Preface

Numbers imitate space, which is of such a different nature
—Blaise Pascal

It is fair to date the study of the foundation of mathematics back to the ancient Greeks. The urge to understand and systematize the mathematics of the time led Euclid to postulate axioms in an early attempt to put geometry on a firm footing. With roots in the *Elements*, the distinctive methodology of mathematics has become *proof*. Inevitably two questions arise: *What are proofs?* and *What assumptions are proofs based on?*

The first question, traditionally an internal question of the field of *logic*, was also wrestled with in antiquity. Aristotle gave his famous syllogistic systems, and the Stoics had a nascent propositional logic. This study continued with fits and starts, through Boethius, the Arabs and the medieval logicians in Paris and London. The early germs of logic emerged in the context of philosophy and theology.

The development of analytic geometry, as exemplified by Descartes, illustrated one of the difficulties inherent in founding mathematics. It is classically phrased as the question of *how one reconciles the arithmetic with the geometric*. Are numbers one type of thing and geometric objects another? What are the relationships between these two types of objects? How can they interact? Discovery of new types of mathematical objects, such as imaginary numbers and, much later, formal objects such as free groups and formal power series make the problem of finding a common playing field for all of mathematics importunate.

Several pressures made foundational issues urgent in the 19th century. The development of alternative geometries created doubts about the view that mathematical truth is part of an absolute all-encompassing logic and caused it to evolve towards one in which mathematical propositions follow logically from assumptions that may vary with context.

Mathematical advances involving the understanding of the relationship between the completeness of the real line and the existence of solutions to equations led inevitably to anxieties about the role of infinity in mathematics.

These too had antecedents in ancient history. The Greeks were well aware of the scientific importance of the problems of the infinite which were put forth, not only in the paradoxes of Zeno, but in the work of Eudoxus, Archimedes and others. Venerable concerns about resolving infinitely divisible lines into individual points and what is now called "Archimedes' Axiom" were recapitulated in 19th century mathematics.

In response, various "constructions" of the real numbers were given, such as those using Cauchy sequences and Dedekind cuts, as a way of understanding the relationship between discrete entities, such as the integers or the rationals and the continuum. Even simple operations, such as addition of arbitrary real numbers began to be understood as infinitary operations, defined by some kind of limiting process. The notion of *function* was liberalized beyond those that can be written in closed form. Sequences and series became routine tools for solving equations.

The situation was made acute when Cantor, working on natural problems involving trigonometric series, discovered the existence of different magnitudes of infinity. The widespread use of inherently infinitary techniques, such as the use of the Baire Category Theorem to prove the existence of important objects, became deeply embedded in standard mathematics, making it impossible to simply reject infinity as part of mathematics.

In parallel 19th century developments, through the work of Boole and others, logic became once again a mathematical study. Boole's algebraization of logic made it grist for mathematical analysis and led to a clear understanding of propositional logic. Dually, logicians such as Frege viewed mathematics as a special case of logic. Indeed a very loose interpretation of the work of Frege is that it is an attempt to base mathematics on a broad notion of logic that subsumed all mathematical objects.

With Russell's paradox and the failure of Frege's program, a distinction began to be made between *logic* and *mathematics*. Logic began to be viewed as a formal epistemological mechanism for exploring mathematical truth, barren of mathematical content and in need of assumptions or axioms to make it a useful tool.

Progress in the 19th and 20th centuries led to the understanding of logics involving quantifiers as opposed to propositional logic and to distinctions such as those between first and second-order logic. With the semantics developed by Tarski and the compactness and completeness theorems of Gödel, first-order logic has become widely accepted as a well-understood, unproblematic answer to the question *What is a proof?*

The desirable properties of first-order logic include:

- Proofs and propositions are easily and uncontroversially recognizable.

- There is an appealing semantics that gives a clear understanding of the relationship between a mathematical structure and the formal propositions that hold in it.

- It gives a satisfactory model of what mathematicians actually do: the "rigorous" proofs given by humans seem to correspond exactly to the

> "formal" proofs of first-order logic. Indeed formal proofs seem to provide a normative ideal towards which controversial mathematical claims are driven as part of their verification process.

While there are pockets of resistance to first-order logic, such as constructivism and intuitionism on the one hand and other alternatives such as second-order logic on the other, these seem to have been swept aside, if simply for no other reason than their comparative lack of mathematical fruitfulness.

To summarize, a well-accepted conventional view of foundations of mathematics has evolved that can be caricatured as follows:

$$\text{Mathematical Investigation} = \text{First-Order Logic} + \text{Assumptions}$$

This formulation has the advantage that it segregates the difficulties with the foundations of mathematics into discussions about the underlying assumptions rather than into issues about the nature of reasoning.

So what are the appropriate assumptions for mathematics? It would be very desirable to find assumptions that:

1. involve a simple primitive notion that is easy to understand and can be used to "build" or develop all standard mathematical objects,

2. are *evident*,

3. are *complete* in that they settle all mathematical questions,

4. can be easily recognized as part of a recursive schema.

Unfortunately Gödel's incompleteness theorems make item 3 impossible. *Any* recursive consistent collection $\mathcal{A}$ of mathematical assumptions that are strong enough to encompass the simple arithmetic of the natural numbers will be *incomplete*; in other words there will be mathematical propositions P that cannot be settled on the basis of $\mathcal{A}$. This inherent limitation is what has made the foundations of mathematics a lively and controversial subject.

Item 2 is also difficult to satisfy. To the extent that we understand mathematics, it is a difficult and complex business. The Euclidean example of a collection of axioms that are easily stated and whose content is simple to appreciate is likely to be misleading. Instead of simple, distinctly conceived and obvious axioms, the project seems more analogous to specifying a complicated operating system in machine language. The underlying primitive notions used to develop standard mathematical objects are combined in very complicated ways. The axioms describe the operations necessary for doing this and the test of the axioms becomes how well they code higher level objects as manipulated in ordinary mathematical language so that the results agree with educated mathematicians' sense of correctness.

Having been forced to give up 3 and perhaps 2, one is apparently left with the alternatives:

2′. Find assumptions that are in accord with the intuitions of mathematicians well versed in the appropriate subject matter.

3′. Find assumptions that *describe* mathematics to as large an extent as is possible.

With regard to item 1, there are several choices that could work for the primitive notion for developing mathematics, such as *categories* or *functions*. With no *a priori* reason for choosing one over another, the standard choice of *sets* (or set membership) as the basic notion is largely pragmatic. Taking sets as the primitive, one can easily do the traditional constructions that "build" or "code" the usual mathematical entities: the empty set, the natural numbers, the integers, the rationals, the reals, $\mathbb{C}$, $\mathbb{R}^n$, manifolds, function spaces—all of the common objects of mathematical study.

In the first half of the 20th century a standard set of assumptions evolved, the axiom system called the Zermelo-Fraenkel axioms with the Axiom of Choice (ZFC). It is pragmatic in spirit; it posits sufficient mathematical strength to allow the development of standard mathematics, while explicitly rejecting the type of objects held responsible for the various paradoxes, such as Russell's.

While ZFC is adequate for most of mathematics, there are many mathematical questions that it does not settle. Most prominent among them is the first problem on Hilbert's celebrated list of problems given at the 1900 International Congress of Mathematicians, the *Continuum Hypothesis*.

In the jargon of logic, a question that cannot be settled in a theory T is said to be *independent* of T. Thus, to give a mundane example, the property of being Abelian is independent of the axioms for group theory. It is routine for normal axiomatizations that serve to synopsize an abstract concept internal to mathematics to have independent statements, but more troubling for axiom systems intended to give a definitive description of mathematics itself. However, independence phenomena are now known to arise from many directions; in essentially every area of mathematics with significant infinitary content there are natural examples of statements independent of ZFC.

This conundrum is at the center of most of the chapters in this Handbook. Its investigation has left the province of abstract philosophy or logic and has become a primarily mathematical project. The intent of the Handbook is to provide graduate students and researchers access to much of the recent progress on this project. The chapters range from expositions of relatively well-known material in its mature form to the first complete published proofs of important results. The introduction to the Handbook gives a thorough historical background to set theory and summaries of each chapter, so the comments here will be brief and general.

The chapters can be very roughly sorted into four types. The first type consists of chapters with theorems demonstrating the independence of mathematical statements. Understanding and proving theorems of this type require a thorough understanding of the mathematics surrounding the source of the problem in question, reducing the ambient mathematical constructions to combinatorial statements about sets, and finally using some method (primarily forcing) to show that the combinatorial statements are independent.

A second type of chapter involves delineating the edges of the independence phenomenon, giving proofs in ZFC of statements that on first sight would be suspected of being independent. Proofs of this kind are often extremely subtle and surprising; very similar statements are independent and it is hard to detect the underlying difference.

The last two types of chapters are motivated by the desire to *settle* these independent statements by adding assumptions to ZFC, such as large cardinal axioms. Proposers of augmentations to ZFC carry the burden of marshaling sufficient evidence to convince informed practitioners of the reasonableness, and perhaps truth, of the new assumptions as descriptions of the mathematical universe. (Proposals for axiom systems intended to *replace* ZFC carry additional heavier burdens and appear in other venues than the Handbook.)

One natural way that this burden is discharged is by determining what the supplementary axioms *say*; in other words by investigating the consequences of new axioms. This is a strictly mathematical venture. The theory is assumed and theorems are proved in the ordinary mathematical manner. Having an extensive development of the consequences of a proposed axiom allows researchers to see the overall picture it paints of the set-theoretic universe, to explore analogies and disanalogies with conventional axioms, and judge its relative coherence with our understanding of that universe. Examples of this include chapters that posit the assumption that the Axiom of Determinacy holds in a model of Zermelo-Fraenkel set theory that contains all of the real numbers and proceed to prove deep and difficult results about the structure of definable sets of reals.

Were there an obvious and compelling unique path of axioms that supplement ZFC and settle important independent problems, it is likely that the last type of chapter would be superfluous. However, historically this is not the case. Competing axioms systems have been posited, sometimes with obvious connections, sometimes appearing to have nothing to do with each other.

Thus it becomes important to compare and contrast the competing proposals. The Handbook includes expositions of some stunningly surprising results showing that one axiom system actually implies an apparently unrelated axiom system. By far the most famous example of this are the proofs of determinacy axioms from large cardinal assumptions.

Many axioms or independent propositions are not related by implication, but rather by *relative consistency* results, a crucial idea for the bulk of the Handbook. A remarkable meta-phenomenon has emerged. There appears to be a central spine of axioms to which all independent propositions are comparable in consistency strength. This spine is delineated by large cardinal axioms. There are no known counterexamples to this behavior.

Thus a project initiated to understand the relationships between disparate axiom systems seems to have resulted in an understanding of most known natural axioms as somehow variations on a common theme—at least as far as consistency strength is concerned. This type of unifying deep structure is taken as strong evidence that the axioms proposed reflect some underlying reality and is often cited as a primary reason for accepting the existence of large cardinals.

The methodology for settling the independent statements, such as the Continuum Hypothesis, by looking for evidence is far from the usual deductive paradigm for mathematics and goes against the rational grain of much philosophical discussion of mathematics. This has directed the attention of some members of the philosophical community towards set theory and has been grist for many discussions and message boards. However interpreted, the investigation itself is entirely mathematical and many of the most skilled practitioners work entirely as mathematicians, unconcerned about any philosophical anxieties their work produces.

Thus set theory finds itself at the confluence of the foundations of mathematics, internal mathematical motivations and philosophical speculation. Its explosive growth in scope and mathematical sophistication is testimony to its intellectual health and vitality.

The Handbook project has some serious defects, and does not claim to be a remotely complete survey of set theory; the work of Shelah is not covered to the appropriate extent given its importance and influence and the enormous development of classical descriptive set theory in the last fifteen years is nearly neglected. While the editors regret this, we are consoled that those two topics, at least, are well documented elsewhere. Other parts of set theory are not so lucky and we apologize.

We the editors would like to thank all of the authors for their labors. They have taken months or years out of their lives to contribute to this project. We would especially like to thank the referees, who are the unsung heroes of the story, having silently devoted untold hours to carefully reading the manuscripts simply for the benefit of the subject.

Irvine

Let me express a special gratitude to the Lichtenberg-Kolleg at Göttingen. Awarded an inaugural 2009–2010 fellowship, I was provided with a particularly supportive environment at the Gauss Sternwarte, in the city in which David Hilbert, Ernst Zermelo, and Paul Bernays did their formative work on the foundations of mathematics. Thus favored, I was able to work in peace and with inspiration to complete the final editing and proof-reading of this Handbook.

Introduction

Akihiro Kanamori

Contents

M. Foreman, A. Kanamori (eds.), *Handbook of Set Theory*,
DOI 10.1007/978-1-4020-5764-9_1,

Set theory has entered its prime as an advanced and autonomous research field of mathematics with broad foundational significance, and this Handbook with its expanse and variety amply attests to the fecundity and sophistication of the subject. Indeed, in set theory's further reaches one sees tremendous progress both in its continuing development of its historical heritage, the investigation of the transfinite numbers and of definable sets of reals, as well as its analysis of strong propositions and consistency strength in terms of large cardinal hypotheses and inner models.

This introduction provides a historical and organizational frame for both modern set theory and this Handbook, the chapter summaries at the end being a final elaboration. To the purpose of drawing in the serious, mathematically experienced reader and providing context for the prospective researcher, we initially recapitulate the consequential historical developments leading to modern set theory as a field of mathematics. In the process we affirm basic concepts and terminology, chart out the motivating issues and driving initiatives, and describe the salient features of the field's internal practices. As the narrative proceeds, there will be a natural inversion: Less and less will be said about more and more as one progresses from basic concepts to elaborate structures, from seminal proofs to complex argumentation, from individual moves to collective enterprise. We try to put matters in a succinct yet illuminating manner, but be that as it may, according to one's experience or interest one can skim the all too familiar or too obscure. To the historian this account would not properly be history—it is, rather, a deliberate arrangement, in significant part to lay the ground for the coming chapters. To the seasoned set theorist there may be issues of under-emphasis or over-emphasis, of omissions or commissions. In any case, we take refuge in a wise aphorism: If it's worth doing, it's worth doing badly.

1. Beginnings

1.1. Cantor

Set theory was born on that day in December 1873 when Georg Cantor (1845–1918) established that *the continuum is not countable*—there is no one-to-one correspondence between the real numbers and the natural numbers $0, 1, 2, \ldots$. Given a (countable) sequence of reals, Cantor defined nested intervals so that any real in their intersection will not be in the sequence. In the course of his earlier investigations of trigonometric series Cantor had developed a definition of the reals and had begun to entertain infinite totalities of reals for their own sake. Now with his uncountability result Cantor embarked on a full-fledged investigation that would initiate an expansion of the very concept of number. Articulating cardinality as based on bijection (one-to-one correspondence) Cantor soon established positive results about the existence of bijections between sets of reals, subsets of the plane, and the like. By 1878 his investigations had led him to assert that there are only two infinite cardinalities embedded in the continuum: *Every infinite set of reals is either countable or in bijective correspondence with all the reals.* This was the Continuum Hypothesis (CH) in its nascent context, and the *continuum problem*, to resolve this hypothesis, would become a major motivation for Cantor's large-scale investigations of infinite numbers and sets.

In his magisterial *Grundlagen* of 1883 Cantor developed the *transfinite numbers* and the key concept of *well-ordering*, in large part to take a new, structured approach to infinite cardinality. The transfinite numbers follow the natural numbers $0, 1, 2, \ldots$ and have come to be depicted in his later notation in terms of natural extensions of arithmetical operations:

$$\begin{aligned} &\omega, \omega+1, \omega+2, \ldots \omega+\omega (= \omega{\cdot}2), \\ &\quad \ldots \omega{\cdot}3, \ldots \omega{\cdot}\omega (= \omega^2), \ldots \omega^3, \ldots \omega^\omega, \ldots \omega^{\omega^\omega}, \ldots . \end{aligned}$$

A *well-ordering* on a set is a linear ordering of it according to which every non-empty subset has a least element. Well-orderings were to carry the sense of sequential counting, and the transfinite numbers served as standards for gauging well-orderings. Cantor developed cardinality by grouping his transfinite numbers into successive number classes, two numbers being in the same class if there is a bijection between them. Cantor then propounded a basic principle: "It is always possible to bring any *well-defined* set into the form of a *well-ordered* set." Sets are to be well-ordered, and they and their cardinalities are to be gauged via the transfinite numbers of his structured conception of the infinite.

The transfinite numbers provided the framework for Cantor's two approaches to the continuum problem, one through cardinality and the other through definable sets of reals, these each to initiate vast research programs. As for the first, Cantor in the *Grundlagen* established results that reduced the continuum problem to showing that the continuum and the countable transfinite numbers have a bijection between them. However, despite several announcements Cantor could never develop a workable correlation, an emerging problem being that he could not *define* a well-ordering of the reals.

As for the approach through definable sets of reals, Cantor formulated the key concept of a *perfect* set of reals (non-empty, closed, and containing no isolated points), observed that perfect sets of reals *are* in bijective correspondence with the continuum, and showed that every closed set of reals is either countable or else have a perfect subset. Thus, Cantor showed that "CH holds for closed sets". The *perfect set property*, being either countable or else having a perfect subset, would become a focal property as more and more definable sets of reals came under purview.

Almost two decades after his initial 1873 result, Cantor in 1891 subsumed it through his celebrated *diagonal* argument. In logical terms this argument turns on the use of the validity $\neg\exists y\forall x(Pxx \longleftrightarrow \neg Pyx)$ for binary predicates P parametrizing unary predicates and became, of course, fundamental to the development of mathematical logic. Cantor stated his new, general result in terms of functions, ushering in totalities of arbitrary functions into mathematics, but his result is cast today in terms of the power set $P(x) = \{y \mid y \subseteq x\}$ of a set x: *For any set x, $P(x)$ has a larger cardinality than x.* Cantor had been extending his notion of set to a level of abstraction beyond sets of reals and the like; this new result showed for the first time that there is a set of a larger cardinality than that of the continuum.

Cantor's *Beiträge* of 1895 and 1897 presented his mature theory of the transfinite, incorporating his concepts of *ordinal number* and *cardinal number*. The former are the transfinite numbers now reconstrued as the "order-types" of well-orderings. As for the latter, Cantor defined the addition, multiplication, and exponentiation of cardinal numbers primordially in terms of set-theoretic operations and functions. Salient was the incorporation of "all" possibilities in the definition of exponentiation: If $\mathfrak{a}$ is the cardinal number of A and $\mathfrak{b}$ is the cardinal number of B then $\mathfrak{a}^{\mathfrak{b}}$ is the cardinal number of the totality, nowadays denoted ${}^{B}A$, of all functions from B into A. As befits the introduction of new numbers Cantor introduced a new notation, one using the Hebrew letter aleph, $\aleph$. $\aleph_0$ is to be the cardinal number of the natural numbers and the successive alephs

$$\aleph_0, \aleph_1, \aleph_2, \ldots, \aleph_\alpha, \ldots$$

indexed by the ordinal numbers are now to be the cardinal numbers of the successive number classes from the *Grundlagen* and thus to exhaust all the infinite cardinal numbers. Cantor pointed out that the exponentiated $2^{\aleph_0}$ is the cardinal number of the continuum, so that CH could now have been stated as

$$2^{\aleph_0} = \aleph_1.$$

However, with CH unresolved Cantor did not even mention the hypothesis in the *Grundlagen*, only in correspondence. Every well-ordered set has an aleph as its cardinal number, but where is $2^{\aleph_0}$ in the aleph sequence?

Cantor's great achievement, accomplished through almost three decades of prodigious effort, was to have brought into being the new subject of set theory as bolstered by the mathematical objectification of the actual infinite and moreover to have articulated a fundamental problem, the continuum problem. Hilbert made this the very first of his famous problems for the 20th Century, and he drew out Cantor's difficulty by suggesting the desirability of "actually giving" a well-ordering of the real numbers.

1.2. Zermelo

Ernst Zermelo (1871–1953), already estimable as an applied mathematician, turned to set theory at Göttingen under the influence of Hilbert. Zermelo analyzed Cantor's well-ordering principle by reducing it to the Axiom of Choice (AC), the abstract existence assertion that every set x has a *choice function*, i.e. a function f with domain x such that for every non-empty $y \in x$,

$f(y) \in y$. Zermelo's 1904 proof of the Well-Ordering Theorem, that with AC *every set can be well-ordered*, would anticipate the argument two decades later for transfinite recursion:

With x a set to be well-ordered, let f be a choice function on the power set $P(x)$. Call $y \subseteq x$ an *f-set* if there is a well-ordering R of y such that for any $a \in y$, $a = f(\{b \in x \mid b \text{ does not } R\text{-precede } a\})$. The well-orderings of f-sets are thus determined by f, and f-sets cohere. It follows that the union of f-sets is again an f-set and must in fact be x itself.

Zermelo's argument provoked open controversy because of its appeal to AC, and the subsequent tilting toward the acceptance of AC amounted to a conceptual shift in mathematics toward arbitrary functions and abstract existence principles. Responding to his critics Zermelo in 1908 published a second proof of the Well-Ordering Theorem and then the first full-fledged axiomatization of set theory, one similar in approach to Hilbert's axiomatization of geometry and incorporating set-theoretic ideas of Richard Dedekind. This axiomatization duly avoided the emerging "paradoxes" like Russell's Paradox, which Zermelo had come to independently, and served to buttress the Well-Ordering Theorem by making explicit its underlying set-existence assumptions. Zermelo's axioms, now formalized, constitute the familiar theory Z, *Zermelo set theory*:

Extensionality (sets are equal if they contain the same members), Empty Set (there is a set having no members), Pairs (for any sets x and y there is a set $\{x, y\}$ consisting exactly of x and y), Union (for any set x there is a set $\bigcup x$ consisting exactly of those sets that are members of some member of x), Power Set (for any set x there is a set $P(x)$ consisting exactly of the subsets of x), Choice (for any set x consisting of non-empty, pairwise disjoint sets, there is a set c such that every member of x has exactly one member in c), Infinity (there is a certain, specified infinite set); and Separation (for any set x and "definite" property P, there is a set consisting exactly of those members of x having the property P).

Extensionality, Empty Set, and Pairs lay the basis for sets. Infinity and Power Set ensure sufficiently rich settings for set-theoretic constructions. Power Set legitimizes "all" for subsets of a given set, and Separation legitimizes "all" for elements of a given set satisfying a property. Finally, Union and Choice (formulated reductively in terms of the existence of a "transversal" set meeting each of a family of sets in one member) complete the encasing of the Well-Ordering Theorem.

Zermelo's axiomatization sought to clarify vague subject matter, and like strangers in a strange land, stalwarts developed a familiarity with sets guided hand-in-hand by the axiomatic framework. Zermelo's own papers, with work of Dedekind as an antecedent, pioneered the reduction of mathematical concepts and arguments to set-theoretic concepts and arguments from axioms. Zermelo's analysis moreover served to draw out what would come to be generally regarded as set-theoretic and combinatorial out of the presumptively logical, with Infinity and Power Set salient and the process being strategically advanced by the segregation of the notion of property to Separation.

Taken together, Zermelo's work in the first decade of the 20th Century initiated a major transmutation of the notion of set after Cantor. With AC Zermelo shifted the notion away from Cantor's inherently well-ordered sets, and with his axiomatization Zermelo ushered in a new abstract, prescriptive view of sets as structured solely by membership and governed and generated by axioms. Through his set-theoretic reductionism Zermelo made evident how his set theory is adequate as a basis for mathematics.

1.3. First Developments

During this period Cantor's two main legacies, the extension of number into the transfinite and the investigation of definable sets of reals, became fully incorporated into mathematics in direct initiatives. The axiomatic tradition would be complemented by another, one that would draw its life more directly from the mathematics.

The French analysts Emile Borel, René Baire, and Henri Lebesgue took on the investigation of definable sets of reals in what would be a typically "constructive" approach. Cantor had established the perfect set property for closed sets and formulated the concept of *content* for a set of reals, but he did not pursue these matters. With these as antecedents the French work would lay the basis for measure theory as well as *descriptive set theory*, the definability theory of the continuum.

Borel, already in 1898, developed a theory of *measure* for sets of reals; the formulation was axiomatic, and at this early stage, bold and imaginative. The sets measurable according to his measure are the now well-known *Borel sets.* Starting with the open intervals (a, b) of reals assigned measure $b-a$, the Borel sets result when closing off under complements and countable unions, measures assigned in a corresponding manner.

Baire in his 1899 thesis classified those real functions obtainable by starting with the continuous functions and closing off under pointwise limits—the *Baire functions*—into classes indexed by the countable ordinal numbers, providing the first transfinite hierarchy after Cantor. Baire's thesis also introduced the now basic concept of *category.* A set of reals is *nowhere dense iff* its closure under limits includes no open set, and a set of reals is *meager* (or *of first category*) *iff* it is a countable union of nowhere dense sets—otherwise, it is *of second category.* Generalizing Cantor's 1873 argument, Baire established the Baire Category Theorem: *Every non-empty open set of reals is of second category.* His work also suggested a basic property: A set of reals A has the *Baire property iff* there is an open set O such that the symmetric difference $(A-O)\cup(O-A)$ is meager. Straightforward arguments show that every Borel set has the Baire property.

Lebesgue's 1902 thesis is fundamental for modern integration theory as the source of his concept of measurability. Lebesgue's concept of measurable set subsumed the Borel sets, and his analytic definition of measurable function subsumed the Baire functions. In simple terms, any *arbitrary* subset of a Borel measure zero set is a Lebesgue measure zero, or *null*, set, and a set is *Lebesgue measurable* if it is the union of a Borel set and a null set, in which case the measure assigned is that of the Borel set. It is this "completion" of Borel measure through the introduction of arbitrary subsets which gives Lebesgue measure its complexity and applicability and draws in wider issues of constructivity. Lebesgue's subsequent 1905 paper was the seminal paper of descriptive set theory: He correlated the Borel sets with the Baire functions, thereby providing a transfinite hierarchy for the Borel sets, and then applied Cantor's diagonalization argument to show both that this hierarchy is proper (new sets appear at each level) and that there is a Lebesgue measurable set which is not Borel.

As descriptive set theory was to develop, a major concern became the extent of the *regularity properties*, those indicative of well-behaved sets of reals, of which prominent examples were Lebesgue measurability, having the Baire property, and having the perfect set property. Significantly, the context was delimited by early explicit uses of AC in the role of providing a well-ordering of the reals: In 1905 Giuseppe Vitali established that there is a non-Lebesgue measurable set, and in 1908 Felix Bernstein established that there is a set without the perfect set property. Thus, Cantor's early contention that the reals are well-orderable precluded the universality of his own perfect set property, and it would be that his new, enumerative approach to the continuum would steadily provide focal examples and counterexamples.

The other, more primal Cantorian legacy, the extension of number into the transfinite, was considerably advanced by Felix Hausdorff, whose work was first to suggest the rich possibilities for a mathematical investigation of the uncountable. A mathematician *par excellence*, he took that sort of mathematical approach to set theory and extensional, set-theoretic approach to mathematics that would come to dominate in the years to come. In a 1908 paper, Hausdorff provided an elegant analysis of scattered linear orders (those having no dense sub-ordering) in a transfinite hierarchy. He first stated the Generalized Continuum Hypothesis (GCH)

$$2^{\aleph_\alpha} = \aleph_{\alpha+1} \quad \text{for every } \alpha.$$

He emphasized cofinality (the *cofinality* $\mathrm{cf}(\kappa)$ of a cardinal number κ is the least cardinal number λ such that a set of cardinality κ is a union of λ sets each of cardinality less than κ) and the distinction between *singular* ($\mathrm{cf}(\kappa) < \kappa$) and *regular* ($\mathrm{cf}(\kappa) = \kappa$) cardinals. And for the first time he broached a "large cardinal" concept, a regular limit cardinal $> \aleph_0$. Hausdorff's work around this time on sets of real functions ordered under eventual domination and having no uncountable "gaps" led to the first plausible mathematical proposition that entailed the denial of CH.

Hausdorff's 1914 text, *Grundzüge der Mengenlehre*, broke the ground for a generation of mathematicians in both set theory and topology. Early on, he defined an ordered pair of sets in terms of (unordered) pairs, formulated functions in terms of ordered pairs, and ordering relations as collections of ordered pairs. He in effect capped efforts of logicians by making these moves in mathematics, completing the set-theoretic reduction of relations and functions. He then presented Cantor's and Zermelo's work systematically, and of particular interest, he used a well-ordering of the reals to provide what is now known as Hausdorff's Paradox. The source of the later and better known Banach-Tarski Paradox, Hausdorff's Paradox provided an implausible decomposition of the sphere and was the first, and a dramatic, synthesis of classical mathematics and the new Zermelian abstract view.

A decade after Lebesgue's seminal 1905 paper, descriptive set theory came into being as a distinct discipline through the efforts of the Russian mathematician Nikolai Luzin. He had become acquainted with the work of the French analysts while in Paris as a student, and in Moscow he began a formative seminar, a major topic of which was the "descriptive theory of functions". The young Pole Wacław Sierpiński was an early participant while he was interned in Moscow in 1915, and undoubtedly this not only kindled the decade-long collaboration between Luzin and Sierpiński but also encouraged the latter's involvement in the development of a Polish school of mathematics and its interest in descriptive set theory. In an early success, Luzin's student Pavel Aleksandrov (and independently, Hausdorff) established the groundbreaking result that *the Borel sets have the perfect set property*, so that "CH holds for the Borel sets".

In the work that really began descriptive set theory, another student of Luzin's, Mikhail Suslin, investigated the *analytic sets* after finding a mistake in Lebesgue's paper. In a brief 1917 note Suslin formulated these sets in terms of an explicit operation $\mathcal{A}$ drawn from Aleksandrov's work and announced two fundamental results: *a set B of reals is Borel iff both B and its complement $\mathbb{R}-B$ are analytic;* and *there is an analytic set which is not Borel.* This was to be his sole publication, for he succumbed to typhus in a Moscow epidemic in 1919 at the age of 25. In an accompanying note Luzin announced that *every analytic set is Lebesgue measurable and has the perfect set property*, the latter result attributed to Suslin. Luzin and Sierpiński in joint papers soon provided proofs, in work that shifted the emphasis to the *co-analytic sets*, complements of analytic sets, and provided for them a basic *tree representation* based on well-foundedness (having no infinite branches) from which the main results of the period flowed.

After this first wave in descriptive set theory had crested, Luzin and Sierpiński in 1925 extended the domain of study to the *projective sets*. For $Y \subseteq \mathbb{R}^{k+1}$, the *projection of* Y is $pY = \{\langle x_1, \ldots, x_k\rangle \mid \exists y(\langle x_1, \ldots, x_k, y\rangle \in Y)\}$. Suslin had essentially noted that *a set of reals is analytic iff it is the projection of a Borel subset of* $\mathbb{R}^2$. Luzin and Sierpiński took the geometric operation of projection to be basic and defined the projective sets as those sets obtainable from the Borel sets by the iterated applications of projection and complementation. The corresponding hierarchy of projective subsets of

$\mathbb{R}^k$ is defined, in modern notation, as follows: For $A \subseteq \mathbb{R}^k$,

$$A \text{ is } \mathbf{\Sigma}^1_1 \quad \textit{iff} \quad A = pY \text{ for some Borel set } Y \subseteq \mathbb{R}^{k+1},$$

A is *analytic* as for $k = 1$, and for $n > 0$,

$$\begin{aligned} A \text{ is } \mathbf{\Pi}^1_n \quad & \textit{iff} \quad \mathbb{R}^k - A \text{ is } \mathbf{\Sigma}^1_n, \\ A \text{ is } \mathbf{\Sigma}^1_{n+1} \quad & \textit{iff} \quad A = pY \text{ for some } \mathbf{\Pi}^1_n \text{ set } Y \subseteq \mathbb{R}^{k+1}, \text{ and} \\ A \text{ is } \mathbf{\Delta}^1_n \quad & \textit{iff} \quad A \text{ is both } \mathbf{\Sigma}^1_n \text{ and } \mathbf{\Pi}^1_n. \end{aligned}$$

($\mathbf{\Sigma}^1_n$ is also written $\underset{\sim}{\Sigma}{}^1_n$; $\mathbf{\Pi}^1_n$ is also written $\underset{\sim}{\Pi}{}^1_n$; and $\mathbf{\Delta}^1_n$ is also written $\underset{\sim}{\Delta}{}^1_n$. One can formulate these concepts with continuous images instead of projections, e.g. A is $\mathbf{\Sigma}^1_{n+1}$ iff A is the continuous image of some $\mathbf{\Pi}^1_n$ set $Y \subseteq \mathbb{R}$. If the basics of continuous functions are in hand, this obviates the need to have different spaces.)

Luzin and Sierpiński recast Lebesgue's use of the Cantor diagonal argument to show that the projective hierarchy is proper, and soon its basic properties were established. However, this investigation encountered obstacles from the beginning. Whether the $\mathbf{\Pi}^1_1$ subsets of $\mathbb{R}$, the co-analytic sets at the bottom of the hierarchy, have the perfect set property and whether the $\mathbf{\Sigma}^1_2$ sets are Lebesgue measurable remained unknown. Besides the regularity properties, the properties of *separation, reduction,* and especially *uniformization* relating sets to others were studied, but there were accomplishments only at the first projective level. The one eventual success and a culminating result of the early period was the Japanese mathematician Motokiti Kondô's 1937 result, the $\mathbf{\Pi}^1_1$ Uniformization Theorem: *Every* $\mathbf{\Pi}^1_1$ *relation can be uniformized by a* $\mathbf{\Pi}^1_1$ *function.* This impasse with respect to the regularity properties would be clarified, surprisingly, by penetrating work of Gödel involving metamathematical methods.

In modern set theory, what has come to be taken for the "reals" is actually *Baire space*, the set of functions from the natural numbers into the natural numbers (with the product topology). Baire space, the "fundamental domain" of a 1930 Luzin monograph, is homeomorphic to the irrational reals and so equivalent for all purposes having to do measure, category, and perfect sets. Already by then it had become evident that a set-theoretic study of the continuum is best cast in terms of Baire space, with geometric intuitions being augmented by combinatorial ones.

During this period AC and CH were explored by the new Polish school, most notably by Sierpiński, Alfred Tarski, and Kazimierz Kuratowski, no longer as underlying axiom and primordial hypothesis but as part of ongoing mathematics. Sierpiński's own earliest publications, culminating in a 1918 survey, not only dealt with specific constructions but also showed how deeply embedded AC was in the informal development of cardinality, measure, and the Borel hierarchy. Even more than AC, Sierpiński investigated CH, and summed up his researches in a 1934 monograph. It became evident how having not only a well-ordering of the reals but one as given by CH whose initial segments are countable led to striking, often initially counter-intuitive, examples in analysis and topology.

1.4. Replacement and Foundation

In the 1920s, fresh initiatives in axiomatics structured the loose Zermelian framework with new features and corresponding axioms, the most consequential moves made by John von Neumann (1903–1957) in his doctoral work, with anticipations by Dmitry Mirimanoff in an informal setting. Von Neumann effected a Counter-Reformation of sorts that led to the incorporation of a new axiom, the Axiom of Replacement: *For any set x and property $P(v, w)$ functional on x (i.e. for any $a \in x$ there is exactly one b such that $P(a, b)$), $\{b \mid P(a, b)$ for some $a \in x\}$ is a set.* The transfinite numbers had been central for Cantor but peripheral to Zermelo; von Neumann reconstrued them as *bona fide* sets, the ordinals, and established their efficacy by formalizing transfinite recursion, the method for defining sets in terms of previously defined sets applied with transfinite indexing.

Ordinals manifest the basic idea of taking precedence in a well-ordering simply to be membership. A set x is *transitive iff* $\bigcup x \subseteq x$, so that x is "closed" under membership, and x is an *ordinal iff* x is transitive and well-ordered by $\in$. Von Neumann, as had Mirimanoff before him, established the key instrumental property of Cantor's ordinal numbers for ordinals: *Every well-ordered set is order-isomorphic to exactly one ordinal with membership.* Von Neumann took the further step of ascribing to the ordinals the role of Cantor's ordinal numbers. To establish the basic ordinal arithmetic results that affirm this role, von Neumann saw the need to establish the Transfinite Recursion Theorem, the theorem that validates definitions by transfinite recursion. The proof was anticipated by the Zermelo 1904 proof, but Replacement was necessary even for the very formulation, let alone the proof, of the theorem. Abraham Fraenkel and Thoralf Skolem had independently proposed Replacement to ensure that a specific collection resulting from a simple recursion be a set, but it was von Neumann's formal incorporation of transfinite recursion as method which brought Replacement into set theory. With the ordinals in place von Neumann completed the restoration of the Cantorian transfinite by defining the *cardinals* as the *initial ordinals*, i.e. those ordinals not in bijective correspondence with any of its predecessors. The infinite initial ordinals are now denoted

$$\omega = \omega_0, \omega_1, \omega_2, \ldots, \omega_\alpha, \ldots,$$

so that ω is to be the set of natural numbers in the ordinal construal. It would henceforth be that we take

$$\omega_\alpha = \aleph_\alpha$$

conflating extension with intension, with the left being a von Neumann ordinal and the right being the Cantorian cardinal concept. Every infinite set x, with AC, is well-orderable and hence in bijective correspondence with a unique initial ordinal ω_α, and the cardinality of x is $|x| = \aleph_\alpha$. It has become customary to use the lower case Greek letters to denote ordinals; $\alpha < \beta$ to denote $\alpha \in \beta$ construed as ordering; On to denote the ordinals; and the middle letters $\kappa, \lambda, \mu, \ldots$ to denote the initial ordinals in their role as the infinite cardinals, with κ^+ denoting the cardinal successor of κ.

Von Neumann provided a new axiomatization of set theory, one that first incorporated what we now call proper classes. A *class* is the totality of all sets that satisfy a specified property, so that membership in the class amounts to satisfying the property, and von Neumann axiomatized the ways to have these properties. Only sets can be members, and so the recourse to possibly proper classes, classes not represented by sets, avoids the contradictions arising from formalizing the known paradoxes. Actually, von Neumann took functions to be primitive in an involved framework, and Paul Bernays in 1930 re-constituted the von Neumann axiomatization with sets and classes as primitive. Classes would not remain a formalized component of modern set theory, but the informal use of classes as objectifications of properties would become increasingly liberal, particularly to convey large-scale issues in set theory.

Von Neumann (and before him Mirimanoff, Fraenkel, and Skolem) also considered the salutary effects of restricting the universe of sets to the *well-founded sets*. The well-founded sets are the sets in the class $\bigcup_\alpha V_\alpha$, where the "ranks" V_α are defined by transfinite recursion:

$$V_0 = \emptyset; \qquad V_{\alpha+1} = P(V_\alpha); \quad \text{and} \quad V_\delta = \textstyle\bigcup_{\alpha<\delta} V_\alpha \quad \text{for limit ordinals } \delta.$$

Von Neumann entertained the Axiom of Foundation: *Every nonempty set x has an $\in$-minimal element, i.e. a $y \in x$ such that $x \cap y$ is empty.* (With AC this is equivalent to having no infinite $\in$-descending sequences.) This axiom amounts to the assertion that the *cumulative hierarchy* exhausts the universe V of sets:

$$V = \textstyle\bigcup_\alpha V_\alpha.$$

In modern terms, the ascribed well-foundedness of $\in$ leads to a ranking function $\rho : V \to \mathrm{On}$ defined recursively by $\rho(x) = \bigcup\{\rho(y) + 1 \mid y \in x\}$, so that $V_\alpha = \{x \mid \rho(x) < \alpha\}$, and one can establish results for all sets by induction on rank.

Zermelo in a 1930 paper offered his final axiomatization of set theory as well as a striking, synthetic view of a procession of models that would have a modern resonance. Proceeding in what we would now call a second-order context, Zermelo amended his 1908 axiomatization Z by adjoining both Replacement and Foundation while leaving out Infinity and AC, the latter being regarded as part of the underlying logic. The now standard axiomatization of set theory

ZFC, *Zermelo-Fraenkel with Choice*,

is recognizable if we inject Infinity and AC, the main difference being that ZFC is a first-order theory (as discussed below). "Fraenkel" acknowledges the early suggestion by Fraenkel to adjoin Replacement; and the Axiom of Choice is explicitly mentioned.

ZF, *Zermelo-Fraenkel*,

is ZFC without AC and is a base theory for the investigation of weak Choice-type propositions as well as propositions that contradict AC.

Zermelo herewith completed his transmutation of the notion of set, his abstract view stabilized by further axioms that structured the universe of sets. Replacement and Foundation focused the notion of set, with the first providing the means for transfinite recursion and induction and the second making possible the application of those means to get results about *all* sets, they appearing in the cumulative hierarchy. Foundation is the one axiom unnecessary for the recasting of mathematics in set-theoretic terms, but the axiom is also the salient feature that distinguishes investigations specific to set theory as a field of mathematics. With Replacement and Foundation in place Zermelo was able to provide natural models of his axioms, each a V_κ where κ is an *inaccessible* cardinal (regular and *strong limit*: if $\lambda < \kappa$, then $2^\lambda < \kappa$), and to establish algebraic isomorphism, initial segment, and embedding results for his models. Finally, Zermelo posited an endless procession of such models, each a set in the next, as natural extensions of their cumulative hierarchies.

Inaccessible cardinals are at the modest beginnings of the theory of *large cardinals*, now a mainstream of modern set theory devoted to the investigation of strong hypotheses and consistency strength. The journal volume containing Zermelo's paper also contained Stanisław Ulam's seminal paper on measurable cardinals, which would become focal among large cardinals. In modern terminology, a *filter over* a set Z is a family of subsets of Z closed under the taking of supersets and of intersections. (Usually excluded from consideration as trivial are $\{X \subseteq Z \mid A \subseteq X\}$ for some set $A \subseteq Z$, the *principal* filters.) An *ultrafilter U over Z* is a maximal filter over Z, i.e. for any $X \subseteq Z$, either $X \in U$ or else $Z - X \in U$. For a cardinal λ, a filter is λ*-complete* if it is closed under the taking of intersections of fewer than λ members. Finally, an uncountable cardinal κ is *measurable iff* there is a κ-complete ultrafilter over κ. In a previous, 1929 note Ulam had constructed, using a well-ordering of the reals, an ultrafilter over ω. Measurability thus generalizes a property of ω, and Ulam showed moreover that *measurable cardinals are inaccessible.* In this work, Ulam was motivated by measure-theoretic considerations, and he viewed his work as about $\{0, 1\}$-valued measures, the measure 1 sets being the sets in the ultrafilter. To this day, ultrafilters of all sorts in large cardinal theory are also called measures.

A decade later Tarski provided a systematic development of these concepts in terms of ideals. An *ideal over* a set Z is a family of subsets of Z closed under the taking of subsets and of unions. This is the "dual" notion to filters; if I is an ideal (resp. filter) over Z, then $\breve{I} = \{Z - X \mid X \in I\}$ is its dual filter (resp. ideal). An ideal is λ-*complete* if its dual filter is. A more familiar conceptualization in mathematics, Tarski investigated a general notion of ideal on a Boolean algebra in place of the power set algebra $P(Z)$. Although filters and ideals in large cardinal theory are most often said to be *on* a cardinal κ, they are more properly *on* the Boolean algebra $P(\kappa)$. Moreover, the measure-theoretic terminology has persisted: For an ideal $I \subseteq P(Z)$, the I-*measure zero* (negligible) sets are the members of I, the I-*positive measure* (non-negligible) sets are the members of $P(Z) - I$, and the I-*measure one* (all but negligible) sets are the members of the dual filter $\{Z - X \mid X \in I\}$.

Returning to the axiomatic tradition, Zermelo's 1930 paper was in part a response to Skolem's advocacy of the idea of framing Zermelo's 1908 axioms in *first-order logic*, the logic of formal languages based on the quantifiers $\forall$ and $\exists$ interpreted as ranging over the *elements* of a domain of discourse. First-order logic had emerged in 1917 lectures of Hilbert as a delimited system of logic amenable to mathematical investigation. Entering from a different, algebraic tradition, Skolem in 1920 had established a seminal result for semantic methods with the Löwenheim-Skolem Theorem, that a countable collection of first-order sentences, if satisfiable, is satisfiable in a countable domain. For this he introduced what we now call Skolem functions, functions added formally for witnessing $\exists x$ assertions. For set theory Skolem in 1923 proposed formalizing Zermelo's axioms in the first-order language with $\in$ and $=$ as binary predicate symbols. Zermelo's "definite" properties were to be those expressible in this first-order language in terms of given sets, and the Axiom of Separation was to become a *schema* of axioms, one for each first-order formula. As an argument against taking set theory as a foundation for mathematics, Skolem pointed out what has come to be called *Skolem's Paradox*: Zermelo's 1908 axioms cast in first-order logic is a countable collection of sentences, and so if they are satisfiable at all, they are satisfiable in a countable domain. Thus, we have the paradoxical existence of countable models for Zermelo's axioms although they entail the existence of uncountable sets. Zermelo found this antithetical and repugnant. However, strong currents were at work leading to a further, subtler transmutation of the notion of set as based on first-order logic and incorporating its relativism of set-theoretic concepts.

2. New Groundwork

2.1. Gödel

Kurt Gödel (1906–1978) substantially advanced the mathematization of logic by submerging metamathematical methods into mathematics. The main vehicle was the direct coding, "the arithmetization of syntax", in his celebrated 1931 Incompleteness Theorem, which worked dialectically against a program of Hilbert's for establishing the consistency of classical mathematics. But starting an undercurrent, the earlier 1930 Completeness Theorem for first-order logic clarified the distinction between the formal syntax and semantics of first-order logic and secured its key instrumental property with the Compactness Theorem.

Tarski in the early 1930s provided his systematic "definition of truth", exercising philosophers to a surprising extent ever since. Tarski simply schematized truth as a correspondence between formulas of a formal language and set-theoretic assertions about an intended structure interpreting the language and provided a recursive definition of the *satisfaction* relation, when a formula holds in the structure, in set-theoretic terms. The eventual effect of Tarski's mathematical formulation of semantics would be not only to make mathematics out of the informal notion of satisfiability, but also to enrich ongoing mathematics with a systematic method for forming mathematical analogues of several intuitive semantic notions. Tarski would only be explicit much later about satisfaction-in-a-structure for arbitrary structures, this leading to his notion of logical consequence. For coming purposes, the following affirms notation and concepts in connection with Tarski's definition.

For a first-order language, a structure N interpreting that language (i.e. a specification of a domain of discourse as well as interpretations of the function and predicate symbols), a formula $\varphi(v_1, v_2, \ldots, v_n)$ of the language with the (free) variables as displayed, and $a_1, a_2, \ldots, a_n$ in the domain of N,

$$N \models \varphi[a_1, a_2, \ldots, a_n]$$

asserts that the formula φ is satisfied in N according to Tarski's recursive definition when v_i is interpreted as a_i. A subset y of the domain of N is *first-order definable over N iff* there is a $\psi(v_1, v_2, \ldots, v_{n+1})$ and $a_1, a_2, \ldots, a_n$ in the domain of N such that

$$y = \{z \in N \mid N \models \psi[a_1, a_2, \ldots, a_n, z]\}.$$

(The first-order definability of k-ary relations is analogously formulated with v_{n+1} replaced by k variables.)

Through Tarski's recursive definition and an "arithmetization of syntax" whereby formulas are systematically coded by natural numbers, the satisfaction relation $N \models \varphi[a_1, a_2, \ldots, a_n]$ for *sets* N is definable in set theory. On the other hand, by Tarski's result on the "undefinability of truth", the satisfaction relation for V itself is not first-order definable over V.

Set theory was launched as a distinctive field of mathematics by Gödel's construction of the class L leading to the relative consistency of the Axiom of Choice and the Generalized Continuum Hypothesis. In a brief 1939 account Gödel informally presented L essentially as is done today: For any set x let $\mathrm{def}(x)$ denote the collection of subsets of x first-order definable over the structure $\langle x, \in \rangle$ with domain x and the membership relation restricted to it. Then define:

$$L_0 = \emptyset; \qquad L_{\alpha+1} = \mathrm{def}(L_\alpha), \qquad L_\delta = \bigcup\{L_\alpha \mid \alpha < \delta\} \quad \text{for limit ordinals } \delta;$$

and the *constructible universe*

$$L = \bigcup_\alpha L_\alpha.$$

Gödel pointed out that L "can be defined and its theory developed in the formal systems of set theory themselves". This is actually the central feature of the construction of L. L is definable in ZF via transfinite recursion based on the formalizability of def(x), which was reaffirmed by Tarski's definition of satisfaction. With this, one can formalize the Axiom of Constructibility $V = L$, i.e. $\forall x(x \in L)$. To set a larger context, we affirm the following for a class X: for a set-theoretic formula φ, φ^X denotes φ with its quantifiers restricted to X and this extends to set-theoretic terms t (like $\bigcup x$, $P(x)$, and so forth) through their definitions to yield t^X. X is an *inner model iff* X is a transitive class containing all the ordinals such that φ^X is a theorem of ZF for every axiom φ of ZF. What Gödel did was to show in ZF that L is an inner model which satisfies AC and GCH. He thus established a relative consistency which can be formalized as an assertion: Con(ZF) implies Con(ZFC + GCH).

In the approach via def(x) it is necessary to show that def(x) remains unaltered when applied in L with quantifiers restricted to L. Gödel himself would never establish this *absoluteness of first-order definability* explicitly. In a 1940 monograph, Gödel worked in Bernays' class-set theory and used eight binary operations producing new classes from old to generate L set by set via transfinite recursion. This veritable "Gödel numbering" with ordinals eschewed def(x) and made evident certain aspects of L. Since there is a direct, definable well-ordering of L, choice functions abound in L, and AC holds there. Of the other axioms the crux is where first-order logic impinges, in Separation and Replacement. For this, "algebraic" closure under Gödel's eight operations ensured "logical" Separation for *bounded* formulas, formulas having only quantifiers expressible in terms of $\forall v \in w$, and then the full exercise of Replacement (in V) secured all of the ZF axioms in L.

Gödel's proof that L satisfies GCH consisted of two separate parts. He established the implication $V = L \rightarrow$ GCH, and, in order to apply this implication within L, that $(V = L)^L$. This latter follows from the aforementioned absoluteness of def(x), and in his monograph Gödel gave an alternate proof based on the absoluteness of his eight binary operations.

Gödel's argument for $V = L \rightarrow$ GCH rests, as he himself wrote in his 1939 note, on "a generalization of Skolem's method for constructing enumerable models". This was the first significant use of Skolem functions since Skolem's own to establish the Löwenheim-Skolem theorem, and with it, Skolem's Paradox. Ironically, though Skolem sought through his paradox to discredit set theory based on first-order logic as a foundation for mathematics, Gödel turned paradox into method, one promoting first-order logic. Gödel specifically established his "Fundamental Theorem":

> For infinite γ, every constructible subset of L_γ
> belongs to some L_β for a β of the same cardinality as γ.

For infinite α, L_α has the same cardinality as that of α. It follows from the Fundamental Theorem that in the sense of L, the power set of L_{ω_α} is included in $L_{\omega_{\alpha+1}}$, and so GCH follows in L.

The work with L led, further, to the resolution of difficulties in descriptive set theory. Gödel announced, in modern terms: *If* $V = L$, *then* (a) *there is a* $\mathbf{\Delta}^1_2$ *set of reals that is not Lebesgue measurable, and* (b) *there is a* $\mathbf{\Pi}^1_1$ *set of reals without the perfect set property.* Thus, the early descriptive set theorists were confronting an obstacle insurmountable in ZFC! When eventually confirmed and refined, the results were seen to turn on a "good" $\mathbf{\Sigma}^1_2$ well-ordering of the reals in L defined via reals coding well-founded structures and thus connected to the well-founded tree representation of $\mathbf{\Pi}^1_1$ sets. Gödel's results (a) and (b) constitute the first real synthesis of abstract and descriptive set theory, in that the axiomatic framework is incorporated into the investigation of definable sets of reals.

Gödel brought into set theory a method of construction and of argument which affirmed several features of its axiomatic presentation. Most prominently, he showed how first-order definability can be formalized and used to achieve strikingly new mathematical results. This significantly contributed to a lasting ascendancy for first-order logic which, in addition to its sufficiency as a logical framework for mathematics, was seen to have considerable operational efficacy. Moreover, Gödel's work buttressed the incorporation of Replacement and Foundation into set theory, the first immanent in the transfinite recursion and arbitrary extent of the ordinals, and the second as underlying the basic cumulative hierarchy picture that anchors L.

In later years Gödel speculated about the possibility of deciding propositions like CH with large cardinal hypotheses based on the heuristics of *reflection*, and later, *generalization*. In a 1946 address he suggested the consideration of "stronger and stronger axioms of infinity" and reflection down from V: "Any proof of a set-theoretic theorem in the next higher system above set theory (i.e. any proof involving the concept of truth, etc.) is replaceable by a proof from such an axiom of infinity". In a 1947 expository article on the continuum problem Gödel presumed that CH would be shown independent from ZF and speculated more concretely about possibilities with large cardinals. He argued that the axioms of set theory do not "form a system closed in itself" and so the "very concept of set on which they are based suggests their extension by new axioms that assert the existence of still further iterations of the operation of 'set of'". In an unpublished footnote toward a 1966 revision of the article, Gödel acknowledged "extremely strong axioms of infinity of an entirely new kind", generalizations of properties of ω "supported by strong arguments from analogy". These heuristics would surface anew in the 1960s, when the theory of large cardinals developed a self-fueling momentum of its own, stimulated by the emergence of forcing and inner models.

2.2. Infinite Combinatorics

For decades Gödel's construction of L stood as an isolated monument in the axiomatic tradition, and his methodological advances would only become fully assimilated after the infusion of model-theoretic techniques in the 1950s. In the mean time, the direct investigation of the transfinite as extension of number was advanced, gingerly at first, by the emergence of *infinite combinatorics.*

The 1934 Sierpiński monograph on CH (discussed earlier) having considerably elaborated its consequences, a new angle in the combinatorial investigation of the continuum was soon broached. Hausdorff in 1936 reactivated his early work on gaps in the orderings of functions to show that the reals can be partitioned into $\aleph_1$ Borel sets, answering an early question of Sierpiński. Hausdorff had newly cast his work in terms of functions from ω to ω, the members of Baire space or the "reals", under the ordering of *eventual dominance*: $f \leq^* g$ if $f(n) \leq g(n)$ for all but finitely many $n \in \omega$. Work on this structure and definable sets of reals in the 1930s, and particularly of Fritz Rothberger through the 1940s, isolated what is now called the *dominating number* $\mathfrak{d}$, the least cardinality of a subset of Baire space cofinal in $\leq^*$. $\aleph_1 \leq \mathfrak{d} \leq 2^{\aleph_0}$, but absent CH $\mathfrak{d}$ assumed an independent significance as a pivotal cardinal. Rothberger established incisive results which we now cast as about the relationships to other pivotal cardinals, results which provided new understandings about the structure of the continuum but would become vacuous with the blanket assumption of CH. The investigation of $\mathfrak{d}$ and other "cardinal characteristics (or invariants) of the continuum" would blossom with the advent of forcing.

Taking up another thread, Frank Ramsey in 1930, addressing a problem of formal logic, established a generalization of the pigeonhole principle for finite sets, and in a move transcending purpose and context he also established an infinite version implicitly applying the now familiar Kőnig's Lemma for trees. In modern terms, for ordinals α, β, and δ and $n \in \omega$ the *partition relation*

$$\beta \longrightarrow (\alpha)^n_\delta$$

asserts that for any partition $f : [\beta]^n \to \delta$ of the n-element subsets of β into δ cells, there is an $H \subseteq \beta$ of order type α *homogeneous* for the partition, i.e. all the n-element subsets of H lie in the same cell. Ramsey's theorem for finite sets is: *For any $n, k, i \in \omega$ there is an $r \in \omega$ such that $r \longrightarrow (k)^n_i$.* The "Ramsey numbers", the least possible r's for various n, k, i, are unknown except in a few basic cases. The (infinite) Ramsey's Theorem is: *$\omega \longrightarrow (\omega)^n_i$ for every $n, i \in \omega$.*

A *tree* is a partially ordered set T such that the predecessors of any element are well-ordered. The *αth level* of T consists of those elements whose predecessors have order-type α, and the *height* of T is the least α such that the αth level of T is empty. A *chain* of T is a linearly ordered subset, and an *antichain* is a subset consisting of pairwise incompatible elements. A *cofinal branch* of T is a chain with elements at every non-empty level of T.

Finally, for a cardinal κ, a *κ-tree* is a tree of height κ each of whose levels has cardinality less than κ, and κ has the *tree property iff* every κ-tree has a cofinal branch. Kőnig's Lemma, of 1927, is the assertion that *ω has the tree property.*

The first systematic study of transfinite trees was carried out in Djuro Kurepa's 1935 thesis, and several properties emerging from his investigations, particularly for ω_1-trees as the first broaching context, would later become focal in the combinatorial study of the transfinite. An *Aronszajn tree* is an ω_1-tree without a cofinal branch, i.e. a counterexample to the tree property for ω_1. Kurepa acknowledged and gave Nachman Aronszajn's proof that *there is an Aronszajn tree.* A *Suslin tree* is an ω_1-tree with no uncountable chains or antichains. Kurepa reduced a hypothesis growing out of a 1920 question of Suslin about the characterizability of the ordering of the reals to a combinatorial property of ω_1, Suslin's Hypothesis (SH): *There are no Suslin trees.* Finally, a *Kurepa tree* is an ω_1-tree with at least ω_2 cofinal branches, and *Kurepa's Hypothesis* deriving from a later 1942 paper of Kurepa's is the assertion that such trees exist. Much of this would be rediscovered, and both Suslin's Hypothesis and Kurepa's Hypothesis would be resolved decades later with the advent of forcing, several of the resolutions in terms of large cardinal hypotheses. Kurepa's work also anticipated another development from a different quarter.

Paul Erdős, although an itinerant mathematician for most of his life, was the prominent figure of a strong Hungarian tradition in combinatorics, and through some seminal results he introduced major initiatives into the detailed combinatorial study of the transfinite. Erdős and his collaborators simply viewed the transfinite numbers as a combinatorially rich source of intrinsically interesting problems, the concrete questions about graphs and mappings having a natural appeal through their immediacy. One of the earliest advances was an 1943 paper of Erdős and Tarski which concluded enticingly with an intriguing list of six combinatorial problems, the positive solution to any, as it was to turn out, amounting to the existence of a large cardinal. In a footnote various implications were noted, one of them being essentially that *for inaccessible κ, the tree property for κ implies $\kappa \longrightarrow (\kappa)^2_2$*, a generalization of Ramsey's $\omega \longrightarrow (\omega)^2_2$ drawing out the Kőnig Lemma property needed.

The detailed investigation of partition relations began in earnest in the 1950s, with a 1956 paper of Erdős and Richard Rado's being representative. For a cardinal κ, set $\beth_0(\kappa) = \kappa$ and $\beth_{n+1}(\kappa) = 2^{\beth_n(\kappa)}$. What became known as *the* Erdős-Rado Theorem asserts: *For any infinite cardinal κ and $n \in \omega$,*

$$\beth_n(\kappa)^+ \longrightarrow (\kappa^+)^{n+1}_\kappa.$$

This was established using the basic tree argument underlying Ramsey's results, whereby a homogeneous set is not constructed recursively, but a tree is constructed such that its branches provide homogeneous sets, and a counting argument ensures that there must be a homogeneous set of sufficient cardinality. The Erdős-Rado Theorem is the transfinite analogue of Ramsey's theorem for finite sets, with both having the form: given α, δ and n there is a β such that $\beta \longrightarrow (\alpha)^n_\delta$. However, while what the Ramsey numbers are is largely unknown, the $\beth_n(\kappa)^+$ are known to be optimal. Kurepa in effect had actually established the case $n = 1$ and shown that $\beth_1(\kappa)^+$ is the least possible, and the $\beth_n(\kappa)^+$ was also shown to be the least possible in the general case by a "negative stepping-up" lemma.

Still among the Hungarians, Géza Fodor in 1956 established a now basic fact about the uncountable that has become woven into its sense, so operationally useful and ubiquitous it has become in infinite combinatorics. For a cardinal λ and a set $C \subseteq \lambda$, C is *closed unbounded* (or "club") in λ *iff* C contains its limit (or "accumulation") points, i.e. those $0 < \alpha < \lambda$ such that $\sup(C \cap \alpha) = \alpha$, and is cofinal, i.e. $\bigcup C = \lambda$. The use of "closed" and "unbounded" are as for $\langle \lambda, < \rangle$ with the order topology. A set $S \subseteq \lambda$ is *stationary in λ iff* for any C closed unbounded in λ, $S \cap C$ is not empty. For regular $\lambda > \omega$, the intersection of fewer than λ sets closed unbounded in λ is again closed unbounded in λ, and so the closed unbounded subsets of λ generate a λ-complete filter, the *closed unbounded filter*, denoted $\mathcal{C}_\lambda$. The nonstationary subsets of λ constitute the dual *nonstationary ideal*, denoted NS_λ. Now Fodor's (or Regressive Function or "Pressing Down") Lemma: *For regular $\lambda > \omega$, if a function f is regressive on a set $S \subseteq \lambda$ stationary in λ, i.e. $f(\alpha) < \alpha$ for every $\alpha \in S$, then there is a $T \subseteq S$ stationary in λ on which f is constant.*

Fodor's Lemma is a basic fact and its proof a simple exercise now, but then it was the culmination of a progression of results beginning with a seminal 1929 observation of Aleksandrov that a regressive function on ω_1 must be constant on an uncountable set. The subsets of a regular $\lambda > \omega$ naturally separate out into the nonstationary sets, the stationary sets, and among them the closed unbounded sets as the negligible, non-negligible, and all but negligible sets according to NS_λ. Fodor's Lemma is intrinsic to stationarity, and can be cast as a substantive characterization of the concept. It would be that far-reaching generalizations of stationarity, e.g. stationary towers, would become important in modern set theory.

2.3. Definability

Descriptive set theory was to become transmuted by the turn to definability following Gödel's work. After his fundamental work on recursive function theory in the 1930s, Stephen Kleene expanded his investigations of effectiveness and developed a general theory of definability for relations on ω. In the early 1940s Kleene investigated the *arithmetical relations* on reals, those relations obtainable from the recursive relations by applications of number quantifiers. Developing canonical representations, he classified these relations into a hierarchy according to quantifier complexity and showed that the hierarchy is proper. In the mid-1950s Kleene investigated the *analytical* *relations*, those relations obtainable from the arithmetical relations by applications of function ("real") quantifiers. Again he worked out representation and hierarchy results, and moreover he established an elegant theorem that turned out to be an effective version of Suslin's characterization of the Borel sets.

Kleene was developing what amounted to the effective content of classical descriptive set theory, unaware that his work had direct antecedents in the papers of Lebesgue, Luzin, Sierpiński, and Tarski. Kleene's student John Addison then established that there is an exact correlation between the hierarchies of classical and effective descriptive set theory (as described below). The development of effective descriptive set theory considerably clarified the classical context, injected recursion-theoretic techniques into the subject, and placed definability considerations squarely at its forefront. Not only were new approaches to classical problems provided, but results and questions could now be formulated in a refined setting.

Second-order arithmetic is the two-sorted structure

$$\mathcal{A}^2 = \langle \omega, {}^{\omega}\omega, ap, +, \times, <, 0, 1 \rangle,$$

where ω and ${}^{\omega}\omega$ (Baire space or the "reals") are two separate domains connected by the binary operation $ap : {}^{\omega}\omega \times \omega \to \omega$ of *application* given by $ap(x, m) = x(m)$, and $+, \times, <, 0, 1$ impose the usual arithmetical structure on ω. The underlying language has two sorts of variables, those ranging over ω and those ranging over ${}^{\omega}\omega$, and corresponding *number quantifiers* $\forall^0$, $\exists^0$ and *function quantifiers* $\forall^1$, $\exists^1$.

For relations $A \subseteq ({}^{\omega}\omega)^k$,

$$\begin{aligned} A \text{ is } \textit{arithmetical} \quad \textit{iff} \quad & A \text{ is definable over } \mathcal{A}^2 \text{ by a formula} \\ & \text{without function quantifiers,} \\ A \text{ is } \textit{analytical} \quad \textit{iff} \quad & A \text{ is definable over } \mathcal{A}^2. \end{aligned}$$

Through the manipulation of quantifiers the analytical sets can be classified in the *analytical hierarchy*, the levels of which are the (lightface) Σ^1_n, Π^1_n, and Δ^1_n classes defined as follows: For relations $A \subseteq ({}^{\omega}\omega)^k$ and $n > 0$,

$$\begin{aligned} A \in \Sigma^1_n \quad & \textit{iff} \quad \forall \mathbf{w}(A(\mathbf{w}) \leftrightarrow \exists^1 x_1 \forall^1 x_2 \ldots Q x_n R(\mathbf{w}, x_1, \ldots, x_n)), \quad \text{and} \\ A \in \Pi^1_n \quad & \textit{iff} \quad \forall \mathbf{w}(A(\mathbf{w}) \leftrightarrow \forall^1 x_1 \exists^1 x_2 \ldots Q x_n R(\mathbf{w}, x_1, \ldots, x_n)) \end{aligned}$$

for some arithmetical $R \subseteq ({}^{\omega}\omega)^{k+n}$, where Q is $\exists^1$ if n is odd and $\forall^1$ if n is even in the first and *vice versa* in the second. Finally,

$$A \in \Delta^1_n \quad \textit{iff} \quad A \in \Sigma^1_n \cap \Pi^1_n.$$

The correlation of the effective ("lightface") and classical ("boldface") hierarchies was established by Addison in 1958 through the simple expedient of relativization to real parameters. For $a \in {}^{\omega}\omega$, *second-order arithmetic in* a is the expanded structure

$$\mathcal{A}^2(a) = \langle \omega, {}^{\omega}\omega, ap, +, \times, <, 0, 1, a \rangle$$

where a is regarded as a binary relation on ω. Replacing $\mathcal{A}^2$ by $\mathcal{A}^2(a)$ in the preceding, we get the corresponding relativized notions: *arithmetical in* a, *analytical in* a, $\Sigma^1_n(a)$, $\Pi^1_n(a)$, and $\Delta^1_n(a)$. The correlation of the hierarchies is then as follows: *Suppose that* $A \subseteq ({}^\omega\omega)^k$ *and* $n > 0$. *Then* $A \in \mathbf{\Sigma}^1_n$ *iff* $A \in \Sigma^1_n(a)$ *for some* $a \in {}^\omega\omega$, *and similarly for* $\mathbf{\Pi}^1_n$. Loosely speaking, a projective set can be analyzed with a real parameter coding the construction of the underlying Borel set, $\exists^1$ corresponding to projection, and $\forall^1$ through $\neg\exists^1\neg$ corresponding to complementation.

Joseph Shoenfield in 1961 advanced the study of projective sets into the new definability context by providing a tree representation for $\mathbf{\Sigma}^1_2$ sets based on well-foundedness as charted out to ω_1. The classical Luzin-Sierpiński tree representation of $\mathbf{\Pi}^1_1$ sets turned, in the new terms, on the f of the function quantifier $\forall f$ imputing infinite branches through a tree arithmetical in a for some $a \in {}^\omega\omega$ that must be cut off. This well-foundedness can be cast as having an order-preserving ranking function into ω_1, which Shoenfield pointed out can be recast as having an infinite branch through a tree built on the countable ordinals.

T is a *tree on* $\omega \times \kappa$ *iff* (a) T consists of pairs $\langle s, t\rangle$ where s is a finite sequence drawn from ω and t is a finite sequence drawn from κ of the same length, and (b) if $\langle s, t\rangle \in T$, s' is an initial segment of s and t' is a initial segment of t of the same length, then also $\langle s', t'\rangle \in T$. For such T, $[T]$ consists of pairs $\langle f, g\rangle$ corresponding to infinite branches, i.e. f and g are ω-sequences such that for any finite initial segment s of f and finite initial segment t of g of the same length, $\langle s, t\rangle \in T$. In modern terms, $A \subseteq {}^\omega\omega$ is κ-*Suslin iff* there is a tree on $\omega \times \kappa$ such that $A = p[T] = \{f \mid \exists g(\langle f, g\rangle \in [T])\}$. $[T]$ is a closed set in the space of $\langle f, g\rangle$'s where $f : \omega \to \omega$ and $g : \omega \to \kappa$, and so otherwise complicated sets of reals, if shown to be κ-Suslin, are newly comprehended as projections of closed sets. The analytic ($\mathbf{\Sigma}^1_1$) sets are exactly the ω-Suslin sets.

Shoenfield established that *every* $\mathbf{\Sigma}^1_2$ *set is* ω_1-*Suslin*, and his proof, emphasizing constructibility, showed that if $A \subseteq {}^\omega\omega$ is Σ^1_2, then $A = p[T]$ for a tree T on $\omega \times \omega_1$ such that $T \in L$. Shoenfield applied well-foundedness in the $\forall$ sense (no infinite descending sequences) and the $\exists$ sense (there is a ranking function) to establish that Σ^1_2 *relations are absolute (or "correct") for* L: For any $\mathbf{w} \in L$, $\mathcal{A}^2 \models \exists^1 x \forall^1 y \varphi[x, y, \mathbf{w}]$ *iff* $(\mathcal{A}^2 \models \exists^1 x \forall^1 y \varphi[x, y, \mathbf{w}])^L$ when φ has no function quantifiers.

Many substantive propositions of classical analysis as well as of metamathematical investigation are Σ^1_2 or Π^1_2, and if they can be established from $V = L$ (or just CH), then they can be established in ZF alone. It would be that in the years to come more and more projective sets of reals would be comprehended through κ-Suslin representations for larger and larger cardinals κ.

András Hajnal and Azriel Levy, in their theses of the mid-1950s, developed generalizations of L that were to become basic in a richer setting. For a set A, Hajnal formulated the *constructible closure* $L(A)$ *of* A, i.e. the smallest inner model M such that $A \in M$, and Levy formulated the *class* $L[A]$ *of sets constructible relative to* A, i.e. the smallest inner model M such that for every $x \in M$, $A \cap x \in M$. To formulate $L(A)$, define: $L_0(A) =$ the smallest transitive set $\supseteq \{A\}$ (to ensure that the resulting class is transitive); $L_{\alpha+1}(A) = \mathrm{def}(L_\alpha(A))$; $L_\delta(A) = \bigcup_{\alpha<\delta} L_\alpha(A)$ for limit $\delta > 0$; and finally $L(A) = \bigcup_\alpha L_\alpha(A)$. To formulate $L[A]$, first let $\mathrm{def}^A(x)$ denote the collection of subsets of x first-order definable over $\langle x, \in, A \cap x\rangle$, i.e. $A \cap x$ is now allowed as a predicate in the definitions. Then define: $L_0[A] = \emptyset$; $L_{\alpha+1}[A] = \mathrm{def}^A(L_\alpha[A])$; $L_\delta[A] = \bigcup_{\alpha<\delta} L_\alpha[A]$ for limit $\delta > 0$; and finally $L[A] = \bigcup_\alpha L_\alpha[A]$. With the "trace" $\overline{A} = A \cap L[A]$ one has $L_\alpha[\overline{A}] = L_\alpha[A]$ for every α and so $L[\overline{A}] = L[A]$.

$L(A)$ realizes the algebraic idea of building up a model starting from a set of generators, and $L[A]$ the idea of building up a model using A construed as a predicate. $L(A)$ may not satisfy AC since it may not have a well-ordering of A, yet $L[A]$ always satisfies that axiom. This distinction was only to surface later, as both Hajnal and Levy took A to be a set of ordinals, when $L(A) = L[A]$, and used these models to establish conditional independence results of the sort: if the failure of CH is consistent, then so is that failure together with $2^\lambda = \lambda^+$ for sufficiently large cardinals λ. In the coming expansion of the 1960s, both Hajnal and Levy would be otherwise engaged, with Hajnal becoming a major combinatorial set theorist and collaborator with Erdős, and Levy, a pioneer in the investigation of independence results.

2.4. Model-Theoretic Techniques

Model theory began in earnest with the appearance in 1949 of the method of diagrams in Abraham Robinson's thesis and the related method of constants in Leon Henkin's thesis, which gave a new proof of the Gödel Completeness Theorem. Tarski had set the stage with the formulation of formal languages and semantics in set-theoretic terms, and with him established at the University of California at Berkeley, a large part of the development in the 1950s and 1960s would take place there. Tarski and his students carefully laid out satisfaction-in-a-structure; *theories* (deductively closed collections of sentences) and their *models*; algebratization with *Skolem functions* and *hulls*; and *elementary substructures and embeddings*. $j : \mathcal{A} \to \mathcal{B}$ is an *elementary embedding* if for any $a_1, \ldots, a_n$ from the domain of $\mathcal{A}$, $\langle a_1, \ldots, a_n\rangle$ satisfies in $\mathcal{A}$ the same formulas that $\langle j(a_1), \ldots, j(a_n)\rangle$ does in $\mathcal{B}$; and when j is the identity $\mathcal{A}$ is an *elementary substructure* of $\mathcal{B}$, denoted $\mathcal{A} \prec \mathcal{B}$. The construction of models freely used transfinite methods and soon led to new questions in set theory, but also set theory was to be decisively advanced by the infusion of model-theoretic methods.

A precursory result was a 1949 generalization by Andrzej Mostowski of the Mirimanoff-von Neumann result that every well-ordered set is order-isomorphic to exactly one ordinal with membership. A binary relation R on a set X is *extensional* if distinct members of X have distinct R-predecessors, and *well-founded* if every non-empty $Y \subseteq X$ has an R-minimal element (or, assuming AC, there is no infinite R-descending sequence). *If R is an extensional, well-founded relation on a set X, then there is a unique transitive set T and an isomorphism of $\langle X, R\rangle$ onto $\langle T, \in\rangle$, i.e. a bijection $\pi : X \to T$ such that for any $x, y \in X$, $x\,R\,y$ iff $\pi(x) \in \pi(y)$.* $\langle T, \in\rangle$ is the *transitive collapse* of X, and π the *collapsing isomorphism.* Thus, the linearity of well-orderings has been relaxed to analogues of Extensionality and Foundation, and transitive sets become canonical representatives as ordinals are for well-orderings. Well-founded relations other than membership had surfaced much earlier, most notably in the Luzin-Sierpiński tree representation of $\mathbf{\Pi}^1_1$ sets. The general transitive collapse result would come to epitomize how well-foundedness made possible a coherent theory of models of set theory.

After Richard Montague applied reflection phenomena to establish that ZF is not finitely axiomatizable, Levy also formulated reflection principles and established their broader significance. The 1960 Montague-Levy Reflection Principle for ZF asserts: *For any (first-order) formula $\varphi(v_1, \ldots, v_n)$ and any ordinal β, there is a limit ordinal $\alpha > \beta$ such that for any $x_1, \ldots, x_n \in V_\alpha$,*

$$\varphi[x_1, \ldots, x_n] \quad \textit{iff} \quad V_\alpha \models \varphi[x_1, \ldots, x_n].$$

Levy showed that this schema is equivalent to the conjunction of the Replacement schema together with Infinity in the presence of the other axioms of ZF. Moreover, he formulated reflection principles in local form that characterized the *Mahlo* cardinals, conceptually the least large cardinals after the inaccessible cardinals. Also William Hanf and Dana Scott posited analogous reflection principles for higher-order formulas, leading to what are now called the *indescribable cardinals*. The model-theoretic reflection idea thus provided a coherent scheme for viewing the bottom of an emerging hierarchy of large cardinals as a generalization of Replacement and Infinity.

