 Theorem. *If $\kappa < \lambda$ are uncountable regular cardinals with $2^{<\kappa} < \lambda$, then $I[\lambda] \restriction S^\lambda_\kappa$ is generated over the nonstationary ideal by a single set, that is, there is a set $A^\lambda_\kappa \subseteq S^\lambda_\kappa$ such that $S \subseteq S^\lambda_\kappa$ is in $I[\lambda]$ if and only if $S \setminus A^\lambda_\kappa$ is nonstationary.*

Proof. Let $\mathfrak{M}$ be a λ-approximating sequence with $\kappa \in M_0$. Note that if there is a generator as in the conclusion of the theorem, then there is such a generator in M_0. A simple argument then shows that this set must be equal to $S[\mathfrak{M}] \cap S^\lambda_\kappa$ modulo the nonstationary ideal. Thus, it makes sense to define

$$A^\lambda_\kappa := S[\mathfrak{M}] \cap S^\lambda_\kappa,$$

and work to show that $S \cap A^\lambda_\kappa \neq \emptyset$ for every $S \subseteq S^\lambda_\kappa$ in $I[\lambda]$.

Let $\mathfrak{N} = \langle N_\alpha : \alpha < \lambda\rangle$ be a λ-approximating sequence over $\{\kappa, S, \mathfrak{M}\}$, and choose $\delta \in S$ such that $N_\delta \cap \lambda = \delta$. Since $S \in N_0$, it follows that $\delta \in S[\mathfrak{N}]$; our goal is to prove that $\delta \in S[\mathfrak{M}]$ as well.

Let c be a closed unbounded subset of δ with $\mathrm{ot}(c) = \kappa$ such that every proper initial segment of c is in N_δ. Let $\langle \alpha_\epsilon : \epsilon < \kappa\rangle$ be the increasing enumeration of c, and in the model $M_{\delta+1}$, let $\langle \beta_\epsilon : \epsilon < \kappa\rangle$ enumerate another closed unbounded subset of δ.

Since κ has uncountable cofinality, the set

$$e := \{\epsilon < \kappa : \alpha_\epsilon = \beta_\epsilon\}$$

is closed unbounded in κ. Furthermore, since $2^{<\kappa} < \lambda$ and $M_0 \cap \lambda$ is an initial segment of λ, we know that every bounded subset of e is in M_0. By the choice of $\{\beta_\epsilon : \epsilon < \kappa\}$, it follows that for any $\zeta < \kappa$ the set $\{\beta_\epsilon : \epsilon \in e \cap \zeta\}$ is in $M_{\delta+1}$; our goal is to show that in fact it is in M_δ—this is enough to prove that $\delta \in A^\lambda_\kappa$.

To do this, note that $\{\alpha_\epsilon : \epsilon \in e \cap \zeta\}$ is in N_δ, as it is definable from an initial segment of c and an initial segment of e. Thus

$$\{\beta_\epsilon : \epsilon \in e \cap \zeta\} = \{\alpha_\epsilon : \epsilon \in e \cap \zeta\} \in N_\delta \cap M_{\delta+1}. \tag{15.42}$$

However, we know that $\mathfrak{M} \in N_\delta$ and $N_\delta \cap \lambda = \delta$. From this it follows

$$N_\delta \cap \bigcup\nolimits_{i<\lambda} M_i = M_\delta. \tag{15.43}$$

Together (15.42) and (15.43) tell us that $\{\beta_\epsilon : \epsilon \in e \cap \zeta\}$ is in M_δ, and so the set $\{\beta_\epsilon : \epsilon \in e\}$ puts δ into A^λ_κ. $\dashv$

3.32 Corollary. *If $\lambda = \mu^+$ for μ strong limit singular, then $I[\lambda]$ contains a maximal set modulo the nonstationary ideal.*

We call this maximal set (should it exist) *the set of approachable points* of λ. In general, the sets A^λ_κ from Theorem 3.31 are unique modulo the nonstationary ideal, so we refer to A^λ_κ as the set of approachable points of cofinality κ. In some of Shelah's work, A^λ_κ is called *the good set of cofinality* κ, but the adjective good will be reserved for a related concept that we shall explore later.

Our goal for the rest of this section is to prove another theorem relating $I[\lambda]$ to colorings of pairs from λ, and then to derive several results illuminating the connection between $I[\lambda]$ and the problem of stationary reflection.

3.33 Theorem. *Suppose that $\kappa < \lambda$ are regular cardinals with $2^{<\kappa} < \lambda$, and let $d : [\lambda]^2 \to \theta$ for some $\theta < \kappa$. If $\mathfrak{M}$ is a λ-approximating sequence over $\{\theta, \kappa, d\}$, then for every δ in $S[\mathfrak{M}] \cap S^\lambda_\kappa$, there exists a cofinal $H \subseteq \delta$ of order-type κ homogeneous for d.*

Proof. If $\delta \in S[\mathfrak{M}] \cap S^\lambda_\kappa$, then we can find a set $a = \{\alpha_i : i < \kappa\}$ cofinal in δ such that $\{a_i : i < \zeta\} \in M_\delta$ for all $\zeta < \kappa$. By induction on $i < \kappa$, we define objects ϵ_i and f_i as follows:

1. $\epsilon_0 = \alpha_0$,
2. $f_i : i \to \theta$ is given by $f_i(j) = d(\epsilon_j, \delta)$,
3. we ask if there is an ordinal α greater than α_i and ϵ_j for all $j < i$ such that $d(\epsilon_j, \alpha) = f_i(j)$ for all $j < i$. If the answer is yes, then ϵ_i is the least such α; otherwise, the construction terminates.

The above construction generates an increasing sequence $\{\epsilon_i : i < i^*\}$ for some $i^* \leq \kappa$. For any $i < i^*$, the sequence $\{\epsilon_j : j \leq i\}$ is definable from the parameters $\{\alpha_j : j < i\}$, d, and f_i. The first of these is in M_δ by our choice of $\{\alpha_i : i < \kappa\}$, while $f_i \in M_\delta$ as well because $2^{<\kappa} < \lambda$. Thus, every proper initial segment of $\{\epsilon_i : i < i^*\}$ lies in M_δ. From this, we conclude that $i^* = \kappa$—this is because at every stage of our construction, the answer to the question posed in (3) above is "yes", as demonstrated by the ordinal δ. The rest of the proof is standard—let $f : \kappa \to \theta$ be defined by

$$f(i) = d(\epsilon_i, \delta).$$

Since $\theta < \kappa$ and κ is regular, there is a single ζ such that $\{i < \kappa : f(i) = \zeta\}$ is unbounded in κ. It is routine to check that

$$H_\delta := \{\epsilon_i : f(i) = \eta\}$$

has all the required properties. ⊣

The next definition is natural in light of the preceding theorem.

3.34 Definition. Suppose that $d : [\lambda]^2 \to \theta$ for some θ and λ. We define $S(d)$ to be the set of those $\delta < \lambda$ that have a cofinal subset H_δ of order-type $\mathrm{cf}(\delta)$ homogeneous for d.

3.35 Corollary. *Suppose that $\lambda = \mu^+$ for μ strong limit singular, and let d be a normal transitive coloring. Then $S(d) \cup S^\lambda_{\le \mathrm{cf}(\mu)}$ generates $I[\lambda]$ over the nonstationary ideal.*

Proof. By Corollary 3.29 and Theorem 3.33. ⊣

3.36 Corollary. *If $\kappa < \lambda$ are regular cardinals with $2^{<\kappa} < \lambda$ and d is a function from $[\lambda]^2$ to θ for some $\theta < \kappa$, then $S(d)$ includes A^λ_κ modulo the nonstationary ideal.*

We now return once more to the topic of stationary reflection, and investigate the extent to which the structure of $I[\lambda]$ limits the patterns of reflection that can arise. Our first step is the following result of Shelah [83, 90].

3.37 Theorem. *Suppose that $\sigma < \tau < \lambda$ are regular cardinals with $2^{<\sigma} < \tau$, and let $d : [\lambda]^2 \to \theta$ for some $\theta < \sigma$. If $\langle \delta_i : i < \tau \rangle$ is a strictly increasing and continuous sequence of ordinals with supremum $\delta < \lambda$, then*

$$\{\delta_i : i \in A^\tau_\sigma\} \setminus S(d) \text{ is nonstationary.} \tag{15.44}$$

Proof. Note that A^τ_σ exists because $2^{<\sigma} < \tau$, so (15.44) makes sense. Define $d^* : [\tau]^2 \to \theta$ by

$$d^*(i, j) = d(\delta_i, \delta_j).$$

We apply Corollary 3.36 to σ, τ, and d^* and conclude that $A^\tau_\sigma \setminus S(d^*)$ is a nonstationary subset of τ. Note as well that if $i \in S(d^*)$ then $\delta_i \in S(d)$ because of the way d^* was defined, so (15.44) follows. ⊣

Our intent is to mine Theorem 3.37 for more information concerning the connection between $I[\lambda]$ and the problem of stationary reflection. For the time being, let us assume the following:

- $\lambda = \mu^+$ for μ a strong limit singular cardinal,
- $d : [\lambda]^2 \to \theta$ for some $\theta < \mu$, and
- $S^*(d) := \lambda \setminus S(d)$ is stationary.

This situation occurs if AP_μ fails, for example. In the remainder of this section, we show that the above assumptions have strong implications for stationary reflection. We begin with a easy result.

3.38 Proposition. *$S^*(d)$ cannot reflect outside of itself.*

Proof. Suppose that $\delta \in S(d)$, and let H be a cofinal subset of δ homogeneous for the coloring d. Then any $\alpha < \delta$ with $\alpha = \sup(H \cap \alpha)$ is also in $S(d)$, and so $S(d)$ contains a closed unbounded subset of δ. The result now follows immediately. ⊣

The next theorem illustrates that there are connections between $I[\lambda]$ and $I[\tau]$ for certain regular $\tau < \mu$. In the statement of the theorem, $S^*_\sigma(d)$ denotes $S^*(d) \cap S^\lambda_\sigma$.

3.39 Theorem. *Let $\sigma < \tau$ be regular cardinals below μ with $2^{<\sigma} < \tau$. If $S^*_\sigma(d) \cap \delta$ is stationary in δ for some $\delta \in S^\lambda_\tau$, then $S^\tau_\sigma \notin I[\tau]$.*

Proof. If $S^\tau_\sigma \in I[\tau]$, then Corollary 3.36 implies that $S(d)$ contains a closed unbounded subset of δ relative to the ordinals of cofinality σ. This is impossible if $S^*_\sigma(d) \cap \delta$ is stationary in δ. ⊣

The following lemma tells us that cardinal arithmetic assumptions have some influence on the structure of $I[\lambda]$. We state the result in terms of τ because we will apply it in conjunction with Theorem 3.39.

3.40 Lemma. *Let $\sigma < \tau$ be regular cardinals such that $\epsilon^{<\sigma} < \tau$ for all $\epsilon < \tau$. Then $S^\tau_\sigma \in I[\tau]$.*

Proof. Let $\mathfrak{M} = \langle M_\alpha : \alpha < \tau \rangle$ be a τ-approximating sequence. We know that $M_\alpha \cap \tau$ is an initial segment of τ for each $\alpha < \tau$. Since $|M_\alpha|^{<\sigma} < \tau$ for each α, it follows (since $M_\alpha \in M_{\alpha+1}$) that

$$[M_\alpha]^{<\sigma} \subseteq M_{\alpha+1}. \tag{15.45}$$

Now suppose that $\delta \in S^\tau_\sigma$ satisfies $\delta = M_\delta \cap \lambda$, and let $A \subseteq \delta$ be any cofinal set of order-type σ. Each initial segment of A is in $[M_\alpha]^{<\sigma}$ for some $\alpha < \sigma$. Since δ is a limit ordinal, it follows from (15.45) that each initial segment of A is in M_δ and therefore $\delta \in S[\mathfrak{M}]$. Since $I[\tau]$ is a normal ideal and $S[\mathfrak{M}] \in I[\tau]$, we conclude that $S^\tau_\sigma \in I[\tau]$ as well. ⊣

We are now in a position to deduce a somewhat unexpected corollary of Theorem 3.39. This is a reformulation of one of the main theorems in [83], and it shows that the fact that $\mathrm{AP}_{\aleph_\omega}$ holds in the model of Theorem 2.15 is no accident.

3.41 Corollary. *If $\aleph_\omega$ is a strong limit and $\mathrm{AP}_{\aleph_\omega}$ fails, then* $\mathrm{Refl}(\aleph_{\omega+1})$ *fails as well.*

Proof. Assume $\aleph_\omega$ is a strong limit and $\mathrm{AP}_{\aleph_\omega}$ fails. Let $d : [\aleph_{\omega+1}]^2 \to \omega$ be a normal transitive function, and let $S^*(d) = \aleph_{\omega+1} \setminus S(d)$. Since $\mathrm{AP}_{\aleph_\omega}$ fails, we know that $S^*(d)$ is stationary and hence there is an $n < \omega$ for which the set S of ordinals in $S^*(d)$ of cofinality $\aleph_{n+1}$ is stationary. Note that

$$2^{\aleph_n} \leq \sigma < \aleph_\omega \quad \Longrightarrow \quad \sigma^{\aleph_n} = \sigma^{<\aleph_{n+1}} = \sigma, \tag{15.46}$$

and so an application of Theorem 3.39 tells us that S cannot reflect in any cofinality greater than $2^{\aleph_n}$.

Now we claim that S has a non-reflecting stationary subset. To see this, fix $k < \omega$ such that $2^{\aleph_n} = \aleph_{n+k}$ and consider the sequence of sets defined by

$$S_0 = S,$$
$$S_{i+1} = \{\delta < \aleph_{\omega+1} : S_i \cap \delta \text{ is stationary in } \delta\}.$$

Standard arguments tell us that

$$\delta \in S_i \quad \Longrightarrow \quad \mathrm{cf}(\delta) \geq \aleph_{n+1+i}, \tag{15.47}$$

and that $S_{i+1} \subseteq S_i$ for $i \geq 1$ (though S_1 need not be a subset of S_0).

We know that S does not reflect in an ordinal of cofinality greater than $\aleph_{n+k}$ and therefore S_k is empty. Let i^* be the first natural number less than k for which S_{i^*+1} is nonstationary. The set S_{i^*} is therefore a stationary set that does not reflect stationarily often. By removing a nonstationary set from S_{i^*}, we can obtain a stationary $T \subseteq S_{i^*}$ that does not reflect at all. Thus $\mathrm{Refl}(\aleph_{\omega+1})$ fails. ⊣

Shelah's paper [87] uses similar arguments to establish the following curious result which shows that supercompact cardinals actually impose a limit on the amount of stationary reflection present.

3.42 Theorem (Shelah [87]). *If* GCH *holds and κ is a $\kappa^{+\omega+1}$-supercompact cardinal, then there are singular cardinals $\zeta < \eta < \kappa$ of countable cofinality for which* $\mathrm{Refl}(S^{\eta^+}_{\zeta^+})$ *fails.*

The bulk of [87] is devoted to showing that the large cardinal assumption in the preceding theorem is sharp.

3.43 Theorem (Shelah [87]). *If the universe contains "sufficiently many" supercompact cardinals, then in some forcing extension there is a κ which is $\kappa^{+\omega}$-supercompact,* GCH *holds, and* $\mathrm{Refl}(S^{\tau}_{\sigma})$ *holds for every regular σ and τ with $\sigma^+ < \tau$.*

We close this section with yet another application of the $S(d)$ characterization of $I[\lambda]$—we sketch a proof that consistently $\mathrm{AP}_{\aleph_\omega}$ fails.

3.44 Theorem. $\neg\,\mathrm{AP}_{\aleph_\omega}$ *is consistent relative to the existence of a supercompact cardinal.*

Proof. Let κ be a supercompact cardinal, and assume that GCH holds. Set $\mu = \kappa^{+\omega}$ and $\lambda = \mu^+$, and let $d : [\lambda]^2 \to \omega$ be a normal transitive function. We know from Theorem 3.20 that there is a cardinal $\theta < \kappa$ for which $S^{\lambda}_{\theta} \notin I[\lambda]$. Since μ is a strong limit cardinal, it follows that

$$A^{\lambda}_{\theta} = S(d) \cap S^{\lambda}_{\theta} \tag{15.48}$$

modulo the nonstationary ideal, and $B := S^\lambda_\theta \setminus S(d)$ is stationary.

Our model of $\neg\,\mathrm{AP}_{\aleph_\omega}$ is obtained as a two-step iteration $\mathbb{P} * \dot{\mathbb{Q}}$, where $\mathbb{P} = \mathrm{Col}(\aleph_0, {<}\theta)$ makes all cardinals less than θ countable using finite conditions, and

$$V^{\mathbb{P}} \models \dot{\mathbb{Q}} = \mathrm{Col}(\aleph_1, \kappa),$$

so forcing with $\dot{\mathbb{Q}}$ collapses κ to $\aleph_1$ using countable conditions.

The iteration $\mathbb{P} * \dot{\mathbb{Q}}$ preserves the stationarity of subsets of λ using a chain condition argument analogous to the standard argument that $\aleph_1$-chain condition forcings preserve stationary subsets of ω_1. Also, after forcing with $\mathbb{P} * \dot{\mathbb{Q}}$ the cardinal θ becomes $\aleph_1$, while μ becomes $\aleph_\omega$ and λ becomes $\aleph_{\omega+1}$. The function d is still normal and transitive after the forcing, so it suffices to prove that our forcing cannot change the truth-value of "$\delta \in S(d)$" for $\delta \in S^\lambda_\theta$.

We show this first for $\mathbb{P}$—the relevant property of $\mathbb{P}$ that we need is that among any θ conditions, there is a pairwise compatible subfamily of size θ. Why does this suffice? It is clear that if $\delta \in S(d)$ in the ground model, then δ remains in $S(d)$ in the extension, so assume $\delta \in S^\lambda_\theta$ and

$$p \Vdash \text{“}\delta \in S(d)\text{”}.$$

What this means is that δ has a cofinal d-homogeneous set H of order-type θ in $V^{\mathbb{P}}$; we claim that such a set must exist already in the ground model. Without loss of generality, there is a specific $n < \omega$ and a $\mathbb{P}$-name $\dot{H}$ such that

$$p \Vdash \text{“}\dot{H} \text{ is a cofinal subset of } \delta \quad \text{and } d \restriction [\dot{H}]^2 \text{ is constant with value } n\text{”}.$$

Let $\langle \delta_\alpha : \alpha < \theta \rangle$ be an increasing sequence with limit δ. For each $\alpha < \theta$, we can find a condition $p_\alpha \leq p$ and an ordinal $\beta_\alpha < \delta$ such that

$$p_\alpha \Vdash \text{“}\beta_\alpha \text{ is the least element of } \dot{H} \text{ above } \delta_\alpha\text{”}.$$

There is a set $I \subseteq \theta$ of size θ with the property that p_α and p_γ are compatible whenever $\alpha < \gamma$ in I. It is clear that $\delta_\alpha < \beta_\alpha$ and so $\{\beta_\alpha : \alpha \in I\}$ is cofinal in δ; by thinning out I we can assume that the sequence $\langle \beta_\alpha : \alpha \in I \rangle$ is increasing as well. Given $\alpha < \gamma$ in I, there is a condition q extending both p_α and p_γ. Since q extends p as well, it must be the case that

$$q \Vdash \text{“}d(\beta_\alpha, \beta_\gamma) = n\text{”},$$

but then $d(\beta_\alpha, \beta_\gamma) = n$ in the ground model as well. Thus, $\{\beta_\alpha : \alpha \in I\}$ puts δ into $S(d)$ in the ground model.

We leave the corresponding argument for $\dot{\mathbb{Q}}$ to the reader—the property that one uses is

$$V^{\mathbb{P}} \models \dot{\mathbb{Q}} \text{ is } \aleph_1\text{-closed}.$$

Thus, if G is a generic subset of $\mathbb{P} * \dot{\mathbb{Q}}$, it follows that

$$V[G] \models S^{\aleph_{\omega+1}}_{\aleph_1} \notin I[\aleph_{\omega+1}],$$

and hence $\mathrm{AP}_{\aleph_\omega}$ fails. $\dashv$

The proof of the preceding theorem furnishes us with a model in which $\aleph_\omega$ is a strong limit and

$$S^{\aleph_{\omega+1}}_{\aleph_1} \notin I[\aleph_{\omega+1}];$$

it does not generalize to get us a model where, for example, $S^{\aleph_{\omega+1}}_{\aleph_2}$ fails to be in $I[\aleph_{\omega+1}]$. The question of whether or not $I[\aleph_{\omega+1}]$ must contain a closed unbounded set relative to the ordinals of cofinality $\aleph_2$ is a major open question in this area. Foreman's survey [32] contains more information on this, as well as many other related open questions.

3.6. An Application—the Existence of Scales

We come now to another extremely important tool for investigating successors of singular cardinals, namely *scales*. The importance of scales in this context was noticed very early by Shelah in his investigations of Jónsson cardinals. For example, the paper [82] dates to 1978.

3.45 Definition. Let μ be a singular cardinal. A *scale of length β for μ* is a triple $(\vec{\mu}, \vec{f}, I)$ where

1. $\vec{\mu} = \langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ is an increasing sequence of regular cardinals such that $\sup_{i<\mathrm{cf}(\mu)} \mu_i = \mu$.
2. I is an ideal on $\mathrm{cf}(\mu)$.
3. $\vec{f} = \langle f_\alpha : \alpha < \beta\rangle$ is a sequence of functions such that
   (a) $f_\alpha \in \prod_{i<\mathrm{cf}(\mu)} \mu_i$.
   (b) If $\gamma < \delta < \beta$ then $f_\gamma <_I f_\beta$.
   (c) If $f \in \prod_{i<\mathrm{cf}(\mu)} \mu_i$ then there is an $\alpha < \beta$ such that $f <_I f_\alpha$.

The preceding is just a special case of notions studied in pcf theory—the statement "$(\vec{\mu}, \vec{f}, I)$ is a scale of length β for μ" says exactly the same thing as

$$\vec{f} \text{ witnesses } \mathrm{tcf}\big(\textstyle\prod_{i<\mathrm{cf}(\mu)}\mu_i, <_I\big) = \beta.$$

In this chapter, we will concern ourself almost exclusively with a special case of the previous definition—scales of length μ^+ where I is the ideal of bounded sets.

3.46 Definition. Let μ be a singular cardinal. A *scale for* μ is a pair $(\vec{\mu}, \vec{f})$ such that $(\vec{\mu}, \vec{f}, J^{\mathrm{bd}})$ is a scale of length μ^+ for μ, where J^{bd} denotes the ideal of bounded subsets of $\mathrm{cf}(\mu)$. Just as in Proposition 1.19, we let $<^*$ stand for $<_{J^{\mathrm{bd}}}$.

Our goal in this subsection is to prove the fundamental result of Shelah that scales exist for every singular cardinal μ. Before showing this, our plan is to investigate how some of the concepts isolated in the presentation of the theory of exact upper bounds as presented in Sect. 2.1 of Abraham and Magidor's chapter [1] in this Handbook simplify in the context of scales. In particular, we will look closely at their notion of *strongly increasing sequences* and $(*)_\kappa$:

3.47 Definition (Definition 2.4 in [1]). Suppose that I is an ideal over A, L is a set of ordinals, and $\vec{f} = \langle f_\xi : \xi \in L\rangle$ is a sequence of functions with $f_\xi : A \to \mathsf{On}$. We say that $\vec{f}$ is *strongly increasing* if for each $\xi \in L$, there is a set $Z_\xi \in I$ such that for $\xi_1 < \xi_2$ in L,

$$a \in A \setminus (Z_{\xi_1} \cup Z_{\xi_2}) \implies f_{\xi_1}(a) < f_{\xi_2}(a).$$

In the context of interest to us, we shall see that strongly increasing sequences have a much simpler description.