In those 1946 remarks by Gödel where he broached the heuristic of reflection, Gödel also entertained the concept of ordinal definable set. A set x is *ordinal definable iff* there are ordinals $\alpha_1, \ldots, \alpha_n$ and a formula $\varphi(v_0, \ldots, v_n)$ such that $\forall y(y \in x \leftrightarrow \varphi[y, \alpha_1, \ldots, \alpha_n])$. This ostensible dependence on the satisfaction relation for V can be formally recast through a version of the Reflection Principle for ZF, so that one can define the class OD of ordinal definable sets. With $\mathrm{tc}(y)$ denoting the smallest transitive superset of y, let $\mathrm{HOD} = \{x \mid \mathrm{tc}(\{x\}) \subseteq \mathrm{OD}\}$, the class of *hereditarily ordinal definable sets.*

As noted by Gödel, HOD is an inner model in which AC, though not necessarily CH, holds. The basic results about this inner model were to be rediscovered several times. In these several ways reflection phenomena both as heuristic and as principle became incorporated into set theory, bringing to the forefront what was to become a basic feature of the study of well-foundedness.

The set-theoretic generalization of first-order logic allowing transfinitely indexed logical operations was to clarify the size of measurable cardinals. Extending familiarity by abstracting to a new domain, Tarski in 1962 formulated the *strongly compact* and *weakly compact* cardinals by ascribing natural generalizations of the key compactness property of first-order logic to the corresponding infinitary languages. These cardinals had figured in that 1943 Erdős-Tarski paper in equivalent combinatorial formulations that were later seen to imply that *a strongly compact cardinal is measurable,* and *a measurable cardinal is weakly compact.* Tarski's student Hanf then established, using the satisfaction relation for infinitary languages, that *there are many inaccessible cardinals (and Mahlo cardinals) below a weakly compact cardinal. A fortiori, the least inaccessible cardinal is not measurable.* This breakthrough was the first result about the size of measurable cardinals since Ulam's original 1930 paper and was greeted as a spectacular success for metamathematical methods. Hanf's work radically altered size intuitions about problems coming to be understood in terms of large cardinals and ushered in model-theoretic methods into the study of large cardinals beyond the Mahlo cardinals.

Weak compactness was soon seen to have a variety of characterizations, most notably *κ is weakly compact iff $\kappa \to (\kappa)^2_2$ iff $\kappa \to (\kappa)^n_\lambda$ for every $n \in \omega$ and $\lambda < \kappa$ iff κ is inaccessible and has the tree property,* and this was an early, significant articulation of the large cardinal extension of context for effecting known proof ideas and methods.

The concurrent emergence of the *ultraproduct construction* in model theory set the stage for the development of the modern theory of large cardinals. The ultraproduct construction was brought to the forefront by Tarski and his students after Jerzy Łoś's 1955 adumbration of its fundamental theorem. The new method of constructing concrete models brought set theory and model theory even closer together in a surge of results and a lasting interest in ultrafilters.

The ultraproduct construction was driven by the algebraic idea of making a structure out of a direct product of structures as modulated (or "reduced") by a filter. The particular case when all the structures are the same, the *ultrapower*, was itself seen to be substantive. To briefly describe a focal case for set theory, let N be a set, construed as a structure with $\in$, and U an ultrafilter over a set Z. On ${}^Z N$, the set of functions from Z to N, define

$$f =_U g \quad \textit{iff} \quad \{i \in Z \mid f(i) = g(i)\} \in U.$$

The filter properties of U imply that $=_U$ is an equivalence relation on ${}^Z N$, so with $(f)_U$ denoting the corresponding equivalence class of f, set ${}^Z N/U = \{(f)_U \mid f \in {}^Z N\}$. Next, the filter properties of U show that a binary relation E_U on ${}^Z N/U$ can be unambiguously defined by

$$(f)_U E_U (g)_U \quad \textit{iff} \quad \{i \in Z \mid f(i) \in g(i)\} \in U.$$

$=_U$ is thus a *congruence* relation, one that preserves the underlying structure; this sort of preservation is crucial in ultraproduct and classical, antecedent constructions with filters. (For example, in the space L^∞ in which two bounded measurable functions are equated when they agree on a set in the filter of full measure sets, the algebraic structure of + and × have many of the properties that + and × for the real numbers have. If the filter is extended to an ultrafilter, we get an ultrapower.) The *ultrapower* of N by U is then defined to be the structure $\langle {}^Z N/U, E_U\rangle$. The crux of the construction is the fundamental *Łoś's Theorem*: *For a formula* $\varphi(v_1, \ldots, v_n)$ *and* $f_1, \ldots, f_n \in {}^Z N$*,*

$$\langle {}^Z N/U, E_U\rangle \models \varphi[(f_1)_U, \ldots, (f_n)_U] \quad \textit{iff}$$
$$\{i \in Z \mid \mathcal{N} \models \varphi[f_1(i), \ldots, f_n(i)]\} \in U.$$

Satisfaction in the ultrapower is thus reduced to satisfaction on a large set of coordinates, large in the sense of U. The proof is by induction on the complexity of φ using the filter properties of U, the ultrafilter property for the negation step, and AC for the existential quantifier step.

E_U is an extensional relation, and crucially, well-founded when U is $\aleph_1$-complete. In that case by Mostowski's theorem there is a collapsing isomorphism π of the ultrapower onto its transitive collapse $\langle M, \in\rangle$. Moreover, if for $x \in N$, c_x is the constant function: $N \to \{x\}$ and $j_U : N \to M$ is defined by $j_U(x) = \pi((c_x)_U)$, then j_U is an elementary embedding, i.e. for any formula $\varphi(v_1, \ldots, v_n)$ and $a_1, \ldots, a_n \in N$,

$$\langle N, \in\rangle \models \varphi[a_1, \ldots, a_n] \quad \textit{iff} \quad \langle M, \in\rangle \models \varphi[j_U(a_1), \ldots, j_U(a_n)]$$

by Łoś's Theorem. When we have well-foundedness, the ultrapower is identified with its transitive collapse and denoted $\mathrm{Ult}(N, U)$.

All of the foregoing is applicable, and will be applied, with proper classes N, as long as we replace the equivalence class $(f)_U$ by sets

$$(f)^0_U = \{g \in (f)_U \mid g \text{ has minimal rank}\}$$

("Scott's trick"), and take Łoś's Theorem as a schema for formulas.

The model theorist H. Jerome Keisler established penetrating connections between combinatorial properties of ultrafilters and of their ultraproducts, and in particular took the ultrapower of a measurable cardinal κ by a κ-complete ultrafilter over κ to provide a new proof of Hanf's result that there are many large cardinals below a measurable cardinal. With Ulam's concept shown in a new light as providing well-founded ultrapowers, Dana Scott then struck on the idea of taking the ultrapower of the entire universe V by a κ-complete ultrafilter over a measurable κ, exploiting the resulting well-foundedness to get an elementary embedding $j : V \to \mathrm{Ult}(V, U)$. Importantly, κ is the *critical point*, i.e. $j(\alpha) = \alpha$ for every $\alpha < \kappa$ yet $\kappa < j(\kappa)$: Taking e.g. the identity function $\mathrm{id} : \kappa \to \kappa$, $\{\xi < \kappa \mid \alpha < \xi < \kappa\} \in U$ for every $\alpha < \kappa$, so that $\kappa \le \pi((\mathrm{id})_U) < j(\kappa)$ by Łoś's Theorem. If $V = L$, then $\mathrm{Ult}(V, U) = L$ by the definability properties of L, but this confronts $\kappa < j(\kappa)$, e.g. if κ were the least measurable cardinal. (One could also appeal to the general fact that $U \notin \mathrm{Ult}(V,U)$; that one "loses" the ultrafilter when taking the ultrapower would become an important theme in later work.) With this Scott established that *if there is a measurable cardinal, then* $V \neq L$. Large cardinal assumptions thus assumed a new significance as a means for "maximizing" possibilities away from Gödel's delimitative construction.

The ultrapower construction provided one direction of a new characterization that established a central structural role for measurable cardinals: *There is an elementary embedding* $j : V \to M$ *for some* M *with critical point* δ *iff* δ *is a measurable cardinal.* Keisler provided the converse direction: With j as hypothesized, $U_j \subseteq P(\delta)$ defined "canonically" by $X \in U_j$ *iff* $\delta \in j(X)$ is a δ-complete ultrafilter over δ. Generating ultrafilters thus via "ideal" elements would become integral to the theory of ultrafilters and large cardinals.

This characterization, when viewed with the focus on elementary embeddings, raises a point that will be even more germane, and thus will be emphasized later, in connection with strong hypotheses. That a $j : V \to M$ is elementary is not formalizable in set theory because of the appeal to the satisfaction relation for V, let alone the assertion that there is such a class j. Thus the "characterization" is really one of giving a formalization, one that provides operative sense through the ultrapower construction. Ulam's original concept was thus made intrinsic to set theory with the categorical imperative of elementary embeddings. In any event ZFC is never actually transcended in consistency results; one can always work in a sufficiently large V_α through the Reflection Principle for ZF.

In Scott's $j : V \to M = \mathrm{Ult}(V,U)$ the concreteness of the ultrapower construction delivered ${}^{\kappa}M \subseteq M$, i.e. M is closed under the taking of arbitrary (in V) κ-sequences, so that in particular $V_{\kappa+1} \cap M = V_{\kappa+1}$. Through this agreement strong reflection conclusions can be drawn. U is *normal iff* $\pi((\mathrm{id})_U) = \kappa$, the identity function is a "least non-constant" function, a property that can be easily arranged. For such U, since κ is inaccessible, it is so in M and hence by Łoś's Theorem $\{\xi < \kappa \mid \xi \text{ is inaccessible}\} \in U$—the inaccessible cardinals below κ have measure one. An analogous argument applies to any $V_{\kappa+1}$ property of κ like weak compactness, and so, as would typify large cardinal hypotheses, measurability articulates its own sense of transcendence over "smaller" large cardinals.

Normality went on to become staple to the investigation of ideals and large cardinals. Formulated for an ideal I over a cardinal λ, I is *normal iff* whenever a function f is regressive on an $S \in P(\lambda) - I$, there is a $T \in P(S) - I$ on which f is constant. Fodor's Lemma is then just the assertion that the nonstationary ideal NS_λ is normal for regular $\lambda > \omega$, and a multitude of "smallness" properties other than nonstationarity has been seen to lead to normal ideals.

Through model-theoretic methods set theory was brought to the point of entertaining elementary embeddings into well-founded models. It was soon to be transfigured by a new means for getting well-founded *extensions* of well-founded models.

3. The Advent of Forcing

3.1. Cohen

Paul Cohen (1934–2007) in April 1963 established the independence of AC from ZF and the independence of CH from ZFC. That is, Cohen established that Con(ZF) implies Con(ZF + $\neg$AC) and that Con(ZFC) implies Con(ZFC + $\neg$CH). Already prominent as an analyst, Cohen had ventured into set theory with fresh eyes and an open-mindedness about possibilities. These results solved two central problems of set theory. But beyond that, Cohen's proofs were the inaugural examples of a new technique, *forcing*, which was to become a remarkably general and flexible method for extending models of set theory. Forcing has strong intuitive underpinnings and reinforces the notion of set as given by the first-order ZF axioms with prominent uses of Replacement and Foundation. If Gödel's construction of L had launched set theory as a distinctive field of mathematics, then Cohen's method of forcing began its transformation into a modern, sophisticated one.

Cohen's approach was to start with a model M of ZF and adjoin a set G that witnesses some desired new property. This would have to be done in a minimal fashion in order that the resulting extension also model ZF, and so Cohen devised special conditions on both M and G. To be concrete, Cohen started with a countable transitive model $\langle M, \in \rangle$ of ZF. The ordinals of M would then coincide with the predecessors of some ordinal ρ, and M would be the cumulative hierarchy $M = \bigcup_{\alpha<\rho} V_\alpha \cap M$. Cohen recursively defined in M a system of terms (or "names") to denote members of the new model, working with a ramified language. In a streamlined rendition, for each $x \in M$ let $\check{x}$ be a corresponding constant; let $\dot{G}$ be a new constant; and for each $\alpha < \rho$ introduce quantifiers $\forall_\alpha$ and $\exists_\alpha$. Then define: $\dot{M}_0 = \{\dot{G}\}$, and for limit ordinals $\delta < \rho$, $\dot{M}_\delta = \bigcup_{\alpha<\delta} \dot{M}_\alpha$. At the successor stage, let $\dot{M}_{\alpha+1}$ be the collection of constants $\check{x}$ for $x \in V_\alpha \cap M$ and class terms corresponding to formulas allowing parameters from $\dot{M}_\alpha$ and quantifiers $\forall_\alpha$ and $\exists_\alpha$—a syntactical analogue of the operator def(x) for Gödel's L. Once a set G is provided from the outside, a model $M[G] = \bigcup_{\alpha<\rho} M_\alpha[G]$ would be determined by the terms.

But what properties can be imposed on G to ensure that $M[G]$ be a model of ZF? Cohen's key idea was to tie G closely to M through a partially ordered system of sets in M called *conditions* that would approximate G. While G may not be a member of M, G is to be a subset of some $Y \in M$ (with $Y = \omega$ a basic case), and these conditions would "force" some assertions about the eventual $M[G]$ e.g. by deciding some of the membership questions, whether $x \in G$ or not, for $x \in Y$. The assertions are to be just those expressible in the ramified language, and Cohen developed a corresponding *forcing relation* $p \Vdash \varphi$, "p forces φ", between conditions p and formulas φ, a relation with properties reflecting his approximation idea. For example, if $p \Vdash \varphi$ and $p \Vdash \psi$, then $p \Vdash \varphi \wedge \psi$. The conditions are ordered according to the constraints they impose on the eventual G, so that if $p \Vdash \varphi$, and q is a stronger condition, then $q \Vdash \varphi$. It was crucial to Cohen's approach that the forcing relation, like the ramified language, be definable in M.

The final ingredient which gives this whole scaffolding life is the incorporation of a certain kind of set G. Stepping out of M and making the only use of its countability, Cohen enumerated the formulas of the ramified language in a countable sequence and required that G be completely determined by a sequence of stronger and stronger conditions $p_0, p_1, p_2, \ldots$ such that for every formula φ of the ramified language exactly one of φ or $\neg\varphi$ is forced by some p_n. Such a G is called a *generic* set. The language is congenial; with the forcing conditions naturally topologized, a generic set meets every open dense set in M and is thus generic in a classical topological sense.

Cohen was able to show that the resulting $M[G]$ does indeed satisfy the axioms of ZF: Every assertion about $M[G]$ is already forced by some condition; the forcing relation is definable in M; and so the ZF axioms holding in M, most crucially Replacement and Foundation, can be applied to the ramified terms and language to derive corresponding forcing assertions about the ZF axioms holding in $M[G]$.

Cohen first described the case when $G \subseteq \omega$ and the conditions p are functions from some finite subset of ω into $\{0, 1\}$ and $p \Vdash \dot{n} \in \dot{G}$ if $p(n) = 1$ and $p \Vdash \dot{n} \notin \dot{G}$ if $p(n) = 0$. Today, a G so adjoined to M is called a *Cohen real over* M. If subsets of ω are identified with reals as traditionally construed, that G is generic can be extrinsically characterized by saying that G meets every open dense set of reals lying in M. Generally, a $G \subseteq \kappa$ analogously adjoined with conditions of cardinality less than κ is called a *Cohen subset of* κ. Cohen established the independence of CH by adjoining a set which in effect is a sequence of many Cohen reals. It was crucial that the cardinals in the ground model and generic extension coincide, and with two forcing conditions said to be *incompatible* if they have no common, stronger condition, Cohen to this end drew out and relied on the important *countable chain condition* (c.c.c.): Any antichain, i.e. collection of mutually incompatible conditions, is countable.

Cohen established the independence of AC by a version of the above scheme, where in addition to $\dot{G}$ there are also new constants $\dot{G}_i$ for $i \in \omega$, and $\dot{G}$ is interpreted by a set X of Cohen reals, each an interpretation of some $\dot{G}_i$. The point is that X is not well-orderable in the extension, since there are permutations of the forcing conditions that induce a permutation of the G_i's yet leave X fixed.

Several features of Cohen's arguments would quickly be reformulated, reorganized, and generalized, but the thrust of his approach through definability and genericity would remain. Cohen's great achievement lies in devising a concrete procedure for extending well-founded models of set theory in a minimal fashion to well-founded models of set theory with new properties but without altering the ordinals.

The extent and breadth of the expansion of set theory described henceforth dwarfs all that has been described before, both in terms of the numbers of people involved and the results established, and we are left to paint with even broader strokes. With clear intimations of a new and concrete way of building models, set theorists rushed in and, with forcing becoming method, were soon establishing a cornucopia of relative consistency results, truths in a wider sense, with some illuminating classical problems of mathematics. Just in the first weeks after Cohen's discovery, Solomon Feferman, who had been extensively consulted by Cohen as he was coming up with forcing, established further independences elaborating ¬AC and about definability; Levy soon joined in this work and pursued both directions, formulating the "Levy collapse" of an inaccessible cardinal; and Stanley Tennenbaum established the failure of Suslin's Hypothesis by generically adjoining a Suslin tree. Soon, ZFC became quite unlike Euclidean geometry and much like group theory, with a wide range of models being investigated for their own sake.

3.2. Method of Forcing

Robert Solovay above all epitomized this period of sudden expansion in set theory with his mathematical sophistication and central results about and with forcing, and in the areas of large cardinals and descriptive set theory. Following initial graduate study in differential topology, Solovay turned to set theory after hearing a May 1963 lecture by Cohen. Just weeks after, Solovay elaborated the independence of CH by characterizing the possibilities for the size of 2^κ for regular κ and made the first exploration of a range of cardinals. Building on this William Easton in late 1963 established the definitive result for powers of regular cardinals: *Suppose that* GCH *holds and F is a class function from the class of regular cardinals to cardinals such that for regular $\kappa \leq \lambda$, $F(\kappa) \leq F(\lambda)$ and the cofinality* $\mathrm{cf}(F(\kappa)) > \kappa$. *Then there is a (class) forcing extension preserving cofinalities in which $2^\kappa = F(\kappa)$ for every regular κ.* Thus, as Solovay had seen locally, the *only* restriction beyond monotonicity on the power function for regular cardinals is that given by a well-known constraint, the classical Zermelo-Kőnig inequality that $\mathrm{cf}(2^\kappa) > \kappa$ for any cardinal κ. Easton's result enriched the theory of forcing with the introduction of proper classes of forcing conditions, the basic idea of a product analysis, and the now familiar concept of *Easton support*. The result focused interest on the possibilities for powers of *singular* cardinals and the Singular Cardinals Hypothesis (SCH), which asserts that 2^κ for singular κ is the least possible with respect to the powers 2^μ for $\mu < \kappa$ as given by monotonicity and the Zermelo-Kőnig inequality. This requires in particular that for singular strong limit cardinals κ, $2^\kappa = \kappa^+$. With Easton's models satisfying SCH, the *singular cardinals problem*, to determine the range of possibilities for powers of singular cardinals, would become a major stimulus for the further development of set theory much as the continuum problem had been for its early development.

In the Spring of 1964 Solovay established a result remarkable for its mathematical depth and revelatory of what standard of argument was possible with forcing: *If there is an inaccessible cardinal, then in a* ZF *inner model of a forcing extension the Principle of Dependent Choices* (DC) *holds and every set of reals is Lebesgue measurable, has the Baire property, and has the perfect set property.* Solovay's inner model is precluded from having a well-ordering of the reals, but DC is a choice principle implying the regularity of ω_1 and sufficient for the formalization of the traditional theory of measure and category on the real numbers. Thus, Solovay's work vindicated the early descriptive set theorists in the sense that the regularity properties can consistently hold for all sets of reals in a *bona fide* model for the classical mathematical analysis of the reals. To prove his result Solovay applied the Levy collapse of an inaccessible cardinal to make it ω_1. For the Lebesgue measurability he introduced a new kind of forcing beyond Cohen's direct ways of adjoining new sets of ordinals or collapsing cardinals, that of adding a *random real* given by forcing with the Borel sets of positive measure as conditions and p stronger than q when $p - q$ is null. In contrast to Cohen reals, a random real meets every measure one subset of the unit interval lying in the ground model. Solovay's work not only opened the door to a wealth of different forcing arguments, but to this day his original definability arguments remain vital to descriptive set theory.

The perfect set property, central to Cantor's direct approach to the continuum problem through definability, led to the first acknowledged instance of a new phenomenon in set theory: the derivation of *equi-consistency* results between large cardinal hypotheses and combinatorial propositions about low levels of the cumulative hierarchy. Forcing showed just how relative the Cantorian concept of cardinality is, since bijective functions could be adjoined to models of set theory and powers like $2^{\aleph_0}$ can be made arbitrarily large with relatively little disturbance. For instance, large cardinals were found to satisfy substantial propositions even after they were "collapsed" to ω_1 or ω_2, i.e. a bijective function was adjoined to render the cardinal the first or second uncountable cardinals respectively. Conversely, such propositions were found to entail large cardinal propositions in an L-like inner model, mostly pointedly the very same initial large cardinal hypothesis. Thus, for some large cardinal property $\varphi(\kappa)$ and proposition ψ, there is a direction $\mathrm{Con}(\exists\kappa\varphi(\kappa)) \to \mathrm{Con}(\psi)$ established by a collapsing forcing argument, and a converse direction $\mathrm{Con}(\psi) \to \mathrm{Con}(\exists\kappa\varphi(\kappa))$ established by witnessing $\varphi(\kappa)$ in an inner model.

Solovay's result provided the forcing direction from an inaccessible cardinal to the proposition that every set of reals has the perfect set property and ω_1 is regular. But Ernst Specker in 1957 had in effect established that if this obtains, then ω_1 (of V) is inaccessible in L. Thus, Solovay's use of an inaccessible cardinal was actually necessary, and its collapse to ω_1 complemented Specker's observation. The emergence of such equi-consistency results is a subtle realization of earlier hopes of Gödel for deciding propositions via large cardinals. Forcing, however, quickly led to the conclusion that there could be no direct implication for CH itself: Levy and Solovay, also in 1964, established that measurable cardinals neither imply nor refute CH, with an argument generalizable to other inaccessible large cardinals. Rather, CH and many other propositions would be reckoned with in terms of consistency, the methods of forcing and inner models being the operative modes of argument.

Building on his Lebesgue measurability result Solovay in 1965 reactivated the classical descriptive set theory program of investigating the extent of the regularity properties (in the presence of AC) by providing characterizations in terms of forcing and definability concepts for the $\mathbf{\Sigma}^1_2$ sets, the level at which Gödel established from $V = L$ the failure of the properties. This led to the consistency relative to ZFC of the Lebesgue measurability of all $\mathbf{\Sigma}^1_2$ sets. Also, the characterizations showed that the regularity properties for $\mathbf{\Sigma}^1_2$ sets follow from existence of a measurable cardinal. Thus, although measurable cardinals do not decide CH, they do establish the perfect set property for $\mathbf{\Sigma}^1_2$ sets so that "CH holds for the $\mathbf{\Sigma}^1_2$ sets". A coda after many years: Although Solovay's use of an inaccessible cardinal for universal Lebesgue measurability seemed *ad hoc* at the time, in 1979 Saharon Shelah established in a *tour de force* that if ZF + DC and all Σ^1_3 sets of reals are Lebesgue measurable, then ω_1 is inaccessible in L.

In a separate initiative, Solovay in 1966 established the equi-consistency of the existence of a measurable cardinal and the "real-valued" measurability of $2^{\aleph_0}$, i.e. that there is a (countably additive) measure extending Lebesgue measure to all sets of reals. For the forcing direction, Solovay starting with a measurable cardinal adjoined random reals and applied the Radon-Nikodym Theorem of analysis, and for the converse direction, he starting with a real-valued measure enlisted the inner model constructed relative to the ideal of measure zero sets. This consistency result provided context for an extended investigation of the possibilities for the continuum as structured by such a measure. Through this work the concept of *saturated ideal*, first studied by Tarski, was brought to prominence as a generalization of having a measurable cardinal applicable to the low levels of the cumulative hierarchy. For an ideal over a cardinal κ, I is λ-*saturated iff* for any $\{X_\alpha \mid \alpha < \lambda\} \subseteq P(\kappa) - I$ there are $\beta < \gamma < \lambda$ such that $X_\beta \cap X_\gamma \in P(\kappa) - I$ (i.e. the corresponding Boolean algebra has no antichains of cardinality λ). The ideal of measure zero sets is $\aleph_1$-saturated, and Solovay showed that if I is any κ-complete λ-saturated ideal over κ for some $\lambda < \kappa$, then $L[I] \models$ "κ is measurable".

Solovay's work also brought to the foreground the concept of *generic ultrapower* and *generic elementary embedding*. For an ideal I over κ, forcing with the members of $P(\kappa) - I$ as conditions and p stronger than q when $p - q \in I$ engenders an ultrafilter on the ground model $P(\kappa)$. With this one can construct an ultrapower of the ground model in the generic extension and a corresponding elementary embedding. It turns out that the κ^+-saturation of the ideal ensures that this generic ultrapower is well-founded. Thus, a synthesis of forcing and ultrapowers is effected, and this raised enticing possibilities for having such large cardinal-type structure low in the cumulative hierarchy.

The development of the theory of forcing went hand in hand with this procession of central results. Solovay had first generalized forcing to arbitrary partial orders of conditions, proceeding in terms of incompatible members and dense sets and Levy's concept of *generic filter.* In his work on the Baire property for his 1964 model, Solovay came to the idea of assigning values to formulas from a complete Boolean algebra. Loosely speaking, the value would be the supremum of all the conditions forcing it. Working independently, Solovay and Scott developed the idea of recasting forcing entirely in terms of *Boolean-valued models.* This approach showed how to replace Cohen's ramified languages by a more direct induction on rank and how to avoid his dependence on a countable model. Boolean-valued functions play the role of sets, and formulas involving these functions are assigned Boolean-values by recursion respecting logical connectives and quantifiers. By establishing in ZFC that e.g. there is a complete Boolean algebra assigning the formula expressing $\neg$CH Boolean value one, a semantic construction was replaced by a syntactic one that directly secured relative consistency.

Still, the view of forcing as a way of actually extending models held the reservoir of sense and the promise of discovery, and after Shoenfield popularized an approach to the forcing relation that captured the gist of the Boolean-valued approach, forcing has been generally cast as a matter of partial orders and generic filters. Boolean algebras would nonetheless underscore and enhance the setting: partial orders are to have a maximum element 1; one is attuned to the *separativity* of partial orders, the property that ensures that they are densely embedded in their canonical Boolean completions; Boolean-values are used when illuminating; and embedding results for forcing partial orders are cast, as most algebraically informative, in terms of Boolean algebras.

By the 1970s there would be a further assimilation of both the syntactic and semantic approaches in that generic extensions would be "taken" of V. In this the current approach then, a partial order $\langle P, < \rangle$ of conditions is specified to a purpose, with $p < q$ for p being stronger than q. A class V^P of P-names defined recursively is used in forcing assertions, with a canonical name $\check{x}$ corresponding to $x \in V$. A $D \subseteq P$ is *dense* if for any $p \in P$ there is a $d \in D$ with $d \leq p$. An $F \subseteq P$ is a *filter* if (i) if $p \in F$ and $p \leq q$, then $q \in F$, and (ii) if $p_1, p_2 \in F$ then there is an $r \in F$ with $r \leq p_1$ and $r \leq p_2$. Finally, $G \subseteq P$ is a V*-generic filter* if G is a filter such that for every dense $D \subseteq P$, $G \cap D \neq \emptyset$. One posits such a G and takes a generic extension $V[G]$, its properties argued for on the basis of combinatorial properties of P. For inner or transitive set models M, one proceeds analogously to define M*-generic filters* meeting every dense set belonging to M and takes generic extensions $M[G]$.

In this one goes against the sense of V as *the* universe of all sets and Tarski's "undefinability of truth", but actually V has become *schematic* for a ground model. Generic extensions of inner models M are taken with M-generic G, and moreover, successive iterated extensions are taken, exacerbating any preoccupation with a single universe of sets. As the techniques of forcing were advanced, the methodology was itself soon to be woven into set theory as part of its postulations.

Solovay and Tennenbaum earlier in 1965 had established the consistency of Suslin's Hypothesis, that there are no Suslin trees, illuminating a classical question from 1920 with a ground-breaking use of iterated forcing to keep "killing Suslin trees" in intermediate extensions. D. Anthony Martin pointed out that the Solovay-Tennenbaum argument actually established the consistency of a closure of forcing extensions of a certain kind, an instrumental "axiom" now known as Martin's Axiom (MA): *For any* c.c.c. *partial order P and collection $\mathcal{D}$ of fewer than $2^{\aleph_0}$ dense subsets of P, there is a filter $G \subseteq P$ meeting every member of $\mathcal{D}$.* Thus method became axiom, and many consistency results could now be simply stated as direct consequences of a single umbrella proposition. CH technically implies MA, but the Solovay-Tennenbaum argument established the consistency of MA with the continuum being arbitrarily large.

While classical results with CH had worked on an $\aleph_0 \,/\, \aleph_1$ dichotomy, MA established a $<2^{\aleph_0} / \, 2^{\aleph_0}$ dichotomy. For example, Martin and Solovay established that MA implies that the union of fewer than $2^{\aleph_0}$ Lebesgue measure zero sets is again Lebesgue measure zero. Sierpiński in 1925 had established that every $\mathbf{\Sigma}^1_2$ set of reals is the union of $\aleph_1$ Borel sets. Hence, MA and $2^{\aleph_0} > \aleph_1$ implies that every $\mathbf{\Sigma}^1_2$ set of reals is Lebesgue measurable. Many further results plied the $<2^{\aleph_0} / \, 2^{\aleph_0}$ dichotomy to show that under MA inductive arguments can be carried out in $2^{\aleph_0}$ steps that previously succeeded under CH in $\aleph_1$ steps. The continuum problem was newly illuminated as a matter of method, by showing that CH as a construction principle could be generalized to $2^{\aleph_0}$ being arbitrarily large.

Glancing across the wider landscape, forcing provided new and diverse ways of adjoin generic reals and other sets, and these led to new elucidations, for example about cardinal characteristics, or invariants, of the continuum and combinatorial structures and objects, like ultrafilters over ω. The work on Suslin's Hypothesis in hand and with the possibilities afforded by Martin's Axiom, the investigation of general topological notions gathered steam. With Mary Ellen Rudin and her students at Wisconsin breaking the ground, new questions were raised for general topological spaces about separation properties, compactness-type covering properties, separability and metrizability, and corresponding cardinal characteristics.

3.3. $0^{\#}$, $L[U]$, and $L[\mathcal{U}]$

The infusion of forcing into set theory induced a broad context extending beyond its applications and sustained by model-theoretic methods, a context which included central developments about large cardinals having their source in Scott's 1961 result that measurable cardinals contradict $V = L$. Haim Gaifman invented *iterated ultrapowers* and established seminal results about and with the technique, results which most immediately stimulated definitive work in the formative theses of Silver and Kunen.

Jack Silver in his 1966 Berkeley thesis provided a structured sense of transcendence over L in terms of the existence of a special set of natural numbers $0^{\#}$ ("zero sharp") which refined an earlier formulation of Gaifman and was quickly investigated by Solovay in terms of definability. Mostowski and Andrzej Ehrenfeucht in 1956 had developed theories whose models have *indiscernibles*, implicitly ordered members of the domain all of whose n-tuples satisfy the same formulas. They had applied Ramsey's Theorem in compactness arguments to get models generated by indiscernibles, models consequently having many automorphisms. Silver applied partition properties satisfied by measurable cardinals to produce indiscernibles *within* given structures, particularly in the initial segment $\langle L_{\omega_1}, \in\rangle$ of the constructible universe. With definability and Skolem hull arguments, Silver was able to isolate a canonical collection of sentences to be satisfied by indiscernibles, a theory whose models cohere to get L itself as generated by canonical ordinal indiscernibles—a dramatic accentuation of the original Gödel generation of L. $0^{\#}$ is that theory coded as a real, and as Solovay emphasized, $0^{\#}$ is the only possible real to satisfy a certain Π^1_2 relation, one whose complexity arises from its asserting that to every countable well-ordering there corresponds a well-founded model of the coded theory. The canonical class, closed and unbounded, of ordinal indiscernibles is often called the *Silver indiscernibles*. Having these indiscernibles substantiates $V \neq L$ in drastic ways: Each indiscernible ι has various large cardinal properties and satisfies $L_\iota \prec L$, so that by a straightforward argument the satisfaction relation for L is definable from $0^{\#}$. The theory of $0^{\#}$ was seen to relativize, and for reals $a \in {}^\omega\omega$ the analogous $a^{\#}$ for the inner model $L[a]$ would play focal roles in descriptive set theory as based on definability.

Kunen's main large cardinal results emanating from his 1968 Stanford thesis would be the definitive structure results for inner models of measurability. For U a normal κ-complete ultrafilter over a measurable cardinal κ, the inner model $L[U]$ of sets constructible relative to U is easily seen with $\overline{U} = U \cap L[U]$ to satisfy $L[U] \models$ "$\overline{U}$ is a normal κ-complete ultrafilter". With no presumption that κ is measurable (in V) and taking $U \in L[U]$ from the beginning, call $\langle L[U], \in, U\rangle$ a *κ-model iff* $\langle L[U], \in, U\rangle \models$ "U is a normal κ-complete ultrafilter over κ". Solovay observed that in a κ-model, the GCH holds above κ by a version of Gödel's argument for L and that κ is the only measurable cardinal by a version of Scott's argument. Silver then established that the full GCH holds, thereby establishing the relative consistency of GCH and measurability; Silver's proof turned on a local structure $L_\alpha[U]$ being *acceptable* in the later parlance of inner model theory.

Kunen made Gaifman's technique of iterated ultrapowers integral to the subject of inner models of measurability. For a κ-model $\langle L[U], \in, U\rangle$, the ultrapower of $L[U]$ by U with corresponding elementary embedding j provides a $j(\kappa)$-model $\langle L[j(U)], \in, j(U)\rangle$, and this process can be repeated. At limit stages, one can take the direct limit of models, which when well-founded can be identified with the transitive collapse. Indeed, by Gaifman's work these iterated ultrapowers are always well-founded, i.e. κ-models are *iterable.* Kunen showed that the λth iterate of a κ-model for any regular $\lambda > \kappa^+$ is of form $\langle L[\mathcal{C}_\lambda], \in, \mathcal{C}_\lambda \cap L[\mathcal{C}_\lambda]\rangle$, where $\mathcal{C}_\lambda$ again is the closed unbounded filter over λ, so that remarkably, constructing relative to a filter definable in set theory leads to an inner model of measurability. With this, there can be *comparison* of κ-models and κ'-models by iterating them up to a sufficiently large λ. This comparison possibility let to the structure results: (1) *for any κ-model and κ'-model with $\kappa < \kappa'$, the latter is an iterated ultrapower of the former,* and (2) *for any κ, there is at most one κ-model.* It then followed that if κ is measurable and U_1 and U_2 are any κ-complete ultrafilters over κ, then $L[U_1] = L[U_2]$. These various results argued forcefully for the coherence and consistency of the concept of measurability. And it would be that iterability and comparison would remain as basic features in inner model theory in its subsequent development.

Kunen's contribution to the theory of iterated ultrapowers was that iterated ultrapowers can be taken of an inner model M with respect to an ultrafilter U even if $U \notin M$, as long U is an *M-ultrafilter*, i.e. U in addition to having M related ultrafilter properties also satisfies an "amenability" condition for M. A crucial dividend was a characterization of the existence of $0^\#$ that secured its central importance in inner model theory. With $0^\#$, any increasing shift of the Silver indiscernibles provides an elementary embedding $j : L \to L$. Kunen established conversely that such an embedding generates indiscernibles, so that $0^\#$ *exists iff there is a (non-identity) elementary embedding $j : L \to L$.* Starting with such an embedding Kunen defined the corresponding ultrafilter U over the critical point and showed that U is an L-ultrafilter with which the iterated ultrapowers of L are well-founded. The successive images of the critical point were seen to be indiscernibles for L, giving $0^\#$. As inner model theory was to develop, this sharp analysis would become schematic: the "sharp" of an inner model M would encapsulate transcendence over M, and the *non-rigidity* of M, that there is a (non-identity) elementary embedding $j : M \to M$, would provide equivalent structural sense.

William Mitchell in 1972, just after completing a pioneering Berkeley thesis on Aronszajn trees, provided the first substantive extension of Kunen's inner model results and brought to prominence a new large cardinal hypothesis. For normal κ-complete ultrafilters U and U' over κ, define the *Mitchell order* $U' \lhd U$ *iff* $U' \in \mathrm{Ult}(V, U)$, i.e. there is an $f : \kappa \to V$ representing U' in the ultrapower, so that $\{\alpha < \kappa \mid f(\alpha)$ is a normal α-complete ultrafilter over $\alpha\} \in U$ and κ is already a limit or measurable cardinals. $U \lhd U$ always fails, and generally, $\lhd$ is a well-founded relation by a version of Scott's argument that measurable cardinals contradict $V = L$. Consequently, to each U can be recursively assigned a rank $o(U) = \sup\{o(U') + 1 \mid U' \lhd U\}$, and to a cardinal κ, the supremum $o(\kappa) = \sup\{o(U) + 1 \mid U$ is a normal κ-complete ultrafilter over $\kappa\}$. By a cardinality argument, if $2^\kappa = \kappa^+$ then $o(\kappa) \le \kappa^{++}$.

The hypothesis $o(\kappa) = \delta$ provided an "order" of measurability calibrated by δ, with larger δ corresponding to stronger assumptions on κ. For the investigation of these orders, Mitchell devised the concept of a *coherent* sequence of ultrafilters ("measures") and was able to establish canonicity results for inner models $L[\mathcal{U}] \models$ "$\mathcal{U}$ is a coherent sequence of ultrafilters". A coherent sequence $\mathcal{U}$ is a doubly indexed system of normal α-complete ultrafilters $\mathcal{U}(\alpha,\beta)$ over α such that $\mathcal{U}(\kappa,\beta) \lhd \mathcal{U}(\kappa,\beta')$ for $\beta < \beta'$ at the κth level, and the earlier levels contain just enough ultrafilters necessary to represent these $\lhd$ relationships in the respective ultrapowers. (Technically, if $j : V \to \mathrm{Ult}(V, \mathcal{U}(\kappa,\beta'))$, then $j(\mathcal{U})\restriction\{(\alpha,\beta) \mid \alpha \le \kappa\} = \mathcal{U}\restriction\{(\alpha,\beta) \mid \alpha < \kappa \vee (\alpha = \kappa \wedge \beta < \beta')\}$, i.e. $j(\mathcal{U})$ through κ is exactly $\mathcal{U}$ "below" (κ,β').)

Mitchell first affirmed that these $L[\mathcal{U}]$'s are *iterable* in that arbitrary iterated ultrapowers via ultrafilters in $\mathcal{U}$ and its successive images are always well-founded. He then effected a comparison: *Any $L[\mathcal{U}_1]$ and $L[\mathcal{U}_2]$ have respective iterated ultrapowers $L[\mathcal{W}_1]$ and $L[\mathcal{W}_2]$ such that $\mathcal{W}_1$ is an initial segment of $\mathcal{W}_2$ or vice versa.* This he achieved through a process of *coiteration* of least differences: At each stage, one finds the lexicographically least coordinate at which the current iterated ultrapowers of $L[\mathcal{U}_1]$ and $L[\mathcal{U}_2]$ differ and takes the respective ultrapowers by the differing ultrafilters; the difference is eliminated as ultrafilters never occur in their ultrapowers. Note that this iteration process is external to $L[\mathcal{U}_1]$ and $L[\mathcal{U}_2]$, further drawing out the advantages of working externally to models as Kunen had first done with his M-ultrafilters. With this coiteration, Mitchell established that in $L[\mathcal{U}]$ the only normal α-complete ultrafilters over α for any α are those that occur in $\mathcal{U}$ and other propositions like GCH that showed these models to be L-like. Coiteration would henceforth be embedded in inner model theory, and with his models $L[\mathcal{U}]$ modeling $o(\kappa) = \delta$ for $\delta < \kappa^{++L[\mathcal{U}]}$, $\exists\kappa(o(\kappa) = \kappa^{++})$ would become the delimitative proposition of his analysis.

3.4. Constructibility

These various results were set against a backdrop of an increasing articulation of Gödel's original notion of constructibility. Levy in 1965 had put forward the appropriate hierarchy for the first-order formulas of set theory: A formula is Σ_0 and Π_0 if it is bounded, i.e. having only quantifiers expressible in terms of $\forall v \in w$ and $\exists v \in w$, and recursively, a formula is Σ_{n+1} if it is of the form $\exists v_1 \ldots \exists v_k \varphi$ where φ is Π_n and is Π_{n+1} if it is of the form $\forall v_1 \ldots \forall v_k \varphi$ where φ is Σ_n. Two basic points about discounting bounded quantifiers are that Σ_0 formulas are absolute for transitive structures, i.e. they hold in such structures just in case they hold in V, and that if φ is Σ_n (resp. Π_n) then $\exists v \in w\varphi$ and $\forall v \in x\varphi$ are equivalent in ZFC to Σ_n (resp. Π_n) formulas by uses of Replacement. Levy wove in Shoenfield's Σ^1_2 absoluteness result to establish the Shoenfield-Levy Absoluteness Lemma: *For any Σ_1 sentence σ,* ZF + DC $\vdash \sigma \longleftrightarrow \sigma^L$. Levy actually showed that L here can be replaced by a countable L_γ fixed for all σ, and as such the lemma can be seen as a refinement of the Reflection Principle for ZF, one that was to find wide use in the burgeoning field of admissible set theory.

Gödel's original GCH result with L was newly seen in light of the structured context for definability. For N and M construed as structures with $\in$, $j : N \to M$ is a Σ_n*-elementary embedding iff* for any Σ_n $\varphi(v_1, \ldots, v_k)$ and $x_1, \ldots, x_k \in N$, $N \models \varphi[x_1, \ldots, x_k]$ *iff* $M \models \varphi[j(x_1), \ldots, j(x_k)]$. N is a Σ_n*-elementary substructure* of M, denoted $N \prec_n M$, *iff* the identity map is Σ_n-elementary. Analysis of the satisfaction relation established that being an L_α is a Σ_1 property, and this led to the Condensation Lemma:

If α is a limit ordinal and $N \prec_1 L_\alpha$,

then the transitive collapse of N is L_β for some $\beta \leq \alpha$.

Operatively, one applies this lemma with Skolem's algebraic approach to logic by taking N to be a Σ_1 *Skolem hull* in L_α: For any Σ_0 formula $\varphi(v_1, \ldots, v_n, v_{n+1})$ and $x_1, \ldots, x_n \in L_\alpha$, if $\langle L_\alpha, \in \rangle \models \varphi[x_1, \ldots x_n, y]$ for $y \in L_\alpha$, let $f_\varphi(x_1, \ldots, x_n)$ be such a y. Then let N be the algebraic closure of some subset of L_α under these Skolem functions. The road from the Condensation Lemma to Gödel's Fundamental Theorem for the consistency of GCH is short. Generally, the lemma articulates a crucial hierarchical cohesion, and its various emanations would become fundamental to all inner model theory.

The consummate master of constructibility was to be Ronald Jensen, whose first systematic analysis transformed the subject with the introduction of the *fine structure theory* for L. Jensen's work is distinguished by the persistent pursuit of internal logical structure, the sophistication of the local apparatus developed, and a series of remarkable successes with reverberations throughout the whole expanse of set theory. After his 1964 Bonn dissertation on models of arithmetic, Jensen moved with strength into investigations with forcing and of definability, two directions that would steadily complement each other in his work. He, like Solovay, saw the great potential of forcing, and he soon derived the Easton results independently. In the direction of definability he in 1965 worked out with Carol Karp a theory of primitive recursive set functions, and with these he began his investigation of L. In his 1967 Habilitationsschrift he had definite anticipations of fine structure, although notably he had no particular application for it in mind at that time.

In 1968 Jensen made a major breakthrough by showing that $V = L$ *implies the failure of Suslin's Hypothesis*, i.e. (there is a Suslin tree)^L, applying L for the first time after Gödel to establish a relative consistency result about a classical proposition. The initial breakthrough had been when Tennenbaum had adjoined a Suslin tree with forcing and Thomas Jech had provided another forcing argument; Jensen at first pitched his construction in the guise of a forcing argument, one in fact like Jech's. This is the paradigmatic case of what would become a recurring phenomenon: A combinatorial existence assertion is first shown to be relatively consistent with ZFC using forcing, and then the assertion is shown to hold in L, the minimal inner model.

The lack of cofinal branches in Suslin trees is complemented by their abundance in Kurepa trees. Inspired by Jensen's construction the ubiquitous Solovay established: (there is a Kurepa tree)^L. Here too the relative consistency of the proposition had been established first through forcing.

Jensen isolated the combinatorial features of L that enabled these constructions and together with Kunen in 1969 worked out a larger theory. The focus was mainly on two combinatorial principles of Jensen's for a regular cardinal κ, $\diamondsuit_\kappa$ ("diamond") and a strengthening, $\diamondsuit_\kappa^+$ ("diamond plus"). Stating the first,

$\diamondsuit_\kappa$ There is a sequence $\langle S_\alpha \mid \alpha < \kappa\rangle$ with $S_\alpha \subseteq \alpha$ such that for any $X \subseteq \kappa$, $\{\alpha < \kappa \mid X \cap \alpha = S_\alpha\}$ is stationary in κ.

Just $\diamondsuit$ is implicitly $\diamondsuit_{\omega_1}$. $\diamondsuit_\kappa$ implies $\bigcup_{\alpha<\kappa} \kappa^{|\alpha|} = \kappa$ (so that $\diamondsuit$ implies CH) as every bounded subset of κ occurs in a $\diamondsuit_\kappa$ sequence. Indeed, a $\diamondsuit_\kappa$ sequence is an enumeration of the bounded subsets of κ that can accommodate every $X \subseteq \kappa$ in anticipatory constructions where $X \cap \alpha$ appearing in the enumeration for many α's suffices. Within a few years $\diamondsuit$ would be on par with CH as a construction principle with wide applications in topology, algebra, and analysis. (Another coda of Shelah's after many years: In 2007 he established that for successors $\lambda^+ > \omega_1$, $2^\lambda = \lambda^+$ actually implies $\diamondsuit_{\lambda^+}$, so that the two are equivalent.)

Jensen abstracted his Suslin tree result to: (1) *if $V = L$, then $\diamondsuit_\kappa$ holds from every regular $\kappa > \omega$*, and (2) *if $\diamondsuit_{\omega_1}$ holds, then there is a Suslin tree.* Solovay's result was abstracted to higher, *κ-Kurepa trees*, κ-trees with at least κ^+ cofinal branches, in terms of a new cardinal concept, *ineffability*, arrived at independently by Jensen and Kunen: *If $V = L$ and $\kappa > \omega$ is regular, then $\diamondsuit_\kappa^+$ holds iff κ is not ineffable.* Ineffable cardinals, stronger than weakly compact cardinals, would soon be seen to have a range of involvements and an elegant theory. As for "higher" Suslin trees, they would involve the use of a new combinatorial principle, one that first figured in a sophisticated forcing argument.

The crowning achievement of the investigation of Suslin's Hypothesis was its joint consistency with CH, Con(ZFC) $\to$ Con(ZFC + CH + SH), established by Jensen. In the Solovay-Tennenbaum consistency proof for SH, cofinal branches had been adjoined iteratively to Suslin trees as they arose and direct limits were taken at limit stages, a limiting process that conspired to adjoin new reals so that CH fails. Jensen, with considerable virtuosity for the time, devised a way to kill Suslin trees less directly and effected the iteration according to a curtailed tree-like indexing—so that no new reals are ever adjoined. That indexing is captured by the $\kappa = \omega_1$ case of the combinatorial principle $\square_\kappa$ ("square"):

$\square_\kappa$ There is a sequence $\langle C_\alpha \mid \alpha$ a limit ordinal $< \kappa^+\rangle$ such that for $\alpha < \kappa^+$:

(a) $C_\alpha \subseteq \alpha$ is closed unbounded in α,

(b) for β a limit point of C_α, $C_\alpha \cap \beta = C_\beta$, and

(c) for $\omega \leq \mathrm{cf}(\alpha) < \kappa$, the order-type of C_α is less than κ.

$\square_\omega$ is immediate, as witnessed by any ladder system, i.e. a sequence $\langle C_\alpha \mid \alpha$ a limit ordinal $< \omega_1\rangle$ such that C_α is of order-type ω and cofinal in α. $\square_\kappa$ for $\kappa > \omega$ brings out the tension between the desired (b) and the needed (c). As such, $\square_\kappa$ came to guide many a construction of length κ^+ based on components of cardinality $< \kappa$.

$\square_\kappa$ can be adjoined by straightforward forcing with initial approximations; Jensen established: *If $V = L$, then $\square_\kappa$ holds for every κ.* As for higher Suslin trees, a *κ-Suslin tree* is expectedly a κ-tree with no chains or antichains of cardinality κ. It was actually Jensen's work on these trees that motivated his formulation of $\square_\kappa$, and he established, generalizing his result for $\kappa = \omega_1$: (1) *for any κ, $\diamondsuit_{\kappa^+}$ and $\square_\kappa$ imply that there is a κ^+-Suslin tree,* and, for limit cardinals κ, the characterization (2) *there is a κ-Suslin tree iff κ is not weakly compact.* It is a notable happenstance that Suslin's early, 1920 speculation would have such extended ramifications in modern set theory.

Jensen's results that $\square_\kappa$ holds in L and (2) above were the initial applications of his fine structure theory. Unlike Gödel who had focused with L on relative consistency, Jensen regarded the investigation of how the constructible hierarchy grows by examining its behavior at arbitrary levels as of basic and intrinsic interest. And with his fine structure theory Jensen developed a considerable and intricate machinery for this investigation. A pivotal question became: when does an ordinal α first get "singularized", i.e. what is the least β such that there is in $L_{\beta+1}$ an unbounded subset of α of smaller order-type, and what definitional complexity does this set have? One is struck by the contrast between Jensen's attention to such local questions as this one, at the heart of his proof of $\square_\kappa$, and how his analysis could lead to major large-scale results of manifest significance.

For a uniform development of his fine structure theory, Jensen switched from the hierarchy of L_α's to a hierarchy of J_α's, the *Jensen hierarchy*, where $J_{\alpha+1}$ is the closure of $J_\alpha \cup \{J_\alpha\}$ under the "rudimentary" functions (the primitive recursive set functions without the recursion scheme). For $L[A]$, there is an analogous hierarchy of J_α^A where one also closes off under the function $x \longmapsto A \cap x$. For a set N, construed as a structure with $\in$ and possibly with some $A \cap N$ as a predicate, a relation is $\Sigma_n(N)$ *iff* it is first-order definable over N by a Σ_n formula. For every α, both $\langle J_\xi \mid \xi < \alpha\rangle$ and a well-ordering $<_L$ of L restricted to J_α are Σ_1 definable over J_α *uniformly*, in that the same formula works for all the J_α's.

In these terms, fine structure addresses the classical issue of Skolem functions through definability. For $(k+1)$-ary relations R and S,

$$\begin{aligned}&R \text{ is } \textit{uniformized} \text{ by } S \quad \textit{iff}\\ &\quad S \subseteq R \text{ and } \forall \mathbf{w}(\exists y R(\mathbf{w}, y) \longleftrightarrow \exists ! y S(\mathbf{w}, y)),\end{aligned}$$

where $\exists!$ is "there exists exactly one". This amounts to the assertion that S refines R to a function on the same $\mathbf{w}$'s and is thus a form of AC. In systematic applications of the Condensation Lemma one deduces, toward the construction of Σ_1 Skolem hulls, that $\Sigma_0(J_\alpha)$, and hence $\Sigma_1(J_\alpha)$, relations are uniformizable by $\Sigma_1(J_\alpha)$ relations that choose $<_L$-least witnesses. Weaving together all such relations into one universal one, one gets a Skolem function h Σ_1 definable over J_α uniformly, with the property that for any $X \subseteq J_\alpha$ an application of h to X yields an elementary substructure of J_α.

What about $\Sigma_2(J_\alpha)$ relations? Choosing $<_L$-least witnesses as before leads only to a $\Sigma_3(J_\alpha)$ uniformizing relation, since asserting that no predecessor in the Σ_1 definable well-ordering satisfies the Σ_2 formula adds to the quantifier complexity. Jensen saw that a palatable analysis of definability stable through various transformations would require a $\Sigma_2(J_\alpha)$ uniformizing relation. He achieved this by applying the basic elements of fine structure: As a measure of the lack of closure under definability, let the *(first) projectum* $\rho_\alpha \leq \alpha$ be the least γ for which there is a $\Sigma_1(J_\alpha)$ subset of γ which is not a member of J_α. There is then a $\Sigma_1(J_\alpha)$ map of a subset of J_{ρ_α} onto J_α, essentially a Skolem function as in the previous paragraph. The $\Sigma_1(J_\alpha)$ definitions involved here can be construed as depending on one parameter in J_α, and one can fix the $<_L$-least possibility—the *standard parameter*. With this one can consider the *projectum structure* $\langle J_{\rho_\alpha}, A_\alpha \rangle$ where A_α the *standard code*—the $<_L$-least among certain *master codes*—a predicate that codes Σ_1 satisfaction for J_α so that the part of any $\Sigma_2(J_\alpha)$ relation in J_{ρ_α} can be taken to be a $\Sigma_1(\langle J_{\rho_\alpha}, A_\alpha \rangle)$ relation. The relation can then be uniformized by a $\Sigma_1(\langle J_{\rho_\alpha}, A_\alpha \rangle)$ function, one that can subsequently be projected up to be a $\Sigma_2(J_\alpha)$ uniformizing function with the available $\Sigma_1(J_\alpha)$ mapping of a subset of J_{ρ_α} onto J_α.

The foregoing sets out the salient features of fine structure theory, and Jensen carried out this analysis in general to establish for every $n \geq 1$ the Σ_n Uniformization Theorem: *For every α, every $\Sigma_n(J_\alpha)$ relation can be uniformized by a $\Sigma_n(J_\alpha)$ relation.* In truth, as often with the thrust of method, fine structure would become autonomous in that it would be the actual fine structure workings of this lemma, rather than just its statement, which would be used. Jensen also gave expression to canonicity with what is now known as the *Downward Extension of Embeddings Lemma*, which for the foregoing situation asserts that if $e : N \to \langle J_{\rho_\alpha}, A_\alpha \rangle$ is Σ_0-elementary, then N itself is the projectum structure of a unique J_β and e can be extended uniquely to a Σ_1-elementary $\overline{e} : J_\beta \to J_\alpha$. Jensen moved forward with this fine structure theory to uncover and articulate the combinatorial structure of the constructible universe.

4. Strong Hypotheses

4.1. Large Large Cardinals

With elementary embedding having emerged as a systemic concept in set theory, Solovay and William Reinhardt at Berkeley in the late 1960s formulated inter-related large cardinal hypotheses stronger than measurability. Reinhardt conceived *extendibility*, and he and Solovay independently, *supercompactness*. A cardinal κ is *γ-supercompact iff* there is an elementary embedding $j : V \to M$ for some inner model M, with critical point κ and $\gamma < j(\kappa)$ such that ${}^{\gamma}M \subseteq M$, i.e. M is closed under the taking of arbitrary γ-sequences. κ is *supercompact iff* κ is γ-supercompact for every γ. Evidently, the heuristics of generalization and reflection were at work here, as κ is measurable *iff* κ is κ-supercompact, and stronger closure properties imposed on the target model M ensure stronger reflection properties. For example, if κ is 2^{κ}-supercompact with witnessing $j : V \to M$, then $M \models$ "κ is measurable", since ${}^{2^{\kappa}}M \subseteq M$ implies that every ultrafilter over κ is in M, and so if $U_j \subseteq P(\kappa)$ is defined canonically from j by $X \in U_j$ *iff* $\kappa \in j(X)$, then $\{\xi < \kappa \mid \xi \text{ is measurable}\} \in U_j$ by Łoś's Theorem. Supercompactness was initially viewed as an ostensible strengthening of Tarski's strong compactness in that, with the focus on elementary embedding, reflection properties were directly incorporated. Whether strong compactness is actually equivalent to supercompactness became a new "identity crisis" issue.

Reinhardt entertained a *prima facie* extension of these ideas, that there is a (non-identity) elementary embedding $j : V \to V$. With suspicions soon raised, Kunen dramatically established in 1970 that this is inconsistent with ZFC by applying an Erdős-Hajnal partition relation result, a combinatorial contingency making prominent use of the Axiom of Choice. This contingency pointed out a specific lack of closure of the target model: *For any elementary embedding $j : V \to M$ with critical point κ, let λ be the supremum of $\kappa < j(\kappa) < j^2(\kappa) < \cdots$. Then, $V_{\lambda+1} \not\subseteq M$.* This lack of closure has essentially stood as the weakest known to this day.

A net of hypotheses consistency-wise stronger than supercompactness was soon cast across the conceptual space delimited by Kunen's inconsistency. For $n \in \omega$, κ is *n-huge iff* there is an elementary embedding $j : V \to M$, for some inner model M, with critical point κ such that ${}^{j^n(\kappa)}M \subseteq M$. κ is *huge iff* κ is 1-huge. If κ is huge, then $V_\kappa \models$ "there are many supercompact cardinals". Thematically close to Kunen's inconsistency were several hypotheses articulated for further investigation, e.g. there is a (non-identity) elementary embedding $j : V_\lambda \to V_\lambda$ for some λ.

The appearance of proper classes in these various formulations raises issues about legitimacy. By Tarski's "undefinability of truth", the satisfaction relation for V is not definable in ZFC, and the elementary embedding characterization of measurability already suffers from this shortcoming. However, the γ-supercompactness of κ can be analogously formulated in terms of the existence of a "normal" ultrafilter over the set $P_\kappa\gamma = [\gamma]^{<\kappa} = \{x \subseteq \gamma \mid |x| < \kappa\}$. Similarly, n-hugeness can also be recast. As for Kunen's inconsistency, his argument can be regarded as establishing: *There is no (non-identity) elementary embedding $j : V_{\lambda+2} \to V_{\lambda+2}$ for any λ.*

The details on γ-supercompactness drew out new, generalizing concepts for filters (and so, for ideals). Suppose that Z is a set and F a filter over $P(Z)$ (so $F \subseteq P(P(Z))$). Then F is *fine iff* for any $a \in Z$, $\{x \in P(Z) \mid a \in x\} \in F$. F is *normal iff* whenever f is a function satisfying $\{x \in P(Z) \mid f(x) \in x\} \in F$, i.e. f is a choice function on a set in F, there is an $a \in Z$ such that $\{x \in P(Z) \mid f(x) = a\} \in F$, i.e. f is constant on a set in F. When Z is a cardinal κ and $\kappa = \{x \in P(\kappa) \mid x \in \kappa\} \in F$, then this new normality reduces to the previous concept. With an analogous reduction to filters over $P_\kappa\gamma = [\gamma]^{<\kappa} = \{x \in P(\gamma) \mid |x| < \kappa\}$, we have the formulation: κ is γ-supercompact *iff* there is a κ-complete, fine, normal ultrafilter over $P_\kappa\gamma$. This inspired a substantial combinatorial investigation of filters over sets $P_\kappa\gamma$, and a general, structural approach to filters over sets $P(Z)$.

Whether it is in these large cardinal hypotheses or the transition from V to $V[G]$ in forcing, the appeal to the satisfaction relation for V is liberal and unabashed in modern set-theoretic practice. Yet ZFC remains parsimoniously the official theory and this carries with it the necessary burden of formalization. On the other hand, it is the formalization that henceforth carries the operative sense; for example, the ultrafilter characterization of γ-supercompactness delivers through the concreteness of the ultrapower construction critical properties that become part of the concept in its use. It has become commonplace in modern set theory that informal assertions and schematic procedures often convey an incipient intentional sense, but formalization refines that sense with workable structural articulations.

Although large large cardinals were developed particularly to investigate the possibilities for elementary embeddings and were quickly seen to have a simple but elegant basic theory, what really intimated their potentialities were new forcing results in the 1970s and 1980s, especially from supercompactness, that established new relative consistencies, even of assertions low in the cumulative hierarchy. The earliest, orienting result along these lines addressed the singular cardinals problem. The "Prikry-Silver" result provided the first instance of a failure of the Singular Cardinal Hypothesis by drawing together two results of independent significance, themselves crucial as methodological advances.

Karel Prikry in his 1968 Berkeley thesis had set out a simple but elegant notion of forcing that changed the cofinality of a measurable cardinal while not collapsing any cardinals. With U a normal κ-complete ultrafilter over κ, *(basic) Prikry forcing* for U has as conditions $\langle p, A\rangle$ where p is a finite subset of κ and $A \in U$. For conditions $\langle p, A\rangle$ and $\langle q, B\rangle$, the first is stronger than the second if $p \supseteq q$ and $\alpha \in p - q$ implies $\alpha > \max(q)$, and $A \cup (p - q) \subseteq B$. A condition thus specifies a finite initial part of a new ω-cofinalizing subset of κ, and further members are to be added on top from a set large in the sense of being in U. Applying a partition property available for normal ultrafilters, Prikry established that for any condition $\langle p, A\rangle$ and forcing statement, there is a $B \subseteq A$ such that $B \in U$ and $\langle p, B\rangle$ decides the statement, i.e. extending p is unnecessary. Hence, e.g. the κ-completeness of U implies that V_κ remains unchanged in the forcing extension yet the cofinality of κ now becomes ω.

Prikry forcing may at first have seemed a curious possibility for singularization. However, that a Prikry generic sequence also generates the corresponding U in simple fashion and also results from indiscernibles made them a central feature of measurability. Prikry forcing would be generalized in various directions and for a variety of purposes. With the capabilities made available for changing cofinalities, equi-consistency connections would eventually be established between large cardinals on the one hand and formulations in connection with the singular cardinals problem on the other.

Silver in 1971 first established the relative consistency of having a measurable cardinal κ satisfying $2^\kappa > \kappa^+$, a proposition that Kunen had shown to be substantially stronger than measurability. Forcing over the model constructed by Silver with Prikry forcing yielded the first counterexample to the Singular Cardinals Hypothesis by providing a singular strong limit cardinal κ satisfying $2^\kappa > \kappa^+$.

To establish his result, Silver provided a technique for extending elementary embeddings into generic extensions and thereby preserving large cardinal properties. To get at what is at issue, suppose that $j : V \to M$ is an elementary embedding, P is a notion of forcing, and G is V-generic for P. To extend (or "lift") j to an elementary embedding for $V[G]$, the natural scheme would be to get a M-generic G' for $j(P)$ and extend j to an elementary embedding from $V[G]$ into $M[G']$. But for this to work with the forcing terms, it would be necessary to enforce

$$(*) \qquad \forall p \in G\,(j(p) \in G').$$

For getting a measurable cardinal κ satisfying $2^\kappa = \kappa^{++}$, Silver started with an elementary embedding as above with critical point κ and devised a P for adjoining κ^{++} Cohen subsets of κ. In order to establish a close connection between P and $j(P)$ toward securing $(*)$, he took P to be a uniform iteration of forcings to adjoin λ^{++} Cohen subsets of λ for every inaccessible cardinal λ up to and including κ itself. Then with the shift from κ to $j(\kappa)$, $j(P)$ can be considered a two-stage iteration of P followed by a further iteration Q. Now with G V-generic for P, G is also M-generic for P, and in $M[G]$ one should devise an H $M[G]$-generic for Q such that the combined generic $G' = G * H$ satisfies $(*)$.

But how is this to be arranged? Silver was able to control the $j(p)$'s for $p \in G$ by a single, *(strong) master condition* $q \in Q$, and build in $V[G]$ an H $M[G]$-generic over Q with $q \in H$ to satisfy $(*)$. For getting both q and H, he needed that M be closed under arbitrary κ^{++}-sequences. Thus he established: *If κ is κ^{++}-supercompact, then there is a forcing extension in which κ is measurable and $2^\kappa = \kappa^{++}$.* (To mention an elegant coda, work of Woodin and Gitik in the 1980s showed that having a measurable cardinal satisfying $2^\kappa > \kappa^+$ is equi-consistent with having a κ with $o(\kappa) = \kappa^{++}$ in the Mitchell order.) Silver's preparatory "reversed Easton" forcing with Easton support and master condition constructions of generic filters would become staple ingredients for the generic extension of elementary embeddings.

What about the use of very strong hypotheses in consistency results? A signal, 1972 result of Kunen brought into play the strongest hypothesis to that date for establish a consistency result about the low levels of the cumulative hierarchy. Earlier, Kunen had established that having a κ-complete κ^+-saturated ideal over a successor cardinal κ had consistency strength stronger than having a measurable cardinal. Kunen now showed: *If κ is huge, then there is forcing extension in which $\kappa = \omega_1$ and there is an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1.* With a $j : V \to M$ with critical point κ, $\lambda = j(\kappa)$, and ${}^\lambda M \subseteq M$ as given by the hugeness of κ, Kunen collapsed κ to ω_1 and followed it was a collapse of λ to ω_2 in such a way so as to be able to define a saturated ideal. Crucially, the first collapse was a "universal" collapse P iteratively constructed so that the second collapse can be absorbed into $j(P)$ in a way consistent with j applied to P, and this required ${}^\lambda M \subseteq M$. Hence, a sufficient algebraic argument was contingent on a closure property for an elementary embedding, one plucked from the emerging large cardinal hierarchy. In the years to come, Kunen's argument would be elaborated and emended to become the main technique for getting various sorts of saturated ideals over accessible cardinals. As for the proposition that there is an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1 itself, Kunen's result set an initial, high bar for the stalking of its consistency strength, but definitive work of the 1980s would show that far less than hugeness suffices.

4.2. Determinacy

The investigation of the determinacy of infinite games is the most distinctive and intriguing development of modern set theory, and the correlations eventually achieved with large cardinals the most remarkable and synthetic. Notably, the mathematics of games first came to the attention of pioneers of set theory as an application of the emerging subject. Zermelo in a 1913 note discussed chess and worked with the concepts of *winning strategy* and *determined game*, and Kőnig in the paper that introduced his well-known tree lemma extended Zermelo's work to games with infinitely many positions. Von Neumann, lauding set-theoretic formulation, established the crucial minimax theorem, the result that really began the mathematical theory of games, and by the mid-1940s he and Oskar Morgenstern had codified the theory and its analysis of economic behavior, stimulating research for decades to come.

The investigation of infinitely long games that can be cast in a simple, abstract way would draw game-theoretic initiatives back into set theory. For a set X and $A \subseteq {}^\omega X$, let $G_X(A)$ denote the following "infinite two-person game with perfect information": There are two players, *I* and *II*. *I* initially chooses an $x(0) \in X$; then II chooses an $x(1) \in X$; then I chooses an $x(2) \in X$; then II chooses an $x(3) \in X$; and so forth:

$$\begin{array}{llllll} I: & x(0) & & x(2) & & \ldots \\ II: & & x(1) & & x(3) & \ldots \end{array}$$

Each player before making each of his moves is privy to the sequence of previous moves ("perfect information"); and the players together specify an $x \in {}^{\omega}X$. I wins $G_X(A)$ if $x \in A$, and otherwise II wins. A *strategy* is a function that tells a player what move to make given the sequence of previous moves. A *winning strategy* is a strategy such that if a player plays according to it he always wins no matter what his opponent plays. A is *determined* if either I or II has a winning strategy in $G_X(A)$.

David Gale and James Stewart in 1953 initiated the study of these games and observed that *if $A \subseteq {}^{\omega}X$ is open (in the product topology) then A is determined.* The simple argument turned on how membership is secured at a finite stage, and a basic stratagem in the further investigations of determinacy would be the reduction to such "open games". Focusing on the basic case $X = \omega$ and noting that a strategy then can itself be construed as a real, Gale and Stewart showed by diagonalizing through all strategies that *assuming* AC *there is an undetermined $A \subseteq {}^{\omega}\omega$.* Determinacy itself would come to be regarded as a regularity property, but there were basic difficulties from the beginning. Gale and Stewart asked whether all Borel sets of reals are determined, and in the decade that followed only sets very low in the Borel hierarchy were shown to be determined.

Infinitely long games involving reals had been considered as early as in the 1920s by mathematicians of the Polish school. With renewed interest in the subject in the 1950s, and with determinacy increasingly seen to be potent in its consequences, Jan Mycielski and Hugo Steinhaus in 1962 proposed the following axiom, now known as the *Axiom of Determinacy* (AD):

$$\text{Every } A \subseteq {}^{\omega}\omega \text{ is determined.}$$

With AD contradicting AC they proposed from the beginning that in the ZFC context the axiom should hold in some inner model. Solovay pointed out that the natural candidate $L(\mathbb{R})$, the constructible closure of the reals $\mathbb{R} = {}^{\omega}\omega$, observing that if AD holds then $\mathrm{AD}^{L(\mathbb{R})}$, i.e. AD holds in $L(\mathbb{R})$. Further restricted hypotheses would soon be applied to the tasks at hand: Projective Determinacy (PD) asserts that every projective $A \subseteq {}^{\omega}\omega$ is determined; $\mathbf{\Sigma}^1_n$-determinacy, that every $\mathbf{\Sigma}^1_n$ set A is determined; and so forth.

By 1964, games to specific purposes had been devised to show that for $A \subseteq {}^{\omega}\omega$ there is a closely related $B \subseteq {}^{\omega}\omega$ (a continuous preimage) so that if B is determined, then A is Lebesgue measurable, and similarly for the Baire property and the perfect set property. Moreover, AD does imply a limited choice principle, *every countable set consisting of sets of reals has a choice function.* Thus, the groundwork was laid for the reign of AD in $L(\mathbb{R})$ to enforce the regularity properties for all sets of reals there as well as a local choice principle, with unfettered uses of AC relegated to the universe at large.

In 1967 two results drew determinacy to the foreground of set theory, one about the transfinite and the other about definable sets of reals. Solovay established that AD *implies that* ω_1 *is measurable*, injecting emerging large cardinal techniques into a novel setting without AC. David Blackwell provided a new proof via the determinacy of open games of a classical result of Kuratowski that *the* $\mathbf{\Pi}^1_1$ *sets have the reduction property.* These results stimulated interest because of their immediacy and new approach to proof, that of devising a game and appealing to the existence of winning strategies to deduce a dichotomy. Martin in particular saw the potentialities at hand and soon made incisive contributions to investigations with and of determinacy. He initially made a simple but crucial observation based on the construal of strategies as reals that would have myriad applications; he showed that *under* AD *the filter over the Turing degrees generated by the cones is an ultrafilter.*

After seeing Blackwell's argument, Martin and Addison quickly and independently came to the idea of *assuming* determinacy hypotheses and pointed out that $\mathbf{\Delta}^1_2$-determinacy implies that $\mathbf{\Sigma}^1_3$ sets have the reduction property. Then Martin and Yiannis Moschovakis independently in 1968 extended the reduction property through the projective hierarchy by playing games and assuming PD, realizing a methodological goal of the classical descriptive set theorists by carrying out an inductive propagation. This was Martin's initial application of his ultrafilter on Turing cones, and the idea of ranking ordinal-valued functions via ultrafilters, so crucial in later arguments, first occurred here.

Already in 1964 Moschovakis had abstracted a property stronger and more intrinsic than reduction, the prewellordering property, from the classical analysis of $\mathbf{\Pi}^1_1$ sets. A relation $\preceq$ is a *prewellordering* if it is a well-ordering except possibly that there could be distinct x and y such that $x \preceq y$ and $y \preceq x$. While a well-ordering of a set A corresponds to a bijection of A into an ordinal, a prewellordering corresponds to a surjection onto an ordinal—a stratification of A into well-ordered layers. A class $\mathbf{\Gamma}$ of sets of reals has the *prewellordering property* if for any $A \in \mathbf{\Gamma}$ there is a prewellordering of A such that both it and its complement are in $\mathbf{\Gamma}$ in a strong sense. This property supplanted the reduction property in the Martin-Moschovakis First Periodicity Theorem, which implied that under PD the prewellordering property holds periodically for the projective classes: $\mathbf{\Pi}^1_1$, $\mathbf{\Sigma}^1_2$, $\mathbf{\Pi}^1_3$, $\mathbf{\Sigma}^1_4, \ldots$.

As for Solovay's result, he in fact established that *under* AD *the closed unbounded filter* $\mathcal{C}_{\omega_1}$ *is an ultrafilter* by using a game played with countable ordinals and simulating it with reals. Martin provided an alternate proof using his ultrafilter on Turing cones, and then Solovay in 1968 used Martin's approach to establish that *under* AD ω_2 *is measurable.* With an apparent trend set, quite unexpected was the next advance. Martin in 1970 established that under AD the ω_n's for $3 \leq n < \omega$ are all singular with cofinality ω_2! This was a by-product of Martin's incisive analysis of $\mathbf{\Sigma}^1_3$ sets under AD.

Martin and Solovay had by 1969 established results about the $\mathbf{\Sigma}^1_3$ sets assuming $a^\#$ exists for every $a \in {}^\omega\omega$, and Martin went on to make explicit a "Martin-Solovay" tree representation for $\mathbf{\Sigma}^1_3$ sets. Just as Shoenfield had dualized the classical tree representation of $\mathbf{\Pi}^1_1$ sets by reconstruing well-foundedness as having order-preserving ranking functions, so too Martin was able to dualize the Shoenfield tree. For this he used the existence of sharps to order ordinal-valued functions and secure important *homogeneity* properties to establish that *if $a^\#$ exists for every $a \in {}^\omega\omega$, then every $\mathbf{\Sigma}^1_3$ set is ω_2-Suslin.* This careful analysis with indiscernibles led to the aforementioned singularity of the ω_n's for $3 \leq n < \omega$ under AD.

Martin also reactivated the earlier project of securing more and more determinacy by establishing that if there is a measurable cardinal, then $\mathbf{\Pi}^1_1$-determinacy holds, or in refined terms, *if $a^\#$ exists, then $\Pi^1_1(a)$-determinacy holds.* The proof featured a remarkably simple reduction to an open game, based on indiscernibles and homogeneity properties, of form $G_X(A)$ for a set X of ordinals. This ground-breaking proof served both to make plausible the possibility of getting PD from large cardinals as well as getting $\mathbf{\Delta}^1_1$-determinacy, Borel Determinacy, in ZFC—both directions to be met with complete success in later years.