3.48 Definition. Let μ be a singular cardinal, and suppose that we are given a pair $(\vec{\mu}, \vec{f})$ such that $\vec{\mu} = \langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ is an increasing sequence of regular cardinals with limit μ, and $\vec{f} = \langle f_\alpha : \alpha < \gamma\rangle$ is a $<^*$-increasing sequence of functions in $\prod_{i<\mathrm{cf}(\mu)} \mu_i$. An ordinal $\delta < \gamma$ is said to be *good for* $\vec{f}$ (or simply *good* if $\vec{f}$ is clear from context) if $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$, and there is a cofinal $A \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ and an $i^* < \mathrm{cf}(\mu)$ such that

$$f_\beta(i) < f_\alpha(i) \quad \text{for } \beta < \alpha \text{ in } A \text{ and } i > i^*.$$

Note that if $\delta < \gamma$ is of cofinality less than $\mathrm{cf}(\mu)$, then a set A as in the above definition automatically exists. This helps to explain why we restrict ourselves to considering only δ with $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$. Also, one can define good points for $<_I$-increasing sequences where I is not necessarily the ideal of bounded subsets of I—the equivalent formulations of goodness exhibited in Theorem 3.50 below show us how to formulate this.

Our aim is to explore the relationship between good points and strongly increasing sequences. Before we undertake this investigation, we need the following definition.

3.49 Definition. Suppose that $\langle f_i : i < \gamma\rangle$ and $\langle g_j : j < \delta\rangle$ are two $<^*$-increasing sequences of limit length. We say that they are *cofinally interleaved* if every function in one sequence is $<^*$ some function in the other sequence. Equivalently,

$$h <^* f_i \text{ for some } i < \gamma \iff h <^* g_j \text{ for some } j < \delta.$$

3.50 Theorem. *Let μ be a singular cardinal, and let $\vec{\mu} = \langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ be an increasing sequence of regular cardinals cofinal in μ. Furthermore, assume that $\vec{f} = \langle f_\alpha : \alpha < \gamma\rangle$ is a $<^*$-increasing sequence of functions in $\prod_{i<\mathrm{cf}(\mu)} \mu_i$. Then the following statements are equivalent for an ordinal $\delta < \gamma$ of cofinality greater than $\mathrm{cf}(\mu)$.*

1. *δ is good for $\vec{f}$.*
2. *$\langle f_\alpha : \alpha < \delta\rangle$ has an exact upper bound h such that $\mathrm{cf}(h(i)) = \mathrm{cf}(\delta)$ for all $i < \mathrm{cf}(\mu)$.*
3. *$\langle f_\alpha : \alpha < \delta\rangle$ is cofinally interleaved with an increasing sequence $\langle h_\xi : \xi < \mathrm{cf}(\delta)\rangle$.*
4. *If X is a cofinal subset of δ, then there is a set $X_0 \subseteq X$, cofinal in δ of order-type $\mathrm{cf}(\delta)$, such that $\langle f_\alpha : \alpha \in X_0\rangle$ is strongly increasing.*

Proof. (1) $\to$ (2). Let $A \subseteq \delta$ be cofinal of order-type $\mathrm{cf}(\delta)$ and suppose that $i^* < \mathrm{cf}(\mu)$ satisfies

$$f_\beta(i) < f_\alpha(i) \quad \text{for } \beta < \alpha \text{ in } A \text{ and } i^* < i < \mathrm{cf}(\mu).$$

Define

$$h(i) = \begin{cases} \delta & \text{if } i \leq i^*, \\ \sup\{f_\alpha(i) : \alpha \in A\} & \text{otherwise.} \end{cases}$$

Clearly $\mathrm{cf}(h(i)) = \mathrm{cf}(\delta)$ for all $i < \mathrm{cf}(\mu)$, and h is an upper bound for $\langle f_\alpha : \alpha < \delta\rangle$. Why is it an exact upper bound?

It suffices to prove that if $g < h$, then $g <^* f_\alpha$ for some α. Given such a g, for each $i > i^*$ we define

$$\alpha(i) = \text{least } \alpha \in A \text{ such that } g(i) < f_{\alpha(i)}(i).$$

Since $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$, we know

$$\alpha^* := \sup_{i<\mathrm{cf}(\mu)} \alpha(i) < \delta,$$

and clearly $g <^* f_{\alpha^*}$. We remark that (2) explains why good points are sometimes referred to as *flat points* in the literature.

(2) $\to$ (3). Suppose that h is as in (2). For each $i < \mathrm{cf}(\mu)$, let $\langle e_i(\xi) : \xi < \mathrm{cf}(\delta)\rangle$ be the increasing enumeration of a cofinal subset of $h(i)$. For $\xi < \mathrm{cf}(\delta)$, define

$$h_\xi(i) = e_i(\xi).$$

Clearly the sequence $\langle h_\xi : \xi < \mathrm{cf}(\delta)\rangle$ is increasing, and $h_\xi(i) < h(i)$ for all $\xi < \mathrm{cf}(\delta)$ and $i < \mathrm{cf}(\mu)$. We claim that $\langle f_\alpha : \alpha < \delta\rangle$ and $\langle h_\xi : \xi < \mathrm{cf}(\delta)\rangle$ are cofinally interleaved.

Given $\xi < \mathrm{cf}(\delta)$, we know there is an $\alpha < \delta$ with $h_\xi <^* f_\alpha$ because h is an exact upper bound of $\langle f_\alpha : \alpha < \delta \rangle$.

Given $\alpha < \delta$, we know there is an $i_\alpha < \mathrm{cf}(\mu)$ such that $f_\alpha(i) < h(i)$ for $i > i_\alpha$. Thus, for each $i > i_\alpha$ there is a $\xi(\alpha, i) < \mathrm{cf}(\delta)$ such that

$$f_\alpha(i) < e_i(\xi(\alpha, i)).$$

Since $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$, it follows that

$$\xi_\alpha := \sup\{\xi(\alpha, i) : i_\alpha < i < \mathrm{cf}(\mu)\} < \mathrm{cf}(\delta).$$

For $i > i_\alpha$, we have

$$f_\alpha(i) < e_i(\xi(\alpha, i)) \leq e_i(\xi_\alpha) = h_{\xi_\alpha}(i)$$

and so $f_\alpha <^* h_{\xi_\alpha}$, and we have finished the proof that the two sequences are cofinally interleaved.

(3) $\to$ (4). Assume $\langle f_\alpha : \alpha < \delta \rangle$ is cofinally interleaved with the increasing sequence $\langle h_\xi : \xi < \mathrm{cf}(\delta) \rangle$. Since X is cofinal in δ, then clearly $\langle f_\alpha : \alpha \in X \rangle$ is cofinally interleaved with $\langle h_\xi : \xi < \mathrm{cf}(\delta) \rangle$ as well. Thus we can choose sequences $\langle \alpha(\zeta) : \zeta < \mathrm{cf}(\delta) \rangle$ and $\langle \xi(\zeta) : \zeta < \mathrm{cf}(\delta) \rangle$ increasing to δ and $\mathrm{cf}(\delta)$ respectively such that $\{\alpha(\zeta) : \zeta < \mathrm{cf}(\delta)\} \subseteq X$, and for each $\xi < \mathrm{cf}(\delta)$,

$$f_{\alpha(\eta)} <^* h_\xi(\zeta) <^* f_\alpha(\zeta) \quad \text{for all } \eta < \zeta.$$

For each $\zeta < \mathrm{cf}(\delta)$, there is an $i(\zeta)$ such that

$$h_{\xi(\zeta)}(i) < f_{\alpha(\zeta)}(i) < h_{\xi(\zeta+1)}(i) \quad \text{for all } i > i(\zeta).$$

Since $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$, we can find an unbounded $A \subseteq \delta$ and $i^* < \mathrm{cf}(\mu)$ such that $i(\zeta) = i^*$ for all $\zeta \in A$. In particular, for $\eta < \zeta$ in A and $i > i^*$, we have

$$f_{\alpha(\eta)}(i) < h_{\xi(\eta+1)}(i) \leq h_{\xi(\zeta)}(i) < f_{\alpha(\zeta)}(i).$$

If we let $X_0 = \{\alpha(\zeta) : \zeta \in A\}$ then clearly $\langle f_\alpha : \alpha \in X_0 \rangle$ is strongly increasing.

(4) $\to$ (1). Suppose that X_0 is a cofinal subset of δ of order-type $\mathrm{cf}(\delta)$ such that $\langle f_\alpha : \alpha \in X_0 \rangle$ is strongly increasing. For each $\alpha \in X_0$, there is a corresponding set Z_α bounded below $\mathrm{cf}(\mu)$; we note that without loss of generality $Z_\alpha = [0, i_\alpha]$ for some $i_\alpha < \mathrm{cf}(\mu)$. Again, since $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$ there is an unbounded $A \subseteq X_0$ and $i^* < \mathrm{cf}(\mu)$ such that $i_\alpha = i^*$ for all $\alpha \in A$. From the definition of strongly increasing, it follows that

$$f_\beta(i) < f_\alpha(i) \quad \text{for } \beta < \alpha \text{ in } A \text{ and } i > i^*.$$

Thus δ is good for $\vec{f}$. $\dashv$

The preceding theorem allows us to characterize when $<^*$-increasing sequences have nice exact upper bounds.

3.51 Theorem. *Let μ be a singular cardinal, and suppose that $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ is an increasing sequence of regular cardinals with limit μ. Let $\vec{f} = \langle f_i : i < \mu^+\rangle$ be a $<^*$-increasing sequence of functions in $\prod_{i<\mathrm{cf}(\mu)} \mu_i$, and suppose that $\mathrm{cf}(\mu) < \kappa = \mathrm{cf}(\kappa) < \mu$. Then the following two statements are equivalent:*

1. *$\vec{f}$ has an exact upper bound h such that*

$$|\{i < \mathrm{cf}(\mu) : \mathrm{cf}(h(i)) < \kappa\}| < \mathrm{cf}(\mu).$$

2. *The set $\{\delta \in S^{\mu^+}_{\kappa} : \delta$ is good for $\vec{f}\}$ is stationary.*

Proof. The key here is the concept denoted $(*)_\kappa$ in the chapter of Abraham and Magidor (see [1, Definition 2.8]) in this Handbook. We recall the definition:

3.52 Definition. Suppose that I is an ideal over a set A, λ is a regular cardinal $> |A|$, and $\vec{f} = \langle f_\xi : \xi < \lambda\rangle$ is a $<_I$-increasing sequence of functions mapping A to On. If $|A| < \kappa \leq \lambda$, then $(*)_\kappa$ denotes the following statement:

$(*)_\kappa$ Whenever $X \subseteq \lambda$ is unbounded, then for some $X_0 \subseteq X$ of order-type κ, $\langle f_\xi : \xi \in X_0\rangle$ is strongly increasing.

In Theorem 2.13 of [1], it is shown (among other things) that statement (1) of the current theorem is equivalent to $(*)_\kappa$; we will show that our statement (2) is equivalent to $(*)_\kappa$.

Suppose that $(*)_\kappa$ holds, where κ is a regular cardinal such that $\mathrm{cf}(\mu) < \kappa < \mu$. Let S be the set of $\delta \in S^{\mu^+}_\kappa$ for which there is a cofinal $X_0 \subseteq \delta$ of order-type κ with $\langle f_\xi : \xi \in X_0\rangle$ strongly increasing. Clearly $(*)_\kappa$ implies that S must be stationary, and (2) follows from Theorem 3.50.

Conversely, suppose that (2) holds and X is a cofinal subset of μ^+. Our assumptions imply that there is a good δ of cofinality κ for which $\delta = \sup(X \cap \delta)$. We apply Theorem 3.50 once more to find $X_0 \subseteq X \cap \delta$ with the required properties. ⊣

Now at last we are in a position to prove Shelah's theorem (Theorem 1.5 from Chap. II of [89]) that scales exist for every singular cardinal.

3.53 Theorem. *If μ is singular, then there exists a scale for μ.*

Proof. Let $\lambda = \mu^+$ for μ singular, and let $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ be a strictly increasing sequence of regular cardinals cofinal in μ with $\mathrm{cf}(\mu) < \mu_0$. Let I be the ideal of bounded subsets of $\mathrm{cf}(\mu)$; we shall consider the structure

$$\mathfrak{B} = \prod_{i<\mathrm{cf}(\mu)} \mu_i$$

ordered by $<_I$. It is quite easy to see that $(\mathfrak{B}, <_I)$ is λ-directed, that is, if we are given a family $\mathcal{F} \subseteq \mathfrak{B}$ of size $\leq \mu$, then there is a single function $f \in \mathfrak{B}$ that is above (in the sense of $<_I$) all members of $\mathcal{F}$.

Let $\langle M_\alpha : \alpha < \lambda\rangle$ be a λ-approximating sequence over $\mathfrak{B}$, and for each $\alpha < \lambda$ let g_α be the $<_\chi$-least function in $\mathfrak{B}$ that dominates $M_\alpha \cap \mathfrak{B}$. (Recall that $<_\chi$ is the well-ordering of $H(\chi)$ built into the ambient structure $\mathfrak{A}$.) Note that $g_\alpha \in M_{\alpha+1}$, and the sequence $\langle g_\alpha : \alpha < \lambda\rangle$ is $<_I$-increasing.

3.54 Claim. *The sequence $\langle g_\alpha : \alpha < \lambda\rangle$ has an exact upper bound g with the property that for each regular $\kappa < \mu$,*

$$\{i < \mathrm{cf}(\mu) : \mathrm{cf}(g(i)) < \kappa\} \text{ is bounded below } \mu.$$

Proof of Claim. Given a regular cardinal $\kappa < \mu$, we know that S^λ_κ has a stationary subset in $I[\lambda]$. In fact, we know that there is a stationary $S \subseteq S^\lambda_\kappa$ with the property that for each $\delta \in S$, there is an IA chain of submodels $\langle N_i : i < \kappa\rangle$ such that

- $|N_\xi| < \kappa$,
- $N_\xi \subseteq M_\delta$ for all $\xi < \kappa$, and
- $M_\alpha \in N$ for unboundedly many $\alpha < \delta$, where $N := \bigcup_{\xi<\kappa} N_\xi$.

(This follows from Theorem 3.11.) Assume now that $\mathrm{cf}(\mu) < \kappa$ and fix such a δ and sequence $\langle N_i : i < \kappa\rangle$.

For $\xi < \kappa$ and $i < \mathrm{cf}(\mu)$, we define

$$h_\xi(i) := \sup(N_\xi \cap \mu_i),$$

and

$$h(i) := \sup(N \cap \mu_i).$$

For each $i < \mathrm{cf}(\mu)$, the sequence $\langle h_\xi(i) : \xi < \kappa\rangle$ is increasing with limit $h(i)$, and it follows easily that h is an exact upper bound for $\langle h_\xi : \xi < \kappa\rangle$.

We claim now that h is an exact upper bound for $\langle g_\alpha : \alpha < \delta\rangle$. Note that h is an upper bound for $\langle g_\alpha : \alpha < \delta\rangle$ because N contains M_α for cofinally many $\alpha < \delta$. If $f <_I h$ then $f <_I h_\xi$ for some ξ. But $h_\xi \in N \subseteq M_\delta$ hence $h_\xi \in M_\alpha$ for some $\alpha < \delta$. It follows that

$$f <_I h_\xi <_I g_\alpha,$$

and hence h is an exact upper bound for the sequence $\langle g_\alpha : \alpha < \delta\rangle$.

We conclude that the sequence $\langle g_\alpha : \alpha < \lambda\rangle$ has stationarily many good points of cofinality κ for each regular $\kappa < \mu$ greater than $\mathrm{cf}(\mu)$. The conclusion of the claim follows from Theorem 3.51. $\dashv$

To recap, we have constructed a $<^*$-increasing sequence $\langle g_\alpha : \alpha < \mu^+\rangle$ in $\prod_{i<\mathrm{cf}(\mu)} \mu_i$ with an exact upper bound g such that for all $\kappa < \mu$,

$$|\{i < \mathrm{cf}(\mu) : \mathrm{cf}(g(i)) < \kappa\}| < \mathrm{cf}(\mu). \tag{15.49}$$

By making inessential modifications to g and each g_α, we may assume that

- $\mathrm{cf}(\mu) < \mathrm{cf}(g(i))$ for all $i < \mathrm{cf}(\mu)$, and
- $g_\alpha(i) < g(i)$ for all $\alpha < \mu^+$ and $i < \mathrm{cf}(\mu)$.

Let B be the set of cardinals of the form $\mathrm{cf}(g(i))$ for some $i < \mathrm{cf}(\mu)$. The set B is cofinal in μ of order-type $\mathrm{cf}(\mu)$ by (15.49). Let $\vec{\theta} = \langle \theta_\xi : \xi < \mathrm{cf}(\mu) \rangle$ enumerate B in increasing order, and for $\xi < \mathrm{cf}(\mu)$ let

$$B_\xi := \{i < \mathrm{cf}(\mu) : \mathrm{cf}(g(i)) = \theta_\xi\}.$$

Our goal is to construct a $<^*$-increasing sequence $\vec{f} = \langle f_\alpha : \alpha < \mu^+ \rangle$ in $\prod_{\xi < \mathrm{cf}(\mu)} \theta_\xi$ so that $(\vec{\theta}, \vec{f})$ is a scale for μ^+. To do this, we use the fact that there is a natural mapping

$$\Phi : \textstyle\prod_{i<\mathrm{cf}(\mu)} g(i) \to \prod_{\xi<\mathrm{cf}(\mu)} \theta_\xi$$

defined as follows:

For each $i < \mathrm{cf}(\mu)$, let $\langle e_i(\epsilon) : \epsilon < \mathrm{cf}(g(i)) \rangle$ be the increasing enumeration of a cofinal subset of $g(i)$. For $h \in \prod_{i<\mathrm{cf}(\mu)} g(i)$, we define

$$\Phi[h](\xi) = \text{the least } \epsilon < \theta_\xi \text{ such that } h(i) \leq e_i(\epsilon) \text{ for all } i \in B_\xi.$$

Note that $\Phi[h] \in \prod_{\xi<\mathrm{cf}(\mu)} \theta_\xi$, and clearly

$$h \leq^* h' \quad \Longrightarrow \quad \Phi[h] \leq^* \Phi[h'].$$

Thus, $\langle \Phi[g_\alpha] : \alpha < \mu^+ \rangle$ is a $\leq^*$-increasing sequence in $\prod_{\xi<\mathrm{cf}(\mu)} \theta_\xi$.

We claim now that if h is in $\prod_{\xi<\mathrm{cf}(\mu)} \theta_\xi$, then there is an α such that $h \leq^* \Phi[g_\alpha]$. Given such an h, define $h' \in \prod_{i<\mathrm{cf}(\mu)} g(i)$ by

$$h'(i) = e_i(h(\xi)) \quad \text{for the unique } \xi < \mathrm{cf}(\mu) \text{ with } i \in B_\xi.$$

Clearly $h' \in \prod_{i<\mathrm{cf}(\mu)} g(i)$ and furthermore $\Phi[h'] = h$. Since g is an exact upper bound for the g_α's, there is an $\alpha < \mu^+$ with $h' \leq^* g_\alpha$ and so

$$h = \Phi[h'] \leq^* \Phi(g_\alpha).$$

As an immediate corollary, it follows that for all $h \in \prod_{\xi<\mathrm{cf}(\mu)} \theta_\xi$ there is a $\gamma < \mu^+$ such that $h <^* \Phi[g_\gamma]$ (and not just $h \leq^* \Phi[g_\gamma]$). Now we define $\vec{f}$ in the obvious manner:

Given $\langle f_\beta : \beta < \alpha \rangle$, we let $f_\alpha = \Phi[g_\gamma]$ where $\gamma < \mu^+$ is the least ordinal greater than or equal to α such that $f_\beta <^* \Phi[g_\gamma]$ for all $\beta < \alpha$. The verification that $(\vec{\theta}, \vec{f})$ is a scale for μ^+ is now routine. $\dashv$

We remark that in the above context, if $S \in I[\lambda]$ is a stationary set of ordinals of cofinality larger than $\mathrm{cf}(\mu)$, then the preceding construction gives us a scale that is good at almost every point of S. In fact, much more is true—given such an $S \in I[\lambda]$ and *any* scale $(\vec{\mu}, \vec{f})$ for μ, a similar argument establishes that almost every point of S is good for $\vec{f}$.

3.55 Theorem (Cummings, Foreman, and Magidor [17]). *Let $\lambda = \mu^+$ where μ is singular, and suppose that $(\vec{\mu}, \vec{f})$ is a scale for μ. If $S \in I[\lambda]$, then almost all points of S with cofinality greater than* $\mathrm{cf}(\mu)$ *are good for $\vec{f}$.*

The above theorem can be summarized by the statement "approachable points are good". With regard to the converse, we mention that Gitik and Sharon [39] have constructed a model in which $\aleph_{\omega^2+1}$ carries a scale for which all points are good, but $\mathrm{AP}_{\aleph_{\omega^2}}$ fails. We discuss this model more at the end of Sect. 4.7. Whether this can happen at $\aleph_\omega$ is still open, but the following result of Cummings, Foreman, and Magidor [17] gives some information.

3.56 Theorem. *If $\square_{\aleph_n}$ holds for all finite n, then in $\aleph_{\omega+1}$ all good points of cofinality greater than $\aleph_1$ are approachable.*

4. Applications of Scales and Weak Squares

4.1. Weakenings of $\square$—Part I

If one views a $\square_\mu$-sequence as a sequence of sets endowed with strong global coherence properties, then two natural means of weakening this combinatorial principle become apparent—one might require the coherence properties to hold only some of the time, or one might weaken the amount of coherence required. Both of these ideas are important and we look at them in this subsection and the next.

4.1 Definition. Suppose that λ is a regular cardinal and η is an ordinal. We say that a set $S \subseteq \lambda$ *carries a partial square as a subset of* λ if there is a sequence $\langle C_\delta : \delta \in S\rangle$ and an ordinal $\eta < \lambda$ such that

1. C_δ is a closed and unbounded subset of C_δ for all limit $\delta \in S$,
2. $\mathrm{ot}(C_\delta) < \eta$, and
3. if $\gamma \in \mathrm{acc}(C_\alpha) \cap \mathrm{acc}(C_\beta)$, then $C_\alpha \cap \gamma = C_\beta \cap \gamma$.

We suppress reference to λ if λ is clear from context. We call the sequence $\langle C_\alpha : \alpha < \lambda\rangle$ a partial square for S, and if we wish to emphasize the value of η then we say S *carries a partial square type-bounded by* η. If S is a subset of S^λ_κ for some $\kappa < \lambda$, then it is standard practice to require $\eta = \kappa + 1$.

Note that if S carries a partial square, then it is straightforward to extend the partial square sequence to the set

$$S^+ := S \cup \bigcup_{\delta \in S} \mathrm{acc}(C_\delta). \tag{15.50}$$

We note as well that if a set $S \subseteq S^\lambda_\kappa$ carries a partial square, then S can be written as a union of fewer than λ sets, each of which carries a partial square type-bounded by $\kappa+1$. This means that in practice, the demand of the last sentence from Definition 4.1 is not a serious one.

For $\lambda = \mu^+$, it is clear that $\square_\mu$ holds if and only if λ carries a partial square sequence type-bounded by $\mu+1$. On the other hand, if $S \subseteq \lambda$ carries a partial square, then an argument similar to that of Theorem 3.13 shows that S is in $I[\lambda]$. The following theorem shows us that a result analogous to Theorem 2.4 holds in the presence of partial squares.

4.2 Theorem. *Suppose that $S \subseteq \lambda$ carries a partial square. Then every stationary $T \subseteq \lambda$ has a stationary subset T^* which does not reflect at any ordinal in S.*

Proof. Let $\langle C_\delta : \delta \in S\rangle$ be a partial square on S, type-bounded by some $\eta < \lambda$. By the comments after Definition 4.1, we may assume

$$\delta \in S \implies \operatorname{acc}(C_\delta) \subseteq S.$$

This implies that $S \cap \delta$ contains a closed unbounded subset of δ for all $\delta \in S$ of uncountable cofinality.

Let T be a stationary subset of λ. If $T \setminus S$ is stationary then the remarks in the preceding paragraph imply that $T \setminus S$ cannot reflect at an ordinal in S and we are done.