The next advance would be by way of what would become the central structural concept in the investigation of the projective sets under determinacy. The classical issue of uniformization had been left unaddressed by the prewellordering property, and so Moschovakis in 1971 isolated a strengthening abstracted from the proof of the classical, Kondô $\mathbf{\Pi}^1_1$ Uniformization Theorem. A *scale* on a set $A \subseteq {}^\omega\omega$ is an ω-sequence of ordinal-valued functions on A satisfying certain convergence and continuity properties, and a class $\mathbf{\Gamma}$ of sets of reals has the *scale property* if for any $A \in \mathbf{\Gamma}$ there is a scale on A whose corresponding graph relations are in $\mathbf{\Gamma}$ in a strong sense. Having a scale on A corresponds to having $A = p[T]$ for a tree T in such a way that, importantly, from A is definable a member of A through a minimization process ("choosing the honest leftmost branch").

Instead of carrying out a tree dualizing procedure directly à la Shoenfield and Martin-Solovay, Moschovakis used a game argument to establish the Second Periodicity Theorem, which implied that under PD the scale property, and therefore uniformization, holds for the same projective classes as for prewellordering: $\mathbf{\Pi}^1_1$, $\mathbf{\Sigma}^1_2$, $\mathbf{\Pi}^1_3$, $\mathbf{\Sigma}^1_4, \ldots$.

In the early 1970s Moschovakis, Martin, and Alexander Kechris proceeded with scales to provide a detailed analysis of the projective sets under PD in terms of Borel sets and as projections of trees, based on the *projective ordinals* $\boldsymbol{\delta}^1_n (= \underset{\sim}{\delta}^1_n)$ = the supremum of the lengths of the $\mathbf{\Delta}^1_n$ prewellorderings. For example, the $\mathbf{\Sigma}^1_{2n+2}$ sets are exactly the $\boldsymbol{\delta}^1_{2n+1}$-Suslin sets. The further analysis would be based on Moschovakis's Coding Lemma, which with determinacy provides for an arbitrary set meeting the layers of a prewellordering an appropriately definable subset meeting those same layers, and his Third Periodicity Theorem, which with determinacy asserts that when winning strategies exist there are appropriately definable such strategies. The projective ordinals themselves were subjected to considerable scrutiny, with penetrating work of Kunen particularly advancing the theory, and were found to be measurable and to satisfy strong partition properties. However, where exactly the $\boldsymbol{\delta}^1_n$ for $n \geq 5$ are in the aleph hierarchy would remain a mystery until the latter 1980s, when Steve Jackson in a *tour de force* settled the question with a deep analysis of the ultrafilters and partition properties involved. As an otherwise complete structure theory for projective sets was being worked out into the 1970s, Martin in 1974 returned to a bedrock issue for the regularity properties and established in ZFC that $\boldsymbol{\Delta}^1_1$-determinacy, Borel Determinacy, holds.

4.3. Silver's Theorem and Covering

In mid-1974 Silver established that *if κ is a singular cardinal with* $\mathrm{cf}(\kappa) > \omega$ *and $2^\lambda = \lambda^+$ for $\lambda < \kappa$, then $2^\kappa = \kappa^+$.* This was a dramatic event and would stimulate dramatic developments. There had been precious little in the way of results provable in ZFC about cardinal arithmetic, and in the early ruminations about the singular cardinals problem it was quite unforeseen that the power of a singular cardinal can be so constrained. An analogous preservation result had been observed by Scott for measurable cardinals, and telling was that Silver used large-cardinal ideas connected with generic ultrapowers.

Silver's result spurred broad-ranging investigations both into the combinatorics and avenue of proof and into larger, structural implications. The basis of his argument was a ranking of ordinal-valued functions on $\mathrm{cf}(\kappa)$. Let $\langle \gamma_\alpha \mid \alpha < \mathrm{cf}(\kappa) \rangle$ be a sequence of ordinals unbounded in κ and for $\alpha < \mathrm{cf}(\kappa)$ let $\tau_\alpha : P(\gamma_\alpha) \to 2^{\gamma_\alpha}$ be a bijection. For $X \subseteq \kappa$ let f_X on $\mathrm{cf}(\kappa)$ be defined by: $f_X(\alpha) = \tau_\alpha(X \cap \gamma_\alpha)$, noting that $X_1 \neq X_2$ implies f_{X_1} and f_{X_2} differ for sufficiently large α. Then 2^κ is mirrored through these eventually different functions, which one can work to order according to an ideal over the uncountable $\mathrm{cf}(\kappa)$. The combinatorial possibilities of such rankings led to a series of limitative results on the powers of singular cardinals of uncountable cofinality, starting with the results of Fred Galvin and Hajnal, of which the paradigmatic example is that if $\aleph_{\omega_1}$ is a strong limit cardinal, then $2^{\aleph_{\omega_1}} < \aleph_{(2^{\aleph_1})^+}$.

In the wake of Silver's proof, Jech and Prikry defined a κ-complete ideal over κ to be *precipitous iff* the corresponding generic ultrapower à la Solovay is well-founded. They thus put the focus on a structural property of saturated ideals that Silver had simulated to such good effect. Jech and Prikry pointed out that a proof of Kunen's for saturated ideals using iterated ultrapowers can be tailored to show: *If there is a precipitous ideal over κ, then κ is measurable in an inner model.* Then Mitchell showed: *If a measurable cardinal is Levy collapsed to ω_1, then there is a precipitous ideal over ω_1.* Hence, a first equi-consistency result was achieved for measurability and ω_1.

With combinatorial characterizations of precipitousness soon in place, well-foundedness as thus modulated by forcing became a basic ingredient in a large-scale investigation of strong properties tailored to ideals and generic elementary embeddings.

The most dramatic and penetrating development from Silver's Theorem was Jensen's work on covering for L and its first extensions, the most prominent advances of the 1970s in set theory. Jensen had found Silver's result a "shocking discovery", and was stimulated to intense activity. By the end of 1974 he had made prodigious progress, solving the singular cardinals problem in the absence of $0^\#$ in three manuscripts, "Marginalia to a Theorem of Silver" and its two sequels. The culminating result featured an elegant and focal formulation of intuitive immediacy, the Covering Theorem (or "Lemma") for L: *If $0^\#$ does not exist, then for any uncountable set X of ordinals there is a $Y \in L$ with $|Y| = |X|$ such that $Y \supseteq X$.* (Without the "uncountable" there would be a counterexample using "Namba forcing".) This covering property expresses a global affinity between V and L, and its contrapositive provides a surprisingly simple condition sufficient for the existence of $0^\#$ and the ensuing indiscernible generation of L. As such, Jensen's theorem would find wide applications for implicating $0^\#$ and would provide a new initiative in inner model theory for encompassing stronger hypotheses.

The Covering Theorem gave the essence of Jensen's argument that in the absence of $0^\#$ the Singular Cardinals Hypotheses holds: Suppose that κ is singular and for reckoning with the powers of smaller cardinals consider $\lambda = \sup\{2^\mu \mid \mu < \kappa\}$. If there is a $\nu < \kappa$ such that $\lambda = 2^\nu$, then the functions f_X defined as above adapted to the present situation satisfy $f_X : \mathrm{cf}(\kappa) \to 2^\nu$, and so $\lambda \leq 2^\kappa \leq (2^\nu)^{\mathrm{cf}(\kappa)} \leq \lambda$. If on the other hand λ is the strict supremum of increasing 2^μ's, then $\mathrm{cf}(\lambda) = \mathrm{cf}(\kappa)$ and so the Zermelo-Kőnig inequality would dictate the least possibility for 2^κ to be λ^+. However, if for any $X \subseteq \kappa$ the range of f_X is covered by a $Y \subseteq \lambda$ with $Y \in L$ of cardinality $\mathrm{cf}(\kappa) \cdot \aleph_1$, then: there are $2^{\mathrm{cf}(\kappa)\cdot\aleph_1}$ subsets of each such Y and by the GCH in L, at most $|\lambda^{+L}|$ such Y. Hence, we would have $2^\kappa \leq 2^{\mathrm{cf}(\kappa)\cdot\aleph_1} \cdot |\lambda^{+L}| \leq \lambda^+$.

The Covering Theorem also provided another dividend that would grow in separate significance as having *weak covering property*: *Assume that $0^\#$ does not exist. If κ is singular, then $\kappa^{+L} = \kappa^+$.* If to the contrary $\kappa^{+L} < \kappa^+$, then $\mathrm{cf}(\kappa^{+L}) < \kappa$. Let $X \subseteq \kappa^{+L}$ be unbounded so that $|X| < \kappa$ and let $Y \in L$ cover X with $|Y| = |X| \cdot \aleph_1$. But then, the order-type of Y would be less than κ, contradicting the regularity of κ^{+L} in L.

A crucial consequence of weak covering is that *in the absence of $0^\#$, $\square_\kappa$ holds for singular κ*, since a $\square_\kappa$ sequence in the sense of L is then a $\square_\kappa$ sequence in V. The weak covering property would itself become pivotal in the study of inner models corresponding to stronger and stronger hypotheses, and the failure of $\square_\kappa$ for singular κ would become a delimitative proposition. Solovay had already established an upper bound on consistency by showing in the early 1970s that *if κ is λ^+-supercompact and $\lambda \geq \kappa$, then $\square_\lambda$ fails.*

Jensen's ingenious proof of the Covering Theorem for L proceeded by taking a counterexample X to covering with $\tau = \sup(X)$ and $|X|$ minimal; getting a certain Σ_1-elementary $j : J_\gamma \to J_\tau$ which contains X in its range through a Skolem hull construction so that $|\gamma| = |X|$ and, as X cannot be covered, γ is a cardinal in L; and extending j to an elementary embedding from L into L, so that $0^\#$ exists. The procedure for extending j up to some large J_δ was to consider a directed system of embeddings of structures generated by $\xi \cup p$ for some $\xi < \gamma$ and p a finite subset of J_δ, the transitized components of the system all being members of J_γ as γ is a cardinal in L, and to consider the corresponding directed system consisting of the j images. The choice of γ insured that the new directed system is also well-founded, and so isomorphic to some J_ζ. For effecting embedding extendibility, Jensen established the fine structural *Upward Extension of Embeddings Lemma*, according to which if N is the projectum structure for J_α and a Σ_1-elementary $e : N \to M$ is *strong* in that it preserves the well-foundedness of Σ_1 relations, then M itself is the projectum structure of some unique J_β and e can be extended uniquely to a Σ_1-elementary $\overline{e} : J_\alpha \to J_\beta$.

How can the proof of the Covering Theorem be adapted to establish a stronger result? The only possibility was to consider a larger inner model M and to establish that M has the *covering property*: for any uncountable set X of ordinals there is a $Y \in M$ with $|Y| = |X|$ such that $Y \supseteq X$. In groundbreaking work for inner model theory, Solovay in the early 1970s had developed a fine structure theory for inner models of measurability. Whilst a research student at Oxford University Anthony Dodd worked through this theory, and in early 1976 he and Jensen laid out the main ideas for extending the Covering Theorem to a new inner model, now known as the *Dodd-Jensen core model*, denoted K^{DJ}.

If $\langle L[U], \in, U\rangle$ is an inner model of measurability, say the κ-model, then there is a generic extension in which covering fails: If G is Prikry generic for U over $L[U]$, then G cannot be covered by any set in $L[U]$ of cardinality less than κ. Drawing back, there remains the possibility of "iterating out" the measurable cardinal: If $\langle L[U], \in, U\rangle$ is the κ-model, then $\langle L[W], \in, W\rangle$ is the λ-model for some $\lambda > \kappa$ exactly when it is an iterate of $\langle L[U], \in, U\rangle$, in which case $L[W] \subseteq L[U]$, $V_\kappa \cap L[U] = V_\kappa \cap L[W]$, and $U \notin L[W]$. Thus, if $\langle L[U_\alpha] \mid \alpha \in \mathrm{On}\rangle$ enumerates the inner models of measurability, then starting with any one of them, the process of iterating it through the ordinals converges to a proper class $\bigcap_\alpha L[U_\alpha]$ which has no inner models of measurability, with the stabilizing feature that for any γ, $V_\gamma \cap \bigcap_\alpha L[U_\alpha] = V_\gamma \cap L[U_\beta]$ for sufficiently large β. Assuming that there are inner models of measurability, K^{DJ} is in fact characterizable as this residue class. Aspiring to this, but without making any such assumption, Dodd and Jensen provided a formulation of K^{DJ} in ZFC.

K^{DJ} was the first inner model of ZFC since Gödel's L developed using distinctly new generating principles. Dodd and Jensen's approach was to take K^{DJ} as the union of L together with "mice". Loosely speaking, a *mouse* is a set $L_\alpha[U]$ such that

$$\langle L_\alpha[U], \in, U\rangle \models U \text{ is a normal ultrafilter over } \kappa$$

satisfying: (i) there is a subset of κ in $L_{\alpha+1}[U] - L_\alpha[U]$, so that U is on the verge of not being an ultrafilter; (ii) $\langle L_\alpha[U], \in, U\rangle$ is iterable in that all the iterated ultrapowers are well-founded; and (iii) fine structure conditions about a projectum below κ leading to (i). Mice can be compared by taking iterated ultrapowers, so that there is a natural prewellordering of mice, and moreover, crucial elements about L can be lifted to the new situation because there is a generalization of condensation: Σ_1-elementary substructures of mice, when transitized, are again mice. This led to $K^{\mathrm{DJ}} \models \mathrm{GCH}$, and that K^{DJ} in the sense of K^{DJ} is again K^{DJ}.

Mice generate indiscernibles through iteration, and so if $0^\#$ does not exist, then $K^{\mathrm{DJ}} = L$; if $0^\#$ exists but $0^{\#\#}$ does not, then $K^{\mathrm{DJ}} = L[0^\#]$; and this continues through the transfinite by coding sequences of sharps. On the other hand, K^{DJ} has no simple constructive analysis from below and is rather like a maximal inner model on the brink of measurability: Its own "sharp", that there is an elementary embedding $j : K \to K$, is equivalent to the existence of an inner model of measurability. Indeed, this was Dodd and Jensen's primary motivation for the formulation of K^{DJ}. They used it in place of the elementary embedding characterization of the existence of $0^\#$, together with the L-like properties of K^{DJ}, to establish the *Covering Theorem for* K^{DJ}*: If there is no inner model of measurability, then* K^{DJ} *has the covering property.* This has the attendant consequences for the singular cardinals problem. Moreover, Dodd and Jensen were able to establish a covering result for inner models of measurability that accommodates Prikry forcing. Solovay had devised a set of integers $0^\dagger$ ("zero dagger"), analogous to $0^\#$, such that $0^\dagger$ exists exactly when for some κ-model $L[U]$ there is an elementary embedding $j : L[U] \to L[U]$ with critical point above κ. Dodd and Jensen established: *If* $0^\dagger$ *does not exist yet there is an inner model of measurability, then for the* κ*-model* $L[U]$ *with* κ *least, either* (a) $L[U]$ *has the covering property, or* (b) *there is a Prikry generic* G *for* U *over* $L[U]$ *such that* $L[U][G]$ *has the covering property.* Prikry forcing provides the only counterexample to covering! Hence, the inner models thus far considered were also "core models", models on the brink so that the lack of covering leads to the next large cardinal hypothesis.

In the light of the Dodd-Jensen work, Mitchell in the later 1970s developed the core model $K[\mathcal{U}]$ for coherent sequences $\mathcal{U}$ of ultrafilters, which corresponds to his $L[\mathcal{U}]$ as K^{DJ} does to $L[U]$. The mice are now sets of form $J_\alpha[W]$ with iterability and fine structure properties, where W is an ultrafilter sequence with $\mathcal{U}$ as an initial segment. Under the assumption that there is no inner model satisfying $\exists\kappa(o(\kappa) = \kappa^{++})$, Mitchell established the weak covering property for $K[\mathcal{U}]$, i.e. that $(\kappa^+)^{K[\mathcal{U}]} = \kappa^+$ for singular κ. With this he showed that several propositions have at least the consistency strength of $\exists\kappa(o(\kappa) = \kappa^{++})$. One such proposition was that there is an $\aleph_1$-complete

$\aleph_2$-saturated ideal over ω_1, establishing a new lower bound in consistency strength for Kunen's consistency result from a huge cardinal. Mitchell eventually established, generalizing the Dodd-Jensen result with Prikry generic sets, a full covering theorem for $K[\mathcal{U}]$ cast in terms of coherent systems of indiscernibles and drew further conclusions about singular cardinals.

4.4. Forcing Consistency Results

Through the 1970s a wide range of forcing consistency results were established at a new level of sophistication that clarified relationships among combinatorial propositions and principles and often drew in large cardinal hypotheses and stimulated the development of method, especially in iterated forcing. A conspicuous series of results resolved questions of larger mathematics (Whitehead's Problem, Borel's Conjecture, Kaplansky's Conjecture, the Normal Moore Space Problem) in terms of relative consistency and set-theoretic principles, newly affirming the efficacy and adjudicatory character of set theory. In what follows, as we have begun to already, we pursue the larger longitudinal themes and results, necessarily saying less and less about matters of increasing complexity.

Much of the early formative work on strong large cardinal hypotheses and their integration into modern set theory through consistency results was carried out by Menachem Magidor, whose subsequent, broad-ranging initiatives have considerably advanced the entire subject. After completing his Hebrew University thesis in 1972 on supercompact cardinals, Magidor in the 1970s established a series of penetrating forcing consistency results involving strong hypotheses. In 1972–1973 he illuminated the "identity crisis" issue of whether supercompactness and strong compactness are distinct concepts by establishing: (1) *It is consistent that the least supercompact cardinal is also the least strong compact cardinal*, and (2) *It is consistent that the least strong compact cardinal is the least measurable cardinal (and so much smaller than the least supercompact cardinal).* The proofs showed how changing many cofinalities with Prikry forcing to destroy measurable cardinals can be integrated into arguments about extending elementary embeddings.

In 1974 Magidor made a basic contribution to the theory of changing cofinalities, the first after Prikry. Magidor established: *If a measurable cardinal κ is of Mitchell order $o(\kappa) \geq \lambda$ for a regular $\lambda < \kappa$, then there is a forcing extension preserving cardinals in which* $\mathrm{cf}(\kappa) = \lambda$. Generalizing Prikry forcing, Magidor's conditions consisted of a finite sequence of ordinals and a sequence of sets drawn from normal ultrafilters in the Mitchell order, the sets providing for the possible ways of filling out the sequence. Like Prikry's forcing, Magidor's may at first have seemed a curious possibility for a new singularization. However, one of the subsequent discernments of Mitchell's core model for coherent sequences of measures is that, remarkably: *If a regular cardinal κ in V satisfies $\omega < \mathrm{cf}(\kappa) < \kappa$ in a generic extension, then V has an inner model in which $o(\kappa)$ is at least that cofinality.* Thus, the capability of changing cofinalities was exactly gauged; "Prikry-Magidor" generic sets as sequences of indiscernibles would become a basic component of Mitchell's covering work.

The most salient results of Magidor's of this period were two of 1976 that provided counterweight to Jensen's covering results on the singular cardinal problem. Magidor showed: (1) *If κ is supercompact, there is a forcing extension in which κ is $\aleph_\omega$ as a strong limit cardinal yet* $2^{\aleph_\omega} > \aleph_{\omega+1}$, and (2) *If κ is a huge cardinal, then there is a forcing extension in which $\kappa = \aleph_\omega$, $2^{\aleph_n} = \aleph_{n+1}$ for $n \in \omega$, yet $2^{\aleph_\omega} > \aleph_{\omega+1}$.* Thus, forcing arguments showed that the least singular cardinal can be a counterexample to the Singular Cardinals Hypothesis; the strong elementary embedding hypotheses allowed for an elaborated Prikry forcing interspersed with Levy collapses. The Prikry-Silver and the Magidor results showed through initial incursions of Prikry forcing how to arrange high powers for singular strong limit cardinals; it would be one of the great elaborations of method that equi-consistency results would eventually be achieved with weaker hypotheses.

With respect to the Jech-Prikry-Mitchell equi-consistency of measurability and precipitousness, Magidor showed that absorptive properties of the Levy collapse of a measurable cardinal to ω_1 can be exploited by subsequently "shooting" closed unbounded subsets of ω_1 through stationary sets to get: *If there is a measurable cardinal κ, then there is a forcing extension in which $\kappa = \omega_1$ and NS_{ω_1} is precipitous.* Thus a basic, definable ideal can be precipitous, and this naturally became a principal point of departure for the investigation of ideals.

The move of Saharon Shelah into set theory in the early 1970s brought in a new and exciting sense of personal initiative that swelled into an enhanced purposiveness across the subject, both through his solutions of major outstanding problems as well as through his development of new structural frameworks. A phenomenal mathematician, Shelah from his 1969 Hebrew University thesis on has worked in model theory and eventually infused it with a transformative, abstract classification theory for models. In both model theory and set theory he has remained eminent and has produced results at a furious pace, with nearly 1000 items currently in his bibliography (his papers are currently archived at http://shelah.logic.at/).

In set theory Shelah was initially stimulated by specific problems. He typically makes a direct, frontal attack, bringing to bear extraordinary powers of concentration, a remarkable ability for sustained effort, an enormous arsenal of accumulated techniques, and a fine, quick memory. When he is successful on the larger problems, it is often as if a resilient, broad-based edifice has been erected, the traditional serial constraints loosened in favor of a wide, fluid flow of ideas, and the final result almost incidental to the larger structure. *What* has been achieved is more than a just succinctly stated theorem but rather the erection of a whole network of robust arguments.

Shelah's written accounts have acquired a certain notoriety that in large part has to do with his insistence that his edifices be regarded as autonomous conceptual constructions. Their life is to be captured in the most general forms, and this entails the introduction of many parameters. Often, the network of arguments is articulated by complicated combinatorial principles and transient hypotheses, and the forward directions of the flow are rendered as elaborate transfinite inductions carrying along many side conditions. The ostensible goal of the construction, that succinctly stated result that is to encapsulate it, is often lost in a swirl of conclusions.

Shelah's first and very conspicuous advance in set theory was his 1973, definitive results on Whitehead's Problem in abelian group theory: Is every Whitehead group, an abelian group G satisfying $\mathrm{Ext}^1(G, \mathbb{Z}) = 0$, free? Shelah established that $V = L$ implies that this is so, and that Martin's Axiom implies that there is a counterexample. Shelah thus established for the first time that a strong purely algebraic statement is undecidable in ZFC. With his L result specifically based on diamond-type principles, Shelah brought them into prominence with his further work on them, which were his first incursions into iterated forcing. As if to continue to get his combinatorial bearings, Shelah successfully attacked several problems on an Erdős-Hajnal list for partition relations, developing in particular a "canonization" theory for singular cardinals. By the late 1970s his increasing understanding of and work in iterated forcing would put a firm spine on much of the variegated forcing arguments about the continuum.

With an innovative argument pivotal for iterated forcing, Richard Laver in 1976 established the consistency of Borel's conjecture: *Every set of reals of strong measure zero is countable.* CH had provided a counterexample, and Laver established the consistency with $2^{\aleph_0} = \aleph_2$. His argument featured the adjunction of what are now called *Laver reals* in the first clearly set out *countable support iteration*, i.e. an iteration with non-trivial local conditions allowed only at countably many coordinates. The earlier Solovay-Tennenbaum argument for the consistency of MA had relied on finite support, and a Mitchell argument about Aronszajn trees, on an involved countable support with a "termspace" forcing, which would also find use. Laver's work showed that countable support iteration is both manageable and efficacious for preserving certain framing properties of the continuum to establish the consistency of propositions with $2^{\aleph_0} = \aleph_2$. Interestingly, a trade-off would develop however: while finite support iterations put all cardinals $\geq \aleph_2$ on an equal footing with respect to the continuum, countable support iterations restricted the continuum to be at most $\aleph_2$. With a range of new generic reals coming into play with the widening investigation of the continuum, James Baumgartner formulated a property common to the corresponding partial orders, *Axiom A*, which in particular ensured the preservation of ω_1. He showed that the countable support iteration of Axiom A forcings is Axiom A, thereby uniformizing the iterative adjunction of the known generic reals.

All this would retrospectively have a precursory air, as Shelah soon established a general, subsuming framework. Analyzing Jensen's consistency argument for SH + CH and coming to grips with forcing names in iterated forcing, Shelah came to the concept of *proper forcing* as a general property that preserves ω_1 and is preserved in countable support iterations. The instrumental formulation of properness is given in an appropriately broad setting:

First, for a regular cardinal λ, let $H(\lambda) = \{x \mid |\mathrm{tc}(\{x\})| < \lambda\}$, the sets hereditarily of cardinality less than λ. The $H(\lambda)$'s provide another cumulative hierarchy for V, one stratified into layers that each satisfy Replacement; whereas the V_α's for limit α satisfy every ZFC axiom except possibly Replacement, the $H(\lambda)$'s satisfy every ZFC axiom except possibly Power Set. A partial order $\langle P, < \rangle$ is *proper* if for any regular $\lambda > 2^{|P|}$ and countable $M \prec H(\lambda)$ with $P \in M$, every $p \in P \cap M$ has a $q \leq p$ such that $q \Vdash \dot{G} \cap M$ is M-generic. (Here, $\dot{G}$ a canonical name for a generic filter with respect to P, and q forcing this genericity assertion has various combinatorial equivalents.)

A general articulation of how all countable approximations are to have generic filters has been achieved, and its countable support iteration exhibited the efficacy of this remarkable move to a new plateau. Shelah soon devised variants and augmentations, and in a timely 1982 monograph *Proper Forcing* revamped forcing for combinatorics and the continuum with systemic proofs of new and old results. Proper forcing, presented in Chap. 5 of this Handbook, has become a staple part of the methods of modern set theory, with its applications wide-ranging and the development of its extended theory a fount of research.

In light of Shelah's work and Martin's Axiom, Baumgartner in the early 1980s established the consistency of a new encompassing forcing axiom, the *Proper Forcing Axiom* (PFA): *For any proper partial order P and collection $\mathcal{D}$ of $\aleph_1$ dense subsets of P, there is a filter $G \subseteq P$ meeting every member of $\mathcal{D}$.* Unlike MA, the consistency of PFA required large cardinal strength and moreover could not be achieved by iteratively taking care of the partial orders at issue, as new proper partial orders occur arbitrarily high in the cumulative hierarchy. Baumgartner established: *If there is a supercompact cardinal κ, then there is a forcing extension in which $\kappa = \omega_2$ and* PFA *holds.* In an early appeal to the full global reflection properties available at a supercompact cardinal Baumgartner iteratively took care of the emerging proper partial orders along a special diamond-like sequence that anticipates all possibilities. Laver first formulated this sequence, the "Laver diamond", toward establishing what has become a useful result for forcing theory; in a forcing extension he made a supercompact cardinal "indestructible" by any further forcing from a substantial, useful class of forcings. PFA became a widely applied forcing axiom, showcasing Shelah's concept, but beyond that, it would itself become a pivotal hypothesis in the large cardinal context.

Two points of mathematical practice should be mentioned in connection with Shelah's move into set theory. First, through his work with proper forcing it has become routine to appeal in proofs to structures $\langle H(\lambda), \in, <^*, \ldots \rangle$ for regular λ sufficiently large, with $<^*$ some well-ordering of $H(\lambda)$ and $\ldots$ including all the sets concerned. One then develops systems of elementary substructures generated uniformly by Skolem functions defined via $<^*$. This technique, in providing some of the structure available in L-like inner models, has proved highly efficacious over a wide range from combinatorics to large cardinals.

Second, several of a developing Israeli school in set theory have followed Shelah in writing "$p > q$" for p being a stronger condition than q instead of "$p < q$". The former is argued for as more natural, whereas the latter had been motivated structurally by Boolean algebras. This revisionism has no doubt led to confusion, until one realizes that it is a particular stamp of the Israeli school.

5. New Expansion

5.1. Into the 1980s

The 1980s featured a new and elaborating expansion in set theory significantly beyond the successes, already remarkable, of the previous decade. There were new methods and results of course, but more than that there were successful *maximizations* in several directions—definitive and evidently optimal results—and successful *articulations* at the interstices—new concepts and refinements that filled out the earlier explorations. A new wave of young researchers entered the fray, including the majority of the authors contributing to this Handbook, soon to become the prominent experts in their respective, newly variegated subfields. Our narrative now becomes even more episodic in increasingly inverse relation to the broad-ranging and penetrating developments, leaving accounts of details and some whole subjects to the chapter summaries at the end.

In 1977 Lon Radin toward his Berkeley thesis developed an ultimate generalization of the Prikry and Magidor forcings for changing cofinalities, a generalization that could in fact adjoin a closed unbounded subset, consisting of formerly regular cardinals, to a large cardinal κ while maintaining its regularity and further substantive properties. As graduate students at Berkeley, Hugh Woodin and Matthew Foreman saw the possibilities abounding in Radin forcing. While an undergraduate at Caltech Woodin did penetrating work on the consistency of Kaplansky's Conjecture (Is every homomorphism on the Banach algebra of continuous functions on the unit interval continuous?) and now with Radin forcing in hand would produce his first series of remarkable results. By 1979 Foreman and Woodin had the essentials for establishing: *If there is a supercompact cardinal κ, then there is forcing extension in which V_κ as a model of* ZFC *in which* GCH *fails everywhere, i.e. $2^\lambda > \lambda$ for every λ.* This conspicuously subsumed the Magidor result getting $\aleph_\omega$ a strong limit yet $2^{\aleph_\omega} > \aleph_{\omega+1}$ and put Radin forcing on the map for establishing global consistency results.

Shelah soon established two re-orienting results about powers of singular cardinals. Having come somewhat late into the game after Silver's Theorem, Shelah had nonetheless extended some of the limitative results about such powers, even to singular κ such that $\aleph_\kappa = \kappa$. Shelah subsequently established: *If there is a supercompact cardinal κ and α is a countable ordinal, then there is a forcing extension in which κ is $\aleph_\omega$ as a strong limit cardinal yet* $2^{\aleph_\omega} = \aleph_{\alpha+1}$. He thus extended Magidor's result by showing that the power of $\aleph_\omega$ can be made arbitrarily large below $\aleph_{\omega_1}$. In 1980 Shelah established the general result that *for any limit ordinal δ, $\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$, so that in particular if $\aleph_\omega$ is a strong limit cardinal, then* $2^{\aleph_\omega} < \aleph_{(2^{\aleph_0})^+}$. Not only was he able to get an absolute upper bound in ZFC, but he had brought countable cofinality, the one cofinality unattended to by Silver's Theorem, into the scheme of things. Shelah's argument, based on the possible cofinalities of "reduced products" of a cofinal subset of $\aleph_\delta$, would evolve into a generally applicable method by the late 1980's, the remarkable *pcf theory.*

In 1978, Mitchell made a new breakthrough for the inner model theory of large large cardinals by developing such a model for "hypermeasurable cardinals", e.g. a measurable cardinal κ such that for some normal ultrafilter U over κ, $P(P(\kappa)) \subseteq \mathrm{Ult}(V, U)$, so that every ultrafilter over κ is in the ultrapower. This at least captured a substantial consequence of the 2^κ-supercompactness of κ, and so engendered the hope of getting L-like inner models for such strong hypotheses. Supercompactness, while increasingly relied on in relative consistency results owing to its reflection properties, was out of reach, but the Mitchell result suggested an appropriate weakening: A cardinal κ is *α-strong iff* there is an elementary embedding $j : V \to M$ for some inner model M, with critical point κ and $\alpha < j(\kappa)$ such that $V_\alpha \subseteq M$. (One can alternately require that the αth iterated power set $P^\alpha(\kappa)$ be a subset of M, which varies the definition for small α like $\alpha = 2$ but makes the definition more germane for them.) κ is *strong iff* it is α-strong for every α.

Dodd and Jensen soon simplified Mitchell's presentation in what turned out to be a basic methodological advance for the development of inner model theory. While introducing certain redundancies, they formulated a general way of analyzing an elementary embedding in terms of *extenders.* The idea, anticipated in Jensen's proof of the Covering Theorem, is that elementary embeddings between inner models can be approximated arbitrarily closely as direct limits of ultrapowers with concrete features reminiscent of iterated ultrapowers.

Suppose that N and M are inner models of ZFC, $j : N \to M$ is elementary with a critical point κ, and $\beta > \kappa$. Let $\zeta \geq \kappa$ be the least ordinal satisfying $\beta \leq j(\zeta)$; the simple ("short") case is $\zeta = \kappa$, and the general case is for the study of stronger hypotheses. For each finite subset a of β, define E_a by:

$$X \in E_a \quad \textit{iff} \quad X \in P([\zeta]^{|a|}) \cap N \ \wedge \ a \in j(X).$$

This is another version of generating ultrafilters from embeddings. E_a may not be in N, but $\langle N, \in, E_a \rangle \models$ "E_a is a κ-complete ultrafilter over $[\zeta]^{|a|}$". The (κ, β)-*extender derived from j* is $E = \langle E_a \mid a \text{ is a finite subset of } \beta \rangle$.

For each finite subset a of β, $\mathrm{Ult}(N, E_a)$ is seen to be elementarily embeddable into M, so that in particular $\mathrm{Ult}(N, E_a)$ is well-founded and hence identified with its transitive collapse, say M_a. Next, for $a \subseteq b$ both finite subsets of β, corresponding to how members of a sit in b there is a natural elementary embedding $i_{ab} : M_a \to M_b$. Finally,

$$\langle\langle M_a \mid a \text{ is a finite subset of } \beta\rangle, \langle i_{ab} \mid a \subseteq b\rangle\rangle$$

is seen to be a directed system of structures with commutative embeddings, so stipulate that $\langle M_E, \in_E\rangle$ is the direct limit, and let $j_E : N \to M_E$ be the corresponding elementary embedding. We thus have the *extender ultrapower* of N by E as a direct limit of ultrapowers. The crucial point is that the direct limit construction ensures that j_E and M_E approximate j and M "up to β", e.g. if $|V_\alpha|^M \leq \beta$, then $|V_\alpha|^M = |V_\alpha|^{M_E}$, i.e. the cumulative hierarchies of M and M_E agree up to α. Having formulated extenders derived from an embedding, a (κ, β)-*extender* is a sequence $E = \langle E_a \mid a \text{ is a finite subset of } \beta\rangle$ that satisfies various abstracted properties that enable the above construction.

In a manuscript circulated in 1980, Dodd and Jensen worked out inner models for strong cardinals. Building on the previous work of Mitchell, Dodd and Jensen formulated *coherent sequences of extenders*, built inner models relative to such, and established GCH in these models. The arguments were based on extending the established techniques of securing iterability and comparison through coiteration. The GCH result was significant as precursory for the further developments in inner model theory based on "iteration trees". Thus, with extenders the inner model theory was carried forward to encompass strong cardinals, newly arguing for the coherence and consistency of the concept. There would however be little further progress until 1985, for the aspiration to encompass stronger hypotheses had to overcome the problem of "overlapping extenders", having to carry out comparison through coiteration for local structures built on (κ_1, β_1)-extenders and (κ_2, β_2)-extenders with $\kappa_1 \leq \kappa_2 < \beta_1$. The difficulty here is one of "moving generators": if an extender ultrapower is taken with a (κ_1, β_1)-extender and then with a (κ_2, β_2)-extender, then $\kappa_2 < \beta_1$ implies that the generating features of the first extender ultrapower has been shifted by the second ultrapower and so one can no longer keep track of that ultrapower in the coiteration process. In any event, a crucial inheritance from this earlier work was the *Dodd-Jensen Lemma* about the minimality of iterations copied across embeddings, which would become crucial for all further work in inner model theory.

In the direction of combinatorics and the study of continuum, there was considerable elaboration in the 1970s and into the 1980s, particularly as these played into the burgeoning field of *set-theoretic topology.* Not only were there new elucidations and new transfinite topological examples, but large cardinals and even the Proper Forcing Axiom began to play substantial roles in new relative consistency results. The 1984 *Handbook of Set-Theoretic Topology* summed up the progress, and its many articles set the tone for further work.

In particular, Eric van Douwen's article provided an important service by standardizing notation for the cardinal characteristics, or invariants, of the continuum in terms of the lower case Fraktur letters. We have discussed the dominating number $\mathfrak{d}$, the least cardinality of a subset of Baire space cofinal under eventual dominance $<^*$. There is the *bounding number* $\mathfrak{b}$, the least cardinality of a subset of Baire space unbounded under eventual dominance $<^*$; there is the *almost disjoint number* $\mathfrak{a}$, the least cardinality of a subset of $P(\omega)$ consisting of infinite sets pairwise having finite intersection; there is a *splitting number* $\mathfrak{s}$, the least cardinality of a subset $S \subseteq P(\omega)$ such that any infinite subset of ω has infinite intersection with both a member of S and its complement; and, now, many more. The investigation of the possibilities for the cardinality characteristics and their ordering relations with each other would itself have sustained interest in the next decades, becoming a large theory to which both Chaps. 6 and 7 of this Handbook are devoted.

Conspicuous in combinatorics and topology would be the work of Stevo Todorcevic. Starting with his doctoral work with Kurepa in 1979 he carried out an incisive analysis of uncountable trees—Suslin, Aronszajn, Kurepa trees and variants—and their linearizations and isomorphism types. In 1983 he dramatically re-oriented the sense of strength for the Proper Forcing Axiom by showing that PFA *implies that* $\Box_\kappa$ *fails for every* $\kappa > \omega$. PFA had previously been shown consistent relative to the existence of a supercompact cardinal. With the failure of $\Box_\kappa$ for singular κ having been seen as having quite substantial consistency strength, PFA was itself seen for the first time as a very strong proposition. Todorcevic would go from strength to strength, making substantial contributions to the theory of partition relations, eventually establishing definitive results about ω_1 as the archetypal uncountable order-structure. His chapter in this Handbook presents that single-handedly developed combinatorial theory of sequences and walks.

Starting in 1980 Foreman made penetrating inroads into the possibilities for very strong propositions holding low in the cumulative hierarchy based on the workings of generic elementary embeddings. Extending Kunen's work and deploying Silver's master condition idea, Foreman initially used 2-huge cardinals to get model-theoretic transfer principles to hold and saturated ideals to exist among the range of $\aleph_n$'s. He would soon focus on generic elementary embeddings and corresponding ideals themselves, even making them postulational for set theory. This general area of research has become fruitful, multi-faceted, and enormous, as detailed in Foreman's chapter on this subject in this Handbook.

In a major 1984 collaboration in Jerusalem, Foreman, Magidor, and Shelah established penetrating results that led to a new understanding of strong propositions and the possibilities with forcing. The focus was on a new, maximal forcing axiom: A partial order P *preserves stationary subsets of* ω_1 *iff* stationary subsets of ω_1 remain stationary in any forcing extension by P, and with this we have *Martin's Maximum* (MM): *For any* P *preserving stationary subsets of* ω_1 *and collection* $\mathcal{D}$ *of* $\aleph_1$ *dense subsets of* P*, there is a filter* $G \subseteq P$ *meeting every member of* $\mathcal{D}$*.* This subsumes PFA and is a maximally strong forcing axiom in that there is a P which does not preserve stationary subsets of ω_1 for which the conclusion fails. Foreman, Magidor, and Shelah established: *If there is a supercompact cardinal κ, then there is a forcing extension in which $\kappa = \omega_2$ and* MM *holds.*

Shelah had considered a weakening of properness called *semiproperness*, a notion for forcing that could well render uncountable cofinalities countable. To iterate such forcings, it had to be faced that the countable cofinality of limit stages cannot be ascertained in advance, and so he developed *revised countable support iteration* (RCS) based on names for the limit stage indexing. Foreman, Magidor, and Shelah actually carried out Baumgartner's PFA consistency proof for semiproper forcings with RCS iteration to establish the consistency of the analogous *Semiproper Forcing Axiom* (SPFA). Their main advance was that, although a partial order that preserves stationary subsets of ω_1 is not necessarily semiproper, it is in this supercompact collapsing context. (Eventually, Shelah did establish that MM and SPFA are equivalent.)

Foreman, Magidor, and Shelah then established the relative consistency of several propositions by deriving them directly from MM. One such proposition was that NS_{ω_1} is $\aleph_2$-saturated. Hence, not only was the upper bound for the consistency strength of having an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1 considerably reduced from Kunen's huge cardinal, but for the first time the consistency of NS_{ω_1} itself being $\aleph_2$-saturated was established relative to large cardinals. Another formative result was simply that MM implies that $2^{\aleph_0} = \aleph_2$, starting a train of thought about forcing axioms actually determining the continuum. It would be by different and elegant means that Todorcevic would show in 1990 that PFA already implies that $2^{\aleph_0} = \aleph_2$.

With their work Foreman, Magidor, and Shelah had overturned a long-held view about the scaling down of large cardinal properties. In the first flush of new hypotheses and propositions, Kunen had naturally enough collapsed a large cardinal to ω_1 in order to transmute strong properties of the cardinal into an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1, and this sort of direct connection had become the rule. The new discovery was that a collapse of a large cardinal to ω_2 instead can provide enough structure to secure such an ideal. In fact, Foreman, Magidor, and Shelah showed that even the usual Levy collapse of a supercompact cardinal to ω_2 engenders an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1. In terms of method, the central point is that the existence of sufficiently large cardinals implies the existence of substantial generic elementary embeddings with small critical points like ω_1. Woodin's later strengthenings and elaborations of these results would have far-reaching consequences.

5.2. Consistency of Determinacy

The developments of the 1980s which are the most far-reaching and presentable as sustained narrative have to do with the stalking of the consistency of determinacy. By the late 1970s a more or less complete structure theory for the projective sets was in place, a resilient edifice founded on determinacy with both strong buttresses and fine details. In 1976 the researchers had started the Cabal Seminar in the Los Angeles area, and in a few years, with John Steel and Woodin having joined the ranks, attention began to shift to sets of reals beyond the projective sets, to inner models, and to questions of overall consistency. Most of the work before the crowning achievements of the later 1980s appears in the several proceedings of the Cabal Seminar appearing in 1978, 1981, 1983, and 1988.

With the growing sophistication of methods, the inner model $L(\mathbb{R})$ increasingly became the stage for the play of determinacy, both as the domain to extend the structural consequences of AD and as the natural inner model for AD that can exhibit characterizations. Scales having held the key to the structure theory for the projective sets, Martin and Steel established a limiting case for the scale property; with the $\mathbf{\Sigma}^2_1$ sets of reals being those definable with one existential third-order quantifier, they showed that AD and $V = L(\mathbb{R})$ imply that $\mathbf{\Sigma}^2_1$ is the largest class with the scale property. Steel moreover developed a fine structure theory for $L(\mathbb{R})$, and analyzing the minimal complexity of scales there, he extended some of the structure theory under AD to sets of reals in $L(\mathbb{R})$. As for characterizations, Kechris and Woodin showed that in $L(\mathbb{R})$, AD is equivalent to the existence of many ("Suslin") cardinals that have strong partition properties. Woodin also established that in $L(\mathbb{R})$, AD is equivalent to *Turing Determinacy*, determinacy for only sets of reals closed under Turing equivalence.

The question of the overall consistency of determinacy came increasingly to the fore. Is AD consistent relative to some large cardinal hypothesis? Or, with its strong consequences, can AD subsume large cardinals in some substantial way or be somehow orthogonal? Almost a decade after his initial result that the existence of a measurable cardinal implies $\mathbf{\Pi}^1_1$-determinacy, Martin and others showed that determinacy for sets in the "difference hierarchy" built on the $\mathbf{\Pi}^1_1$ sets implies the existence of corresponding inner models with many measurable cardinals. Then in 1978 Martin, returning to the homogeneity idea of his early $\mathbf{\Pi}^1_1$ result, applied it with the Martin-Solovay tree representation for $\mathbf{\Pi}^1_2$ sets, together with algebraic properties of elementary embeddings posited close to Kunen's large cardinal inconsistency, to establish $\mathbf{\Pi}^1_2$-determinacy. A direction was set but generality only came in 1984, when Woodin showed that an even stronger large cardinal hypothesis implies $\mathrm{AD}^{L(\mathbb{R})}$. So, a mooring was secured for AD after all in the large cardinal hierarchy. With Woodin's hypothesis apparently too remote, it would now be a question of scaling it down according to the methods becoming available for proofs of determinacy, perhaps even achieving an equi-consistency result.

The rich 1984 Foreman-Magidor-Shelah work would have crucial consequences for the stalking of consistency also for determinacy. Shelah carried out a version of their collapsing argument that does not add any new reals but nonetheless gets an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1. Woodin then pointed out that with no new reals adjoined the generic elementary embedding induced by such an ideal can be used to establish that the ground model $L(\mathbb{R})$ reals are actually Lebesgue measurable. Thus Shelah and Woodin had established an outright result: *If there is a supercompact cardinal, then every set of reals in $L(\mathbb{R})$ is Lebesgue measurable.* This result not only portended the possibility of getting $\mathrm{AD}^{L(\mathbb{R})}$ from a supercompact cardinal, but through the specifics of the argument stimulated the reducing of the hypothesis. While Woodin was visiting Jerusalem in June 1984, he came up with what is now known as a *Woodin cardinal.* The hypothesis was then reduced as follows: *If there are infinitely many Woodin cardinals with a measurable cardinal above them, then every set of reals in $L(\mathbb{R})$ is Lebesgue measurable.* An early suggestion of optimality of hypothesis was that if the "infinitely" is replaced by "n" for some $n \in \omega$, then one can conclude that every $\mathbf{\Sigma}^1_{n+2}$ set of reals is Lebesgue measurable. The measurable cardinal hovering above would be a recurring theme, the purpose loosely speaking to maintain a stable environment with the existence of sharps.

Especially because of its subsequent centrality, it is incumbent to give an operative definition of Wooding cardinal: For a set A, κ is *α-A-strong iff* there is an elementary embedding $j : V \to M$ witnessing that κ is α-strong which moreover preserves A: $A \cap V_\alpha = j(A) \cap V_\alpha$. A cardinal δ is *Woodin iff* for any $A \subseteq V_\delta$, there is a $\kappa < \delta$ which is α-A-strong for every $\alpha < \delta$.

A Woodin cardinal, evidently a technical, consistency-wise strengthening of a strong cardinal, is an important example of concept formation through method. The initial air of contrivance gives way to seeing that Woodin cardinal seemed to encapsulate just wanted is needed to carry out the argument for Lebesgue measurability. That argument having been based on first collapsing a large cardinal to get a saturated ideal and then applying the corresponding generic elementary embedding, Woodin later in 1984 stalked the essence of method and formulated *stationary tower forcing.* An outgrowth of the Foreman-Magidor-Shelah work, this notion of forcing streamlines their forcing arguments to show that a Woodin cardinal suffices to get a generic elementary embedding $j : V \to M$ with critical point ω_1 and ${}^\omega M \subseteq M$. With a new, minimizing large cardinal concept isolated, there would now be dramatic new developments both in determinacy and inner model theory. One important scaling down result was the early 1985 result of Shelah: *If κ is Woodin, then in a forcing extension $\kappa = \omega_1$ and NS_{ω_1} is $\aleph_2$-saturated.* The large cardinal strength now seemed minimal for getting such an ideal, and there was anticipation of achieving an equi-consistency.

Steel in notes of Spring 1985 developed an inner model for a weak version of Woodin cardinal. While inner models for strong cardinals had only required linear iterations for comparison, the new possibility of overlapping extenders and moving generators had led Mitchell in 1979 to develop *iteration trees* of iterated ultrapowers for searching for possible well-founded limits of models along branches. A particularly simple example of an iteration tree is an *alternating chain*, a tree consisting of two ω-length branches with each model in the tree an extender ultrapower of the one preceding it on its branch, via an extender taken from a corresponding model in the other branch. Initially, Steel tried to avoid alternating chains, but the Foreman-Magidor-Shelah work showed that for dealing with Woodin cardinals they would be a necessary part. Their use soon led to a major breakthrough in the investigation of determinacy.

In the Fall of 1985 Martin and Steel showed that Woodin cardinals imply the existence of alternating chains in which both branches have well-founded direct limits, and used this to establish: *If there are infinitely many Woodin cardinals, then* PD *holds.* This was a culmination of method in several respects. In the earlier Martin results getting $\mathbf{\Pi}^1_1$-Determinacy and $\mathbf{\Pi}^1_2$-Determinacy, trees on $\omega \times \kappa$ for some cardinal κ had been used, to each node of which were attached ultrafilters in a coherent way that governed extensions. Kechris and Martin isolated the relevant concept of *homogeneous tree*, the point being that sets of reals which are the projections $p[T]$ of such trees T—the *homogeneously Suslin sets*—are determined. With PD, the scale property had been propagated through the projective hierarchy. Now with Woodin cardinals, having representations via homogeneous trees was propagated, getting determinacy itself. In particular, Martin and Steel established: *If $n \in \omega$ and there are n Woodin cardinals with a measurable cardinal above them, then $\mathbf{\Pi}^1_{n+1}$-determinacy holds.*

Within weeks after the Martin-Steel breakthrough, Woodin used it together with stationary towers to investigate tree representations in $L(\mathbb{R})$ to establish: *If there are infinitely Woodin cardinals with a measurable cardinal above them, then* $\mathrm{AD}^{L(\mathbb{R})}$ *holds.* With the consistency strength of AD having been gauged by this result, Woodin soon established the crowning equi-consistency result: *The existence of infinitely many Woodin cardinals is equi-consistent with the Axiom of Determinacy.* Both directions of this result, worked out with hindsight in Chaps. 22 and 23 of this Handbook, involve substantial new arguments.

This was a remarkable achievement of the concerted effort to establish the consistency strength of AD along the large cardinal hierarchy. But even this would just be a beginning for Woodin, who would go from strength to strength to establish many structural results involving AD and stronger principles, to become preeminent with Shelah in set theory.

5.3. Later Developments

We conclude our historical survey by describing here some prominent developments of the later 1980s and early 1990s, those in the broad directions of inner model theory and singular cardinal combinatorics to be elaborated in sequences of chapters of this Handbook. Other prominent developments, more individuated, are appropriately described within the chapter summaries themselves that follow at the end. Set theory would continue to expand and broaden in further directions, but we are inevitably limited in what can be covered here and in the Handbook.

In inner model theory, Martin and Steel in 1986 took the analysis of iteration trees beyond their determinacy work to develop inner models of Woodin cardinals. In order to effect comparison, they for the first time came to grips with the central iterability problem of the existence and uniqueness of iteration trees extending a given iteration tree. They were thus able to establish that "the measurable cardinal above" cannot be eliminated from their determinacy result by showing: *If $n \in \omega$ and there are n Woodin cardinals, then there is an inner model with n Woodin cardinals and a Δ^1_{n+2} well-ordering of the reals.* (The existence of such a well-ordering precludes $\mathbf{\Pi}^1_{n+1}$-determinacy.) These models were of form $L[\vec{E}]$ where $\vec{E}$ is a coherent sequence of extenders, but the comparison process used did not involve the models themselves, but rather a large model constructed from a sequence of *background extenders*, extenders in the sense of V whose restrictions to $L[\vec{E}]$ led to the sequence $\vec{E}$. With the comparison process thus external to the models, their structure remained largely veiled, and for example only CH, not GCH, could be established.

In 1987 Stewart Baldwin made a suggestion, one which Mitchell then newly forwarded, which led to a crucial methodological advance. Up to then, the extender models $L[\vec{E}\,]$ constructed relative to a coherent sequence of extenders $\vec{E}$ had each extender in the sequence "measure" all the subsets in $L[\vec{E}\,]$ of its critical point. The Baldwin-Mitchell idea was to construct only with "partial" extenders E which if indexed at γ only measures the sets in $L_\gamma[\vec{E}{\restriction}\gamma]$. This together with a previous Mitchell strategy of carrying out the comparison process using finely calibrated partial ultrapowers ("dropping to a mouse") led to a comparison process internal to $L[\vec{E}\,]$ based on the use of fine structure. The infusion of fine structure made the development of the new extender models more complex, but with this came the important dividends of a more uniform presentation, a much stronger condensation, and a more systematic comparison process. During 1987–1989, Mitchell and Steel worked out the details and showed that if there is a Woodin cardinal then there is an inner model $L[\vec{E}\,]$, L-like in satisfying GCH and so forth, in which there is a Woodin cardinal. The process involved the correlating of iteration trees for $L[\vec{E}\,]$ with iteration trees in V and applying the former Martin-Steel results. A canonical, fine structural inner model of a Woodin cardinal newly argued for the consistency of the concept, as well as provided a great deal of understanding about it as set in a finely tuned, layer-by-layer hierarchy.

What about a core model "up to" a Woodin cardinal, in analogy to K^{DJ} for $L[U]$? In 1990, Steel solved the "core model iterability problem" by showing that large cardinals in V are not necessary for showing that certain models $L[\vec{E}\,]$ have sufficient iterability properties. With this, he constructed a new core model, first building a "background certified" K^c based on extenders in V and then the "true" core model K. Steel was thus able to extend the previous work of Mitchell on the core model $K[\mathcal{U}]$ up to $\exists\kappa(o(\kappa) = \kappa^{++})$ to establish e.g.: *If there is an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1 and* *a measurable cardinal, then there is an inner model with a Woodin cardinal.* Thus, Shelah's 1985 forcing result and Steel's, except for the artifact of "the measurable cardinal above", had calibrated an important consistency strength, and what had become a central goal of forcing and inner model theory was handily achieved.

In the early 1990s, Steel, Mitchell, and Ernest Schimmerling pushed the Jensen covering argument over the hurdles of the new fine structural Steel core model K to establish a covering lemma up to a Woodin cardinal. Schimmerling both established combinatorial principles in K as well established new consistency strengths, e.g. PFA *implies that there is an inner model with a Woodin cardinal.*

The many successes would continue in inner model theory, but we bring our narrative to a close at a fitting point. Mitchell's Chap. 18 in this Handbook is given over to the concerted study of covering over various models; Steel's Chap. 19 provides the outlines of inner model theory in general terms as well as an important application to HOD; and Schimmerling's Chap. 20 develops Steel's core model K up to a Woodin cardinal as well as provide applications across set theory.

The later 1980s featured a distinctive development that led to a new conceptual framework of applicability to singular cardinals, new incisive results in cardinal arithmetic, and a re-orienting of set theory to new possibilities for outright theorems of ZFC. Starting in late 1987 Shelah returned to the work on bounds for powers of singular cardinals and drew out an extensive underlying structure of possible cofinalities of reduced products, soon codified as *pcf theory.* With this emerged new work in *singular cardinal combinatorics*, with Shelah himself initially providing applications to model theory, partition relations, Jónsson algebras, Boolean algebras, and cardinal arithmetic. This last was epitomized by a dramatic result that exhibited how the newly seen structural constraints impose a tight bound: *If δ is a limit ordinal with $|\delta|^{\mathrm{cf}(\delta)} < \aleph_\delta$ then $\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{+4})}$, so that in particular if $\aleph_\omega$ is a strong limit cardinal, then $2^{\aleph_\omega} < \aleph_{\omega_4}$.* Quite remarkably, a ZFC result bounds $2^{\aleph_\omega}$ with a small aleph not indexed in terms of the power set operation!

Suppose that A is an infinite set of cardinals and F is a filter over A. The *product* ΠA consists of functions f with domain A such that $f(a) \in a$ for every $a \in A$. For $f, g \in \Pi A$, the relation $=_F$ defined by $f =_F g$ *iff* $\{a \in A \mid f(a) = g(a)\} \in F$ is an equivalence relation on ΠA, and the *reduced product* $\Pi A/F$ consists of the equivalence classes. We can impose order, officially on $\Pi A/F$ but still working with functions themselves, by: $f <_F g$ *iff* $\{a \in A \mid f(a) < g(a)\} \in F$.

Shelah's new theory took as central the investigation of the possible cofinalities function:

$$\mathrm{pcf}(A) = \{\mathrm{cf}(\Pi A/D) \mid D \text{ is an ultrafilter over } A\}$$

as calibrated by the ideals

$$J_{<\lambda}[A] = \{b \subseteq A \mid \mathrm{cf}(\Pi A/D) < \lambda \text{ whenever } D \text{ is an ultrafilter over } A \text{ such that } b \in D\}.$$

These concepts had appeared before in Shelah's work, notably in his 1980 result $\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$, but now they became autonomous and were propelled forward by the discovery of unexpectedly rich structure.

With an eye to substantive cofinal subsets A of a singular cardinal, the abiding assumption was that A is a set of regular cardinals satisfying $|A| < \min(A)$. With this one gets that for any ultrafilter D over A, $\mathrm{cf}(\Pi A/D) < \lambda$ *iff* $D \cap J_{<\lambda}[A] \neq \emptyset$, and further, that $\mathrm{pcf}(A)$ has a maximum element. At the heart is the striking result that $J_{<\lambda^+}[A]$ is generated by $J_{<\lambda}[A]$ together with a single set $B_\lambda \subseteq A$. Shelah in fact got "nice" generators B_λ derived from imposing the structure of elementary substructures of a sufficiently large $H(\Psi)$. This careful control on the possible cofinalities then led, when A consists of all the regular cardinals in an interval of cardinals, to $|\mathrm{pcf}(A)| \leq |A|^{+++}$, and in particular to the $\aleph_{\omega_4}$ bound mentioned above.

Shelah's work on pcf theory to 1993 appeared in his 1994 book *Cardinal Arithmetic*, and since then he has further developed the theory and provided wide-ranging applications. Through its applicability pcf theory has to a significant extent been woven into modern set theory as part of the ZFC facts of singular cardinal combinatorics. Chapter 14 of this Handbook presents a version of pcf theory and its applications to cardinal arithmetic, and the theory makes it appearance elsewhere as well, most significantly in Chap. 15.

The Singular Cardinal Hypothesis (SCH) and the train of results starting with the Prikry-Silver result of the early 1970s were to be decisively informed by results of Moti Gitik. Gitik's work exhibits a steady engagement with central and difficult issues of set theory and a masterful virtuosity in the application of sophisticated techniques over a broad range. Gitik by 1980 had established, through an iterated Prikry forcing, the conspicuous singularization result: *If there is a proper class of strongly compact cardinals, then in a* ZF *inner model of a class forcing extension every infinite cardinal has cofinality* ω. Mentioned earlier was the mid-1970s result that NS_{ω_1} being precipitous is equi-consistent with having a measurable cardinal. In 1983, Gitik established: *The precipitousness of* NS_{ω_2} *is equi-consistent with having a measurable cardinal* κ *such that* $o(\kappa) = 2$ *in the Mitchell order.* The difficult, forcing direction required considerable ingenuity because of inherent technical obstructions.

Turning to the work on SCH, in 1988 Woodin dramatically weakened the large cardinal hypothesis needed to get a measurable cardinal κ satisfying $2^\kappa > \kappa^+$, and hence the failure of SCH with the subsequent use of Prikry forcing, to a proposition technically strengthening measurability. He also showed that one can in fact get Magidor's conclusion that $\aleph_\omega$ could be the least cardinal at which GCH fails. Soon afterwards Gitik established both directions of an equi-consistency: First, he established that one can get the consistency of Woodin's proposition from just $\exists\kappa(o(\kappa) = \kappa^{++})$. Then, he applied a result from Shelah's pcf theory to Mitchell's $K[\mathcal{U}]$ analysis to establish, bettering a previous result of Mitchell, that $\exists\kappa(o(\kappa) = \kappa^{++})$ is actually necessary to get the failure of SCH. Hence, *The failure of* SCH *is equi-consistent with* $\exists\kappa(o(\kappa) = \kappa^{++})$.

Woodin's model in which GCH first fails at $\aleph_\omega$ required a delicate construction to arrange GCH below and an ingenious idea to get $2^{\aleph_\omega} = \aleph_{\omega+2}$. How about getting $2^{\aleph_\omega} > \aleph_{\omega+2}$? In a signal advance of method, Gitik and Magidor in 1989 provided a new technique to handle the general singular cardinals problem with appropriately optimal hypotheses. The Prikry-Silver two-stage approach, first making 2^κ large and then singularizing κ without adding any new bounded subsets or collapsing cardinals, had been the basic model for attacking the singular cardinals problem. Gitik and Magidor showed how to add many subsets to a large cardinal κ while *simultaneously* singularizing it without adding any new bounded subsets or collapsing cardinals. Thus, it became much easier to arrange any particular continuum function behavior below κ, like achieving GCH below, while at the same time making 2^κ arbitrarily large. Moreover, the new method smacked of naturalness and optimality.

The new Gitik-Magidor idea was to add many new Prikry ω-sequences corresponding to κ-complete ultrafilters over κ while maintaining the basic properties of Prikry forcing. There is an evident danger that if these Prikry sequences are too independent, information can be read from them that corresponds to new reals being adjoined. The solution was to start from a sufficient strong large cardinal hypothesis and develop an extender-based Prikry forcing structured on a "nice system" of ultrafilters $\langle U_\alpha \mid \alpha < \lambda\rangle$, a system such that for many $\alpha \leq \beta < \lambda$ there is a ground model function $f : \kappa \to \kappa$ such that: For all $X \subseteq \kappa$, $X \in U_\alpha$ *iff* $f^{-1}(X) \in U_\beta$. (Having such a projection function is the classical way of connecting two ultrafilters together, and one writes that $U_\alpha \leq_{\mathrm{RK}} U_\beta$ under the Rudin-Keisler partial order.) By this means one has the possibility of adding new subsets of κ, corresponding to different Prikry sequences, which are still dependent on each other so that no new bounded subsets need necessarily be added in the process. Gitik and Magidor worked out how their new approach leads to what turns out to be optimal or near optimal consistency results, and incorporating collapsing maps as in previous arguments of Magidor and Shelah, they got models in which GCH holds below $\aleph_\omega$ yet $2^{\aleph_\omega} = \aleph_{\alpha+1}$ for any prescribed countable ordinal α.

In subsequent work Gitik, together with Magidor, Mitchell, and others, have considerably advanced the investigation of powers of singular cardinals. Equi-consistency results have been achieved for large powers of singular cardinals along the Mitchell order and with α-strong cardinals, and uncountable cofinalities have been encompassed, the investigation ongoing and with dramatic successes. Much of this work is systematically presented in Gitik's Chap. 16 in this Handbook.

We now leave the overall narrative, having pursued several longitudinal themes to appropriate junctures. Stepping back to gaze at modern set theory, the thrust of mathematical research should deflate various possible metaphysical appropriations with an onrush of new models, hypotheses, and results. Shedding much of its foundational burden, set theory has become an intriguing field of mathematics where formalized versions of truth and consistency have become matters for manipulation as in algebra. As a study couched in well-foundedness ZFC together with the spectrum of large cardinals serves as a court of adjudication, in terms of relative consistency, for mathematical propositions that can be informatively contextualized in set theory by letting their variables range over the set-theoretic universe. Thus, set theory is more of an open-ended framework for mathematics rather than an elucidating foundation. It is as a field of mathematics proceeding with its own internal questions and capable of contextualizing over a broad range that set theory has become an intriguing and highly distinctive subject.

6. Summaries of the Handbook Chapters

This Handbook is divided into three volumes with the first devoted to Combinatorics, the Continuum, and Constructibility; the second devoted to Elementary Embeddings and Singular Cardinal Combinatorics; and the third devoted to Inner Models and Determinacy.

The following chapter summaries engage the larger historical contexts as they serve to introduce and summarize the contents. In many cases we build on our preceding survey as a framework and proceed to elaborate it in the directions at hand, and in some cases we introduce the topics as new offshoots and draw them in. Consequently, some summaries are shorter on account of the leads from the survey and others longer because of the new lengths to which we go.

VOLUME I

1. Stationary Sets. The veteran set theorist Thomas Jech is the author of *Set Theory* (third millennium edition, 2002), a massive and impressive text that comprehensively covers the full range of the subject up to the elaborations of this Handbook. In this first chapter, Jech surveys the work directly involving stationary sets, a subject to which he has made important contributions. In charting out the ramifications of a basic concept buttressing the uncountable, the chapter serves, appropriately, as an anticipatory guide to techniques and results detailed in subsequent chapters.

The first section provides the basic theory of stationary subsets of a regular uncountable cardinal κ. The next describes the possibilities for *stationary set reflection*: For $S \subseteq \kappa$ stationary in κ, is there an $\alpha < \kappa$ such that $S \cap \alpha$ is stationary in α? With reflection having become an important heuristic in set theory, stationary set reflection commended itself as a specific, combinatorial possibility for investigation. Focusing on the non-stationary ideal, the third section surveys the possibilities for its saturation and precipitousness.

The later sections study these various issues as adapted to notions of closed unbounded and stationary for subsets of $P_\kappa\lambda = \{x \in P(\lambda) \mid |x| < \kappa\}$, a study that the author had pioneered in the early 1970s. The wide-ranging involvements in proper forcing, Boolean algebras and stationary tower forcing are described. Of particular interest are reflection principles based on $P_{\aleph_1}\lambda$. Foreman, Magidor, and Shelah in their major 1984 work had shown that Martin's Maximum implies that a substantial reflection principle holds for stationary subsets of $P_{\aleph_1}\lambda$ for every $\lambda \geq \omega_2$. Todorcevic then showed that a stronger reflection principle SRP follows from MM, one from which substantial consequences of MM already follow, like the $\aleph_2$-saturation of NS_{ω_1}. Qi Feng and Jech subsequently formulated a streamlined principle PRS equivalent to SRP.

2. Partition Relations. In this chapter two prominent figures in the field of partition relations, András Hajnal and Jean Larson, team up to present the recent work, the first bringing to bear his expertise in relations for uncountable cardinals and the second her expertise in relations for countable ordinals. The investigation of partition relations has been a steady, rich, and concrete part of the combinatorial investigation of the transfinite, a source of intrinsically interesting problems that have stimulated the application of a variety of emerging techniques.

With the classical, 1956 Erdős-Rado Theorem $\beth_n(\kappa)^+ \longrightarrow (\kappa^+)^{n+1}_\kappa$ having established the context as the transfinite generalization of Ramsey's Theorem, extensive use of the basic tree or "ramification" method had led by the mid-1960s to an elaborately parametrized theory. This theory was eventually presented in the 1984 Erdős-Hajnal-Rado-Máté book, which is initially reflected in the first two sections of the chapter.

The next sections emphasize new methods as leading not only to new results but also providing new proofs of old results, and in this spirit they develop a 1991 method of Baumgartner, Hajnal, and Todorcevic and establish their generalizations of the Erdős-Rado Theorem. This method involves taking chains of elementary substructures of a sufficiently rich structure $\langle H(\lambda), \in, <^*, \ldots \rangle$ and associating ideals along the way. Next, the enhanced method of the recent, 1998 Foreman-Hajnal result on successors of measurable cardinals is used establish a watershed, 1972 Baumgartner-Hajnal Theorem in the special case $\omega_1 \longrightarrow (\alpha)^2_m$ for any $\alpha < \omega_1$ and $m \in \omega$. Shelah, with his considerable combinatorial prowess, has steadily made important contributions to the theory of partition relations, and several are presented, among them a recent result involving strongly compact cardinals and another invoking his pcf theory.

The investigation of partition relations for small countable ordinals was a current from the beginnings of the general theory in the late 1950s and has focused, for natural reasons, on the relation $\alpha \longrightarrow (\alpha, m)^2$ for finite m, the assertion that if the pairs from α are assigned 0 or 1, then either there is an $H \subseteq \alpha$ of order-type α all of whose pairs are assigned 0, or m elements in α

all of whose pairs are assigned 1. A formative early 1970s result was Chen-Chung Chang's that with ordinal exponentiation, $\omega^\omega \to (\omega^\omega, 3)^2$, the proof considerably simplified by Larson. Remarkably, after the passing of more than two decades Carl Darby and Rene Schipperus working independently established the first new positive and negative results, the latter by way of the same counterexamples. In the last two sections, a negative result $\omega^{\omega^2} \not\to (\omega^{\omega^2}, 6)$ and a positive result $\omega^{\omega^\omega} \to (\omega^{\omega^\omega}, 3)$ are established, the careful combinatorial analysis in terms of blocks of ordinals and trees illustrative of some of the most detailed work with small order-types.

3. Coherent Sequences. This chapter is a systematic account by Stevo Todorcevic of his penetrating analysis of uncountable order structures, with ω_1 being both a particular and a paradigmatic case. The chapter is a short version of his recent monograph *Walks on Ordinals and Their Characteristics* (2007), but has separate value for being more directed and closer to the historical route of discovery.

The analysis for a regular cardinal θ begins with a *C-sequence* $\langle C_\alpha \mid \alpha < \theta\rangle$ where for successors $\alpha = \beta + 1$, $C_\alpha = \{\beta\}$, and for limits α, C_α is a closed unbounded subset of α. In the case $\theta = \omega_1$, one requires that for limits α, C_α has order-type ω, so that we have a "ladder system". One can climb up, but also walk down: Given $\alpha < \beta < \theta$, let β_1 be the least member of $C_\beta - \alpha$, let β_2 the least member of $C_{\beta_1} - \alpha$, and so forth, yielding the *walk* $\beta > \beta_1 > \cdots > \beta_n = \alpha$. Through a sustained analysis Todorcevic has shown that these walks have a great deal of structure as conveyed by various "distance functions" or "characteristics" ρ on $[\theta]^2$, where $\rho(\alpha, \beta)$ packages information about the walk from β to α.

Initially, Todorcevic in 1985 used such a function to settle the main partition problem about the complexity of ω_1, by establishing the negative "square brackets partition relation" $\omega_1 \not\to [\omega_1]^2_{\omega_1}$: There is a function $f : [\omega_1]^2 \to \omega_1$ such that for any unbounded $X \subseteq \omega_1$, $f``[X]^2 = \omega_1$, i.e. for any $\zeta < \omega_1$ there are $\alpha < \beta$ both in X such that $f(\alpha, \beta) = \zeta$. Todorcevic's f was based on the property that if $S \subseteq \omega_1$ is stationary, then for any unbounded $X \subseteq \omega_1$ there are $\alpha < \beta$ both in X such that the walk from β to α has a member of S. More generally, Todorcevic introduced the *oscillation map* to effect a version of this property for regular $\theta > \omega_1$ to show that if there is a stationary $S \subseteq \theta$ which does not reflect, i.e. there is no $\alpha < \theta$ such that $S \cap \alpha$ is stationary in α, then the analogous $\theta \not\to [\theta]^2_\theta$ holds.

The first sections of the chapter develops several distance functions for the case $\theta = \omega_1$ as paradigmatic. Systematic versions of "special" Aronszajn trees and the (Shelah) result that adding a Cohen real adds a Suslin tree are presented, as well as a range of applications to Hausdorff gaps, Banach spaces, model theory, graph theory and partition relations.

The later sections encompass general θ, with initial attention given to systematic characterizations of Mahlo and weakly compact cardinals. There is soon a focus on *square* (or *coherent*) sequences, those C-sequences $\langle C_\alpha \mid \alpha < \theta\rangle$ such that $C_\alpha = C_\beta \cap \alpha$ whenever α is a limit of C_β. With these a range of applications is provided involving the principle $\square_\kappa$, higher Kurepa trees, and Jensen matrices. The oscillation map is latterly introduced, and with it the proof of the general negative square brackets partition relation as stated above. Finally, elegant characterizations of Chang's Conjecture are presented. Throughout, there is the impression that one has gotten at the immanent structure of the uncountable from which a wide range of combinatorial consequences flow.

4. Borel Equivalence Relations. Descriptive set theory as fueled by the incentive for generalization is appropriately construed as the investigation of definable sets in *Polish spaces*, i.e. separable, completely metrizable spaces. For such spaces one can define the Borel and projective sets and the corresponding hierarchies through definability. In the 1990s fresh incentives came into play that expanded the investigation into quotient spaces X/E for a Polish space X and a definable equivalence relation E on X, such quotients capturing various important structures in mathematics. New methods had to be developed, in what amounts to the investigation of definable equivalence relations on Polish spaces.

In this short chapter Greg Hjorth provides a crisp survey of Borel equivalence relations on Polish spaces as organized around the Borel reducibility ordering $\leq_B$. In an initial disclaimer, he points out how he is leaving aside several other approaches, but in any case his account provides a worthy look at a modern, burgeoning subject.

For Polish spaces X and Y, a function $f : X \to Y$ is *Borel* if the preimage of any Borel set is Borel. An equivalence relation on X is *Borel* if it is Borel as a subset of $X \times X$. If E is a Borel equivalence relation on X and F is a Borel equivalence relation on Y, then $E \leq_B F$ asserts that there is a Borel $f : X \to Y$ such that $x_1 E x_2 \leftrightarrow f(x_1) F f(x_2)$. The emphasis here is on the equivalence relations, with only the Borel sets of the underlying spaces being at issue. There is the correlative $E <_B F$, and with $\mathrm{id}(X)$ indicating the identity relation on X, an example is $\mathrm{id}(\mathbb{R}) <_B E_0$, where E_0 is the equivalence relation of eventual agreement on ${}^\omega 2$. E_0 is a reconstrual of Vitali's classical equivalence relation, with which he established that with AC there is a non-Lebesgue measurable set. The seminal Harrington-Kechris-Louveau "Glimm-Effros dichotomy" result is: *For any Borel equivalence relation E, exactly one of $E \leq_B \mathrm{id}(\mathbb{R})$ or $E_0 \leq_B E$ holds.*

Starting with this seminal result the author discusses various structure theorems, concluding with his work on *turbulence.* Next is the work on countable Borel equivalence relations, i.e. those whose equivalence classes are all countable. This topic has notable interactions across diverse fields of mathematics, and an enduring problem is how to characterize the *hyperfinite* Borel equivalence relations. The author next discusses $\leq_B$ as effective cardinality, bringing in his results with determinacy. The final topic is classification problems, problems of locating variously given Borel equivalence relations in the structure given by $\leq_B$. The range of issues here speaks to the importance and relevance of Borel equivalence relations in larger mathematics.

5. Proper Forcing. Uri Abraham provides a lucid exposition of Shelah's proper forcing. In a timely monograph *Proper Forcing* (1982) and a book *Proper and Improper Forcing* (1998), Shelah had set out his penetrating, wide-ranging work on and with proper forcing. Striking a nice balance, Abraham presents the basic theory of proper forcing and then some of the variants and their uses that illustrate its wide applicability. This chapter is commended to the reader conversant even with only the basics of forcing to assimilate what has become a staple part of the theory and practice of forcing. To be noted is that being of the Israeli school, Abraham writes "$p > q$" for p being a stronger condition than q.

In the first two sections, basic forcing notions are reviewed, and proper forcing is motivated and formulated. The basic lemma that properness is preserved in countable support iterations is carefully presented, as well as the basic fact that under CH a length $\leq \omega_2$ iteration of $\aleph_1$ size proper forcings satisfies the $\aleph_2$-chain condition and so preserves all cardinals.

A forcing partial order P is *${}^\omega\omega$-bounding iff* the ground model reals are cofinal under eventual dominance $<^*$ in the reals of any generic extension by P. The third section presents the preservation of ${}^\omega\omega$-bounding properness in countable support iterations. With this is established a finely wrought result of Shelah's, answering a question of classical model theory, that it is consistent that there are two countable elementarily equivalent structures having no isomorphic ultrapowers by any ultrafilter over ω.

A forcing partial order P is *weakly ${}^\omega\omega$-bounding iff* the ground model reals are unbounded under eventual dominance $<^*$ in the reals of any generic extension by P. The fourth section presents the preservation of weakly ${}^\omega\omega$-bounding properness, one that deftly and necessarily has to assume a stronger property at successor stages. With this is established another finely wrought result of Shelah's, answering a question in the theory of cardinal characteristics, that it is consistent with $2^{\aleph_0} = \aleph_2$ that the bounding number $\mathfrak{b}$ is less than the splitting number $\mathfrak{s}$.