If on the other hand $T \setminus S$ is nonstationary, then without loss of generality $T \subseteq S \setminus \eta$. Just as in the proof of Theorem 2.4, there is a stationary $T^* \subseteq T$ and an ordinal $\xi < \eta$ such that $\operatorname{ot}(C_\alpha) = \xi$ for all $\alpha \in T^*$. If $\delta \in S$ has uncountable cofinality, then $T^* \cap \operatorname{acc}(C_\delta)$ has at most one element and so $T^* \cap \delta$ is not stationary in δ. ⊣

The next theorem is due to Shelah [87], and it gives us information about $I[\lambda]$ in the case where λ is the successor of a regular cardinal.

4.3 Theorem. *If $\tau < \sigma$ are regular cardinals, then $S^{\sigma^+}_\tau$ can be written as the union of σ sets, each of which carries a partial square.*

Proof. As usual, let χ be a sufficiently large regular cardinal, and let $\mathfrak{A}$ be the structure $\langle H(\chi), \in, <_\chi\rangle$. Given $\alpha \in S^{\sigma^+}_\tau$ and $\zeta < \sigma$, we define

$$M(\alpha,\zeta) = \operatorname{Sk}^{\mathfrak{A}}(\{\alpha\} \cup \zeta).$$

For each $\alpha \in S^{\sigma^+}_\tau$ there is a least $\zeta = \zeta(\alpha) \geq \tau$ such that

- $M(\alpha,\zeta) \cap \sigma$ is an initial segment of σ, and
- $\operatorname{cf}(M(\alpha,\zeta) \cap \sigma) > \aleph_0$,

and we define

$$N_\alpha := M(\alpha, \zeta(\alpha)).$$

4.4 Claim. *$N_\alpha \cap \alpha$ is an ω-closed unbounded subset of α.*

Proof. We know $N_\alpha \cap \alpha$ is unbounded in α since $\mathrm{cf}(\alpha) = \tau \leq \zeta(\alpha) \subseteq N_\alpha$ and $\alpha \in N_\alpha$. Thus, we need only prove that $N_\alpha \cap \alpha$ is ω-closed.

Let x be a countable subset of $N_\alpha \cap \alpha$, and assume by way of contradiction that $\beta := \sup x \notin N_\alpha$. Note that this assumption implies that β is an ordinal of countable cofinality strictly less than α, so we can define

$$\gamma := \min(N_\alpha \cap \alpha \setminus \beta).$$

Since $\gamma \in N_\alpha$, it follows that $\beta < \gamma$, and $N_\alpha \cap \gamma$ is bounded below γ. Note as well that $\mathrm{cf}(\gamma) = \sigma$, for if it were less than σ, then N_α would contain every member of a cofinal subset of γ because $\mathrm{cf}(\gamma)$ would be in an element of N_α and $N_\alpha \cap \sigma$ is an initial segment of σ.

Since both σ and γ are in N_α, we can find an increasing continuous function $f : \sigma \to \gamma$ in N_α whose range is unbounded in γ. If we step outside of N_α, we see that $f \restriction N_\alpha \cap \sigma$ is an increasing function from $N_\alpha \cap \sigma$ to a cofinal subset of β. This gives a contradiction, as $N_\alpha \cap \sigma$ has uncountable cofinality, while the cofinality of β is countable. ⊣

For each $\alpha \in S^{\sigma^+}_\tau$, let D_α be the closure of $N_\alpha \cap \alpha$ in α. Given ρ and ϵ less than σ, we define

$$S(\rho, \epsilon) := \{\alpha \in S^{\sigma^+}_\tau : N_\alpha \cap \sigma = \rho \text{ and } \mathrm{ot}(D_\alpha) = \epsilon\}.$$

We claim that $\langle D_\alpha : \alpha \in S(\rho, \epsilon)\rangle$ is a partial square sequence on $S(\rho, \epsilon)$, and the following claim suffices.

4.5 Claim. *If α and β are in $S(\rho, \epsilon)$, then*

$$\gamma \in \mathrm{acc}(D_\alpha) \cap \mathrm{acc}(D_\beta) \quad \Longrightarrow \quad D_\alpha \cap \gamma = D_\beta \cap \gamma. \tag{15.51}$$

Proof. Assume first that γ is of countable cofinality. Then by Claim 4.4, γ is an element of both N_α and N_β. We know $|\gamma| \leq \sigma$, and since $N_\alpha \cap \sigma = N_\beta \cap \sigma = \rho$, it follows that $N_\alpha \cap \gamma = N_\beta \cap \gamma$.

If $\mathrm{cf}(\gamma) > \aleph_0$, then γ is a limit of ordinals from $\mathrm{acc}(D_\alpha) \cap \mathrm{acc}(D_\beta)$ of countable cofinality, and so the result follows by the previous paragraph. ⊣

Since $S^{\sigma^+}_\tau = \bigcup_{\rho, \epsilon < \sigma} S(\rho, \epsilon)$, the proof of the theorem is complete. ⊣

The preceding theorem has the following corollary, which was promised back in Sect. 3.3.

4.6 Corollary. *If σ is a regular cardinal, then $S^{\sigma^+}_{<\sigma} \in I[\sigma^+]$.*

Proof. We know that $S^{\sigma^+}_{<\sigma}$ is the union of σ sets each carrying a partial square. By the remarks preceding Theorem 4.2, each of these sets is in $I[\sigma^+]$, and now the result follows immediately because $I[\sigma^+]$ is a normal ideal. ⊣

The following theorem due to Džamonja and Shelah [21] serves as the counterpart to Theorem 4.3 at the successor of a singular cardinal.

4.7 Theorem. *Suppose that μ is singular, $\lambda = \mu^+$, and $\kappa < \mu$ is an uncountable cardinal such that* $\mathrm{cf}([\mu]^\kappa, \subseteq) = \mu$. *Then the set $S^\lambda_{\leq\kappa}$ is the union of μ sets, each of which carries a partial square type-bounded by κ^+.*

There are many open questions concerning the notion of partial square. In particular, the question of whether S^λ_κ has a stationary subset which carries a partial square is still open in many cases—for example, if λ is inaccessible, or $\lambda = \mu^+$ for μ singular with $\mathrm{cf}(\mu) \leq \kappa$ (see [91, Question 5.9]). We shall see in Sect. 4.3 that these matters are related to an open problem involving $\diamondsuit$, while Foreman and Todorčević [35] have investigated some consequences of the conjecture that for all successor λ, the set $S^\lambda_{\aleph_1}$ contains a stationary subset on which there is a partial square.

We close this subsection with a discussion of partial squares above a supercompact cardinal κ. Foreman and Magidor [34] used ideas of Baumgartner to establish the following theorem:

4.8 Theorem. *If κ is supercompact, then there is a forcing extension which preserves the supercompactness of κ and in which, letting λ denote $\kappa^{+\omega+1}$, we have*

$$S^\lambda_{\geq\kappa} \textit{ carries a partial square type-bounded by } \kappa^{+\omega}. \tag{15.52}$$

The preceding theorem tells us that the reflection result from Theorem 2.5 is sharp, for we have the following corollary.

4.9 Corollary. *Let κ is a supercompact cardinal for which (15.52) holds, and let S be a stationary subset of $\lambda = \kappa^{+\omega+1}$. Then* $\mathrm{Refl}(S)$ *holds if and only if $S \cap S^\lambda_{\geq\kappa}$ is nonstationary.*

Proof. If $S \cap S^\lambda_{\geq\kappa}$ is nonstationary, then $\mathrm{Refl}(S)$ holds by way of Theorem 2.5. If $S \cap S^\lambda_{\geq\kappa}$ is stationary, then we can find a regular σ such that $\kappa < \sigma < \kappa^{+\omega}$ and $T := S \cap S^\lambda_\sigma$ is stationary. By Theorem 4.2, T has a stationary subset T^* that does not reflect in any ordinal of cofinality κ or greater. But S^λ_σ only reflects in ordinals of cofinality greater than σ, and therefore T^* cannot reflect at all. ⊣

4.2. Weakenings of □—Part II

In this subsection, we examine yet another way to weaken $\square_\kappa$—we reduce the amount of coherence required by the sequence. We begin with the classic definition (due to Jensen [52]) of *weak square*.

4.10 Definition. Let κ be a cardinal. A $\square^*_\kappa$*-sequence* or *weak square sequence for* κ is a sequence $\langle \mathcal{C}_\alpha : \alpha < \kappa^+ \rangle$ such that

1. $\mathcal{C}_\alpha$ is a family of closed unbounded subsets of α,

2. $|\mathcal{C}_\alpha| \leq \kappa$,

3. $C \in \mathcal{C}_\alpha \Longrightarrow \mathrm{ot}(C_\alpha) \le \kappa$, and
4. $C \cap \beta \in \mathcal{C}_\beta$ for $C \in \mathcal{C}_\alpha$ and $\beta \in \mathrm{acc}(C)$.

$\square^*_\kappa$ is the assertion that there is such a sequence.

An elementary argument establishes that $\square^*_\kappa$ follows if $\kappa^{<\kappa} = \kappa$, so weak square is of greatest interest in the case of singular cardinals. Before we get to some applications, we make a few remarks on the structure of weak square sequences.

First, note that for $\alpha < \kappa^+$ we have

$$\mathrm{cf}(\alpha) < \kappa \quad \Longrightarrow \quad \mathrm{ot}(C) < \kappa \text{ for all } C \in \mathcal{C}_\alpha. \tag{15.53}$$

This follows from the simple fact that such an α has no closed unbounded subset of order-type κ.

Next, we may assume the $\square^*_\kappa$ sequence has the property that each $\mathcal{C}_\alpha$ contains a set of order-type $\mathrm{cf}(\alpha)$. To arrange this, we choose for each limit $\epsilon < \kappa$ a closed unbounded $D_\epsilon \subseteq \epsilon$ of order-type $\mathrm{cf}(\epsilon)$. For each C in $\mathcal{C}_\alpha$, check if the order-type of C is in $\mathrm{acc}(D_\epsilon) \cup \{\epsilon\}$. If so, then add the set $\{\beta \in C : \mathrm{ot}(C_\beta) \in D_\epsilon\}$ to $\mathcal{C}_\alpha$. It is straightforward to verify that this modification does the job.

The preceding observation helps us situate $\square^*_\kappa$ in the hierarchy of combinatorial principles we have been studying. It is clear that $\square_\kappa$ implies $\square^*_\kappa$, and the following easy proposition shows us that $\square^*_\kappa$ implies AP_κ.

4.11 Proposition. *If $\square^*_\kappa$ holds, then so does AP_κ.*

Proof. Let $\bar{\mathcal{C}}$ be a $\square^*_\kappa$ sequence such that $\mathcal{C}_\alpha$ contains a set of order-type $\mathrm{cf}(\alpha)$ for each limit $\alpha < \kappa^+$. Let $\mathfrak{M} = \langle M_i : i < \kappa^+ \rangle$ be a κ^+-approximating sequence over $\bar{\mathcal{C}}$. If $\delta < \kappa^+$ satisfies $\delta = M_\delta \cap \kappa^+$, then any set in $\mathcal{C}_\delta$ of order-type $\mathrm{cf}(\delta)$ establishes that δ is in $S[\mathfrak{M}]$. Thus, $S[\mathfrak{M}]$ contains a closed unbounded set and therefore AP_κ holds. ⊣

None of the implications in the chain $\square_\kappa \Longrightarrow \square^*_\kappa \Longrightarrow \mathrm{AP}_\kappa$ can be reversed. The model of Ben-David and Magidor [7] mentioned in Theorem 2.14 provides a model in which $\square^*_{\aleph_\omega}$ holds and $\square_{\aleph_\omega}$ fails. (Apter and Henle [3] have obtained similar results starting from a κ^+-strongly compact cardinal instead of a κ^+-supercompact cardinal.) On the other hand, an argument outlined in [34, Sect. 5] yields a model in which $\mathrm{AP}_{\aleph_\omega}$ holds and $\square^*_{\aleph_\omega}$ fails.

It turns out that weak square is compatible with strong forms of stationary reflection. For example, we have the following theorem of Cummings, Foreman, and Magidor [16]:

4.12 Theorem. *If the existence of infinitely many supercompact cardinals is consistent, then there is a model of* ZFC *in which $\square^*_{\aleph_\omega}$ holds, and*

> *For $1 \le m \le n < \omega$, if $\langle S_i : i < \aleph_m \rangle$ is a sequence of stationary subsets of $\{\alpha < \aleph_{\omega+1} : \mathrm{cf}(\alpha) < \aleph_m\}$, then there is an ordinal $\delta < \aleph_{\omega+1}$ of cofinality $\aleph_n$ such that the S_i all reflect at δ.*

In the above model, it is clear that $\square_{\aleph_\omega}$ must fail. Ben-David and Shelah [8] claimed to construct a model of $\square^*_{\aleph_\omega}$ in which $\mathrm{Refl}(\aleph_{\omega+1})$ holds, but more recent work of Cummings, Foreman, and Magidor has demonstrated that the purported proof cannot be completed along the lines indicated, as weak square is incompatible with certain forms of generic supercompactness. We refer the reader to [18, Sect. 10] for the actual statement of this result.

Finally, we point out that even though weak square is compatible with stationary reflection, it is still a powerful principle for constructing non-compact objects. This can be seen in the following result of Jensen, which we state without proof. Section 5 of Cummings' paper [14] contains a very nice proof taken from unpublished notes of Magidor [63] concerning Todorčević's paper [97].

4.13 Theorem. *If κ is a cardinal, then $\square^*_\kappa$ is equivalent to the existence of a special κ^+-Aronszajn tree.*

Proof. See [14, Sect. 5]. $\dashv$

We turn our attention now to the gap between $\square_\kappa$ and $\square^*_\kappa$. In the course of investigating the core model for one Woodin cardinal, Schimmerling [74] isolated a spectrum of combinatorial principles that form a natural hierarchy between $\square_\kappa$ and $\square^*_\kappa$.

4.14 Definition. Let $\sigma \leq \kappa$ be cardinals. (We assume κ is infinite, but σ is allowed to be finite.) A $\square^\sigma_\kappa$*-sequence* is a sequence $\langle \mathcal{C}_\alpha : \alpha < \kappa^+\rangle$ such that

1. $\mathcal{C}_\alpha$ is a family of closed unbounded subsets of α,
2. $1 \leq |\mathcal{C}_\alpha| \leq \sigma$,
3. $C \in \mathcal{C}_\alpha \implies \mathrm{ot}(C) \leq \kappa$, and
4. for all $C \in \mathcal{C}_\alpha$,
$$\beta \in \mathrm{acc}(C) \quad\implies\quad C \cap \beta \in \mathcal{C}_\beta.$$

$\square^\sigma_\kappa$ is the assertion that there is such a sequence. One should give $\square^{<\sigma}_\kappa$ the obvious meaning along the lines above.

It follows immediately that $\square^1_\kappa = \square_\kappa$, $\square^\kappa_\kappa = \square^*_\kappa$, and

$$\square^\sigma_\kappa \;\Rightarrow\; \square^\tau_\kappa \quad \text{if } 1 \leq \sigma \leq \tau \leq \kappa.$$

Note that the requirement that $\sigma \leq \kappa$ is natural, as the principle $\square^{\kappa^+}_\kappa$ is true in ZFC—for each $\alpha < \kappa^+$ choose a closed unbounded $C_\alpha \subseteq \alpha$ of order-type $\mathrm{cf}(\alpha)$, and then define $\mathcal{C}_\alpha = \{C_\beta \cap \alpha : \alpha \leq \beta < \kappa^+\}$. This combinatorial principle is more commonly known as *silly square*.

Before continuing our investigation into these principles, it is natural to ask if there are non-trivial implications between them. The following theorem from [16] gives a satisfactory answer.

4.15 Theorem. *Let κ be supercompact, and suppose that $2^{(\kappa^{+\omega})} = \kappa^{+\omega+1}$. Let μ and ν be two cardinals (one or both can be finite) such that*

$$1 \leq \mu < \nu < \aleph_\omega.$$

Then there is a generic extension in which

1. *all cardinals $\leq \nu$ are preserved,*
2. *$\aleph_\omega = \kappa_V^{+\omega}$,*
3. *$\square^{\nu}_{\aleph_\omega}$ holds, and*
4. *$\square^{\mu}_{\aleph_\omega}$ fails.*

With regard to applications of these principles, we restrict attention to their impact on stationary reflection, and a reader seeking more information concerning these principles and their relation to core models is referred to [73, 75, 77, 78], and [15].

We begin our discussion of stationary reflection with two results of Schimmerling.

4.16 Proposition. *If $\kappa^{<\sigma} = \kappa$ and $\square^{<\sigma}_{\kappa}$ holds, then every stationary subset S of κ^+ has a stationary subset that does not reflect at ordinals of cofinality σ or greater.*

Proof. Suppose that $\bar{\mathcal{C}}$ is a $\square^{<\sigma}_{\kappa}$-sequence, and define

$$F(\alpha) = \{\mathrm{ot}(C) : C \in \mathcal{C}_\alpha\}$$

for limit ordinals $\alpha < \kappa^+$. Since $\kappa^{<\sigma} = \kappa$, we note that F has only κ possible values. Thus, given a stationary set $S \subseteq \kappa^+$, there must be a stationary $T \subseteq S$ on which F is constant, say with value X.

If $\mathrm{cf}(\alpha) \geq \sigma$ and $C \in \mathcal{C}_\alpha$, then for each $\beta \in T \cap \mathrm{acc}(C)$ we know the order-type of $C \cap \beta$ is in X. This means that $\mathrm{acc}(C) \cap T$ is bounded below α and therefore $T \cap \alpha$ is not stationary in α. ⊣

As a quick corollary, we see that $\square^{<\omega}_{\kappa}$ implies that $\mathrm{Refl}(S)$ fails for all stationary subsets S of κ^+. Another modification of the argument yields the following proposition at successors of singular cardinals.

4.17 Proposition. *Suppose that μ is singular and $\square^{<\mathrm{cf}(\mu)}_{\mu}$ holds. Then for every stationary subset S of μ^+, there is a stationary $T \subseteq S$ and a $\beta < \mu$ such that T does not reflect at ordinals of cofinality $> \beta$.*

Proof. Let $\bar{\mathcal{C}}$ be a $\square^{<\mathrm{cf}(\mu)}_{\mu}$-sequence, and define $F : \mu^+ \to \mu$ by

$$F(\alpha) = \sup\left(\{\mathrm{ot}(C) : C \in \mathcal{C}_\alpha\}\right).$$

If $S \subseteq \mu^+$ is stationary, then there is a stationary $T \subseteq S$ for which $F \restriction T$ is constant, say with value $\beta < \mu$. If $\mathrm{cf}(\gamma) > \beta$ and $C \in \mathcal{C}_\gamma$, then

$$\beta < \mathrm{cf}(\gamma) \leq \mathrm{ot}(C)$$

so for all sufficiently large $\delta \in \mathrm{acc}(C)$ we have $F(\delta) > \beta$ and hence $\delta \notin T$. $\dashv$

The preceding result of Schimmerling is sharp, as Cummings, Foreman, and Magidor have shown [16, Sect. 10] that it is consistent for a strengthening of $\square^\omega_{\aleph_\omega}$ to hold simultaneously with the statement "every stationary subset of $\aleph_{\omega+1}$ reflects in all sufficiently large cofinalities".

With regard to simultaneous reflection, we have the following result of Cummings, Foreman, and Magidor [16].

4.18 Theorem. *Let μ be a singular cardinal, and assume $\square^\sigma_\mu$ holds for some $\sigma < \mu$. Given a stationary set $T \subseteq \mu^+$, we can find a sequence $\langle S_i : i < \mathrm{cf}(\mu)\rangle$ of stationary subsets of T that do not reflect simultaneously in any ordinal of cofinality greater than $\mathrm{cf}(\mu)$.*

This theorem follows from results presented later in the chapter—see Theorem 4.66. Note that by Theorem 4.12, the conclusion of Theorem 4.18 does not follow from $\square^*_\mu$. The following theorem, again taken from [16], shows that the conclusion of the preceding theorem cannot be strengthened to rule out simultaneous reflection of fewer than $\mathrm{cf}(\mu)$ sets.

4.19 Theorem. *If the existence of infinitely many supercompact cardinals is consistent, then there is a model of* ZFC *in which $\square^\omega_{\aleph_\omega}$ holds, and*

> *For every finite sequence $\langle S_i : i < n\rangle$ of stationary subsets of $\aleph_{\omega+1}$, there is an $M < \omega$ such that for each $m \geq M$ there is an ordinal δ of cofinality $\aleph_m$ such that all S_i reflect at δ.*

The next theorem of Cummings and Schimmerling [15] shows us that $\square^*_{\aleph_\omega}$ cannot be strengthened to $\square^{<\aleph_\omega}_{\aleph_\omega}$ in Theorem 4.12.

4.20 Theorem. *If μ is a singular strong limit cardinal for which $\square^{<\mu}_\mu$ holds, and T is a stationary subset of μ^+, then there is a sequence of stationary sets $\langle S_i : i < \mathrm{cf}(\mu)\rangle$ and a cardinal $\theta < \mu$ such that*

1. *$S_i \subseteq T \cap S^{\mu^+}_{<\theta}$, and*
2. *the sets S_i do not simultaneously reflect at any ordinal of cofinality θ or greater.*

We will give a proof of this theorem because it fits in nicely with other proofs in this subsection, but we need the following easy observation.

4.21 Lemma. *Let μ be a singular cardinal and $\sigma \leq \mu^+$. If $\square^{<\sigma}_\mu$ holds, then there is a $\square^{<\sigma}_\mu$-sequence $\langle \mathcal{D}_\alpha : \alpha < \mu^+\rangle$ with the property that all elements of each $\mathcal{D}_\alpha$ are of order-type less than μ.*

Proof. Let D be a closed unbounded subset of μ of order-type $\mathrm{cf}(\mu)$, and let $\langle \mathcal{C}_\alpha : \alpha < \mu^+ \rangle$ be a $\square_\mu^{<\sigma}$-sequence. If $C \in \mathcal{C}_\delta$, then $\mathrm{ot}(C) \leq \mu$ and we define a set $C^* \subseteq C$ according to the following cases:

- If $\mathrm{ot}(C) \in \mathrm{acc}(D) \cup \{\mu\}$, then $C^* = \{\delta \in C : \mathrm{ot}(C \cap \delta) \in D\}$.
- Otherwise, set $C^* = \{\delta \in C : \max(\mathrm{ot}(C) \cap \mathrm{acc}(D))\}$.

If we define $\mathcal{D}_\alpha$ to be the collection $\{C^* : C \in \mathcal{C}_\alpha\}$, then it is routine to verify that this sequence has the required properties. ⊣

In contrast to the situation with weak square, we cannot guarantee that each $\mathcal{D}_\alpha$ will contain a set of order-type $\mathrm{cf}(\alpha)$. It is shown in [16, Sect. 5] that these "improved" sequences exert slightly more influence on stationary reflection than their unimproved versions.

Proof of Theorem 4.20. Let $\mathcal{C}$ be a $\square_\mu^{<\mu}$-sequence satisfying the conclusion of the preceding lemma, and let $\langle \mu_i : i < \mathrm{cf}(\mu) \rangle$ be an increasing sequence of regular cardinals cofinal in μ. Given a stationary $T \subseteq \mu^+$, we can pass to a stationary $T^* \subseteq T$ such that for some σ and τ,

$$\delta \in T^* \quad \Longrightarrow \quad |\mathcal{C}_\delta| = \sigma \text{ and } \mathrm{cf}(\delta) = \tau. \tag{15.54}$$

Next, let us suppose that $\alpha < \mu^+$ and $j < \mathrm{cf}(\mu)$, and define

$$A(\alpha, j) = \{\mathrm{ot}(C) : C \in \mathcal{C}_\alpha\} \cap \mu_j. \tag{15.55}$$

For each j, there are at most $2^{\mu_j} < \mu$ possible values for $A(\alpha, j)$, and thus we can find a stationary $S_j \subseteq T$ and a set A_j such that

$$\alpha \in S_j \quad \Longrightarrow \quad A(\alpha, j) = A_j. \tag{15.56}$$

Assume now that the sets $\langle S_j : j < \mathrm{cf}(\mu) \rangle$ reflect simultaneously at an ordinal δ, and choose $C \in \mathcal{C}_\delta$.