The final section develops iterated proper forcing that adjoins no new reals. A relatively complex task, this has been a prominent theme in Shelah's work, and to this purpose he has come up with several workable conditions. Abraham motivates one condition, *Dee-completeness*, with his first result in set theory, and then establishes an involved preservation theorem. As pointed out, through this approach one can provide a new proof of Jensen's result that CH + SH is consistent, which for Shelah was an important stimulus in his initial development of proper forcing.

6. Combinatorial Cardinal Characteristics of the Continuum. This and the next chapters cover the recent, increasingly systematic, work across the wide swath having to do with cardinal characteristics, or invariants, of the continuum and their possible order relationships. In this chapter, the broad-ranging Andreas Blass provides a perspicuous account of combinatorial cardinal characteristics through to some of his own work. He deftly introduces characteristics in turn together with more and more techniques for their analysis, and at the end surveys the extensive forcing consistency results.

There is initially a discussion of the dominating number $\mathfrak{d}$ and the bounding number $\mathfrak{b}$, one that introduces several generalizing characteristics corresponding to an ideal $\mathcal{I}$: $\mathbf{add}(\mathcal{I})$, $\mathbf{cov}(\mathcal{I})$, $\mathbf{non}(\mathcal{I})$, $\mathbf{cof}(\mathcal{I})$. The next topic is the splitting number $\mathfrak{s}$ and related characteristics having to do with Ramsey-type partition theorems.

A systematic approach, first brought out by Peter Vojtáš, is then presented for describing many of the characteristics and the relationships among them. A triple $\mathbf{A} = \langle A_-, A_+, A\rangle$ such that $A \subseteq A_- \times A_+$ is simply a *relation*, and its *norm* $\|\mathbf{A}\|$ is the smallest cardinality of any $Y \subseteq A_+$ such that $\forall x \in A_- \exists y \in Y(\langle x, y\rangle \in A)$. The *dual* of $\mathbf{A} = \langle A_-, A_+, A\rangle$ is $\mathbf{A}^\perp = \langle A_+, A_-, \neg\breve{A}\rangle$, where $\neg\breve{A}$ is the complement of the converse $\breve{A}$ of A, i.e. $\langle x, y\rangle \in \neg\breve{A}$ *iff* $\langle y, x\rangle \notin A$. In these terms, for example, if $\mathfrak{D} = \langle {}^\omega\omega, {}^\omega\omega, <^*\rangle$, then $\|\mathfrak{D}\| = \mathfrak{d}$ and $\|\mathfrak{D}^\perp\| = \mathfrak{b}$. A *morphism* for a relation $\mathbf{A} = \langle A_-, A_+, A\rangle$ to another $\mathbf{B} = \langle B_-, B_+, B\rangle$ is a pair $\phi = (\phi_-, \phi_+)$ of functions such that $\phi_- : B_- \to A_-$; $\phi_+ : A_+ \to B_+$; and

$$\forall b \in B_- \forall a \in A_+(\langle \phi_-(b), a\rangle \in A \to \langle b, \phi_+(a)\rangle \in B).$$

It is seen that having such a morphism implies that $\|\mathbf{A}\| \geq \|\mathbf{B}\|$ and $\|\mathbf{A}^\perp\| \leq \|\mathbf{B}^\perp\|$. Through this overlay of relations and morphisms one can efficiently incorporate both categorical combinations of relations as well as conditions on morphisms, like being Borel or continuous, into the study of characteristics.

The author proceeds to discuss characteristics corresponding to the ideal $\mathcal{B}$ of meager sets and to the ideal $\mathcal{L}$ of null sets: $\mathbf{add}(\mathcal{B})$, $\mathbf{cov}(\mathcal{B})$, $\mathbf{non}(\mathcal{B})$, $\mathbf{cof}(\mathcal{B})$, $\mathbf{add}(\mathcal{L})$, $\mathbf{cov}(\mathcal{L})$, $\mathbf{non}(\mathcal{L})$, $\mathbf{cof}(\mathcal{L})$. The main results are established in terms of relations and morphisms, and one gets to the inequalities among these characteristics and $\mathfrak{b}$ and $\mathfrak{d}$ as given by what is known as *Cichoń's diagram*. The characteristics of measure and category are further pursued in the next chapter.

The succeeding topics have to do with cardinalities of families $F \subseteq P(\omega)$ as mediated by $\subseteq^*$, where $X \subseteq^* Y$ *iff* $X - Y$ is finite. Forcing axioms are brought into play as now particularly informative for drawing ordering conclusions. Then characteristics corresponding to maximal almost disjoint (MAD) families and independent families are investigated.

The author finally discusses characteristics related to or developed through his own work. Discussing filters and ultrafilters over ω, he gets to his principle of Near Coherence of Filters (NCF), a principle proved consistent by Shelah, and results about ultrafilters generated from filters in terms of characteristics. He then discusses his *evasion* and *prediction*, which initially had an algebraic motivation but became broadened into a combinatorial framework that provides a unifying approach to many of the characteristics.

The concluding section is largely a survey of what happens to the characteristics when one iteratively adjoins many generic reals of one kind, dealing in turn with the following reals: Cohen, random, Sacks, Hechler, Laver, Mathias, Miller. As such, this is an informative account of these various generic reals and how they mediate the continuum.

7. Invariants of Measure and Category. Tomek Bartoszynski presents the recent work on measure and category as viewed through their cardinal invariants, or characteristics. The account updates the theory presented in the substantive *Set Theory: On the Structure of the Real Line* (1995) by Bartoszynski and Haim Judah, which had stood as a standard reference for this general area for quite some time.

After putting the language of relations and morphisms (see the previous summary) in place, the author pursues an approach, one advocated by Ireneusz Recław, of emphasizing classes of sets "small" according to various criteria corresponding to the ideal invariants. One develops *Borel* morphisms that lead to inclusion relations among the classes and thence to the inequalities of Cichon's diagram. Combinatorial characterizations of membership in these classes and thus of the invariants are given, as well as a new understanding of the ideal of null sets as maximal, in terms of embedding, among analytic P-ideals.

Turning to cofinality, the author establishes Shelah's remarkable and unexpected 1999 result that it is consistent that $\mathrm{cf}(\mathbf{cov}(\mathcal{L})) = \omega$. The author then provides a systematic way of associating to each of the invariants in Cichon's diagram a generic real so that iteration with countable support increases that invariant and none of the others. Corresponding issues about the classes of small sets further draw in proper forcing techniques.

8. Constructibility and Class Forcing. In this chapter Sy Friedman describes work on the limits of possibilities for reals in terms of forcing and constructibility, the supporting technique being *Jensen coding.* In the mid-1960s Solovay, when investigating the remarkable properties of $0^\#$, raised several questions about the scope of the recently devised forcing method. For sets x, y let $x \leq_L y$ denote that x is constructible from y, i.e. $x \in L[y]$, and let $x <_L y$ be correlative. $0^\#$ cannot be adjoined to L by forcing because of its global consequences for L, but $0^\#$ was plausibly considered minimal in this respect. A (weak form of a) question of Solovay's was: If r is a real satisfying $r <_L 0^\#$, does r belong to some generic extension of L?

In 1975–1976 Jensen devised his impressive "coding the universe in a real" technique and with it established (a strong form of): *If* GCH *holds, then there is a class partial order P such that if G is P-generic, then $V[G]$ has the same cardinals and cofinalities yet for some real r there, $V[G] \models$ "$V = L[r]$".* The intricately woven P here was built using fine structure theory in L-like situations and provided a means of coding up more and more layers of the cumulative hierarchy while crucially maintaining its cardinal structure. Not only cofinalities but those properties compatible with models of form $L[r]$ all continue to hold, so that this real r veritably codes the entire universe. Jensen showed that assuming $0^\#$ exists it is consistent that there is such a real

$r <_L 0^\#$, answering Solovay's question in the negative, the intention there having been to address forcing with *set* partial orders. Not only did Jensen bring class forcing into prominence for establishing new consistency results about sets, but also for establishing outright theorems of ZFC + "$0^\#$ exists".

Starting in the mid-1980s Friedman reworked and extended the Jensen theory and established some notable results about $0^\#$ and class forcing, and this work eventually appeared in his book *Fine Structure and Class Forcing* (2000). This chapter is a short version of the book, appropriate to the task of working more directly toward several problems of Solovay and developing techniques where needed. After stating three problems of Solovay as motivation, Friedman develops the criterion of *tameness* for class partial orders for preserving ZFC and gets at the property of *relevance*, having a generic definable in $L[0^\#]$. He then provides his proof of Jensen's coding theorem assuming that $0^\#$ does not exist, this assumption allowing a comparatively simple argument free of fine structure but making appeals to the Jensen Covering Theorem. With this the Solovay problems are addressed in turn. To conclude, wide-ranging applications are given as well as a nice list of open problems.

9. Fine Structure. This and the next chapter deal with fine structure and are complementary in that they present different versions, both due initially to Jensen, as well as applications in different directions. In this chapter Ralf Schindler and Martin Zeman provide an incisive, self-contained account of Jensen's original fine structure theory for the J_α hierarchy relativized to a predicate A. Much is drawn from Zeman's book *Inner Models and Large Cardinals* (2002), but diverging from it Schindler and Zeman steer to the use of the Mitchell-Steel $r\Sigma_n$ formulas for discussing iterated projecta and embeddings. With A being a sequence of extenders this was the approach that had been taken for the use of fine structure in inner model theory. The chapter thus provides the fine structure groundwork for Chaps. 18, 19, and 20 of this Handbook.

After the preliminaries about J-structures, the chapter focuses on the *acceptable* ones, those that satisfy GCH in a strong form. The projecta of these J-structures are described, and then the Downward and Upward Extensions of Embeddings Lemmas are established. Iterated projecta are then formulated and $r\Sigma_n$ introduced for expressing preservation through embeddings using *very good* parameters. Next, standard parameters are fully analyzed and all the considerations about *soundness* and *solidity witnesses* necessary for inner model theory are given.

A later section analyzes *fine ultrapowers*, fine structure preserving ultrapowers by extenders, treating the "short" and "long" cases uniformly, and draws out the connections with the Upward Extensions of Embeddings Lemma. Finally, two illustrative applications to L are presented, with generalizable arguments: a proof, in the absence of $0^\#$, of the "countably closed" weak covering property for L and a proof of $\square_\kappa$ for $\kappa > \omega$.

10. Σ^* Fine Structure. Philip Welch considerably rounds out the discussion of fine structure by presenting the Σ^* version and the extensive work on square principles and morasses, providing commentary throughout about the interactions with inner model theory.

Σ^* fine structure is due to Jensen and detailed in Zeman's book *Inner Models and Large Cardinals* (2002). The theory is a notable advance in that it isolated the "right" classes of formulas for the articulation of fine structure results. The classes form a certain ramified version of the Levy hierarchy, the $\Sigma_k^{(n)}$ formulas for $n, k \in \omega$, which level-by-level are able to capture syntactically the semantic role of standard parameters. In particular, $\Sigma_1^{(n)}(J_\alpha)$ relations can be uniformized by $\Sigma_1^{(n)}(J_\alpha)$ relations defined uniformly for all α. And the $\Sigma_1^{(n)}$ formulas are exactly the formulas preserved by the $r\Sigma_{n+1}$ embeddings involving very good parameters.

The first section of the chapter establishes the Σ^* theory, with the treatment much as in Zeman's book. The Σ^* approach is shown to advantage in the development of the Σ^* *ultrapower*, Σ^* fine structure preserving extender ultrapowers. Then the more general pseudo-ultrapower (which corresponds to the use of "long" extenders) is developed, with a refinement toward coming applications.

The second section is devoted to square principles. Jensen had established that if $V = L$, then in addition to the principles $\square_\kappa$ a global, class version $\square$ holds. Most of the section is taken up by a Σ^* pseudo-ultrapower proof of this result, one that provides a global $\square$ sequence with uniform features.

The section concludes with an extensive and detailed description of the recent investigation of square principles in inner models. Of particular interest is the failure of $\square_\kappa$, this for singular κ precluding covering properties for inner models. Around 2000 an elucidating systemic characterization was achieved. Solovay's initial 1970s result—that if κ is λ^+-supercompact and $\lambda \geq \kappa$, then $\square_\lambda$ fails—had led to refinements, and Jensen had extracted a streamlined large cardinal concept, later dubbed *subcompactness*, still sufficient so that: *If κ is subcompact, then $\square_\kappa$ fails.* Then in a remarkable analysis, Zeman and Schimmerling established: *In "Jensen-style" extender models $L[\vec{E}]$, if $\square_\kappa$ fails, then κ is subcompact.* These results established the reach of $\square_\kappa$ well beyond current inner model theory, in that subcompact cardinals, far stronger than Woodin cardinals, are not known to have canonical inner models. By 2005 Steel established: *If $\square_\kappa$ fails for some singular strong limit cardinal κ, then* $\mathrm{AD}^{L(\mathbb{R})}$ *holds.*

The chapter is brought to an end with a survey of the extensive work on morasses. A $(\kappa, 1)$ morass is a system approximating the L_α's for $\kappa < \alpha \leq \kappa^+$ by means of L_β's for $\beta < \kappa$ and maps $f_{\beta,\beta'}$ between them as regulated by a series of conditions. Just after his development of fine structure Jensen formulated morasses and established their existence in L in order to establish model-theoretic "cardinal transfer" theorems there. A great deal of work has since been carried out on morass structures as providing approximations to large structures in terms of indexed arrays of small structures, and morasses have come to carry the weight of the extent of combinatorial structure in the constructible universe.

VOLUME II

11. Elementary Embeddings and Algebra. In this chapter Patrick Dehornoy describes a notable development arising out of the investigation of algebraic features of very strong elementary embeddings. After Kunen established his result that a strong large cardinal postulation is inconsistent, it was natural to investigate remaining possibilities just weaker and so still of great consistency strength. One was that there exists a (non-identity) elementary embedding $j : V_\lambda \to V_\lambda$ for some limit λ. There is a collective structure here, for letting $\mathcal{E}_\lambda$ be the set of such embeddings, $\mathcal{E}_\lambda$ is closed under functional composition $\circ$, as well as *application*: For $j, k \in \mathcal{E}_\lambda$, let $j[k] = \bigcup_{\gamma<\lambda} j(k \cap V_\gamma)$, regarding k of course as a set of ordered pairs; then $j[k]$ is in $\mathcal{E}_\lambda$ as well. Composition $\circ$ and application $[\,]$ together satisfy a handful of laws, and the latter satisfies the left distributive law $j[k[l]] = j[k][j[l]]$. Martin's 1978 result, that if there is an "iterable" elementary $j : V_\lambda \to V_\lambda$ then $\mathbf{\Pi}^1_2$-Determinacy holds, first used application $[\,]$ and these laws for j applied to itself.

Laver saw that application provided a wealth of elementary embeddings and a proliferation of critical points. With this he initiated a systematic investigation into the structure of $\mathcal{E}_\lambda$ for its own sake. In 1989 he established the freeness of the subalgebra generated by one j in $\langle \mathcal{E}_\lambda, [\,] \rangle$ subject to the left distributive law and the analogous result for $\langle \mathcal{E}, [\,], \circ \rangle$. Moreover, with his analysis Laver established that the corresponding word problem for the left distributive law is solvable, i.e. it is recursively decidable whether two given expressions in the language of one generator and $[\,]$ are equivalent according to the left distributive law. This elicited considerable interest, with a hypothesis near the limits of consistency entailing solvability in finitary mathematics. In 1992 Dehornoy eliminated the large cardinal assumption from the solvability result with an elegant argument that led to unexpected results about the Artin braid group.

Dehornoy in this chapter effectively presents the body of work on $\mathcal{E}_\lambda$ and the left distributive law. Beyond the solvability of the word problem, he also presents the Laver-Steel theorem about the set of critical points of members of $\mathcal{E}_\lambda$ having order-type ω, a result that initially applied results about the Mitchell ordering in inner model theory; Randall Dougherty's result that the growth rate of the critical points is faster than Ackermann's function; and results on the finite "Laver tables" using $\mathcal{E}_\lambda \neq \emptyset$ that thus far have not been established in ZFC alone.

12. Iterated Forcing and Elementary Embeddings. James Cummings provides a lucid exposition of that core part of the mainstream of forcing and large cardinals having to do with iterated forcing and extensions of elementary embeddings. Forcing and large cardinals are elaborated in the directions of ideals and generic elementary embeddings in the next chapter and in the direction of Prikry-type forcings in Chap. 16. Drawing on his wide-ranging knowledge, Cummings provides a well-organized account, in mainly short, crisp sections, starting from the basics and proceeding through a series of techniques, with historical progression a rough guide and conceptual complexity a steady one. This chapter is commended to the reader conversant even with only the basics of forcing and large cardinals to assimilate what have become important techniques of modern set theory.

The early sections proceed through the basics of elementary embeddings, ultrapowers and extenders, large cardinal axioms, forcing, some forcing partial orders, and iterated forcing. The first ascent is to building generic objects to extend ("lift") elementary embeddings in forcing extensions. Describing Silver's Easton support iteration and the key idea of master condition, his 1971 result is established: *If κ is κ^{++}-supercompact, then there is a forcing extension in which κ is measurable and $2^\kappa = \kappa^{++}$.* Next, Magidor's important technique of making do with an "increasingly masterful" sequence of conditions is presented. Then, the general idea of *absorption*, embedding a complex partial order into a simple one, is discussed. This is illustrated with Magidor's 1982 result (also highlighted in Chap. 15): *If there are infinitely many supercompact cardinals, then in a forcing extension in which they become the $\aleph_n$'s, every stationary subset of $\aleph_{\omega+1}$ reflects.*

Precipitousness is the subject of the two longer sections of the chapter. In the first, the Jech-Prikry-Mitchell-Magidor mid-1970s result is established, building on the previous work: *If there is a measurable cardinal κ, then there is a forcing extension in which $\kappa = \omega_1$ and NS_{ω_1} is precipitous.* This involves exploiting the absorptive properties of the initial Levy collapse with iterated "club shooting". In the second, and longest, section a proof is provided of the 1983 Gitik result: *The precipitousness of NS_{ω_2} is equi-consistent with having a measurable cardinal κ such that $o(\kappa) = 2$ in the Mitchell order.* The difficult, forcing direction exhibited Gitik's virtuosity of technique, and all the features of a "preparation forcing" before the iterated club shooting are carefully laid out: Namba forcing, RCS iteration, the S and $\mathbb{I}$ conditions.

The rest of the chapter reverts to short sections that describe a wide range of techniques and results, of which we mention the more conspicuous. Presenting Kunen's universal collapse and Silver's collapse, Kunen's focal 1972 result is established: *If κ is huge, then there is forcing extension in which $\kappa = \omega_1$ and there is an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1.* Laver's termspace forcing for introducing a universal generic object by forcing with a partial order of terms is described and applied to establish Magidor's 1973 result: *It is consistent that the least strong compact cardinal is the least measurable cardinal.* The "Laver diamond" and its original use to make supercompact cardinals "indestructible" is presented, and with this Baumgartner's 1983 consistency result is established: *If there is a supercompact cardinal κ, then there is a forcing extension in which $\kappa = \omega_2$ and* PFA *holds.* Finally, Woodin's technique of "altering generic objects" is used to establish his 1988 consistency result of getting a measurable cardinal κ satisfying $2^\kappa > \kappa^+$ from what turned out, by later work of Gitik, to be the optimal hypothesis. The incorporation of these various, historically important results in one chapter speak to how iterated forcing methods have been comprehensively assimilated in modern set theory.

13. Ideals and Generic Elementary Embeddings. In this the longest chapter of this Handbook, Matthew Foreman provides a wealth of methods and results surrounding the general theme of ideals and generic elementary embeddings. In Cummings's chapter it was shown how to extend large cardinal embeddings after forcing with a partial order P, by doing additional forcing Q. If $G \subseteq P$ is generic, then from the point of view of $V[G]$, this can be viewed as saying that forcing with Q creates a "generic" elementary embedding. Foreman's chapter takes up this theme in more generality; it is concerned with the abstract question of when such a Q exists. What is at play is the basic synthesis of forcing and ultrapowers whereby one starts with an ideal I over a cardinal κ; forces with $P(\kappa) - I$ where p is stronger than q if $p - q \in I$; produces an ultrafilter over the ground model $P(\kappa)$; and then gets a generic elementary embedding of the ground model into the corresponding ultrapower. With the possibilities of ideals occurring low in the cumulative hierarchy, so that large cardinal ideas can be applied to classical problems of set theory, an enormous subject has grown as attested to by this chapter. Indeed, in it a very wide range and variety of material have been marshalled, and this comes together with an informal and inviting engagement that provides if not proofs, sketches of proofs, and if not sketches, outlines that "show".

Not just a miscellany, the chapter has been organized in terms of overall guiding themes. At the broadest level are the "three parameters" describing the strength of a generic elementary embedding $j : V \to M$: how j moves the ordinals; how large and closed M is; and the nature of the forcing that provided j. This last is the new parameter at play beyond the "conventional" large cardinal hypotheses. Ideals through their forcing properties thus assuming a crucial role, another guiding theme is the distinction between "natural" ideals that have intrinsic definitions and ideals "induced" by elementary embeddings. As the chapter progresses, strong ideal assumptions gain an autonomy as "generic large cardinals" in their own right, and the chapter is further delineated according to consequences of generic large cardinals and consistency results about them.

Section 2 introduces the basics of generic ultrapowers and begins the study of the correspondence between combinatorial properties of ideals and structural properties of generic ultrapowers. Topics include criteria for precipitousness, the disjointing property, normality, limitations on closure, canonical functions, selectivity and the use of generic embeddings for reflection.

Section 3 provides a range of examples of natural and induced ideals. Among the natural ideals considered are the nonstationary ideals NS_λ, their important generalizations to nonstationary subsets over power sets $P(X)$, *Chang ideals*, Shelah's $I[\lambda]$ and *club guessing ideals*, *non-diamond ideals*, and *uniformization ideals*. How induced ideals arise is taken up next, with an important example being the *master condition ideals*, with their connections to proper forcing. In a general setting, *goodness* and *self-genericity* are explored for making natural ideals also induced. Self-genericity can be secured through semiproper forcing and can secure the saturation or precipitousness of natural ideals.

Section 4 takes a closer look at combinatorial properties of ideals and structural properties of generic ultrapowers. Topics include a range of saturation properties, *layered ideals*, Rudin-Keisler projections, where the ordinals go under generic elementary embeddings, and the sizes of sets in dual filters. Iterations of generic elementary embeddings are also developed as well as generic elementary embeddings arising from *towers* of ideals, i.e. sequences of ideals interrelated by projection maps.

Section 5 considers consequences of positing strong ideals, or generic large cardinals, low in the cumulative hierarchy. The wide-ranging topics include graphs and groups; Chang's Conjecture, Jónsson cardinals, and $\square_\kappa$; CH, GCH, and SCH; stationary set reflection; Suslin and Kurepa trees; partition properties; descriptive set theory; and non-regular ultrafilters. As emphasized, NS_{ω_1} being $\aleph_2$-saturated importantly has countervailing consequences.

Section 6 discusses limitative results on the possibilities for generic large cardinals. These play a role analogous to the Kunen limitation on conventional large cardinals, and indeed, argumentation for it is initially applied. A range of restrictions on ideal properties is subsequently presented, among them results that stand as remarkable successes: the Gitik-Shelah result that if κ is regular and $\delta^+ < \kappa$, then the ideal generated by NS_κ and $\{\alpha < \kappa \mid \mathrm{cf}(\alpha) = \delta\}$ is not κ^+-saturated; their result that there is no $\aleph_1$-complete $\aleph_0$-dense nowhere prime ideal; the Matsubara-Shioya result that for $\omega < \kappa \leq \lambda$ with κ regular, $I_{\kappa\lambda}$ is not precipitous; and the Foreman-Magidor result that for $\omega < \kappa \leq \lambda$ with κ regular, $\mathrm{NS}_{\kappa\lambda}$ is not λ^+-saturated unless $\kappa = \lambda = \omega_1$.

Having progressed to the middle of the chapter, one sees that the chapter naturally divides into halves, the latter having to do with consistency results for strong ideal assumptions. The long Sect. 7 attends to the main consistency results for induced ideals having strong properties. After developing the basic master condition theory for extending elementary embeddings, a general theorem—the Duality Theorem—is established for characterizing the forcing necessary for constructing the elementary embedding coming from an induced ideal. With this in place, a systematic account of various forcing techniques for getting precipitous and saturated ideals is provided. Highlights are Kunen's technique for getting an $\aleph_1$-complete $\aleph_2$-saturated ideal over ω_1 from a huge cardinal; Magidor's variation for which an "almost huge" cardinal suffices; Foreman's iteration to get κ-complete κ^+-saturated ideals over κ for every regular $\kappa > \omega$; Woodin's $\aleph_1$-complete $\aleph_1$-dense ideal over ω_1 from an almost huge cardinal; and Foreman's $\aleph_1$-complete $\aleph_1$-dense uniform ideal over ω_2 from two coordinated almost huge cardinals.

Section 8 in turn attends to consistency results for natural ideals having strong properties. In the first of two main approaches, one starts with an induced ideal with strong properties and forces that ideal to be a natural ideal while retaining substantial properties. Important examples are the Magidor and Woodin arguments for getting the nonstationary ideal to be precipitous and (somewhere) saturated respectively, and the Foreman-Komjáth argument for getting the tail club guessing filter to be saturated. In the second approach, one starts with a natural ideal and manipulates its antichain structure to make the generic ultrapower have strong properties. The important example is the "antichain catching" technique of the 1984 Foreman-Magidor-Shelah work for getting the nonstationary ideal to be saturated.

Section 9 broaches the extension of the context to towers of ideals. First brought into prominence by Woodin with his stationary tower forcing, this extension allows for more flexibility in minimizing assumptions and in drawing conclusions. After considering "induced" towers, techniques based on antichain catching are presented for getting nice generic ultrapowers. The stationary towers are the "natural" towers, and examples of Woodin and Douglas Burke are described. Finally, examples of stationary tower forcing are provided.

Section 10 briefly discusses the consistency strength of ideal assumptions. How inner model theory has successfully established lower bounds complementing forcing consistency results is quickly summarized. The focus, however, is on how knowing the image of just a few sets under a generic elementary embedding suffices to show that there is a conventional large cardinal in an inner model whose embedding agrees with the generic embedding. Notably, equi-consistency results for very large cardinals like the n-huge cardinals are derived by this means.

Section 11 is a speculative discussion of the possibility of adopting generic large cardinal axioms along with their conventional cousins as additional axioms for mathematics. There is summarizing, comparisons, and prediction, and the reader could profitably read this section before surmounting all the others. Section 12 is an extensive, detailed list of open problems. These two last sections indicate the wealth of possibilities at this general confluence of the methods of forcing and ultrapowers.

14. Cardinal Arithmetic. Uri Abraham and Menachem Magidor provide a broad-based account of Shelah's pcf theory and its applications to cardinal arithmetic, an account that exhibits the gains of considerable experience.

A beginning section sets out a general theory of ordinal-valued functions modulo ideals and cofinal sequences thereof, through to the existence of *exact* upper bounds as derived from a diamond-like *club guessing* principle. Delineating consequences, Silver's Theorem and a covering result of Magidor are established forthwith.

The next sections develop the basic theory of the central pcf function as calibrated by the crucial ideals $J_{<\lambda}[A]$. The various aspects of an unexpectedly rich structure are presented, the surround of the focal result that $J_{<\lambda^+}[A]$ is generated by $J_{<\lambda}[A]$ together with a single set $B_\lambda \subseteq A$.

The latter sections make the ascent to the applications in cardinal arithmetic. First, the general Shelah study of the cofinality of $[\mu]^\kappa = \{x \subseteq \mu \mid |x| = \kappa\}$ under $\subseteq$ is presented. One takes a sufficiently large $H_\Psi (= H(\Psi))$ and structured chains of elementary substructures to get specifically related generators B_λ. With this the 1980 Shelah result $\aleph_\delta^{\mathrm{cf}(\delta)} < \aleph_{(|\delta|^{\mathrm{cf}(\delta)})^+}$ is secured. Proceeding through a finer analysis leading to "transitive" generators B_λ, the now famous result, instantiated by $2^{\aleph_\omega} < \aleph_{\omega_4}$ when $\aleph_\omega$ is a strong limit, is established.

The last section is devoted to Shelah's remarkable "revised GCH" result established in the early 1990s. With his investigation of cofinalities leading to "covering" sets Shelah advocated the consideration of

$$\lambda^{[\kappa]} = \min\bigl\{|\mathcal{P}| \mid \mathcal{P} \subseteq [\lambda]^{\leq\kappa} \ \wedge\ \forall u \in [\lambda]^\kappa \exists x \in [\mathcal{P}]^{<\kappa}\bigl(u = \bigcup x\bigr)\bigr\}$$

as a "revised" power set operation. GCH is equivalent to the assertion that for all regular $\kappa < \lambda$, $\lambda^{[\kappa]} = \lambda$. Using a variant of the pcf function, Shelah established that $\lambda^{[\kappa]} = \lambda$ for every $\lambda \geq \beth_\omega$ (where $\beth_\omega = \sup\{\beth_n \mid n \in \omega\}$ with $\beth_0 = \aleph_0$ and $\beth_{n+1} = 2^{\beth_n}$) and with $\kappa < \lambda$ sufficiently large. Thus, pcf theory provided a viable, substantive version of the GCH provable in ZFC.

15. Successors of Singular Cardinals. The investigation of combinatorial properties at successors of singular cardinals, with $\aleph_{\omega+1}$ being paradigmatic, has emerged as a distinctive subject in modern set theory. Historically, the early forcing arguments to secure substantial propositions low in the cumulative hierarchy by collapsing large cardinals to $\aleph_1$ or $\aleph_2$ did not adapt to $\aleph_{\omega+1}$. The situation became accentuated when the 1970s work on covering properties for inner models showed that the failure of $\Box_\kappa$ for singular κ would require strong large cardinal hypotheses. In the 1980s expansion, the relative consistency of strong propositions about $\aleph_{\omega+1}$ entailing the failure of $\Box_{\aleph_\omega}$ were duly achieved, and with the emergence of pcf theory a new combinatorially elaborated setting was established as well. In recent years, the conceptual space between $\Box_\kappa$-like properties and their antithetical reflection properties has become clarified through methods and principles that have particular applicability at successors of singular cardinals.

Todd Eisworth in this chapter provides a well-organized account of the modern theory for successors of singular cardinals, an account that covers the full range from consistency results to combinatorics. After a first section setting out three illustrative problems about $\aleph_{\omega+1}$ the second section takes on one, stationary set reflection, as its theme. Let $\mathrm{Refl}(\kappa)$ be the assertion that every stationary $S \subseteq \kappa$ reflects, i.e. there is an $\alpha < \kappa$ such that $S \cap \alpha$ is stationary in α. A central tension is brought to the foreground with the discussion of how $\Box_\kappa$ denies $\mathrm{Refl}(\kappa^+)$ in a strong sense and how supercompact cardinals, and even strong compact cardinals through indecomposable ultrafilters, imply versions of stationary set reflection. The rest of the section is devoted to establishing, as an entrée into the issues, Magidor's 1982 result: *If there are infinitely many supercompact cardinals, then in a forcing extension in which they become the $\aleph_n$'s,* $\mathrm{Refl}(\aleph_{\omega+1})$ *holds.*

The third section is given over to a detailed exegesis of the ideal $I[\lambda]$. Part of his deep combinatorial analysis, Shelah isolated $I[\lambda]$ after strands had appeared in his work as early as 1978, and $I[\lambda]$ has grown in importance to become a central concept. In accessible terms, $S \subseteq \lambda$ is in $I[\lambda]$ *iff* there is a sequence $\bar{a} = \langle a_\alpha : \alpha < \lambda \rangle$ with $a_\alpha \subseteq \alpha$ and a closed unbounded $C \subseteq \lambda$ such that every $\delta \in S \cap C$ is singular and has a cofinal $A \subseteq \delta$ of order-type $\mathrm{cf}(\delta)$, each of whose initial segments appears in $\{a_\beta \mid \beta < \delta\}$. This articulates a subtle sense of fast approachability, and for singular μ, AP_μ asserts that $I[\mu^+]$ is an improper ideal, i.e. $\mu^+ \in I[\mu^+]$. $\square_\mu$ implies AP_μ, and through Shelah's incisive analysis of $I[\lambda]$, one gets to the consistency of the failure of $\mathrm{AP}_{\aleph_\omega}$ from a supercompact cardinal. The section is brought to a close with Shelah's result, a bulwark of his pcf theory, on the existence of scales: With μ singular let $A \subseteq \mu$ be a set of regular cardinals cofinal in μ of order-type $\mathrm{cf}(\mu)$ such that $\mathrm{cf}(\mu) < \min(A)$ as in pcf theory. Consider ΠA with respect to the filter $F = \{X \subseteq \mathrm{cf}(\mu) \mid |\mathrm{cf}(\mu) - X| < \mathrm{cf}(\mu)\}$ of co-bounded sets. Then Shelah showed that $\langle \Pi A, <^*_F \rangle$ has a linearly ordered, cofinal sequence of length μ^+—a *scale* for μ. (In terms of pcf theory, $\Pi A/F$ has true cofinality μ^+.)

The fourth section provides an extensive exploration of applications of scales and weak square principles. Attention soon focuses on the Foreman-Magidor Very Weak Square at μ (VWS_μ), particularly its close relationship to $I[\mu^+]$. VWS_μ is a square principle so weak that AP_μ implies it, and moreover, it is consistent to have a supercompact cardinal together with VWS_μ holding for every singular μ. The rest of the section is devoted to how scales with additional properties get us further across the divide between weak square principles and reflection properties. A family consisting of non-empty sets is *free iff* it has an injective choice function, and is *κ-free iff* every subfamily of cardinality less that κ is free. $\mathrm{NPT}(\kappa, \theta)$ is the assertion that there is a κ-free, non-free family of κ non-empty sets each of cardinality less than θ. That $\mathrm{NPT}(\kappa, \aleph_1)$ fails for any singular cardinal κ is part of Shelah's work on singular compactness. The existence of "good" scales leads to $\mathrm{NPT}(\aleph_{\omega+1}, \aleph_1)$, a central result of important work of Magidor and Shelah on the freeness of abelian groups. The notions of "very good" and even "better" scales provide avenues for further combinatorial elucidation.

The last section discusses square-brackets partition relations, with the focus on Jónsson algebras. The existence of such algebras was an important motivation of Shelah's development of pcf theory, and early on Shelah established that $\aleph_{\omega+1}$ carries a Jónsson algebra. The general question of whether every successor of a singular cardinal carries a Jónsson algebra remains unsolved, and the section sketches the expanse of Shelah's work here.

16. Prikry-Type Forcings. In this chapter Moti Gitik presents the full range of forcing techniques that have been developed to investigate powers of singular cardinals and the Singular Cardinal Hypothesis. With his technical virtuosity and persistence Gitik has been the main contributor to the subject, and to the organization and presentation of this chapter he brings his extensive knowledge, providing several simplifications of the previously published work. To be noted is that being of the Israeli school, Gitik writes "$p > q$" for p being a stronger condition than q.

The first half deals with the work on countable cofinality. An initial section presents the basic Prikry forcing and its variants through to a strongly compact version, all having the characteristic property of adjoining new cofinal subsets without adjoining bounded subsets or collapsing cardinals. The next several sections then present the Gitik-Magidor extender-based forcing for adjoining many Prikry sequences with optimal hypotheses. As a warm-up, the simpler case when κ is already singular, $\kappa = \sup\{\kappa_n \mid n \in \omega\}$, is presented. One posits extenders on each κ_n and uses the embeddings to develop a system of ultrafilters $U_{n\alpha}$ on κ_n for adjoining Prikry sequences t_α. The forcing itself relies on getting Cohen subsets of κ^+ to guide the construction. Then the main case of an extender-based Prikry forcing with a single extender on a regular κ is presented. This forcing elaborates the previous by singularizing κ and confronts the added difficulty that the support of a condition may have cardinality κ. Finally, the forcing that additionally brings the whole situation down to render $\kappa = \aleph_\omega$ with interwoven Levy collapses is presented.

The latter half of the chapter begins with the work on uncountable cofinality. First, the basics of Radin forcing for adjoining a closed unbounded subset to a large cardinal consisting of formerly regular cardinals is carefully presented in an extensive section. This forcing had originally been given in terms of an elementary embedding $j : V \to M$, and next, a presentation based on a coherent sequence of ultrafilters is given, this providing a treatment also encompassing Magidor forcing for changing to uncountable cofinality. Then Carmi Merimovich's extender-based Radin forcing is broached.

The last section handles iterations of general "Prikry-type forcings". Such an iteration had first occurred in Magidor's 1973 result that *it is consistent that the least strongly compact cardinal is the least measurable cardinal*, and here Magidor's proof is simplified. After discussing an interesting forcing due to Jeffrey Leaning, the section turns to Easton support iterations of Prikry-type forcings. It is observed that this provides another way of establishing the consistency of the failure of SCH from the optimal hypothesis $\exists\kappa(o(\kappa) = \kappa^{++})$. The chapter ends with five open problems about powers of singular cardinals.

VOLUME III

17. Beginning Inner Model Theory. In this first of several chapters on inner model theory, William Mitchell authoritatively sets out the theory from $L[U]$ and K^{DJ} through to inner models of strong cardinals, the "coarse theory" not requiring fine structure. He thus performs the service of laying out the larger features and strategies of inner model theory that will frame the later chapters. There is iteration, comparison, coherence, and coiteration, and at one end sharps and mice and the other end coherent sequences of (non-overlapping) extenders. Beyond this, he provides two illuminating discussions about the further developments that involve fine structure. One is on the advantages of the modern Baldwin-Mitchell presentation with partial extenders even for the cases that he considers. The other is about what in general the core model should be in set theory, separate from any specific large cardinal assumptions.

18. The Covering Lemma. Mitchell here draws on his experience and expertise to provide an incisive account of the covering leitmotiv for inner models, which has been central to the development of inner model theory. The Jensen argument for the Covering Lemma for L has not only stimulated the formulation of new inner models in which the argument can be applied but has proven to be robust through these models to establish various results about the global affinity between inner models and the universe.

The first two sections discuss variants of the covering lemma and their applications. What is brought out is that the basic Jensen argument as a conceptual construction can be implemented in a range of inner models, but that the conclusions that one can draw depends on the large cardinal hypotheses involved and the complexity that one wants to sustain.

The third section outlines a proof, complete except for some fine structure details, of the Jensen and Dodd-Jensen covering results for L and $L[U]$. Although proofs for these cases have been devised that do not appeal to fine structure, it is deployed here in order to maintain generalizability. In fact, the Baldwin-Mitchell approach with partial extenders is already adopted for the technical advantages of local uniformity that it provides. One significant feature of the $L[U]$ case is that a weak covering property is established first and used to study ultrapower-generated indiscernibles leading to Prikry generic sequences.

The last section is devoted largely to a proof of covering for Mitchell's core model $K[\mathcal{U}]$ for coherent sequences $\mathcal{U}$ of ultrafilters. The previous proof has now to be further elaborated on account of the possible generation of complicated systems of indiscernibles, including possibly those leading to generic sequences for the Magidor forcing for changing to uncountable cofinalities. Drawing out what is possible from the covering argument, an elaborate conclusion is articulated and established. Gitik, for one direction of his culminating equi-consistency result on the Singular Cardinals Hypothesis, had applied this covering conclusion together with elements of Shelah's pcf theory to establish that if SCH fails, then in an inner model $\exists\kappa(o(\kappa) \geq \kappa^{++})$ holds. This synthetic result is next presented as a crucial application. The section, and chapter, concludes with a discussion of how the covering proof and conclusion can be extended to a strong cardinal, and the progress made with weaker versions of covering up to a Woodin cardinal and beyond.

19. An Outline of Inner Model Theory. In this chapter John Steel provides a general theory of extender models, the canonical inner models for large cardinals, getting to his model K^c. Moreover, he provides a remarkable application, to the effect that under $\mathrm{AD}^{L(\mathbb{R})}$, $\mathrm{HOD}^{L(\mathbb{R})}$ up to a high rank V_δ is an extender model. Since it was Steel who in the mid-1990s provided the framework and made the crucial, final advances in this inner model theory, this chapter carries the stamp of experience and authority. The next chapter provides the construction of Steel's core model K up to a Woodin cardinal, a construction based on K^c, and a range of combinatorial applications. Chapter 22 describes how iteration trees, a basic component of the K^c construction, found their first substantial use in determinacy.

After covering the basics of extenders, an early section sets out the carefully wrought definition of a *fine extender sequence* $\vec{E}$. These are coherent sequences enhanced with acceptability for $J^{\vec{E}}$ and the Baldwin-Mitchell idea of having E_α be only an extender for subsets in $J_\alpha^{\vec{E}\restriction\alpha}$. A *potential premouse* is then a structure $J_\alpha^{\vec{E}}$ where $\vec{E}$ is a fine extender sequence. With Chap. 9 preliminaries, fine structure considerations are imposed on potential premice and fine structure preserving ultrapowers are schematically described.

The next section engages the project of comparing two potential premice through coiteration. Iteration trees become central for handling overlapping extenders, and iterability for comparison is articulated in terms of games and iteration strategies for securing well-founded limits of models along branches. Fine structural considerations have become crucial to carrying out the process internally in extender models.

The succeeding section establishes the Dodd-Jensen Lemma about the minimality of iterations copied across fine structure preserving maps, as well as a weak Neeman-Steel version sufficient for present purposes. A further section deals with crucial results about solidity and condensation. These sections, elaborating the analysis starting with iterations trees, carve a fine path through a thicket of detail.

With these preparations, a culminating section provides the K^c construction and the resulting Steel *background certified core model* K^c. The model is an extender model $L[\vec{E}\,]$ for a fine extender sequence $\vec{E}$ defined according to the following stratagem: Given $\vec{E}\restriction\alpha$, an F is next adjoined if it is "certified" by a "background extender" F^*, in that F is the restriction to $J_\alpha^{\vec{E}\restriction\alpha}$ of F^*, an extender in V with sufficiently strong properties to guarantee iterability of $\vec{E}\restriction\alpha^\frown\langle F\rangle$. That such an $\vec{E}$ can be defined canonically is at the heart of the construction.

The concluding two sections bring inner model theory and determinacy together for the analysis of $\mathrm{HOD}^{L(\mathbb{R})}$. Both sections proceed under the assumption that there are infinitely many Woodin cardinals with a measurable cardinal above them, so that in particular $\mathrm{AD}^{L(\mathbb{R})}$ holds. The main thrust of the first section is that the reals in the minimal iterable inner model M_ω satisfying "there are infinitely many Woodin cardinals" are exactly the reals in $\mathrm{OD}^{L(\mathbb{R})}$. The last section builds on this work to establish, using the (full) Dodd-Jensen Lemma, that $\mathrm{HOD}^{L(\mathbb{R})}$ is "almost" an iterate M_∞ of M_ω. Specifically, for δ the large projective ordinal $(\underset{\sim}{\delta}{}^2_1)^{L(\mathbb{R})}$, $\mathrm{HOD}^{L(\mathbb{R})} \cap V_\delta = M_\infty \cap V_\delta$. This suffices in particular to establish under $\mathrm{AD}^{L(\mathbb{R})}$ that $\mathrm{HOD}^{L(\mathbb{R})} \models \mathrm{GCH}$. It is remarkable that an inner model incipiently based on global definability can be shown to have structure as given by local definability and extender analysis.

20. A Core Model Tool Box and Guide. Building on the general theory of the previous chapter, Ernest Schimmerling develops its historical source, Steel's core model K up to a Woodin cardinal, and discusses combinatorial applications of it across set theory. Having been one of the contributors to the covering lemma theory for K and the initiating investigator of combinatorial principles there, Schimmerling provides a measured, wide-ranging account, one with careful accreditations.

The first half of the chapter is devoted to the basic theory of K. Going "up to" a Woodin cardinal, the "anti-large cardinal hypothesis" that there is no inner model with a Woodin cardinal is assumed. But moreover as Steel initially did, an additional "technical hypothesis" that there is a measurable cardinal Ω is assumed. Ω becomes regulative for the construction of K, schematically playing the role of the class On of ordinals. Regarding K^c as now a set premouse of height Ω, one works with *weasels*, other such premice, and uses the crucial simplifying property that if they have no Woodin cardinals, then their iteration trees have at most one cofinal well-founded branch. A definition of K second-order on $H(\Omega)$ is first developed, and then a first-order, recursive definition.

With K in hand, a useful "tools" section provides, without proof, a range of properties of K, from covering, forcing absoluteness and rigidity to combinatorial principles. The next section outlines a proof of the "countably closed" weak covering property for K. The proof assumes familiarity with that of analogous results as given e.g. in Chaps. 9 and 18 and very much depends on the first-order definition of K. The final section provides, without proof, applications of K and generally, core models at the level that involves iteration trees. One sees at a glance how central this inner model theory has become, with the involvements described in determinacy, trees, ideals, forcing axioms, and pcf theory.

21. Structural Consequences of AD. In this first of several chapters on determinacy, Steve Jackson surveys the structural consequences of determinacy for sets of reals. The chapter thus serves as a fitting sequel to Moschovakis's book *Descriptive Set Theory* (1980). The advances have been in two directions, the extension of the scale theory beyond the projective sets into a substantial class of sets of reals in $L(\mathbb{R})$ and the analysis of the fine combinatorial structure of cardinals provided by the computation of the projective ordinals. With both directions calibrated by the analysis of definable sets in terms of definable well-ordered stratifications, the structure theory has remarkable richness and complexity as well as overall coherence.

An early section lays the basis with a review of basic notions: scales and periodicity, the Coding Lemma, projective ordinals, Wadge reducibility—and with some topics already going beyond the scope of the Moschovakis book—

$\mathbf{\Sigma}^2_1$ sets of reals and infinite-exponent partition relations.

The next section develops the scale theory provided by Suslin cardinals under AD, the arguments mainly due to Martin. Let $S(\kappa)$ denote the class of κ-Suslin sets. A cardinal κ is *Suslin iff* $S(\kappa) - \bigcup_{\kappa'<\kappa} S(\kappa') \neq \emptyset$. That $\aleph_1$ is a Suslin cardinal is a classical result, and PD implies that the projective ordinals $\boldsymbol{\delta}^1_n$ for odd $n \in \omega$ are Suslin. The late 1970s Martin-Steel result that AD + $V = L(\mathbb{R})$ implies that $\mathbf{\Sigma}^2_1$ is the largest class with the scale property and $\mathbf{\Sigma}^2_1 = \bigcup_\kappa S(\kappa)$ provides the new, broad context. With $S(\kappa)$ taken as the analogue of the analytic sets, corresponding analogues of the projective hierarchy and projective ordinals are formulated. The scale property is then inductively propagated using Wadge reducibility and the weakly homogeneous trees available. Thus, the scale theory of the projective sets has been successfully abstracted, with the arguments applied in a suitably articulated setting.

The succeeding two sections present a schematic approach to the computation of the projective ordinals, which had been carried out by the author in a *tour de force* in the latter 1980s. $\kappa \longrightarrow (\kappa)^\lambda$ asserts that if the increasing functions from λ into κ are partitioned into two cells, then there is an $H \subseteq \kappa$ of cardinality κ such that all the increasing functions from λ into H are in one cell. The *strong partition property for* κ is the assertion $\kappa \longrightarrow (\kappa)^\kappa$ and the *weak partition property for* κ is the assertion $\forall\lambda < \kappa((\kappa \longrightarrow (\kappa)^\lambda)$. In the early 1970s Martin established under AD the strong partition property for ω_1, a striking result at the time. Kunen then carried out a detailed analysis of ultrapowers that led to the weak partition property for $\boldsymbol{\delta}^1_3$, which Martin had previously shown under AD to be $\aleph_{\omega+1}$, the third uncountable regular cardinal. In the section on "a theory of ω_1", this work is reorganized by starting with the weak partition property for ω_1 and establishing in turn the upper bound $\boldsymbol{\delta}^1_3 \leq \aleph_{\omega+1}$; the strong partition property for ω_1; the lower bound $\aleph_{\omega+1} \leq \boldsymbol{\delta}^1_3$; and the weak partition property for $\boldsymbol{\delta}^1_3$. This is done in terms of generalizable "descriptions", and the section on higher descriptions starts with the weak partition property for $\boldsymbol{\delta}^1_3$ and proceeds analogously to establish the upper bound $\boldsymbol{\delta}^1_5 \leq \aleph_{\omega^{\omega^\omega}+1}$; the strong partition property for $\boldsymbol{\delta}^1_3$; the lower bound $\aleph_{\omega^{\omega^\omega}+1} \leq \boldsymbol{\delta}^1_5$; and the weak partition property for $\boldsymbol{\delta}^1_5$. In this indicated propagation with descriptions, the author's computation of $\boldsymbol{\delta}^1_5$ and larger projective ordinals has been given a fortunate perspicuity and surveyability.

The final section explores the possibilities for extending throughout $L(\mathbb{R})$ the sort of fine analysis given by the computation of the projective ordinals. A weak square principle $\boxminus_{\kappa,\lambda}$ is established toward the goal of getting at global principles that might help propagate the inductive analysis via the Suslin cardinals.

22. Determinacy in $L(\mathbb{R})$. Woodin's culminating result that AD is equi-consistent with the existence of infinitely many Woodin cardinals figures centrally in this and the next chapters, which establish each direction of the equi-consistency in turn. In this chapter Itay Neeman develops the theme of getting determinacy from large cardinals. In getting technically optimal such results through the use of "long" games, Neeman's book *The Determinacy of Long Games* (2004) was an important contribution along these lines. In this chapter Neeman ultimately provides a complete, tailored proof of Woodin's result that if there are infinitely Woodin cardinals with a measurable cardinal above them, then $\mathrm{AD}^{L(\mathbb{R})}$. He first provides the historical and mathematical lines of approach in terms of concepts and methods of wider applicability and then proceeds with his own, well-crafted trajectory to the final conclusion.

The first several sections presents the basic, Martin-Steel theory of iteration trees. Iterability for the needed case of linear compositions of trees of length ω is articulated in terms of games and strategies and then established. The importance of Woodin cardinals is then brought out for creating complex iteration trees, the complexity discussed in terms of the author's notion of *type* for a set of formulas in place of the former Martin-Steel alternating chains.

The next sections start the ascent to the determinacy of sets in $L(\mathbb{R})$. The first vehicle is the concept of a homogeneously Suslin set of reals, a projection of a homogeneous tree and hence determined. After recasting Martin's classical $\mathbf{\Pi}^1_1$-Determinacy result, the 1985 Martin-Steel breakthrough result is presented, with its propagation of determinacy through the projective hierarchy with Woodin cardinals and iteration trees.

The last several sections make the final ascent with the author's specific approach, one based on getting determinacy by making Woodin cardinals countable with forcing rather than using stationary tower forcing as in Woodin's original proof. First, Woodin cardinals, through forcing and absoluteness, are shown to establish the determinacy of an important class of sets of reals wider than the homogeneously Suslin sets, the *universally Baire sets* of Qi Feng, Magidor, and Woodin. Second, getting at the technical heart of the matter, it is shown that given any real, models with many Woodin cardinals can be iterated to absorb the real in a further generic extension. Finally, with a least counter-example argument, AD is established in a "derived model" assuming the existence of infinitely many Woodin cardinals—getting one direction of Woodin's equi-consistency result—and assuming further the existence of a measurable cardinal above, AD is established in L($\mathbb{R}$) itself.

23. Large Cardinals from Determinacy. In this extensive, well-rounded, and sophisticated chapter Peter Koellner and Hugh Woodin set out the latter's work on getting large cardinals from determinacy hypotheses. The focal results were in place by the early 1990s, but this is the first venue where a full-fledged, systematic account is provided. With hindsight the authors are able to present a well-motivated, self-contained development organized around structural themes buttressing the extensive results.

The first two thirds of the chapter are framed as making an ascent to the Generation Theorem, an abstract theorem that provides a template for generating Woodin cardinals from refined determinacy hypotheses. In fact, the early sections add layer upon layer of complexity in an informative, well-motivated manner to get at more and more large cardinal conclusions.

Section 2 casts Solovay's seminal 1967 result that ω_1 is measurable under ZF + AD in a generalizable manner that draws out boundedness and coding techniques for getting normal ultrafilters. The generalizability is then illustrated by showing that under ZF + AD the projective ordinal $(\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})}$, "the least stable in $L(\mathbb{R})$", is a measurable cardinal in $\mathrm{HOD}^{L(\mathbb{R})}$. Gearing up, Sect. 3 reviews the Moschovakis Coding Lemma and provides a strong, uniform version that will become crucial. Section 4 then establishes, as a precursor to the Generation Theorem, that under ZF + DC + AD a pivotal ordinal $\Theta^{L(\mathbb{R})}$ is a Woodin cardinal in $\mathrm{HOD}^{L(\mathbb{R})}$. First, reflection properties are developed that will play the role played earlier by boundedness. Then the notion of *strong normality* is used to establish that $(\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})}$ is λ-strong for cofinally many $\lambda < \Theta^{L(\mathbb{R})}$. Reflection properties and uniform coding are then worked to secure strong normality. Finally, with crucial appeals to AD and special properties of $\mathrm{HOD}^{L(\mathbb{R})}$, the strongness properties established for $(\underset{\sim}{\delta}^2_1)^{L(\mathbb{R})}$ are shown to relativize for $T \subseteq \Theta$ in $\mathrm{HOD}^{L(\mathbb{R})}$ to provide corresponding λ-T-strong cardinals δ_T, thus leapfrogging up to get that $\Theta^{L(\mathbb{R})}$ is Woodin in $\mathrm{HOD}^{L(\mathbb{R})}$.

The heights are reached in Sect. 5 where the work of the previous section is abstracted to establish two theorems on Woodin cardinals in a general setting. The first shows that in certain strong determinacy contexts HOD can contain many Woodin cardinals, and the second is the central Generation Theorem. The aim of this theorem is to show that the construction of Sect. 4 can be driven by lightface determinacy alone. To simulate the previous use of real parameters, the notion of *strategic determinacy* is introduced, a notion that resembles boldface determinacy but can nonetheless hold in settings with AC. Indeed, this notion is motivated by showing that it can hold in $L[S, x]$, where S is a class of ordinals and x is a real. With this in hand the Generation Theorem is finally established, and a number of instantial cases are presented.

Section 6 applies the Generation Theorem to derive the optimal amount of large cardinal strength from both lightface and boldface determinacy. The main lightface result is that ZF + DC + Δ^1_2-determinacy implies that there is a Turing cone of reals x such that $\omega_2^{L[x]}$ is a Woodin cardinal in $\mathrm{HOD}^{L[x]}$. The task here is to show that Δ^1_2-determinacy secures strategic determinacy. The main boldface result is that ZF + AD implies that in a generalized Prikry forcing extension, there are infinitely many Woodin cardinals in the corresponding HOD. The task here is to show that the Generation Theorem can be iteratively applied to generate infinitely many Woodin cardinals.

Section 7 attends to a reduction to second-order Peano Arithmetic. A first localization of the Generation Theorem shows that Δ^1_2-determinacy implies that for a Turing cone of reals x, $\omega_1^{L[x]}$ is a Woodin cardinal in $L[x]$. A second localization then shows that the proof can in fact be carried out in second-order Peano Arithmetic, to establish that if that theory plus Δ^1_2-determinacy is consistent, then so is ZFC + "On is Woodin", the latter assertion to be understood schematically.

The synthetic final Sect. 8 describes the remarkable confluences, seen in the later 1990s, of definable determinacy and inner model theory. First, actual equivalences between propositions of definable determinacy and propositions about the existence of inner models with Woodin cardinals are described. Then, the earlier HOD analysis is revisited in light of the Steel work on $\mathrm{HOD}^{L(\mathbb{R})}$, described in his Chap. 19. The full $\mathrm{HOD}^{L(\mathbb{R})}$ is not itself an extender model, but can nonetheless be comprehended as a fine-structural inner model of a new sort.

24. Forcing over Models of Determinacy. In this last chapter Paul Larson describes work of Woodin on forcing over models of determinacy. We take the opportunity here to describe that work, thereby framing the chapter. After his remarkable successes culminating in his synthetic equiconsistency results about AD and large cardinals, Woodin in the mid-1990s entered a new, middle period of his research with the investigation of $\mathbb{P}_{\max}$ forcing extensions of models of AD. Quickly becoming a far-reaching theory of maximal and canonical forcing extensions that model ZFC, the subject shed new light on the inner workings of determinacy at the level of $P(\omega_1)$ and the extent of structure in ZFC extensions, even to the possible failure of the Continuum Hypothesis.

Woodin's remarkable *The Axiom of Determinacy, Forcing Axioms, and the Nonstationary Ideal* (1999) in nearly one-thousand pages sets out of his work into his middle period. The book's main thrust is the specification of a canonical, maximal model of ZFC in the following sense: *Assume* $\mathrm{AD}^{L(\mathbb{R})}$ *and that there is a Woodin cardinal with a measurable cardinal above it. Then there is in* $L(\mathbb{R})$ *a (countably closed and homogeneous) partial order* $\mathbb{P}_{\max}$ *so that for* G $\mathbb{P}_{\max}$*-generic over* $L(\mathbb{R})$*,* $L(\mathbb{R})[G]$ *models* ZFC*, and: for any* Π_2 *(i.e.* $\forall x \exists y$*) sentence satisfied in the structure* $\langle H(\omega_2), \in, \mathrm{NS}_{\omega_1}\rangle$*, that sentence is already satisfied in* $\langle H(\omega_2), \in, \mathrm{NS}_{\omega_1}\rangle^{L(\mathbb{R})[G]}$*, the structure relativized to the generic extension.*

With $H(\omega_2)$ suitably accommodating $P(\omega_1)$ and the intrinsic ideal NS_{ω_1} participating, Woodin argues that $\langle H(\omega_2), \in, \mathrm{NS}_{\omega_1}\rangle$ is the next natural extension of second-order arithmetic, which is identifiable with $\langle H(\omega_1), \in\rangle$. A pivotal, historical point about $\mathbb{P}_{\max}$ is that since $\neg$CH is equivalent to a Π_2 sentence of $\langle H(\omega_2), \in\rangle$ and there is a generic extension satisfying $\neg$CH yet preserving the hypotheses of the above result, CH actually fails in $L(\mathbb{R})[G]$. Generally, various combinatorial propositions about ω_1 are similarly consistent via "mild" forcing and are expressible as Π_2 assertions about $\langle H(\omega_2), \in, \mathrm{NS}_{\omega_1}\rangle$, and hence, these propositions hold in $L(\mathbb{R})[G]$. In this very substantial sense, $L(\mathbb{R})[G]$ is a canonical generic extension of $L(\mathbb{R})$.

In his book Woodin's presents an axiom that codifies his motivation for formulating $\mathbb{P}_{\max}$:

$$(*) \qquad \mathrm{AD}^{L(\mathbb{R})} \text{ and: } L(\mathcal{P}(\omega_1)) \text{ is a } \mathbb{P}_{\max}\text{-generic extension of } L(\mathbb{R}).$$

Woodin then develops a variant $\mathbb{Q}_{\max}$ of $\mathbb{P}_{\max}$ that provides extensions in which NS_{ω_1} is $\aleph_1$-dense. Woodin had famously shown that NS_{ω_1} being $\aleph_1$-dense is equivalent in ZF to AD, and with $\mathbb{Q}_{\max}$ he provides a systematic treatment of this result.

Woodin subsequently investigates $\mathbb{P}_{\max}$ extensions of AD models larger than $L(\mathbb{R})$. This enterprise is fueled by a corresponding strong form AD^+ of AD, and with it Woodin is able to starting scaling combinatorial propositions about ω_2 and even forms of Chang's Conjecture. In the final chapter of his book Woodin casts a light into the horizon with the formulation of his Ω-logic. With this new logic and AD^+, a more pristine approach can be taken to $\neg$CH, one that can subsume $\mathbb{P}_{\max}$ extensions in a more direct, albeit abstract, formulation. In work of the 21st century, Woodin will argue for the negation of the Continuum Hypothesis on the basis of his Ω-logic and a corresponding Ω Conjecture.

Larson in this final chapter of this Handbook offers a preparatory guide to Woodin's $\mathbb{P}_{\max}$, one that is to be highly appreciated for providing a patient, accessible approach. The first seven sections present a complete, self-contained analysis of the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$ in an illuminating manner, proceeding incrementally by introducing hypotheses and methods as needed. After setting out the theory of iterated generic elementary embeddings fundamental to $\mathbb{P}_{\max}$, the partial order is formulated and its countable closure is established. After developing *A-iterability*, a generalized iterability property, it is applied to establish crucial structural results about the $\mathbb{P}_{\max}$ extension of $L(\mathbb{R})$. Then the heralded Π_2 maximality with respect to $\langle H(\omega_2), \in, \mathrm{NS}_{\omega_1}\rangle$ is established, and assuming Woodin's axiom $(*)$, the notable minimality result that any subset of ω_1 added by a generic filter generates the entire extension.

The last several sections briefly consider $\mathbb{P}_{\max}$ extensions of larger models under AD^+; Woodin's Ω-logic and Ω Conjecture; and several variations of $\mathbb{P}_{\max}$, starting with $\mathbb{Q}_{\max}$. This sampling reflects the accomplishments with $\mathbb{P}_{\max}$ and suggests the expansive possibilities to be explored.

1. Stationary Sets

1. The Closed Unbounded Filter

1.1. Closed Unbounded Sets

Stationary sets play a fundamental role in modern set theory. This chapter attempts to explain this role and to describe the structure of stationary sets of ordinals and their generalizations.

The concept of stationary set first appeared in the 1950's; the definition is due to Gérard Bloch [16], and the fundamental theorem on stationary sets was proved by Géza Fodor [24]. However, the concept of a stationary set is implicit in the work of Paul Mahlo [71].

The precursor of Fodor's Theorem is the 1929 result of Pavel Alexandroff and Pavel Urysohn [2]: If $f(\alpha) < \alpha$ for all α such that $0 < \alpha < \omega_1$, then f is constant on an uncountable set.

Let us call an ordinal function f *regressive* if $f(\alpha) < \alpha$ whenever $\alpha > 0$. Fodor's Theorem (Theorem 1.5) states that every regressive function on a stationary set is constant on a stationary set. As a consequence, a set $S \subseteq \omega_1$ is stationary if and only if every regressive function on S is constant on an uncountable set.

In this section we develop the theory of closed unbounded and stationary subsets of a regular uncountable cardinal.

If X is a set of ordinals, then α is a *limit point* of X if $\alpha > 0$ and $\sup(X \cap \alpha) = \alpha$. A set $X \subseteq \kappa$ is *closed* (in the order topology on κ) if and only if X includes $\mathrm{Lim}(X)$, the set of all limit points of X less than κ.

1.1 Definition. Let κ be a regular uncountable cardinal. A set $C \subseteq \kappa$ is *closed unbounded* (or *club* for short) if it is closed and also an unbounded subset of κ. A set $S \subseteq \kappa$ is *stationary* if $S \cap C \neq \emptyset$ for every closed unbounded $C \subseteq \kappa$.

It is easily seen that the intersection of any number of closed sets is closed. The basic observation is that if C_1 and C_2 are both closed unbounded, then $C_1 \cap C_2$ is also closed unbounded. This leads to the following basic property.

1.2 Proposition. *The intersection of less than κ closed unbounded subsets of κ is closed unbounded.*

Consequently, the closed unbounded sets generate a κ-complete filter on κ called the *closed unbounded filter*. The dual ideal (which is κ-complete and contains all singletons) consists of all sets that are disjoint from some closed unbounded set—the nonstationary sets, and is thus called the *nonstationary* ideal, denoted NS.

If I is any nontrivial ideal on κ, then I^+ denotes the set $P(\kappa) - I$ of all *I-positive* sets. Thus, stationary subsets of κ are exactly those that are NS-positive.

1.3 Definition. Let $\langle X_\alpha : \alpha < \kappa\rangle$ be a κ-sequence of subsets of κ. Its *diagonal intersection* is the set

$$\Delta_{\alpha<\kappa} X_\alpha = \{\xi < \kappa : \xi \in \textstyle\bigcap_{\alpha<\xi} X_\alpha\};$$

its *diagonal union* is

$$\Sigma_{\alpha<\kappa} X_\alpha = \{\xi < \kappa : \xi \in \textstyle\bigcup_{\alpha<\xi} X_\alpha\}.$$

The following lemma states that the closed unbounded filter is closed under diagonal intersections (or dually, that the nonstationary ideal is closed under diagonal unions):

1.4 Lemma. *If $\langle C_\alpha : \alpha < \kappa\rangle$ is a sequence of closed unbounded subsets of κ, then its diagonal intersection is closed unbounded.*

This immediately implies Fodor's Theorem:

1.5 Theorem (Fodor [24]). *If S is a stationary subset of κ and if f is a regressive function on S, then there exists some $\gamma < \kappa$ such that $f(\alpha) = \gamma$ on a stationary subset of S.*

Proof. Let us assume that for each $\gamma < \kappa$ there exists a closed unbounded set C_γ such that $f(\alpha) \neq \gamma$ for each $\alpha \in S \cap C_\gamma$. Let $C = \Delta_{\gamma<\kappa} C_\gamma$. As C is closed unbounded, there exists an $\alpha > 0$ in $S \cap C$. By the definition of C it follows that $f(\alpha) \geq \alpha$, a contradiction. ⊣

A nontrivial κ-complete ideal I on κ is called *normal* (and so is its dual filter) if I is closed under diagonal unions; equivalently, if for every $A \in I^+$, every regressive function on A is constant on some I-positive set. Thus Fodor's Theorem (or Lemma 1.4) states that the nonstationary ideal (and the club filter) is normal. In fact, the nonstationary ideal is the smallest normal κ-complete ideal on κ:

1.6 Proposition. *If F is a normal κ-complete filter on κ, then F contains all closed unbounded sets.*

Proof. If C is a club subset of κ, let $\langle a_\alpha : \alpha < \kappa\rangle$ be the increasing enumeration of C. Then

$$C \supseteq \Delta_{\alpha<\kappa}\{\xi : a_{\alpha+1} < \xi < \kappa\} \in F,$$

because F contains all final segments (being nontrivial and κ-complete). ⊣

In other words, if I is normal, then every I-positive set is stationary.

The quotient algebra $B = P(\kappa)/\mathrm{NS}$ is a κ-complete Boolean algebra, where the Boolean operations $\Sigma_{\alpha<\gamma}$ and $\Pi_{\alpha<\gamma}$ for $\gamma < \kappa$ are induced by $\bigcup_{\alpha<\gamma}$ and $\bigcap_{\alpha<\gamma}$. Fodor's Theorem implies that B is in fact κ^+-complete: If $\{X_\alpha : \alpha < \kappa\}$ is a collection of subsets of κ, then $\Delta_{\alpha<\kappa} X_\alpha$ and $\Sigma_{\alpha<\kappa} X_\alpha$ are, respectively, the greatest lower bound and the least upper bound of the equivalence classes $X_\alpha/\mathrm{NS} \in B$. This observation also shows that if $\langle X_\alpha : \alpha < \kappa\rangle$

and $\langle Y_\alpha : \alpha < \kappa\rangle$ are two enumerations of the same collection, then $\Delta_\alpha X_\alpha$ and $\Delta_\alpha Y_\alpha$ differ only by a nonstationary set.

The following characterization of the club filter is often useful, in particular when used in its generalized form (see Sect. 6). Let $F : [\kappa]^{<\omega} \to \kappa$; an ordinal $\gamma < \kappa$ is a *closure point* of F if $F(\alpha_1, \dots, \alpha_n) < \gamma$ whenever $\alpha_1, \dots, \alpha_n < \gamma$. It is easy to see that the set Cl_F of all closure points of F is a club. Conversely, if C is a club, define $F : [\kappa]^{<\omega} \to \kappa$ by letting $F(e)$ be the least element of C greater than $\max(e)$. It is clear that $Cl_F = \mathrm{Lim}(C)$. Thus every club contains Cl_F for some F, and we have this characterization of the club filter:

1.7 Proposition. *The club filter is generated by the sets Cl_F, for all $F : [\kappa]^{<\omega} \to \kappa$. A set $S \subseteq \kappa$ is stationary if and only if for every $F : [\kappa]^{<\omega} \to \kappa$, S contains a closure point of F.*

1.2. Splitting Stationary Sets

It is not immediately obvious that the club filter is not an ultrafilter—that there exist stationary sets that are *co-stationary*, i.e. whose complement is stationary. The basic result is the following theorem of Solovay:

1.8 Theorem (Solovay [85]). *Let κ be a regular uncountable cardinal. Then every stationary subset of κ can be partitioned into κ disjoint stationary sets.*

Solovay's proof of this basic result of combinatorial set theory uses methods of forcing and large cardinals, and we shall describe it later in this section. For an elementary proof, see e.g. [49, p. 434].

To illustrate the combinatorics involved, let us prove a special case of Solovay's theorem.

1.9 Proposition. *There exist $\aleph_1$ pairwise disjoint stationary subsets of ω_1.*

Proof. For each limit $\alpha < \omega_1$, choose an increasing sequence $\langle a_n^\alpha : n \in \omega\rangle$ with limit α. We claim that there is an n such that for all $\eta < \omega_1$, there are stationary many α such that $a_n^\alpha \geq \eta$: Otherwise there exists, for each n, some η_n such that $a_n^\alpha \geq \eta_n$ for only a nonstationary set of α's. By ω_1-completeness, for all but a nonstationary set of α's the sequences $\{a_n^\alpha\}_n$ are bounded by $\sup_n \eta_n$. A contradiction.

Thus let n be such that for all η, the set $S_\eta = \{\alpha : a_n^\alpha \geq \eta\}$ is stationary. The function $f(\alpha) = a_n^\alpha$ is regressive and so by Fodor's Theorem, there is some $\gamma_\eta \geq \eta$ such that $T_\eta = \{\alpha : a_n^\alpha = \gamma_\eta\}$ is stationary. Clearly, there are $\aleph_1$ distinct values of γ_η and therefore $\aleph_1$ mutually disjoint sets T_η. ⊣

Let κ be a regular uncountable cardinal, and let $\lambda < \kappa$ be regular. Let

$$\mathbf{E}^\kappa_\lambda = \{\alpha < \kappa : \mathrm{cf}(\alpha) = \lambda\}.$$

For each λ, $\mathbf{E}^\kappa_\lambda$ is a stationary set. An easy modification of the proof of Proposition 1.9 above shows that for every regular $\lambda < \kappa$, every stationary subset of $\mathbf{E}^\kappa_\lambda$ can be split into κ disjoint stationary sets.

The union $\bigcup_\lambda \mathbf{E}^\kappa_\lambda$ is the set of all singular limit ordinals less than κ. Its complement is the set $\mathrm{Reg}(\kappa)$ of all regular cardinals less than κ. The set $\mathrm{Reg}(\kappa)$ is stationary just in case κ is a Mahlo cardinal.

1.3. Generic Ultrapowers

Let M be a transitive model of ZFC, and let κ be a cardinal in M. Let U be an M-*ultrafilter*, i.e. an ultrafilter on the set algebra $P(\kappa) \cap M$. Using functions $f \in M$ on κ, one can form an ultrapower $N = \mathrm{Ult}_U(M)$, which is a model of ZFC but not necessarily well-founded:

$$\begin{aligned} f =^* g &\quad\iff\quad \{\alpha : f(\alpha) = g(\alpha)\} \in U, \\ f \in^* g &\quad\iff\quad \{\alpha : f(\alpha) \in g(\alpha)\} \in U. \end{aligned}$$

The (equivalence classes of) constant functions $c_x(\alpha) = x$ provide an elementary embedding $j : (M, \in) \to (N, \in^*)$, where $j(x) = c_x$, for all $x \in M$.

An M-ultrafilter U is M-κ-*complete* if it is closed under intersections of families $\{X_\alpha : \alpha < \gamma\} \in M$, for all $\gamma < \kappa$; U is *normal* if every regressive $f \in M$ is constant on a set in U.

1.10 Proposition. *Suppose that U is a nonprincipal M-κ-complete, normal M-ultrafilter on κ. Then the ordinals of N have a well-ordered initial segment of order type at least $\kappa + 1$, $j(\gamma) = \gamma$ for all $\gamma < \kappa$, and κ is represented in N by the diagonal function $d(\alpha) = \alpha$.*

Now let κ be a regular uncountable cardinal and consider the forcing notion $(P, <)$ where P is the collection of all stationary subsets of κ, and the ordering is by inclusion. Let B be the complete Boolean algebra $B = B(P)$, the completion of $(P, <)$. Equivalently, B is the completion of the Boolean algebra $P(\kappa)/\mathrm{NS}$. Let us consider the generic extension $V[G]$ given by a generic $G \subseteq P$. It is rather clear that G is a nonprincipal V-κ-complete normal ultrafilter on κ. Thus Proposition 1.10 applies, where $N = \mathrm{Ult}_G(V)$. The model $\mathrm{Ult}_G(V)$ is called a *generic ultrapower*.

There is more on generic ultrapowers in Foreman's chapter in this Handbook; here we use them to present the original argument of Solovay's [85]. First we prove a lemma (that will be generalized in Sect. 2):

1.11 Lemma. *Let κ be a regular uncountable cardinal, and let S be a stationary set. Then the set*

$$T = \{\alpha \in S : \text{either } \alpha \notin \mathrm{Reg}(\kappa) \text{ or } S \cap \alpha \text{ is not a stationary subset of } \alpha\}$$

is stationary.

Proof. Let C be a club and let us show that $T \cap C$ is nonempty. Let α be the least element of the nonempty set $S \cap C'$ where $C' = \mathrm{Lim}(C - \omega)$. If α is not regular, then $\alpha \in T \cap C$ and we are done, so assume that $\alpha \in \mathrm{Reg}(\kappa)$. Now $C' \cap \alpha$ is a club subset of α disjoint from $S \cap \alpha$, and so $\alpha \in T$. ⊣

We shall now outline the proof of Solovay's theorem:

Proof of Theorem 1.8. Let S be a stationary subset of κ that cannot be partitioned into κ disjoint stationary sets. By Proposition 1.9 and the remarks following its proof, we have $S \subseteq \operatorname{Reg}(\kappa)$. Let $I = \mathrm{NS}{\restriction}S$, i.e. $I = \{X \subseteq \kappa : X \cap S \in \mathrm{NS}\}$. The ideal I is *κ-saturated*, i.e. every disjoint family $W \subseteq I^+$ has size less than κ; equivalently, $B = P(\kappa)/I$ has the κ-chain condition. I is also κ-complete and normal.

Let $G \subseteq I^+$ be generic, and let $N = \mathrm{Ult}_G(V)$ be the generic ultrapower. As I is κ-saturated, N is well-founded (this is proved by showing that every name $\dot{f}$ for a function in V on κ can be replaced by an actual function on κ). Thus we have (in $V[G]$) an elementary embedding $j : V \to N$ where N is a transitive class, $j(\gamma) = \gamma$ for all $\gamma < \kappa$, and κ is represented in N by the diagonal function $d(\alpha) = \alpha$. Note that if $A \subseteq \kappa$ is any set (in V), then $A \in N$: this is because $A = j(A) \cap \kappa$; in fact A is represented by the function $f(\alpha) = A \cap \alpha$.

Now we use the fact that κ-c.c. forcing preserves stationarity (cf. Theorem 1.13 below). Thus S is stationary in $V[G]$, and because $N \subseteq V[G]$, S is a stationary set in the model N. By the ultrapower theorem we have

$$V[G] \vDash S \cap \alpha \text{ is stationary for } G\text{-almost all } \alpha.$$

This, translated into forcing, gives

$$\{\alpha \in S : S \cap \alpha \text{ is not stationary}\} \in I$$

but that contradicts Lemma 1.11. $\dashv$

Another major application of generic ultrapowers is Silver's Theorem:

1.12 Theorem (Silver [84]). *Let λ be a singular cardinal of uncountable cofinality. If $2^\alpha = \alpha^+$ for all cardinals $\alpha < \lambda$, then $2^\lambda = \lambda^+$.*

Silver's Theorem is actually stronger than this. It assumes only that $2^\alpha = \alpha^+$ for a stationary set of α's (see Sect. 2 for the definition of "stationary" when λ is not regular). The proof uses a generic ultrapower. Even though $\mathrm{Ult}_G(V)$ is not necessarily well founded, the method of generic ultrapowers enables one to conclude that $2^\lambda = \lambda^+$ when $2^\alpha = \alpha^+$ holds almost everywhere.

Silver's Theorem can be proved by purely combinatorial methods [9, 10]. In [29], Galvin and Hajnal used combinatorial properties of stationary sets to prove a substantial generalization of Silver's Theorem (superseded only by Shelah's powerful pcf theory). For further generalizations using stationary sets and generic ultrapowers, see [50] and [51].

One of the concepts introduced in [29] is the *Galvin-Hajnal norm* of an ordinal function. If f and g are ordinal functions on a regular uncountable cardinal κ, let $f < g$ if $\{\alpha < \kappa : f(\alpha) < g(\alpha)\}$ contains a club. The relation

$<$ is a well-founded partial order, and the norm $\|f\|$ is the rank of f in the relation $<$.

We remark that if $f < g$, then in the generic ultrapower (by NS), the ordinal represented by f is smaller than the ordinal represented by g.

By induction on η one can easily show that for each $\eta < \kappa^+$ there exists a *canonical* function $f_\eta : \kappa \to \kappa$ of norm η, i.e. $\|f_\eta\| = \eta$ and whenever $\|h\| = \eta$, then $\{\alpha : f_\eta(\alpha) \le h(\alpha)\}$ contains a club. (Proof: Let $f_0(\alpha) = 0$, $f_{\eta+1}(\alpha) = f_\eta(\alpha) + 1$. If $\eta < \kappa^+$ is a limit ordinal, let $\lambda = \mathrm{cf}(\eta)$ and let $\eta = \lim_{\xi\to\lambda} \eta_\xi$. If $\lambda < \kappa$, let $f_\eta(\alpha) = \sup_{\xi<\lambda} f_{\eta_\xi}(\alpha)$ and if $\lambda = \kappa$, let $f_\eta(\alpha) = \sup_{\xi<\alpha} f_{\eta_\xi}(\alpha)$.)

A canonical function of norm κ^+ may or may not exist; existence is consistent with ZFC (cf. [52]). The existence of canonical functions f_η for all η is equi-consistent with a measurable cardinal [58].

1.4. Stationary Sets in Generic Extensions

Let M and N be transitive models and let $M \subseteq N$. Let κ be a regular uncountable cardinal and let $S \in M$ be a subset of κ. Clearly, if S is stationary in the model N, then S is stationary in M; the converse is not necessarily true, and κ may even not be regular or uncountable in N. It is important to know which forcing extensions preserve stationarity and we shall return to the general case in Sect. 5. For now, we state two important special cases:

1.13 Theorem. *Let κ be a regular uncountable cardinal and let P be a notion of forcing.*

(a) *If P satisfies the κ-chain condition, then every club $C \in V[G]$ has a club subset D in the ground model. Hence every stationary S remains stationary in $V[G]$.*

(b) *If P is λ-closed for every $\lambda < \kappa$, then every stationary S remains stationary in $V[G]$.*

Proof (Outline). (a) This follows from this basic fact on forcing: if P is κ-c.c., then every unbounded $A \subseteq \kappa$ in $V[G]$ has an unbounded subset in V.

(b) Let $p \Vdash \dot{C}$ is a club; we find a $\gamma \in S$ and a $q \le p$ such that $q \Vdash \gamma \in \dot{C}$ as follows: we construct an increasing continuous ordinal sequence $\{\gamma_\alpha\}_{\alpha<\kappa}$ and a decreasing sequence $\{p_\alpha\}$ of conditions such that $p_{\alpha+1} \Vdash \gamma_{\alpha+1} \in \dot{C}$, and if α is a limit ordinal, then $\gamma_\alpha = \lim_{\xi<\alpha} \gamma_\xi$ and p_α is a lower bound of $\{p_\xi\}_{\xi<\alpha}$. There is some limit ordinal α such that $\gamma_\alpha \in S$. It follows that $p_\alpha \Vdash \gamma_\alpha \in \dot{C}$. ⊣

We shall now describe the standard way of controlling stationary sets in generic extensions, called *shooting a club*. First we deal with the simplest case when $\kappa = \aleph_1$. Let S be a stationary subset of ω_1, and consider the following forcing P_S (cf. [12]): The forcing conditions are all bounded closed sets p of countable ordinals such that $p \subseteq S$. A condition q is stronger than p if q end-extends p, i.e. $p = q \cap \alpha$ for some α.

It is clear that this forcing produces ("shoots") a closed unbounded subset of S in the generic extension, thus the complement of S becomes nonstationary. The main point of [12] is that ω_1 is preserved and in fact $V[G]$ adds no new countable sets. Also, every stationary subset of S remains stationary.

The forcing P_S has the obvious generalization to $\kappa > \aleph_1$, but more care is required to guarantee that no new small sets of ordinals are added. For instance, this is the case when S contains the set Sing of all singular ordinals $< \kappa$. For a more detailed discussion of this problem see [1].

1.5. Some Combinatorial Principles

There has been a proliferation of combinatorial principles involving closed unbounded and stationary sets. Most can be traced back to Jensen's investigation of the fine structure of L [59] and generalize either Jensen's *diamond* ($\diamondsuit$) or *square* ($\Box$). We conclude this section by briefly mentioning diamond and *club-guessing*, and only their typical special cases.

1.14 Theorem ($\diamondsuit(\aleph_1)$, Jensen [59]). *Assume $V = L$. There exists a sequence $\langle a_\alpha : \alpha < \omega_1 \rangle$ with each $a_\alpha \subseteq \alpha$, such that for every $A \subseteq \omega_1$, the set $\{\alpha < \omega_1 : A \cap \alpha = a_\alpha\}$ is stationary.*

Note that every $A \subseteq \omega$ is equal to some a_α, and so $\diamondsuit(\aleph_1)$ implies $2^{\aleph_0} = \aleph_1$.

1.15 Theorem ($\diamondsuit(\mathbf{E}^{\aleph_2}_{\aleph_0})$, Gregory [40]). *Assume* GCH. *There exists a sequence $\langle a_\alpha : \alpha \in \mathbf{E}^{\aleph_2}_{\aleph_0} \rangle$ with each $a_\alpha \subseteq \alpha$, such that for every $A \subseteq \omega_2$, the set $\{\alpha < \omega_2 : A \cap \alpha = a_\alpha\}$ is stationary.*

1.16 Theorem (Club-guessing, Shelah [82]). *There exists a sequence $\langle c_\alpha : \alpha \in \mathbf{E}^{\aleph_3}_{\aleph_1} \rangle$, where each c_α is a closed unbounded subset of α, such that for every club $C \subseteq \omega_3$, the set $\{\alpha : c_\alpha \subseteq C\}$ is stationary.*

Unlike most generalizations of square and diamond, Theorem 1.16 is a theorem of ZFC but we note that the gap (between $\aleph_1$ and $\aleph_3$) is essential.

2. Reflection

2.1. Reflecting Stationary Sets

An important property of stationary sets is *reflection*. It is used in several applications, and provides a structure among stationary sets—it induces a well founded hierarchy. Natural questions about reflection and the hierarchy are closely related to large cardinal properties.

We start with a generalization of stationary sets. Let α be a limit ordinal of uncountable cofinality, say $\mathrm{cf}(\alpha) = \kappa > \aleph_0$. A set $S \subseteq \alpha$ is *stationary* if it meets every closed unbounded subset of α. The closed unbounded subsets of α generate a κ-complete filter, and Fodor's Theorem 1.5 yields this:

2.1 Lemma. *If f is a regressive function on a stationary set $S \subseteq \alpha$, then there exists a $\gamma < \alpha$ such that $f(\xi) < \gamma$ on a stationary subset of S.*

If S is a set of ordinals and α is a limit ordinal such that $\operatorname{cf}(\alpha) > \omega$, we say that S is *stationary in* α if $S \cap \alpha$ is a stationary subset of α.

2.2 Definition. Let κ be a regular uncountable cardinal and let S be a stationary subset of κ. If $\alpha < \kappa$ and $\operatorname{cf}(\alpha) > \omega$, S *reflects at* α if S is stationary in α. S *reflects* if it reflects at some $\alpha < \kappa$.

It is implicit in the definition that $\kappa > \aleph_1$.

For our first observation, let $\alpha < \kappa$ be such that $\operatorname{cf}(\alpha) > \omega$. There is a club $C \subseteq \alpha$ of order type $\operatorname{cf}(\alpha)$ such that every element of C has cofinality $< \operatorname{cf}(\alpha)$. Thus if $S \subseteq \kappa$ is such that every $\beta \in S$ has cofinality $\geq \operatorname{cf}(\alpha)$, then S does not reflect at α. In particular, if $\kappa = \lambda^+$ where λ is regular, then the stationary set $\mathbf{E}^\kappa_\lambda$ does not reflect.

On the other hand, if $\lambda < \kappa$ is regular and $\lambda^+ < \kappa$, then $\mathbf{E}^\kappa_\lambda$ reflects at every $\alpha < \kappa$ such that $\operatorname{cf}(\alpha) > \lambda$.

To investigate reflection systematically, let us first look at the simplest case, when $\kappa = \aleph_2$. Let $E_0 = \mathbf{E}^{\aleph_2}_{\aleph_0}$ and $E_1 = \mathbf{E}^{\aleph_2}_{\aleph_1}$. The set E_1 does not reflect; can every stationary $S \subseteq E_0$ reflect?

Let us recall Jensen's Square Principle [59]: ($\square_\kappa$) There exists a sequence

$\langle C_\alpha : \alpha \in \operatorname{Lim}\,(\kappa^+)\rangle$ such that:

(i) C_α is club in α,

(ii) if $\beta \in \operatorname{Lim}(C_\alpha)$, then $C_\beta = C_\alpha \cap \beta$, and

(iii) if $\operatorname{cf}\,\alpha < \kappa$, then $|C_\alpha| < \kappa$.

Now assume that $\square_{\omega_1}$ holds and let $\langle C_\alpha : \alpha \in \operatorname{Lim}(\omega_2)\rangle$ be a square sequence. Note that for each $\alpha \in E_1$, the order type of C_α is ω_1. It follows that there exists a countable limit ordinal η such that the set $S = \{\gamma \in E_0 : \gamma$ is the ηth element of some $C_\alpha\}$ is stationary. But for every $\alpha \in E_1$, S has at most one element in common with C_α, and so S does not reflect.

Thus $\square_{\omega_1}$ implies that there is a nonreflecting stationary subset of $\mathbf{E}^{\aleph_2}_{\aleph_0}$. Since $\square_{\omega_1}$ holds unless $\aleph_2$ is Mahlo in L, the consistency strength of "every $S \subseteq \mathbf{E}^{\aleph_2}_{\aleph_0}$ reflects" is at least a Mahlo cardinal. This is in fact the exact strength:

2.3 Theorem (Harrington-Shelah [41]). *The following are equi-consistent:*

(i) *the existence of a Mahlo cardinal,*

(ii) *every stationary set $S \subseteq \mathbf{E}^{\aleph_2}_{\aleph_0}$ reflects.*

Theorem 2.3 improves a previous result of Baumgartner [6] who proved the consistency of (ii) from a weakly compact cardinal. Note that (ii) implies that every stationary set $S \subseteq \mathbf{E}^{\aleph_2}_{\aleph_0}$ reflects at stationary many $\alpha \in \mathbf{E}^{\aleph_2}_{\aleph_1}$.

A related result of Magidor (to which we return later in this section) gives this equi-consistency:

2.4 Theorem (Magidor [70]). *The following are equi-consistent:*

(i) *the existence of a weakly compact cardinal,*

(ii) *every stationary set $S \subseteq \mathbf{E}^{\aleph_2}_{\aleph_0}$ reflects at almost all $\alpha \in \mathbf{E}^{\aleph_2}_{\aleph_1}$.*

Here, "almost all" means all but a nonstationary set.

Let us now address the question whether it is possible that *every* stationary subset of κ reflects. We have seen that this is not the case when κ is the successor of a regular cardinal. Thus κ must be either inaccessible or $\kappa = \lambda^+$ where λ is singular.

Note that because a weakly compact cardinal is Π^1_1 indescribable, every stationary subset of it reflects. In [68], Kunen showed that it is consistent that every stationary $S \subseteq \kappa$ reflects while κ is not weakly compact. In [76] it is shown that the consistency strength of "every stationary subset of κ reflects" is strictly between greatly Mahlo and weakly compact. (For definition of greatly Mahlo, see Sect. 2.2.)

If, in addition, we require that κ be a successor cardinal, then much stronger assumptions are necessary. The argument we gave above using $\square_{\omega_1}$ works for any κ:

2.5 Proposition (Jensen). *If $\square_\lambda$ holds, then there is a nonreflecting stationary subset of $\mathbf{E}^{\lambda^+}_{\aleph_0}$.*

As the consistency strength of $\neg\square_\lambda$ for singular λ is at least a strong cardinal (as shown by Jensen), one needs at least that for the consistency of "every stationary $S \subseteq \lambda^+$ reflects". In [70], Magidor proved the consistency of "every stationary subset of $\aleph_{\omega+1}$ reflects" from the existence of infinitely many supercompact cardinals.

We mention the following applications of nonreflecting stationary sets:

2.6 Theorem (Mekler-Shelah [76]). *The following are equi-consistent:*

(i) *every stationary $S \subseteq \kappa$ reflects,*

(ii) *every κ-free abelian group is κ^+-free.*

2.7 Theorem (Tryba [90]). *If a regular cardinal κ is Jónsson, then every stationary $S \subseteq \kappa$ reflects.*

2.8 Theorem (Todorčević [88]). *If Rado's Conjecture holds, then for every regular $\kappa > \aleph_1$, every stationary $S \subseteq \mathbf{E}^{\kappa}_{\aleph_0}$ reflects.*

2.2. A Hierarchy of Stationary Sets

Consider the following operation (the *Mahlo operation*) on stationary sets. For a stationary set $S \subseteq \kappa$, the *trace* of S is the set of all α at which S reflects:

$$Tr(S) = \{\alpha < \kappa : \mathrm{cf}(\alpha) > \omega \text{ and } S \cap \alpha \text{ is stationary in } \alpha\}.$$

The following basic properties of trace are easily verified.

2.9 Lemma.

(a) *If* $S \subseteq T$, *then* $Tr(S) \subseteq Tr(T)$,

(b) $Tr(S \cup T) = Tr(S) \cup Tr(T)$,

(c) $Tr(Tr(S)) \subseteq Tr(S)$,

(d) *If* $S \simeq T \bmod \mathrm{NS}$, *then* $Tr(S) \simeq Tr(T) \bmod \mathrm{NS}$.

Property (d) shows that the Mahlo operation may be considered as an operation on the Boolean algebra $P(\kappa)/\mathrm{NS}$.

If $\lambda < \kappa$ is regular, let $\mathbf{M}^\kappa_\lambda = \{\alpha < \kappa : \mathrm{cf}(\alpha) \geq \lambda\}$, and note that $Tr(\mathbf{E}^\kappa_\lambda) = Tr(\mathbf{M}^\kappa_\lambda) = \mathbf{M}^\kappa_{\lambda^+}$.

The Mahlo operation on $P(\kappa)/\mathrm{NS}$ can be iterated α times, for $\alpha < \kappa^+$. Let

$$\begin{aligned} M_0 &= \kappa, \\ M_{\alpha+1} &= Tr(M_\alpha), \\ M_\alpha &= \Delta_{\xi<\kappa} M_{\alpha_\xi} \quad (\alpha \text{ limit, } \alpha = \sup\{\alpha_\xi : \xi < \kappa\}). \end{aligned}$$

The sets M_α are defined mod NS (the limit stages depend on the enumeration of α). The sequence $\{M_\alpha\}_{\alpha<\kappa^+}$ is decreasing mod NS, and when $\alpha < \kappa$, then $M_\alpha = \mathbf{M}^\kappa_\lambda$ where λ is the αth regular cardinal. Note that κ is (weakly) Mahlo just in case $M_\kappa = \mathrm{Reg}(\kappa)$ is stationary, and that by Lemma 1.11, $\{M_\alpha\}_\alpha$ is strictly decreasing (mod NS, as long as M_α is stationary). Following [13], κ is called *greatly Mahlo* if M_α is stationary for every $\alpha < \kappa^+$.

We shall now consider the following relation between stationary subsets of κ.

2.10 Definition (Jech [47]).

$$S < T \text{ iff } S \cap \alpha \text{ is stationary for almost all } \alpha \in T.$$

In other words, $S < T$ iff $Tr(S) \supseteq T \bmod \mathrm{NS}$. As an example, if $\lambda < \mu$ are regular, then $\mathbf{E}^\kappa_\lambda < \mathbf{E}^\kappa_\mu$. Note also that the language of generic ultrapowers gives this description of $<$:

2.11 Proposition. $S < T$ *iff* $T \Vdash S$ *is stationary in* $\mathrm{Ult}_G(V)$.

The following lemma states the basic properties of $<$.

2.12 Lemma.

(a) $A < \mathit{Tr}(A)$,

(b) *If* $A < B$ *and* $B < C$, *then* $A < C$,

(c) *If* $A \simeq A'$ *and* $B \simeq B'$ mod NS, *and if* $A < B$, *then* $A' < B'$.

By (c), $<$ can be considered a relation on $P(\kappa)/\mathrm{NS}$. By Proposition 1.11, $<$ is irreflexive and so it is a partial ordering. The next theorem shows that the partial ordering $<$ is well founded.

2.13 Theorem (Jech [47]). *The relation* $<$ *is well founded.*

Proof. Assume to the contrary that there are stationary sets such that $A_1 > A_2 > A_3 > \cdots$. Therefore there are clubs C_n such that $A_n \cap C_n \subseteq \mathit{Tr}(A_{n+1})$ for $n = 1, 2, \ldots$. For each n, let

$$B_n = A_n \cap C_n \cap \mathrm{Lim}(C_{n+1}) \cap \mathrm{Lim}(\mathrm{Lim}(C_{n+2})) \cap \cdots .$$

Each B_n is stationary, and for every n, $B_n \subseteq \mathit{Tr}(B_{n+1})$. Let $\alpha_n = \min(B_n)$. Since $B_{n+1} \cap \alpha_n$ is stationary, we have $\alpha_{n+1} < \alpha_n$, and therefore, a decreasing sequence $\alpha_1 > \alpha_2 > \alpha_3 > \cdots$. A contradiction. $\dashv$

As $<$ is well founded, we can define the *order* of stationary sets $A \subseteq \kappa$, and of the cardinal κ:

$$o(A) = \sup(\{o(X) + 1 : X < A\}),$$
$$o(\kappa) = \sup(\{o(A) + 1 : A \subseteq \kappa \text{ stationary}\}).$$

We also define $o(\aleph_0) = 0$, and $o(\alpha) = o(\mathrm{cf}(\alpha))$ for every limit ordinal α.

Note that $o(\mathbf{E}^\kappa_{\aleph_0}) = 0$, and in general $o(\mathbf{E}^\kappa_\lambda) = o(\mathbf{M}^\kappa_\lambda) = \alpha$, if λ is the αth regular cardinal. Also, $o(\aleph_n) = n$, $o(\kappa) \geq \kappa + 1$ iff κ is Mahlo, and $o(\kappa) \geq \kappa^+$ iff κ is greatly Mahlo.

2.3. Canonical Stationary Sets

If λ is the αth regular cardinal, then $\mathbf{E}^\kappa_\lambda$ has order α; moreover, the set is canonical, in the sense explained below. In fact, canonical stationary sets exist for all orders $\alpha < \kappa^+$.

Let E be a stationary set of order α. If $X \subseteq E$ is stationary, then $o(X) \geq o(E)$. We call E *canonical of order* α if (i) every stationary $X \subseteq E$ has order α, and (ii) E meets every set of order α.

Clearly, a canonical set of order α is unique (mod NS), and two canonical sets of different orders are disjoint (mod NS). In the following proposition, "maximal" and $\simeq$ is meant mod NS.

2.14 Proposition (Jech [47]). *A canonical set E of order α exists iff there exists a maximal set M of order α. Then (*mod NS*)*

$$E \simeq M - Tr(M), \quad M \simeq E \cup Tr(E), \quad \textit{and} \quad Tr(E) \simeq Tr(M).$$

One can show that the sets M_α obtained by iterating the Mahlo operation are maximal (as long as they are stationary). Thus when we let $E_\alpha = M_\alpha - Tr(M_\alpha)$, we get canonical stationary sets, of all orders $\alpha < \kappa^+$ (for $\alpha < o(\kappa)$).

The canonical stationary sets E_α and the canonical function f_α of Galvin-Hajnal norm α are closely related:

2.15 Proposition (Jech [47]). *For every $\alpha < \kappa^+$, $\alpha < o(\kappa)$,*

$$E_\alpha \simeq \{\xi < \kappa : f_\alpha(\xi) = o(\xi)\}.$$

2.4. Full Reflection

Let us address the question of what is the largest possible amount of reflection, for stationary subsets of a given κ. As $A < B$ means that A reflects at almost all points of B, we would like to maximize the relation $<$. But $A < B$ implies that $o(A) < o(B)$, so we might ask whether it is possible that $A < B$ for any two stationary sets such that $o(A) < o(B)$.

By Magidor's Theorem 2.4 it is consistent that $S < \mathbf{E}^{\aleph_2}_{\aleph_1}$, and therefore $S < T$ for every S of order 0 and every T of order 1. However, this does not generalize, as the following lemma shows that when $\kappa \geq \aleph_3$, then there exist S and T with $o(S) = 0$ and $o(T) = 1$ such that $S \not< T$.

2.16 Lemma (Jech-Shelah [53]). *If $\kappa \geq \aleph_3$, then there exist stationary sets $S \subseteq \mathbf{E}^\kappa_{\aleph_0}$ and $T \subseteq \mathbf{E}^\kappa_{\aleph_1}$ such that S does not reflect at any $\alpha \in T$.*

Proof. Let S_γ, $\gamma < \omega_2$, be pairwise disjoint stationary subsets of $\mathbf{E}^\kappa_{\aleph_0}$, and let C_α, $\alpha \in \mathbf{E}^\kappa_{\aleph_1}$, be such that for every α, C_α is a club subset of α, of order type ω_1. Because at most $\aleph_1$ of the sets S_γ meet each C_α, there exists for each α some $\gamma(\alpha)$ such that $C_\alpha \cap S_{\gamma(\alpha)} = \emptyset$.

There exists some γ such that the set $T = \{\alpha : \gamma(\alpha) = \gamma\}$ is stationary; let $S = S_\gamma$. For every $\alpha \in T$, $S \cap C_\alpha = \emptyset$ and so S does not reflect at α. $\dashv$

This lemma illustrates some of the difficulties involved when dealing with reflection at singular ordinals. This problem is investigated in detail in [53], where the best possible consistency result is proved for stationary subsets of the $\aleph_n$, $n < \omega$.

Let us say that a stationary set $S \subseteq \kappa$ *reflects fully at regular cardinals* if for any stationary set T of regular cardinals $o(S) < o(T)$ implies $S < T$, and let us call *Full Reflection* the statement that every stationary subset of κ reflects fully at regular cardinals.

Full Reflection is of course nontrivial only if κ is a Mahlo cardinal. A modification of Theorem 2.4 shows that Full Reflection for a Mahlo cardinal is equi-consistent with weak compactness. The following theorem establishes the consistency strength of Full Reflection for cardinals in the Mahlo hierarchy:

2.17 Theorem (Jech-Shelah [54]). *The following are equi-consistent, for every $\alpha \le \kappa^+$:*

(i) *κ is Π^1_α-indescribable,*

(ii) *κ is α-Mahlo and Full Reflection holds.*

(A regular cardinal κ is α-Mahlo if $o(\kappa) \ge \kappa + \alpha$; κ is Π^1_1-indescribable iff it is weakly compact.)

Full Reflection is also consistent with large cardinals. The paper [56] proves the consistency of Full Reflection with the existence of a measurable cardinal. This has been improved and further generalized in [38].

Finally, the paper [91] shows that any well-founded partial order of size $\le \kappa^+$ can be realized by the reflection ordering $<$ on stationary subsets of κ, in some generic extension (using $P^2\kappa$-strong κ in the ground model).

3. Saturation

3.1. κ^+-saturation

By Solovay's Theorem 1.8 every stationary subset of κ can be split into κ disjoint stationary sets. In other words, for every stationary $S \subseteq \kappa$, the ideal $\mathrm{NS}{\restriction}S$ is not κ-saturated. A natural question is if the nonstationary ideal can be κ^+-saturated.

An ideal I on κ is κ^+-*saturated* if the Boolean algebra $P(\kappa)/I$ has the κ^+-chain condition. Thus $\mathrm{NS}{\restriction}S$ is κ^+-saturated when there do not exist κ^+ stationary subsets of S such that the intersection of any two of them is nonstationary. The existence and properties of κ^+-saturated ideals have been thoroughly studied since their introduction in [85], and involve large cardinals. The reader will find more details in Foreman's chapter in this Handbook. We shall concentrate on the special case when I is the nonstationary ideal.

The main question, whether the nonstationary ideal can be κ^+-saturated, has been answered. But a number of related questions are still open.

3.1 Theorem (Gitik-Shelah [37]). *The nonstationary ideal on κ is not κ^+-saturated, for every regular cardinal $\kappa \ge \aleph_2$.*

3.2 Theorem (Shelah). *It is consistent, relative to the existence of a Woodin cardinal, that the nonstationary ideal on $\aleph_1$ is $\aleph_2$-saturated.*

The consistency result in Theorem 3.2 was first proved in [87] using a strong determinacy assumption. That hypothesis was reduced in [92] to AD, while in [27], the assumption was the existence of a supercompact cardinal.

Shelah's result (announced in [81]) is close to optimal: by Steel [86], the saturation of NS plus the existence of a measurable cardinal imply the existence of an inner model with a Woodin cardinal.

All the models mentioned in the preceding paragraph satisfy $2^{\aleph_0} > \aleph_1$. This may not be accidental, and it has been conjectured that the saturation of NS on $\aleph_1$ implies that $2^{\aleph_0} > \aleph_1$. In fact, Woodin proved this [94] under the additional assumption that there exists a measurable cardinal. We note in passing that by [27], $2^{\aleph_0} = \aleph_1$ is consistent with NS$\restriction S$ being saturated for some stationary S.

Woodin's construction [94] yields a model (starting from AD) in which the ideal NS on $\aleph_1$ is $\aleph_1$-*dense*, i.e. the algebra $P(\omega_1)/\mathrm{NS}$ has a dense set of size $\aleph_1$. This, and Woodin's more recent work using Steel's inner model theory, gives the following equi-consistency.

3.3 Theorem (Woodin). *The following are equi-consistent:*

(i) ZF + AD*,*

(ii) *There are infinitely many Woodin cardinals,*

(iii) *The nonstationary ideal on* $\aleph_1$ *is* $\aleph_1$*-dense.*

See the Koellner-Woodin chapter of this Handbook for (i) implies (ii), and the Neeman chapter for (ii) implies (i).

As for the continuum hypothesis, Shelah proved in [80] that if NS on $\aleph_1$ is $\aleph_1$-dense, then $2^{\aleph_0} = 2^{\aleph_1}$.

We remark that the mere existence of a saturated ideal affects cardinal arithmetic, cf. [63] and [51].

Let us now return to Theorem 3.1. The general result proved in [37] is this:

3.4 Theorem (Gitik-Shelah [37]). *If* ν *is a regular cardinal and* $\nu^+ < \kappa$*, then* NS$\restriction\mathbf{E}^\kappa_\nu$ *is not* κ^+*-saturated.*

The proof of Theorem 3.4 combines an earlier result of Shelah (Theorem 3.7 below) with an application of the method of guessing clubs (as in Theorem 1.16). The earlier result uses generic ultrapowers and states that if $\kappa = \lambda^+$ and $\nu \neq \mathrm{cf}(\lambda)$ is regular, then no ideal concentrating on $\mathbf{E}^\kappa_\nu$ is κ^+-saturated.

The method of generic ultrapowers is well suited for κ^+-saturated ideals. Forcing with $P(\kappa)/I$ where I is a normal κ-complete κ^+-saturated ideal makes the generic ultrapower $N = \mathrm{Ult}_G(V)$ well founded, preserves the cardinal κ^+, and satisfies $P^N(\kappa) = P^{V[G]}(\kappa)$. It follows that all cardinals $< \kappa$ are preserved in $V[G]$, and it is obvious that if $\mathbf{E}^\kappa_\nu \in G$, then N (and therefore $V[G]$ as well) satisfies $\mathrm{cf}(\kappa) = \nu$.

Shelah's Theorem 3.7 below follows from a simple combinatorial lemma. Let λ be a cardinal and let $\alpha < \lambda^+$ be a limit ordinal. Let us call a family $\{X_\xi : \xi < \lambda^+\}$ a *strongly almost disjoint* (s.a.d.) family of subsets of α if every $X_\xi \subseteq \alpha$ is unbounded, and if for every $\vartheta < \lambda^+$ there exist ordinals $\delta_\xi < \alpha$, for $\xi < \vartheta$, such that the sets $X_\xi - \delta_\xi$, $\xi < \vartheta$, are pairwise disjoint. Note that if κ is a regular cardinal than there is a s.a.d. family $\{X_\xi : \xi < \kappa^+\}$ of subsets of κ.

3.5 Lemma. *If $\alpha < \lambda^+$ and $\mathrm{cf}(\alpha) \neq \mathrm{cf}(\lambda)$, then there exists no strongly almost disjoint family of subsets of α.*

Proof. Assume to the contrary that $\{X_\xi : \xi < \lambda^+\}$ is a s.a.d. family of subsets of α. We may assume that each X_ξ has order type $\mathrm{cf}(\alpha)$. Let f be a function mapping λ onto α. Since $\mathrm{cf}(\lambda) \neq \mathrm{cf}(\alpha)$ there exists for each ξ some $\gamma_\xi < \lambda$ such that $X_\xi \cap f``\gamma_\xi$ is cofinal in α. There is some γ and a set $W \subseteq \lambda^+$ of size λ such that $\gamma_\xi = \gamma$ for all $\xi \in W$. Let $\vartheta > \sup(W)$. By the assumption on the X_ξ there exist ordinals $\delta_\xi < \alpha$, $\xi < \vartheta$, such that the $X_\xi - \delta_\xi$ are pairwise disjoint. Thus $f^{-1}(X_\xi - \delta_\xi)$, $\xi \in W$, are λ pairwise disjoint subsets of γ. A contradiction. $\dashv$

3.6 Corollary (Shelah [79]). *If κ is a regular cardinal and if a notion of forcing P makes $\mathrm{cf}(\kappa) \neq \mathrm{cf}(|\kappa|)$, then P collapses κ^+.*

Proof. Assume that κ^+ is not collapsed; thus in $V[G]$, $(\kappa^+)^V = \lambda^+$ where $\lambda = |\kappa|$. In V there is a s.a.d. family $\{X_\xi : \xi < (\kappa^+)^V\}$, and it remains a s.a.d. family in $V[G]$, of size λ^+. Since $\mathrm{cf}(\kappa) \neq \mathrm{cf}(\lambda)$, in $V[G]$, this contradicts Lemma 3.5. $\dashv$

3.7 Theorem (Shelah). *If $\kappa = \lambda^+$, if $\nu \neq \mathrm{cf}(\lambda)$ is regular and if I is a normal κ-complete κ^+-saturated ideal on κ, then $\mathbf{E}^\kappa_\nu \in I$.*

Proof. If not, then forcing with I-positive subsets of $\mathbf{E}^\kappa_\nu$ preserves κ^+ as well as $\mathrm{cf}(\lambda)$, and makes $\mathrm{cf}(\kappa) = \nu$; a contradiction. $\dashv$

Theorem 3.4 leaves open the following problem: If λ is a regular cardinal, can $\mathrm{NS}{\restriction}\mathbf{E}^{\lambda^+}_\lambda$ be λ^{++}-saturated? (For instance can $\mathrm{NS}{\restriction}\mathbf{E}^{\aleph_2}_{\aleph_1}$ be $\aleph_3$-saturated?) Let us also mention that for all regular ν and κ not excluded by Corollary 3.7, it is consistent that $\mathrm{NS}{\restriction}S$ is κ^+-saturated for some $S \subseteq \mathbf{E}^\kappa_\nu$ (see [33]).

If κ is a large cardinal, then $\mathrm{NS}{\restriction}\mathrm{Reg}(\kappa)$ can be κ^+-saturated, as the following theorem shows. Of course, κ cannot be too large: if κ is greatly Mahlo, then the canonical stationary sets E_α $\kappa \leq \alpha < \kappa^+$ witness nonsaturation.

3.8 Theorem (Jech-Woodin [57]). *For any $\alpha < \kappa^+$, the following are equiconsistent:*

(i) *κ is measurable of order α,*

(ii) *κ is α-Mahlo and the ideal $\mathrm{NS}{\restriction}\mathrm{Reg}(\kappa)$ on κ is κ^+-saturated.*

3.2. Precipitousness

An important property of saturated ideals is that the generic ultrapower is well-founded. It has been recognized that this property is important enough to single out and study the class of ideals that have it. The ideals for which the generic ultrapower is well founded are called *precipitous*. They are described in detail in Foreman's chapter in this Handbook; here we address the question of when the nonstationary ideal is precipitous.

Precipitous ideals were introduced by Jech and Prikry in [50]. There are several equivalent formulations of precipitousness. Let I be an ideal on some set E. An *I-partition* is a maximal family of I-positive sets such that the intersection of any two of them is in I. Let $\mathcal{G}_I$ denote the infinite game of two players who alternately pick I-positive sets S_n such that $S_1 \supseteq S_2 \supseteq S_3 \supseteq \cdots$. The first player wins if $\bigcap_{n=1}^{\infty} S_n = \emptyset$.

3.9 Theorem (Jech-Prikry [50, 45, 46, 30]). *Let I be an ideal on a set E. The following are equivalent:*

(i) *Forcing with $P(E)/I$ makes the generic ultrapower well-founded,*

(ii) *For every sequence $\{W_n\}_{n=1}^{\infty}$ of I-partitions there exists a sequence $\{X_n\}_{n=1}^{\infty}$ such that $X_n \in W_n$ for each n, and $\bigcap_{n=1}^{\infty} X_n \neq \emptyset$,*

(iii) *The first player does not have a winning strategy in the game $\mathcal{G}_I$.*

The problem of whether the nonstationary ideal on κ can be precipitous involves large cardinals. For $\kappa = \aleph_1$ the exact consistency strength is the existence of a measurable cardinal:

3.10 Theorem (Jech-Magidor-Mitchell-Prikry [58]). *The following are equi-consistent:*

(i) *There exists a measurable cardinal,*

(ii) NS *on $\aleph_1$ is precipitous.*

For $\kappa \geq \aleph_2$, stronger large cardinal assumptions are involved. For $\kappa = \aleph_2$, the consistency strength is a measurable of order 2:

3.11 Theorem (Gitik [31]). *The following are equi-consistent:*

(i) *There exists a measurable cardinal of order 2,*

(ii) NS *on $\aleph_2$ is precipitous.*

See Cummings' chapter in this Handbook for proofs of both of these theorems. For the general case, the paper [47] provided lower bounds for the consistency strength of "NS is precipitous" in terms of the Mitchell order, while models with NS precipitous for $\kappa > \aleph_2$ were constructed in [33] and [27] from strong assumptions. In [35] and [36], Gitik established the exact consistency strength of "NS on κ is precipitous" when κ is the successor of a regular cardinal λ (the existence of an $(\omega, \lambda+1)$-repeat point), as well as nearly optimal lower and upper consistency bounds for κ inaccessible. Additional lower bounds for the case $\kappa = \lambda^+$ where λ is a large cardinal appear in [95].

The problem of whether the nonstationary ideal on κ can be precipitous while κ is measurable was first addressed by Kakuda in [61] who proved that many measurables are necessary. This lower bound was improved to having Mitchell order $\kappa^+ + 1$ in [47], and to a repeat point in [34]. Gitik's paper also shows that the existence of a supercompact cardinal suffices for the consistency of the nonstationary ideal on a supercompact cardinal being precipitous.

4. The Closed Unbounded Filter on $P_\kappa\lambda$

4.1. Closed Unbounded Sets in $P_\kappa A$

One of the useful tools of combinatorial set theory is a generalization of the concepts of closed unbounded set and stationary set. This generalization, introduced in [43] and [44], replaces $\langle \kappa, < \rangle$ with $\langle P_\kappa\lambda, \subset \rangle$, and is justified by the fact that the crucial Theorem 1.5 remains true under the generalization.

For κ a regular uncountable cardinal and A a set of cardinality at least κ, let $P_\kappa A$ denote the set $\{x : x \subseteq A \text{ and } |x| < \kappa\}$. Furthermore, we let $[X]^\nu = \{x \subseteq X : |x| = \nu\}$ whenever $|X| \geq \nu$ and ν an infinite cardinal.

4.1 Definition (Jech [44]). Let κ be a regular uncountable cardinal and let $|A| \geq \kappa$.

(a) A set $X \subseteq P_\kappa A$ is *unbounded* (in $P_\kappa A$) if for every $x \in P_\kappa A$ there is a $y \supseteq x$ such that $y \in X$.

(b) A set $X \subseteq P_\kappa A$ is *closed* (in $P_\kappa A$) if for any chain $x_0 \subseteq x_1 \subseteq \cdots \subseteq x_\xi \subseteq \cdots$, $\xi < \alpha$, of sets in X, with $\alpha < \kappa$, the union $\bigcup_{\xi<\alpha} x_\xi$ is in X.

(c) A set $C \subseteq P_\kappa A$ is *closed unbounded* if it is closed and unbounded.

(d) A set $S \subseteq P_\kappa A$ is *stationary* (in $P_\kappa A$) if $S \cap C \neq \emptyset$ for every closed unbounded $C \subseteq P_\kappa A$.

The *closed unbounded filter* on $P_\kappa A$ is the filter generated by the closed unbounded sets. We remark that when $A = \kappa$, then the set $\kappa \subseteq P_\kappa\kappa$ is closed unbounded, and the club filter on κ is the restriction to κ of the club filter on $P_\kappa\kappa$. As before, the basic observation is that the intersection of two clubs is a club, and we have again:

4.2 Proposition. *The club filter on $P_\kappa A$ is κ-complete.*

For the generalization of Theorem 1.5, let us first define the *diagonal intersection.*

$$\Delta_{a\in A} X_a = \{x \in P_\kappa A : x \in \textstyle\bigcap_{a\in x} X_a\}.$$

The generalization of Lemma 1.4 is this:

4.3 Lemma. *If $\langle C_a : a \in A\rangle$ is a sequence of closed unbounded sets in $P_\kappa A$, then its diagonal intersection is closed unbounded.*

Again, this lemma immediately implies the appropriate generalization of Theorem 1.5:

4.4 Theorem (Jech [44]). *If S is a stationary set in $P_\kappa A$ and if f is a function on S such that $f(x) \in x$ for every $x \in S - \{\emptyset\}$, then there exists some $a \in A$ such that $f(x) = a$ on a stationary subset of S.*

In Proposition 1.6 we showed that the club filter is the smallest normal filter on κ. We shall now do the same for $P_\kappa A$. A κ-complete filter F on $P_\kappa A$ is *normal* if for every $a \in A$, $\{x \in P_\kappa A : a \in x\} \in F$, and if F is closed under diagonal intersections.

The following fact (proved by induction on $|D|$) is quite useful; D is $\subseteq$-*directed* if for any $x, y \in D$ there is a $z \in D$ such that $x \cup y \subseteq z$.

4.5 Proposition. *If X is a closed set in $P_\kappa A$, then for any $\subseteq$-directed D with $|D| < \kappa$, $\bigcup D \in X$.*

Let $f : [A]^{<\omega} \to P_\kappa A$; a set $x \in P_\kappa A$ is a *closure point* of f is $f(e) \subseteq x$ whenever $e \subseteq x$. The set Cl_f of all closure points $x \in P_\kappa A$ is easily seen to be a club. More importantly, the sets Cl_f generate the club filter:

4.6 Proposition (Menas [77]). *For every closed unbounded set C in $P_\kappa A$ there is an $f : [A]^{<\omega} \to P_\kappa A$ such that $Cl_f \subseteq C$.*

Proof. By induction on $|e|$ we find an infinite set $f(e) \in C$ such that $e \subseteq f(e)$ and that $f(e') \subseteq f(e)$ whenever $e' \subseteq e$. To see that $Cl_f \subseteq C$, let x be a closure point of f. As $x = \bigcup\{f(e) : e \in [x]^{<\omega}\}$ is the union of a small $\subseteq$-directed subset of C, we have $x \in C$. $\dashv$

4.7 Corollary (Carr [18]). *If F is a normal κ-complete filter on $P_\kappa A$, then F contains all closed unbounded sets.*

Proof. Let F^+ denote the F-positive sets, those whose complement is not in F. A consequence of normality is that if $X \in F^+$ and g is a function on X such that $g(x) \in [x]^{<\omega}$ for all $x \in X$, then g is constant on a set in F^+.

Now assume that there is a club not in F. Thus there is an $f : A \to P_\kappa A$ such that the complement X of Cl_f is F-positive. For each $x \in X$ there is some $e = g(x) \in [x]^{<\omega}$ such that $f(e) \nsubseteq x$. Therefore there is some e such that $\{x : f(e) \nsubseteq x\} \in F^+$. This is a contradiction, because $\{x : f(e) \subseteq x\} \in F$. $\dashv$

As another consequence of Proposition 4.6 we consider *projections* and *liftings* of stationary sets. Let $A \subseteq B$ (and $|A| \geq \kappa$). For $X \in P_\kappa B$, the *projection* of X is the set

$$X \restriction A = \{x \cap A : x \in X\};$$

for $Y \in P_\kappa A$, the *lifting* of Y is

$$Y^B = \{x \in P_\kappa B : x \cap A \in Y\}.$$

4.8 Proposition (Menas [77]). *Let $A \subseteq B$.*

(i) *If S is stationary in $P_\kappa B$, then $S \restriction A$ is stationary in $P_\kappa A$.*

(ii) *If S is stationary in $P_\kappa A$, then S^B is stationary in $P_\kappa B$.*

Proof. (i) is easy and holds because if C is a club in $P_\kappa A$, then C^B is a club in $P_\kappa B$. For (ii), it suffices to prove that if C is a club in $P_\kappa B$, then $C \restriction A$ contains a club in $P_\kappa A$.

If $C \subseteq P_\kappa B$ is a club, by Proposition 4.6 there is an $f : [B]^{<\omega} \to P_\kappa B$ such that $Cl_f \subseteq C$. Let $g : [A]^{<\omega} \to P_\kappa A$ be as follows: let $g(E) =$ (the f-closure of $e) \cap A$. Since $Cl_f \restriction A = Cl_g$, we have $Cl_g \subseteq C \restriction A$. ⊣

When $\kappa = \aleph_1$, Proposition 4.6 can be improved by replacing f by a function with values in A, i.e. an operation on A. For $f : [A]^{<\omega} \to A$, let Cl_f denote the set $\{x : f(e) \in x$ whenever $e \subseteq x\}$. The following characterization of the club filter on $P_{\omega_1} A$ was given in [66]; this and [67] used $P_{\omega_1} A$ in the study of model theory.

4.9 Theorem (Kueker [66]). *The club filter on $P_{\omega_1} A$ is generated by the sets Cl_F where $F : [A]^{<\omega} \to A$.*

When $\kappa > \aleph_1$, then the clubs Cl_F where $F : [A]^{<\omega} \to A$, do not generate the club filter: every F has countable closure points while the set of all uncountable $x \in P_\kappa A$ is closed unbounded. However, a slight modification of Theorem 4.9 works, namely Proposition 4.10 below. Let us call the club Cl_F for $F : [A]^{<\omega} \to A$ *strongly closed unbounded.*

Let us consider $P_\kappa \lambda$ where $\lambda \geq \kappa$. We note that the set

$$\{x \in P_\kappa \lambda : x \cap \kappa \in \kappa\}$$

is closed unbounded. It turns out that the club filter is generated by adding this set to the filter generated by the strongly club sets.

4.10 Proposition (Foreman et al. [27]). *For every club C in $P_\kappa \lambda$ there exists a function $F : [\lambda]^{<\omega} \to \lambda$ such that*

$$\{x \in P_\kappa \lambda : x \cap \kappa \in \kappa \text{ and } F``[x]^{<\omega} \subseteq x\} \subseteq C.$$

Now let us consider $P_\kappa\lambda$ for $\kappa = \nu^+$ where ν is uncountable. As the set $[\lambda]^\nu$ is closed unbounded in $P_{\nu^+}\lambda$, let us consider the restriction of the club filter to $[\lambda]^\nu$. We say that a set $S \subseteq [\lambda]^\nu$ is *weakly stationary* if it meets every strongly club set. It turns out that the question whether weakly stationary sets are stationary involves large cardinals. By Proposition 4.10, this question depends on whether the set $\{x \in [\lambda]^\nu : x \cap \nu^+ \in \nu^+\}$ is in the strongly club filter. The following reformulation, implicit in [27], establishes the relation to large cardinals:

4.11 Proposition. *There exists a weakly stationary nonstationary set in $[\lambda]^\nu$ if and only if the (nonstationary) set $\{x \in [\lambda]^\nu : x \not\supseteq \nu\}$ is weakly stationary.*

4.12 Corollary. *The following are equivalent:*

(i) *The club filter on $[\omega_2]^{\aleph_1}$ is not generated by strongly club sets,*

(ii) *Chang's Conjecture.*

4.2. Splitting Stationary Sets

Let us now address the question whether stationary sets can be split into a large number of disjoint stationary sets. In particular, does Theorem 1.8 generalize to $P_\kappa A$? As only the size of A matters, and the club filter on $P_\kappa\kappa$ is basically just the club filter on κ, we shall consider subsets of $P_\kappa\lambda$ where λ is a cardinal and $\lambda > \kappa$.

We have $|P_\kappa\lambda| = \lambda^{<\kappa}$ and so the maximal possible size of a disjoint family of subsets of $P_\kappa\lambda$ is $\lambda^{<\kappa}$. While it is consistent that every stationary set splits into $\lambda^{<\kappa}$ disjoint stationary subsets (see Corollary 4.18), this is not provable in ZFC. The reason is that there may exist closed unbounded sets in $P_\kappa\lambda$ whose size is less than $\lambda^{<\kappa}$. For instance, [8] shows that there exists a club in $P_{\omega_3}\omega_4$ of size $\aleph_4^{\aleph_1}$; thus if $2^{\aleph_2} > 2^{\aleph_1} \cdot \aleph_4$, then $P_{\omega_3}\omega_4$ is not the union of $\aleph_4^{<\aleph_3}$ disjoint stationary sets. An earlier result [11] proved the consistency of a stationary set $S \subseteq P_{\omega_1}\omega_2$ such that $\mathrm{NS}{\restriction}S$ is $2^{\aleph_0}$-saturated.

A modification of Solovay's proof, using the generic ultrapower by NS, gives this:

4.13 Theorem (Gitik [32]). *Every stationary subset of $P_\kappa\lambda$ can be partitioned into κ disjoint stationary sets.*

The question of splitting stationary sets has been more or less completely solved for splitting into λ sets. Let us first observe that the nonexistence of λ disjoint stationary sets is equivalent to λ-saturation:

4.14 Lemma. *If X_α, $\alpha < \lambda$, are stationary sets in $P_\kappa\lambda$ such that $X_\alpha \cap X_\beta \in$ NS for all $\alpha \neq \beta$, then there exist pairwise disjoint stationary sets Y_α with $Y_\alpha \subseteq X_\alpha$ for all $\alpha < \lambda$.*

Proof. Let $Y_\alpha = X_\alpha \cap \{x : \alpha \in x \text{ and } \forall\beta \in x(\beta \neq \alpha \to x \notin X_\beta)\}$. $\dashv$

A long series of results by Jech [44], Menas [77], Baumgartner, DiPrisco and Marek [19], Matsubara [72, 73] established the following:

4.15 Theorem.

(i) *$P_\kappa\lambda$ can be partitioned into λ disjoint stationary sets.*

(ii) *If κ is a successor cardinal, than every stationary subset of $P_\kappa\lambda$ can be partitioned into λ disjoint stationary sets.*

(iii) *If $0^\#$ does not exist, then every stationary subset of $P_\kappa\lambda$ can be partitioned into λ disjoint stationary sets.*

A complete proof of this theorem can be found in Kanamori's book [62]. The results (ii) and (iii) are best possible, in the following sense:

4.16 Theorem (Gitik [32]). *It is consistent, relative to a supercompact cardinal, that κ is inaccessible, $\lambda > \kappa$, and some stationary set $S \subseteq P_\kappa\lambda$ cannot be partitioned into κ^+ disjoint stationary subsets.*

For a simplification of Gitik's proof, as well as further results, see [83].

The proof of Theorem 4.15 involves the following set, which clearly is stationary:

$$S_0 = \{x \in P_\kappa\lambda : |x \cap \kappa| = |x|\}.$$

This stationary set can be partitioned into λ disjoint stationary sets, and if either $\kappa = \nu^+$ or $0^\#$ does not exist, then S_0 contains a club (cf. [62]).

Clearly, in Gitik's model the set S_0 does not contain a club. Thus the statement that for some κ and λ,

$$\{x \in P_\kappa\lambda : |x \cap \kappa| < |x|\}$$

is stationary, is a consistent large cardinal statement. Its exact consistency strength (between $0^\#$ and Ramsey) is pinned down in [5] and [20].

As for splitting into $\lambda^{<\kappa}$ sets, the following result of Matsubara together with Theorem 4.15 proves the consistency result mentioned earlier:

4.17 Proposition (Matsubara [74]). *Assume* GCH. *If* $\mathrm{cf}(\lambda) < \kappa$, *then every stationary subset of $P_\kappa\lambda$ can be partitioned into λ^+ disjoint stationary sets.*

4.18 Corollary. *Assume* GCH *and that $0^\#$ does not exist. Then every stationary subset of $P_\kappa\lambda$ can be partitioned into $\lambda^{<\kappa}$ disjoint stationary sets.*

4.3. Saturation

By Theorem 4.15, the nonstationary ideal on $P_\kappa\lambda$ is not λ-saturated (even though $\mathrm{NS}{\restriction}S$ can be κ^+-saturated for some S). The next question is whether it can be λ^+-saturated, and the answer is again no.

4.19 Theorem (Foreman-Magidor [26]). *For every regular uncountable cardinal κ and every cardinal $\lambda > \kappa$, the nonstationary ideal on $P_\kappa\lambda$ is not λ^+-saturated.*

See Foreman's chapter in this Handbook for this result. We note that special cases of this theorem had been proved earlier, cf. [4, 73, 60, 17].

When dealing with λ^+-saturation, we naturally employ generic ultrapowers and use the fact that the ultrapower is well founded; a normal λ^+-saturated ideal on $P_\kappa\lambda$ is precipitous. The nonstationary ideal on $P_\kappa\lambda$ (for regular λ) can be precipitous. The consistency, a result of Goldring [39], is relative to a Woodin cardinal, and strengthens an earlier result in [27]. On the other hand, the paper [75] gives instances of κ and λ for which NS on $P_\kappa\lambda$ cannot be precipitous.

5. Proper Forcing and Other Applications

5.1. Proper Forcing

One of the most fruitful applications of the club filter on $P_{\omega_1}A$ is Shelah's concept of *proper forcing*. As proper forcing is discussed in detail in Abraham's chapter in this Handbook, I shall only give a brief account in this section. The rest of Sect. 5 deals with applications of the club filter on $P_{\omega_1}A$ in the theory of Boolean algebras.

When dealing with closed unbounded sets in $P_{\omega_1}A$ we may as well restrict ourselves to infinite sets, and thus consider the space $[A]^{\aleph_0}$ (where A is an uncountable set). By Kueker's Theorem 4.9, a set $X \subseteq [A]^{\aleph_0}$ is in the club filter just in case it contains the set Cl_F of all closure points of some operation on A. Equivalently, X contains all elementary submodels of some model with universe A. A useful modification of this is the following consequence of Proposition 4.8.

5.1 Proposition. *A set $X \subseteq [A]^{\aleph_0}$ is in the club filter if for some sufficiently large λ, X contains $M \cap A$, for all countable $M \prec \mathcal{H}_\lambda$ such that $A \in M$.*

Here $\mathcal{H}_\lambda = \langle H_\lambda, \in \rangle$ where H_λ is the set of all sets hereditarily of power $< \lambda$; "sufficiently large" means $2^{|\mathrm{TC}(A)|} < \lambda$.

Let us now turn to proper forcing. First we remark that the preservation Theorem 1.13 generalizes to $[A]^{\aleph_0}$:

5.2 Theorem.

(a) *If P satisfies the countable chain condition, then every club $C \in V[G]$ in $[A]^{\aleph_0}$ has a club subset in the ground model. Hence every stationary subset of $[A]^{\aleph_0}$ remains stationary in $V[G]$.*

(b) *If P is countably closed, then every stationary subset of $[A]^{\aleph_0}$ remains stationary in $V[G]$.*

For a proof, we refer the reader to [7, Theorem 2.3] or [48, p. 87]. This leads to the important definition, cf. [79]:

5.3 Definition. A notion of forcing P is *proper* if for every uncountable set A, every stationary subset of $[A]^{\aleph_0}$ remains stationary in $V[G]$.

There are several equivalent definitions of properness, most using the club filter on $[A]^{\aleph_0}$. Let me state one of them (see [79, p. 77], [48, p. 97]):

5.4 Proposition. *A complete Boolean algebra B is proper if and only if for every nonzero $a \in B$ for every uncountable λ and every collection $\{a_{\alpha\beta} : \alpha, \beta < \lambda\}$ such that $\Sigma_{\beta<\lambda} a_{\alpha\beta} = a$ for every $\alpha < \lambda$, there exists a club $C \subseteq [\lambda]^{\aleph_0}$ such that $\Pi_{\alpha\in x}\Sigma_{\beta\in x} a_{\alpha\beta} \neq 0$ for all $x \in C$.*

5.2. Projective and Cohen Boolean Algebras

The club filter on $[A]^{\aleph_0}$ turns out to be a useful tool in the study of Boolean algebras. Here we present a uniform approach to the investigation of two related concepts, projective and Cohen Boolean algebras. For simplicity, we consider only atomless Boolean algebras of uniform density.

5.5 Definition.

(a) A Boolean algebra B is *projective* if for some Boolean algebra C, the free product $B \oplus C$ is a free Boolean algebra.

(b) A Boolean algebra B is a *Cohen algebra* if its completion is isomorphic to the completion of a free Boolean algebra.

Projective algebras have several other (equivalent) definitions and are projective in the sense of universal algebra; we refer to [64] for details. Forcing with Cohen algebras adds Cohen reals. In the present context, it is the following equivalences that make these two classes interesting: Let A be a subalgebra of a Boolean algebra B. A is a *relatively complete* subalgebra of B, $A \leq_{\mathrm{rc}} B$, if for each $b \in B$ there is a smallest element $a \in A$ such that $b \leq a$. A is a *regular subalgebra* of B, $A \leq_{\mathrm{reg}} B$, if every maximal antichain in A is maximal in B. Let $\langle A_1 \cup A_2\rangle$ denote the subalgebra generated by $A_1 \cup A_2$.

5.6 Theorem.

(a) (Ščepin [78]) *A Boolean algebra B is projective if and only if the set $\{A \in [B]^{\aleph_0} : A \leq_{\mathrm{rc}} B\}$ contains a club C with the property that for all $A_1, A_2 \in C$, $\langle A_1 \cup A_2\rangle \in C$.*

(b) (Koppelberg [65], Balcar-Jech-Zapletal [3]) *A Boolean algebra B is Cohen if and only if the set $\{A \in [B]^{\aleph_0} : A \leq_{\mathrm{reg}} B\}$ contains a club with the property that for all $A_1, A_2 \in C$, $\langle A_1 \cup A_2\rangle \in C$.*

This leads naturally to the following concepts:

5.7 Definition.

(a) (Ščepin) A Boolean algebra B is *openly generated* if the set $\{A \in [B]^{\aleph_0} : A \leq_{\mathrm{rc}} B\}$ contains a club.

(b) (Fuchino-Jech) A Boolean algebra B is *semi-Cohen* if the set $\{A \in [B]^{\aleph_0} : A \leq_{\mathrm{reg}} B\}$ contains a club.

Openly generated (also called rc-filtered) and semi-Cohen Boolean algebras are investigated systematically in [42] and [3], respectively.

Our first observation is that every projective algebra is openly generated and every Cohen algebra is semi-Cohen; and if $|B| = \aleph_1$ and B is openly generated (or semi-Cohen), then B is projective (or Cohen). Because a σ-closed forcing preserves stationary sets in $[B]^{\aleph_0}$ (by Theorem 5.2), we have:

5.8 Corollary. *B is openly generated (resp. semi-Cohen) iff $V^P \vDash B$ is projective (resp. Cohen), where P is the σ-closed collapse of $|B|$ onto $\aleph_1$.*

An immediate consequence is that the completion of a semi-Cohen algebra is semi-Cohen.

Using some simple algebra and Proposition 4.8, one can show that every rc-subalgebra of an openly generated algebra is openly generated and every regular subalgebra of a semi-Cohen algebra is semi-Cohen. Consequently, we have:

5.9 Corollary.

(a) (Ščepin) *If B is projective and $A \leq_{\mathrm{rc}} B$ has size $\aleph_1$, then A is projective.*

(b) (Koppelberg) *If B is a Cohen algebra and $A \leq_{\mathrm{reg}} B$ has size $\aleph_1$, then A is Cohen.*

Finally, the use of the club filter yields a simple proof of the following theorem:

5.10 Theorem.

(a) (Ščepin [78], Fuchino [28]) *The union of any continuous $\leq_{\mathrm{rc}}$-chain of openly generated algebras is openly generated.*

(b) (Balcar-Jech-Zapletal [3]) *The union of any continuous $\leq_{\mathrm{reg}}$-chain of semi-Cohen algebras is semi-Cohen.*

Proof. Let B be the union and let λ be sufficiently large; by Proposition 5.1 it suffices to show that for every countable $M \prec \mathcal{H}_\lambda$ such that $B \in M$, $B \cap M$ is a relatively complete (resp. regular) subalgebra of B. It is not very difficult to prove this. ⊣

6. Reflection

In Sect. 2 we introduced the important concept of reflection. One can expect that its generalization to $P_\kappa\lambda$ will be equally important. This is indeed the case, and in particular, reflection of stationary sets in $[\lambda]^{\aleph_0}$ at sets of cardinality $\aleph_1$ plays a significant role in applications of Martin's Maximum.

Let us begin with a generalization of reflection of which very little is known (see [55] for a consistency result): Let κ be inaccessible, and let $\lambda > \kappa$. For each $x \in P_\kappa\lambda$, let $\kappa_x = x \cap \kappa$; note that for almost all x, κ_x is a cardinal. When κ_a is regular uncountable, we say that a stationary S reflects at a if $S \cap P_{\kappa_a} a$ is a stationary subset of $P_{\kappa_a} a$.

The following argument shows that there are limitations to reflection: Let $S \subseteq \mathbf{E}^\lambda_{\aleph_0}$ and $T \subseteq \mathbf{E}^\lambda_{\aleph_1}$ be such that S does not reflect at any $\alpha \in T$ (see Lemma 2.16). Let $\widehat{S} = \{x \in P_\kappa\lambda : \sup(x) \in S\}$ and $\widehat{T} = \{a \in P_\kappa\lambda : \sup(a) \in T\}$. Then $\widehat{S}$ does not reflect at any $a \in \widehat{T}$.

A similar generalization leads to significant results in the large cardinal theory and we shall now investigate this generalization.

6.1. Reflection Principles

In [27], Foreman, Magidor and Shelah introduced Martin's Maximum and proved a number of consequences. Let us recall that *Martin's Maximum* (MM) states that whenever P is a notion of forcing that preserves stationary subsets of $\aleph_1$, and D is a family of $\aleph_1$ dense subsets of P, then there exists a D-generic filter on P. By [27] Martin's Maximum is consistent relative to a supercompact cardinal.

Among the consequences of MM proved in [27] are the following:

- The nonstationary ideal on $\aleph_1$ is $\aleph_2$-saturated.
- For every regular $\kappa \geq \aleph_2$, every stationary set $S \subseteq \mathbf{E}^\kappa_{\aleph_0}$ contains a closed set of order type ω_1.
- $2^{\aleph_0} = \aleph_2$.
- For every regular $\kappa \geq \aleph_2$, $\kappa^{\aleph_0} = \kappa$.

The authors of [27] introduced the following *Reflection Principle* and proved that it follows from MM.

If S is a stationary subset of $[\lambda]^{\aleph_0}$ and $X \in [\lambda]^{\aleph_1}$ we say that S *reflects at* X if $S \cap [X]^{\aleph_0}$ is stationary in $[X]^{\aleph_0}$.

6.1 Definition (Reflection Principle, Foreman-Magidor-Shelah [27]). For every regular $\lambda \geq \aleph_2$, every stationary set $S \subseteq [\lambda]^{\aleph_0}$ reflects at some $X \in [\lambda]^{\aleph_1}$ such that $X \supseteq \omega_1$.

For a given regular λ, let us call the property in Definition 6.1 *Reflection Principle at* λ. As for the extra condition $X \supseteq \omega_1$, this is not just an ad hoc requirement. Its role is clarified in the following two propositions. (Compare this with the remark following Theorem 2.3.)

6.2 Proposition (Feng-Jech [21]). *Let $\lambda \geq \aleph_2$ be a regular cardinal.*

(a) *Reflection Principle at λ holds iff for every stationary set $S \subseteq [\lambda]^{\aleph_0}$, the set $\{X \in [\lambda]^{\aleph_1} : S$ reflects at $X\}$ is stationary in $[\lambda]^{\aleph_1}$.*

(b) *Every stationary $S \subseteq [\lambda]^{\aleph_0}$ reflects at some $X \in [\lambda]^{\aleph_1}$ iff for every stationary set $\subseteq [\lambda]^{\aleph_0}$, the set $\{X \in [\lambda]^{\aleph_1} : S$ reflects at $X\}$ is weakly stationary in $[\lambda]^{\aleph_1}$.*

For $\lambda = \aleph_2$ the assumption $X \supseteq \omega_1$ can be dropped; it is unknown if the same is true in general:

6.3 Proposition (Feng-Jech [21]). *Reflection Principle at $\aleph_2$ holds if and only if every stationary $S \subseteq [\omega_2]^{\aleph_0}$ reflects at some $X \in [\omega_2]^{\aleph_1}$.*

The significance of this and related reflection principles is illustrated by the fact that they imply the major consequences of MM. Firstly, Reflection Principle at $\aleph_2$ implies that the continuum is at most $\aleph_2$:

6.4 Theorem (Shelah [80], Todorčević [89]). *If every stationary $S \subseteq [\omega_2]^{\aleph_0}$ reflects at some $X \in [\omega_2]^{\aleph_1}$, then $2^{\aleph_0} \leq \aleph_2$.*

Proof. For each uncountable $\alpha < \omega_2$, let $C_\alpha \subseteq [\alpha]^{\aleph_0}$ be a club of cardinality $\aleph_1$, and let $D = \bigcup_{\omega_1 \leq \alpha < \omega_2} C_\alpha$. By Propositions 6.3 and 6.2(a), the set D contains a club, and we have $|D| = \aleph_2$. However, it is proved in [11] that every club in $[\omega_2]^{\aleph_0}$ has cardinality $\aleph_2^{\aleph_0}$; hence $2^{\aleph_0} \leq \aleph_2$. ⊣

Reflection Principle at $\aleph_2$ is not particularly strong; it is equi-consistent with the existence of a weakly compact cardinal. A modification of Magidor's construction [70] gives a model in which every stationary $S \subseteq [\omega_2]^{\aleph_0}$ reflects at $[\alpha]^{\aleph_0}$ for almost all $\alpha \in \mathbf{E}^{\aleph_2}_{\aleph_1}$.

The general Reflection Principle, for all regular $\lambda \geq \aleph_2$, is a stronger large cardinal property. A modification of the proof of Theorem 25 in [27] shows that the Reflection Principle implies that the nonstationary ideal on ω_1 is presaturated (i.e. precipitous, and forcing with $P(\omega_1)/\mathrm{NS}$ preserves ω_2). This has strong large cardinal consequences.

The Reflection Principle follows from MM and in fact from a weaker forcing axiom MA^+ (σ-closed). (This latter axiom is known to be strictly weaker than MM.) In fact, MA^+ (σ-closed) implies (cf. [14]) for every regular $\lambda \geq \aleph_2$, for every stationary set $\cdot S \subseteq [\lambda]^{\aleph_0}$, the set $\{X \in [\lambda]^{\aleph_1} : S$ reflects at $X\}$ meets every ω_1-closed unbounded set C in $[\lambda]^{\aleph_1}$. This reflection principle was introduced in [23].

Todorčević formulated a strengthening of the Reflection Principle and proved that his *Strong Reflection Principle* (SRP) implies that the nonstationary ideal on ω_1 is $\aleph_2$-saturated, that every stationary subset of $\mathbf{E}^{\kappa}_{\aleph_0}$ contains a closed copy of ω_1 and that for every regular $\kappa \geq \aleph_2$, $\kappa^{\aleph_0} = \kappa$ (cf. [15]).

In [22], another reflection principle is introduced, called *Projective Stationary Reflection*, and proved to be equivalent to the Strong Reflection Principle (SRP = PSR).

6.5 Definition (Feng-Jech [22]). A stationary set $S \subseteq [A]^{\aleph_0}$ where $A \supseteq \omega_1$, is *projective stationary* if for every club $C \subseteq [A]^{\aleph_0}$, the projection $(S \cap C) \restriction \omega_1 = \{x \cap \omega_1 : x \in S \cap C\}$ to ω_1 contains a club.

6.6 Definition (Projective Stationary Reflection (PSR), Feng-Jech [22]). For every regular $\lambda \geq \aleph_2$, every projective stationary set $S \subseteq [H_\lambda]^{\aleph_0}$ contains an increasing continuous $\in$-chain $\{N_\alpha : \alpha < \omega_1\}$ of elementary submodels of H_λ.

If $S \subseteq [H_\lambda]^{\aleph_0}$ is stationary, let P_S be the forcing notion consisting of countable increasing continuous $\in$-chains $\{N_\alpha : \alpha < \gamma\} \subseteq S$ of elementary submodels of H_λ. The set S is projective stationary just in case P_S preserves stationary subsets of ω_1. Thus PSR follows from Martin's Maximum. It is also proved in [22] that PSR implies the Reflection Principle.

6.7 Theorem (Feng-Jech [22]). *Assume* PSR.

(a) *For every regular $\kappa \geq \aleph_2$, every stationary set $S \subseteq \mathbf{E}^\kappa_{\aleph_0}$ contains a closed set of order type ω_1.*

(b) *The nonstationary ideal on ω_1 is $\aleph_2$-saturated.*

Proof. (a) This is proved by applying PSR to the projective stationary set

$$\{N \in [H_\kappa]^{\aleph_0} : S \in N \prec H_\kappa \text{ and } \sup(N \cap \kappa) \in S\},$$

where S is a given stationary subset of $\mathbf{E}^\kappa_{\aleph_0}$.

(b) Let A be a maximal antichain of stationary subsets of ω_1. Then the set

$$X = \{N \in [H_{\omega_2}]^{\aleph_0} : A \in N \prec H_{\omega_2} \text{ and } N \cap \omega_1 \in S \text{ for some } S \in A \cap N\}$$

is projective stationary. By PSR, there exists an $\in$-chain $\{N_\alpha : \alpha < \omega_1\} \subseteq X$, and we let $N = \bigcup_{\alpha<\omega_1} N_\alpha$. One can verify that $A \subseteq N$, and therefore $|A| \leq \aleph_1$. ⊣

Finally, recent work of Woodin shows that Strong Reflection implies that $2^{\aleph_0} = \aleph_2$, in fact $\boldsymbol{\delta}^1_2 = \omega_2$:

6.8 Theorem (Woodin [94]). *Assume* SRP. *Then the set $\{N \in [H_{\omega_3}]^{\aleph_1} : N \prec H_{\omega_3}$ and the order type of $N \cap \omega_3$ is $\omega_1\}$ is weakly stationary. This together with the saturation of the nonstationary ideal, implies that $\boldsymbol{\delta}^1_2 = \omega_2$.*

6.2. Nonreflecting Stationary Sets

The results about reflecting stationary sets in $[\lambda]^{\aleph_0}$ at sets of size $\aleph_1$ do not generalize to $[\lambda]^\kappa$ for $\kappa \geq \aleph_1$. For instance, the analog of the Reflection Principle is false:

6.9 Proposition. *If λ is sufficiently large, then it is not the case that every stationary $S \subseteq [\lambda]^{\aleph_1}$ reflects at some $X \in [\lambda]^{\aleph_2}$ such that $X \supseteq \omega_2$.*

In Sect. 6.1 we mentioned that the Reflection Principle implies that NS on ω_1 is presaturated. To prove Proposition 6.9, one first shows that the generalization of the Reflection Principle would yield presaturation of NS on ω_2, thus (as in Shelah's Corollary 3.7) a forcing notion that changes the cofinality of ω_2 to ω while preserving $\aleph_1$ and $\aleph_3$. But that is impossible.

Specific examples of nonreflecting stationary subsets of $[\lambda]^{\aleph_1}$ are given in [25]. That paper also explains why the consistency proof of Reflection Principle does not generalize. A model of MA^+ (σ-closed) is obtained by Lévy collapsing (to $\aleph_1$) cardinals below a supercompact. A crucial fact is that the collapse preserves stationary sets in $[\lambda]^{\aleph_0}$ (Theorem 5.2(a)). Unfortunately, the analog of this is false in general, as $<\kappa$-closed forcing can destroy stationary sets in $P_\kappa\lambda$.

Following [27], a model $N \prec H_\lambda$ is *internally approachable* (IA) if there exists a chain $\langle N_\alpha : \alpha < \gamma\rangle$ whose initial segments belong to N, with $N = \bigcup_{\alpha<\gamma} N_\alpha$. Let κ be a regular uncountable cardinal and let $\lambda \geq \kappa$ be regular. The set $P_\kappa H_\lambda \cap \mathrm{IA}$ is stationary and its projection to κ contains a club. Moreover, every countable N is internally approachable and so $[H_\lambda]^{\aleph_0} \cap \mathrm{IA}$ contains a club.

It is proved in [25] that every $<\kappa$-closed forcing preserves stationary subsets of $P_\kappa H_\lambda \cap \mathrm{IA}$, and that the $<\kappa$-closed collapse of H_λ shoots a club through $P_\kappa H_\lambda \cap \mathrm{IA}$. As for a generalization of Reflection Principle, they prove that if cardinals between κ and a supercompact are collapsed to κ, then in the resulting model, every stationary set $S \subseteq P_\kappa H_\lambda \cap \mathrm{IA}$ reflects at a set of size κ.

7. Stationary Tower Forcing

In this last section we give a brief description of stationary tower forcing, introduced by Woodin in [93]. See also [69] and Foreman's chapter in this Handbook.

Let δ be an inaccessible cardinal. Let Q and P be the following notions of forcing (*stationary tower forcing*):

A forcing condition in Q is a pair (A, S) where $A \in V_\delta$ and S is a stationary subset of $[A]^{\aleph_0}$; $(A, S) < (B, T)$ if $A \supseteq B$ and $S{\restriction}B \subseteq T$.

A forcing condition in P is a pair (A, S) where $A \in V_\delta$ and S is a weakly stationary subset of $P_{|A|}A$; $(A, S) < (B, T)$ if $A \supseteq B$ and $S{\restriction}B \subseteq T$.

In fact, stationary tower forcing is somewhat more general than these two examples, and uses the following generalization of stationary sets (considered e.g. in [20]). A set S is *stationary* in $P(A)$ if $S \subseteq P(A)$ and if for every $F : [A]^{<\omega} \to A$, S contains a closure point of F, i.e. a set $X \subseteq A$ such that $F(e) \in X$ for all $e \in [X]^{<\omega}$. As in Proposition 4.8, projections and liftings of stationary sets are stationary. Also, the analog of Theorem 4.4 holds. Note that the sets $S{\restriction}P_\kappa A$ are exactly the weakly stationary sets in $P_\kappa A$, and $S{\restriction}\{X \in P_\kappa\lambda : X \cap \kappa \in \kappa\}$ are the stationary sets in $P_\kappa\lambda$.

The general version of stationary tower forcing uses conditions (A, S) where S is stationary in $P(A)$.

If G is a generic filter on Q, then for each $A \in V_\delta$, the set $G_A = \{S : (A, S) \in G\}$ is a V-ultrafilter on $([A]^{\aleph_0})^V$; similarly for P. Moreover, if $A \subseteq B$, then G_B projects to G_A. In $V[G]$ we form a limit ultrapower $M = \mathrm{Ult}_G(V)$ by the G_A, $A \in V_\delta$. The elements of M are represented by functions (in V) whose domain is some $A \in V_\delta$. Let $j : V \to M$ be the *generic embedding*, i.e. the elementary embedding from V into the limit ultrapower.

The ultrapower has a well founded initial segment up to at least δ: each ordinal $\alpha \le \delta$ is represented by the function $f_\alpha(x) = x \cap \alpha$. The identity function $\mathrm{id}(x) = x$ represents the set $j``V_\delta$. Woodin's main tool is the following:

7.1 Theorem (Woodin [93]). *Suppose δ is a Woodin cardinal. If G is a generic on either Q or P, then the generic ultrapower $\mathrm{Ult}_G(V)$ is well founded, and the model M is closed under sequences of length $< \delta$.*

When forcing with Q, one has $\mathrm{crit}(j) = \omega_1$ and $j(\omega_1) = \delta$. For applications, see [93].