Since $\mathrm{ot}(C) < \mu$, there is a $j < \mathrm{cf}(\mu)$ with $\mathrm{ot}(C) < \mu_j$. If $\beta < \gamma$ are members of $\mathrm{acc}(C) \cap S_j$, then $\mathrm{ot}(C \cap \beta)$ and $\mathrm{ot}(C \cap \gamma)$ are distinct elements of A_j. Since $|A_j| < \mu_i$, it follows that $|\,\mathrm{acc}(C) \cap S_j| < \mu_i$ and therefore $\mathrm{cf}(\delta) < \mu_i$. ⊣

We close this subsection with commentary on the compatibility of these combinatorial principles with large cardinals. Burke and Kanamori have observed (see [73]) that if κ is μ^+-strongly compact then $\square_\mu^{<\,\mathrm{cf}(\mu)}$ must fail (even if $\mathrm{cf}(\mu) \geq \kappa$). On the other hand, Cummings, Foreman, and Magidor [16, Sect. 9] demonstrate that $\square_\mu^{\mathrm{cf}(\mu)}$ can consistently hold if κ is supercompact and $\kappa \leq \mathrm{cf}(\mu) < \mu$. This line of research is also continued in the paper [2] of Apter and Cummings.

4.3. On $\diamondsuit$

Our goal in this section is to combine ideas from the previous two sections in order to investigate Jensen's axiom $\diamondsuit$ at successors of singular cardinals. We begin by recalling the following classical definitions:

4.22 Definition. Let κ be an infinite cardinal, and let S be a stationary subset of κ^+. We say that $\diamondsuit(S)$ *holds* if there is a sequence $\langle S_\alpha : \alpha \in S\rangle$ such that for all $X \subseteq \kappa^+$, there are stationarily many $\alpha \in S$ for which

$$X \cap \alpha = S_\alpha.$$

We say that $\diamondsuit^*(S)$ *holds* if there is a sequence $\langle \mathcal{S}_\alpha : \alpha \in S\rangle$ such that $\mathcal{S}_\alpha$ is a family of at most κ subsets of α, and for all $X \subseteq \kappa^+$, the set of α for which $X \cap \alpha \in \mathcal{S}_\alpha$ contains the restriction to S of a closed unbounded subset of κ^+.

It is true that $\diamondsuit^*(S)$ implies $\diamondsuit(T)$ for all stationary $T \subseteq S$, but this is not immediately obvious. The way to see this is through the following classical result, which we state without proof:

4.23 Proposition. *Let κ be an infinite cardinal, and let $S \subseteq \kappa^+$ be stationary. Then $\diamondsuit(S)$ holds if and only if there is a sequence $\langle \mathcal{S}_\alpha : \alpha \in S\rangle$ such that such that $\mathcal{S}_\alpha$ is a family of at most κ subsets of α, and whenever $X \subseteq \kappa^+$, the set $\{\alpha \in S : X \cap \alpha \in \mathcal{S}_\alpha\}$ is stationary in κ^+.*

Proof. See Lemma III.3.4 and Lemma IV.2.6 of [19]. $\dashv$

It is a well-known result of Jensen that $\diamondsuit(\omega_1)$ is independent of ZFC + CH (see [20]). For cardinals above $\aleph_1$, the situation is different. Gregory [41] was the first to note this—he showed that $\diamondsuit^*(S^{\kappa^+}_\sigma)$ holds if $2^\kappa = \kappa^+$ and $\kappa^\sigma = \kappa$. Thus, we have instances of $\diamondsuit$ following from simple cardinal arithmetic assumptions. The question of particular interest to us in this subsection arises from the following related result of Shelah [83].

4.24 Theorem. *Assume μ is a strong limit singular cardinal with $2^\mu = \mu^+$. Then $\diamondsuit^*(\{\delta < \mu^+ : \mathrm{cf}(\delta) \neq \mathrm{cf}(\mu)\})$ holds.*

Proof. To simplify our notation a bit, let λ denote μ^+, and let S denote $\{\delta < \lambda : \mathrm{cf}(\delta) \neq \mathrm{cf}(\mu)\}$. Fix a λ-filtration sequence $\langle b_{\alpha,i} : i < \mathrm{cf}(\mu), \alpha < \lambda\rangle$, and let $\langle A_\alpha : \alpha < \lambda\rangle$ enumerate $[\lambda]^{<\lambda}$ in such a way that each set in $[\lambda]^{<\lambda}$ appears unboundedly often.

Given $\delta \in S$ and $i < \mathrm{cf}(\mu)$, we define

$$\mathcal{S}_{\delta,i} = \left\{\bigcup\nolimits_{\alpha \in I} A_\alpha : I \subseteq b_{\delta,i}\right\}$$

and

$$\mathcal{S}_\delta := \bigcup\nolimits_{i<\mathrm{cf}(\mu)} \mathcal{S}_{\delta,i}.$$

Since μ is a strong limit cardinal, we know that $|\mathcal{S}_\delta| \leq \mu$ for each $\delta \in S$. Now suppose that $A \subseteq \lambda$; we produce a closed unbounded $C \subseteq \lambda$ such that

$$\delta \in C \cap S \quad \Longrightarrow \quad A \cap \delta \in \mathcal{S}_\delta. \tag{15.57}$$

For $\alpha < \lambda$, let $f(\alpha)$ be the least $\beta > \alpha$ such that $A \cap \alpha = A_\beta$. Let $C \subseteq \lambda$ be the closed unbounded set of ordinals that are closed under f; we will show that (15.57) holds for this choice of C.

Give $\delta \in C \cap S$, let $\langle \delta_j : j < \mathrm{cf}(\delta) \rangle$ be an increasing sequence cofinal in δ such that $f(\delta_j) < \delta_{j+1}$. Since $\mathrm{cf}(\mu) \neq \mathrm{cf}(\delta)$, there is some $i^* < \mathrm{cf}(\mu)$ such that

$$|b_{\delta,i^*} \cap \{f(\delta_j) : j < \mathrm{cf}(\delta)\}| = \mathrm{cf}(\delta).$$

Let us define

$$J := \{j < \mathrm{cf}(\delta) : f(\delta_j) \in b_{\delta,i^*}\}$$

and

$$I := \{f(\delta_j) : j \in J\}.$$

Since J is unbounded in $\mathrm{cf}(\delta)$ and $A \cap \delta_j = A_{f(\delta_j)}$, it follows that

$$A \cap \delta = \textstyle\bigcup_{i \in I} A_\alpha.$$

Since $I \subseteq b_{\delta,i^*}$, it follows that $A \cap \delta \in \mathcal{S}_\delta$ as required. $\dashv$

Given Theorem 4.24, it is natural to ask if $\diamondsuit(S^{\mu^+}_{\mathrm{cf}(\mu)})$ follows if μ is a strong limit singular cardinal for which $2^\mu = \mu^+$. This question is still very much open, but we can use ideas of the sort we have been considering in this chapter to give sufficient conditions for this to hold.

4.25 Definition. Suppose that $\lambda = \mu^+$ for μ singular. A set $S \subseteq \lambda$ is said to be *diamond-friendly* if there is a sequence $\langle \mathcal{C}_\alpha : \alpha < \lambda \rangle$ such that

1. $\mathcal{C}_\alpha$ is a family of $\leq\mu$ closed unbounded subsets of α, and

2. there is a closed unbounded $E \subseteq \lambda$ such that for $\delta \in E \cap S$, there is a closed unbounded $C_\delta \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that

$$\alpha \in \mathrm{acc}(C_\delta) \quad \Longrightarrow \quad C_\delta \cap \alpha \in \mathcal{C}_\alpha.$$

If one were to write down a definition analogous to Definition 4.1 for what it means for a set to carry a weak square, one might very well end up with something like the above. We have stayed away from this notation, though, as Džamonja and Shelah have already utilized it in [21] for a related concept. We leave the proof of the following proposition as an easy exercise for the reader—the proposition establishes a connection between diamond-friendliness and the various weak forms of square we have been considering.

4.26 Proposition. *Let $\lambda = \mu^+$ for some singular cardinal μ.*

1. *If $S \subseteq \lambda$ is diamond-friendly, then $S \in I[\lambda]$.*
2. *If $S \subseteq \lambda$ carries a partial square, then S is diamond-friendly.*
3. *If $\square^*_\mu$ holds, then every subset of λ is diamond-friendly.*

We come now to the main theorem of this subsection, the proof of which is a substantial reworking of Shelah's original proof from [85]. Before we state the theorem, we introduce some notation.

4.27 Definition. Let κ be an infinite cardinal.

1. A *potential $\diamondsuit$-sequence for κ^+* is a sequence $\bar{\mathcal{S}} = \langle \mathcal{S}_\alpha : \alpha < \kappa^+\rangle$ such that each $\mathcal{S}_\alpha$ is a collection of at most κ subsets of α.
2. If $\bar{\mathcal{S}}$ is a potential $\diamondsuit$-sequence for κ^+ and $X \subseteq \kappa^+$, then we define

$$\mathrm{Trap}_{\bar{\mathcal{S}}}(X) = \{\alpha < \kappa^+ : X \cap \alpha \in \mathcal{S}_\alpha\}. \tag{15.58}$$

If κ^+ and $\bar{\mathcal{S}}$ are clear from context, then we may suppress explicit reference to them in the notation.

4.28 Theorem. *Let μ be a strong limit singular cardinal with $2^\mu = \mu^+$. If $\{\delta < \mu^+ : \mathrm{cf}(\delta) > \mathrm{cf}(\mu)\}$ contains a diamond-friendly stationary subset S, then there is a potential $\diamondsuit$-sequence $\bar{\mathcal{S}}$ such that for any $X \subseteq \mu^+$, there is a closed unbounded $E \subseteq \mu^+$ with the property that*

$$\delta \in E \cap S \quad \Longrightarrow \quad \mathrm{Trap}_{\bar{\mathcal{S}}}(X) \text{ contains a closed unbounded subset of } \delta. \tag{15.59}$$

Proof. Let λ denote μ^+. We are going to need several auxiliary objects, so we present them as a list:

- $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ is an increasing sequence of regular cardinals cofinal in μ.
- $\bar{A} = \langle A_i : i < \lambda\rangle$ enumerates $[\lambda]^{<\lambda}$.
- $\bar{\mathcal{C}} = \langle \mathcal{C}_\alpha : \alpha < \lambda\rangle$ attests to the diamond-friendliness of S.
- $\bar{e} = \langle e_\alpha : \alpha < \lambda\rangle$ is a sequence of one-to-one functions such that e_α maps α into μ.
- $\mathfrak{M}$ is a λ-approximating sequence over $\{\bar{A}, \bar{\mathcal{C}}, \bar{e}\}$.
- $\bar{\mathcal{S}} = \langle \mathcal{S}_\alpha : \alpha < \lambda\rangle$ is defined by $\mathcal{S}_\alpha := M_{\alpha+1} \cap \mathcal{P}(\alpha)$.

Given $X \subseteq \lambda$, we choose $\mathfrak{N}$ to be a λ-approximating sequence over $\{X, \mathfrak{M}\}$ and let E^* denote the closed unbounded subset of λ consisting of those δ for which $N_\delta \cap \lambda = \delta$. If $\delta \in E^*$, then $M_\delta \cap \lambda = \delta$ and therefore M_δ and N_δ contain the same bounded subsets of λ.

We now work to prove that (15.59) holds for this choice of E. To do this, we fix $\delta \in S \cap E$. The proof consists in defining a certain closed and unbounded $C \subseteq \delta$, and then verifying that this C is contained in $\mathrm{Trap}_{\bar{\mathcal{S}}}(X)$.

Note that since $\bar{\mathcal{C}}$ is in M_0, we can apply the diamond-friendliness of S to find a closed unbounded $C_\delta \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that

$$\alpha \in \mathrm{acc}(C_\delta) \quad \Longrightarrow \quad C_\delta \cap \alpha \in \mathcal{C}_\alpha.$$

Let $\langle \delta_\zeta : \zeta < \mathrm{cf}\,\delta \rangle$ be the increasing enumeration of $C_\delta \cap E^*$.

For $\zeta < \mathrm{cf}\,\delta$, we know $X \cap \delta_\zeta \in N_{\delta_\zeta + 1}$. Since $\delta_\zeta + 1 \leq \delta_{\zeta+1}$ and $\delta_{\zeta+1} \in E^*$, it follows that

$$X \cap \delta_\zeta \in M_{\delta_{\zeta+1}}.$$

This means

$$X \cap \delta_\zeta = A_{\beta_\zeta}$$

for some $\beta_\zeta < \delta_{\zeta+1}$.

In the model $M_{\delta_{\zeta+1}+1}$, we have available the function $e_{\delta_{\zeta+1}} : \delta_{\zeta+1} \to \mu$, and so we can define

$$i(\zeta) := \text{least } i < \mathrm{cf}(\mu) \quad \text{such that} \quad e_{\delta_{\zeta+1}}(\beta_\zeta) \leq \mu_i.$$

Since $\mathrm{cf}(\mu) < \mathrm{cf}(\delta)$, it follows that there is a single $i^* < \mathrm{cf}(\mu)$ such that

$$D := \{\zeta < \mathrm{cf}(\delta) : i(\zeta) \leq i^*\}$$

is unbounded in $\mathrm{cf}(\delta)$. Finally, we define

$$C := \{\delta_\zeta : \zeta = \sup(D \cap \zeta)\}.$$

The set C just constructed is closed and unbounded in δ, so the following claim will finish the proof.

4.29 Claim. $C \subseteq \mathrm{Trap}_{\bar{\mathcal{S}}}(X)$.

Proof. Given $\alpha \in C$, we must prove that $X \cap \alpha$ is in $\mathcal{S}_\alpha$. In light of the definition of $\mathcal{S}_\alpha$, this reduces to showing that $X \cap \alpha$ is in the model $M_{\alpha+1}$. We do this by demonstrating that $X \cap \alpha$ is definable from parameters available in $M_{\alpha+1}$.

By definition, our α is of the form δ_{ζ^*} for some $\zeta^* \in \mathrm{acc}(D)$. In light of this, it suffices to prove that the sequence $\langle X \cap \delta_\zeta : \zeta \in D \cap \zeta^* \rangle$ is an element of $M_{\alpha+1}$.

By the definition of "diamond-friendly", we know that $C_\delta \cap \alpha$ is in $M_{\alpha+1}$, and since $|C_\delta \cap \alpha| < \mathrm{cf}(\delta) < \mu$, it follows that $M_{\alpha+1}$ contains every subset of $C_\delta \cap \alpha$ as well as every increasing enumeration of such a set. Thus, we conclude that $M_{\alpha+1}$ contains the sequence $\langle \delta_\zeta : \zeta < \zeta^* \rangle$.

Similarly, $M_{\alpha+1}$ contains $D \cap \zeta^*$, as well as every function from $D \cap \zeta^*$ to μ_{i^*}. This tells us that the sequence

$$s := \langle e_{\delta_{\zeta+1}}(\beta_\zeta) : \zeta \in D \cap \zeta^* \rangle$$

must be in $M_{\alpha+1}$.

It follows that the sequence $\langle \beta_\zeta : \zeta \in D \cap \zeta^* \rangle$ is in $M_{\alpha+1}$ as it is definable from s and the sequence $\bar{e}$. Since $\bar{A} \in M_0$, we conclude

$$\langle A_{\beta_\zeta} : \zeta \in D \cap \zeta^* \rangle \in M_{\alpha+1},$$

which finishes the proof as $A_{\beta_\zeta} = X \cap \delta_\zeta$. $\dashv$

This claim establishes that $\mathrm{Trap}_{\bar{S}}(X)$ contains a closed unbounded subset of δ for all $\delta \in S \cap E$, and the theorem is proved. $\dashv$

We get the following as an immediate corollary.

4.30 Corollary. *Let μ be a strong limit singular cardinal with $2^\mu = \mu^+$. If $\square^*_\mu$ holds, then $\diamondsuit(S)$ holds for every stationary $S \subseteq \mu^+$ that reflects stationarily often in ordinals of cofinality greater than* $\mathrm{cf}(\mu)$. *In particular, the hypotheses imply $\diamondsuit(S^{\mu^+}_{\mathrm{cf}(\mu)})$.*

The following theorem of Shelah [85] gives a consistency result about the failure of $\diamondsuit$ in the situation we have been considering.

4.31 Theorem (see Conclusion 10 of [85]). *Suppose that μ is a singular strong limit cardinal with $2^\mu = \mu^+$, and S is a non-reflecting stationary subset of $\{\delta < \mu^+ : \mathrm{cf}(\delta) = \mathrm{cf}(\mu)\}$. Then there is a notion of forcing $\mathbb{P}$ such that*

1. *$\mathbb{P}$ adds no new sequences of length less than μ,*
2. *$\mathbb{P}$ satisfies the μ^+-chain condition,*
3. *$\mathbb{P}$ preserves the stationarity of S, and*
4. *$V^{\mathbb{P}} \models \neg\diamondsuit(S)$.*

Note that the above consistency result does not require large cardinals; in light of Corollary 4.30, it is not surprising that the techniques used to obtain the model of Theorem 4.31 cannot make $\diamondsuit$ fail on a stationary set that reflects stationarily often. It is also clear that ZFC still has things to say about this problem, for the following theorem of Shelah [93] shows us that non-trivial consequences of $\diamondsuit(S^{\mu^+}_{\mathrm{cf}(\mu)})$ follow from instances of the Generalized Continuum Hypothesis.

4.32 Theorem. *Assume $\lambda = \mu^+$, where μ is a strong limit singular cardinal. Further assume that $2^\mu = \lambda$, and $S \subseteq \lambda$ is a stationary subset of $S^\lambda_{\mathrm{cf}(\mu)}$. Then we can find a family $\{A_\delta : \delta \in S\}$ such that each A_δ is cofinal in δ of order-type* $\mathrm{cf}(\mu)$, *and, letting $\langle \alpha_{\delta,i} : i < \mathrm{cf}(\mu) \rangle$ enumerate A_δ in increasing order, we have that for every function f with domain λ and range a bounded subset of μ,*

$$\{\delta \in S : f(\alpha_{\delta,2i}) = f(\alpha_{\delta,2i+1}) \text{ for all } i < \mathrm{cf}(\mu)\} \text{ is stationary.}$$

Finally, we remark the Shelah has very recently established an important result on the existence of diamonds. Using pcf theory, he had actually shown the following equivalence:

4.33 Theorem. *If $\beth_\omega \leq \kappa$, then $\diamondsuit(\kappa^+)$ holds if and only if $2^\kappa = \kappa^+$.*

For a proof see Theorem 8.21 of the chapter of Abraham and Magidor in this Handbook. In his recent [80], Shelah used club guessing ideas in an ingenious, short proof to show that the $\beth_\omega$ can be replaced by ω_1, specifically:

4.34 Theorem (Shelah [80]). *If $\omega_1 \leq \kappa$, then $2^\kappa = \kappa^+$ implies that $\diamondsuit(S)$ holds for any stationary $S \subseteq \{\delta < \kappa^+ \mid \mathrm{cf}(\delta) \neq \mathrm{cf}(\kappa)\}$.*

Hence, $\diamondsuit_\kappa$ is actually equivalent to $2^\kappa = \kappa^+$ for all $\kappa \geq \omega_1$. This is optimal in light of the well-known independence result for $\diamondsuit(\omega_1)$ of Jensen, and moreover, the cofinality restriction of the theorem is optimal in light of Theorem 4.31. However, Theorem 4.24 is still germane because of the stronger conclusion of $\diamondsuit^*$; $\diamondsuit^*(\kappa^+)$ fails if a Cohen subset of κ^+ is added, and so one each easily get the consistency of $\diamondsuit(\kappa^+) + \neg\diamondsuit^*(\kappa^+)$.

4.4. Very Weak Square

The purpose of this brief subsection is to establish a connection between the ideas we have been considering and some combinatorial principles discussed in Todorčević's chapter [98] in this Handbook. If μ is singular, then we have seen how the landscape between $\square_\mu$ and AP_μ is filled by a natural hierarchy of square-like principles. In this section, we take a look at combinatorial principles even weaker than AP_μ (in fact, so weak that some of them are consistent with supercompact cardinals) that are still strong enough to have important consequences.

To set the stage, let $\lambda = \mu^+$ for a singular cardinal μ. In our investigation of $I[\lambda]$, we saw that this ideal is the normal ideal generated by sets of the form $S[\mathfrak{M}]$ for $\mathfrak{M}$ a λ-approximating sequence. Recall that $S[\mathfrak{M}]$ is defined to be the set of $\delta < \lambda$ such that

- $M_\delta \cap \lambda = \delta$, and
- there is a cofinal $a \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ with the property that every initial segment of a is M_δ.

In non-specific terms, the ordinal δ is "singularized" by a set a that is in some sense "captured by M_δ". If we vary the meaning of "captured by M_δ", we end up with a family of combinatorial principles related to $I[\lambda]$ and AP_μ.

For example, let us consider the following definition.

4.35 Definition. Suppose that $\lambda = \mu^+$ for some singular cardinal μ, and let $\mathfrak{M} = \langle M_\alpha : \alpha < \lambda\rangle$ be a λ-approximating sequence. Let $S^{\mathrm{VWS}}[\mathfrak{M}]$ be the set of all $\delta < \lambda$ such that

1. $M_\delta \cap \lambda = \delta$, and
2. there is a cofinal $a \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$ such that all bounded countable subsets of a are elements of M_δ.

Some remarks are in order here. First, the designation "VWS" stands for *very weak square*, for reasons which will be made clear below. Second, if $\mathrm{cf}(\delta) > \aleph_0$ and $\delta \in S^{\mathrm{VWS}}[\mathfrak{M}]$, then it must be the case that $(\mathrm{cf}\,\delta)^{\aleph_0} \leq \mu$ because $|M_\delta| = \mu$. Thus, the preceding definition will be of most interest when μ is *countably closed*, that is, when $\tau^{\aleph_0} < \mu$ for all $\tau < \mu$.

Assume now that μ is a countably closed singular cardinal. The sets of the form $S^{\mathrm{VWS}}[\mathfrak{M}]$ generate a normal ideal on λ, which we denote by $I^{\mathrm{VWS}}[\lambda]$. The following proposition captures some of its basic properties.

4.36 Proposition. *Let $\lambda = \mu^+$ for μ a countably closed singular cardinal.*

1. $S^\lambda_{\aleph_0} \in I^{\mathrm{VWS}}[\lambda]$.
2. *If $S \subseteq S^\lambda_{\aleph_1}$, then $S \in I[\lambda] \iff S \in I^{\mathrm{VWS}}[\lambda]$.*
3. $I[\lambda] \subseteq I^{\mathrm{VWS}}[\lambda]$.
4. *If μ has uncountable cofinality, then $\lambda \in I^{\mathrm{VWS}}[\lambda]$.*

Proof. All are easy. For (4), notice that since $\mu^{<\mu} = \mu$, if $\langle M_\alpha : \alpha < \lambda\rangle$ is a λ-approximation sequence and δ has uncountable cofinality, then any countable subset of $M_\delta \cap \lambda$ is in M_δ. ⊣

The next proposition gives us a characterization of $I^{\mathrm{VWS}}[\lambda]$ that does not require the language of elementary submodels. The result is easy, and taken from [23].

4.37 Proposition. *Let $\lambda = \mu^+$ for μ a countably closed singular cardinal. A set $S \subseteq \lambda$ is in $I^{\mathrm{VWS}}[\lambda]$ if and only if there is a sequence $\langle A_\alpha : \alpha < \lambda\rangle$ such that $A_\alpha \subseteq \alpha$ and for some closed unbounded $E \subseteq \lambda$, if $\delta \in E \cap S$ then*

1. *A_δ is cofinal in δ of order-type $\mathrm{cf}(\delta)$, and*
2. *if $\mathrm{cf}(\delta) > \aleph_0$ then $[A_\delta]^{\aleph_0} \subseteq \{A_\alpha : \alpha < \delta\}$.*

Proof. See [23, Claim 2.8]. ⊣

Now we have seen that for singular cardinals μ, the combinatorial principle AP_μ has strength. Since AP_μ is just the statement that $I[\mu^+]$ is an improper ideal, it is natural to use $I^{\mathrm{VWS}}[\mu^+]$ in such a fashion as well. This is a fruitful idea, and it leads us to the *very weak square* principle studied previously by Foreman and Magidor [34].