Forcing with P gives more flexibility and yields various strong forcing results. We conclude this section with a typical application. Assume that $\aleph_\omega$ is strong limit. Let

$$S = \{X \in [V_{\aleph_{\omega+1}}]^{\aleph_\omega} : X \cap \aleph_{\omega+1} \in \aleph_{\omega+1} \text{ and } \mathrm{cf}(X \cap \aleph_{\omega+1}) = \aleph_3\}$$

and let G be a generic on P such that $S \in G$. Then $\mathrm{crit}(j) = \aleph_{\omega+1}$ and $\mathrm{cf}^M(\aleph_{\omega+1}) = \aleph_3$. As $P^{V[G]}(\omega_n) = P^M(\omega_n) = P^V(\omega_n)$ for all n, we conclude that forcing with P (below $(V_{\aleph_{\omega+1}}, S)$) changes the cofinality of $\aleph_{\omega+1}$ to $\aleph_3$ while preserving $\aleph_\omega$.

1. Introduction

The study of partition relations dates back to 1930, when Frank P. Ramsey [49] proved his oft-cited theorem.

1.1 Theorem (Ramsey's Theorem). *Assume* $1 \leq r$, $k < \omega$ *and* $f : [\omega]^r \to k$ *is a partition of the* r *element subsets of* ω *to* k *pieces. Then there is an infinite subset* $X \subseteq \omega$ *homogeneous with respect to this partition. That is, for some* $i < k$, $f``[X]^r = \{i\}$.

In 1941, Ben Dushnik and Edwin Miller [9] looked at partitions of the set of all pairs of elements of an uncountable set, involving Paul Erdős in solving one of their more difficult problems (see Theorem 7.4). In 1942, Erdős [10] proved some basic generalizations of Ramsey's Theorem, including among others the theorem generally called the Erdős-Rado Theorem for pairs. In the early fifties, Erdős and Richard Rado [15, 17] initiated a systematic investigation of quantitative generalizations of this result. They called it the partition calculus. There are cases in mathematical history when a well-chosen notation can enormously enhance the development of a branch of mathematics and a case in point is the ordinary partition symbol (see Definition 1.3)

$$\alpha \to (\beta_\xi)^r_{\xi<\gamma}$$

invented by Rado [16], reducing Ramsey's Theorem to $\omega \to (\omega)^r_\gamma$ for $1 \leq r$, $\gamma < \omega$. It became clear that a careful analysis of the problems according to the size and nature of the parameters leads to an inexhaustible array of problems, each seemingly simple and natural. These classical investigations were completed in the 1965 paper [18] of Erdős, András Hajnal and Rado, and were extended in the book [19] written jointly with Attila Máté. We cite this compendium from time to time for proofs we omit and as a resource for some open problems we include.

In 1967, after the first post-Cohen set theory conference, held in Los Angeles, Erdős and Hajnal wrote a list of unsolved problems for the ordinary partition symbol and related topics. This paper [12] appeared in print four years later.

A great many new results were proved by the *then* young researchers. However, unlike many other classical problems, these problems have resisted full solution. The introduction of new methods and the discovery of new ideas usually has given only incremental progress, and objectively, we are as far as ever from complete answers. However, small steps requiring new methods have been continuously made, quite a few of them during the writing of this paper, and we will concentrate on them.

For easy reference, in the ordinary partition relation $\alpha \to (\beta_\xi)^r_\gamma$, we call α the *resource*, β_ξ the *goals*, and γ the *set of colors*. We will be focusing on two main subjects:

1. New ZFC theorems obtained via the elementary submodel method both for ordinary partition relations and for polarized partition relations (see Definition 1.5).

2. The new results obtained in the late nineties for partition relations with a countable resource.

Section 2 describes the classical proofs of the (balanced) form of the Erdős-Rado Theorem and the Positive Stepping Up Lemma. These are the results where the resource is regular and the goals are equal and of the form τ, or $\tau+1$ for some cardinal τ. In Sect. 2.3 we state but do not prove the Negative Stepping Up Lemma complementing these results.

In Sect. 3, we describe the elementary submodel method and in particular, the use of nonreflecting ideals first introduced in [4]. We give an alternate proof of the balanced Erdős-Rado Theorem, and give a proof of the unbalanced form of it using the new method.

In Sect. 4, especially in Sect. 4.2, we fully develop the method of elementary submodels. We give streamlined proofs of both the balanced and unbalanced forms of the Baumgartner-Hajnal-Todorcevic Theorems [4] in Sects. 4.3 and 4.4. These results generalize the Erdős-Rado Theorem to allow goals which are ordinals more complex than cardinals τ and their ordinal successors, $\tau+1$. We state a result of Matthew Foreman and Hajnal [20] for the successors of measurable cardinals. Using the methods of the Foreman-Hajnal proof, in Sect. 4.5, we give a direct proof of a special case of the Baumgartner-Hajnal Theorem [2].

In Sect. 5, we discuss the Milner-Rado Paradox and the new ordinal $\Omega(\kappa) < \kappa^+$ introduced in the Foreman-Hajnal result [20], which is related to a form of the Milner-Rado Paradox.

In Sect. 6, we discuss a new development, the first in the twenty-first century. Solving a problem of Foreman and Hajnal, Saharon Shelah [59] proved that if there is a strongly compact cardinal, then there are cardinals κ such that $\kappa^+ \to (\kappa+2)^2_\omega$.

In Sect. 7, we briefly discuss the case of singular resources. We state, but do not prove, several theorems on this subject from the 1965 Erdős, Hajnal and Rado paper [18] and the 1975 Shelah paper [56].

In Sect. 8, we describe a new variant of the elementary submodel method called *double ramification*, which was invented by Baumgartner and Hajnal to establish their Theorem 8.2.

In Sect. 8.1, we use it for the proof of

$$(*) \qquad \binom{\kappa^+}{\kappa} \to \binom{\kappa}{\kappa}^{1,1}_{\gamma}$$

where κ is weakly compact and $\gamma < \kappa$. Result $(*)$ was previously known only if $\gamma < \omega$ (see the discussion before Theorem 8.2). In Sect. 8.2, we use the method for the proof of Shelah's Theorem [58] stating that $(*)$ holds for κ a singular strong limit cardinal (of uncountable cofinality) which satisfies $2^\kappa > \kappa^+$ and for $\gamma < \mathrm{cf}(\kappa)$.

In Sect. 9, we discuss the spectacular progress by Carl Darby [7, 8] and Rene Schipperus [53, 51] on the cases where the resource α is a countable ordinal, listing their negative partition results in Theorem 9.9, and give a sample counterexample, $\omega^{\omega^2} \nrightarrow (\omega^{\omega^2}, 6)^2$. This example is not optimal, but was chosen to illustrate the methods of Darby without all the complicating detail.

In Sect. 10, we outline a proof of a special case of the positive results by Schipperus that $\omega^{\omega^\beta} \to (\omega^{\omega^\beta}, 3)^2$ for $\beta \geq 2$ the sum of one or two indecomposable ordinals (Darby independently proved the result for $\beta = 2$).

We close this section with some background definitions.

1.1. Basic Definitions

1.2 Definition. Let X be a set, $r < \omega$ and β, γ be ordinals.

1. A map $f : [X]^r \to \gamma$ is called an *r-partition of X with γ colors.*
2. For $\xi < \gamma$, a subset $Y \subseteq X$ is called *homogeneous for f in color ξ* if $f``[Y]^r = \{\xi\}$.
3. The set $Y \subseteq X$ is *homogeneous for f* if it is homogeneous for f in some color $\xi < \gamma$.
4. A linearly ordered set X has *order type β*, in symbols, $\mathrm{ot}(X) = \beta$, if it is order isomorphic to β.

1.3 Definition. Let α, β_ξ for $\xi < \gamma$, and γ be ordinals and suppose $1 \leq r < \omega$. The *ordinary partition symbol*

$$\alpha \to (\beta_\xi)^r_\gamma$$

means that the following statement is true.

> For every r-partition of α with γ colors, $f : [\alpha]^r \to \gamma$, there exist $\xi < \gamma$ and $X \subseteq \alpha$ such that $\mathrm{ot}(X) = \beta_\xi$ and X is homogeneous for f in color ξ.

We write

$$\alpha \not\to (\beta_\xi)^r_\gamma$$

to indicate that the negation of this statement is true. If all β_ξ equal β, then we write

$$\alpha \to (\beta)^r_\gamma \quad (\text{or } \alpha \not\to (\beta)^r_\gamma).$$

A further more or less self explanatory abbreviation is $\alpha \to (\beta_0, (\beta)_\gamma)^2$ in case $\beta_\xi = \beta$ for $1 \le \xi < \gamma$.

1.4 Remark. Note that the notation of Definition 1.3 is so devised that if we start with a positive partition relation $\alpha \to (\beta_\xi)^r_\gamma$, then the truth of the assertion is preserved under increasing the *resource* ordinal α on the left-hand side of the arrow ($\to$) and decreasing the ordinal *goals* β_ξ, or the colors γ on the right-hand side of the arrow. And this latter statement holds, with some exceptions, for the exponent r as well (see [19]).

We stated Definition 1.3 in this generality, because it will suffice for most of what we will prove. It should be clear that further generalizations can be made. For example, a similar symbol $\Theta \to (\Theta_\xi)^\delta_\gamma$ can be defined where $\Theta, \Theta_\xi, \delta$ are order types, by starting with an arbitrary ordered set $\langle X, \prec\rangle$ for which $\mathrm{ot}(X, \prec) = \Theta$, partitioning its subsets of order type δ,

$$[X]^\delta = \{Y \subseteq X : \mathrm{ot}(Y, \prec) = \delta\},$$

into γ color classes, and as above, looking for homogeneous subsets of the prescribed color and order type. As general Ramsey theory developed in both finite and infinite combinatorics, problems were considered in which the set partitioned was a subset of $[X]^\delta$ rather than all of $[X]^\delta$, and the homogeneous sets consisted of possibly other kinds of subsets of $[X]^\delta$. Partition relations proliferated. For a review of some of them we refer to [19], since we can not try to cover all of them in the limit space of this chapter.

In [18], among other generalizations, polarized partitions were introduced. In fact, this paper is the only place in the published literature where these relations are systematically discussed.

1.5 Definition. Let α,β be ordinals and suppose that $\alpha_0, \alpha_1 \le \alpha$ and $\beta_0, \beta_1 \le \beta$. The *polarized partition relation*

$$\begin{pmatrix}\alpha\\ \beta\end{pmatrix} \to \begin{pmatrix}\alpha_0 & \alpha_1\\ \beta_0 & \beta_1\end{pmatrix}$$

means that the following statement is true.

> For all ordered sets A and B of order type α, β respectively, and all partitions $f : A \times B \to 2$, there is an $i < 2$ and sets $A_i \subseteq A$, $B_i \subseteq B$ such that $\mathrm{ot}(A_i) = \alpha_i$, $\mathrm{ot}(B_i) = \beta_1$ and $f``A_i \times B_i = \{i\}$.

2. Basic Partition Relations

2.1. Ramsey's Theorem

2.1 Definition. Assume $\langle X, \prec\rangle$ is an ordered set and $f : [X]^r \to \gamma$ is an r-partition of length γ of X, $1 \le r < \omega$.

1. For $V \in [X]^{r-1}$, define $f_V : X - V \to \gamma$ by
$$f_V(u) = f(V \cup \{u\}).$$
2. f is *endhomogeneous on* X if for every $V \in [X]^{r-1}$, the function f_V is homogeneous on $X| \succ V = \{u \in X : V \prec u\}$.
3. Let
$$X^- = \begin{cases} X - \{m\} & \text{if } X \text{ has a maximal element } m, \\ X & \text{otherwise.} \end{cases}$$
4. Assume f is endhomogeneous on X. Define $f^- : [X^-]^{r-1} \to \gamma$ by $f^-(V) = \eta$ iff $\forall u \in X| \succ V(f_V(u) = \eta)$ for $V \in [X^-]^{r-1}$.

The next lemma follows immediately from the definitions.

2.2 Lemma. *Using the above notation, if f is endhomogeneous on X, $Y \subseteq X^-$ and f^- is homogeneous on Y then f is homogeneous on Y and on $Y \cup \{m\}$ if m is the maximal element of X.*

We first give a direct proof of the well-known Ramsey's Theorem using non-principal ultrafilters and postponing the more natural *ramification* method to the next section for two reasons. First, Erdős and Rado considered this approach part of their "combinatorics" (Erdős called the ultrafilters "measures"). Second, having given a proof here, we do not have to adapt the formulation of the ramification to cover the case when the resource is a regular limit cardinal.

2.3 Theorem (Ramsey's Theorem).
$$\omega \to (\omega)^r_k \quad \textit{for } 1 \le r, k < \omega.$$

Proof. By induction on r. For $r = 1$ the claim is obvious. Assume $r > 1$ and $f : [\omega]^r \to k$. Let U be a non-principal ultrafilter on ω and $V \in [\omega]^{r-1}$. Define $\tilde{f}(V)$ and $A(V)$ as follows: let $\tilde{f}(V) = i$ for the unique $i < k$ for which the set $A(V, i) := \{u \in \omega - V : f_V(u) = i\}$ is in U, and set $A(V) := A(V, \tilde{f}(V))$.

We can choose by induction on n an increasing sequence $\langle x_n : n < \omega\rangle$ of integers satisfying $x_n \in \bigcap\{A(V) : V \in [\{x_j : j < n\}]^r\}$ for $n < \omega$. Let $X = \{x_n : n < \omega\}$. Then $f^-{\restriction}[X]^{r-1} = \tilde{f}{\restriction}[X]^{r-1}$ and f is endhomogeneous on X. By the induction hypothesis, there is a $Y \subseteq X$ with $\mathrm{ot}(Y) = \omega$ so that Y is homogeneous for f^-. Finally, by Lemma 2.2, Y is the desired set homogeneous for f. $\dashv$

2.2. Ramification Arguments

2.4 Remark (A brief history). The first transfinite generalization of Ramsey's theorem appeared in the paper [9] of Dushnik and Miller. They proved $\kappa \to (\kappa, \omega)^2$ for regular κ and Erdős proved this for singular κ as well. His proof was included in [9]. This theorem, unique of its kind, logically belongs to Sect. 7 where we will discuss it briefly.

The basic theorems about partition relations with exponent $r = 2$ were first stated and proved in 1942 in an almost forgotten paper of Erdős [10]. There he proved $(2^\kappa)^+ \to (\kappa^+)^2_\kappa$ for $\kappa \geq \omega$; he indicated the counterexamples $2^\kappa \not\to (3)^2_\kappa$ and $2^\kappa \not\to (\kappa^+)^2_2$; and he proved $\omega_2 \to (\omega_2, \omega_1)^2$ assuming CH. The Erdős-Rado Theorem for exponent larger than 2 was proved later in [17]. (See Corollary 2.10.) Kurepa also worked on related questions quite early (see the discussion by Todorcevic in Section C of [37]).

Few theorems have been provided with as many simplified proofs as the Erdős-Rado Theorem $(2^\kappa)^+ \to (\kappa^+)^2_\kappa$. Erdős and Rado used the so called "ramification method". We will present this method in the proof of the next theorem. After some "streamlining," it still seems to be the simplest way for obtaining *balanced* partition relations for cardinals, ones in which all the goals are the same cardinal. For the *unbalanced* case, we will present a method worked out in [4]. This method will be used in the proofs of a number of more recent results which will be presented in later sections. Given limitations of time and energy, and a desire for coherence, we decided to focus on results amenable to this method.

2.5 Theorem. *Assume* $2 \leq r < \omega$, $\kappa \geq \omega$, $\gamma < \kappa$, $\lambda = 2^{<\kappa}$ *and*

$$f : [\lambda^+]^r \to \gamma.$$

Then there exists an $X \subseteq \lambda^+$ *with* $\mathrm{ot}(X) = \kappa + 1$ *such that* f *is endhomogeneous*

Proof. For $\alpha < \lambda^+$, define an increasing sequence $\overline{\beta}^\alpha = \langle \beta^\alpha_\eta : \eta < \varphi_\alpha \rangle$ of ordinals less then α and an ordinal φ_α by transfinite recursion on η. For $\alpha = 0$, set $\varphi_0 = 0$ and let $\overline{\beta}^0$ be the empty sequence. For positive α, to start the recursion, let $\beta^\alpha_q := q$ for $q < \max(\{\alpha, r-1\})$, and for $\alpha < r - 1$, let $\varphi_\alpha = \alpha$. To continue the recursion, assume $r - 2 < \eta$ and β^α_ζ is defined for $\zeta < \eta$. Let $\hat{\beta}^\alpha_\eta = \sup(\{\beta^\alpha_\zeta + 1 : \zeta < \eta\})$, and define sets

$$\begin{aligned} B^\alpha_\eta &:= \{\beta^\alpha_\zeta : \zeta < \eta\}, \\ A^\alpha_\eta &:= \{\beta < \alpha : \hat{\beta}^\alpha_\eta \leq \beta \wedge (\forall V \in [B^\alpha_\eta]^{r-1})(f_V(\beta) = f_V(\alpha))\}. \end{aligned}$$

Let $\beta^\alpha_\eta := \min(A^\alpha_\eta)$ if $A^\alpha_\eta \neq \emptyset$. If $A^\alpha_\eta = \emptyset$, put $\varphi_\alpha = \eta$. Clearly for each $\alpha < \lambda^+$, the set $B^\alpha_{\varphi_\alpha} \cup \{\alpha\}$ is an endhomogeneous set of order type $\varphi_\alpha + 1$, and we may define f^-_α on $[B^\alpha_{\varphi_\alpha}]^{r-1}$ as in Definition 2.1. If $\beta \in B^\alpha_{\varphi_\alpha}$, then it is easy to show by induction on $\eta < \varphi_\beta$ that $\beta^\beta_\eta = \beta^\alpha_\eta$. Thus if $\beta \in B^\alpha_{\varphi_\alpha}$, then f^-_α agrees with f^-_β on $[B^\beta_{\varphi_\beta}]^{r-1}$.

Define a relation $\prec$ on λ^+ by $\beta \prec \alpha$ iff $\beta \in B^\alpha_{\varphi_\alpha}$. It is easy to verify that $T := \langle \lambda^+, \prec \rangle$ is a tree on λ^+ and $\operatorname{rank}_T(\alpha) = \varphi_\alpha$ for $\alpha < \lambda^+$. T is called the *canonical partition tree* of f on λ^+, and T_φ, as usual, denotes the $\{\alpha < \lambda^+ : \operatorname{rank}_T(\alpha) = \varphi\}$.

For $\alpha < \lambda^+$, let $C_\alpha : [\varphi_\alpha]^{r-1} \to \gamma$ be defined by $C_\alpha(U) = f^-_\alpha(V)$ where $V = \{\beta^\alpha_\zeta : \zeta \in U\}$. It follows by transfinite induction on φ that for $\alpha, \beta \in T_\varphi$, if $C_\alpha = C_\beta$, then $\alpha = \beta$. Hence $|T_\varphi| \le |\gamma|^{|\varphi|} \le \lambda$ for $\varphi < \kappa$. Then $|\bigcup_{\varphi<\kappa} T_\varphi| \le \lambda$, $T_\kappa \ne \emptyset$ and for all $\alpha \in T_\kappa$, $B^\alpha_\kappa \cup \{\alpha\}$ is a set of order type $\kappa + 1$ which is endhomogeneous for f. ⊣

2.6 Remark. Note that $(2^{<\kappa})^{<\kappa} = 2^{<\kappa}$ can hold for singular κ. Indeed it is easy to see that either $(2^{<\kappa})^{<\kappa} = 2^{<\kappa}$ or $\operatorname{cf}((2^{<\kappa})^{<\kappa}) = \operatorname{cf}(\kappa)$ and $2^{<\kappa} = \sup(\{(2^\tau)^+ : \tau < \kappa\})$. The proof described above gives Theorem 2.5 under the condition $\gamma \le \lambda$ provided $\lambda^{<\kappa} = \lambda$.

2.7 Theorem (The Stepping Up Lemma). *Assume $\kappa \ge \omega$, $1 \le r < \omega$, $\gamma < \kappa$ and $\kappa \to (\alpha_\xi)^r_\gamma$. Then*

$$(2^{<\kappa})^+ \to (\alpha_\xi + 1)^{r+1}_\gamma.$$

This is an immediate consequence of Lemma 2.2 and Theorem 2.5.

2.8 Definition. Define $\exp_i(\kappa)$ by recursion on $i < \omega$:

$$\exp_0(\kappa) = \kappa,$$
$$\exp_{i+1}(\kappa) = 2^{\exp_i(\kappa)}.$$

2.9 Theorem (The Erdős-Rado Theorem). *Assume $\kappa \ge \omega$, $\gamma < \operatorname{cf}(\kappa)$. Then for all $2 \le r < \omega$,*

$$\exp_{r-2}(2^{<\kappa})^+ \to (\kappa + (r-1))^r_\gamma.$$

Proof. Starting from the trivial relation $\kappa \to (\kappa)^1_\gamma$ for $\gamma < \operatorname{cf}(\kappa)$, we get $(2^{<\kappa})^+ \to (\kappa+1)^2_\gamma$, by Theorem 2.7. This is the case $r = 2$ of the theorem. The result follows by induction on r with repeated applications of Theorem 2.7. ⊣

A better known but weaker form of the theorem is the following.

2.10 Corollary. *Assume $\kappa \ge \omega$. Then for all $1 \le r < \omega$,*

$$\exp_{r-1}(\kappa)^+ \to (\kappa^+ + (r-1))^r_\kappa.$$

Note that while Theorem 2.9 guarantees for example that $\kappa^+ \to (\kappa+1)^2_\gamma$ holds for $\gamma < \operatorname{cf}(\kappa)$ for a singular strong limit cardinal κ, Corollary 2.10 does not say anything about this case.

2.3. Negative Stepping Up Lemma

2.11 Theorem (The Negative Stepping Up Lemma). *Assume $\kappa > 0$ is a cardinal, $2 \leq r < \omega$, $1 \leq \gamma$ and $\kappa \nrightarrow (\lambda_\xi)^r_\gamma$, where each $\lambda_\xi > 0$ is a cardinal. Then $2^\kappa \nrightarrow (1+\lambda_\xi)^{r+1}_\gamma$, provided at least one of the following conditions hold:*

1. *$\gamma \geq 2$, $\kappa, \lambda_0, \lambda_1 \geq \omega$ and λ_0 is a regular cardinal;*
2. *$\gamma \geq 2$, $\kappa, \lambda_0 \geq \omega$, λ_0 is a regular cardinal, and $r \geq 4$;*
3. *$\gamma \geq 2$, $\kappa, \lambda_0, \lambda_1 \geq \omega$, and $r \geq 4$;*
4. *$\kappa \geq \omega$ and $\lambda_\xi < \omega$ for all $\xi < \gamma$.*

For a proof, we refer the reader to the compendium by Erdős, Hajnal, Máté and Rado [19], which includes additional negative stepping up results. We do quote one related open problem from that reference.

2.12 Question (Problem 25.8 in [19]). Assume GCH. Does

$$\aleph_{\omega_{\omega+1}+1} \nrightarrow (\aleph_{\omega_{\omega+1}+1}, (4)_\omega)^3?$$

The following theorem provides a context for this question.

2.13 Theorem. *Assume* GCH*. Then*

1. *$\aleph_{\omega+1} \nrightarrow (\aleph_{\omega+1}, (3)_\omega)^2$; and*
2. *$\aleph_{\omega_{\omega+1}} \nrightarrow (\aleph_{\omega_{\omega+1}}, (3)_\omega)^2$.*

3. Partition Relations and Submodels

For the rest of this paper we will adopt the following conventions. Whenever we write "$H(\tau)$", τ will be a regular cardinal, and "$H(\tau)$" will stand for a structure $\mathfrak{A}$ with domain the collection of sets $H(\tau)$ which are of hereditary cardinality $< \tau$. The structure $\mathfrak{A}$ will be an expansion of $\langle H(\tau), \in, \triangle\rangle$, where $\triangle$ is a fixed well-ordering of $H(\tau)$. The expansion will depend on context, and will usually include all of the relevant "data" for the proof at hand. Note that the well-ordering $\triangle$ yields well-defined Skolem hulls for all sets $X \subseteq H(\tau)$.

3.1 Definition. Assume $\kappa \geq \omega$, $2^{<\kappa} = \lambda$. Let $H := H(\lambda^{++})$. A set N is said to be *suitable for* κ if it satisfies the following conditions: $\langle N, \in\rangle \prec H$, $|N| = \lambda$, $[N]^{<\mathrm{cf}(\kappa)} \subseteq N$, $[N]^{<\kappa} \subseteq N$ if $\lambda^{<\kappa} = \lambda$, $\lambda+1 \subseteq N$, $\alpha := N \cap \lambda^+ \in \lambda^+$, $\mathrm{cf}(\alpha) = \mathrm{cf}(\kappa)$. The ordinal $\alpha(N) = \alpha$ will be called the *critical ordinal of* N. Note that $\alpha \subseteq N$ by assumption.

We assume that the reader is familiar with the theory of stationary subsets of an ordinal. To make our terminology definite, for a limit ordinal α, a subset $B \subseteq \alpha$ is a *club* if B is cofinal (unbounded) and closed in the order topology of α. A set $S \subseteq \alpha$ is *stationary* if $B \cap S \neq \emptyset$ for every club subset of α. The notation $\mathrm{Stat}(\alpha)$ will denote the set of stationary subsets of α.

We will make use of the following facts about elementary submodels.

3.2 Facts. Let $\lambda = 2^{<\kappa}$. For every set A with $|A| \leq \lambda$ and $A \in H(\lambda^{++})$, there is an elementary chain $\langle N_0, \in\rangle \prec \cdots \prec \langle N_\alpha, \in\rangle \prec \cdots \prec H$, with $A \subseteq N_0$, indexed by $\alpha < \lambda^+$ that is continuous, and internally approachable (i.e. $N_\beta \in N_{\alpha+1}$ for all $\beta \leq \alpha$), and the set

$$S_0 = \{\alpha < \lambda^+ : \alpha(N_\alpha) = \alpha \text{ and } N_\alpha \text{ is suitable for } \kappa\}$$

the intersection of a club in λ^+ with $S_{\mathrm{cf}(\kappa),\lambda^+} = \{\alpha < \lambda^+ : \mathrm{cf}(\alpha) = \mathrm{cf}(\kappa)\}$.

3.3 Definition. A subset $S \subseteq H(\lambda^{++})$ is *amenable* for this sequence if $S \cap \alpha \in N_{\alpha+1}$ for $\alpha \in S_0$. A function g is *amenable* if $g \restriction \alpha \in N_{\alpha+1}$ for all $\alpha \in S_0$.

Note that S_0 itself may be assumed to be amenable.

In this section we will only use the existence of one N suitable for κ. The ideals defined below were introduced in [4] for regular κ. In most of the later applications we will only consider the regular case.

3.4 Definition. Let N be suitable for $\kappa \geq \omega$, $\lambda = 2^{<\kappa}$, $\alpha(N) = \alpha$. We define a set $I = I_\alpha = I(N) \subseteq \mathcal{P}(\alpha)$ as follows. For $X \subseteq \alpha$,

$$X \in I \quad \Longleftrightarrow \quad (\exists Y)(Y \subseteq \lambda^+ \wedge Y \in N \wedge \alpha \notin Y \wedge |X - Y| < \kappa).$$

Note that for regular κ, the last clause can be replaced by $X \subseteq Y$.

3.5 Lemma. *Let N be suitable for $\kappa \geq \omega$, $\lambda = 2^{<\kappa}$, $\alpha(N) = \alpha$. We define a set $\mathcal{F} = \mathcal{F}_\alpha$ as follows:*

$$\mathcal{F}_\alpha := \{Z \in N : Z \subseteq \lambda^+ \wedge \alpha \in Z\}.$$

Then (i) *$X \notin I = I_\alpha$ if and only if $|X \cap Z| \geq \kappa$ for all $Z \in \mathcal{F}_\alpha$; and* (ii) *the elements Z of $\mathcal{F}_\alpha$ are stationary subsets of λ^+.*

Proof. (i) follows directly from Definition 3.4. To see that (ii) holds, we verify that $\alpha \in Z \subseteq \lambda^+$, $Z \in N$ imply that Z is stationary. Otherwise $Z \cap \beta = \emptyset$ for some club $B \in N$. Then $B \cap \alpha$ is cofinal in α, by elementarity and $\alpha \in B$ since B is closed. ⊣

3.6 Lemma. *If N is suitable for κ, then $I = I(N)$ is a $\mathrm{cf}(\kappa)$-complete proper ideal on $\alpha = \alpha(N)$. Moreover, if $\lambda^{<\kappa} = \lambda$, then I is κ-complete.*

Proof. The completeness clearly follows from $[N]^{<\mathrm{cf}(\kappa)} \subseteq N$ and $[N]^{<\kappa} \subseteq N$ respectively. To see that $\alpha \notin I$, let $Z \in N$ be a subset of λ^+ with $\alpha \in Z$. It is enough to show that $|Z \cap \alpha| = \lambda$. Since $Z \in N$, also $\sup(Z) \in N$. As $\alpha \in Z$ and $N \cap \lambda^+ = \alpha$, it follows that $\sup(Z) = \lambda^+$. Then *a fortiori* there is a one-to-one function $g : \lambda \to Z$. Hence there is a $g \in N$ like this. Using $\lambda + 1 \subseteq N$, we get that $\mathrm{ran}(g) \subseteq N \cap \lambda^+ = \alpha$. ⊣

In what follows we will often suppress details like those given above.

3.7 Definition. Assume N is suitable for κ, $\lambda = 2^{<\kappa}$ and $\alpha = \alpha(N)$. For $X \subseteq \alpha$, we say X *reflects the properties of* α if $X \cap Z \neq \emptyset$ for all $Z \in \mathcal{F}_\alpha$.

3.8 Lemma. *Assume N is suitable for κ, $\lambda = 2^{<\kappa}$ and $\alpha = \alpha(N)$. If $X \subseteq \alpha$ and $X \in I^+$, then X reflects the properties of α, so we call $I = I_\alpha$ the* non-reflecting ideal on α (induced by N).

Notation. Assume $f : [X]^2 \to \gamma$ is a function, $\eta < \gamma$ and $\alpha \in X$. For simplicity, we often write $f(\alpha, \beta)$ for $f(\{\alpha, \beta\})$, specifying which of the ordinals α, β is smaller, if necessary. Denote the set $\{\beta < \alpha : f(\alpha, \beta) = \eta\}$ by $f(\alpha; \eta)$.

3.9 Lemma (Connection Lemma). *Assume $\kappa \geq \omega$ and $\lambda = 2^{<\kappa}$. Further suppose that N is suitable for κ with $\alpha(N) = \alpha$, $f \in N$ is a 2-partition of λ^+ with $\gamma < \mathrm{cf}(\kappa)$ colors, and $X \subseteq f(\alpha; \eta) \cap \alpha$ for some $\eta < \gamma$ is such that $X \notin I = I(N)$. Then there is some $Y \subseteq X$ with $\mathrm{ot}(Y) = \mathrm{cf}(\kappa)$ so that $Y \cup \{\alpha\}$ is homogeneous for f in color η.*

Proof. Let Z be a subset of $X \cup \{\alpha\}$ maximal with respect to the following properties: $\alpha \in Z$ and Z is homogeneous for f in color η. If $|Z| \geq \mathrm{cf}(\kappa)$, then we are done. Assume by way of contradiction that $|Z| < \mathrm{cf}(\kappa)$. Then $\sup(Z \cap \alpha) < \alpha$ and $Z \cap \alpha \in N$. Let $A = \bigcap\{f(u; \eta) : u \in Z \cap \alpha\}$. Then $A \in N$ and $\alpha \in A$. Hence, by the reflection property, $A \cap (X - \sup(Z \cap \alpha)) \neq \emptyset$. If $y \in A \cap (X - \sup(Z \cap \alpha))$, then $\{y\} \cup Z$ is homogeneous for f in color η, contradicting the maximality of Z. ⊣

3.10 Theorem (Erdős-Rado Theorem (unbalanced form)). *Let κ be an infinite cardinal and $\gamma < \mathrm{cf}(\kappa)$. Then*

$$(2^{<\kappa})^+ \to ((2^{<\kappa})^+, (\mathrm{cf}(\kappa) + 1)_\gamma)^2.$$

Proof. Let $\lambda = 2^{<\kappa}$, and suppose $f : [\lambda^+]^2 \to \gamma$ is a 2-partition of λ^+ into γ colors. Use Facts 3.2 to choose N suitable for κ with $f \in N$. For notational simplicity, let $\alpha = \alpha(N)$ and $I = I(N)$. If $f(\alpha; \eta) \cap \alpha \notin I$ for some $1 \leq \eta < \gamma$, then we are done by Lemma 3.9. By Lemma 3.6, we may assume that $\alpha - f(\alpha; 0) \subseteq \bigcup\{f(\alpha; \eta) \cap \alpha : 1 \leq \eta < \gamma\} \in I$. By Definition 3.4, there is a set $Z \in N$ with $Z \subseteq \lambda^+$ and $\alpha \in Z$ for which $|Z - f(\alpha; 0)| < \kappa$. Define a set W in $H(\lambda^{++})$ as follows:

$$W := \{\beta \in Z : |Z - f(\beta; 0)| < \kappa\}.$$

Then $W \in N$ and $\alpha \in W$. Then by Lemma 3.5 we infer that $W \in \mathrm{Stat}(\lambda^+)$ and for $g(\delta) := \{\beta < \delta : f(\beta, \delta) \neq 0\}$, we have $|g(\delta)| < \kappa$ for all $\delta \in W$. By Fodor's Set Mapping Theorem [19], there is a stationary subset $S \subseteq W$ free for g (i.e. $\gamma \notin g(\delta)$ for all $\delta \neq \gamma \in S$), and S is homogeneous for f in color 0. $\dashv$

Note that with some abuse of notation we have proved the following stronger result.

3.11 Theorem. *Let $\kappa \geq \omega$, $\lambda = 2^{<\kappa}$ and suppose $\gamma < \mathrm{cf}(\kappa)$. Then*

$$\lambda^+ \to (\mathrm{Stat}(\lambda^+), (\mathrm{cf}(\kappa) + 1)_\gamma)^2.$$

This theorem should be compared with the case $r = 2$ of Theorem 2.9 and it should be observed that while for regular κ, the above theorem is a strengthening of Corollary 2.10, for singular κ the results are incomparable. It should also be noted that using Theorem 2.7, the above result can be stepped up to the following.

3.12 Corollary. *Assume $\kappa \geq \omega$ and $\gamma < \mathrm{cf}(\kappa)$. Then for all $1 \leq r < \omega$,*

$$\exp_{r-2}(2^{<\kappa})^+ \to ((2^{<\kappa})^+, (\kappa + (r-1))_\gamma)^r.$$

Finally it should be remarked that we did not try to state the strongest possible forms of the Erdős-Rado theorems. Clearly the methods give similar results in cases where the resource cardinal κ is a regular limit cardinal. For a detailed discussion we refer to [19].

4. Generalizations of the Erdős-Rado Theorem

4.1. Overview

In this section we focus on the problem of what positive relations of the form

$$(2^{<\kappa})^+ \to (\alpha_\xi)^2_\gamma$$

can be proved for regular κ and $\gamma < \kappa$ in ZFC. The case for singular κ will be almost entirely omitted because of limitations of space. Many problems remain unsolved, and the simplest of these will be stated at the end of this subsection. We start by discussing limitations, the first of which comes from the next theorem.

4.1 Theorem (Hajnal [25], Todorcevic). *If $2^\kappa = \kappa^+$, then*

$$\kappa^+ \not\to (\kappa^+, \kappa + 2)^2.$$

Proof Outline. We only sketch the proof given in [25], omitting Todorcevic's proof for singular κ, which has been circulated in unpublished notes. Let $\{A_\alpha : \alpha < \kappa^+\}$ be a well-ordering of $[\alpha]^\kappa$. Define a sequence of sets $B_\alpha \in [\kappa^+]^\kappa$ for $\alpha < \kappa^+$ by transfinite recursion on α, in such a way that the following two conditions are satisfied:

1. $|B_\alpha \cap B_\beta| < \kappa$ for all $\beta < \alpha$;
2. $B_\alpha \cap A_\beta \neq \emptyset$ for all $\beta < \alpha$ for which $|A_\beta - \bigcup\{B_\gamma : \gamma \in F\}| = \kappa$ for all $F \in [\alpha]^{<\kappa}$.

To complete the proof, for $\beta < \alpha < \kappa^+$, set $f(\beta, \alpha) = 1$ if and only if $\beta \in B_\alpha$.

The constraint that $|B_\alpha \cap B_\beta| < \kappa$ for all $\beta < \alpha < \kappa^+$ implies that f has no homogeneous subsets of order type $\kappa + 2$ for color 1. The assertion that it has no homogeneous subsets of order type κ^+ for color 0 follows from the claim below.

4.2 Claim. *Assume A is a subset of size κ^+. Then there is a subset B of A of size κ which is not almost contained in the union of fewer than κ many B_β's.*

On the one hand, if fewer than κ many B_β's meet A in a set of size κ, then any subset $B \subseteq A$ of size κ in the complement of the union of these B_α's proves the claim. Otherwise, choose a sequence $B_\beta(\eta)$ indexed by $\eta < \kappa$ of κ many sets whose intersection with A has cardinality κ, and let B be the union of the intersections $A \cap B_\beta(\eta)$. $\dashv$

Henceforth we will assume that the goals, α_ξ, are all ordinals, $\alpha_\xi < \kappa^+$ for $\xi < \gamma$.

For $\kappa = \omega$, the best possible result, $\omega_1 \to (\alpha)^2_k$ for all $\alpha < \omega_1$ and k finite was conjectured by Erdős and Rado [15] in 1952 and proved by James Baumgartner and Hajnal [2] in 1971, already in a more general form. Using a self-explanatory extension of the ordinary partition relation for linear order types, it says

$$\Theta \to (\omega)^1_\omega \quad \text{implies} \quad \Theta \to (\alpha)^2_k \quad \text{for all } \alpha < \omega_1,\ k < \omega.$$

Soon after it was generalized (also in a self-explanatory way) by Todorcevic to partial orders [63]. Schipperus [52] proved a topological version. The Baumgartner-Hajnal proof used "Martin's Axiom + absoluteness". An elementary proof not using this kind of argument was given by Fred Galvin [21] in 1975. We will treat this theorem later in Sect. 4.5, where we will also give a brief history of earlier work on this conjecture, because some of these approaches served as starting points for other investigations.

We will treat first the case $\kappa = \mathrm{cf}(\kappa) > \omega$. The reason for this strange order is really technical. The results to be presented for the case $\kappa > \omega$ were proved later and much of the method of using elementary substructures was worked out while proving them. We will give a new proof of the

Baumgartner-Hajnal Theorem which can be extended to successors of measurable cardinals and uses the methods developed for the treatment of the cases $\kappa > \omega$.

For the cases $\kappa > \omega$, there are further limitations.

4.3 Theorem. *Assume that $\kappa = \tau^+ \geq \omega_1$ and* GCH *holds. Then there are κ-complete, κ^+-c.c. forcing conditions showing the consistency of the following negative partition relations:*

$$\kappa^+ \not\to (\kappa : \tau)^2_2 \quad \textit{and} \quad \kappa^+ \not\to (\kappa : 2)^2_\tau.$$

Here the relations mean that there are no homogeneous sets of the form $[A, B] := \{\{\alpha, \beta\} : \alpha \in A \wedge \beta \in B\}$ where $A < B$, $\mathrm{ot}(A) = \kappa$, and $\mathrm{ot}(B) = \tau$ or $\mathrm{ot}(B) = 2$ respectively. The forcing results are due to Hajnal and stated in [13]. The first result, $\kappa^+ \not\to (\kappa : \tau)^2_2$, was shown by Rebholz [50] to be true in L. It is interesting to remark that while the proofs of Theorem 4.1 really give $\kappa^+ \nrightarrow (\kappa^+, (\kappa : 2))^2$ in the relevant cases, these two statements are really not equivalent. In [35], Komjáth proves it consistent with ZFC that $\omega_1 \nrightarrow (\omega_1, \omega + 2)^2$ and $\omega_1 \to (\omega_1, (\omega : 2))^2$ hold.

In view of the limitations above, the following result of Baumgartner, Hajnal and Todorcevic [4], which we prove in Sect. 4.3 (see Theorem 4.12), is the best possible balanced generalization of the Erdős-Rado Theorem for finitely many colors to ordinal goals: for all regular uncountable cardinals κ and finite γ, if $\rho < \kappa$ is an ordinal with $2^{|\rho|} < \kappa$, then

$$(2^{<\kappa})^+ \to (\kappa + \rho)^2_\gamma.$$

Note that for $\gamma = 2$, this result was proved much earlier by Shelah in Sect. 6 of [55].

As a generalization of the unbalanced form, we prove in Sect. 4.4 (see Theorem 4.18) that for all regular uncountable cardinals κ and all finite m, γ,

$$(2^{<\kappa})^+ \to (\kappa^{\omega+2} + 1, (\kappa + m)_\gamma)^2.$$

In this discussion we have restricted ourselves to 2-partitions, since the situation is different for larger tuples. For example, Albin Jones [27, 31] has shown that for all finite m, n, $\omega_1 \to (\omega + m, n)^3$, complementing the result of Erdős and Rado [17] who showed $\omega_1 \nrightarrow (\omega + 2, \omega)^3$. Eric Milner and Karel Prikry [43] proved that $\omega_1 \to (\omega + \omega + 1, 4)^3$.

We conclude this subsection with some open questions.

4.4 Question. For which $\alpha < \omega_1$ and which $n < \omega$ does the partition relation $\omega_1 \to (\alpha, n)^3$ hold?

4.5 Question. Are the following statements provable in ZFC + GCH?

1. $\omega_3 \to (\omega_2 + \omega, \omega_2 + \omega_1)^2$?
2. $\omega_3 \to (\omega_2 + 2)^2_\omega$?

Though there are additional limitations for $\gamma \geq \omega$, which we will discuss in Sect. 5, both theorems may actually generalize for infinite γ with $2^{|\gamma|} < \kappa$, but nothing like this is known with the exception of the following very recent result a proof of which will be given in Sect. 6.

4.6 Theorem (Shelah [59]). *$\lambda^+ \to (\kappa+\mu)^2_\mu$ for $\mu < \kappa = \mathrm{cf}(\kappa)$ and $\lambda = 2^{<\kappa}$, under the assumption that $\mu < \sigma \leq \kappa$ for some strongly compact cardinal σ.*

4.2. More Elementary Submodels

In this subsection we prove a generalization of Connection Lemma 3.9 for regular κ. Let $\lambda = 2^{<\kappa}$ and assume that $\langle\langle N_\alpha, \in\rangle : \alpha < \kappa^+\rangle$ is a sequence of submodels of $H := H(\lambda^{++})$ satisfying the requirements outlined in Facts 3.2, with $A = \{f\}$ where $f : [\lambda^+]^2 \to \gamma$ is a given 2-partition of λ^+ with γ colors. For notational convenience, we will let

$$S_0 := \{\alpha < \lambda^+ : \alpha \cap N_\alpha = \alpha \text{ and } N_\alpha \text{ is suitable for } \kappa\}.$$

For $\alpha \in S_0$, we will write I_α for the ideal $I(N_\alpha)$ of Definition 3.4.

4.7 Lemma (Set Mapping Lemma). *Assume that $S \subseteq S_0$ is stationary and $g : S \to \mathcal{P}(\lambda^+)$ is a set mapping so that $g(\alpha) \subseteq \alpha$ and $g(\alpha) \cap S \in I_\alpha$ for all $\alpha \in S$. Then there is a stationary set $S' \subseteq S$ which is free for g. That is, $g(\alpha) \cap S' = \emptyset$ for all $\alpha \in S'$. Moreover, if S and g are amenable, then so is S'.*

Proof. Since S is a set of limit ordinals, for each $\alpha \in S$, we can choose $\beta_\alpha < \alpha$ and $Y_\alpha \subseteq \lambda^+$ so that $\alpha \notin Y_\alpha \in N_{\beta_\alpha}$ and $g(\alpha) \subseteq Y_\alpha$. By Fodor's Theorem, first β_α and then Y_α stabilize on a stationary set. That is, for some stationary $S' \subseteq S$ and some $Y \subseteq \lambda^+$, we have $\alpha \notin Y$ and $g(\alpha) \subseteq Y$ for all $\alpha \in S'$. ⊣

4.8 Corollary. *Suppose $S \subseteq S_0$. An element $\alpha \in S$ is a* reflection point *of S if $S \cap \alpha \notin I_\alpha$. Then the set $S - \tilde{S}$ is non-stationary, where $\tilde{S}$ denotes the set of reflection points of S. Moreover, if S is amenable, then so is S'.*

Proof. Assume by way of contradiction that $S' := S - \tilde{S}$ is stationary, and define $g(\alpha) := S' \cap \alpha$ for $\alpha \in S'$. By the Set Mapping Lemma 4.7, there is a stationary subset $S'' \subseteq S'$ so that S'' is free for g. On the other hand, if $\beta < \alpha$ are both in $S'' \subseteq S'$, then $\beta \in g(\alpha) := S' \cap \alpha$, contradicting the freeness of S'' for g. ⊣

4.9 Definition. For $\alpha < \lambda^+$ and $\sigma \in {}^{<\omega}\gamma$, we define ideals $I(\alpha, \sigma)$ by recursion on $|\sigma|$. To start the recursion, we set

$$I(\alpha, \emptyset) := \begin{cases} \mathcal{P}(\alpha) & \text{if } \alpha \notin S_0, \quad \text{and} \\ I_\alpha & \text{if } \alpha \in S_0. \end{cases}$$

If $\sigma = \tau^\frown\langle i\rangle$ and $I(\alpha, \tau)$ has been defined, then for all $X \subseteq \alpha$,

$$X \in I(\alpha, \sigma) \quad \Longleftrightarrow \quad \{\beta < \alpha : X \cap \beta \cap f(\alpha; i) \notin I(\beta, \tau)\} \in I(\alpha, \emptyset).$$

4.10 Lemma. *Suppose $\alpha < \lambda^+$ and $\sigma \in {}^{<\omega}\gamma$.*

1. *$I(\alpha, \sigma)$ is a κ-complete ideal;*
2. *if $\alpha \notin S_0$, then $I(\alpha, \sigma) = \mathcal{P}(\alpha)$;*
3. *$I(\alpha, \emptyset) \subseteq I(\alpha, \sigma)$.*

Proof. In the special case of $\sigma = \emptyset$, (1) follows either from Lemma 3.6 or the triviality that $\mathcal{P}(\alpha)$ is κ-complete. Use recursion on $|\sigma|$ to complete the proof of (1), since at each successor stage, $I(\alpha, \tau^\frown\langle i\rangle)$ is gotten by averaging κ-complete ideals according to a κ-complete ideal.

Note that (2) follows immediately from the definition of $I(\alpha, \sigma)$.

(3) is also proved by induction on $|\sigma|$ simultaneously for all $\alpha < \lambda^+$. For $\alpha \notin S_0$, it follows from the second item, so assume $\alpha \in S_0$. It is trivial for $\sigma = \emptyset$, so assume it is true for $I(\alpha, \tau)$ where $\sigma = \tau^\frown\langle i\rangle$, and let $X \in I(\alpha, \emptyset) = I_\alpha = I(N_\alpha)$ be arbitrary. By definition of $I(N_\alpha)$, there is some $Y \subseteq \lambda^+$ so that $\alpha \notin Y \in N_\alpha$ and $X \subseteq Y$. Since α is limit, there is a $\beta_0 < \alpha$ with $Y \in N_{\beta_0}$. Since the sequence of submodels is continuous, $Y \in N_\beta$ for all β with $\beta_0 < \beta < \alpha$, and for $\beta \notin Y$, we either have $X \cap \beta \in I_\beta$ if $\beta \in S_0$ or have $X \cap \beta \in I(\beta, 0)$ otherwise. Hence by the induction hypothesis, $X \cap \beta \in I(\beta, \tau)$ for $\beta \notin Y$ with $\beta_0 < \beta < \alpha$. That is, if $\beta < \alpha$ and $X \cap \beta \notin I(\beta, \tau)$, then $\beta \in Y \cup (\beta_0 + 1)$. So $X \in I(\alpha, \sigma)$, since $\alpha \notin Y - (\beta_0 + 1) \in N_\alpha$. ⊣

We postpone the proof that some of these ideals are proper.

4.11 Lemma (Second Connection Lemma). *Suppose $X \subseteq \alpha$, $X \notin I(\alpha, \sigma)$ and suppose $i \in \mathrm{ran}(\sigma)$. Then there is a subset $Y \subseteq X \cup \{\alpha\}$ with $\mathrm{ot}(Y) = \kappa + 1$ homogeneous for f in color i.*

Proof. The proof is by induction on $|\sigma|$. If $\sigma = \emptyset$, then there is nothing to prove. Next suppose $\sigma = \tau^\frown\langle j\rangle$ for some $j < \gamma$. By Lemma 4.10, we know that $X \cap \beta \notin I(\beta, \tau)$ for some $\beta < \alpha$ with $\beta \in X$. Thus the induction hypothesis gives the statement for $i \in \mathrm{ran}(\tau)$. Next assume $i = j$. Then by Lemma 4.10(3), we know that $X \notin I_\alpha$ and Connection Lemma 3.9 yields the desired result. ⊣

4.3. The Balanced Generalization

In this subsection we will prove, as announced earlier, the following balanced generalization of the Erdős-Rado Theorem.

4.12 Theorem (Baumgartner, Hajnal, Todorcevic [4]). *Suppose κ is a regular uncountable cardinal, γ is finite and $\rho < \kappa$ is an ordinal with $2^{|\rho|} < \kappa$. Then*

$$(2^{<\kappa})^+ \to (\kappa + \rho)^2_\gamma.$$

For notational simplicity, we are fixing κ, $\lambda = 2^{<\kappa}$, a 2-partition $f : [\lambda^+]^2 \to \gamma$, and ρ as in the statement of the theorem throughout this subsection, and we continue the notation introduced in Sects. 4.1 and 4.2. In what follows, it will be convenient to look at the least indecomposable ordinal $\xi \geq \rho$, rather than ρ directly. In preparation for the proof, we give several preliminary facts about ideals.

4.13 Definition. For ordinals ξ, sets $x \subseteq \lambda^+$ and sequences $\sigma \in {}^{<\omega}\gamma$, define *$x$ is (ξ,σ)-canonical for f* by recursion on $|\sigma|$. To begin the recursion, we say *x is $(\xi,\emptyset)$-canonical for f* if $x = \{\alpha\}$ for some $\alpha < \lambda^+$. For $\sigma = \tau^\frown\langle i\rangle$, we say *$x$ is (ξ,σ)-canonical for f* if x is the union of a $<$-increasing sequence $\langle x_\eta : \eta < \xi\rangle$ so that each x_η is (ξ,τ)-canonical for $\eta < \xi$ and $f(u,v) = i$ for all $u \in x_\eta$ and $v \in x_\zeta$ with $\eta < \zeta < \xi$.

The following lemma is left to the reader as an exercise.

4.14 Lemma. *Assume that ξ is an indecomposable ordinal and $\sigma \in {}^{n}\gamma$ for some $n < \omega$. Then*

1. $\mathrm{ot}(x) = \xi^n$ *for all x which are (ξ,σ)-canonical for f;*
2. *if x is (ξ,σ)-canonical for f, then every $y \subseteq x$ with $\mathrm{ot}(y) = \xi^n$, is also (ξ,σ)-canonical for f and $J := \{z \subseteq y : \mathrm{ot}(z) < \xi^n\}$ is a proper ideal;*
3. *if x is (ξ,σ)-canonical for f, then for every $i \in \mathrm{ran}(\sigma)$, there is some $y \subseteq x$ with $\mathrm{ot}(y) = \xi$ which is homogeneous for f in color i.*

4.15 Lemma (Reflection Lemma). *Assume $X \notin I(\alpha,\sigma)$ for some $\alpha < \lambda^+$, $\sigma \in {}^{<\omega}\gamma$, and further suppose that $\xi < \kappa$ is indecomposable. Then there is a set $x \subseteq X$ which is (ξ,σ)-canonical for f.*

Proof. The proof is by induction on $|\sigma|$. To start, notice the lemma is vacuously true for $\sigma = \emptyset$. Next suppose $\sigma = \tau^\frown\langle i\rangle$. Construct a sequence $\langle x_\eta : \eta < \xi\rangle$ by recursion on $\eta < \xi$. Assume that $\zeta < \xi$ and that the sets $x_\eta \subseteq X \cap f(\alpha;i)$ are (ξ,τ)-canonical for f for $\eta < \zeta$. Let $Z = \{\beta < \lambda^+ : (\forall \eta < \zeta)(\forall \delta \in x_\eta)(f(\delta,\beta) = i)\}$. Since $\langle x_\eta : \eta < \xi\rangle \in N_\alpha$, we have $Z \in N_\alpha$ and $\alpha \in Z$. Since $\{\beta < \alpha : X \cap \beta \cap f(\alpha;i) \notin I(\beta,\tau)\} \notin I_\alpha$, we can choose $\beta < \alpha$ so that $\beta \in Z \in N_\beta$, $X \cap \beta \cap f(\alpha;i) \notin I(\beta,\tau)$ and $\sup(\bigcup\{x_\eta < \zeta\}) < \beta$. By the induction hypothesis, we can choose a set $x_\zeta \subseteq X \cap Z$ which is (ξ,τ)-canonical for f with $x_\eta < x_\zeta$ for all $\eta < \zeta$.

This recursion defines $\langle x_\zeta : \zeta < \xi\rangle$, and $x = \bigcup\{x_\zeta : \zeta < \xi\}$ is the required set (ξ,σ)-canonical for f. ⊣

We need one more lemma which will be used in the proof of the unbalanced version (Theorem 4.18) as well.

4.16 Lemma. *Assume $S \subseteq S_0$ is stationary and $\Gamma \subseteq \gamma$ is non-empty. Then there are $S' \subseteq S$ stationary and $\sigma \in {}^{<\omega}\Gamma$ with σ one-to-one such that*

1. *$S \cap \beta \cap f(\alpha; j) \in I(\beta, \sigma)$, for every $\beta, \alpha \in S'$ with $\beta < \alpha$ and every $j \in \Gamma - \mathrm{ran}(\sigma)$; but*

2. *$S \cap \alpha \notin I(\alpha, \sigma)$ for $\alpha \in S'$.*

Moreover, if S is amenable, then so is S'.

Proof. Let σ be of maximal length so that $\mathrm{ran}(\sigma) \subseteq \Gamma$, σ is one-to-one, and

$$S'' := \{\alpha \in S : S \cap \alpha \notin I(\alpha, \sigma)\} \quad \text{is stationary.}$$

For $j \in \Gamma - \mathrm{ran}(\sigma)$, let

$$g_j(\alpha) := \{\beta < \alpha : S \cap \beta \cap f(\alpha; j) \notin I(\beta, \sigma)\}.$$

By the maximality of σ, it follows that $g_j(\alpha) \cap S'' \in I_\alpha$ for all but non-stationarily many $\alpha \in S$. By Lemma 4.7, there is a stationary subset $S' \subseteq S''$ which is free for g_j. ⊣

Let $\mathbb{S} := \{\sigma \in {}^{<\omega}\gamma : \sigma \text{ is one-to-one}\}$.

For $\alpha < \lambda^+$ and $\sigma \in \mathbb{S}$, say (X, Y) *fits* (α, σ) if $X \subseteq \alpha$, $X \notin I(\alpha, \sigma)$ and $f(\beta; j) \cap X \in I(\alpha, \sigma)$ for all $\beta \in Y$ and $j \notin \mathrm{ran}(\sigma)$.

From Lemma 4.16 we get the following corollary by applying the lemma with $\Gamma = \gamma$.

4.17 Corollary. *For every stationary set $S \subseteq S_0$, there are $\sigma \in \mathbb{S}$, $\alpha \in S$ and a stationary subset $S' \subseteq S$ so that $(S \cap \alpha, S')$ fits (α, σ).*

With these lemmas in hand, we turn to the proof of the main theorem of this subsection.

Proof of Theorem 4.12. Using Corollary 4.17, we define $\alpha_m \in S_0$, $\sigma_m \in \mathbb{S}$, and stationary $Z_m \subseteq S_0$ by recursion on m so that the following conditions are satisfied:

1. $\alpha_0 < \cdots < \alpha_m < \cdots$; $Z_0 \supseteq \cdots \supseteq Z_m \supseteq \cdots$; and

2. $(Z_m \cap \alpha_m, Z_{m+1})$ fits (α_m, σ_m).

Since $\mathbb{S}$ is finite, $\sigma_k = \sigma_n$ for some $k < n < \omega$. We conclude that there are a sequence $\sigma \in \mathbb{S}$, ordinals $\beta_0 < \beta_1$, and sets X_0, X_1 such that the following statement is true:

> $X_0 < X_1$, $X_i \notin I(\beta_i, \sigma)$ for $i < 2$, and $f(\eta; j) \cap X_0 \in I(\beta_0, \sigma)$ for every $j \notin \mathrm{ran}(\sigma)$ and every $\eta \in X_1$.

Let ξ be the least indecomposable ordinal with $\rho \leq \xi$. By the Reflection Lemma 4.15, there is a $y \subseteq X_1$ such that y is (ξ, σ)-canonical for f.

We shrink X_0 to $X = X_0 - \bigcup\{f(\delta; j) : j \notin \mathrm{ran}(\sigma) \text{ and } \delta \in y\}$. Then $X \notin I(\beta_0, \sigma)$ since $I(\beta_0, \sigma)$ is κ-complete, $|y| < \kappa$ and $f(\delta; j) \in I(\beta_0, \sigma)$ for $j \notin \mathrm{ran}(\sigma)$, $\delta \in y \subseteq X_1$.

Let $J = \{Z \subseteq y : Z$ is not (ξ, σ)-canonical for $f\}$. By Lemma 4.14, J is a proper ideal on y.

For every $\delta \in X$, there is an $i(\delta) \in \operatorname{ran}(\sigma)$ so that $f(\delta; i) \cap y \notin J$. Thus for every $\delta \in X$, by Lemma 4.14(3), there is a $y(\delta) \subseteq y$ of order type ρ such that $\{\delta\} \cup y(\delta)$ is homogeneous for f in color $i(\delta)$.

Using the fact that $\omega^{|\rho|} = 2^{|\rho|} \cdot \omega < \kappa$, we now obtain $i_0 \in \operatorname{ran}(\sigma)$, $y' \subseteq y$ and $X' \subseteq X$ with $X' \notin I(\alpha, \sigma)$ so that $i(\delta) = i_0$ and $y(\delta) = y'$ for all $\delta \in X'$. Thus $f(\delta_0, \delta_1) = i_0$ for all $\delta_0 \in X'$ and $\delta_1 \in y'$.

By the Second Connection Lemma 4.11, we get an $X'' \subseteq X'$ of order type κ homogeneous for f in color i_0. Finally $X'' \cup y'$ is the required set of order type $\kappa + \rho$ homogeneous for f in color i_0. ⊣

4.4. The Unbalanced Generalization

4.18 Theorem (Baumgartner, Hajnal, Todorcevic [4]). *Suppose κ is a regular uncountable cardinal, and m, γ are finite. Then*

$$(2^{<\kappa})^+ \to (\kappa^{\omega+2} + 1, (\kappa + m)_\gamma)^2.$$

This subsection is devoted to the proof of this theorem, and for notational convenience we set $\lambda = 2^{<\kappa}$ throughout. Also, fix a partition $f : [\lambda^+]^2 \to 1 + \gamma$. We also continue to use the notation introduced in Sects. 4.1, 4.2 and 4.3.

The strategy of the proof is to derive Theorem 4.18 from the following auxiliary assumption:

$$Q(\kappa) \qquad 2^{<\kappa} = \kappa \quad \text{and} \quad \forall \langle f_\alpha : \alpha < \kappa^+ \rangle \subseteq {}^\kappa\kappa \ \exists g \in {}^\kappa\kappa \ (f_\alpha \prec g)$$

where $\prec$ is the relation of eventual domination on ${}^\kappa\kappa$ (i.e. $h_1 \prec h_2$ iff $h_1(\alpha) < h_2(\alpha)$ for all but less than κ many α).

Then as in the original proof of the Baumgartner-Hajnal Theorem [2], we observe that the assumption $Q(\kappa)$ is unnecessary, and therefore that Theorem 4.18 holds in ZFC.

Let us justify this observation before going on to prove the theorem from the assumption of $Q(\kappa)$.

Let P_0 be the natural κ-closed forcing for collapsing $2^{<\kappa}$ onto κ. Then in V^{P_0} we have $\lambda = \kappa$. Working in V^{P_0} and using a standard iterated forcing argument (as in [1]) we can force every sequence of functions in ${}^\kappa\kappa$ of length κ to be eventually dominated via a partial ordering P_1 that is κ-closed and has the λ^+-chain condition. Let $P = P_0 * P_1$. Then P is κ-closed and in V^P, both $\lambda = \kappa$ and $Q(\kappa)$ hold. Note that in V^P, we will have $2^\kappa > \kappa^+$, since this inequality is implied by $Q(\kappa)$.

Assuming we have proved Theorem 4.18 under the assumption of $Q(\kappa)$, we may assume it holds in V^P. Suppose that $f : [\lambda^+]^2 \to \gamma + 1$ is a 2-partition in V. Then in V^P, there is some $A \subseteq \lambda^+$ such that either (a) A is homogeneous for f in color 0 and $\operatorname{ot}(A) = \kappa^{\omega+2} + 1$, or (b) A is homogeneous for f in color $i > 0$ and $\operatorname{ot}(A) = \kappa + m$. Suppose (a) holds. Note that $\kappa^{\omega+2}+1$ is the same whether computed in V or in V^P. Let $h : \kappa \to \kappa^{\omega+2} + 1$ be a bijection with $h \in V$. In V^P, fix an order-isomorphism $j : \kappa^{\omega+2} + 1 \to A$. Now, working in V, find a decreasing sequence $\langle p_\xi : \xi < \kappa\rangle$ of elements of P and a sequence $\langle \alpha_\xi : \xi < \kappa\rangle$ of elements of λ^+ such that for all ξ, $p_\xi \Vdash j(h(\xi)) = \alpha_\xi$. This is easy to do by recursion on ξ, using the fact that P is κ-closed. But now it is clear that $\{\alpha_\xi : \xi < \kappa\} \in V$ has order type $\kappa^{\omega+2}+1$ and is homogeneous for f in color 0. Case (b) may be handled the same way.

For the rest of this subsection, assume $Q(\kappa)$ holds. We may also assume that $\kappa > \omega$ since for $\kappa = \omega$ we have the much stronger result Theorem 4.30.

First we prove a consequence of $Q(\kappa)$.

4.19 Lemma. *Assume $Q(\kappa)$. For all positive $\ell < \omega$ and every sequence $\langle X_\alpha : \alpha < \kappa^+\rangle$ of subsets of κ^ℓ of order type $< \kappa^\ell$, there is a sequence $\langle Z_\nu : \nu < \kappa\rangle$ of subsets of κ^ℓ of order type $< \kappa^\ell$ such that every X_α is a subset of some Z_ν.*

Proof. Use induction on ℓ. For $\ell = 1$, the sets $X_\alpha \subseteq \kappa^1 = \kappa$ are bounded and we may define $Z_\nu := \nu$.

For the induction step, assume $\langle X_\alpha : \alpha < \kappa^+\rangle$ is a given sequence of subsets of κ^{k+1} of order type $< \kappa^{k+1}$. Write $\kappa^{k+1} = \bigcup_{\nu<\rho} U_\rho$ as the union of an increasing sequence $U_0 < \cdots < U_\rho < \cdots$ in which $\operatorname{ot}(U_\rho) = \kappa^k$. For each $\alpha < \kappa^+$ and $\rho < \kappa$, define

$$Y_{\alpha,\rho} := \begin{cases} X_\alpha \cap U_\rho, & \text{if } \operatorname{ot}(X_\alpha \cap U_\rho) < \kappa^k,\\ \emptyset, & \text{otherwise.}\end{cases}$$

Since each U_ρ is isomorphic to κ^k, we may apply the induction hypothesis to each sequence $\langle Y_{\alpha,\rho} : \alpha < \kappa^+\rangle$ to get $\langle W_{\mu,\rho} : \mu < \kappa\rangle$, so that every $Y_{\alpha,\rho}$ is a subset of some $W_{\mu,\rho}$ and each $W_{\mu,\rho}$ is a subset of U_ρ of order type less than κ^k.

For each $\alpha < \kappa^+$, define $g_\alpha : \kappa \to \kappa$ by $g_\alpha(\rho)$ is the least μ so that $Y_{\alpha,\rho} \subseteq W_{\mu,\rho}$. Choose an increasing $g : \kappa \to \kappa$ eventually dominating all the g_α for $\alpha < \kappa$. Define

$$Z_\nu := \bigcup\nolimits_{\mu<\nu} \cup \bigcup\{W_{\mu,\rho} : \rho \geq \nu \wedge \mu \leq g(\rho)\}.$$

Then $\langle Z_\nu : \nu < \kappa\rangle$ satisfies the requirements of the lemma for $\ell = k + 1$.

Therefore by induction, the lemma follows. $\dashv$

From this point forward in the subsection, we assume that there is no homogeneous set for color 0 of the order type required. We may also assume that the result is true for $\gamma' < \gamma$.

4.20 Lemma. *Assume $S \subseteq S_0$ is stationary. For all $\Sigma \subseteq [1, \gamma]$ with $\Sigma \neq \emptyset$, there are a stationary set $S' \subseteq S$ and a one-to-one function $\sigma \in {}^{<\omega}\Sigma$ such that the following two properties hold:*

1. *for every stationary* $S'' \subseteq S'$ *there is some* $\alpha \in S''$ *with* $S'' \cap \alpha \notin I(\alpha, \sigma)$*;*
2. *for all* $j \in \Sigma - \operatorname{ran}(\sigma)$ *and all* $\beta, \alpha \in S'$*, if* $\beta < \alpha$*, then* $f(\alpha; j) \cap \beta \cap S' \in I(\beta, \sigma)$*.*

Proof. By induction on $|\Sigma|$. For the basis case of $|\Sigma| = 1$, suppose $\Sigma = \{i\}$ for some positive $i \leq \gamma$. Then either $\operatorname{ran}(\sigma) = \{i\}$, the first property holds with $S' = S$ and the second holds vacuously, or by the Set Mapping Lemma 4.7, there is a stationary subset $S' \subseteq S$ free for color i.

For the induction step, assume the lemma is true for some non-empty proper subset $T \subseteq [1, \gamma]$ and let $i \in [1, \gamma] - T$. We must show the statement is also true for $\Sigma = T \cup \{i\}$. Let $S_T \subseteq S$ and τ witness that the lemma is true for T. Consider two cases depending on whether or not the following statement is true, where $\operatorname{Stat}(S_T) := \operatorname{Stat}(\lambda^+) \cap \mathcal{P}(S_T)$:

$$(*) \qquad \forall S^* \in \operatorname{Stat}(S_T)\ \exists \alpha \in S^*(\{\beta < \alpha : S^* \cap \beta \cap f(\alpha; i) \notin I(\beta, \tau)\} \notin I_\alpha).$$

For the first case, assume that $(*)$ holds. Then we can choose $S_\Sigma = S_T$ and $\sigma = \tau^\frown\langle i \rangle$, since the first item holds by $(*)$ and the second remains true since no new j comes into play.

For the second case, assume that $(*)$ fails and choose a stationary $S^* \subseteq S_T$ showing the failure. Define

$$g(\alpha) := \{\beta < \alpha : S^* \cap \beta \cap f(\alpha; i) \notin I(\beta, \tau)\}.$$

Applying the Set Mapping Lemma 4.7 to g and S^*, we get a stationary $S_\Sigma \subseteq S^*$ free for g which together with $\sigma = \tau$ satisfy the required two conditions. ⊣

Our next lemma uses the fact that by $Q(\kappa)$, we have $2^{<\kappa} = \kappa$. For notational convenience, for each $\alpha \in S_0$, define

$$\mathcal{F}_\alpha := \{Z \in N_\alpha : Z \subseteq \kappa^+ \wedge \alpha \in Z\}.$$

Also, for any $0 < \ell \leq \gamma$ and any one-to-one function $\sigma \in {}^{\ell-1}[1, \gamma]$, call a set Y (α, σ)-*slim* if $Y \subseteq S_0$, $\operatorname{ot}(Y) = \kappa^\ell$, $Y \notin I(\alpha, \sigma)$, and for all $W \subseteq Y$, the equivalence $W \notin I(\alpha, \sigma)$ if and only if $\operatorname{ot}(W) = \kappa^\ell$ holds.

4.21 Lemma. *For all one-to-one functions* $\sigma \in {}^{<\omega}[1, \gamma]$*, for all* $X \subseteq S_0$ *with* $X \notin I(\alpha, \sigma)$*, if* $\ell - 1$ *is the length of* σ*, then there exists* $Y \subseteq X$ *such that* Y *is* (α, σ)*-slim.*

Proof. To start the induction, note that if $X \notin I(\alpha, \emptyset) = I_\alpha$ for some $\alpha \in S_0$, then there is some $Y \subseteq X$ with $\operatorname{ot}(Y) = \kappa$ so that $Y \notin I_\alpha$. This implication is true because $\mathcal{F}_\alpha$ has cardinality at most κ and can be diagonalized in X. Then Y is $(\alpha, \emptyset)$-slim, by the κ-completeness of I_α. The rest follows by induction on the length of σ. ⊣

The following corollary is immediate from the previous two lemmas.

4.22 Corollary. *There are a stationary set $S_1 \subseteq S_0$, a nonempty subset $\Sigma \subseteq [1,\gamma]$ and a one-to-one function $\sigma \in {}^{\ell-1}\Sigma$ such that the following two conditions hold:*

1. *for all stationary $S \subseteq S_1$, there are $\alpha \in S$ and $X \subseteq \alpha$ of order type κ^ℓ so that $X \notin I(\alpha,\sigma)$;*
2. *for all $\beta < \alpha \in S_1$ and all $j \in [1,\gamma] - \Sigma$, one has $f(\alpha; j) \cap \beta \in I(\beta,\sigma)$.*

For notational convenience, write $X = \Sigma_{\nu<\kappa} X_\nu$ to indicate that $X_0 < \cdots < X_\nu < \cdots$ and $X = \bigcup_{\nu<\kappa} X_\nu$. For the remainder of this section, let $S_1 \subseteq S_0$, σ and ℓ as in the previous corollary be fixed.

4.23 Definition. For $\alpha \in S_0$, define $\mathcal{H}(\alpha,n)$ by recursion on $n < \omega$. To start the recursion, define

$$\mathcal{H}(\alpha,0) := \{X \subseteq S_1 : X \text{ is } (\alpha,\sigma)\text{-slim}\}.$$

If $\mathcal{H}(\alpha,n)$ has been defined, then $X \in \mathcal{H}(\alpha,n+1)$ if and only if the following conditions are satisfied:

1. $X \subseteq S_1$ and there exists $\langle X_\nu \in \mathcal{H}(\alpha,n) : \nu < \kappa\rangle$ with $X = \Sigma_{\nu<\kappa} X_\nu$;
2. for all $F \in \mathcal{F}_\alpha$, there exists ν_F so that $X_\nu \subseteq F$ for all $\nu > \nu_F$;
3. for all $\nu < \nu' < \kappa$ and $x \in X_\nu$, $y \in X_{\nu'}$, one has $f(x,y) = 0$.

Note that every $X \in \mathcal{H}(\alpha,n)$ has $\mathrm{ot}(X) = \kappa^{\ell+n}$ and X contains a subset of order κ^n homogeneous for f in color 0. Furthermore, every $Y \subseteq X$ of order type $\kappa^{\ell+n}$ has a subset in $\mathcal{H}(\alpha,n)$.

We now prove the lemma containing the main idea of the proof.

4.24 Lemma (Key Lemma). *Suppose $\alpha \in S_1$, $n < \omega$ and $X \subseteq S_1$ with $X \in \mathcal{H}(\alpha,n)$. Then there are $\beta_0 \in S_1$ with $\beta_0 > \alpha$ and $\langle T_\nu \subseteq X : \nu < \kappa\rangle$ with* $\mathrm{ot}(T_\nu) = \kappa^{\ell+n}$ *so that for all $\beta \in S_1$ with $\beta > \beta_0$, there is some $\nu < \kappa$ such that* $\mathrm{ot}(T_\nu - f(\beta;0)) < \kappa^{\ell+n}$.

Proof. Let M be a maximal subset of S_1 with the property that for all $V \in [M]^{<\omega}$, $\mathrm{ot}(\bigcap\{X - f(\beta;0) : \beta \in V\}) = \kappa^{\ell+n}$. We claim that $|M| \leq \kappa$ and then we are done, by the maximality of M.

Assume for the sake of a contradiction that $|M| = \kappa^+$, and let

$$\Pi := \left\{\bigcap_{\beta\in V} X - f(\beta;0) : V \in [M]^{<\omega}\right\}.$$

Extend $\Pi \cup \{X - Y : Y \subseteq X \wedge \mathrm{ot}(X) < \kappa^{\ell+n}\}$ to an ultrafilter U on X. Then for every $\beta \in M$, there is a $j(\beta) \in \Sigma$ so that $X \cap f(\beta; j(\beta)) \in U$. Hence there is some $j \in \Sigma$ so that the set $M_j := \{\beta \in M : j(\beta) = j\}$ has cardinality κ^+. By $\kappa^+ \to (\kappa^+, n)^2$, there is a set $H \subseteq M_j$ of size n which is homogeneous for f in color j. Now $X \cap \bigcap\{f(\beta; j) : \beta \in H\}$ is in U, so it must have order type $\kappa^{\ell+n}$. By Lemma 4.11 it contains a set W of type κ homogeneous for f in color j. This is the contradiction that proves the lemma. $\dashv$

4.25 Lemma. *Assume $S \subseteq S_1$ is stationary. Then for all $n < \omega$, there are $\alpha \in S$ and $X \subseteq S$ so that $X \in \mathcal{H}(\alpha, n)$.*

Proof. Work by induction on n. For the basis case, $n = 0$, the statement follows from Corollary 4.22 and Lemma 4.21.

For the induction step, a standard ramification argument gives the result. Assume the claim is true for some n. Let $\alpha \in S$ be arbitrary. We define a sequence

$$\{X_\xi : \xi < \kappa\} \subseteq \mathcal{H}(\alpha_\xi, n)$$

by recursion on $\xi < \kappa$. Assume that $X_\eta \in \mathcal{H}(\alpha_\eta, n)$, $X_\eta \subseteq S \cap f(\alpha; 0)$ are defined for $\eta < \xi$. Let $S_\xi = \{\beta \in S : \bigcup\{X_\eta : \eta < \xi\} \subseteq f(\beta; 0)\}$. Then $\alpha \in S_\xi$ and $S_\xi \in N_\alpha$. Then S_ξ is stationary, and so by the induction hypothesis it contains a subset $X \in \mathcal{H}(\alpha_\xi, n)$ for some $\alpha_\xi \in \alpha \cap S_\xi$. By elementarity, we may assume $X \in N_\alpha$. By the Key Lemma, there are $T_\nu \subseteq X$ for $\nu < \kappa$ such that $\mathrm{ot}(T_\nu) = \kappa^{\ell+n}$ and $|S - \bigcup_{\nu<\kappa} Z_\nu| \leq \kappa$ where

$$Z_\nu = \{\beta < \kappa : \mathrm{ot}(T_\nu - f(\beta; 0)) < \kappa^{\ell+n}\}.$$

Then, by elementarity $S - \bigcup_{\nu<\kappa} Z_\nu \subseteq \alpha$, hence $\alpha \in Z_\nu$ for some $\nu < \kappa$ and $X_\nu = T_\nu \cap f(\alpha; 0)$ satisfies the requirement. $\bigcup_{\nu<\kappa} X_\nu \in \mathcal{H}(\alpha, n+1)$ and as a bonus we have that $\bigcup_{\nu<\kappa} X_\nu \subseteq f(\alpha; 0)$. ⊣

The same ramification argument gives the next lemma as well.

4.26 Lemma. *Assume $S \subseteq S_1$ is stationary. Then there exist an increasing sequence $\langle \alpha_\xi \in S : \xi < \kappa \rangle$ and a family $\langle X_{\xi,n} \subseteq S : \xi < \kappa \wedge n < \omega \rangle$ with each $X_{\xi,n} \in \mathcal{H}(\alpha_\xi, n)$ so that if either $\xi < \eta$ or $\xi = \eta$ and $k < \ell$, then $X_{\xi,k} < X_{\eta,\ell}$ and $f(x, y) = 0$ for all $x \in X_{\xi,k}$, $y \in X_{\eta,\ell}$.*

The above lemma gives the result for $\kappa^{\omega+1}$, since the set

$$X := \bigcup\{X_{\xi,n} : \xi < \kappa \wedge n < \omega\}$$

is homogeneous for f in color 0.

To finish the proof, we use yet another ramification argument.

4.27 Lemma. *Let X be a set of order type $\kappa^{\omega+1}$ as described above, and let $X_n := \bigcup\{X_{\xi,n} : \xi < \kappa\}$. Note that $\mathrm{ot}(X_n) = \kappa^{\ell+n+1}$. Let*

$$J := \{Y \subseteq X : \exists n_0 < \omega \ \forall n > n_0 \ (\mathrm{ot}(Y \cap X_n) < \kappa^{\ell+n})\}.$$

Then J is an ideal and there are $\{T_\nu \in J^+ : \nu < \kappa\}$ and $\beta_0 \in S_1$ such that for all $\beta \in S_1$ with $\beta > \beta_0$, the set $T_\nu - f(\beta; 0)$ is in J.

Let M be a maximal subset of S_1 so that $\bigcap_{\beta \in V} X - f(\beta; 0) \notin J$ for finite $V \subseteq M$.

To see that $|M| = \kappa$, we proceed just like in the proof of Lemma 4.24. We only need the fact that if $Z \subseteq X$ and $Z \notin J$, then for all $j \in \Sigma$, the set Z contains a subset of type κ homogeneous for f in color j.

Since $|M| = \kappa$, the set $\Pi := \{\bigcap_{\beta\in V} X - f(\beta;0) : V \in [M]^{<\omega}\}$ is a family of size κ such that for all $\beta \notin M$, there is some $Z \in \Pi$ so that $Z - f(\beta;0) \subseteq Y$ for some $Y \in \Pi$.

The next lemma is the final tool we need.

4.28 Lemma. *Assume $T \in J^+$. Then there is a $\overline{J} \subseteq J$ with $|\overline{J}| \leq \kappa$ such that for all $\beta \in S_1$ with $T - f(\beta;0) \in J$, there is a $Y \in \overline{J}$ so that $T - f(\beta;0) \subseteq Y$.*

Proof. Choose $J_n \subseteq [X_n]^{\ell+n+1}$ with $|J_n| \leq \kappa$ so that for all $\beta \in S_1$ with $\mathrm{ot}(X_n - f(\beta;0)) < \kappa^{\ell+n+1}$ there is a $Y_n \in J_n$ with $T - f(\beta;0) \subseteq Y_n$. Let

$$J_0 := \left\{\bigcup_{n<\omega} Y_n : \forall n < \omega\ Y_n \in J_n\right\}.$$

Note that $|J_0| = \kappa^\omega = \kappa$. Finally, set

$$\overline{J} := \left\{A \cup B : A \in J_0 \text{ and } B = \bigcup\{X_i : i \leq n\} \text{ for some } n < \omega\right\}.$$

Then $\overline{J}$ will do the job. $\dashv$

4.5. The Baumgartner-Hajnal Theorem

Here is a brief overview of the history of the Baumgartner-Hajnal Theorem and some of its generalizations. Erdős and Rado conjectured that $\omega_1 \to (\alpha)^2_k$ and $\lambda_0 \to (\alpha)^2_k$, for λ_0 the order type of the reals, and for all $k < \omega$, $\alpha < \omega_1$.

Fred Galvin figured out, for order types Θ, that $\Theta \to (\omega)^1_\omega$ would be the right necessary and sufficient condition for $\Theta \to (\alpha)^2_k$ to hold for all $\alpha < \omega_1$.

Hajnal [25] proved in 1960 that $\lambda_0 \to (\eta_0, \alpha \vee \alpha^*)^2$ where η_0 is the order type of the rationals. More significantly, Galvin proved $\lambda_0 \to (\alpha)^2_2$, for $\alpha < \omega_1$, but contrary to the first expectations, this proof provided no clues for the general case. For the resource ω_1, Galvin could only prove $\omega_1 \to (\omega^2, \alpha)^2$ for $\alpha < \omega_1$.

Another result of Prikry [48] said $\omega_1 \to (\alpha, (\omega : \omega_1))^2$. This result was later generalized by Todorcevic [64] to

$$\omega_1 \to ((\alpha)_k, (\alpha : \omega_1))^2 \quad \text{for all } \alpha < \omega_1.$$

Finally we mention a very significant consistency result of Todorcevic [63] that PFA (Proper Forcing Axiom) implies

$$\omega_1 \to (\omega_1, \alpha)^2 \quad \text{for all } \alpha < \omega_1.$$

(For context, recall that PFA implies that $\mathfrak{c} = \omega_2$.)

Before going back to the main line of discussion, we make another detour. It was already asked in the Erdős-Hajnal problem lists [12, 13] if the partition relations $\omega_2 \to (\alpha)^2_2$ were consistent for $\alpha < \omega_2$. Though there is nothing to refute such consistency, the results going in this direction are weak and rare.

The first consistency result was obtained by Richard Laver [40] in 1982, and independently discovered by Akihiro Kanamori [33], using what is now called a *Laver ideal* I on κ (a non-trivial, κ-complete ideal with the strong saturation property that given κ^+ sets not in the ideal, there are κ^+ of them so that the intersection of any $< \kappa$ of these is also not in the ideal). He proved that if there is a Laver ideal on κ, then

$$\kappa^+ \to (\kappa \cdot 2 + 1, \alpha)^2 \quad \text{holds for all } \alpha < \kappa^+.$$

Laver also proved the consistency of the hypothesis that there is a Laver ideal on ω_1 and derived as a corollary the consistency (relative to a large cardinal, of course) of

$$\omega_2 \to (\omega_1 \cdot 2 + 1, \alpha)^2 \quad \text{holds for all } \alpha < \omega_2.$$

Foreman and Hajnal [20] tried to get a stronger consistency result for ω_2 from the stronger assumption that ω_1 carries a dense ideal, and indeed, they proved that in this case

$$\omega_2 \to ({\omega_1}^2 + 1, \alpha)^2 \quad \text{holds for all } \alpha < \omega_2.$$

They however discovered that their proof gives a much stronger result for successors.

4.29 Theorem (Foreman and Hajnal [20]). *Suppose $\kappa > \omega$ is measurable and $m < \omega$. Then $\kappa^+ \to (\alpha)^2_m$ for all $\alpha < \Omega(\kappa)$.*

Here $\kappa < \Omega(\kappa) < \kappa^+$ is a rather large ordinal. We will comment about these results in detail in Sect. 5, but for lack of space and energy we will not include proofs.

4.30 Theorem (Baumgartner and Hajnal [2]). *If an order type Θ satisfies $\Theta \to (\omega)^1_\omega$, then it also satisfies $\Theta \to (\alpha)^2_k$ for all $\alpha < \omega_1$ and finite k.*

4.31 Corollary. *For all $\alpha < \omega_1$ and $m < \omega$,*

$$\omega_1 \to (\alpha)^2_m.$$

So we decided to give a proof of Corollary 4.31 using the ideas of the Foreman-Hajnal proof. This will serve two purposes. It will make the text almost complete as far as the old results are concerned, and it will communicate most of the ideas of the new Foreman-Hajnal proof.

Notation. Let $\langle\langle N_\alpha, \in\rangle : \alpha < \omega_1\rangle$ be a sequence of elementary submodels of $H(\omega_2)$ satisfying Facts 3.2 with $\lambda = \kappa = \omega$, $A = \{f\}$ where $f : [\omega_1]^2 \to m$, and

$$S_0 := \{\alpha < \omega_1 : \omega_1 \cap N_\alpha = \alpha \text{ and } N_\alpha \text{ is suitable for } \omega\}.$$

Here S_0 is a club set in ω_1. We may assume S_0 is amenable.

4.32 Definition. We define S_ρ by transfinite recursion on $\rho < \omega_1$: S_0 has already been defined; $S_{\rho+1} := \tilde{S}_\rho$, the set of reflection points of S_ρ (see Corollary 4.8); and $S_\rho := \bigcap_{\sigma<\rho} S_\sigma$ for ρ a limit.

4.33 Lemma. *For all $\rho < \omega_1$, the set S_ρ is amenable.*

Proof. Use induction on ρ and Corollary 4.8 to prove that $\langle S_\sigma : \sigma < \rho \rangle \subseteq N_{\alpha+1}$ for $\alpha \in S_\rho$. The details and the remainder of the proof are left to the reader. $\dashv$

Next we are going to define *diagonal sets*, *cross sets*, and *cross systems*.

4.34 Definition. For $\alpha \in S_0$, for the sake of brevity, we put

$$\mathcal{F}_\alpha := \{Z \in N_\alpha : Z \subseteq \omega_1 \wedge \alpha \in Z\}.$$

(Note that for $X \subseteq \alpha$, we have $X \notin I_\alpha$ if and only if $X \cap Z \neq \emptyset$ for all $Z \in \mathcal{F}_\alpha$; see the discussion of notation after Lemma 3.6.)

Call $D \subseteq \alpha$ a *diagonal set for $\alpha \in S_0$* if $\sup(D) = \alpha$ and $|D - Z| < \omega$ for all $Z \in \mathcal{F}_\alpha$.

Clearly every diagonal set D for α has order type ω, and every cofinal subset of it is also diagonal. Moreover, a diagonal set D for α is *reflecting for α* in the sense described after Lemma 3.6.

4.35 Lemma. *For all $\alpha \in S_0$ and $X \subseteq \alpha$ with $X \notin I_\alpha$, there is a diagonal set $D \subseteq X$ for α. If $X \in N_{\alpha+1}$, then D can be chosen in $N_{\alpha+1}$.*

Proof. Since $|\mathcal{F}_\alpha| = \omega$, we can diagonalize it. $\dashv$

Notation. Assume that $\langle D_n : n < \omega \rangle$ is a sequence of sets of ordinals and $\alpha \in S_0$. Then the sequence *converges to α in N_α*, in symbols, $D_n \implies \alpha$, if and only if for every $Z \in \mathcal{F}_\alpha$ there is some n_0 so that for all $n > n_0$, $D_n \subseteq Z$.

For a set D of ordinals, we denote by $\overline{D}$ its closure in the ordinal topology.

4.36 Definition. By transfinite recursion on $\rho < \omega_1$, we define, for $\alpha \in S_\rho$, the concept *D is a cross set of rank ρ for α* as follows:

1. For $\alpha \in S_0$, the set $\{\alpha\}$ is cross set of rank 0 for α.
2. For $\rho > 0$, the set D is cross set of rank ρ for α if $\alpha \in S_\rho$ and there is a witnessing sequence $\langle D_n : n < \omega \rangle$ satisfying the following conditions:
   (a) each D_n is a cross set of rank ρ_n for α_n for some $\rho_n < \rho$ and for $\alpha_n := \sup(D_n)$;
   (b) $D_0 \cup \{\alpha_0\} < \cdots < D_n \cup \{\alpha_n\} < \cdots$;
   (c) $\overline{D}_n \implies \alpha$;
   (d) if $\rho = \sigma + 1$, then $\rho_n = \sigma$ for all $n < \omega$; if ρ is a limit, then $\rho = \sup(\rho_n)$;
   (e) $D = \bigcup_{n<\omega} D_n$.

4.37 Remark. Note that a cross set D of rank 1 for α is a diagonal set for α, and if $\{\alpha_n : n < \omega\}$ is the set of $\alpha_n := \sup(D_n)$ for a witnessing sequence for D, then $\{\alpha_n : n < \omega\}$ is also a diagonal set for α.

The next lemma is proved by induction on ρ.

4.38 Lemma. *If D is a cross set for α of rank ρ, then* $\mathrm{ot}(D) = \omega^\rho$.

We now define the concept of a cross system of rank ρ for α. Informally, this is just the closure of a cross set of rank ρ for α, equipped with functions that remember the sets appearing in the definition of the cross set of rank α.

4.39 Definition. By transfinite recursion on $\rho < \omega_1$, we define, for $\alpha \in S_\rho$, the concept $\mathcal{D} = \langle \overline{D}, <_D, \mathrm{rank}_D, \mathrm{succ}_D \rangle$ *is a cross system of rank ρ for α* as follows:

1. For $\alpha \in S_0$, a quadruple $\mathcal{D} = \langle \overline{D}, <_D \mathrm{rank}_D, \mathrm{succ}_d \rangle$ is a *cross system of rank* 0 *for α* if and only if $D = \{\alpha\}$, $<_D = \emptyset$, $\mathrm{rank}(\alpha) = 0$, and $\mathrm{succ}(\alpha) = \emptyset$.

2. For $\rho > 0$, a quadruple $\mathcal{D} = \langle \overline{D}, <_D, \mathrm{rank}_D, \mathrm{succ}_D \rangle$ is a *cross system of rank ρ for α* with underlying cross set D if there is a witnessing sequence $\langle \mathcal{D}_n : n < \omega \rangle$ of cross systems so that

   (a) $\mathcal{D}_n$ is a cross system of rank ρ_n for α_n for all $n < \omega$;

   (b) $D = \bigcup\{D_n : n < \omega\}$ is a cross set with witnessing sequence $\langle D_n : n < \omega \rangle$, where D_n underlies $\mathcal{D}_n$;

   (c) $\overline{D} = \bigcup\{\overline{D}_n : n < \omega\} \cup \{\alpha\}$;

   (d) $<_D$ is defined by $\alpha <_D \beta$ for all $\beta \in \overline{D} - \{\alpha\}$, and $<_D \restriction \overline{D}_n = <_{D_n}$ for $n < \omega$.

   (e) under $<_D$, D is a (rooted) tree with root α;

   (f) $\mathrm{rank}_D : \overline{D} \to \rho + 1$ is defined by $\mathrm{rank}_D(\alpha) = \rho$, and $\mathrm{rank}_D \restriction \overline{D}_n = \mathrm{rank}_{D_n}$ for $n < \omega$.

   Finally, $\mathrm{succ}_D(\beta)$ is just a redundant notation for the set of immediate successors of β in the tree under $<_D$.

Note that for $\rho > 0$ and $n < \omega$, under the notation of Definition 4.36, $\mathrm{succ}_D(\alpha) = \{\alpha_n : n < \omega\}$ and $\mathrm{rank}_D(\alpha_n) = \rho_n$.

Note that the underlying set of a cross system is definable as the set of elements in $\overline{D}$ of rank 0.

4.40 Lemma. *Assume $\mathcal{D} = \langle \overline{D}, <_D, \mathrm{rank}_D, \mathrm{succ}_D \rangle$ is a cross system of rank ρ for α. Then for all $\beta \in \overline{D}$, $\mathrm{rank}_D(\beta) = \emptyset$ if and only if $\beta \in D$.*

The next two lemmas are proved by induction on ρ.

4.41 Lemma (Reflection Lemma). *Assume $\mathcal{D}$ is a cross system of rank ρ for α. Then for $\gamma \in \overline{D} - D$, $\mathrm{succ}_D(\gamma)$ is a diagonal set for γ.*

4.42 Definition. Assume $\mathcal{D}$ is a cross system of rank ρ for α with underlying set D. We say that C is a *full subset of* $\overline{D}$ if $\alpha \in C$ and $C \cap \operatorname{succ}_D(\beta)$ is infinite for $\beta \in C$ with $\operatorname{rank}_D(\beta) > 0$.

4.43 Lemma (Induction lemma for cross systems). *Assume $\mathcal{D}$ is a cross system of rank ρ for α with underlying set D. For every full subset C of $\overline{D}$, there is a set $B \subseteq C \cap D$ so that $\overline{B} \subseteq C$ and B is the underlying set for a cross system of rank ρ for α.*

4.44 Definition. By recursion on $\rho < \omega_1$ define, for $\alpha \in S_\rho$, the concept $\mathcal{D}$ *is an f-canonical cross system of rank ρ for α* as follows.

1. For $\alpha \in S_0$, the unique cross system of rank 0 for α is an f-canonical cross set of rank 0.
2. For $\rho > 0$, $\mathcal{D}$ is an f-canonical cross system of rank ρ for α if it is a cross system of rank ρ for α with a witnessing sequence $\langle \mathcal{D}_n : n < \omega \rangle$ for which the following additional conditions hold:
   - (g) for $n < \omega$, $\mathcal{D}_n$ is an f-canonical cross system of rank ρ_n for α_n;
   - (h) there is some i so that $f(\beta, \gamma) = i$ for all $\beta \in D_n$ and $\gamma \in D_p$ with $n < p < \omega$.

This usage is slightly different from the use of the word "canonical" in Definition 4.13. In this section we do not use the term (ξ, σ)-canonical.

The following is one of the oldest ideas in the subject.

4.45 Lemma (Homogeneity Lemma). *For all $\sigma < \omega_1$ there is some $\rho < \omega_1$ so that if $\mathcal{D}$ is an f-canonical cross system of rank ρ, then there is a set $H \subseteq D$ of order type ω^σ which is homogeneous for f.*

The proof is left to the reader. Detailed proofs can be found in both [2] and in [21] of Galvin, where the first elementary proof of Theorem 4.30 was given.

We need one more technical lemma, a strengthening of Lemma 4.43, before launching into the main proof.

4.46 Lemma (Induction lemma for canonical cross systems). *Assume $\mathcal{D}$ is an f-canonical cross system of rank ρ for α. Suppose C is a full subset of $\overline{D}$. Then there is a set $B \subseteq C \cap D$ so that $\overline{B} \subseteq C$ and B is the underlying set of an f-canonical system of rank ρ for α.*

Proof. Use induction on ρ and the fact that every cofinal subset of a diagonal set for β is diagonal for β. $\dashv$

By the Homogeneity Lemma 4.45, the following lemma will be sufficient to prove Corollary 4.31.

4.47 Lemma (Main Lemma). *For all $\rho < \omega_1$, $\alpha \in S_\rho$ and $F \in \mathcal{F}_\alpha$, there is an f-canonical system $\mathcal{D}$ of rank ρ for α with $\overline{D} \subseteq S_0 \cap F$ and $\mathcal{D} \in N_{\alpha+1}$.*

Note that it would be sufficient to prove Lemma 4.47 without the last clause, which is needed to support induction.

The rest of this section is devoted to the proof of Lemma 4.47. We need further preliminaries. In what follows, U is a fixed non-principal ultrafilter on ω with $U \in N_0$.

4.48 Definition. Define, by recursion on $\rho < \omega_1$, *deference functions* $i_{\mathcal{D}}$ where $\mathcal{D}$ is a cross system of rank ρ for α. For $\alpha \in S_0$ and a cross system $\mathcal{D}$ of rank 0 for α, define $i_{\mathcal{D}}(\xi)$ for ξ with $\alpha < \xi < \omega_1$ by $i_{\mathcal{D}}(\xi) = i$ if and only if $f(\{\alpha, \xi\}) = i$. Assume $\rho > 0$ and deference functions have been defined for cross systems of rank $\sigma < \rho$. For a cross system $\mathcal{D}$ of rank ρ for α, define $i_{\mathcal{D}}(\xi)$ for ξ with $\alpha < \xi < \omega_1$ by $i_{\mathcal{D}}(\xi) = i$ if and only if $\{n < \omega : i_{\mathcal{D}_n}(\xi) = i\} \in U$ where $\langle \mathcal{D}_n : n < \omega \rangle$ is the witnessing sequence of cross systems for $\mathcal{D}$.

Notice that if $\mathcal{D} \in N_{\alpha+1}$, then the deference function $i_{\mathcal{D}} : \omega_1 - (\alpha+1) \to m$ is also in $N_{\alpha+1}$. Note also that $i_{\mathcal{D}}(\xi)$ can be defined "inside $\mathcal{D}$" for a fixed ξ, as follows.

4.49 Definition. Assume $\mathcal{D}$ is a cross system of rank ρ for α and $\alpha < \xi < \omega_1$. Define $j_{\mathcal{D}}(\beta, \xi)$ for $\beta \in \overline{D}$ by transfinite recursion on $\mathrm{rank}_D(\beta)$ as follows. If $\mathrm{rank}_D(\beta) = 0$, then $j_{\mathcal{D}}(\beta, \xi) = f(\{\beta, \xi\})$. For $\sigma > 0$ and β with $\mathrm{rank}_D(\beta) = \sigma$, set $j_{\mathcal{D}}(\beta, \xi) = j$ for that $j < m$ so that $\{n < \omega : j_{\mathcal{D}}(\beta_n, \xi) = j\} \in U$, where β_n is the nth element of $\mathrm{succ}_D(\beta)$.

The proof that these two definitions coincide is left to the reader.

4.50 Lemma. *Assume $\mathcal{D}$ is a cross system of rank ρ for α. Then for all ξ with $\alpha < \xi < \omega_1$, $j_{\mathcal{D}}(\alpha, \xi) = i_{\mathcal{D}}(\xi)$.*

Note that $j_{\mathcal{D}}$ is an element of $N_{\alpha+1}$ if $D \in N_{\alpha+1}$.

Next we use a fixed enumeration of pairs of natural numbers to define a *standard well-ordering* for $\overline{D}$ where $\mathcal{D}$ is a cross system. For the remainder of this section, assume $\varphi : \omega \times \omega \to \omega - \{0\}$ is a fixed bijection which is monotonic in both variables, and which is in N_0.

4.51 Definition. Define, by recursion on positive $\rho < \omega_1$, for cross systems $\mathcal{D}$ of rank ρ, a *standard well-ordering of $\overline{D}$.*

1. For $\alpha \in S_1$, if $D = \{\alpha_n : n < \omega\}$ is the underlying set of a cross system $\mathcal{D}$ of rank 1, then the standard well-ordering of $\overline{D}$ has least element $d_0 = \alpha$, and for positive k, has kth element $d_k = \alpha_{k-1}$.

2. For $\rho > 1$, if $D = \bigcup\{D_n : n < \omega\}$ is the underlying set of a cross system $\mathcal{D}$ of rank ρ where D_n is the underlying set of $\mathcal{D}_n$ of the witnessing sequence of $\mathcal{D}$, then the standard well-ordering of $\overline{D}$ has least element $d_0 = \alpha$, and for positive $k = \varphi(n, j)$, has kth element $d_k = d_{n,j}$, where $d_{n,j}$ is the jth element of $\overline{D_n}$.

By some abuse of notation, we write d_n for the nth element of the standard well-ordering.

4.52 Lemma. *For all positive $\rho < \omega_1$ and all $\alpha \in S_\rho$, if $\mathcal{D}$ is a cross system of rank ρ for α and $\langle d_k : k < \omega \rangle$ is the standard well-ordering of $\overline{D}$, then for all positive $n < \omega$, there is some $m < n$ so that $d_n \in \mathrm{succ}_D(d_m)$.*

Proof. The proof is by induction on ρ over the recursive definition of standard well-orderings. ⊣

Proof of the Main Lemma 4.47. The proof is by induction on ρ. For $\rho = 0$, the lemma is trivial.

For the induction step, assume $\rho > 0$ and the lemma is true for all $\sigma < \rho$. Let $\alpha \in S_\rho$ and $F \in \mathcal{F}_\alpha$ be arbitrary. If $\rho = \sigma + 1$, then let $\rho_n = \sigma$ for all $n < \omega$. If ρ is a limit, then let $\langle \rho_n : n < \omega \rangle \in N_{\alpha+1}$ be a strictly increasing cofinal sequence with limit ρ, and assume $\rho_0 \geq 1$.

Now, for all $n < \omega$, $\alpha \in S_{\rho_n+1}$, so α is a limit of ordinals in S_{ρ_n} and $\alpha \in \tilde{S}_{\rho_n}$. Temporarily fix an enumeration of $\mathcal{F}_\alpha$ as $\{G_n : n < \omega\}$. By definition of $\tilde{S}_{\rho_n}$, $(S_{\rho_n} \cap F \cap G_0 \cap \cdots \cap G_n) \cap \alpha \notin I_\alpha$.

Define by recursion sequences $\langle \alpha_n : n < \omega \rangle$ and $\langle \mathcal{D}_n : n < \omega \rangle$. To start, choose $\alpha_0 \in (S_{\rho_0} \cap F \cap G_0) \cap \alpha$ large enough so that F, $G_0 \in N_{\alpha_0}$. Then F, $G_0 \in \mathcal{F}_{\alpha_n}$. Use the induction hypothesis on ρ_0, α_0, $F'_0 = F \cap G_0$ to find an f-canonical cross system $\mathcal{D}_0 \in N_{\alpha_0+1}$ of rank ρ_0 for α_0 so that $\overline{D}_0 \subseteq S_0 \cap F'_0$.

Continue, taking care to make sure the sequence of α_n's increases to α. If α_n has been defined, then choose $\alpha_{n+1} \in (S_{\rho_{n+1}} \cap F \cap G_0 \cap \cdots \cap G_{n+1} - (\alpha_n{+}1)) \cap \alpha$ large enough so that $F, G_0, G_0, \ldots, G_{n+1} \in N_{\alpha_0}$. Then $F, G_0, \ldots, G_{n+1} \in \mathcal{F}_{\alpha_{n+1}}$. Use the induction hypothesis on ρ_{n+1}, α_{n+1}, $F'_{n+1} = F'_n \cap G_{n+1} \cap \omega_1 - (\alpha_{n+1} + 1)$ to find an f-canonical cross system $\mathcal{D}_{n+1} \in N_{\alpha_{n+1}+1}$ of rank ρ_{n+1} for α_{n+1} so that $\overline{D}_{n+1} \subseteq S_0 \cap F'_{n+1}$.

Also, since m is finite, there is an infinite subsequence of $\langle \alpha_n : n < \omega \rangle \in N_{\alpha+1}$ and an $i < m$ so that $i_{\mathcal{D}_n}(\alpha) = i$ for all n in the subsequence. By shrinking if necessary, we may assume, without loss of generality, that this subsequence is the entire sequence. Now $\langle D_n : n < \omega \rangle$ is a witnessing sequence for a cross set of rank ρ for α by construction. Hence $\langle \mathcal{D}_n : n < \omega \rangle$ is a witnessing sequence for a cross system of rank ρ for α.

Finally, as $N_\alpha, \alpha \in N_{\alpha+1}$, and since S_ρ is amenable by Lemma 4.33, we may assume that $\langle \mathcal{D}_n : n < \omega \rangle$ is defined in $N_{\alpha+1}$.

Claim. *There is an infinite set $T \subseteq \omega$ with $T \in N_{\alpha+1}$ and a family $\{C_n : n \in T\}$ so that C_n is a full subset of $\overline{D_n}$ for $n \in T$ and $f(\beta, \gamma) = i$ for all $\beta \in C_n$ and $\gamma \in C_p$ with $n, p \in T$ and $n < p$.*

The induction step of the Main Lemma follows from the claim by Lemma 4.46, as each C_n can be replaced by an f-canonical system $\mathcal{C}_n \in N_{\alpha_n+1}$ and $\langle \mathcal{C}_n : n \in T \rangle$ is the witnessing sequence of the desired f-canonical system of rank ρ for α.

To prove the claim, we will pick elements of $\{\alpha\} \cup \bigcup \{\overline{D}_n : n \in \omega\}$ according to a certain bookkeeping. We pick α first. Infinitely often we pick a new element n for T, larger than any element of T picked earlier. Our choice of

n means we have picked the top point α_n of $\overline{D}_n$. For each point n of T, we promise that infinitely often we will pick an element of $\overline{D}_n$ according to the standard well-ordering of $\overline{D}_n$.

For notational convenience, let $n(\beta)$ denote that value of n with $\beta \in \overline{D}_n$.

Assume we have picked a finite non-empty set $A \subseteq \{\alpha\} \cup \bigcup\{\overline{D_n} : n < \omega\}$ which satisfies the following condition:

$$*(A) \qquad \begin{array}{l} \text{For any } n < p,\ \beta \in \overline{D}_n \cap A \text{ and } \xi \in \overline{D}_p \cap A, \\ j_{\mathcal{D}_n}(\beta, \xi) = j_{\mathcal{D}_n}(\beta, \alpha) = i. \end{array}$$

We have to pick a new point γ for A so that the enlarged set still satisfies the condition $*(A \cup \{\gamma\})$.

For the first scenario, suppose we want to add a new α_p to A. That is, we want to add a new value p to T. Let

$$Z_0 = Z_0(A) = \bigcap\{\{\xi : j_{\mathcal{D}_{n(\beta)}}(\beta, \xi) = i\} : \beta \in A\}.$$

Note that Z_0 is in N_α and $\alpha \in Z_0$. As $\mathrm{succ}(\alpha)$ is reflecting, we can choose the desired $\alpha_p \in \mathrm{succ}(\alpha)$ as large as we want.

For the second scenario, assume we want to pick a β to add to A so that $\beta \in \overline{D}_p$ for some $p \in T$ where $\alpha_p \in A$ and so that $\beta \in \mathrm{succ}(\gamma)$ for some $\gamma \in A \cap \overline{D}_p$. There are three cases, $\alpha_p = \min(A \cap \mathrm{succ}_{\mathcal{D}}(\alpha))$, $\alpha_p = \max(A \cap \mathrm{succ}_{\mathcal{D}}(\alpha))$, and $\min(A \cap \mathrm{succ}_{\mathcal{D}}(\alpha)) < \alpha_p < \max(A \cap \mathrm{succ}_{\mathcal{D}}(\alpha))$. We sketch only the last, and leave the others to the reader. Let $A^- := A \cap \bigcup\{\overline{D}_n : n < p\}$, and $A^+ := A \cap \bigcup\{\overline{D}_n : n > p\}$, and define

$$Z^+ = Z^+(A) := \bigcap\{\delta \in \mathrm{succ}_{\mathcal{D}_p}(\gamma) : j_{\mathcal{D}_p}(\delta, \xi) = i \wedge \xi \in A^+\}.$$

Now Z^+ is a subset of $\mathrm{succ}_{\mathcal{D}_p}(\gamma)$ which is a reflecting subset of γ by the Reflection Lemma 4.41. Since by $*(A)$, $j_{\mathcal{D}_p}(\gamma, \xi) = i$ for $\xi \in A$, and A is finite, it follows that Z^+ is a reflecting subset of γ. Next define

$$Z^- = Z^-(A) := \bigcap\{\xi < \omega_1 : j_{\mathcal{D}_{n(\delta)}}(\delta, \xi) = i \wedge \delta \in A^-\}.$$

By Lemma 4.50, $Z^- \in N_{\max(A^-)+1}$. Since $\max(A^-) < \gamma$, it follows that $Z^- \in N_\gamma$. By $*(A)$, $\gamma \in Z^-$. Hence $Z^+ \cap Z^-$ is infinite and any element of $Z^+ \cap Z^-$ is a suitable choice for β.

Use the technique of "jumping around" and these two scenarios to intertwine the recursive definitions of T and of all the C_n's for $n \in T$. Specifically, use the standard well-ordering of α to define a sequence $\langle \eta_k : k < \omega \rangle$. At stage 0, pick $\eta_0 = \alpha$. Suppose η_ℓ has been defined for $\ell < k$. Look at d_k. If $d_k \in \mathrm{succ}_D(\alpha)$, then use the first scenario to choose $\eta_k \in \mathrm{succ}_D(\alpha)$. If $d_k \in \mathrm{succ}_D(\eta_\ell)$ for some $\ell < k$, then use the second scenario to choose $\eta_k \in \mathrm{succ}_D(\eta_\ell)$. Otherwise, set $\eta_k = \eta_{k-1}$. Finally, let $E = \{\eta_k : k < \omega\}$.

Let $T = \{p < \omega : (\exists k)(\eta_k = \alpha_p)\}$. Since the standard order lists all the successors of α, the set T is infinite and in $N_{\alpha+1}$. For $p \in T$, let $C_p = E \cap \overline{D}_p$. Temporarily fix $p \in T$. For any $\gamma \in C_p$, since $\alpha_p = d_\ell$ for some ℓ, and

$\operatorname{succ}_{D_n}(\gamma)$ forms an infinite monotonic subsequence of $\{d_k : k < \omega\}$, the set C_p has infinitely many successors of γ. Thus C_p is full. Therefore T and the sets $\{C_p : p \in T\}$ are the ones required to prove the claim.

As noted above, the claim suffices to complete the induction step of the Main Lemma, so it follows. ⊣

5. The Milner-Rado Paradox and $\Omega(\kappa)$

Erdős and Rado considered Ramsey's Theorem to be a generalization of the pigeon-hole principle (for cardinals). In 1965, Milner and Rado [44] turned around this view, noting that the pigeon-hole principle is a partition relation with exponent 1, and that a partition relation with exponent 1 and ordinal resource and goal would be a pigeon-hole principle for ordinals.

A case in point of this approach is the easily checked family of partition relations $\kappa^n \to (\kappa^n)^1_\gamma$ for $\kappa \geq \omega$, $n < \omega$, and $\gamma < \operatorname{cf}(\kappa)$. Soon Milner and Rado discovered that basically nothing stronger is true.

5.1 Theorem (Milner-Rado [44]). *For all cardinals $\kappa \geq \omega$ and all $\alpha < \kappa^+$,*

$$\alpha \not\to (\kappa^n)^1_{n<\omega}.$$

Proof. It is sufficient to prove

$$(*) \qquad \kappa^\rho \not\to (\kappa^n)^1_{n<\omega} \quad \text{for } \rho < \kappa^+.$$

Clearly we may assume $\kappa > \omega$. We prove $(*)$ by transfinite induction on ρ. We can write $\kappa^\rho = \bigcup_{\nu<\sigma} A_\nu$ with $A_0 < \cdots < A_\nu < \cdots$ and each $\operatorname{ot}(A_\nu) = \kappa^{\rho_\nu}$ for some $\rho_\nu < \rho$, where $\sigma = \operatorname{cf}(\rho)$ if $\operatorname{cf}(\rho) > 1$ and $\sigma = \kappa$ otherwise. By the induction hypothesis, each $A_\nu = \bigcup_{n<\omega} A_{\nu,n}$ where $\operatorname{ot}(A_{\nu,n}) < \kappa^n$ for $\nu < \sigma$, $n < \omega$. In the case of $\sigma = \omega$, define a witnessing partition $\kappa^\rho = \bigcup_{j<\omega} B_j$ where $B_j = A_{\nu,n}$ for $j = 2^\nu(2n+1)$. In the case of $\sigma > \omega$, let $B_0 := \emptyset$, $B_{n+1} := \bigcup\{A_{\nu,n} : \nu < \sigma\}$. Clearly $\kappa^\rho = \bigcup_{n<\omega} B_n$; and $\operatorname{ot}(B_{n+1}) \leq \sum_{\nu<\sigma} \kappa^n \leq \kappa^{n+1} < \kappa^\omega$. ⊣

We state one consequence of the above theorem giving further limitations on to positive relations (as discussed in Theorem 4.3).

5.2 Theorem. *For all cardinals $\kappa \geq \omega$, $\kappa^+ \not\to (\kappa^n)^2_{n<\omega}$.*

Proof. For $\alpha < \kappa^+$, use Theorem 5.1 to choose partitions $\alpha = \bigcup_{n<\omega} A^\alpha_n$ with $\operatorname{ot}(A^\alpha_n) < \kappa^n$ for each $n < \omega$. Define $f : [\kappa^+]^2 \to \omega$ as follows: for $\alpha < \beta < \kappa^+$, set $f(\alpha,\beta) = n+1$ if and only if $\alpha \in A^\beta_n$. ⊣

The word *paradox* was used in reference to Theorem 5.1 because this result was so contrary to expectations. It turned out that the phenomena described in Theorem 5.1 is involved in many problems concerning uncountable cardinals, and often it leads to unexpected difficulties.

In this section we are trying to turn this tide and use the paradox in our favor. For the remainder of this section, let κ be a fixed infinite cardinal.

5.3 Definition. For $\alpha < \kappa^+$, call a partition $\alpha = \bigcup_{\gamma\in\Gamma} A_\gamma$ with $\Gamma < \kappa$ an MR-*decomposition of* α if there is a sequence $\langle n_\gamma : \gamma < \Gamma\rangle \in {}^\Gamma\omega$ such that $\mathrm{ot}(A_\gamma) = \kappa^{n_\gamma}$.

From Theorem 5.1 and the fact that any $\delta < \kappa^n$ is the finite sum of ordinals of the form $\kappa^m \cdot \nu$ where $m < n$ and $\nu < \kappa$, we get the following corollary.

5.4 Corollary. *Each* $\alpha < \kappa^+$ *has an* MR-*decomposition.*

Another way to put Definition 5.3 is that α has an MR-decomposition if there are sequences $\langle n_\gamma : \gamma < \Gamma\rangle \in {}^\Gamma\omega$ and functions $\Psi_\gamma : [\kappa]^{n_\gamma} \to \alpha$ for $\gamma < \Gamma < \kappa$ such that Ψ_γ is the canonical monotone map from $[\kappa]^{n_\gamma}$ ordered lexicographically into α.

The next definition from [20] is motivated by this formulation.

5.5 Definition. Call $\alpha < \kappa^+$ *codeable* if there are $\Gamma < \kappa$ and sequences $\langle n_\gamma : \gamma < \Gamma\rangle \in {}^\Gamma\omega$ and $\langle \Psi_\gamma : \gamma < \Gamma\rangle$ so that $\Psi_\gamma : [\kappa]^{n_\gamma} \to \alpha$ for $\gamma < \Gamma$ and for every $A \in [\kappa]^\kappa$,

$$\mathrm{ot}\big(\textstyle\bigcup_{\gamma<\Gamma} \Psi_\gamma\text{“}[A]^{n_\gamma}\big) = \alpha.$$

5.6 Definition. Let $\Omega(\kappa)$ be defined as the least ordinal $\Omega \leq \kappa^+$ so that each $\alpha < \Omega$ is codeable.

Note that this definition from [20] is only interesting if κ is a large cardinal, say at least a Jónsson cardinal.

The following list of properties of $\Omega(\kappa)$ proved in [20] gives some sense of this ordinal for a measurable cardinal $\kappa > \omega$.

1. $\Omega(\kappa) < \kappa^+$;
2. $\Omega(\kappa)$ is closed under the operations of ordinal addition, multiplication, exponentiation, and taking fixed points of these operations;
3. $\Omega(\kappa)$ cannot be changed by (κ,∞)-distributive forcing;
4. if $V \subseteq W$ and both V and W are models of ZFC + “κ is measurable”, then $\Omega(\kappa)^V \leq \Omega(\kappa)^W$;
5. by using generic elementary embeddings in the situation of 4., it is possible to make $\Omega(\kappa)^V < \Omega(\kappa)^W$.

Moreover, $\Omega(\kappa)$ is big, e.g. if U is a normal ultrafilter on κ and ν is the least ordinal such that $L_\nu[U] \cap \kappa^{<\kappa} = L[U] \cap \kappa^{<\kappa}$, then $L[U] \models \Omega(\kappa) = \nu$. Since the statement $\delta < \Omega(\kappa)$ is upwards absolute, this implication shows that the value of $\Omega(\kappa)^V$ is at least as big as ν. Moreover ν is much bigger than, for example, the first $\eta > \kappa$ such that $L_\eta[U]$ is an admissible structure, but much to our regret, we must omit the proofs.

However, we have to confess that we know very little about the combinatorial properties involved in the definitions of $\Omega(\kappa)$. In fact, we do not know if $\Omega(\kappa)$ would become smaller if we stipulated that the mappings Ψ_γ be monotone.

6. Shelah's Theorem for Infinitely Many Colors

In this section we prove Shelah's Theorem 4.6, that $\lambda^+ \to (\kappa+\mu)^2_\mu$ for $\mu < \kappa = \mathrm{cf}(\kappa)$ and $\lambda = 2^{<\kappa}$, under the assumption that $\mu < \sigma \le \kappa$ for some strongly compact cardinal σ.

We say that $B \subseteq \lambda^+$ *has essential colors for* $g, \mathcal{I}$, where g is a 2-partition of λ^+ and $\mathcal{I}$ is a normal ideal on λ^+, if $B \notin \mathcal{I}$ and every $C \subseteq B$ with $C \notin \mathcal{I}$ satisfies $g``[C]^2 = g``[B]^2$.

6.1 Lemma (Reduction to essential colors). *Assume $\mu < \kappa = \mathrm{cf}(\kappa)$, and $\lambda := 2^{<\kappa}$. Further suppose that $g : [\lambda^+]^2 \to \mu$ is a 2-partition of λ^+ with μ colors, I is a normal ideal concentrating on S_{κ,λ^+}, and $A \subseteq \lambda^+$ is not in I.*

Then there are a subset $B \subseteq A$ and a normal ideal $J \supseteq I$, such that B has essential colors for g, J.

Proof. By the normality of I and Facts 3.2 we can choose $N \prec H(\lambda^{++})$ suitable for κ such that $g, I, A \in N$, $N \cap \lambda^+ = \alpha < \lambda^+$, $\alpha \in A$, and N satisfies the following condition:

$$(*) \qquad \text{for all } C \in N, \text{ if } \alpha \in C \subseteq \lambda^+, \text{ then } C \notin I.$$

To see this situation may be assumed, choose an elementary chain $N_0 \prec \cdots \prec N_\alpha \prec H(\lambda^{++})$ as in Sect. 4.4 and use normality to see that

$$\{\alpha \in S_0 : (*) \text{ fails for some } C\} \in I.$$

To prove the lemma, define a decreasing sequence $\langle A_\xi : \xi < \kappa \rangle$ of subsets of λ^+ by recursion on $\xi < \kappa$. To start the recursion, let $A_0 := A$. Assume $0 < \xi < \kappa$ and A_ζ is defined for $\zeta < \xi$ in such a way that

$$A_\zeta \in N \quad \text{and} \quad \alpha \in A_\zeta \subseteq \lambda^+, \quad \text{for } \zeta < \xi.$$

Put $A_\xi = \bigcap_{\zeta<\xi} A_\zeta$ in case ξ is a limit ordinal.

Suppose A_ζ has been defined, and set $\Gamma_\zeta = g``[A_\zeta]^2$. Let I_ζ be the normal ideal generated on A_ζ from

$$I \cap \mathcal{P}(A_\zeta) \cup \{x \subseteq A_\zeta : g``[x]^2 \subsetneqq \Gamma_\zeta\}.$$

If $A_\zeta \notin I_\zeta$, then set $A_{\zeta+1} = A_\zeta$. If $A_\zeta \in I_\zeta$, then it is a finite or diagonal union of elements of the generating set. We treat the case where there is a sequence $\mathcal{B}_\zeta = \langle B_{\zeta,\eta} : \eta < \lambda^+ \rangle$ such that $A_\zeta = \bigcup_{\eta<\lambda^+} B_{\zeta,\eta}$, and for $\eta < \lambda^+$, $B_{\zeta,\eta} \cap (\eta+1) = \emptyset$, and either $B_{\zeta,\eta} \in I$ or $g``[B_{\zeta,\eta}]^2 \subsetneqq \Gamma_\zeta$.

Then, by elementarity, there is a sequence $\mathcal{B}_\zeta \in N$ as described above. Moreover, $\alpha \in B_{\zeta,\eta}$ for some $\eta < \lambda^+$ with $\eta < \alpha$ and $\eta \in N$, and thus $B_{\zeta,\eta} \in N$ for this η. We set $A_{\zeta+1} = B_{\zeta,\eta}$ for this η. Note that in this case, $\alpha \in A_{\zeta+1} \notin I$ and $g``[A_{\zeta+1}]^2 \subsetneqq g``[A_\zeta]^2$. This defines the sequence $\langle A_\eta : \eta < \kappa\rangle$.

Since g maps pairs from λ^+ into μ, there are at most $\mu < \kappa$ many ζ with $A_\zeta \subsetneqq A_{\zeta+1}$. Let ζ be the least ordinal with $A_\zeta = A_{\zeta+1}$, and set $B := A_\zeta$. Then I_ζ is a proper ideal on B. The ideal J generated from $I \cup I_\zeta$ is normal, and $B \notin J$. So by definition of I_ζ, B has essential colors for g, J. ⊣

Given a 2-partition g, we say that y and z are *color equivalent over* x and write $y \equiv^g_x z$ if $x < y$, $x < z$, $\mathrm{ot}(y) = \mathrm{ot}(z)$, and the order isomorphism $\pi : x \cup y \to x \cup z$ has $\pi{\restriction}x = \mathrm{id}$ and is color preserving: $g(\zeta, \eta) = g(\pi(\zeta), \pi(\eta))$.

6.2 Corollary. *For any 2-partition $g : [\lambda^+]^2 \to \mu$, and any normal ideal J, if B has essential colors for g, J, then there is a set $C \subseteq B$ with $B - C \in J$ such that for all $\alpha \in C$, for all $x \in [\alpha]^{<\kappa}$, and for all $\gamma \in \Gamma := g``[B]^2$, the set $D(\alpha, x, \gamma)$ is J-positive, where*

$$D(\alpha, x, \gamma) := \{\beta \in C : \alpha < \beta \wedge \{\alpha\} \equiv^g_x \{\beta\} \wedge g(\alpha, \beta) = \gamma\}.$$

Proof. To see that the set B has the desired property, assume to the contrary that for all α in some J-positive set $X \subseteq B$, there are $x(\alpha) \in [\alpha]^{<\kappa}$ and $\gamma(\alpha) \in g``[B]^2$ such that the set $D(\alpha, x(\alpha), \gamma(\alpha)) \in J$. By normality and $\mathrm{cf}(\alpha) = \kappa$, there are $Y \subseteq X$ with $Y \notin J$ such that for some x, γ one has $x(\alpha) = x$, $\gamma(\alpha) = \gamma$ for all $\alpha \in Y$. Then for some $Z \subseteq Y$ with $Z \notin J$ the condition $\{\alpha\} \equiv^g_x \{\beta\}$ holds for all $\alpha, \beta \in Z$. If for each $\alpha \in Z$ the set $\{\beta \in Z : g(\alpha, \beta) = \gamma\} \in J$, then, because of the normality, for the set $W := \{\delta \in Z : \forall \beta \in \delta \cap Z\ (g(\beta, \delta) \neq \gamma)\}$ both $W \notin J$ and $\gamma \notin g``[W]^2$ would hold, contradicting the fact that B has essential colors for g, J. ⊣

The above lemma and corollary are to be used with different 2-partitions, and hence were stated in generality. Now fix a 2-partition $f : [\lambda^+]^2 \to \mu$ for which we seek a homogeneous set of type $\kappa + \mu$.

6.3 Lemma (Pulldown Lemma). *There is a subset $S_0 \subseteq S_{\kappa,\lambda^+}$ closed in S_{κ,λ^+} such that for all $\alpha \in S_0$, for all $x \in [\alpha]^{<\kappa}$, and for all $z \in [\lambda^+ - (\alpha + 1)]^{<\kappa}$, there is a $y \in [\alpha - \sup(x)]^{<\kappa}$ such that $y \equiv^f_x z$.*

Proof. Let S_0 be as in Facts 3.2. Then Lemma 6.3 is true by reflection. ⊣

The Pulldown Lemma 6.3 does not say anything about the colors of edges that go between the sets y and z, while Corollary 6.2 detailed a situation in which any essential color may be pre-selected.

We apply Lemma 6.1 to f and the smallest normal ideal on λ^+, the non-stationary ideal, to get $B_0 \subseteq S_0$ and J_0, so J_0 is a normal ideal extending the non-stationary ideal, and B_0 has essential colors for f, J_0. We apply Corollary 6.2 to get $A_0 \subseteq B_0$ so that $B_0 - A_0 \in J_0$ and the other conditions of the corollary hold for all $\alpha \in A_0$. Then we choose $\alpha_0 \in A_0$, and put $T := A_0 - \alpha_0$.

6.4 Lemma. *There exists a function $h : T \times T \to \mu$ such that for all $x \in [\alpha_0]^{<\kappa}$ and $z \in [T]^{<\sigma}$ there is a $y \in [\alpha_0 - \sup(x)]^{<\sigma}$ such that*

(a) $y \equiv^f_x z$ via $\pi : x \cup y \to x \cup z$; and

(b) $f(\zeta, \zeta') = h(\pi(\zeta), \zeta')$ for all $\zeta \in y$, $\zeta' \in z, \pi(\zeta) \neq \zeta'$.

Proof. As σ is strongly compact is suffices to show that for every $Z \in [T]^{<\sigma}$ there exists a function $H : Z \times Z \to \mu$ as required.

Assume for the sake of contradiction that for every $H : Z \times Z \to \mu$ there is an $x_H \in [\alpha]^{<\sigma}$ such that for all $y \subseteq \alpha - \sup(x_H)$ satisfying (a), the function given by (b) is not H.

Let $x = \bigcup\{x_H : \ H : Z \times Z \to \mu\}$. Then $|x| < \sigma$ as $|x| \le \mu^{|Z|} < \sigma$, since σ is strongly inaccessible.

By Lemma 6.3, there is a y satisfying (a). Then (b) defines a function $H : Z \times Z \to \mu$. By the definition of x, the set $x_H \subseteq x$ is a set on which the function defined by (b) for y is not H, and that is a contradiction. ⊣

Now we define $k : [\lambda^+]^2 \to \mu \times \mu$ for $u, v \in \lambda^+$ with $u < v$ by

$$k(u, v) = \langle f(u, v), h(u, v)\rangle.$$

Next apply Lemma 6.1 and Corollary 6.2 to k and the normal ideal J_0 and the set T.

6.5 Corollary. *We get a normal ideal $J_1 \supseteq J_0$, a non-empty set $\Gamma \subseteq \mu \times \mu$, and subsets $S_1 \subseteq B_1 \subseteq T$ with $B_1 \notin J_1$, $B_1 - S_1 \in J_1$ such that B_1 has essential colors for k, J_1, and for each $\alpha \in S_1$ and for each $x \in [\alpha]^{<\kappa}$ and $\langle\gamma, \delta\rangle \in \Gamma$ the set $E(\alpha, x, \langle\gamma, \delta\rangle)$ is J_1-positive, where*

$$E(\alpha, x, \langle\gamma, \delta\rangle) := \{\beta \in S_1 : \alpha < \beta \wedge \{\alpha\} \equiv^k_x \{\beta\} \wedge k(\alpha, \beta) = \langle\gamma, \delta\rangle\}.$$

6.6 Lemma. *There is a subset $a \in [S_1]^{<\sigma}$ such that for every partition of a, say $a = \bigcup\{a_\zeta : \zeta < \mu\}$, there is a $\zeta < \mu$ such that for every $\gamma < \mu$, there is a subset $b_{\zeta,\gamma}$ of a_ζ of type μ homogeneous for f in the color γ.*

Proof. Notice that $S_1 \notin J$. We claim that if $A \subseteq S_1$ does not contain a subset of order type μ homogeneous for f in color γ for some $\gamma \in \mu$, then $A \in J$. Indeed, for each $\alpha \in A$ choose a maximal subset $M_\alpha \subseteq (\alpha + 1) \cap A$ homogeneous for f in color γ with $\alpha \in M_\alpha$. If $A \notin J$ then, by the normality of J, M_α is constant on a set not in J, and that yields, using the normality of J, a set not in J not containing any edge of color γ in f, just as in the proof of the Erdős-Rado Theorem 3.10. Hence S_1 has the property that any partition of it into μ pieces has a part A which contains a homogeneous subset of type μ for every $\gamma \in f``[S_1]^2$.

By the strong compactness of σ, there must be a set $a \subseteq S_1$ of size $< \sigma$ satisfying the same statement as S_1 about f, all partitions into μ parts and the existence of homogeneous subsets of type μ for all colors $\gamma \in f``[S_1]^2$. ⊣

We now describe the construction of the required homogeneous set.

Recall that immediately following Lemma 6.3 we chose α_0. Next choose a as in Lemma 6.1 Then choose $\alpha_1 \in S_1$ satisfying Corollary 6.5.

Then $\alpha_0 < a < \alpha_1$.

Define $a_{\gamma,\delta} := \{u \in a : k(u, \alpha_1) = \langle\gamma, \delta\rangle\}$.

By Lemma 6.6 there is a $\langle\gamma_0, \delta_0\rangle \in \Gamma$ such that a_{γ_0,δ_0} contains a subset of type μ homogeneous for color γ for every γ, hence it contains a subset $b \subseteq \alpha_{\gamma_0,\delta_0}$ of type $\mathrm{ot}(b) = \mu$ homogeneous for f in color δ_0. This will be "our color" and b will be the "μ-part" of our set. We are going to construct the "λ-part" of the set by transfinite recursion on $\xi < \kappa$ as follows. Assume $\xi < k$ and we have constructed $X = X_\xi$ of order type ξ homogeneous for f in color δ_0 and so that all edges from X to $b \cup \{\alpha_1\}$ have color δ_0.

We now apply Corollary 6.2 to α_1, and $X \cup b$ and we obtain an $\alpha_2 \in S_1$, with $\alpha_1 < \alpha_2$ such that $\{\alpha_1\} \equiv^k_{X\cup b} \{\alpha_2\}$ and $k(\alpha_1, \alpha_2) = \langle\gamma_0, \delta_0\rangle$.

As a corollary of this we have $\delta_0 = f(u, \alpha_1) = f(u, \alpha_2)$ for $u \in X$, since $\delta_0 = f(u, \alpha_1)$ for $u \in X$ is assumed, and $h(v, \alpha_1) = h(v, \alpha_2) = \delta_0$ for $v \in b$, by the choice of b.

Apply Lemma 6.4 for α_0 to $X$and $b \cup \{\alpha_1, \alpha_2\} \subseteq T$. We get $b' \cup \{\alpha_1', \alpha_2'\}$. We claim that $X_{\xi+1} = X \cup \{\alpha_2'\}$ is homogeneous in color δ_0 and sends all edges to $b \cup \{\alpha_1\}$ of color δ_0.

Indeed $f(u, \alpha_2') = f(u, \alpha_2) = \delta_0$ for $u \in X$ by the equivalence over X. For $v \in b$, we have $f(\alpha_2', v) = f(v, \alpha_2') = h(v, \alpha_2) = h(v, \alpha_1) = \delta_0$. By choice of α_2, we have $k(\alpha_1, \alpha_2) = \langle g(\alpha_1, \alpha_2),\ h(\alpha_2, \alpha_1)\rangle = \langle\gamma_0, \delta_0\rangle$. Hence $f(\alpha_2', \alpha_1) = \delta_0$ also.

7. Singular Cardinal Resources

It should be clear to the attentive reader that neither the ramification method as described in Remark 2.4 nor its refinements discussed up to now can yield any specific partition results for a singular resource. To get such results the method of *canonization* was invented in [18].

7.1 Definition. Assume $f : [\kappa]^r \to \gamma$ is an r-partition of length γ of κ, and $\langle A_\nu : \nu < \mu\rangle$ is a sequence of disjoint subsets of κ. Then f is said to be *canonical on* $\langle A_\nu : \nu < \mu\rangle$ if $f(x) = f(y)$ for all $x, y \in A := \bigcup_{\nu<\mu} A_\nu$ whenever x, y are positioned the same way in the sequence, i.e. if

$$|x \cap A_\nu| = |y \cap A_\nu| \quad \text{for all } \nu < \mu.$$

The idea is that, for a singular cardinal κ, we want to find a sequence $\langle A_\nu : \nu < \mathrm{cf}(\kappa)\rangle$ with $|A_\nu| < \kappa$ for $\nu < \mathrm{cf}(\kappa)$, and $A := \bigcup\{A_\nu : \nu < \mathrm{cf}(\kappa)\}$ of power κ such that f is canonical on $\langle A_\nu : \nu < \mathrm{cf}(\kappa)\rangle$ and use it to piece together large homogeneous sets. The following is the classical canonization theorem.

7.2 Theorem (General Canonization Lemma [18]). *Suppose that $\tau \geq 2$ is a cardinal, $r \geq 1$ is an integer, $\langle \kappa_\xi : \xi < \mu \rangle$ is a strictly increasing sequence of infinite cardinals with $\kappa_0 \geq \tau^{|\mu|}$ and $\exp_{\binom{r}{2}}(\kappa_\xi) < \exp_{\binom{r}{2}}(\kappa_\eta)$ for $\xi < \eta < \mu$. For any disjoint union $A = \dot{\bigcup}\{A_\nu : \nu < \mu\}$, and any coloring $f : [A]^r \to \tau$, if $|A_\nu| \geq (\exp_{\binom{r}{2}}(\kappa_\nu))^+$ for all $\nu < \mu$, then there are sets $B_\nu \subseteq A_\nu$ for $\nu < \mu$ so that $|B_\nu| \geq {\kappa_\nu}^+$ and the sequence $\langle B_\nu : \nu < \mu \rangle$ is canonical with respect to f.*

We are omitting the proof, since any reader with some experience in combinatorics should be able to reconstruct it, and since neither this proof nor the subsequent proofs fall into the line of the methods we are describing. We include canonization results because we think that no chapter on partition relations would be complete without them.

Here is the very first application of Theorem 7.2.

7.3 Theorem (Reduction Theorem). *Assume $\kappa > \mathrm{cf}(\kappa)$ is a strong limit cardinal. Then $\kappa \to (\kappa, \kappa_\nu)^2_{1 \leq \nu < \gamma}$ if and only if $\mathrm{cf}(\kappa) \to (\mathrm{cf}(\kappa), \kappa_\nu)^2_{1 \leq \nu < \gamma}$.*

Indeed, the next theorem is the only one obtained for a singular resource using a method different from canonization. The elementary proof of the theorem is left to the reader (see [19]).

7.4 Theorem (Erdős; Dushnik and Miller [9]). *For every infinite cardinal κ, $\kappa \to (\kappa, \omega)^2$.*

See also [19] for a proof. The General Canonization Lemma implies Theorem 7.4 for singular strong limit κ and for $\mathrm{cf}(\kappa) > \omega$ it yields $\kappa \to (\kappa, \omega + 1)^2$. It has been a longstanding problem if this partition relation holds if we do not assume that κ is strong limit. Recently Shelah [54] proved this partition relation holds under the much weaker condition that $2^{\mathrm{cf}(\kappa)} < \kappa$.

Erdős, Hajnal and Rado in [18] pursued the idea of finding the right generalization of the form $\kappa \to (\kappa, \omega_1)^2$ for singular κ. The first possible case is $\kappa = \aleph_{\mathfrak{c}^+}$, where $\mathfrak{c} = 2^\omega$, and the Reduction Theorem 7.3 gives a positive answer in case κ is a strong limit. The very first question of the Erdős-Hajnal problem list [12] asks if this additional hypothesis is necessary. Shelah and Stanley in [60] and [61] proved that the partition relation $\kappa \to (\kappa, \omega_1)^2$ can be both false and true if κ is not a strong limit cardinal. A description of this deep result is beyond the scope of this section.

There is one more *canonization* result that we want to mention. It was isolated during the discussion of the ordinary partition relation in the book [19] that the following result should be true, and Shelah later proved it.

7.5 Theorem (Shelah [56]). *Assume that κ is a singular cardinal of weakly compact cofinality. If $\kappa < 2^{<\kappa}$ and $2^\rho < 2^{<\kappa}$ for $\rho < \kappa$, then*

$$2^{<\kappa} \to (\kappa)^2_2.$$

To prove this partition relation, Shelah worked out a new group of canonization results in [56]. We only state here one of the main results. Call a sequence of cardinals $\langle \kappa_\nu : \nu < \mu \rangle$ *exponentially increasing* if $\xi < \nu < \mu$ implies $2^{\kappa_\xi} < 2^{\kappa_\nu}$. A sequence of sets $\langle B_\nu : \nu < \mu \rangle$ is *weakly canonical* if $f(u) = f(v)$ whenever $u, v \in [\bigcup_{\nu<\mu} B_\nu]^r$ and $|u \cap B_\nu| = |v \cap B_\nu| \leq 1$ for every $\nu < \mu$. A set $F \subseteq \mathcal{P}(A)$ *sustains* A over κ if for every $X \subseteq A$ with $|X| = (2^\kappa)^+$, there is a $Y \in F$ so that $Y \subseteq X$ and $|Y| = \kappa^+$.

7.6 Theorem (Shelah's Canonization Lemma [56]). *Suppose $\langle \kappa_\xi : \xi < \mu \rangle$ is an exponentially increasing sequence of infinite cardinals with $\kappa_0 \geq \tau, \mu, \omega$, for a cardinal $\tau \geq 2$. Then for any disjoint union $A = \dot{\bigcup}\{A_\nu : \nu < \mu\}$, any sequence $\langle F_\nu \subseteq \mathcal{P}(A_\nu) : \nu < \mu \rangle$, and any coloring $f : [A]^2 \to \tau$, if $|A_\nu| > 2^{\kappa_\nu}$ and F_ν sustains A_ν for all $\nu < \mu$, then there is a sequence $\langle B_\nu : \nu < \mu \rangle$ weakly canonical with respect to f with $|B_\nu| = {\kappa_\nu}^+$ for all $\nu < \mu$.*

8. Polarized Partition Relations

Polarized partition relations were defined in the introduction. We do not have the space to give an orderly discussion of the problems and results on this partition relation. Rather, we will only give a few examples, where the method of elementary submodels described in the previous section can be resourcefully used. The first appearance in the literature of the use of elementary submodels for the proofs of polarized partition relations is the following theorem of Jones which generalizes a result of Erdős, Hajnal and Rado [18] from 1965:

8.1 Theorem (Jones [30]). *Let κ be an infinite cardinal and $\lambda = 2^{<\kappa}$. Then the following polarized partition relation holds:*

$$\binom{\lambda^+}{\lambda^+} \to \begin{pmatrix} \lambda^+ & & \gamma & \kappa+1 \\ & or & & \\ \gamma & & \lambda^+ & \kappa+1 \end{pmatrix}^{1,1}.$$

In the remainder of this section, we apply the method of elementary submodels using the "method of double ramification".

8.1. Successors of Weakly Compact Cardinals

The first example is chosen with an eye to a clean presentation of the method.

8.2 Theorem (Baumgartner and Hajnal [3]). *Suppose that κ is a weakly compact cardinal. Then*

$$\binom{\kappa^+}{\kappa} \to \binom{\kappa}{\kappa}^{1,1}_{\gamma} \quad \text{for } \gamma < \kappa.$$

Before going into the details of the proof, we give some historical remarks and state an open problem. In [26], Hajnal proved that for measurable κ, the following partition relations holds:

$$\binom{\kappa^+}{\kappa} \to \binom{\alpha}{\kappa}^{1,n}_{<\kappa} \quad \text{for } n < \omega \text{ and } \alpha < \kappa^+.$$

In an early paper of Choodnovsky [6], it was claimed that

$$\binom{\kappa^+}{\kappa} \to \binom{\alpha}{\kappa}^{1,1}_{<\kappa} \quad \text{for } \alpha < \kappa^+$$

remains valid for weakly compact κ, but no proof was given. Realizing that this claim was by no means obvious, both Kanamori [32] and Wolfsdorf [66] published proofs that the relation is true for two colors:

$$\binom{\kappa^+}{\kappa} \to \binom{\alpha}{\kappa}^{1,1}_{2} \quad \text{for } \alpha < \kappa^+.$$

Theorem 8.2 was generalized in the thesis of Jones [29, 28], who proved, using elementary submodels, that for weakly compact cardinals κ,

$$\binom{\kappa^+}{\kappa} \to \left(\binom{\alpha}{\kappa}_m, \binom{\kappa^n}{\kappa}_\gamma\right)^{1,1} \quad \text{for } m, n < \kappa,\ \gamma < \kappa,\ \alpha < \kappa^+.$$

To the best of our knowledge, the following problem remains unsolved.

8.3 Question. Does the partition relation

$$\binom{\kappa^+}{\kappa} \to \binom{\alpha}{\kappa}^{1,1}_{\omega} \quad \text{hold for all weakly compact } \kappa \ge \omega,\ \alpha \ge \kappa^\omega?$$

The rest of this subsection is devoted to the proof of Theorem 8.2 for $\kappa > \omega$. To that end, let $\kappa > \omega$ be a weakly compact cardinal, and let $f : \kappa^+ \times \kappa \to \gamma$ be a fixed partition. We outline background assumptions below, using work from earlier sections.

8.4 Definition. Let $\langle\langle N_\alpha, \in\rangle : \alpha < \kappa^+\rangle$ be a sequence of elementary submodels of $H(\kappa^{++})$ satisfying Facts 3.2 with $\lambda = \kappa^{<\kappa} = \kappa$ and $A = \{f\}$. Let $\langle I_\alpha : \alpha < \kappa^+\rangle$ be the ideals defined in Definition 3.4 and let

$$S_0 := \{\alpha < \kappa^+ : \alpha(N_\alpha) = \alpha \wedge \mathrm{cf}(\alpha) = \kappa \wedge N_\alpha \text{ is suitable}\}$$

as defined in Sect. 4.2. Note that for $\alpha \in S_0$, I_α is a κ-complete proper ideal, by Lemma 3.6.

8.5 Definition. Call $\mathcal{N} = \langle N_{\alpha,\xi} : \alpha < \kappa^+ \wedge\ \xi < \kappa\rangle$ a *double ramification system for* $\langle N_\alpha : \alpha < \kappa^+\rangle$ as in Definition 8.4 if for each $\alpha < \kappa^+$, the sequence $\langle N_{\alpha,\xi} : \xi < \kappa\rangle \in N_{\alpha+1}$ is an increasing continuous sequence of elementary submodels of N_α with $\bigcup\{N_{\alpha,\xi} : \xi < \kappa\} = N_\alpha$ such that $|N_{\alpha,\xi}| < \kappa$ for $\xi < \kappa$.

We use the name *double ramification system* since, as we explained in the proof of the Erdős-Rado Theorem, the N_α's play the role of the ramification system of Erdős and Rado.

Just like in Facts 3.2, using general facts about elementary submodels, and the uncountability and strong Mahloness of κ, we can see that there is a system satisfying the next definition.

8.6 Definition. Let $\mathcal{N} = \langle N_{\alpha,\xi} : \alpha < \kappa^+ \wedge\ \xi < \kappa\rangle$ be a double ramification system such that for each $\alpha \in S_0$ there is a $T^0_\alpha \subseteq \kappa$, with $T^0_\alpha \in \mathrm{Stat}(\kappa)$ satisfying the following conditions for all $\xi \in T^0_\alpha$:

1. $N_{\alpha,\xi} \cap \kappa = \xi > \gamma$;
2. ξ is a regular cardinal; and
3. $[N_{\alpha,\xi}]^{<\xi} \subseteq N_{\alpha,\xi}$.

Next we relativize certain important sets to the submodels of the double ramification system.

8.7 Definition. For each $\alpha \in S_0$ and $\xi \in T^0_\alpha$, define the following sets:

1. $X_{\alpha,\xi} := N_{\alpha,\xi} \cap \kappa^+$;
2. $I_{\alpha,\xi} := \{X \subseteq \xi : (\exists Y)(Y \subseteq \kappa \wedge Y \in N_{\alpha,\xi} \wedge \xi \notin Y \wedge X \subseteq Y)\}$;
3. $\hat{I}_{\alpha,\xi} := \{X \subseteq X_{\alpha,\xi} : (\exists Y)(Y \subseteq \kappa^+ \wedge Y \in N_{\alpha,\xi} \wedge \alpha \notin Y \wedge X \subseteq Y)\}$.

8.8 Lemma. *For $\alpha \in S_0$ and $\xi \in T^0_\alpha$, both $I_{\alpha,\xi}$ and $\hat{I}_{\alpha,\xi}$ are ξ-complete ideals, and $I_{\alpha,\xi}$ is proper.*

Proof. The first statement follows from the fact that $[N_{\alpha,\xi}]^{<\xi} \subseteq N_{\alpha,\xi}$. To see that $I_{\alpha,\xi}$ is proper, then just like in Lemma 3.6, assume $Z \subseteq \kappa$, $\xi \in Z$ and $Z \in N_{\alpha,\xi}$. Then $\sup(Z) \in N_{\alpha,\xi}$, hence $\sup(Z) = \kappa$ and $\sup(Z) \cap \xi = \xi$. This implies $\xi \notin I_{\alpha,\xi}$. ⊣

Note that $\hat{I}_{\alpha,\xi}$ is proper for many α and ξ as well (see Corollary 8.11 below).

Notation. For all $\nu < \gamma$, let

$$f^{\downarrow}(\alpha;\nu) := \{\xi < \kappa : f(\alpha,\xi) = \nu\} \quad \text{for } \alpha < \kappa^+,$$
$$f^{\uparrow}(\xi;\nu) := \{\alpha < \kappa^+ : f(\alpha,\xi) = \nu\} \quad \text{for } \xi < \kappa.$$

8.9 Definition. For $\alpha \in S_0$ and $\xi \in T^0_\alpha$, let

$$a_{\alpha,\xi} := \{\nu < \gamma : f^{\downarrow}(\alpha;\nu) \cap \xi \notin I_{\alpha,\xi}\}.$$

Note that $a_{\alpha,\xi} \neq \emptyset$ by Lemma 8.8 and the fact that $\gamma < \xi$.

8.10 Lemma (Main Lemma). *There are subsets $a \subseteq \gamma$ and $S \subseteq S_0$ with $S \in \mathrm{Stat}(\kappa^+)$, and for each $\alpha \in S$, there is a subset $T_\alpha \subseteq T^0_\alpha$ with $T_\alpha \in \mathrm{Stat}(\kappa)$, so that $f(\alpha,\eta) \in a = a_{\alpha,\eta}$ for all $\alpha \in S$ and $\eta \in \bigcup\{T_\beta : \beta \in S\}$.*

Proof. First thin each T^0_α for $\alpha \in S_0$ to a stationary subset T^1_α so that for some a_α, one has $a_{\alpha,\xi} = a_\alpha$ for all $\xi \in T^1_\alpha$. Then thin S_0 to a stationary subset S_1 so that for some $a \subseteq \gamma$ and for all $\alpha \in S_1$, $a_\alpha = a$. We may assume without loss of generality that $\gamma < \xi$ for all $\xi \in T^1_\alpha$.

Notice that for all $\alpha \in S_1$ and all $\xi \in T^1_\alpha$, if $\nu \notin a$, then $f^\downarrow(\alpha;\nu) \cap \xi \in I_{\alpha,\xi}$. Hence, by the definition of $f^\downarrow$ and the ξ-completeness of $I_{\alpha,\xi}$, it follows that $\{\eta < \xi : f(\alpha,\eta) \notin a\} \in I_{\alpha,\xi}$. By Definition 8.7, for $\alpha \in S_1$ and $\xi \in T^1_\alpha$, we can choose sets $Y_{\alpha,\xi} \subseteq \kappa$ such that $\xi \notin Y_{\alpha,\xi} \in N_{\alpha,\xi}$ and $\{\eta < \xi : f(\alpha,\eta) \notin a\} \subseteq Y_{\alpha,\xi}$. Using Fodor's Theorem twice, we get $Y \subseteq \kappa$, $S \subseteq S_1$ with $S \in \mathrm{Stat}(\kappa^+)$, and $\langle T_\alpha \subseteq T^1_\alpha : \alpha \in S\rangle$ such that $T_\alpha \in \mathrm{Stat}(\kappa)$ for all $\alpha \in S$, and $Y_{\alpha,\xi} = Y$ for $\alpha \in S$ and $\xi \in T_\alpha$.

Consequently, for all $\xi \in \bigcup\{T_\beta : \beta \in S\}$, we have $\xi \notin Y$, since $\xi \notin Y_{\beta,\xi} = Y$. However, if $\alpha \in S$ and $\eta < \kappa$ are such that $f(\alpha,\eta) \notin a$, then for some $\xi \in T_\alpha$, one has $\eta \in Y_{\alpha,\xi} = Y$, so the theorem follows. ⊣

8.11 Corollary. *There is an $\alpha < \kappa^+$, so that for κ-many ξ, the following condition holds:*

$$(+) \qquad (\exists \nu < \gamma)(f^\downarrow(\alpha;\nu) \cap \xi \notin I_{\alpha,\xi} \wedge f^\uparrow(\xi;\nu) \cap X_{\alpha,\xi} \notin \hat{I}_{\alpha,\xi}).$$

Proof. Let α be such that $S \cap \alpha \notin I_\alpha$. Such an α must exist by Corollary 4.8. A standard argument shows that if $S \cap \alpha \notin I_\alpha$, then $W = \{\xi < \kappa : S \cap \alpha \cap X_{\alpha,\xi} \in \hat{I}_{\alpha,\xi}\}$ is non-stationary in κ. By Main Lemma 8.10, $f(\beta,\xi) \in a$ for $\xi \in T_\alpha$ and $\beta \in S \cap \alpha \cap X_{\alpha,\xi}$. Hence $f^\uparrow(\xi;\nu) \cap X_{\alpha,\xi} \notin \hat{I}_{\alpha,\xi}$ for some $\nu \in a$ and for every $\xi \in T_\alpha - W$. On the other hand, $f^\downarrow(\alpha;\nu) \cap \xi \notin I_{\alpha,\xi}$ for all $\nu \in a$ and for every $\xi \in T_\alpha$. ⊣

8.12 Lemma (Compactness Lemma). *Assume that for some $\alpha < \kappa^+$ there are κ-many ξ so that for some $A_\xi \subseteq X_{\alpha,\xi}$, $B_\xi \subseteq \xi$ with $\mathrm{ot}(A_\xi) = \mathrm{ot}(B_\xi) = \xi$, the set $A_\xi \times B_\xi$ is homogeneous for f. Then there are $A \subseteq \kappa^+$, $B \subseteq \kappa$ with $\mathrm{ot}(A) = \kappa + 1$ and $\mathrm{ot}(B) = \kappa$ such that $A \times B$ is homogeneous for f.*

Proof. Use the weak compactness of κ via its Π^1_1-indescribability. ⊣

After all these preliminaries, Theorem 8.2 now follows from Corollary 8.11, the Compactness Lemma 8.12 above, and the Reflection Lemma below.