4.38 Definition. Let $\lambda = \mu^+$ for a countably closed singular cardinal μ. A sequence $\langle A_\alpha : \alpha < \mu^+\rangle$ is a *very weak square sequence for* μ if there is a closed unbounded $E \subseteq \mu^+$ such that for all $\alpha \in E$ of uncountable cofinality,

1. A_α is unbounded in α, and
2. $[A_\alpha]^{\aleph_0} \subseteq \{A_\beta : \beta < \alpha\}$.

We say that *very weak square holds at* μ (denoted VWS_μ) if there is a very weak square sequence for μ.

The reader may note that the sets A_α are not required to be closed. This is quite important, and the change gives rise to a combinatorial principle known as *not-so-very-weak square* studied briefly by Foreman and Magidor in [34]. The paper [34] contains several applications of the very weak square principle. We limit ourselves to the following characterization of VWS_μ, which recalls the characterization of AP_μ given in Theorem 3.16. The proof is similar, and we remark that such arguments have been used many times in the literature, going back to work of Jensen and Silver in [52].

4.39 Theorem. *Let* μ *be a countably closed of countable cofinality, and let* $\lambda = \mu^+$. *Then* VWS_μ *holds if and only if for every* $x \in H(\chi)$, *there is a* λ*-approximating sequence* $\mathfrak{M} = \langle M_\alpha : \alpha < \lambda\rangle$ *over* x *with the property that if we are given* δ *satisfying* $M_\delta \cap \lambda = \delta$ *and a set* $A \subseteq M_\delta$ *satisfying* $\aleph_0 < |A| = \mathrm{cf}\,|A| < \mu$, *then there is* $B \subseteq A$ *such that*

1. $|B| = |A|$, *and*
2. $[B]^{\aleph_0} \subseteq M_\delta$.

Proof. We mirror the proof of Theorem 3.16. Let $\bar{A} = \langle A_\alpha : \alpha < \lambda\rangle$ be a very weak square sequence for λ, with E the associated closed unbounded set. Let $\langle \mu_i : i < \omega\rangle$ be an increasing sequence of regular cardinals with limit μ such that $\mu_i^{\aleph_0} < \mu_{i+1}$.

Now build a matrix $\langle M^i_\alpha : \alpha < \lambda, i < \omega\rangle$ of elementary submodels of $H(\chi)$ such that (letting $M_\alpha := \bigcup_{i<\omega} M^i_\alpha$)

1. $\langle M_\alpha : \alpha < \lambda\rangle$ is a λ-approximating sequence over $\{x, \bar{C}, E\}$,
2. $|M^i_\alpha| = \mu_i$,
3. $M^i_\alpha \subseteq M^j_\alpha$ for $i < j$,
4. $\mu_{i+1} \cup [M^i_{\alpha+1}]^{\aleph_0} \subseteq M^{i+1}_{\alpha+1}$, and
5. if C_α is countable, then for each $i < \omega$,

$$\left[\bigcup_{\beta \in C_\alpha} M^i_\beta\right]^{\aleph_0} \subseteq M_{\alpha+1}. \tag{15.60}$$

Now let τ be an uncountable regular cardinal below μ and suppose that A is in $[M_\alpha]^\tau$ for some $\alpha < \lambda$. There are three cases that arise.

Case 1. α a successor ordinal.

In this case, we fix an $i < \omega$ for which $B := A \cap M^i_\alpha$ has cardinality τ. Our construction then guarantees that every countable subset of B is in M^{i+1}_α, which is a subset of M_α.

Case 2. α a limit ordinal with $\mathrm{cf}(\alpha) \neq \tau$.

For such an α, there must be a $\beta < \alpha$ for which $A \cap M_{\beta+1}$ has cardinality τ. The argument for Case 1 then gives us $B \in [A]^\tau$ with $[B]^{\aleph_0} \subseteq M_\alpha$.

Case 3. α a limit ordinal of cofinality τ.

In this situation, we know $M_\alpha = \bigcup_{i<\omega} \bigcup_{\gamma \in C_\alpha} M^i_\gamma$, and so there is an $i < \omega$ for which the set

$$B := A \cap \bigcup\nolimits_{\gamma \in C_\alpha} M^i_\gamma$$

has cardinality τ.

If K is a countable subset of B, then there is a countable $J \subseteq C_\alpha$ with

$$K \subseteq \bigcup\nolimits_{\gamma \in J} M^i_\gamma.$$

Since $\alpha \in E$, we know that J appears as C_β for some $\beta < \alpha$. But then

$$K \subseteq \bigcup\nolimits_{\gamma \in C_\beta} M^i_\gamma \subseteq M_{\beta+1} \subseteq M_\alpha.$$

Thus, B is a subset of A of cardinality τ with $[B]^{\aleph_0} \subseteq M_\alpha$, as required.

For the converse, let $\mathfrak{M}$ be a λ-approximating sequence with the properties claimed. We show that $S^{\mathrm{VWS}}[\mathfrak{M}]$ contains the closed unbounded set of ordinals δ with $\delta = M_\delta \cap \lambda$. Clearly we may assume $\mathrm{cf}(\delta)$ is uncountable, so let $A \subseteq \delta$ be cofinal of order-type $\mathrm{cf}(\delta)$. Then our choice of $\mathfrak{M}$ gives us a cofinal $B \subseteq A$, all of whose countable subsets are in M_δ. Thus, $\delta \in S^{\mathrm{VWS}}[\mathfrak{M}]$ and VWS_μ holds. $\dashv$

We will not pursue combinatorial applications of VWS_μ here. We remark that VWS_μ is equivalent to the existence of a Jensen matrix (see [98, Definition 11.14]) in many situations—one can find a proof of this in [34]; it is similar to the proof of the preceding theorem. Todorčević demonstrates the relationship between Jensen matrices and cofinal Kurepa families; the reader is referred to his chapter [98] (in particular, Sect. 11) in this Handbook for more information.

With regard to the relationship between VWS_μ and AP_μ, we mention the following theorem of Foreman and Magidor [34]:

4.40 Theorem. *Suppose that* GCH *holds and κ is a supercompact cardinal. Then there is a class forcing extension of V that preserves cardinals and cofinalities in which* VWS_μ *holds for all singular μ and where κ remains supercompact.*

Thus, through successive weakenings, we have finally arrived at versions of square that are compatible with supercompact cardinals. Oddly enough, even though modifications of Foreman and Magidor's argument proves that very weak square is consistent even with huge cardinals, the principle not-so-very-weak square mentioned earlier necessarily fails at the successor of a limit of infinitely many supercompact cardinals. Thus, the two principles are not equivalent. We will not pursue this, but the proof appears in [34]. Returning to the topic at hand, we note the following corollary of the preceding theorem.

4.41 Corollary. *If κ is supercompact, then it is consistent that* $\mathrm{VWS}_{\kappa^{+\omega}}$ *holds even though* $\mathrm{AP}_{\kappa^{+\omega}}$ *necessarily fails.*

The situation at $\aleph_\omega$ is a bit strange, though, for Shelah has shown that under GCH, the two principles are equivalent at $\aleph_\omega$. The following theorem from [23] gives a tighter formulation.

4.42 Theorem. *Let $\lambda = \mu^+$ for μ a singular strong limit cardinal of countable cofinality. If $\kappa < \mu$ is countably closed, then $I[\lambda] \restriction S^\lambda_\kappa = I^{\mathrm{VWS}} \restriction S^\lambda_\kappa$.*

Proof. By the third statement in Proposition 4.36, we need only take an $S \subseteq S^\lambda_\kappa$ in $I^{\mathrm{VWS}}[\lambda]$ and prove it is in $I[\lambda]$. By way of Proposition 4.37, we fix a sequence $\bar{A} = \langle A_\alpha : \alpha < \lambda\rangle$ and closed unbounded $E \subseteq \lambda$ such that for $\delta \in E \cap S$, we have

1. A_δ is cofinal in δ with $\mathrm{ot}(A_\delta) = \kappa$, and
2. $[A_\delta]^{\aleph_0} \subseteq \{A_\alpha : \alpha < \delta\}$.

By thinning out A_δ if necessary, we may assume as well that

3. for $\delta \in E \cap S$, if $\alpha \in A_\delta$ then $[A_\delta \cap \alpha]^{\aleph_0} \subseteq \{A_\gamma : \gamma < \alpha\}$.

Notice that the above makes use of the facts that κ is countably closed and A_δ need not be a closed subset of δ.

Let $\langle \mu_n : n < \omega\rangle$ be an increasing sequence of regular cardinals cofinal in μ. An easy induction lets us define a λ-filtration sequence $\bar{b} = \langle b_{\alpha,n} : n < \omega\rangle$ with $|b_{\alpha,n}| \le \mu_n$, and such that for all $\alpha < \lambda$

$$\beta \in b_{\alpha,n} \quad \Longrightarrow \quad b_{\beta,n} \subseteq b_{\alpha,n} \tag{15.61}$$

and

$$|A_\alpha| = \aleph_0 \quad \Longrightarrow \quad A_\alpha \subseteq b_{\alpha,0}. \tag{15.62}$$

Let $\mathfrak{M}$ be a λ-approximating sequence over $\{\bar{A}, S, E, \bar{B}\}$. We will show that $S \subseteq S[\mathfrak{M}]$.

With this in mind, suppose that $\delta \in S$ satisfies $\delta = M_\delta \cap \lambda$. Since E is in M_0, it is clear that δ must be in E as well. Our goal is to establish that every initial segment of A_δ is in the model M_δ. As a first step toward this, we claim the following:

$$\alpha \in A_\delta \quad \Longrightarrow \quad A_\delta \cap \alpha \subseteq b_{\alpha,n} \text{ for some } n < \omega. \tag{15.63}$$

Assume by way of contradiction that (15.63) fails. Then for each $i < \omega$ we can choose an ordinal β_i such that

$$\beta_i \in (A_\delta \cap \alpha) \setminus b_{\alpha,i}. \tag{15.64}$$

Since $\delta \in E \cap S$, by condition (3) above, there is an ordinal $\gamma < \alpha$ with $\{\beta_i : i < \omega\} = A_\gamma$.

Choose n such that $\gamma \in b_{\alpha,n}$. By (15.61), we know $b_{\gamma,n} \subseteq b_{\alpha,n}$. But

$$\{\beta_i : i < \omega\} = A_\gamma \subseteq b_{\gamma,0} \subseteq b_{\gamma,n} \subseteq b_{\alpha,n},$$

and this contradicts (15.64) for the choice $n = i$. Therefore, (15.63) must hold.

Now suppose that $\alpha \in A_\delta$. Choose an $n < \omega$ such that $A_\delta \cap \alpha \in b_{\alpha,n}$. The set $b_{\alpha,n}$ is in M_δ and of cardinality at most μ_n. Since μ is a strong limit cardinal, it follows that every subset of $b_{\alpha,n}$ is in M_δ. In particular, $A_\delta \cap \alpha \in M_\delta$ and the proof is finished. ⊣

4.43 Corollary. *If* GCH *holds, then* $I[\aleph_{\omega+1}] = I^{\mathrm{VWS}}[\aleph_{\omega+1}]$.

Proof. By assumption, $S^{\aleph_{\omega+1}}_{\aleph_0}$ lies in both ideals. By the second claim in Proposition 4.36, the ideals are the same when restricted to ordinals of cofinality $\aleph_1$. Under GCH, the cardinals $\aleph_n$ for $1 < n < \omega$ are all countably closed, and so the preceding theorem applies. It follows easily now that the ideals coincide. ⊣

4.5. NPT and Good Scales

This section deals with yet another failure of compactness of interest in combinatorial set theory.

4.44 Definition.

1. If A is a family of non-empty sets, then a *transversal* for A is a one-to-one choice function on A.

2. A family A of non-empty sets is said to be κ*-free* if every subfamily of cardinality less than κ has a transversal. We say that A is *free* if the entire family has a transversal.

3. $\mathrm{PT}(\kappa, \theta)$ means that every κ-free family $A = \langle A_\alpha : \alpha < \kappa \rangle$ with each A_α of size less than θ is free.

4. $\mathrm{NPT}(\kappa, \theta)$ denotes the negation of $\mathrm{PT}(\kappa, \theta)$.

We begin with an easy application of the compactness theorem for propositional logic.

4.45 Proposition. *An* ω*-free family of finite sets is free. Thus,* $\mathrm{PT}(\kappa, \aleph_0)$ *holds for any infinite* κ.

Proof. Suppose that $\{A_\alpha : \alpha < \kappa\}$ is an ω-free family of finite sets, and fix an enumeration of each A_α. For each $\alpha < \kappa$ and $i < |A_\alpha|$, we let $p_{\alpha,i}$ be a propositional variable and consider the theory consisting of the following propositional sentences:

1. $\bigvee_{i<|A_\alpha|} p_{\alpha,i}$ for each $\alpha < \kappa$,
2. $p_{\alpha,i} \to \neg p_{\alpha,j}$ for each $\alpha < \kappa$ and $i \neq j$, and
3. $p_{\alpha,i} \to \neg p_{\beta,j}$ whenever $\alpha \neq \beta$ and the ith element of A_α is the jth element of A_β.

Any valuation v satisfying this theory gives rise to a transversal F for the family $\{A_\alpha : \alpha < \kappa\}$—for each $\alpha < \kappa$ it follows from (1) and (2) that there is a unique $i < |A_\alpha|$ with $v(p_{\alpha,i}) = 1$, and so we can define a function F by the rule

$$F(\alpha) = \text{ the } i\text{th element of } A_\alpha \text{ for the unique } i \text{ with } v(p_{\alpha,i}) = 1.$$

Since our valuation satisfies the sentences from (3), it follows that F is one-to-one.

With the preceding interpretation in mind, it is clear that our collection of formulas is finitely satisfiable because the family $\{A_\alpha : \alpha < \kappa\}$ is ω-free. An application of the compactness theorem for propositional logic gives us a valuation satisfying the entire theory, and therefore the family has a transversal. ⊣

In the other direction, we show that instances of NPT arise from non-reflecting stationary sets.

4.46 Proposition. *Let $\kappa < \lambda$ be regular cardinals. If* $\mathrm{Refl}(S^\lambda_\kappa)$ *fails, then* $\mathrm{NPT}(\lambda, \kappa^+)$ *holds.*

Proof. Let $\kappa < \lambda$ be regular cardinals, and assume that there is a non-reflecting stationary set $S \subseteq S^\lambda_\kappa$. For each $\delta \in S$, let A_δ be a cofinal subset of δ of order-type κ. The family $\{A_\delta : \delta \in S\}$ is λ-free by Lemma 2.12, but the existence of a transversal would contradict Fodor's Theorem. ⊣

As a corollary, we see that $\mathrm{NPT}(\kappa^+, \kappa^+)$ holds for all regular κ. The following theorem of Milner and Shelah [67] shows that non-reflecting stationary sets can be used to lift examples of NPT to larger cardinals.

4.47 Theorem. *Let $\theta < \kappa < \lambda$ be regular cardinals. If* $\mathrm{NPT}(\kappa, \theta)$ *holds and there is a non-reflecting stationary $S \subseteq S^\lambda_\kappa$, then* $\mathrm{NPT}(\lambda, \theta)$ *holds as well.*

Proof. Let $\mathcal{A} = \{A_\gamma : \gamma < \kappa\}$ be an instance of $\mathrm{NPT}(\kappa, \theta)$. For each $\alpha \in S$ we choose an increasing function $e_\alpha : \kappa \to \alpha$ with range cofinal in α. Given $\alpha \in S$ and $\gamma < \kappa$, we define

$$B_{\alpha,\gamma} = (\{\alpha\} \times A_\gamma) \cup \{e_\alpha(\gamma)\}.$$

We claim that the family

$$\mathcal{B} = \{B_{\alpha,\gamma} : \alpha \in S, \gamma < \kappa\}$$

will witness $\mathrm{NPT}(\lambda, \theta)$.

First, we show that $\mathcal{B}$ does not have a transversal. Suppose by way of contradiction that the family $\mathcal{B}$ has a transversal F. Since $\mathcal{A}$ does not have a transversal, it follows that for each $\alpha \in S$ there must be a $\gamma_\alpha < \kappa$ with

$$F(\alpha, \gamma_\alpha) = e_\alpha(\gamma_\alpha).$$

An application of Fodor's Theorem gives us a stationary $T \subseteq S$ and $\gamma^* < \kappa$ such that $e_\alpha(\gamma_\alpha) = \gamma^*$ for all $\alpha \in T$, and this means that our F cannot be one-to-one.

To finish the proof, we must prove that the family $\mathcal{B}$ is λ-free. It suffices to prove that for each $\alpha < \lambda$, the family $\{B_{\beta,\gamma} : \beta \in S \cap \alpha, \gamma < \kappa\}$ has a transversal.

By Lemma 2.12, we can find for each $\beta \in S \cap \alpha$ an ordinal $\eta_\beta < \kappa$ so that all sets of the form $\{e_\beta(\gamma) : \eta_\beta < \gamma < \kappa\}$ for $\beta \in S \cap \alpha$ are disjoint. We then choose $F(\beta, \gamma)$ so that

$$F(\beta, \gamma) = e_\beta(\gamma) \quad \text{for } \eta_\beta < \gamma < \kappa$$

and such that

$$\langle F(\beta, \gamma) : \gamma \leq \eta_\beta \rangle \text{ is a transversal for } \{\beta\} \times \{A_\gamma : \gamma \leq \eta_\beta\}.$$

There are no problems in doing this, and evidently this gives the desired transversal. $\dashv$

4.48 Corollary. $\mathrm{NPT}(\aleph_n, \aleph_1)$ *holds for* $1 \leq n < \omega$.

Proof. We see that $\mathrm{NPT}(\aleph_1, \aleph_1)$ holds by way of Proposition 4.46, and a trivial induction argument using Theorem 4.47 lifts this to $\mathrm{NPT}(\aleph_n, \aleph_1)$ for $1 \leq n < \omega$. $\dashv$

The following corollary will be superseded by results later in the subsection, but we record it for later use.

4.49 Corollary. *If* $\mathrm{Refl}(\aleph_{\omega+1})$ *fails, then* $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$ *holds.*

Proof. If $\mathrm{Refl}(\aleph_{\omega+1})$ fails, then $\mathrm{Refl}(S^{\aleph_{\omega+1}}_{\aleph_n})$ must fail for some $n < \omega$. The conclusion follows from the preceding corollary and Theorem 4.47. $\dashv$

For the rest of this subsection we focus our attention on $\mathrm{NPT}(\kappa, \theta)$ for the special case $\theta = \aleph_1$. Such questions are of particular interest, because Shelah [81] has shown that $\mathrm{NPT}(\kappa, \aleph_1)$ is equivalent to the existence of a κ-free Abelian group (that is, all subgroups of cardinality less than κ are free) of size κ that is not itself free. It is still an open problem whether the "Abelian" can be dropped in the preceding result—it is known that $\mathrm{NPT}(\kappa, \aleph_1)$ implies the existence of a κ-free non-free group of cardinality κ, but whether the reverse implication holds is still unsolved. We refer the reader to the introduction of [65] for a much more extensive discussion of such matters and how they fit into a much more general setting.

The following result of Shelah settles our question for the case of singular cardinals. The result is a special case of his theorem on singular compactness [81].

4.50 Theorem. $\mathrm{PT}(\kappa, \aleph_1)$ *holds for every singular* κ.

Proof. We refer the reader to [14, Sect. 12] for a nice proof of this result. $\dashv$

Thus, the behavior of $\aleph_\omega$ stands in contrast to that of $\aleph_n$ for $1 \leq n < \omega$. At successors of singular cardinals the situation is much more delicate. Magidor and Shelah [65] have shown that $\mathrm{NPT}(\aleph_{\omega \cdot n+1}, \aleph_1)$ holds for each $n < \omega$, while $\mathrm{PT}(\aleph_{\omega^2+1}, \aleph_1)$ is consistent relative to large cardinals. Their arguments make use of the combinatorics of scales, and though a presentation of the consistency of $\mathrm{PT}(\aleph_{\omega^2+1}, \aleph_1)$ is beyond the scope of the paper, we will develop the techniques needed to see the relationship between scales and transversals. The following definition is the key to unlocking this connection.

4.51 Definition. Let μ be a singular cardinal. A scale $(\vec{\mu}, \vec{f})$ is *good* if every ordinal α of cofinality greater than $\mathrm{cf}(\mu)$ is a good point for $\vec{f}$, that is, if $\alpha < \mu^+$ satisfies $\mathrm{cf}(\alpha) > \mathrm{cf}(\mu)$, there is an unbounded $A \subseteq \alpha$ and $i < \mathrm{cf}(\mu)$ such that the sequence $\langle f_\beta(j) : \beta \in A \rangle$ is strictly increasing for all $j > i$.

The following easy proposition shows that good scales follow from the Approachability Property.

4.52 Proposition. *Let* μ *be a singular cardinal. If* AP_μ *holds, then all scales* $(\vec{\mu}, \vec{f})$ *for* μ *are good.*

Proof. Suppose that $(\vec{\mu}, \vec{f})$ is a scale for μ, and let $\mathfrak{M}$ be a λ-approximating sequence over $(\vec{\mu}, \vec{f})$. Given $\delta \in S[\mathfrak{M}]$ with cofinality greater than $\mathrm{cf}(\mu)$, the proof of Claim 3.54 shows that δ is a good point for $\vec{f}$. We have assumed AP_μ, and therefore $S[\mathfrak{M}]$ contains a closed unbounded $E \subseteq \mu^+$. If we enumerate E as $\langle \alpha_i : i < \mu^+ \rangle$ and define $g_i = f_{\alpha_i}$, then it is not hard to show that $\vec{g}$ is a good scale. $\dashv$

We now move on to the application of goodness to questions about NPT. The following theorem is due to Magidor and Shelah [65], though our presentation is based on that in Cummings' survey [14].

4.53 Theorem. *If* μ *is a singular cardinal of countable cofinality and there is a good scale* $(\vec{\mu}, \vec{f})$ *for* μ*, then* $\mathrm{NPT}(\mu^+, \aleph_1)$.

Proof. Let S denote the set $S^{\mu^+}_{\aleph_1}$, and for each $\alpha \in S$, define

$$A_\alpha = \{(m, f_\alpha(m)) : m < \omega\}.$$

The following lemma captures a key property of the family $\{A_\alpha : \alpha \in S\}$.

4.54 Lemma. *For every $\alpha < \mu^+$, we can choose objects B_β and D_β for $\beta \in S \cap \alpha$ such that*

1. *B_β is a cofinite subset of A_β,*
2. *D_β is a closed unbounded subset of β, and*
3. *$\{B_\beta \times D_\beta : \beta \in S \cap \alpha\}$ is a disjoint family of sets.*

Before given the proof, we show that the lemma implies $\mathrm{NPT}(\mu^+, \aleph_1)$. We start by choosing, for each $\alpha \in S$, a closed unbounded $E_\alpha \subseteq \alpha$ of order-type ω_1. By Lemma 4.54, the collection $\{A_\alpha \times E_\alpha : \alpha \in S\}$ is an instance of $\mathrm{NPT}(\mu^+, \aleph_2)$, but we need to work harder to obtain a witness for $\mathrm{NPT}(\mu^+, \aleph_1)$.

To do this, choose for each limit $\delta < \omega_1$ a cofinal set C_δ of order-type ω. Let $\langle e_\alpha(\gamma) : \gamma < \omega_1 \rangle$ be the increasing enumeration of E_α. Finally, for $\alpha \in S$ and limit $\delta < \omega_1$, we define

$$B_{\alpha,\delta} = (C_\delta \times \{\alpha\}) \cup (A_\alpha \times \{e_\alpha(\delta)\})$$

and set

$$\mathcal{B} = \{B_{\alpha,\delta} : \alpha \in S,\ \delta \text{ countable limit}\}.$$

4.55 Claim. *The collection $\mathcal{B}$ is an instance of* $\mathrm{NPT}(\mu^+, \aleph_1)$.

Proof. It is clear that each $B_{\alpha,\delta}$ is countable. To see that there is no transversal for $\mathcal{B}$, assume by way of contradiction that F is a one-to-one choice function for the collection.

For a fixed $\alpha \in S$, Fodor's Theorem implies that $F(\alpha, \delta)$ is of the form $(x, e_\alpha(\delta))$ for almost all δ, and therefore we can find a countable limit ordinal δ_α such that

$$F(\alpha, \delta_\alpha) = (x_\alpha, e_\alpha(\delta_\alpha))$$

for some $x_\alpha \in A_\alpha$. There are only μ possibilities for x_α, and therefore we can find a stationary $S^* \subseteq S$ and a single $x^* \in \omega \times \mu$ such that

$$\alpha \in S^* \quad \Longrightarrow \quad x_\alpha = x^*.$$

Since $e_\alpha(\delta_\alpha) < \alpha$, another application of Fodor's Theorem contradicts our assumption that F is one-to-one. Thus, there can be no transversal for the family $\mathcal{B}$.

To see that $\mathcal{B}$ is μ^+-free, it suffices to show for each $\alpha < \mu^+$ that a transversal exists for the collection

$$\{B_{\beta,\delta} : \beta \in S \cap \alpha \text{ and } \delta < \omega_1 \text{ is a limit}\}. \tag{15.65}$$

With this end in mind, let us fix an $\alpha < \lambda$ and work toward defining a transversal F for the collection (15.65). Given $\beta \in S \cap \alpha$, the set of $\delta < \omega_1$ with $e_\beta(\delta) \notin D_\beta$ is nonstationary. An appeal to Lemma 2.12 gives us a transversal G_β for the collection $\{C_\delta : e_\beta(\delta) \notin D_\beta\}$, and we define $F(\beta, \delta)$ for such δ by

$$F(\beta, \delta) = (G_\beta(\delta), \beta).$$

It remains to define $F(\beta, \delta)$ for those δ with $e_\beta(\delta) \in D_\beta$. This is done by choosing $x_\beta \in B_\beta$ and defining

$$F(\beta, \delta) = (x_\beta, e_\beta(\delta)).$$

In either case, $F(\beta, \delta)$ is an element of $B_{\beta,\delta}$, and the proof that F is one-to-one is straightforward. $\dashv$

We now turn our attention to the heart of the matter—the proof of Lemma 4.54.

Proof of Lemma 4.54. We prove by induction on $\alpha < \mu^+$ that for any $\delta < \alpha$ we can find B_β and D_β for $\beta \in S \cap (\delta, \alpha]$ such that

1. B_β is a cofinite subset of A_β,
2. D_β is closed and unbounded in β,
3. $\{B_\beta \times D_\beta : \beta \in S \cap (\delta, \alpha]\}$ is a disjoint family, and
4. $D_\beta \cap \delta = \emptyset$.

If we do this, then Lemma 4.54 follows immediately. It is worth pointing out that in general,

$$(B \times D) \cap (B^* \times D^*) = \emptyset \iff \text{either } B \cap B^* = \emptyset \text{ or } D \cap D^* = \emptyset. \quad (15.66)$$

We will use the above observation implicitly in the proof.

Case 1. α is a successor.

Since $\alpha \notin S$, the result follows from the induction hypothesis applied to the predecessor of α.

Case 2. $\mathrm{cf}(\alpha) = \aleph_0$.

Given $\delta < \alpha$, let $\langle \epsilon_n : n < \omega\rangle$ enumerate a cofinal ω-sequence in α with $\epsilon_0 = \delta$. For each n, we apply our induction hypothesis to the ordinals $\epsilon_n < \epsilon_{n+1}$. This gives us B_β and D_β for each $\beta \in S \cap (\epsilon_n, \epsilon_{n+1}]$ with the additional property that $D_\beta \cap \epsilon_n = \emptyset$, and from this it follows that the entire family $\{B_\beta \times D_\beta : \beta \in S \cap (\delta, \alpha]\}$ is disjoint.

Case 3. $\mathrm{cf}(\alpha) = \aleph_1$.

Given $\delta < \alpha$, we proceed very much as in the previous case with the added complication that B_α and D_α must also be defined. Notice as well that it suffices to prove the result for the case where δ is a successor ordinal, so we may assume that $\delta \notin S$.

Let D_α be a closed unbounded subset of α of order-type ω_1 chosen so that $\min(D_\alpha) = \delta$ and $D_\alpha \cap S = \emptyset$. Let $\langle \epsilon_i : i < \omega_1\rangle$ be the increasing enumeration of D_α.

Given $i < \omega_1$, we apply our induction hypothesis to the ordinals $\epsilon_i < \epsilon_{i+1}$ to obtain B_β and D_β for all $\beta \in S \cap (\epsilon_i, \epsilon_{i+1}]$. Since removing an initial segment of D_β causes no harm, we may assume that D_β is completely contained in the interval $(\epsilon_i, \epsilon_{i+1})$. In particular, $D_\beta \cap D_\alpha = \emptyset$.

Since $D_\alpha \cap S = \emptyset$, the preceding paragraph defines B_β and D_β for all $\beta \in S \cap (\delta, \alpha)$, and the family $\{B_\beta \times D_\beta : \beta \in S \cap (\delta, \alpha)\}$ is disjoint. We have arranged things so that $D_\alpha \cap D_\beta = \emptyset$ for all $\beta \in S \cap (\delta, \alpha)$, and so if we define B_α to be A_α, we have what we need.

Case 4. $\mathrm{cf}(\alpha) > \aleph_1$.

This is the interesting case, for it is here that the goodness of our scale becomes important. In order to remove a bit of clutter, we omit reference to the ordinal δ (that is, we give the proof for $\delta = 0$) as the obvious modifications give the result in full generality.

We begin by recalling that α is a good point for our scale, and therefore we can find a cofinal $A \subseteq \alpha$ and an $i^* < \omega$ with the property that the sequence $\langle f_\beta(i) : \beta \in A\rangle$ is strictly increasing for all $i > i^*$.

Define C to be the set of $\beta < \alpha$ with $\sup(A \cap \beta) = \beta$. We say that $\beta \in S \cap \alpha$ is of *Type I* if β is not in $\mathrm{acc}(S)$, while members of $S \cap \mathrm{acc}(C)$ are said to be of *Type II*.

The choice of B_β and C_β for β of Type I is along the lines of what was done in previous cases—if $\epsilon < \gamma$ are consecutive elements of C, then our induction hypothesis gives us B_β and D_β for all $\beta \in S \cap (\epsilon, \gamma]$. Since we are free to discard initial segments of D_β, we can also assume that D_β is entirely contained in the interval (ϵ, γ).

The preceding paragraph defines B_β and D_β for all β of Type I, and it does so in such a fashion that $D_\beta \cap C = \emptyset$ for all β of Type I. We now turn our attention to the β of Type II.

For each $\beta \in S \cap \mathrm{acc}(C)$, let $D_\beta := C \cap \beta$. This guarantees that D_β and D_{β^*} are disjoint whenever β is of Type II and β^* is of Type I. We now show that it is possible to choose B_β for each β of Type II in such a way that each B_β is a cofinite subset of A_β, and the family $\{B_\beta : \beta \in S \cap \mathrm{acc}(C)\}$ is disjoint.

Thus, let β be a fixed ordinal of Type II. Recall that $i^* < \omega$ has the property that for each $i > i^*$, the sequence $\langle f_\eta(i) : \eta \in A\rangle$ is strictly increasing. Since $\beta \in S$, we know $\mathrm{cf}(\beta) = \omega_1$ and thus there exists an $m_\beta < \omega$ and a cofinal $E \subseteq A \cap \beta$ such that

$$f_\eta(i) < f_\beta(i) \quad \text{for } i > m_\beta \text{ and } \eta \in E.$$

By the choice of A, this means that

$$f_\eta(i) < f_\beta(i) \quad \text{for all } \eta \in A \cap \beta \text{ and } i > \max\{i^*, m_\beta\}.$$

Let $\epsilon(\beta)$ be the least member of A above β, and choose

$$n(\beta) > \max\{i^*, m_\beta\}$$

so large that

$$f_\beta(i) < f_{\epsilon(\beta)}(i) \quad \text{for all } i > n(\beta).$$

Finally, we define

$$B_\beta := \{(m, f_\beta(m)) : m > n(\beta)\}.$$

Note that B_β is a cofinite subset of A_β, and the following claim shows us that this choice of B_β has the desired property.

4.56 Claim. *The family* $\{B_\beta : \beta \in S \cap \operatorname{acc}(C)\}$ *is disjoint.*

Proof. By way of contradiction, assume that $\beta < \beta^*$ are two elements of $S \cap \operatorname{acc}(C)$ for which $B_\beta \cap B_{\beta^*} \neq \emptyset$. A point in this intersection must have the form (m, η) for some $m > \max\{n(\beta), n(\beta^*)\}$ with

$$\eta = f_\beta(m) = f_{\beta^*}(m). \tag{15.67}$$

Because $\epsilon(\beta)$ is in $A \cap \beta^*$, it follows that

$$f_\beta(m) < f_{\epsilon(\beta)}(m) < f_{\beta^*}(m). \tag{15.68}$$

The statements (15.67) and (15.68) are contradictory, therefore B_β and B_{β^*} are disjoint. ⊣

Thus, we have defined B_β and D_β for all $\beta \in S \cap \alpha$ in the case where $\operatorname{cf}(\alpha) > \aleph_1$. Using our observation (15.66), it is straightforward to verify that $\{B_\beta \times D_\beta : \beta \in S \cap \alpha\}$ is a disjoint collection. ⊣

This completes the proof of Lemma 4.54, and Theorem 4.53. ⊣

4.57 Corollary. AP_μ *implies* $\mathrm{NPT}(\mu^+, \aleph_1)$ *for singular* μ *of countable cofinality.*

We are in a position to deduce the following corollary (essentially a restatement of one of the main results of [83]), but we shall soon see that the strong limit assumption is unnecessary.

4.58 Corollary. *If* $\aleph_\omega$ *is a strong limit, then* $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$ *holds.*

Proof. Since $\aleph_\omega$ is assume to be a strong limit, Corollary 3.41 implies that either $\mathrm{AP}_{\aleph_\omega}$ holds or $\mathrm{Refl}(\aleph_{\omega+1})$ fails. In the former case, the result follows from Corollary 4.57, while in the latter case, the result follows from Corollary 4.49. ⊣

Our attention now focuses on a result of Magidor and Shelah [65] stating that $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$ always holds, whether or not $\aleph_\omega$ is a strong limit. This will give us the opportunity to delve a bit more deeply into the structure of scales, and the key result we use is *Shelah's Trichotomy Theorem.*

4.59 Theorem (Shelah's Trichotomy Theorem). *Let I be an ideal on the set A, and let $\langle f_\alpha : \alpha < \delta\rangle$ be a $<_I$-increasing sequence with* $\operatorname{cf}(\delta) > |A|^+$. *Then exactly one of the following possibilities holds:*

1. *There is an exact upper bound h such that $\mathrm{cf}(h(x)) > |A|$ for all $x \in A$.*

2. *There is an ultrafilter U on A disjoint to I, and for each $x \in A$ a set S_x of cardinality at most $|A|$ such that some subfamily of $\prod_{x \in A} S_x$ is cofinally interleaved with $\langle f_\alpha : \alpha < \delta \rangle$ modulo U.*

3. *There is a function h such that the sequence*

$$\langle \{x \in A : f_\alpha(x) < h(x)\} : \alpha < \delta \rangle$$

is not eventually constant modulo I.

The preceding theorem is central in some presentations of the theory of exact upper bounds, for example, that found in Kojman [55, 56]. In Shelah [89], it appears as Claim 1.2 on page 41, while in Abraham and Magidor [1], one finds it as Exercise 2.27. One sometimes sees the three alternatives presented under the names good, bad, and ugly; we have stayed away from this because "good" conflicts with the notion of "good point" (they are related, but not the same thing), and even in [65] the adjective "good" is used for yet another related concept.

We will not prove the Trichotomy Theorem, but we do make a couple of observations before moving on to the proof of $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$. First, we remark that in the situation of the Trichotomy Theorem, if $\mathrm{cf}(\delta) > 2^{|A|}$ then the first alternative necessarily holds by cardinality considerations. Second, if the second (respectively, third) alternative holds for the sequence $\langle f_\alpha : \alpha < \delta \rangle$ then there is a closed unbounded $C \subseteq \delta$ such that the second (respectively, third) alternative holds for all initial segments $\langle f_\alpha : \alpha < \epsilon \rangle$ of our sequence where ϵ is in C and $\mathrm{cf}(\epsilon) > |A|$.

We now turn our attention to the special case of scales for $\aleph_\omega$. To simplify our notation a bit, we note that for such scales it makes sense to speak of a pair $(A, \vec{f})$ where $A \subseteq \omega$ instead of $(\vec{\mu}, \vec{f})$, that is, we view $\vec{f}$ as a $<^*$-increasing sequence of functions in $\prod_{n \in A} \aleph_n$ instead of re-indexing and dealing with a sequence $\langle \mu_i : i < \omega \rangle$.

4.60 Lemma. *Let $(A, \vec{f})$ be a scale for $\aleph_\omega$, and let $\delta < \aleph_{\omega+1}$ be an ordinal of uncountable cofinality for which the sequence $\langle f_\alpha : \alpha < \delta \rangle$ has an exact upper bound g with $\mathrm{cf}(g(n)) > \aleph_0$ for all $n \in A$ (that is, the first alternative of the Trichotomy Theorem holds at δ). Then δ is a good point for $\vec{f}$.*

Proof. By Theorem 3.50, it suffices to prove that $\mathrm{cf}(g(n)) = \mathrm{cf}(\delta)$ for all sufficiently large $n \in A$. Assume by way of contradiction that this fails, so $\mathrm{cf}(g(n)) \neq \mathrm{cf}(\delta)$ for unboundedly many $n \in A$. We split into two cases:

Case 1. $\mathrm{cf}(\delta) < \mathrm{cf}(g(n))$ for unboundedly many $n \in A$.

Let $B \subseteq A$ be the set of n for which $\mathrm{cf}(\delta) < \mathrm{cf}(g(n))$. Let $\langle e(\epsilon) : \epsilon < \mathrm{cf}(\delta) \rangle$ enumerate an unbounded subset of δ. Since $\mathrm{cf}(\delta) > \aleph_0$, we may assume that there is a fixed n^* such that

$$f_{e(\epsilon)}(n) < g(n) \quad \text{for all } \epsilon < \mathrm{cf}(\delta) \text{ and } n \in A \setminus n^*.$$

Now define $h \in \prod_{n \in A} \aleph_n$ by

$$h(n) = \begin{cases} \sup\{f_{e(\epsilon)}(n) : \epsilon < \mathrm{cf}(\delta)\} & \text{if } n \in B \setminus n^*, \text{ and} \\ 0 & \text{otherwise.} \end{cases}$$

It is clear that $h < g$, so there must exist an $\epsilon < \mathrm{cf}(\delta)$ with $h <^* f_{e(\epsilon)}$. Clearly this is absurd.

Case 2. $\aleph_0 < \mathrm{cf}(g(n)) < \mathrm{cf}(\delta)$ for unboundedly many $n \in A$.

Let B be the set of $n \in A$ for which $\aleph_0 < \mathrm{cf}(g(n)) < \mathrm{cf}(\delta)$. There are only finitely many infinite cardinals below $\mathrm{cf}(\delta)$, and so by thinning out B, we may assume that there is a regular cardinal $\kappa < \mathrm{cf}(\delta)$ such that

$$\aleph_0 < \mathrm{cf}(g(n)) = \kappa < \mathrm{cf}(\delta)$$

for all $n \in B$.

For each $n \in B$, we let $\langle e_n(\epsilon) : \epsilon < \kappa \rangle$ be the increasing enumeration of a cofinal subset of $g(n)$ and define $g_\epsilon \in \prod_{n \in B} \aleph_n$ by

$$g_\epsilon(n) = e_n(\epsilon).$$

The sequence $\langle g_\epsilon : \epsilon < \kappa \rangle$ is increasing, and cofinally interleaved with $\langle f_\alpha \restriction B : \alpha < \delta \rangle$. This is impossible, because $\mathrm{cf}(\delta) \neq \kappa$. ⊣

We remark that it is possible for an exact upper bound to exist at a non-good point in a scale (we will see this phenomenon in the proof of Theorem 4.63 below), so the first alternative in the Trichotomy Theorem is not the same as "goodness" in general.

The following corollary translates some of our prior observations into the situation at hand.

4.61 Corollary. *Let $(A, \vec{f})$ be a scale for $\aleph_\omega$.*

1. *If $2^{\aleph_0} < \aleph_\omega$, then all ordinals $\delta < \aleph_{\omega+1}$ with $\mathrm{cf}(\delta) > 2^{\aleph_0}$ are good.*

2. *Let S be the set of good points for $\vec{f}$ of cofinality $\aleph_1$. If δ is not good and $\mathrm{cf}(\delta) > \aleph_1$, then $S \cap \delta$ is a nonstationary subset of δ.*

Proof. The first part follows because as we noted above, the first alternative of the Trichotomy must hold for the sequence $\langle f_\alpha : \alpha < \delta \rangle$, and by Lemma 4.60 this means that δ is a good point for the scale. The second statement of the corollary is just a reformulation of one of the observations made after the statement of Theorem 4.59 in light of the information given by Lemma 4.60. ⊣

We now come to the promised result of Magidor and Shelah [65] that lets us drop the strong limit condition from the statement of Corollary 4.58.

4.62 Theorem. $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$ *holds.*

Proof. Let $(A, \vec{f})$ be a scale for $\aleph_\omega$. The construction is essentially the same as that given in the proof of Theorem 4.53, so we will only outline the required changes. (A full proof of a much more general theorem can be found in the first section of [65].)

The first change is to replace $S^{\aleph_{\omega+1}}_{\aleph_1}$ by the set S of good points for $\vec{f}$ of cofinality $\aleph_1$. The proof of Lemma 4.54 goes through for this choice of S, but now the fourth case (where $\mathrm{cf}(\alpha) > \aleph_1$) splits into two subcases, depending on whether or not α is a good point for the scale.

If α is good, then the same proof works. If α is not good, then by an appeal to Corollary 4.61 we find a closed unbounded $C \subseteq \alpha$ such that $C \cap S = \emptyset$, and an argument as in the second and third cases of Theorem 4.53 completes the proof. ⊣

We finish this section by investigating situations where no good scales exist. Since AP_μ implies that all scales for μ are good, it is clear that large cardinals must be involved. It should be no surprise by now that supercompact cardinals are the place to look, and we have the following result of Shelah [89].

4.63 Theorem. *Suppose that κ is supercompact and μ is a singular cardinal such that $\mathrm{cf}(\mu) < \kappa < \mu$. Then there is no good scale for μ.*

Proof. Let $(\vec{\mu}, \vec{f})$ be a scale for μ, and let $j : V \to M$ be a μ^+-supercompact embedding with $\mathrm{crit}(j) = \kappa$. Let

$$j(\vec{\mu}) = \langle \mu^j_i : i < \mathrm{cf}(\mu)\rangle,$$

and

$$j(\vec{f}) = \langle f^j_\alpha : \alpha < j(\mu^+)\rangle.$$

We know that $(j(\vec{\mu}), j(\vec{f}))$ is a scale for $j(\mu)$.

As usual, let $\rho = \sup\{j(\alpha) : \alpha < \mu^+\}$ (which is less than $j(\mu^+)$). We claim that ρ is not a good point for $j(\vec{f})$; we do this by proving that the sequence $\langle f^j_\alpha : \alpha < \rho\rangle$ has an exact upper bound g with the property that $\mathrm{cf}(g(i)) = \mu_i$ for all $i < \mathrm{cf}(\mu)$. Since exact upper bounds are (modulo the ideal) unique, it follows from Theorem 3.50 that ρ is not a good point for $j(\vec{f})$.

It is clear that if we define

$$g(i) = \sup\{j(\epsilon) : \epsilon < \mu_i\},$$

then g is an upper bound for $\langle f^j_\alpha : \alpha < \rho\rangle$; we claim that g is indeed an exact upper bound for $\langle f^j_\alpha : \alpha < \rho\rangle$.

Given $h <^* g$ in $\prod_{i<\mathrm{cf}(\mu)} j(\mu_i)$, we can find $h' \in \prod_{i<\mathrm{cf}(\mu)} \mu_i$ such that $h <^* j(h')$. Since $(\vec{\mu}, \vec{f})$ is a scale, there is an $\alpha < \mu^+$ such that $h' <^* f_\alpha$, hence

$$h <^* j(f_\alpha) = f^j_{j(\alpha)}.$$

Since $j(\alpha) < \rho$, we are done.

To finish the proof, we apply the elementarity of j to conclude that $(\vec{\mu}, \vec{f})$ is not a good scale. $\dashv$

We note that essentially the same proof we gave for the consistency of $\neg\, \mathrm{AP}_{\aleph_\omega}$ yields the consistency of there being no good scales for $\aleph_\omega$—a reader seeking more details can find them in Sect. 18 of Cummings' survey [14]. Magidor [64] has shown that Martin's Maximum implies that no scale for $\aleph_\omega$ is good (again, [14] contains a proof), while Foreman and Magidor [34] give a proof that there is no good scale for $\aleph_\omega$ if the model-theoretic transfer principle

$$(\aleph_{\omega+1}, \aleph_\omega) \twoheadrightarrow (\aleph_1, \aleph_0)$$

holds. This version of Chang's Conjecture was proved consistent by Levinski, Magidor, and Shelah—see [61].

4.6. Varieties of Nice Scales

The previous section illustrated that for a singular cardinal μ, the existence of a "well-behaved" scale can function as a construction principle along the lines of $\square_\mu$ or AP_μ. We continue with this theme in the current section by considering scales with even stronger properties and analyzing the consequences of their existence. We begin with a strengthening of goodness studied by Cummings, Foreman, and Magidor in [16].

4.64 Definition. Let $(\vec{\mu}, \vec{f})$ be a scale for the singular cardinal μ. We say $(\vec{\mu}, \vec{f})$ is a *very good scale for* μ if for each $\alpha < \mu^+$ with $\mathrm{cf}(\alpha) > \mathrm{cf}(\mu)$, there are a closed unbounded $C \subseteq \alpha$ and $i < \mathrm{cf}(\mu)$ such that

$$f_\beta(j) < f_\gamma(j) \quad \text{for all } \beta < \gamma \text{ in } C \text{ and all } j > i. \tag{15.69}$$

We let VGS_μ abbreviate the statement that a very good scale for μ exists.

It is clear that a very good scale is also good, and the next few results (taken from [16]) show us that very good scales fit into the hierarchy of combinatorial principles we have been considering in this chapter.

4.65 Theorem. *Suppose that μ is singular and $\square^\sigma_\mu$ holds for some $\sigma < \mu$. Then VGS_μ holds.*

Proof. Let $(\vec{\mu}, \vec{f})$ be any scale for μ, and let $\langle \mathcal{C}_\alpha : \alpha < \mu^+\rangle$ be a $\square^\sigma_\mu$ sequence with the property that all members of each $\mathcal{C}_\alpha$ are of order-type less than μ (see Lemma 4.21). We also assume without loss of generality that σ is less than μ_0, the first cardinal in the sequence $\vec{\mu}$.

Build a sequence $\vec{g} = \langle g_\alpha : \alpha < \mu^+\rangle$ of functions in $\prod_{i<\mathrm{cf}(\mu)} \mu_i$ according to the following recipe:

$$g_0 = f_0,$$
$$g_{\alpha+1}(i) = \max\{f_{\alpha+1}(i), g_\alpha(i)\}.$$

For α limit, we choose $g_\alpha \in \prod_{i<\mathrm{cf}(\mu)} \mu_i$ such that

1. $f_\alpha < g_\alpha$,
2. $g_\gamma <^* g_\alpha$ for all $\gamma < \alpha$, and
3. $g_\alpha(i) > \sup\big(\{\sup_{\beta \in C} g_\beta(i) : C \in \mathcal{C}_\alpha, |C| < \mu_i\}\big)$.

There are no obstacles in the above construction, and clearly $(\vec{\mu}, \vec{g})$ is a scale for μ. Given a limit ordinal $\alpha < \mu^+$ such that $\mathrm{cf}(\alpha) > \mathrm{cf}(\mu)$, we can choose $C \in \mathcal{C}_\alpha$ and $i < \mathrm{cf}(\mu)$ such that $|C| < \mu_i$. If $j \geq i$ and $\beta < \gamma$ in C, then $C \cap \beta \in \mathcal{C}_\beta$, $\gamma \in C \cap \beta$, and $|C \cap \beta| < \mu_j$. This means $g_\gamma(j) < g_\beta(j)$, as required. $\dashv$

4.66 Theorem. *Suppose that μ is singular, and* VGS_μ *holds. Then for every stationary $S \subseteq \mu^+$, there is a sequence $\langle S_i : i < \mathrm{cf}(\mu)\rangle$ of stationary subsets of S with the property that for all $\delta < \mu^+$ of cofinality greater than* $\mathrm{cf}(\mu)$*,*

$$|\{i < \mathrm{cf}(\mu) : S_i \cap \delta \textit{ is stationary in } \delta\}| < \mathrm{cf}(\mu).$$

Proof. Let $(\vec{\mu}, \vec{f})$ be a very good scale for μ, and let $S \subseteq \mu^+$ be stationary. For each $i < \mathrm{cf}(\mu)$, we can find $\gamma_i < \mu_i$ and a stationary $S_i \subseteq S$ such that

$$\alpha \in S_i \quad \Longrightarrow \quad f_\alpha(i) = \gamma_i. \tag{15.70}$$

By way of contradiction, suppose that we can find an ordinal $\delta < \mu^+$ such that $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$ and $S_i \cap \delta$ is stationary in δ for unboundedly many $i < \mathrm{cf}(\mu)$. Since $\vec{f}$ is a very good scale, there is a closed unbounded $C \subseteq \delta$ and an $i < \mathrm{cf}(\mu)$ such that $f_\alpha(j) < f_\beta(j)$ for all $\alpha < \beta$ in C and all $j > i$.

If we choose $j > i$ with $S_j \cap \delta$ stationary in δ, then we can find $\alpha < \beta$ in $C \cap S_j$. By choice of C and i, it must be the case that $f_\alpha(j) < f_\beta(j)$. On the other hand, the choice of S_j implies $f_\alpha(j) = f_\beta(j)$, and so we have a contradiction. $\dashv$

The preceding two theorems now yield the proof of Theorem 4.18, which states that the conclusion of Theorem 4.66 follows if $\square^\sigma_\mu$ holds for some $\sigma < \mu$. Before leaving the topic of very good scales, we mention two corollaries of the preceding theorem.

4.67 Corollary. *If* $\mathrm{VGS}_{\aleph_\omega}$ *holds, then there is a family $\{S_n : n < \omega\}$ of stationary subsets of $\aleph_{\omega+1}$ with the property that no infinite subfamily can reflect simultaneously.*

4.68 Corollary. $\mathrm{VGS}_{\aleph_\omega}$ *does not follow from* $\square^*_{\aleph_\omega}$.

Proof. This follows from Corollary 4.67 and Theorem 4.12. $\dashv$

We mention that question of whether VGS_μ follows from $\square_\mu^{<\mu}$ is still open. The result of Cummings in Theorem 4.20 shows us that $\square_\mu^{<\mu}$ has similar consequences with regard to stationary reflection.

We have seen that for singular μ, AP_μ implies the existence of good scales, while $\square_\mu^\sigma$ for some $\sigma < \mu$ implies the existence of very good scales. Taken together with Corollary 4.68, these facts suggest the question of whether one can formulate a weaker version of VGS_μ that will be a consequence of $\square_\mu^*$, yet strong enough to have interesting consequences. Again the paper [16] provides us with a satisfying answer.

4.69 Definition. A scale $(\vec{\mu}, \vec{f})$ for a singular cardinal μ is *better* if for every $\alpha < \mu^+$ with $\mathrm{cf}(\alpha) > \mathrm{cf}(\mu)$, there is a closed unbounded $C \subseteq \alpha$ such that

1. $\mathrm{ot}(C) = \mathrm{cf}(\alpha)$, and
2. for all $\beta \in C$, there is an $i < \mathrm{cf}(\mu)$ such that $f_\gamma(j) < f_\beta(j)$ for all $j > i$ and $\gamma \in C \cap \beta$.

We note that ordinals $\alpha < \mu^+$ with $\mathrm{cf}(\alpha) \leq \mathrm{cf}(\mu)$ automatically enjoy the "betterness" property of the preceding definition—we will need this fact in the proof of Theorem 4.72 given below.

As noted by the authors of [16], better scales can be constructed from weak square.

4.70 Theorem. *Let μ be a singular cardinal. If $\square_\mu^*$ holds, then there is a better scale for μ.*

Proof. Let $\langle \mathcal{C}_\alpha : \alpha < \mu^+ \rangle$ be a $\square_\mu^*$ sequence with the property that each $\mathcal{C}_\alpha$ contains a set of order-type $\mathrm{cf}(\alpha)$. Given a scale $(\vec{\mu}, \vec{g})$ for μ, we construct a new scale $(\vec{\mu}, \vec{f})$ by induction on $\alpha < \mu^+$:

Case 1. $\alpha = 0$.
In this case, we simply define f_0 to be g_0.

Case 2. α is a successor.
In this case, we define $f_{\beta+1} = g_\gamma$ where γ is chosen so large that $f_\beta <^* g_\gamma$.

Case 3. α is a limit.
If α is a limit ordinal, then for each $C \in \mathcal{C}_\alpha$ we define a function f_C by

$$f_C(i) = \begin{cases} \sup_{\gamma \in C} f_\gamma(i) & \text{if } \mathrm{ot}(C) < \mu_i, \\ 0 & \text{otherwise.} \end{cases} \tag{15.71}$$

We let $f_\alpha = g_\gamma$ for $\gamma < \mu^+$ so large that

- $f_C <^* g_\gamma$ for all $C \in \mathcal{C}_\alpha$, and
- $f_\beta <^* g_\gamma$ for all $\beta < \alpha$.

This is possible because $\prod_{i < \mathrm{cf}(\mu)} \mu_i$ is μ^+-directed under $<^*$ and $|\mathcal{C}_\alpha| \leq \mu$.

The above construction produces a $<^*$-increasing sequence $\vec{f}$, and clearly

$(\vec{\mu}, \vec{f})$ is a scale for μ. It remains to verify that $(\vec{\mu}, \vec{f})$ is a better scale.

Given $\delta < \mu$ with $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$, we fix a $C \in \mathcal{C}_\delta$ with $\mathrm{ot}(C) < \mu$. If $\alpha \in \mathrm{acc}(C)$, then $C \cap \alpha \in \mathcal{C}_\alpha$ and by our construction, we have

$$f_{C\cap\alpha} <^* f_\alpha.$$

Since $\mu_i > \mathrm{ot}(C \cap \alpha)$ for all sufficiently large $i < \mathrm{cf}(\mu)$, there is an $i < \mathrm{cf}(\mu)$ such that

$$f_{C\cap\alpha}(j) = \sup_{\gamma \in C\cap\alpha} f_\gamma(j) \quad \text{for all } j > i.$$

Now let D be any closed unbounded subset of $\mathrm{acc}(C)$ with $\mathrm{ot}(D) = \mathrm{cf}(\delta)$; it follows easily that for all $\alpha \in D$ there is an $i < \mathrm{cf}(\mu)$ such that $f_\beta(j) < f_\alpha(j)$ whenever $\beta \in C \cap \alpha$ and $j > i$. ⊣

We now turn to the topic of the utility of better scales as a construction principle. The following concept (studied first by Shelah in [84]) will help us give show that better scales are indeed quite useful objects.

4.71 Definition. Let κ be a cardinal. A sequence $\langle A_\alpha : \alpha < \kappa^+\rangle$ is an ADS-*sequence for* κ if each A_α is a unbounded subset of κ, and for every $\beta < \kappa^+$ there is a function $F_\beta : \beta \to \kappa$ such that the sets $\langle A_\alpha \setminus F_\beta(\alpha) : \alpha < \beta\rangle$ are pairwise disjoint. We say that ADS_κ *holds* if there is an ADS-sequence for κ.

The designation ADS stands for "almost disjoint sets". Note as well that such sequences always exist if κ is regular, as any collection of κ^+ almost disjoint subsets of κ gives rise to an ADS-sequence for κ. On the other hand, if μ is singular and $\langle A_\alpha : \alpha < \mu^+\rangle$ is an ADS_μ-sequence, then we get an example of $\mathrm{NPT}(\mu^+, (\mathrm{cf}\,\mu)^+)$ by choosing for each $\alpha < \mu^+$ an unbounded subset of A_α of order-type $\mathrm{cf}(\mu)$. It follows that ADS_μ does not automatically hold in the case of singular μ, but the following result from [16] shows that the existence of a better scale for μ is strong enough to imply that it does.

4.72 Theorem. *If there is a better scale for* μ*, then* ADS_μ *holds.*

Proof. Let $(\vec{\mu}, \vec{f})$ be a better scale. Without loss of generality, we assume $\mathrm{cf}(\mu) < \mu_0$ and

$$\sup_{j<i} \mu_j < f_\alpha(i) \quad \text{for all } \alpha < \mu^+ \text{ and } i < \mathrm{cf}(\mu). \tag{15.72}$$

We claim that $\langle \mathrm{ran}(f_\alpha) : \alpha < \mu^+\rangle$ is an ADS-sequence for μ. To see this, we first prove the following statement by induction on $\alpha < \mu^+$:

$\oplus_\alpha$ There is function $F_\alpha : \alpha \to \mathrm{cf}(\mu)$ such that if $\gamma < \beta < \alpha$ and $i > \max\{F_\alpha(\gamma), F_\alpha(\beta)\}$, then $f_\gamma(i) < f_\beta(i)$.

Once we have this, it is not difficult to finish the proof. To see this, fix $\alpha < \mu^+$ and let F_α be a function as in $\oplus_\alpha$. For $\beta < \alpha$, define

$$B_\beta := \{f_\beta(i) : i > F_\alpha(\beta)\}.$$

If $\gamma < \beta < \alpha$ and $x \in B_\gamma \cap B_\beta$, then

$$x = f_\gamma(i) = f_\beta(j)$$

for some $i > F_\alpha(\gamma)$ and $j > F_\alpha(\beta)$. Because of condition (15.72), it must be the case that $i = j$ and therefore

$$i \geq \max\{F_\alpha(\gamma), F_\alpha(\beta)\}.$$

This gives us a contradiction, as $\oplus_\alpha$ implies

$$f_\gamma(i) < f_\beta(i),$$

so we conclude that $\langle B_\beta : \beta < \alpha\rangle$ is a disjoint family.

The proof of $\oplus_\alpha$ is by induction on α, with the case $\alpha = 0$ being trivial.

Case 1. $\alpha = \beta + 1$.

Let $F_\beta : \beta \to \mathrm{cf}(\mu)$ witness $\oplus_\beta$. We define $F_\alpha(\beta)$ to be 0, and for $\gamma < \beta$ we choose $F_\alpha(\gamma) < \mathrm{cf}(\mu)$ so large that

- $F_\alpha(\gamma) \geq F_\beta(\gamma)$, and
- $f_\gamma(i) < f_\beta(i)$ for all $i > F_\alpha(\gamma)$

It is straightforward to verify that F_α satisfies the demands of $\oplus_\alpha$.

Case 2. α is a limit.

Since $(\vec{\mu}, \vec{f})$ is a better scale, there is a closed unbounded $C \subseteq \alpha$ of order-type $\mathrm{cf}(\alpha)$ such that for $\beta \in C$, there is an $i < \mathrm{cf}(\mu)$ with $f_\gamma(j) < f_\beta(j)$ for all $\gamma \in C \cap \beta$ and $j > i$.

For each $\delta \in \mathrm{nacc}(C)$, let F_δ be a function with the properties required by $\oplus_\delta$. If $\gamma < \alpha$, then γ lies in an interval of the form $[\sup(C \cap \delta), \delta)$ for some unique $\delta \in \mathrm{nacc}(C)$. Let $\epsilon = \sup(C \cap \delta)$, and note that $\epsilon \in C$ except for the case where $\delta = \min(C)$.

We now define $F_\alpha(\gamma) < \mathrm{cf}(\mu)$ to be so large that

1. $F_\alpha(\gamma) \geq F_\delta(\gamma)$,
2. $f_\epsilon(i) \leq f_\gamma(i) < f_\delta(i)$ for all $i > F_\alpha(\gamma)$, and
3. $f_{\epsilon^*}(i) < f_\epsilon(i)$ for all $\epsilon^* \in C \cap \epsilon$ and $i > F_\alpha(\gamma)$.

Note that condition (3) is where our choice of C is important, and the conjunction of (2) and (3) guarantees

$$f_\zeta(i) \leq f_\gamma(i) \quad \text{for all } \zeta \in C \cap \gamma \text{ and } i > F_\alpha(\gamma). \tag{15.73}$$

All that remains is to prove that the function F_α defined above satisfies all the requirements of $\oplus_\alpha$. Given $\gamma < \beta < \alpha$, we need to prove

$$i > \max\{F_\alpha(\gamma), F_\alpha(\beta)\} \quad \Longrightarrow \quad f_\gamma(i) < f_\beta(i). \tag{15.74}$$

We break the verification of (15.74) into two subcases.

Subcase 1. There is a $\delta \in \mathrm{nacc}(C)$ such that $\sup(C \cap \delta) \leq \gamma < \beta < \delta$.

Our construction guarantees that $F_\alpha(\gamma) \geq F_\delta(\gamma)$ and $F_\alpha(\beta) \geq F_\delta(\beta)$. Since F_δ satisfies the requirements of $\oplus_\delta$, (15.74) follows immediately.

Subcase 2. Subcase 1 fails.

In this situation, there must be ordinals $\delta^* < \delta$ in $\mathrm{nacc}(C)$ such that

$$\gamma < \delta^* \leq \sup(C \cap \delta) \leq \beta < \delta.$$

If $i > F_\alpha(\gamma)$, then $f_\gamma(i) < f_{\delta^*}(i)$ by requirement (2) in our definition of $F_\alpha(\gamma)$. If $i > F_\alpha(\beta)$, then an appeal to (15.73) tells us that $f_{\delta^*}(i) \leq f_\beta(i)$. Thus, (15.74) holds for this subcase as well.

Now that we have established $\oplus_\alpha$ for all $\alpha < \mu^+$, the proof of Theorem 4.72 is complete. ⊣

In the remainder of this subsection, we discuss some applications of the principle ADS_μ for μ a singular cardinal. Our first stop is the following theorem of Shelah (originally appearing in [84], but see also Lemma 4.9 in Chap. VII of [89]).

4.73 Theorem. *If $W \subseteq V$ are models of* ZFC *such that*

$$W \models \theta \textit{ is a cardinal and } \mathrm{ADS}_\theta \textit{ holds,}$$

and $(\theta^+)^W$ remains a cardinal in V, then

$$V \models \mathrm{cf}(\theta) = \mathrm{cf}(|\theta|). \tag{15.75}$$

Proof. In W, let $\langle A_\alpha : \alpha < (\theta^+)^W \rangle$ be an ADS_θ-sequence and suppose by way of contradiction that

$$V \models \mathrm{cf}(\theta) \neq \mathrm{cf}(|\theta|). \tag{15.76}$$

We begin by stepping into the model V and assessing the situation. First, it is clear from (15.76) that θ is not a cardinal, and so there is a cardinal κ such that $\kappa < \theta < \kappa^+ = (\theta^+)^W$. Thus, the ADS_θ-sequence from W looks like a sequence $\langle A_\alpha : \alpha < \kappa^+ \rangle$ of subsets of the ordinal θ from the point of view of V.

Still inside of V, let σ be the cofinality of the ordinal θ and let τ be the cofinality of κ. There is a increasing sequence of sets $\langle B_i : i < \tau \rangle$ with union θ such that $|B_i| < \kappa$ for each $i < \tau$. Given $\alpha < \kappa^+$, we know that A_α has cofinality σ (as a set of ordinals). Since $\tau \neq \sigma$ and the sequence $\langle B_i : i < \tau \rangle$ is increasing, it follows that there is an ordinal $i(\alpha) < \tau$ with $A_\alpha \cap B_{i(\alpha)}$ unbounded in θ.

Fix $i^* < \tau$ so that $Z = \{\alpha < \kappa^+ : i(\alpha) = i^*\}$ is of size κ^+, and let α^* be the κth member of Z. By choice of $\langle A_\alpha : \alpha < \kappa^+ \rangle$, there is a function

$F : \alpha^* \to \theta$ such that the family $\{A_\alpha \setminus F(\alpha) : \alpha < \alpha^*\}$ is disjoint. Since $A_\alpha \cap B_{i^*}$ is unbounded in A_α for all $\alpha \in Z$, it follows that

$$\{A_\alpha \cap B_{i^*} \setminus F(\alpha) : \alpha \in Z \cap \alpha^*\} \tag{15.77}$$

is disjoint family of κ non-empty subsets of B_{i^*}. However, this is absurd as $|B_{i^*}| < \kappa$. ⊣

The preceding theorem also sheds light on a question of Bukovský and Copláková-Hartová [9], who ask if there can exist two models $W \subseteq V$ of ZFC with $\aleph^W_{\omega+1} = \aleph^V_2$. This problem and its natural generalizations have been studied by Cummings [12]. He has shown that the assumption of ADS_θ in Theorem 4.73 can be replaced, in the interesting case where θ is singular, by the existence of a good scale for θ. He also discusses how these results connect to other problems concerning singular cardinal combinatorics.

We end this subsection with an application of ADS to reflection of generalized stationary sets in the sense of Jech [50]. We use the following definition, which Kueker [57] has shown to be equivalent to Jech's original definition.

4.74 Definition. Let X be an uncountable set. A set $S \subseteq [X]^{\aleph_0}$ is *stationary* if and only if for all $F : {}^{<\omega}X \to X$, there is an $A \in S$ closed under F.

Jech's chapter [49] in this Handbook contains a much more comprehensive treatment of generalized stationary sets. We, however, will rest content with just the following definitions.

4.75 Definition. Let X be an uncountable transitive set.

1. A stationary set $S \subseteq [X]^{\aleph_0}$ *reflects to* $Y \subseteq X$ if $|Y| \subseteq Y$ and $S \cap [Y]^{\aleph_0}$ is stationary in $[Y]^{\aleph_0}$.
2. If S is stationary in $[X]^{\aleph_0}$, then we say $\mathrm{Refl}^*(S)$ *holds* if every stationary $T \subseteq S$ reflects to some $Y \in [X]^{\aleph_1}$ with $\mathrm{cf}(\mathrm{ot}(Y \cap \mathsf{On})) = \aleph_1$.

The vocabulary of the preceding definition now allows us to state the following theorem from [16].

4.76 Theorem. *Suppose that μ is singular of countable cofinality. If* ADS_μ *holds then* $\mathrm{Refl}^*([\mu^+]^{\aleph_0})$ *fails.*

Proof. Let $\langle A_\alpha : \alpha < \mu^+\rangle$ be an ADS_μ-sequence. Clearly we may assume that each A_α is of order-type ω, and we define

$$S = \{X \in [\mu^+]^{\aleph_0} : A_{\sup(X)} \subseteq X\}.$$

4.77 Claim. *The set S is stationary in $[\mu^+]^{\aleph_0}$.*

Proof. Let $F : {}^{<\omega}\mu^+ \to \mu^+$ be a finitary function. There is a closed unbounded set of $\alpha < \mu^+$ that are closed under F. Suppose now that $\mu < \alpha < \mu^+$, $\mathrm{cf}(\alpha) = \aleph_0$, and α is closed under F. Let C be an unbounded ω-sequence in α, and define A to be the closure of $C \cup A_\alpha$ under the function F. Since $\sup(A) = \alpha$, it follows that $A \in S$ and therefore S is stationary in $[\mu^+]^{\aleph_0}$. ⊣

Let us now assume by way of contradiction that $\mathrm{Refl}^*([\mu^+]^{\aleph_0})$ holds. This gives us a $Y \in [\mu^+]^{\aleph_1}$ such that

- $\omega_1 \subseteq Y$,
- $\mathrm{ot}(Y)$ has cofinality $\aleph_1$, and
- $S \cap [Y]^{\aleph_0}$ is stationary in $[Y]^{\aleph_0}$.

Note that if $X \in [Y]^{\aleph_0}$ then $\sup(X) < \sup(Y)$.

By our assumptions, there is a function $F : \sup(Y) \to \mu$ such that the sequence $\langle A_\alpha \setminus F(\alpha) : \alpha < \sup(Y)\rangle$ is disjoint. For $X \in S \cap [Y]^{\aleph_0}$, let

$$h(X) = \min(A_{\sup(X)} \setminus F(\sup(X))).$$

Note that $h(X) \in X$ because $A_{\sup(X)} \subseteq X$, and

$$\sup(X_0) \neq \sup(X_1) \implies h(X_0) \neq h(X_1) \tag{15.78}$$

because of the properties of F.

By Jech's generalization of Fodor's Theorem (see [49, Sect. 4]), there is a stationary $T \subseteq S \cap [Y]^{\aleph_0}$ on which h is constant. It follows immediately from (15.78) that there is a β such that $\sup(X) = \beta$ for all $X \in T$.

Since $\mathrm{cf}(\beta) = \aleph_0 < \aleph_1 = \mathrm{cf}(\sup(Y))$, it follows that $\beta < \sup(Y)$. But then it is easy to see that $\{X \in [Y]^{\aleph_0} : \sup(X) = \beta\}$ is nonstationary—a contradiction. $\dashv$

By work of Foreman, Magidor, and Shelah [36], Martin's Maximum implies $\mathrm{Refl}^*([\lambda]^{\aleph_0})$ for all regular $\lambda \geq \aleph_2$. As a consequence, Martin's Maximum implies that $\mathrm{ADS}_{\aleph_\omega}$ fails. Since $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$ always holds, we see that $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$ does not imply $\mathrm{ADS}_{\aleph_\omega}$.

4.7. Some Consequences of $\mathrm{pp}(\mu) > \mu^+$

In the Analytical Guide appendix to [89], Shelah writes

> **14.6** Up to now we have many consequences of GCH (or instances of it) and few of the negations of such statements. We now begin to have consequences of the negation ... so we can hope to have proofs by division to cases. For example, let λ be strong limit singular; if $\mathrm{pp}\,\lambda > \lambda^+$ then $\mathrm{NPT}(\lambda^+, \mathrm{cf}\,\lambda)$ [$\mathrm{NPT}(\lambda^*, (\mathrm{cf}\,\lambda)^+)$ in the conventions adopted in this chapter] and if $\mathrm{pp}(\lambda) \leq \lambda^+$ then $2^\lambda = \lambda^+$ (and $\diamondsuit^*_{\{\delta<\lambda^+:\mathrm{cf}(\delta)\neq\mathrm{cf}(\lambda)\}}$) and so various constructions are possible.

In this section, we take advantage of better scales to illustrate his point. The following theorem is a restatement of part of Claim 1.3 from Chap. II of [89].

4.78 Theorem. *Let μ be a singular cardinal. If $\mathrm{pp}(\mu) > \mu^+$, then there is a better scale for μ.*

Proof. By Proposition 1.19, there is an increasing sequence $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ of regular cardinals with limit μ such that

$$\left(\prod_{i<\mathrm{cf}(\mu)}\mu_i, <^*\right) \text{ is } \mu^{++}\text{-directed.} \tag{15.79}$$

For each limit $\delta < \mu^+$, choose a closed unbounded $C_\delta \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$, and define

$$\mathcal{C}_\delta = \{C_\alpha \cap \delta : \delta \leq \alpha < \mu^+,\ \alpha \text{ limit}\}.$$

Note that $|\mathcal{C}_\delta| \leq \mu^+$, so our sequence is essentially a $\square_\mu^{\mu^+}$-sequence. As mentioned before, such a sequence is referred to as a *silly square sequence* in the literature.

If $\prod_{i<\mathrm{cf}(\mu)} \mu_i$ we construct a $<^*$-increasing sequence $\langle g_\alpha : \alpha < \mu^+\rangle$ such that for every limit $\delta < \mu^+$ and $C \in \mathcal{C}_\delta$,

$$f_C <^* g_\delta,$$

where f_C is defined as in (15.71). Note that this construction is the place where (15.79) is used in a crucial manner.

Note as well that our construction guarantees that every limit $\delta < \mu^+$ satisfying $\mathrm{cf}(\delta) > \mathrm{cf}(\mu)$ is a good point for $\vec{g}$. From our earlier work, it follows that $\vec{g}$ has an exact upper bound g with the property that

$$|\{i < \mathrm{cf}(\mu) : \mathrm{cf}(g(i)) < \kappa\}| < \mathrm{cf}(\mu)$$

for all $\kappa < \mu$.

The rest of the proof parallels that of Theorem 3.53—one uses g to find an increasing sequence $\vec{\theta} = \langle \theta_\xi : \xi < \mathrm{cf}(\mu)\rangle$ of regular cardinals with limit μ with the property that there is a natural operation Φ that transforms the sequence $\vec{g}$ into a sequence $\vec{f}$ of functions in $\prod_{\xi<\mathrm{cf}(\mu)} \theta_\xi$ in such a way that $(\vec{\theta}, \vec{f})$ is a scale for μ. The only detail that must be checked is that this transformation preserves the "betterness" that is built into $\vec{g}$, and this is straightforward. $\dashv$

4.79 Corollary. *If μ is a strong limit singular cardinal and $2^\mu > \mu^+$, then there is a better scale for μ. Hence* $\mathrm{ADS}(\mu)$ *and* $\mathrm{NPT}(\mu^+, (\mathrm{cf}\,\mu)^+)$ *hold as well.*

Proof. The proof of the corollary follows immediately once we know that the assumptions imply $\mathrm{pp}(\mu) > \mu^+$. If μ has uncountable cofinality, then this follows from Conclusion 5.5 on page 93 of Shelah's [89] (or see Theorem 9.1.3 on page 271 of [46] for a more explicit statement). If $\mathrm{cf}(\mu) = \aleph_0$, then we get what we need (that is, $\mathrm{pp}(\mu) > \mu^+$) from Conclusion 5.10 on page 410 of [89]. $\dashv$

We conclude this section with a result designed to complement Proposition 1.19 from the introduction to this chapter.

4.80 Theorem. *The following statements are equivalent for a singular cardinal μ.*

1. $\mathrm{pp}(\mu) = \mu^+$.
2. *If $\vec{\mu} = \langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ is an increasing sequence of regular cardinals with limit μ, then there is an unbounded $I \subseteq \mathrm{cf}(\mu)$ such that $\vec{\mu} \restriction I$ admits a scale for μ, that is, we can find $\vec{f}$ such that $(\vec{\mu} \restriction I, \vec{f})$ is a scale for μ.*

If in addition we know $\mathrm{cf}(\mu) = \aleph_0$, then we can add

3. *Every increasing sequence $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ of regular cardinals with limit μ admits a scale for μ.*

Proof. Note that the implication from (2) to (1) follows immediately from Proposition 1.19 by taking the contrapositive, so we concentrate on the implication from (1) to (2). Assume now that $\mathrm{pp}(\mu) = \mu^+$, and let $\vec{\mu}$ be given.

We may assume that $\mathrm{cf}(\mu) < \mu_0$, so that the set $A = \{\mu_i : i < \mathrm{cf}(\mu)\}$ is a progressive set of regular cardinals cofinal in μ. It is clear from the definitions involved that $\mu^+ \in \mathrm{pcf}(A)$, so let $B = B_{\mu^+}[A]$ be the corresponding generator and recall that

$$\mathrm{tcf}\big(\prod B, <_{J_{<\mu^+}[A]}\big) = \mu^+. \tag{15.80}$$

The set B is unbounded in A (this follows easily from the assumption that $\mathrm{pp}(\mu) = \mu^+$) and so there is an unbounded $I \subseteq \mathrm{cf}(\mu)$ for which $B = \{\mu_i : i \in I\}$. Observe as well that any subset of B in $J_{<\mu^+}[A]$ must be bounded in B—if D is any ultrafilter A disjoint to $J^{\mathrm{bd}}[A]$, then $\mathrm{cf}(\prod A/D) \geq \mu^+$. When we combine this observation with (15.80), it follows that

$$\mathrm{tcf}\big(\prod B, <_{J^{\mathrm{bd}}[B]}\big) = \mu^+,$$

and from this we see that $\vec{\mu} \restriction I$ admits a scale.

It is clear that (1) follows from (3) by the same reason that it follows from (2). For the other direction, we actually prove something a little stronger than required—we show that for any singular μ with $\mathrm{pp}(\mu) = \mu^+$ (regardless of cofinality), if we are given an increasing sequence of regular cardinals $\langle \mu_i : i < \mathrm{cf}(\mu)\rangle$ with limit μ that in addition satisfies

$$\max \mathrm{pcf}\{\mu_j : j < i\} < \mu_i \quad \text{for all } i < \mathrm{cf}(\mu), \tag{15.81}$$

then $\vec{\mu}$ admits a scale. If $\mathrm{cf}(\mu) = \aleph_0$, then any relevant $\vec{\mu}$ will satisfy this property, and so this will be sufficient to prove that (1) implies (3) under those circumstances.

Suppose now that $\vec{\mu}$ satisfies (15.81), and let $A = \{\mu_i : i < \mathrm{cf}(\mu)\}$. If D is any ultrafilter on A, then either D contains a bounded subset of A (and hence $\mathrm{cf}(\prod A/D) < \mu$ by (15.81), or D is disjoint to $J^{\mathrm{bd}}[A]$ (in which case

$\mathrm{cf}(\prod A/D) = \mu^+$ because $\mathrm{pp}(\mu) = \mu^+$). We conclude that $\max \mathrm{pcf}(A) = \mu^+$ and hence A is the pcf generator $B_{\mu^+}[A]$ corresponding to μ^+. Thus,

$$\mathrm{tcf}\bigl(\prod A, <_{J_{<\mu^+}[A]}\bigr) = \mu^+.$$

It follows from work earlier in the current proof that

$$J_{<\mu^+}[A] \subseteq J^{\mathrm{bd}}[A],$$

and clearly

$$J^{\mathrm{bd}}[A] \subseteq J_{<\mu^+}[A]$$

because of our assumption (15.81). Putting these three statements together, we see that

$$\mathrm{tcf}\bigl(\prod A, <_{J^{\mathrm{bd}}[A]}\bigr) = \mu^+,$$

and therefore $\vec{\mu}$ admits a scale. ⊣

In closing the section, we mention that the relationship between failures of the Singular Cardinals Hypothesis and reflection phenomena is a very active area of current research, as evidenced by the following recent results:

- (Sharon [79]) It is consistent that there is a strong limit singular cardinal μ such that $2^\mu > \mu^+$ and $\mathrm{Refl}(\mu^+)$ holds.
- (Gitik and Sharon [39]) It is consistent that $\aleph_{\omega^2}$ is a strong limit cardinal, $2^{\aleph_{\omega^2}} > \aleph_{\omega^2+1}$, $\mathrm{VGS}_{\aleph_{\omega^2}}$ holds, but $\mathrm{AP}(\aleph_{\omega^2})$ fails.

The latter result gives us an example where goodness is not the same as approachability. Their work leaves open the question of whether it is consistent that $\aleph_\omega$ is a strong limit, $2^{\aleph_\omega} > \aleph_{\omega+1}$, and $\neg\Box^*_{\aleph_\omega}$, as well as the question of whether it is consistent to have a strong limit singular μ with $2^\mu > \mu^+$ such that $\Box^*_\mu$ fails *and* such that GCH holds beneath μ.

4.8. Trees at Successors of Singular Cardinals

Early on in the chapter we lamented that some material that should be covered in such a survey had to be sacrificed in the interest of keeping the chapter to a manageable length. Thus, this subsection will be quite short, and little more than a list of open problems, but the topic we cover is too important to be left out altogether. We speak of trees at successors of singular cardinals.

Throughout the earlier parts of the chapter, we have used reflection properties of stationary sets as a lens to study the various combinatorial principles uncovered in the course of the narrative. We could just as easily have used trees to study the fine gradations in strength in the hierarchy of concepts we have examined.

Let us start with Jensen's result [52] that $\Box_\kappa$ together with the GCH implies the existence of a κ^+-Souslin tree. Schimmerling [76] notes that in fact, a simple modification of Jensen's argument shows that it suffices to assume only the principle $\square_\kappa^{<\omega}$ in addition to GCH. He goes on to suggest the following family of questions:

> Assume μ is a singular cardinal and GCH holds. Find the least θ such that $\square_\mu^{<\theta}$ does not imply the existence of a μ^+-Souslin tree. Does the existence of an $\aleph_{\omega+1}$-Souslin tree follow from GCH and $\square_{\aleph_\omega}^*$? What about GCH and $\square_{\aleph_\omega}^\omega$?

With regard to Aronszajn trees, recall that $\square_\kappa^*$ is equivalent to the existence of a special κ^+-Aronszajn tree (see Theorem 4.13). Shelah proved that if μ is a singular limit of strongly compact cardinals, then there are no μ^+-Aronszajn trees at all. This result appears in [66], along with his joint work with Magidor wherein starting with a 2-huge cardinal, they prove the consistency of there being no $\aleph_{\omega+1}$-Aronszajn trees at all.

Foreman's collection of open questions [32] lists several problems concerning Aronszajn trees at successors of singular cardinals. At the forefront is the general task of discerning the relationship between the failure of the singular cardinals hypothesis, weak versions of square, and the existence of Aronszajn trees. We offer the following list of questions taken from [32] as an example of some specific manifestations of the general problem:

- If $\aleph_\omega$ is a strong limit and $2^{\aleph_\omega} > \aleph_{\omega+1}$, does there exist an $\aleph_{\omega+1}$-Aronszajn tree?
- If $\aleph_\omega$ is a strong limit and $2^{\aleph_\omega} > \aleph_{\omega+1}$, does $\square_{\aleph_\omega}^*$ holds?
- Does the existence of a μ^+-Aronszajn tree follow from the existence of a very good scale for μ?
- If $\mathrm{cf}(\mu) = \aleph_0$ and AP_μ holds, does there exist a μ^+-Aronszajn tree?

With these questions, we leave the topic of trees and push on into the last section of the chapter.

5. Square-Bracket Partition Relations

In the opening of this chapter, we dealt briefly with the following well-known open question:

$$\text{If } \mu \text{ is singular, is there a Jónsson algebra on } \mu^+? \tag{15.82}$$

This question has been responsible for a great deal of the development of pcf theory and club guessing technology by Shelah. As we shall see, there are many partial results, but a final resolution remains elusive. In this final section of the chapter, we consider this open question and some of its special cases.

5.1. Colorings of Finite Subsets

We begin with our "official" definition of Jónsson cardinals—we gave a different definition in Definition 1.3, but we shall see that the two are equivalent.

5.1 Definition.

1. An *algebra* is a structure $\mathcal{A} = \langle A, f_n \rangle_{n<\omega}$, where each f_n is a finitary function mapping A to A.

2. A *Jónsson algebra* is an algebra without a proper subalgebra of the same cardinality.

3. A cardinal λ is a *Jónsson cardinal* if there is **no** Jónsson algebra of cardinality λ, that is, every algebra of cardinality λ has a proper subalgebra of cardinality λ.

We refer the reader to [53, Chap. 12] for the basic theory of Jónsson cardinals, for we do not have room to explore in detail the ways in which such cardinals fit into the general scheme of large cardinals. We also cite the follow result from [53], which appears as Exercise 8.12.

5.2 Theorem. *The following are equivalent:*

1. *λ is a Jónsson cardinal.*

2. *$\lambda \to [\lambda]^{<\omega}_{\lambda}$, that is, whenever $F : [\lambda]^{<\omega} \to \lambda$, we can find an $H \subseteq \lambda$ of size λ such that the range of $F \restriction [H]^{<\omega}$ is a proper subset of λ.*

3. *Any structure for a countable first-order language with domain of cardinality λ has a proper elementary substructure with domain of the same cardinality.*

The equivalence of (1) and (2) is due to Erdős and Hajnal [26], while the equivalence of (1) and (3) was first shown by Keisler and Rowbottom [54]. We will need one more standard fact about Jónsson cardinals; we give a proof to illustrate the technique of utilizing Skolem functions.

5.3 Theorem. *The following statements are equivalent for a cardinal λ:*

1. *λ carries a Jónsson algebra.*

2. *For every sufficiently large regular $\chi > \lambda$, if M is a elementary submodel of $\langle H(\chi), \in, <_\chi \rangle$ such that*

   (a) $\lambda \in M$, and

   (b) $|M \cap \lambda| = \lambda$,

   then $\lambda \subseteq M$.

Proof. Assume that λ carries a Jónsson algebra. By condition (2) of Theorem 5.2, there is a function $F : [\lambda]^{<\omega} \to \lambda$ with the property that

$$A \in [\lambda]^\lambda \quad \Longrightarrow \quad \operatorname{ran}(F \restriction [A]^{<\omega}) = \lambda.$$

Given a model M as above, by elementarity there is such a function F inside of M. Given $\alpha < \lambda$, there must be a set $a \in [M \cap \lambda]^{<\omega}$ such that $F(a) = \alpha$. Since a is also an element of M (any finite sequence of elements from M is in M as well!), we see that α is definable from parameters in M and therefore $\alpha \in M$. Thus $\lambda \subseteq M$ as required.

For the other direction, let $\mathfrak{A}$ be the structure $\langle H(\chi), \in, \lambda, <_\chi \rangle$ and let $\langle f_n : n < \omega \rangle$ be a complete set of Skolem functions for $\mathfrak{A}$. We assume without loss of generality that f_n is k_n-ary for some $k_n \leq n$. We define a function F with domain $[\lambda]^{<\omega}$ as follows:

$$F(\alpha_1, \ldots, \alpha_n) = \begin{cases} f_n(\alpha_1, \ldots, \alpha_{k_n}) & \text{if this is an ordinal below } \lambda \text{, and} \\ 0 & \text{otherwise.} \end{cases} \tag{15.83}$$

The definition of F guarantees that for every subset B of λ, the range of F restricted to $[B]^{<\omega}$ coincides with $\mathrm{Sk}^{\mathfrak{A}}(B) \cap \lambda$. Thus, statement (2) implies that this particular F witnesses that $\lambda \nrightarrow [\lambda]^{<\omega}_\lambda$. By Fact 5.2, λ is not a Jónsson cardinal. ⊣

Note that the proof of the preceding theorem actually establishes more than is claimed—in addition, we may require that the models M in (2) contain some fixed $x \in H(\chi)$. Theorem 5.3 is quite useful, and as an illustration we prove a theorem (due independently to Tryba [99] and Woodin) that shows that (15.82) is connected to stationary reflection.

5.4 Theorem. *If λ is a regular Jónsson cardinal, then every stationary subset of λ reflects.*

Proof. Let λ be a regular Jónsson cardinal, and suppose that $M \prec H(\chi)$ (for a sufficiently large regular χ) is such that $\lambda \in M$, $|M \cap \lambda| = \lambda$, but $\lambda \nsubseteq M$. It suffices to prove that every stationary $S \in M$ reflects—if λ had a non-reflecting stationary subset then there would be one in M.

Given such an S, we claim that $S \setminus M$ must be stationary. To see why, assume by way of contradiction that there is a closed unbounded $E \subseteq \lambda$ with $E \cap S \subseteq M$. In the model M, we can find a function $f : S \to \lambda$ such that $S_\alpha := f^{-1}(\{\alpha\})$ is stationary for each $\alpha < \lambda$. Fix $\alpha < \lambda$ such that $\alpha \notin M$. Since $S_\alpha \subseteq S$, we know $E \cap S_\alpha \subseteq M$. Given $\beta \in E \cap S_\alpha$, since $f \in M$ and $\beta \in M$ we conclude $\alpha = f(\beta) \in M$, a contradiction.

Thus, we can find $\delta \in S \setminus M$ such that $\delta = \sup(M \cap \delta)$. Let us define

$$\beta_\delta := \min(M \cap \lambda \setminus \delta). \tag{15.84}$$

Since δ is not in M, we clearly have $\delta < \beta_\delta$. Furthermore, an easy argument establishes that β_δ is a limit ordinal of uncountable cofinality. To finish the proof, we establish that $S \cap \beta_\delta$ is a stationary subset of β_δ.

Assume by way of contradiction that this fails. Since S and β_δ are both members of M, the model M contains a closed unbounded subset C of β_δ disjoint to S. Now $M \cap \delta$ is cofinal in δ, and so for any $\alpha < \delta$ there is a $\beta \in M \cap \lambda$ with $\alpha < \beta < \delta$. Furthermore, since

$$M \models C \text{ is unbounded in } \beta_\delta,$$

there is a $\gamma \in M \cap C$ with $\beta < \gamma$. By our choice of β_δ, it must be the case that $\gamma < \delta$. Thus, δ is a limit point of C. But C is closed, and so δ must be in C as well. This contradicts our assumption that S and C are disjoint. $\dashv$

As an immediate corollary, we see that successors of regular cardinals carry Jónsson algebras.

5.5 Corollary. *If κ is regular, then κ^+ carries a Jónsson algebra.*

The fact that successors of regular cardinals cannot be Jónsson cardinals is put to good use in the following lemma which provides a strengthening of Theorem 5.3.

5.6 Lemma. *The following two statements are equivalent:*

1. *λ is a Jónsson cardinal.*
2. *For every sufficiently large regular $\chi > \lambda$ whenever we are given a cardinal κ satisfying $\kappa^+ < \lambda$, there is an $M \prec \langle H(\chi), \in, <_\chi\rangle$ such that*
   (a) *$\{\lambda, \kappa\} \in M$,*
   (b) *$|M \cap \lambda| = \lambda$,*
   (c) *$\lambda \nsubseteq M$, and*
   (d) *$\kappa + 1 \subseteq M$.*

Proof. The implication (2) $\to$ (1) is immediate by the comments following Theorem 5.3. For the other direction, assume that λ is a Jónsson cardinal, but χ and κ provide a counterexample to (2). Let $\mathfrak{A}$ be the structure $\langle H(\chi), \in, \lambda, \kappa, <_\chi\rangle$. Since λ is a Jónsson cardinal, we can find and elementary submodel M of $\mathfrak{A}$ such that $|M \cap \lambda| = \lambda$ but $\lambda \nsubseteq M$. Let $B = M \cap \lambda$; without loss of generality $M = \mathrm{Sk}^{\mathfrak{A}}(B)$.

Since κ is in M, our choice of κ implies $\kappa \nsubseteq M$. The cardinal κ^{++} is in M as well, and since κ^{++} carries a Jónsson algebra by Corollary 5.5, it follows that

$$\sup(M \cap \kappa^{++}) < \kappa^{++}.$$

Now let $N = \mathrm{Sk}^{\mathfrak{A}}(B \cup \kappa)$. Since $\kappa + 1 \subseteq N$, our choice of κ implies $\lambda \subseteq N$. In particular, $\sup(N \cap \kappa^{++}) = \kappa^{++}$. This is a contradiction, as Lemma 1.6 tells us that $\sup(M \cap \kappa^{++}) = \sup(N \cap \kappa^{++}) < \kappa^{++}$. $\dashv$

We now fulfill a promise made in the introductory section of the chapter—we prove that $\aleph_{\omega+1}$ cannot be a Jónsson cardinal. The proof is due to Shelah [82] and furnishes yet another instance of the utility of scales.

5.7 Theorem. *Suppose that $\lambda = \mu^+$ where μ is a singular cardinal, and assume $(\vec{\mu}, \vec{f})$ is a scale for μ with the property that μ_i carries a Jónsson algebra for each i. Then there is a Jónsson algebra on λ.*

Proof. Let M be an elementary submodel of $H(\chi)$ such that

- both λ and $(\vec{\mu}, \vec{f})$ are in M,
- $\mathrm{cf}(\mu) \subseteq M$, and
- $|M \cap \lambda| = \lambda$.

The conclusion follows from Lemma 5.6 provided that we establish $\lambda \subseteq M$.

This will follow provided we can show $|M \cap \mu_i| = \mu_i$ for arbitrarily large $i < \mathrm{cf}(\mu)$—since each μ_i is in M and no μ_i is a Jónsson cardinal, we could conclude $\mu \subseteq M$ and then an easy argument yields $\lambda = \mu^+ \subseteq M$ as well.

Thus, suppose by way of contradiction that $|M \cap \mu_i| < \mu_i$ for all sufficiently large $i < \mathrm{cf}(\mu)$, and let $\mathrm{Ch}_M^{\vec{\mu}}$ be the *characteristic function of M on $\vec{\mu}$*, defined by

$$\mathrm{Ch}_M^{\vec{\mu}}(i) := \begin{cases} \sup(M \cap \mu_i) & \text{if } \sup(M \cap \mu_i) < \mu_i, \\ 0 & \text{otherwise.} \end{cases} \tag{15.85}$$

Clearly $\mathrm{Ch}_M^{\vec{\mu}} \in \prod_{i<\mathrm{cf}(\mu)} \mu_i$, and $\mathrm{Ch}_M^{\vec{\mu}}(i) = \sup(M \cap \mu_i)$ for all sufficiently large $i < \mathrm{cf}(\mu)$ by our assumptions.

Since $M \cap \lambda$ is unbounded in λ and $(\vec{\mu}, \vec{f})$ is a scale, it follows that there is an $\alpha \in M \cap \lambda$ such that

$$\mathrm{Ch}_M^{\vec{\mu}}(i) < f_\alpha(i) \quad \text{for all sufficiently large } i < \mathrm{cf}(\mu). \tag{15.86}$$

Since $f_\alpha \in M$ and $\mathrm{dom}(f_\alpha) \subseteq M$, it follows that $f_\alpha(i) \in M$ for all $i < \mathrm{cf}(\mu)$, and this contradicts (15.86). $\dashv$

5.8 Corollary. *$\aleph_{\omega+1}$ is not a Jónsson cardinal.*

Theorem 5.7 is quite powerful, especially when taken in conjunction with results in pcf theory. The following corollary collects a few of the more important consequences of Theorem 5.7.

5.9 Corollary. *Let μ be a singular cardinal, and assume μ^+ is a Jónsson cardinal.*

1. μ is a limit of regular Jónsson cardinals.

2. $\mathrm{pp}(\mu) > \mu^+$.

3. If $\mathrm{cf}(\mu)$ *is uncountable, then* $\{\theta < \mu : \theta^+$ *is a Jónsson cardinal*$\}$ *is closed and unbounded in* μ*.*

Proof. If μ^+ is a Jónsson cardinal, then we conclude from Theorem 5.7 that whenever $(\vec{\mu}, \vec{f})$ is a scale for μ, it must be the case that μ_i is a Jónsson cardinal for all sufficiently large $i < \mathrm{cf}(\mu)$. From this, (1) follows easily.

We regard to (2), note that Theorem 5.7 implies that if $\vec{\mu}$ is an increasing sequence of successors of regular cardinals with limit μ, then $\vec{\mu}$ does not admit a scale for μ. By Theorem 4.80, it follows that $\mathrm{pp}(\mu) > \mu^+$.

Statement (3) follows for essentially the same reason as (1); the missing ingredient here is Theorem 2.23 in the chapter of Abraham and Magidor in this Handbook on cardinal arithmetic [1]. ⊣

Concerning statement (2) in Corollary 5.9, we mention that here is a relatively easy "pcf free" proof due to Erdős, Hajnal, and Rado that 2^μ must be greater than μ^+ if μ^+ is a Jónsson cardinal. Since their argument makes use of colorings of pairs, we examine it in the next subsection (see Proposition 5.11). Also, Shelah [92] has proved a generalization of Theorem 5.7 that implies, among other things, that the cardinal $\beth_\omega^+$ carries a Jónsson algebra.

5.2. Colorings of Pairs

The second part of Theorem 5.2 showed us that Jónsson cardinals can be characterized by a certain *square-bracket partition relation.* The notation below is due originally to Erdős, Hajnal, and Rado [27], and we refer the reader to Chap. XI of [28] for a survey of the elementary theory of square-bracket partition relations.

5.10 Definition. Given cardinals κ, λ, and μ, and an ordinal γ, the notation

$$\kappa \to [\mu]^\lambda_\gamma$$

means that given a partition $f : [\kappa]^\lambda \to \gamma$, there is a set $H \subseteq \kappa$ of cardinality μ such that

$$\mathrm{ran}(f \restriction [H]^\lambda) \text{ is a proper subset of } \gamma.$$

The negation of this assertion is denoted

$$\kappa \nrightarrow [\mu]^\lambda_\gamma.$$