8.13 Lemma. *Assume that for α as in Corollary 8.11 and for some $\nu < \gamma$, the ordinal ξ satisfies the formula (+) of Corollary 8.11. Then there are $A \subseteq X_{\alpha,\xi}$, $B \subseteq \xi$ with $\mathrm{ot}(A_\xi) = \mathrm{ot}(B_\xi) = \xi$ so that $A \times B$ is homogeneous for f in color ν.*

Proof. Let $\overline{A} := f^{\uparrow}(\xi;\nu) \cap X_{\alpha,\xi}$ and let $\overline{B} = f^{\downarrow}(\alpha;\nu) \cap \xi$. Since (+) holds for ν and ξ, we know that $\overline{B} \notin I_{\alpha,\xi}$ and $\overline{A} \notin \hat{I}_{\alpha,\xi}$. These last two statements imply the existence of the sets A, B as required. Indeed, we can define sequences $A = \{a_\mu : \mu < \xi\} \subseteq \overline{A}$ and $B = \{b_\mu : \mu < \xi\} \subseteq \overline{B}$ by transfinite recursion on $\mu < \xi$ so that for all $\mu', \mu'' < \xi$,

$$\begin{aligned} f(a_{\mu'}, b_{\mu''}) = \nu, \\ a_{\mu'} \in f^{\uparrow}(\xi;\nu), \\ b_{\mu''} \in f^{\downarrow}(\alpha;\nu). \end{aligned}$$

At stage $\mu < \xi$, assume this has been done for $\mu', \mu'' < \mu$. First choose a_μ. Toward that end, let

$$Z^-_\mu := \{\beta < \kappa^+ : f(\beta, b_{\mu''}) = \nu \text{ for all } \mu'' < \mu\}.$$

Then $\alpha \in Z^-_\mu$ since $b_{\mu''} \in f^{\downarrow}(\alpha;\nu)$ for all $\mu'' < \mu$. Since f, $\{b_{\mu''} : \mu'' < \mu\} \in N_{\alpha,\xi}$, it follows that $Z^-_\mu \in N_{\alpha,\xi}$. So $Z^-_\mu \cap \overline{A} - \{a_{\mu'} : \mu' < \mu\}$ is not in $\hat{I}_{\alpha,\xi}$, so we can choose α_μ from it.

Then choose b_μ similarly using $f^{\uparrow}(\xi;\nu)$ in the role of $f^{\downarrow}(\alpha;\nu)$ and $I_{\alpha,\xi}$ instead of $\hat{I}_{\alpha,\xi}$ and taking care to make $f(a_{\mu'}, b_\mu) = \nu$ for $\mu' \leq \mu$. ⊣

8.2. Successors of Singular Cardinals

In this subsection we investigate the following question.

8.14 Question. Assume κ is a singular strong limit cardinal and $\gamma < \kappa$. Under what circumstances does the following partition relation hold?

$$(*) \qquad \binom{\kappa^+}{\kappa} \to \binom{\kappa}{\kappa}^{1,1}_{\gamma}.$$

The problem was isolated in Problem 11 of [18], where it was asked if $(*)$ holds for $\kappa = \aleph_{\omega_1}$ under GCH. In the same paper, it was proved that $(*)$ holds provided $\mathrm{cf}(\kappa) = \omega$, but we omit the proof of this fact.

After about thirty years, a shocking partial result was proved by Shelah.

8.15 Theorem (Shelah [58]). *Assume κ is a singular strong limit cardinal of uncountable cofinality. Then $(*)$ holds if $2^\kappa > \kappa^+$.*

For another proof of this result, see Kojman [34]. A little extra information is contained in an unpublished result of Foreman, which we prove here using the result of Shelah.

8.16 Theorem (Foreman unpublished). *Suppose that κ is a singular strong limit cardinal in V and $(2^\kappa)^V > (\kappa^+)^V$. Then there is a κ-complete partial order P which satisfies the $(2^\kappa)^+$-chain condition so that*

$$V^P \models 2^\kappa = \kappa^+ \quad \text{and} \quad \binom{\kappa^+}{\kappa} \to \binom{\kappa}{\kappa}^{1,1}_{\gamma} \quad \text{for } \gamma < \kappa.$$

Proof. We can choose for P the κ^+-complete Levy collapse of $2^{<\kappa}$ to κ^+. For every $p \in P$ and every name for a partition $\dot{f}$, we can define in V a decreasing sequence $\langle p_\alpha \mid \alpha < \kappa^+\rangle$ of conditions and a function $g : \kappa^+ \times \kappa \to \gamma$ such that $p_0 = p$ and

$$\forall \alpha < \kappa^+ \; \forall \beta \leq \alpha \; \forall \xi < \kappa p_\alpha \Vdash \dot{f}(\beta, \xi) = g(\beta, \xi).$$

By Theorem 8.15, we can choose A, B such that $A \times B$ is homogeneous for g and $|A| = |B| = \kappa$. For some $\alpha < \kappa$, we have $A, B \subseteq \alpha$ and then

$$p_\alpha \Vdash \exists A \; \exists B(|A| = |B| = \kappa \wedge A \times B \text{ is homogeneous for } \dot{f}).$$

Hence V^P satisfies the claim. $\dashv$

All other problems remain unsolved, even for $\gamma = 2$. For notational convenience, for the rest of this section let $\mu = \mathrm{cf}(\kappa)$. We may assume that $\mu > \omega$, and we will embark on a lengthy proof of a mild strengthening of the result of Shelah.

8.17 Theorem. *Suppose that κ is a singular strong limit cardinal of uncountable cofinality μ. Then $(**)$ holds if $2^\kappa > \kappa^+$:*

$$(**) \qquad \binom{\kappa^+}{\kappa} \to \binom{\kappa+1}{\kappa}_\gamma .$$

The proof we are going to describe will be a double ramification, quite similar in structure to the proof of Theorem 8.2 and different from the simplified proof of Theorem 8.15 in Kojman [34].

8.18 Definition. Choose $\vec{\kappa} = \langle \kappa_\nu : \nu < \mu\rangle$ to be an increasing continuous sequence of cardinals satisfying the following properties:

1. $\sup(\{\kappa_\nu : \nu < \mu\}) = \kappa$;
2. $\mu < \kappa_0$; and
3. $2^{\kappa_\nu} < \kappa_{\nu+1} = \mathrm{cf}(\kappa_{\nu+1})$ for $\nu < \mu$.

We use results of Shelah's pcf theory [57] (see also the Abraham-Magidor chapter in this Handbook) to guarantee the existence of the sequence delineated in the next definition.

8.19 Definition. Choose $\vec{\lambda} = \langle \lambda_\nu : \nu < \mu\rangle$ to be an increasing sequence of regular cardinals with $\kappa_\nu < \lambda_\nu < \kappa$ for $\nu < \mu$ such that the product $\Pi := \prod_{\nu<\mu} \lambda_\nu$ satisfies

$$(\forall \{\varphi_\alpha : \alpha < \kappa^+\} \subseteq \Pi)(\exists \varphi \in \Pi)(\forall \alpha < \kappa^+)(\varphi_\alpha \prec \varphi)$$

where $\prec$ is the relation of eventual domination on Π.

We now choose a sequence of models to serve as the skeleton of a double ramification.

8.20 Definition. Let $A := \mu \cup \{\mu, f, \vec{\kappa}, \vec{\lambda}\}$. Using Facts 3.2, we can choose an increasing chain $\langle\langle N_\alpha, \in\rangle : \alpha < \kappa^+\rangle$ of elementary submodels of $H(\kappa^{++})$ with $A \in N_0$ such that

$$S_0 := \{\alpha < \kappa^+ : \alpha(N_\alpha) = \alpha > \kappa \wedge \mathrm{cf}(\alpha) = \mu \wedge N_\alpha \text{ is suitable for } \kappa\}$$

is a club in S_{μ,κ^+}. As in Definition 3.4, we define

$$I_\alpha := \{X \subseteq \alpha^+ : \exists Y\ (Y \subseteq \kappa^+ \wedge Y \in N_\alpha \wedge \alpha \notin Y \wedge |X - Y| < \kappa)\},$$

and note that since κ is singular, the last condition may no longer be replaced by $X \subseteq Y$.

8.21 Facts. The following statements hold.

1. I_α is a μ-complete proper ideal for all $\alpha \in S_0$;
2. for every stationary $S \subseteq S_0$, there is some $\alpha \in S$ so that $S \cap \alpha \notin I_\alpha$;
3. for every $\alpha \in S_0$, every $X \in \mathcal{P}(\alpha) - I_\alpha$ and every $\tau < \kappa$, there is some $W \subseteq X$ with $|W| = \tau$ so that $W \in N_\alpha$.

Proof. The first item follows from Lemma 3.6, and the second from Corollary 4.8. To see that the third item holds, fix $\alpha \in S_0$, and assume $X \in \mathcal{P}(\alpha) - I_\alpha$. By the definition of I_α, we have $|X| \geq \kappa$. Let $\tau < \kappa$ be given. Since $\mathrm{cf}(\kappa) = \mu < \kappa$, there is a $\beta < \alpha$ with $|X \cap \beta| \geq \tau$. Since $N_\alpha \prec H(\kappa^{++})$ and $\beta \in N_\alpha$, there is some U in N_α with $|U| < \kappa$ and $|X \cap U| \geq \tau$. Then any $W \subseteq X \cap U$ with $|W| = \tau$ satisfies the requirement of the item since $|\mathcal{P}(U)| < \kappa$ and therefore $\mathcal{P}(U) \subseteq N_\alpha$. ⊣

For notational convenience, we use the same names for our double ramification system here as in the proof of Theorem 8.2.

8.22 Definition (Double ramification). For each $\alpha \in S_0$, we choose $<_\alpha$, a well-ordering of type κ of N_α. Choose $\mathcal{N} = \langle N_{\alpha,\nu} : \alpha < \kappa^+ \wedge \nu < \mu\rangle$ for the skeleton chosen above so that for $\alpha \in S_0$, the sequence $\langle N_{\alpha,\nu} : \nu < \mu\rangle$ is increasing, continuous and internally approachable and satisfies the following conditions:

1. $A \in N_{\alpha,0}$;
2. $\kappa_\nu \subseteq N_{\alpha,\nu}$, $|N_{\alpha,\nu}| = \kappa_\nu$, and $N_{\alpha,\nu}$ contains the νth section of $N_{\alpha,\nu}$ in the well-ordering $<_\alpha$ for each $\nu < \mu$.

Next we relativize certain important sets to the submodels of the double ramification system.

Notation. For each $\alpha \in S_0$, define the set $X_{\alpha,\nu} := N_{\alpha,\nu} \cap \lambda_\nu$ for $\nu < \mu$ and the function $\varphi_\alpha : \mu \to \kappa$ so that $\varphi_\alpha(\nu) := \sup(X_{\alpha,\nu})$.

The following facts follow from Definition 8.19 of Π and $\vec{\lambda}$.

8.23 Lemma. *For every $\alpha \in S_0$, the function φ_α is in Π, and there is a function $\varphi \in \Pi$ which eventually dominates all the φ_α for $\alpha \in S_0$. That is, for each $\alpha \in S_0$, there is some $\nu_\alpha < \mu$, so that $\varphi_\alpha(\nu) < \varphi(\nu)$ for all ν with $\nu_\alpha \leq \nu < \mu$.*

For the remainder of this section, fix a function φ which eventually dominates all the φ_α for $\alpha \in S_0$, and let ν_α as above be the point at which domination sets in.

8.24 Definition. For $\alpha \in S_0$ and ν with $\nu_\alpha \leq \nu < \mu$, define

$$I_{\alpha,\nu} := \{X \subseteq \nu : \exists Y\ (Y \subseteq \lambda \wedge Y \in N_{\alpha,\nu} \wedge \varphi(\nu) \notin Y \wedge |X - Y| < \kappa_\nu)\}.$$

8.25 Lemma. *Let $\alpha \in S_0$ and ν with $\nu_\alpha \leq \nu < \mu$ be given. Then*

1. *$I_{\alpha,\nu}$ is a proper ideal;*
2. *for each $X \subseteq X_{\alpha,\nu}$ with $X \in I^+_{\alpha,\nu}$, there is a $W \subseteq X$ with $|W| = \kappa_\nu$ so that $W \in N_{\alpha,\nu+1}$.*

Proof. For the first item, note that the set $I_{\alpha,\nu}$ is an ideal because $N_{\alpha,\nu}$ is closed with respect to finite unions. To see that $X_{\alpha,\nu} \notin I_{\alpha,\nu}$, let $Z \in N_{\alpha,\nu}$ be a subset of λ_ν with $\varphi(\nu) \in Z$. It is enough to show $|Z \cap X_{\alpha,\nu}| \geq \kappa_\nu$. Now $Z \in N_{\alpha,\nu}$ and $\sup(Z) \in N_{\alpha,\nu}$. Hence $\sup(Z) = \lambda_\nu$. Thus there is a one-to-one function $g : \kappa_\nu \to Z$. Using the fact that κ_ν and λ_ν are in $N_{\alpha,\nu}$, by elementarity, there is a function $g \in N_{\alpha,\nu}$ like this. Using the fact that $\kappa_\nu + 1 \subseteq N_{\alpha,\nu}$, we get that $\operatorname{ran}(g) \subseteq N_{\alpha,\nu} \cap \lambda_\nu = X_{\alpha,\nu}$.

For the second item, there is a subset $W \subseteq X$ with $|W| = \kappa_\nu$ by Definition 8.24. Also, by Definition 8.22, we know that $X_{\alpha,\nu} \in N_{\alpha,\nu+1}$, $2^{\kappa_\nu} < \kappa_{\nu+1}$ and $\mathcal{P}(X_{\alpha,\nu}) \subseteq N_{\alpha,\nu+1}$. Therefore $W \in N_{\alpha,\nu+1}$ as required. ⊣

Recall the notation $f^\downarrow(\alpha; i)$ introduced after Lemma 8.8:

$$f^\downarrow(\alpha; i) := \{\xi < \kappa : f(\alpha, \xi) = i\} \quad \text{for } \alpha < \kappa^+,\ i < \gamma.$$

Using the facts that $\gamma, \omega < \mu$ and $2^\mu < \kappa$, we can show directly that

$$\binom{\kappa^+}{\mu} \to \binom{\operatorname{Stat}(\kappa^+)}{\operatorname{Stat}(\mu)}^{1,1}_{\gamma}.$$

We get the next lemma by applying this partition relation to the coloring $f \circ \varphi$ of $\kappa^+ \times \mu$.

8.26 Lemma. *There are $S \subseteq S_0$, $T \subseteq \mu$, $\overline{\nu} < \mu$ and $i < \gamma$ such that $S \in \operatorname{Stat}(\kappa^+)$, $T \in \operatorname{Stat}(\mu)$, $\overline{\nu} \cap T = \emptyset$, φ“$T \subseteq f^\downarrow(\alpha; i)$ and $\nu_\alpha = \overline{\nu}$ for all $\alpha \in S$.*

We now prove our main claim.

8.27 Lemma (Main Claim). *There is an $\alpha \in S$ such that $S \cap \alpha \notin I_\alpha$ and*

$$\{\nu \in T : f^{\downarrow}(\alpha; i) \cap X_{\alpha,\nu} \notin I_{\alpha,\nu}\} \in \mathrm{Stat}(\mu).$$

Proof. By Corollary 4.8, it is sufficient to see that

$$\{\alpha \in S : \{\nu \in T : f^{\downarrow}(\alpha; i) \cap X_{\alpha,\nu} \notin I_{\alpha,\nu}\} \in \mathrm{Stat}(\mu)\} \in \mathrm{Stat}(\kappa^+).$$

Let $T_\alpha := \{\nu \in T : f^{\downarrow}(\alpha, i) \cap X_{\alpha,\nu} \in I_{\alpha,\nu}\}$ for $\alpha \in S$. Assume by way of contradiction that for some $S' \in \mathrm{Stat}(\kappa^+) \cap \mathcal{P}(S)$, one has $T_\alpha \in \mathrm{Stat}(\mu)$ for all $\alpha \in S'$.

For $\alpha \in S'$, $\nu \in T_\alpha$, choose $Y_{\alpha,\nu}$ satisfying the following conditions: $Y_{\alpha,\nu} \subseteq \lambda_\nu$, $Y_{\alpha,\nu} \in N_{\alpha,\nu}$, $\varphi(\nu) \notin Y_{\alpha,\nu}$, and $|f^{\downarrow}(\alpha; i) \cap X_{\alpha,\nu} - Y_{\alpha,\nu}| < \kappa_\nu$. For each $\alpha \in S'$, by Fodor's Theorem, the sets $Y_{\alpha,\nu}$ stabilize on a stationary subset of T_α. That is, for each $\alpha \in S'$, there are $T'_\alpha \subseteq T_\alpha$ with $T'_\alpha \in \mathrm{Stat}(\mu)$, Y_α and $\rho_\alpha < \kappa$ such that $Y_{\alpha,\nu} = Y_\alpha$ and $|f^{\downarrow}(\alpha; i) \cap X_{\alpha,\nu} - Y_{\alpha,\nu}| \leq \rho_\alpha$ for $\nu \in T'_\alpha$ and

$$Y_\alpha \cap \{\varphi(\nu) : \nu \in T'_\alpha\} = \emptyset.$$

Note that $\bigcup\{X_{\alpha,\nu} : \nu \in T'_\alpha\} = \kappa$, hence

$$|f^{\downarrow}(\alpha; i) - Y_\alpha| \leq \rho_\alpha.$$

Now, using Fodor's Theorem again, Y_α stabilizes on a stationary subset of S'. That is, there are $T' \in \mathrm{Stat}(\mu)$, Y and ρ such that for some $S'' \in \mathrm{Stat}(\kappa^+) \cap \mathcal{P}(S')$, one has $T'_\alpha = T'$, $Y_\alpha = Y$ and $\rho_\alpha = \rho$ for all $\alpha \in S''$.

Now choose two elements $\alpha', \beta' \in S''$ with $\alpha' < \beta'$, and let $\nu' \in T'$ be such that $\beta' \in N_{\alpha',\nu'}$ and $\kappa_{\nu'} > \rho$. Since $\alpha' \in S'' \subseteq S$ and $\nu' \in T' \subseteq T$, it follows that $f(\beta', \varphi(\nu')) = i$ by Lemma 8.26. In other words, $\varphi(\nu') \in f^{\downarrow}(\beta'; i)$. However, $f^{\downarrow}(\beta'; i) \in N_{\alpha',\nu'}$, hence

$$f^{\downarrow}(\beta'; i) \cap X_{\alpha',\nu'} \notin I_{\alpha',\nu'}.$$

This last fact contradicts the inequality $|f^{\downarrow}(\beta'; i) - Y| < \rho$ and the lemma follows. $\dashv$

To finish the proof of Theorem 8.17 using the Main Claim 8.27, we want to define sequences $\langle A_\xi : \xi < \mu\rangle$ with $A_\xi \subseteq \kappa$ and $\langle B_\xi : \xi < \mu\rangle$ with $B_\xi \subseteq S_0$ so that the sets are pairwise disjoint, $|A_\xi| = |B_\xi| = \kappa_\xi$, $A_\xi, B_\xi \in N_{\alpha,\nu_\xi}$ for some $\nu_\xi \in T^0$, where $T^0 := \{\nu \in T : f^{\downarrow}(\alpha; i) \cap X_{\alpha,\nu} \notin I_{\alpha,\nu}\}$ is the set defined in the Main Claim 8.27, and f is constantly i on the set

$$\textstyle\bigcup_{\xi<\mu} B_\xi \cup \{\alpha\} \times \bigcup_{\xi<\mu} A_\xi.$$

To carry out an induction of length μ to define the desired sequences, we only need the following lemma.

8.28 Lemma. *Assume $A, B \in N_{\alpha,\nu}$ for some $\nu \in T^0$, $B \subseteq S$, $\rho < \kappa$, and f is homogeneous of color i on $(B \cup \{\alpha\}) \times A$. Then the following two statements hold.*

1. *There is a $C \in [\kappa - (A \cup B)]^\rho$ with $C \subseteq \bigcap\{f^\downarrow(\beta; i) : \beta \in B \cup \{\alpha\}\}$ so that for some $\nu' \in T^0$ with $\kappa_{\nu'} > \nu$, one has $C \in N_{\alpha,\nu'}$.*

2. *There is a $D \in [S - (A \cup B)]^\rho$ with $A \subseteq \bigcap\{f^\downarrow(\beta; i) : \beta \in D\}$ so that for some $\nu' \in T^0$ with $\kappa_{\nu'} > \nu$, one has $D \in N_{\alpha,\nu'}$.*

Proof. For the first item, choose $\nu' \in T^0$ with $\nu' > \nu$ and $\kappa_{\nu'} > \rho$. By the definition of S, we know $f(\beta, \varphi(\nu')) = i$ for $\beta \in B \cup \{\alpha\}$. By the Main Claim 8.27, we know that $f^\downarrow(\alpha; i) \cap X_{\alpha,\nu'} \notin I_{\alpha,\nu'}$. Let $Z = \bigcap\{f^\downarrow(\beta; i) : \beta \in B\}$. Then $Z \in N_{\alpha,\nu'}$ and $\varphi(\nu') \in Z$. Hence $|Z \cap f^\downarrow(\alpha; i) \cap X_{\alpha,\nu'}| \geq \rho$ by Lemma 8.25, and we can choose a subset of this intersection for C.

For the second item, the set $Z := \bigcap\{f^\uparrow(\eta; i) : \eta \in A\}$ is in $N_{\alpha,\nu}$ and $\alpha \in Z$. Since $S \cap \alpha \notin I_\alpha$, we can choose a suitable D by Facts 8.21. $\dashv$

9. Countable Ordinal Resources

9.1. Some History

In this section we look at ordinal partition relations of the form $\alpha \to (\beta, m)^2$ for limit ordinals α and β of the same cardinality. The goal m will be taken to be finite, since if $\pi : \alpha \to |\alpha|$ is a one-to-one mapping, then the partition defined on pairs $x < y < \alpha$ by

$$f(x, y) = \begin{cases} 0, & \text{if } x < y \text{ and } \pi(x) < \pi(y), \\ 1, & \text{if } x < y \text{ and } \pi(x) > \pi(y) \end{cases}$$

shows that $\alpha \not\to (|\alpha| + 1, \omega)^2$.

This particular branch of the partition calculus dates back to the 1950's, in particular to the seminal paper of Erdős and Rado [17] which introduced the partition calculus for linear order types and to the paper of Ernst Specker [62], in which he proves the following theorem.

9.1 Theorem (Specker [62]). *The following partition relations hold:*

1. *$\omega^2 \to (\omega^2, m)^2$ for all $m < \omega$;*

2. *$\omega^n \not\to (\omega^n, 3)^2$ for all $3 \leq n < \omega$.*

The finite powers of ω are all *additively indecomposable* (AI), since they cannot be written as the sum of two strictly smaller ordinals. It is well-known that the additively indecomposable ordinals are exactly those of the form ω^γ (see Exercise 5 on page 43 of Kunen [36]). We will focus on additively indecomposable α and β. There are additional combinatorial complications for decomposable ordinals.

For notational convenience in discussions of $\alpha \to (\beta, m)^2$, call α the *resource*, β the 0-*goal* and m the 1-*goal*.

For a specified countable 0-goal β and finite 1-goal m, it is possible to determine an upper bound for the resource α needed to ensure that the positive partition relation holds. In particular, Erdős and Milner showed $\omega^{1+\mu m} \to (\omega^{1+\mu}, 2^m)^2$. This result dates back to 1959 and a proof appeared in Milner's thesis in 1962. See also pages 165–168 of [65] where the proof is given via the following stepping up result:

9.2 Theorem. *Suppose γ, δ are countable and k is finite. If $\omega^\gamma \to (\omega^{1+\delta}, k)^2$, then $\omega^{\gamma+\delta} \to (\omega^{1+\delta}, 2k)^2$.*

9.3 Corollary (Erdős and Milner [14]). *If $m < \omega$ and $\mu < \omega_1$, then $\omega^{1+\mu\cdot\ell} \to (\omega^{1+\mu}, 2^\ell)^2$.*

The partition calculus for finite powers of ω is largely understood via the results below of Nosal. Her work built on Corollary 9.3 and earlier work by Galvin (unpublished), Hajnal, Haddad and Sabbagh [24], Milner [42].

9.4 Theorem (Nosal [46, 47]).

1. *If $1 \le \ell < \omega$, then $\omega^{2+\ell} \to (\omega^3, 2^\ell)^2$ and $\omega^{2+\ell} \not\to (\omega^3, 2^\ell + 1)^2$.*
2. *If $1 \le \ell < \omega$ and $4 \le r < \omega$, then $\omega^{1+r\cdot\ell} \to (\omega^{1+r}, 2^\ell)^2$ and $\omega^{r+r\cdot\ell} \not\to (\omega^{1+r}, 2^\ell + 1)^2$.*

Some progress has been made for the case in which the goal is ω^4. Nosal showed in her thesis that $\omega^6 \not\to (\omega^4, 3)^2$, which is sharp, since $\omega^7 \to (\omega^4, 4)^2$ by Corollary 9.3. Darby (unpublished) has shown that $\omega^9 \not\to (\omega^4, 5)^2$.

9.2. Small Counterexamples

In this section we look at partition relations of the form $\alpha \not\to (\alpha, m)^2$ for limit ordinals α and $m < \omega$.

In the previous section, we noted that Specker proved that $\omega^n \not\to (\omega^n, 3)^2$. In the 1970's, Galvin used *pinning*, defined below, to exploit the counterexample $\omega^3 \not\to (\omega^3, 3)^2$ to the full.

9.5 Definition. Suppose α and β are ordinals. A mapping $\pi : \alpha \to \beta$ is a *pinning map of α to β* if $\mathrm{ot}(X) = \alpha$ implies $\mathrm{ot}(\pi``X) = \beta$ for all $X \subseteq \alpha$. We say *α can be pinned to β*, in symbols, $\alpha \to \beta$, if there is a pinning map of α to β.

9.6 Theorem (Galvin [22]). *For all countable ordinals $\beta \geq 3$, if β is not* AI *and $\alpha = \omega^\beta$, then $\alpha \not\to (\alpha, 3)^2$.*

The first countable ordinal not covered by the Specker and Galvin results mentioned so far is ω^ω. Chang showed that $\omega^\omega \to (\omega^\omega, 3)^2$ and Milner modified his proof to work for all $m < \omega$.

9.7 Theorem (Chang [5]; Milner; see also [38, 65]). *For all $m < \omega$,*

$$\omega^\omega \to (\omega^\omega, m)^2.$$

Chang's original manuscript was about 90 pages long, and he received \$250 from Erdős for this proof, one of the largest sums Erdős had paid to that time. Erdős continued to focus attention on partition relations of the form $\alpha \to (\alpha, m)^2$ through offering money. In 1985, he [11] offered \$1000 for a complete characterization of those countable α for which $\alpha \to (\alpha, 3)^2$.

9.8 Definition. Any ordinal α can be uniquely written as the sum of AI ordinals, $\alpha = \alpha_0 + \cdots + \alpha_k$ with $\alpha_0 \geq \cdots \geq \alpha_k$. This sum is called the *additive normal form* (ANF) of α, and in this case, we say *the* ANF *of α has $k+1$ summands.* The summand α_k is called the *final summand.* The *initial part of the* ANF *of α* is $\alpha_0 + \cdots + \alpha_{k-1}$ if $k > 0$ and, for notational convenience, is 0 if α is AI.

An AI ordinal α is *multiplicatively indecomposable* (MI) if it is cannot be written as a product $\gamma \cdot \delta$ where γ, δ are AI and $\alpha > \gamma \geq \delta$. Any AI ordinal α can be written uniquely as a product of MI ordinals $\alpha = \alpha_0 \cdot \cdots \cdot \alpha_k$ with $\alpha_0 \geq \cdots \geq \alpha_k$. This product is called the *multiplicative normal form* (MNF) of α, and in this case, we say *the* MNF *of α has $k+1$ factors.* The factor $\widehat{\alpha} := \alpha_k$ is called the *final factor.* The *initial part of the* MNF *of α* is $\overline{\alpha} := \alpha_0 + \cdots + \alpha_{k-1}$ if $k > 0$ and, for notational convenience, is $\overline{\alpha} := 1$ if α is MI.

Note that if $\alpha = \omega^\beta$, then α is MI exactly when β is AI. Thus Galvin's result (Theorem 9.6) may be rephrased to say that for all countable ordinals $\alpha > \omega^2$, if α is not MI, then $\alpha \not\to (\alpha, 3)^2$. In the 1990's, Darby [7] and Schipperus [53, 51], working independently, came up with new families of counterexamples for MI ordinals α. Larson [39] built on their work to improve one of the results obtained by both of them.

9.9 Theorem.

1. (Darby) *If $\beta = \omega^{\alpha+1}$ and $m \to (4)^3_{2^{32}}$, then $\omega^{\omega^\beta} \not\to (\omega^{\omega^\beta}, m)^2$.*
2. (Darby; Schipperus; Larson) *If $\beta \geq \gamma \geq 1$, then $\omega^{\omega^{\beta+\gamma}} \not\to (\omega^{\omega^{\beta+\gamma}}, 5)^2$.*
3. (Darby; Schipperus) *If $\beta \geq \gamma \geq \delta \geq 1$, then $\omega^{\omega^{\beta+\gamma+\delta}} \not\to (\omega^{\omega^{\beta+\gamma+\delta}}, 4)^2$.*
4. (Schipperus) *If $\beta \geq \gamma \geq \delta \geq \varepsilon \geq 1$, then $\omega^{\omega^{\beta+\gamma+\delta+\varepsilon}} \not\to (\omega^{\omega^{\beta+\gamma+\delta+\varepsilon}}, 3)^2$.*

We plan to sketch a proof that there is some finite k so that $\omega^{\omega^2} \not\to (\omega^{\omega^2}, k)^2$, using the basic approach developed by Darby and some of his construction lemmas. Surprisingly, the partition counterexamples developed by Darby and Schipperus were the same, even if their approaches to uniformization were at least cosmetically different.

Rather than working directly with the ordinals, we use collections of finite increasing sequences from ω under the lexicographic ordering. Since our sequences are increasing, we will identify them with the set of their elements.

We write $\mathbf{s}^\frown\mathbf{t}$ for the concatenation of the two sequences under the assumption that the last element of $\mathbf{s}$ is smaller than the first element of $\mathbf{t}$, in symbols $\mathbf{s} < \mathbf{t}$.

We extend the notion of concatenation from individual sequences to sets of sequences by setting

$$S^\frown T := \{\mathbf{s}^\frown\mathbf{t} \mid \mathbf{s} \in S \wedge \mathbf{t} \in T \wedge \mathbf{s} < \mathbf{t}\}.$$

9.10 Definition. Define sets G_α for $\alpha = \omega^\ell$ by recursion on $1 \leq \ell < \omega$.

$$G_\omega := \{\langle m\rangle^\frown\langle k_1, k_2, \dots, k_m\rangle \mid m < k_1 < k_2 < \cdots < k_m < \omega\},$$

$$G_{\omega^{k+1}} := \bigcup\Big\{\{\langle m\rangle\}^\frown\overbrace{G_{\omega^k}{}^\frown \cdots {}^\frown G_{\omega^k}}^{m \text{ copies}} \mid m < \omega\Big\}.$$

Given a collection of sequences S and a particular sequence t, write $S(t) := \{s \in S \mid t \sqsubseteq s\}$ for the set of extensions of t in S.

9.11 Lemma. *For $1 \leq \ell, m, p < \omega$, $\mathrm{ot}(G_{\omega^\ell}(\langle m\rangle)) = (\omega^{\omega^{\ell-1}})^m$, $\mathrm{ot}(G_{\omega^\ell}) = \omega^{\omega^\ell}$, and*

$$\mathrm{ot}\Big(\overbrace{G_{\omega^\ell}{}^\frown \cdots {}^\frown G_{\omega^\ell}}^{p \text{ copies}}\Big) = (\omega^{\omega^\ell})^p.$$

Proof. First observe that $\mathrm{ot}(G_\omega(\langle m\rangle)) = \omega^m$ for all $1 \leq m < \omega$ and $\mathrm{ot}(G_\omega) = \omega^\omega$. Next notice that for subsets S and $T \subseteq [\omega]^{<\omega}$ which have indecomposable order types and which have arbitrarily large first elements, the order type of the concatenation $S^\frown T$ is the product of the order types $\mathrm{ot}(T) \cdot \mathrm{ot}(S)$. Then use induction on ℓ, m, and p. ⊣

9.12 Remark. Darby [7, Definition 2.8] defines G_α for all $\alpha < \omega_1$ so that $\mathrm{ot}(G_\alpha) = \omega^\alpha$ using a nice ladder system to assign to each limit ordinal an increasing cofinal sequence of type ω. In particular, for $\alpha = \overline{\alpha} \cdot \omega$ where $\overline{\alpha}$ is an AI ordinal, the cofinal sequence is $\alpha_m = \overline{\alpha} \cdot m$.

Our main interest is in G_α for α AI. We defined G_{ω^k} for $k < \omega$ in Definition 9.10. If $\alpha = \overline{\alpha} \cdot \omega$ where $\overline{\alpha}$ is an AI ordinal, then

$$G_\alpha = \bigcup\Big\{\{\langle m\rangle\}^\frown\overbrace{G_{\overline{\alpha}}{}^\frown \cdots {}^\frown G_{\overline{\alpha}}}^{m \text{ copies}} \mid m < \omega\Big\}.$$

If $\alpha \geq \omega^\omega$ is an AI ordinal not of the form $\alpha = \overline{\alpha}\cdot\omega$, then the cofinal sequence is a strictly increasing sequence $\langle \alpha_m : m < \omega\rangle$ of AI ordinals and G_α is the union of $\{\langle m\rangle\}^\frown G_{\alpha_m}$.

Recall we write $\mathbf{s} \sqsubseteq \mathbf{t}$ to indicate that $\mathbf{s}$ is an *initial segment* of $\mathbf{t}$, and $\mathbf{s} \sqsubset \mathbf{t}$ to indicate it is a *proper initial segment.*

9.13 Definition. For any collection of increasing sequences $S \subseteq [\omega]^{<\omega}$, let S^* denote the collection of initial segments of elements of S. For any $\mathbf{s} \in S^*$, let $S(\mathbf{s}) := \{\mathbf{t} \in S \mid \mathbf{s} \sqsubseteq \mathbf{t}\}$ be the set of all extensions of $\mathbf{s}$ that are in S.

9.14 Definition (See Definition 3.1 of [7]). Suppose $\omega < \alpha = \overline{\alpha}\cdot\widehat{\alpha} < \omega_1$ is AI but not MI with initial part $\overline{\alpha}$ and final factor $\widehat{\alpha}$. Call a non-empty sequence $\mathbf{p} \in G^*_\alpha$ a *level prefix of* G_α if $\mathrm{ot}(G_\alpha(\mathbf{p})) = \omega^\gamma$ where the final summand in the ANF of γ is $\overline{\alpha}$.

The next lemma is of particular interest when $\mathbf{s}$ is a level prefix.

9.15 Lemma (See Lemma 2.9 of [7]). *Suppose $\gamma \leq \alpha < \omega_1$ where the* ANF *of γ is $\gamma = \gamma_0 + \gamma_1 + \cdots + \gamma_k$ for $k > 0$. Further suppose that $\mathbf{s} \in G^*_\alpha \setminus \{\emptyset\}$. If* $\mathrm{ot}(G_\alpha(\mathbf{s})) = \omega^\gamma$*, then $G_\alpha(\mathbf{s}) = \{\mathbf{s}\}^\frown G_{\gamma_k}{}^\frown \cdots {}^\frown G_{\gamma_0}$.*

Proof. We only prove this in the special case where $\alpha = \overline{\alpha}\cdot\omega$ and $\gamma = \overline{\alpha}\cdot n$. In this case, $\mathbf{s}$ has an extension in $G_\alpha(\langle m\rangle) = \{\langle m\rangle\}^\frown G_{\overline{\alpha}}{}^\frown \cdots {}^\frown G_{\overline{\alpha}}$ for $m = \min(\mathbf{s})$ by Definition 9.10 or Remark 9.12. Let $\mathbf{t} \sqsubseteq \mathbf{s}$ be the longest initial segment of $\mathbf{s}$ for which $G_\alpha(\mathbf{t})$ is the concatenation of $\{\mathbf{t}\}$ with some finite number of copies of $G_{\overline{\alpha}}$. There must be such a $\mathbf{t}$ since $\langle m\rangle$ has this property. If $\mathbf{s} = \mathbf{t}$, then we are done. So assume by way of contradiction that $\mathbf{u} = \mathbf{s} \setminus \mathbf{t} \neq \emptyset$. By the maximality of $\mathbf{t}$, it follows that $\mathbf{u} \in G^*_{\overline{\alpha}} \setminus G_{\overline{\alpha}}$. Since $\mathbf{u} \neq \emptyset$, $G_{\overline{\alpha}}(\mathbf{u})$ has order type δ for some $\delta < \omega^{\overline{\alpha}}$ with $\delta > 1$. Let r be the number of copies of $G_{\overline{\alpha}}$ in the decomposition of $G_\alpha(\mathbf{t})$. If $r = 1$, then $G_\alpha(\mathbf{s}) = \{\mathbf{t}\}^\frown G_{\overline{\alpha}}(\mathbf{u})$ has order type $\delta < \omega^{\overline{\alpha}}$. If $r > 1$, then $G_\alpha(\mathbf{s})$ is the concatenation of $\{\mathbf{t}\}^\frown G_{\overline{\alpha}}(\mathbf{u})$ with $r-1$ copies of $G_{\overline{\alpha}}$, so has order type $\omega^{\overline{\alpha}\cdot(r-1)}\cdot\delta$, by the argument of Lemma 9.11. In both cases, since $\delta \neq 1$ and $\delta \neq \omega^{\overline{\alpha}}$, we have a contradiction to the assumption that $\mathrm{ot}(G_\alpha(\mathbf{s})) = \omega^{\overline{\alpha}\cdot n}$. $\dashv$

9.16 Definition (See Definition 3.1 of [7]). Suppose the MNF of $\alpha < \omega_1$ has at least four factors. Call $\mathbf{t} \in G^*_\alpha$ a *sublevel prefix of* G_α if there are a level prefix $\mathbf{p}$ for G_α and a level prefix $\mathbf{q}$ for $G_{\overline{\alpha}}$ so that $\mathbf{t} = \mathbf{p}^\frown\mathbf{q}$. Call $\mathbf{u} \in G^*_\alpha$ a *sub-sublevel prefix of* G_α if there are a sublevel prefix $\mathbf{t}$ for G_α and a level prefix $\mathbf{r}$ for $G_{\overline{\overline{\alpha}}}$ so that $\mathbf{u} = \mathbf{t}^\frown\mathbf{r}$.

If we look at a pair $s \leq_{\mathrm{lex}} t$ from G_α, if s and t are disjoint as sets, then they partition one another into convex segments. That is, s and t can be expressed as concatenations, $s = s_0{}^\frown s_1{}^\frown \cdots {}^\frown s_{n-1}({}^\frown s_n)$ and $t = t_0{}^\frown t_1{}^\frown \cdots {}^\frown t_{n-1}$ where $s_0 < t_0 < s_1 < t_1 < \cdots < s_{n-1} < t_{n-1} (< s_n)$.

The next definition uses Definition 9.16 to identify four types of segments used in the proofs of the negative partition relations 2–4 of Theorem 9.9.

9.17 Definition. Suppose the MNF of $\alpha < \omega_1$ has at least four factors. Further suppose that $\mathbf{s} \in G_\alpha$ has been decomposed into a convex partition $\mathbf{s} = \mathbf{s}_0{}^\frown\mathbf{s}_1{}^\frown \cdots {}^\frown\mathbf{s}_n$ where $\mathbf{s}_0 < \mathbf{s}_1 < \cdots < \mathbf{s}_n$.

1. Call $\mathbf{s}_i$ a $\square$-*segment of* $\mathbf{s}$ if $i = 0$ or $i = n$ or there are a level prefix $\mathbf{t}$ of G_α and $\mathbf{a} \in G_{\overline{\alpha}}$ so that $\mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1} \sqsubset \mathbf{t} \sqsubset \mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1}{}^\frown\mathbf{s}_i \sqsubseteq \mathbf{t}^\frown\mathbf{a}$.

2. Call $\mathbf{s}_i$ a $\triangle$-*segment of* $\mathbf{s}$ if it is not a $\square$-segment of $\mathbf{s}$ and there are a sublevel prefix $\mathbf{u}$ of G_α and $\mathbf{b} \in G_{\overline{\overline{\alpha}}}$ so that $\mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1} \sqsubset \mathbf{u} \sqsubset \mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1}{}^\frown\mathbf{s}_i \sqsubseteq \mathbf{u}^\frown\mathbf{b}$.

3. Call $\mathbf{s}_i$ a $\blacksquare$-*segment of* $\mathbf{s}$ if it is not a $\square$ or $\triangle$-segment of $\mathbf{s}$ and there are a sub-sublevel prefix $\mathbf{u}$ of G_α and $\mathbf{c} \in G_{\overline{\overline{\overline{\alpha}}}}$ so that $\mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1} \sqsubset \mathbf{v} \sqsubset \mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1}{}^\frown\mathbf{s}_i \sqsubset \mathbf{v}^\frown\mathbf{c}$.

4. Call $\mathbf{s}_i$ a $\bullet$-*segment of* $\mathbf{s}$ there are a sub-sublevel prefix $\mathbf{u}$ of G_α and $\mathbf{c} \in G_{\overline{\overline{\overline{\alpha}}}}$ so that $\mathbf{v} \sqsubset \mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1}$ and $\mathbf{s}_0{}^\frown \cdots {}^\frown\mathbf{s}_{i-1}{}^\frown\mathbf{s}_i \sqsubseteq \mathbf{v}^\frown\mathbf{c}$.

For simplicity, we include an example for which only $\square$-segments are needed to illustrate the technique. We have chosen to give an example that is easy to discuss rather than an optimal one.

9.18 Proposition. *The following partition relation holds:* $\omega^{\omega^2} \not\to (\omega^{\omega^2}, 6)^2$.

The remainder of this section is devoted to the proof of Proposition 9.18. We define a graph Γ on $G = G_{\omega_2}$ below. Then in Lemma 2, we show it has no 1-homogeneous set of size 6. After considerably more work, in Lemma 9.31, we show it has no 0-homogeneous subset of order type ω^{ω^2}. These two lemmas complete the proof.

9.19 Definition. Let $G = G_{\omega^2}$. Call a coordinate x of $\mathbf{x} \in G$ a *box coordinate* if it is either the minimum or the maximum of $\mathbf{x}$ or if $x = \min(\mathbf{x} - \mathbf{p})$ for some level prefix $\mathbf{p} \sqsubseteq \mathbf{x}$. Define a graph $\Gamma : [G]^2 \to 2$ by $\Gamma(\mathbf{x}, \mathbf{y}) = 1$ if and only if there are convex partitions

$$\mathbf{x} = X_0{}^\frown X_1{}^\frown X_2{}^\frown X_3{}^\frown X_4 \quad \text{and} \quad \mathbf{y} = Y_0{}^\frown Y_1{}^\frown Y_2{}^\frown Y_3$$

with $X_0 < Y_0 < X_1 < Y_1 < X_2 < Y_2 < X_3 < Y_3 < X_4$ so that all of X_0, X_2, X_4 are $\square$-segments of $\mathbf{x}$, Y_0, Y_3 are $\square$-segments of $\mathbf{y}$, and none of X_1, X_3, Y_1, Y_2 have box coordinates of $\mathbf{x}$, $\mathbf{y}$, respectively.

For notational convenience, let $\gamma^-(\mathbf{x}, \mathbf{y}) = \max(Y_1)$, $\gamma^+(\mathbf{x}, \mathbf{y}) = \min(Y_2)$, $\delta^-(\mathbf{x}, \mathbf{y})$ be the largest box coordinate of Y_0, and $\delta^+(\mathbf{x}, \mathbf{y})$ be the smallest box coordinate of Y_3. The graphical display below shows how the two sequences are interlaced and which have box coordinates if $\Gamma(\mathbf{x}, \mathbf{y}) = 1$.

$$\begin{array}{ccccccccc} \boxed{X_0} & & X_1 & & \boxed{X_2} & & X_3 & & \boxed{X_4} \\ & \boxed{Y_0} & & Y_1 & & Y_2 & & \boxed{Y_3} & \end{array}$$

9.20 Lemma. *The graph* Γ *has no* 1*-homogeneous set of size six.*

Proof. The proof starts with a series of claims which delineate basic properties of the partition.

Claim A. Suppose $\mathbf{x} < \mathbf{y}$, $\Gamma(\mathbf{x}, \mathbf{y}) = 1$.

1. There is a box coordinate $x \in \mathbf{x}$ with $\min(\mathbf{y}) < x < \max(\mathbf{y})$.

2. For any box coordinate $x \in \mathbf{x}$ with $\min(\mathbf{y}) < x < \max(\mathbf{y})$, the inequalities $\gamma^-(\mathbf{x}, \mathbf{y}) < x < \gamma^+(\mathbf{x}, \mathbf{y})$ hold.

3. There is no sequence $x < y < x' \in \mathbf{x}$ where $\min(\mathbf{y}) < x \in \mathbf{x}$, $x' < \max(\mathbf{y})$ and y is a box coordinate of $\mathbf{y}$.

Proof. Use the diagram above to verify these basic properties. $\dashv$

Claim B. Suppose $\{\mathbf{x}, \mathbf{y}, \mathbf{z}\}_< \subseteq G$ is 1-homogeneous for Γ. If $\Box x \in \mathbf{x}$, $\Box y \in \mathbf{y}$, and $\Box z \in \mathbf{z}$ are box coordinates and $\min(\mathbf{z}) < \Box x, \Box y < \max(\mathbf{z})$, then either $\Box x, \Box y < \Box z$ or $\Box z < \Box x, \Box y$.

Proof. Suppose the hypothesis holds but the conclusion fails. Then either (a) $\Box x < \Box z < \Box y$ or (b) $\Box y < \Box z < \Box x$. Note that $\min(\mathbf{y}) < \min(\mathbf{z}) < \Box x$ and $\Box x < \max(\mathbf{z}) < \max(\mathbf{y})$, since $\mathbf{y} < \mathbf{z}$. By Claim A(2), $\gamma^-(\mathbf{x}, \mathbf{y}) < \Box x < \gamma^+(\mathbf{x}, \mathbf{y})$. Use the definition of Γ to find $x^-, x^+ \in \mathbf{x}$ such that $\delta^-(\mathbf{x}, \mathbf{y}) < x^- < \gamma^-(\mathbf{x}, \mathbf{y})$ and $\gamma^+(\mathbf{x}, \mathbf{y}) < x^+ < \delta^+(\mathbf{x}, \mathbf{y})$. If (a) holds, then either $\Box x < \Box z < x^+$ or $\gamma^+(\mathbf{x}, \mathbf{y}) < \Box z < \Box y$ is a sequence that contradicts Claim A(3). If (b) holds, then either $\Box y < \Box z < \gamma^-(\mathbf{x}, \mathbf{y})$ or $x^- < \Box z < \Box x$ is a sequence that contradicts Claim A(3). Thus the above claim follows. $\dashv$

Claim C. Suppose $\{\mathbf{x}, \mathbf{y}, \mathbf{z}\}_< \subseteq G$ is 1-homogeneous for Γ. If $\Box x \in \mathbf{x}$, $\Box y \in \mathbf{y}$ are box coordinates with $\min(z) < \Box x, \Box y < \max(z)$, then some coordinate z of $\mathbf{z}$ lies between $\Box x$ and $\Box y$.

Proof. For the first case, suppose $\Box x < \Box y$. In this case, let $z = \gamma^+(\mathbf{x}, \mathbf{z})$. Then $z \in \mathbf{z}$ and by Claim A, $\Box x < z$. By definition of Γ, there is some $x' \in \mathbf{x}$ with $z < x' < \max(\mathbf{z})$. Since $\mathbf{y} < \mathbf{z}$, it follows that $x' < \max(\mathbf{y})$, so $x' < \delta^+(\mathbf{x}, \mathbf{y}) \leq \Box y$. By transitivity, $\Box x < z < \Box y$. The second case for $\Box y < \Box x$ is left to the reader with the hint that $z = \gamma^-(\mathbf{x}, \mathbf{z})$ works. $\dashv$

Now prove the lemma from the claims. Assume by way of contradiction that $U = \{\mathbf{a}, \mathbf{b}, \mathbf{c}, \mathbf{d}, \mathbf{e}, \mathbf{f}\}_< \subseteq G$ is 1-homogeneous for Γ. Use Claim A to choose box coordinates $\varepsilon_0 \in \mathbf{a}$, $\varepsilon_1 \in \mathbf{b}$, $\varepsilon_2 \in \mathbf{c}$, $\varepsilon_3 \in \mathbf{d}$, $\varepsilon_4 \in \mathbf{e}$, so that $\min(\mathbf{f}) < \varepsilon_i < \max(\mathbf{f})$. Let $ijk\ell$ be a permutation of 0123 so that $\varepsilon_i < \varepsilon_j < \varepsilon_k < \varepsilon_\ell$. Use Claim C to choose coordinates $e', e'' \in \mathbf{e}$ and $f' \in \mathbf{f}$ with $\varepsilon_i < e' < \varepsilon_j < f' < \varepsilon_k < e'' < \varepsilon_\ell$. By Claim B, either (a) $\varepsilon_4 < \varepsilon_i$ or (b) $\varepsilon_\ell < \varepsilon_4$. Choose coordinate $f'' \in \mathbf{f}$ between ε_4 and the appropriate one of ε_i and ε_ℓ.

Let $\mathbf{x}, \mathbf{y} \in U$ be such that $\varepsilon_i \in \mathbf{x}$ and $\varepsilon_\ell \in \mathbf{y}$. By Claim A, $\delta^-(\mathbf{x}, \mathbf{f}) < \gamma^-(\mathbf{x}, \mathbf{f}) < \varepsilon_i$ and $\varepsilon_\ell < \gamma^+(\mathbf{y}, \mathbf{f}) < \delta^+(\mathbf{y}, \mathbf{f})$.

Let $\mathbf{e} = E_0{}^\frown E_1{}^\frown E_2{}^\frown E_3{}^\frown E_4$, $\mathbf{f} = F_0{}^\frown F_1{}^\frown F_2{}^\frown F_3$ be the partition that witnesses $\Gamma(\mathbf{e}, \mathbf{f}) = 1$. Note that $\varepsilon_4 \in E_2$.

If (a) holds, then $\delta^+(\mathbf{y}, \mathbf{f}) \in F_3$, and

$$\varepsilon_4 < f'' < e' < f' < e'' < \delta^+(\mathbf{y}, \mathbf{f}).$$

However, this inequality contradicts the definition of g, since there are only two blocks between E_2 and F_3. If (b) holds, then $\delta^-(\mathbf{x}, \mathbf{f}) \in F_0$, and

$$\delta^-(\mathbf{x}, \mathbf{f}) < e' < f' < e'' < f'' < \varepsilon_4.$$

This inequality also contradicts the definition of g, since there are only two blocks between F_0 and E_2. In either case we have reached the contradiction required to prove the lemma. ⊣

Now we turn to the task of showing that every subset $X \subseteq G$ of order type ω^{ω^2} includes a pair $\{\mathbf{x}, \mathbf{y}\}_< \subseteq X$ so that $\Gamma(\mathbf{x}, \mathbf{y}) = 1$. The first challenge is to guarantee that when we build a segment of one of $\mathbf{x}$ and $\mathbf{y}$, we will be able to extend it starting above the segment of the other that we will have constructed in the meanwhile. To that end, we introduce *β-prefixes* and *maximal β-prefixes.*

9.21 Definition. Suppose $\alpha < \omega_1$. Call a sequence $\mathbf{s} \in G^*_\alpha$ a *β-prefix* of $W \subseteq G_\alpha$ if $\mathrm{ot}(W(\mathbf{s})) = \beta$, and a *maximal β-prefix* if no proper extension is a β-prefix.

9.22 Lemma (Galvin; see Lemma 4.5 of [7]). *Suppose $\mathbf{s} \in G^*_\alpha$ and β is* AI. *If $W \subseteq G_\alpha$ has* $\mathrm{ot}(W(\mathbf{s})) \geq \beta$, *then there is an extension $\mathbf{t} \sqsupseteq \mathbf{s}$ so that $\mathbf{t}$ is a maximal β-prefix for W.*

The proof of the above lemma depends on the fact that the sequences in G_α are well-founded under extension. We use the next lemma for sequences $\mathbf{r}$ which are either maximal ω^2-prefixes or maximal ω^3-prefixes.

9.23 Lemma. *Suppose $\delta < \beta \leq \omega^\alpha$ for AI δ and β. Further suppose $W \subseteq G_\alpha$ and $\mathbf{r}$ is a maximal β-prefix for W. Then $\mathbf{r}$ has infinitely many one point extensions $r^\frown\langle p\rangle \in W^*$ with* $\mathrm{ot}(W(r^\frown\langle p\rangle)) \geq \delta$. *Also, for any sequence $\mathbf{s}$, there is a sequence $\mathbf{t}$ so that $\mathbf{s} < \mathbf{t}$, $\mathbf{r}^\frown\mathbf{t} \in W^*$, and $\mathbf{r}^\frown\mathbf{t}$ is a maximal δ-prefix for W.*

Proof. Since $\mathbf{r}$ is a maximal β-prefix for W, $\mathrm{ot}(W(\mathbf{r}^\frown\langle p\rangle)) < \beta$ for all $p < \omega$. Consequently, since β is AI, it follows that $\sum_{q<p<\omega} \mathrm{ot}(W(\mathbf{r}^\frown\langle p\rangle)) = \beta$ for all $q < \omega$. Since $\sum_{q<p<\omega} \gamma_p \leq \delta$ if each $\gamma_p < \delta$, it follows that for infinitely many $p < \omega$, $W(\mathbf{r}^\frown\langle p\rangle)$ has order type $\geq \delta$. Thus given $\mathbf{s}$, there is a $p > \max(\mathbf{s})$ with $\mathrm{ot}(W(\mathbf{r}^\frown\langle p\rangle)) \geq \delta$. In particular, $W(\mathbf{r}^\frown\langle p\rangle) \neq \emptyset$. To complete the proof, apply Lemma 9.22 to get $\mathbf{t} \sqsupseteq \langle p\rangle$ so that $\mathbf{r}^\frown\mathbf{t}$ is a maximal δ-prefix. ⊣

In our construction of $\mathbf{x}$, $\mathbf{y}$, we must be able to iterate the process of extending to a level prefix. To that end, we introduce the notion of *levels.*

9.24 Definition (See Definition 5.2 of [7]). Suppose α is AI but not MI and $\mathbf{q}$ is a level prefix of G_α. The *level of W prefixed by* $\mathbf{q}$ is the set

$$L(W, \mathbf{q}) := \{\mathbf{a} \in G_{\overline{\alpha}} \mid W(\mathbf{q}^\frown \mathbf{a}) \neq \emptyset\}.$$

A non-empty sequence $\mathbf{s} \in G^*_\alpha - G_\alpha$ *ends in the level of W prefixed by* $\mathbf{q}$ if there is some $\mathbf{a} \in L(W, \mathbf{q})$ so that $\mathbf{q} \sqsubseteq \mathbf{s} \sqsubset \mathbf{q}^\frown \mathbf{a}$.

Next we state without proof a series of lemmas from Darby [7] that lead up to Lemma 9.29. The interested reader can fill in the proofs for the case where $\alpha = \omega^\ell < \omega^\omega$.

9.25 Lemma (See Lemmas 4.6, 4.7 of [7]). *Suppose $\delta \leq \gamma \leq \alpha < \omega_1$, where δ, γ are* AI *and $\gamma \cdot \delta \leq \alpha$. If $\mathbf{s} \in G^*_\alpha$ is a maximal $\gamma \cdot \delta$-prefix for $W \subseteq G_\alpha$, then the following set has order type δ:*

$$W(\beta, \mathbf{s}) := \{\mathbf{p} \in G^*_\alpha \mid \mathbf{s} \sqsubseteq \mathbf{p} \textit{ and } \mathbf{p} \textit{ is a maximal } \gamma\textit{-prefix for } W\}.$$

9.26 Lemma (See Lemma 5.5 of [7]). *Suppose $\alpha < \omega_1$ is* AI *but not* MI*, $\mathbf{q}$ is a level prefix of G_α and $W \subseteq G_\alpha$. If $\mathbf{s}$ ends in level $L(W, \mathbf{q})$ and* $\operatorname{ot}(W(\mathbf{s})) \geq \omega^{\overline{\alpha} \cdot n}$*, then for any $\gamma < \overline{\alpha}$, there is an $\mathbf{a} \in L(W, \mathbf{q})$ so that $\mathbf{s} \sqsubset \mathbf{q}^\frown \mathbf{a}$ and* $\operatorname{ot}(W(\mathbf{q}^\frown \mathbf{a})) \geq \omega^{\overline{\alpha}(n-1)+\gamma}$*.*

9.27 Lemma (See Lemma 5.6 of [7]). *Suppose $\alpha < \omega_1$ is* AI *but not* MI*, $W \subseteq G_\alpha$ and every level of W has order type $\leq \omega^\delta$. If $\mathbf{s} \in G^*_\alpha$ and* $\operatorname{ot}(G_\alpha(\mathbf{s})) = \omega^{\overline{\alpha} \cdot \beta}$*, then* $\operatorname{ot}(W(\mathbf{s})) \leq \omega^{\delta \cdot \beta}$*.*

9.28 Lemma (See Lemma 5.7 of [7]). *Suppose $\alpha < \omega_1$ is* AI *but not* MI*, $W \subseteq G_\alpha(\langle m \rangle)$ and* $\operatorname{ot}(W) > \omega^\gamma$*. Then for any δ so that $\delta \cdot m < \gamma$, there is a level of W of order type $> \omega^\delta$.*

The following lemma of Darby, mildly rephrased since the general definition of G_α has been omitted, is the key to constructing pairs 1-colored by any generalization of the graph Γ to a Γ_α defined for $\alpha = \overline{\alpha} \cdot \omega$, since it allows one to plan ahead: one takes a sufficiently large set, thins it to something tractable, dives into a large level to work within, knowing that on exit from the level, one will have a large enough set of extensions to continue according to plan.

9.29 Lemma (See Lemma 5.9 of [7]). *Suppose α is* AI *but not* MI*, $0 < m < \omega$ and* $\operatorname{ot}(G_\alpha(\langle m \rangle)) = \omega^{\overline{\alpha} \cdot \beta}$*. Further suppose $W \subseteq G_\alpha(\langle m \rangle)$ and* $\operatorname{ot}(W) \geq \omega^{\overline{\alpha} \cdot n + \varepsilon}$ *where $\varepsilon \leq \overline{\alpha}$ and $0 < n < \omega$, and assume δ is such that $\delta \cdot \beta < \varepsilon$. Then there is a set $U \subseteq W$ and a level prefix $\mathbf{q}$ so that $U = U(\mathbf{q})$,* $\operatorname{ot}(L(U, \mathbf{q})) > \omega^\delta$ *and* $\operatorname{ot}(U(\mathbf{q}^\frown \mathbf{a})) \geq \omega^{\overline{\alpha} \cdot (n-1)+\varepsilon}$ *for all $\mathbf{a} \in L(U, \mathbf{q})$.*

Here our focus is on ω^{ω^k} for finite k, that is, on $\alpha = \omega^k$. In this case, $G_\alpha(\langle m \rangle)$ has order type $\omega^{\omega^{k-1} \cdot m}$, so the β of the previous lemma is simply m. The following weaker version of the above lemma suffices for our purposes.

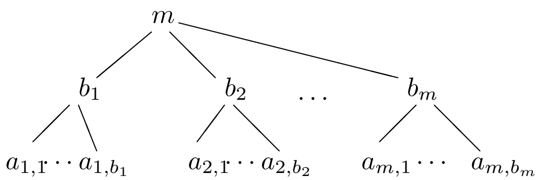
9.30 Lemma. *Suppose* $\alpha = \overline{\alpha} \cdot \omega$ *is* AI *but not* MI, $0 < n \leq m < \omega$, *and* $W \subseteq G_\alpha(\langle m \rangle)$ *has order type* $\geq \omega^{\overline{\alpha} \cdot n}$. *Further assume* δ *is such that* $\delta \cdot m < \overline{\alpha}$. *Then there is a set* $U \subseteq W$ *and a level prefix* $\mathbf{q}$ *so that* $U = U(\mathbf{q})$, $\mathrm{ot}(L(U, \mathbf{q})) > \omega^\delta$ *and* $\mathrm{ot}(U(\mathbf{q}^\frown \mathbf{a})) \geq \omega^{\overline{\alpha} \cdot (n-1)}$ *for all* $\mathbf{a} \in L(U, \mathbf{q})$.

9.31 Lemma. *Suppose* $W \subseteq G_{\omega^2}$ *has order type* ω^{ω^2}. *Then there is a pair* $\mathbf{x}$, $\mathbf{y}$ *from* W *so that* $\Gamma(\mathbf{x}, \mathbf{y}) = 1$.

Proof. We revisit the set G_{ω^2} to better understand how it is constructed by unraveling the recursive construction. A typical element σ is

$$\langle m \rangle^\frown \langle b_1 \rangle^\frown \langle a_1^1, \ldots, a_{b_1}^1 \rangle^\frown \langle b_2 \rangle^\frown \langle a_1^2, \ldots, a_{b_2}^2 \rangle \cdots {}^\frown \langle b_m \rangle^\frown \langle a_1^m, \ldots, a_{b_m}^m \rangle.$$

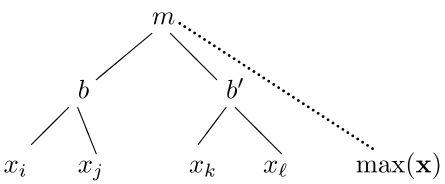
Notice that the initial element, m, tells how many levels there will be, and each level starts with a box coordinate, b_i, which determines the order type of the level, ω^{b_i}. To make the identification of the various types of elements visually immediate, we fold the sequence σ into a tree, with the initial element at the top, the box coordinates as immediate successors, and the remaining coordinates as terminal nodes. To rebuild the sequence from the tree, one walks through the tree in depth first, left-to-right order.

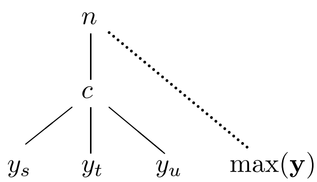


Use Lemmas 9.22, 9.23, and 9.30 to build $\mathbf{x} = X_0{}^\frown X_1{}^\frown X_2{}^\frown X_3{}^\frown X_4$ and $\mathbf{y} = Y_0{}^\frown Y_1{}^\frown Y_2{}^\frown Y_3$ one convex segment at a time so that

$$X_0 < Y_0 < X_1 < Y_1 < X_2 < Y_2 < X_3 < Y_3 < X_4.$$

For notational convenience, we plan to let $i < j < k < \ell$ be such that $\max(X_0) = x_i$, $\max(X_1) = x_j$, $\max(X_2) = x_k$, $\max(X_3) = x_\ell$. Similarly, we plan to let $s < t < u$ be such that $\max(Y_0) = y_s$, $\max(Y_1) = y_t$, $\max(Y_2) = y_u$. In addition it will be convenient to write b for the largest box coordinate of X_0, b' for the largest box coordinate of X_2, and $c = \delta^-(\mathbf{x}, \mathbf{y})$ for the largest box coordinate of Y_0. Here is a pair of subtrees of the trees we get by folding the sequences we build for $\mathbf{x}$ and $\mathbf{y}$, that include only the critical coordinates named above, together with $\max(\mathbf{x})$, $\max(\mathbf{y})$. These subtrees highlight the relationships between the critical coordinates, and allow one to see at a glance which of the segments are $\square$-segments.





Observe that since G is the union of $G(\langle 0\rangle), G(\langle 1\rangle), G(\langle 2\rangle), \ldots$, it follows that for $\beta < \omega^2$, there are infinitely many $m_\beta < \omega$ with $\mathrm{ot}(W \cap G(\langle m_\beta\rangle)) \geq \omega^\beta$. We start our construction by choosing m so that $U_0 := W \cap G(\langle m\rangle)$ has order type at least $\omega^{\omega\cdot 4}$.

Next we apply Lemma 9.30 to find a set $U_1 \subseteq U_0$ and a level prefix $\mathbf{p}$ so that $U_1 = U_1(\mathbf{p})$, $\mathrm{ot}(L(U_1, \mathbf{p})) > \omega^5$, and $\mathrm{ot}(U_1(\mathbf{p}^\frown \mathbf{a})) \geq \omega^{\omega\cdot 3}$ for all $\mathbf{a} \in L(U_1, \mathbf{p})$. Apply Lemma 9.22 to get $\mathbf{u}$, a maximal ω^4 prefix in $L(U_1, \mathbf{p})$. Then $b = \min(\mathbf{u})$ is the box coordinate of our diagram. We set $X_0 = \mathbf{p}^\frown \mathbf{u}$ and note that $\max(\mathbf{u}) = x_i$ on our diagram.

Choose $n > x_i$ so that $V_0 := W \cap G(\langle n\rangle)$ has order type at least $\omega^{\omega\cdot 4}$. Continue as in the previous step. Use Lemma 9.30 to find a set $V_1 \subseteq V_0$ and a level prefix $\mathbf{q}$ so that $V_1 = V_1(\mathbf{q})$, $\mathrm{ot}(L(V_1, \mathbf{q})) > \omega^7$, and $\mathrm{ot}(V(\mathbf{q}^\frown \mathbf{a})) \geq \omega^{\omega\cdot 3}$ for all $\mathbf{a} \in L(V_1, \mathbf{q})$. Let $\mathbf{v}$ be a maximal ω^6 prefix in $L(V_1, \mathbf{q})$. Then $c = \min(\mathbf{v})$ is the box coordinate of our diagram. We set $Y_0 = \mathbf{q}^\frown \mathbf{v}$ and note that $\max(\mathbf{v}) = y_s$ on our diagram.

By Lemma 9.23, there is a sequence X_1 with $Y_0 < X_1$ so that $\mathbf{u}^\frown X_1$ is a maximal ω^3 prefix in $L(U_1, \mathbf{p})$. Note that $X_0{}^\frown X_1$ is not a level prefix nor is any one point extension.

By Lemma 9.23, there is a sequence Y_1 with $X_1 < Y_1$ so that $\mathbf{v}^\frown Y_1$ is a maximal ω^5 prefix in $L(V_1, \mathbf{q})$.

By Lemma 9.23, the sequence $\mathbf{u}^\frown X_1$ has infinitely many one point extensions in $L(U_1, \mathbf{p})^*$. By choosing a suitable one point extension and then extending it into $L(U_1, \mathbf{p})$, we find $\mathbf{w}$ so that $Y_1 < \mathbf{w}$ and $\mathbf{u}^\frown X_1{}^\frown \mathbf{w} \in L(U_1, \mathbf{p})$. By choice of U_1 and $\mathbf{p}$, we know $\mathrm{ot}(U_1(\mathbf{p}^\frown(\mathbf{u}^\frown X_1{}^\frown \mathbf{w}))) \geq \omega^{\omega\cdot 3}$. Use Lemma 9.30 to find $U_2 \subseteq U_1(\mathbf{p}^\frown(\mathbf{u}^\frown X_1{}^\frown \mathbf{w}))$ and a level prefix $\mathbf{p}'$ so that $U_2 = U_2(\mathbf{p}')$, $\mathrm{ot}(L(U_2, \mathbf{p}')) > \omega^5$, and $\mathrm{ot}(U_2(\mathbf{p}'^\frown \mathbf{a})) \geq \omega^{\omega\cdot 3}$ for all $\mathbf{a} \in L(U_2, \mathbf{p}')$. Then $\mathbf{p}^\frown(\mathbf{u}^\frown X_1{}^\frown \mathbf{w}) \sqsubseteq \mathbf{p}'$. Apply Lemma 9.22 to get $\mathbf{u}'$, a maximal ω^4 prefix in $L(U_2, \mathbf{p}')$. Then $b' = \min(\mathbf{u}')$ is another box coordinate in our diagram. Then $\mathbf{p}'^\frown \mathbf{u}'$ is not a level prefix of U_2, nor is any one point extension of it a level prefix. We set $X_2 = \mathbf{p}' \setminus (X_0{}^\frown X_1)$, and note that $\max(X_2) = \max(\mathbf{u}') = x_k$ on our diagram.

By Lemma 9.23, there is a sequence Y_2 with $X_2 < Y_2$ so that $\mathbf{v}^\frown Y_1{}^\frown Y_2$ is a maximal ω^4 prefix in $L(V_1, \mathbf{q})$.

By Lemma 9.23, there is a sequence X_3 with $Y_2 < X_3$ so that $\mathbf{u}'^\frown X_3$ is a maximal ω^3 prefix in $L(U_2, \mathbf{p}')$.

By Lemma 9.23, the sequence $\mathbf{v}^\frown Y_1{}^\frown Y_2$ has infinitely many one point extensions in $L(V_1, \mathbf{q})^*$. Hence by first choosing a suitable one point extension and then extending it into $L(V_1, \mathbf{q})$, and finally extending it into V_1, we can find Y_3 so that $X_3 < Y_3$ and $\mathbf{y} = Y_0{}^\frown Y_1{}^\frown Y_2{}^\frown Y_3 \in V_1 \subseteq W$.

By Lemma 9.23, the sequence $\mathbf{u}'^\frown X_3$ has infinitely many one point extensions in $L(U_2, \mathbf{p}')^*$. Hence by first choosing a suitable one point extension and then extending it into $L(U_2, \mathbf{p}')$, and finally extending it into U_2, we can find X_4 so that $Y_3 < X_4$ and $\mathbf{x} = X_0{}^\frown X_1{}^\frown X_2{}^\frown X_3{}^\frown X_4 \in U_2 \subseteq W$.

By construction, X_0, X_2, X_4 and Y_0, Y_3 are all $\square$-segments, while X_1, X_3 and Y_1, Y_2 have no box coordinates. Thus $\mathbf{x}, \mathbf{y}$ witnesses the fact that W is not a 0-homogeneous set for Γ. $\dashv$

Lemmas 9.20 and 9.31 show that Γ is a witness to $\omega^{\omega^2} \nrightarrow (\omega^{\omega^2}, 6)^2$. The coloring can easily be generalized to ω^{ω^α} where α is decomposable, since it was described using only box segments and segments without box coordinates. Hence the proof of Lemma 9.20 carries through for these generalizations. In the proof of Lemma 9.31, we have taken advantage of the fact that $\alpha = 2$ is a successor ordinal, but use of lemmas from Darby's paper allow one to modify the given construction suitably.

The proof of the previous lemma gives some evidence for the following remark.

9.32 Remark. We have the following heuristic for building pairs. Suppose σ is a list of specifications of convex segments detailing which have box, triangle, bar (or dot) coordinates and which do not. If the first two and last two segments are to be box segments, then for any ordinal α of sufficient decomposability for the description to make sense, there is a disjoint pair $\mathbf{x}, \mathbf{y} \in G_{\omega^\alpha}$ so that the sequence of convex segments they create fits the description.

For the actual construction, one needs to iterate the process of taking levels and look at the approach taken carefully.

10. A Positive Countable Partition Relation

The previous section focused on countable counterexamples. Here we survey positive ordinal partition relations of the form $\alpha \to (\alpha, m)^2$ for countable limit ordinals α and sketch the proof of one of them.

Darby [7] and Schipperus [53, 51] independently extended Chang's positive result for ω^ω and $m = 3$ to larger countable limit ordinals.

10.1 Theorem (Chang for $\beta = 1$ (see Theorem 9.7); Darby for $\beta = 2$ [7]; Schipperus for $\beta \geq 2$ [53]). *If the additive normal form of $\beta < \omega_1$ has one or two summands, then $\omega^{\omega^\beta} \to (\omega^{\omega^\beta}, 3)^2$.*

Recall that Erdős [11] offered \$1000 for a complete characterization of the countable ordinals α for which $\alpha \to (\alpha, 3)^2$. It is not difficult to show that additively decomposable ordinals fail to satisfy this partition relation. Recall that additively indecomposable ordinals are powers of ω. Specker showed that finite powers of ω greater than ω^2 fail to satisfy it. Galvin showed (see Theorem 9.6) that additively decomposable powers of ω greater than ω^2 fail to satisfy it. Thus attention has been on indecomposable powers of ω, $\alpha = \omega^{\omega^\beta}$, that is, the countable ordinals that are multiplicatively indecomposable. Schipperus (see Theorem 9.9) showed that if the additive normal form of β has at least four summands, then $\alpha \not\to (\alpha, 3)^2$. Thus to complete the characterization of which countable ordinals α satisfy this partition relation it suffices to characterize it for ordinals of the form $\alpha = \omega^{\omega^\beta}$ where the additive normal form of β has exactly three summands. We list below the first open case.

10.2 Question. Does $\omega^{\omega^3} \to (\omega^{\omega^3}, 3)^2$?

In light of Theorem 9.9, Darby and Larson have completed the characterization of the set of $m < \omega$ for which $\omega^{\omega^2} \to (\omega^{\omega^2}, m)^2$ with the following result.

10.3 Theorem (Darby and Larson [8]). $\omega^{\omega^2} \to (\omega^{\omega^2}, 4)^2$.

We complete this subsection with a sketch of the Schipperus proof that $\omega^{\omega^\omega} \to (\omega^{\omega^\omega}, 3)^2$, using somewhat different notation than he used originally. The sketch will be divided into seven subsections:

1. representation of ω^{ω^ω} as a collection $\mathcal{T}(\omega)$ of finite trees;
2. analysis of *node labeled* trees;
3. description of a two-player game $\mathcal{G}(h, N)$ for h a 2-partition of $\mathcal{T}(\omega)$ into 2 colors and $N \subseteq \omega$ infinite;
4. uniformization of play of the game $\mathcal{G}(h, N)$ via constraint on the second player to a *conservative style* of play determined by an infinite set $H \subseteq N$ and a bounding function b;
5. construction of a three element 1-homogeneous set when the first player has a winning strategy for all games in $\mathcal{G}(h, N)$ in which the second player makes conservative moves;
6. construction of an almost 0-homogeneous set of order type ω^{ω^ω} when the first player has no such strategy;
7. completion of the proof.

10.1. Representation

Recall that, by convention, we are identifying a finite set of natural numbers with the increasing sequence of its members. The trees we have in mind for our representation are subsets of $[\omega]^{<\omega}$ which are trees under the subset relation, and the subset relation is the same as the end-extension relation when the subsets are regarded as increasing sequences.

In the proof that the coloring Γ had no independent subset of order type ω^{ω^2}, we found it convenient to fold an element

$$\mathbf{x} = \langle m, n_1, a_1^1, \ldots, a_{n_1}^1, n_2, a_1^2, \ldots, a_{n_2}^2, \ldots, n_m, a_1^m, \ldots, a_{n_m}^m \rangle$$

of G_{ω^2} into a tree with root $\langle m\rangle$, immediate successors $\langle m, n_i\rangle$ and terminal nodes $\langle m, n_i, a^i_j\rangle$. Then we could walk through the tree, node by node, so that the maximum element of each node continually increased along the walk, just as the elements of $\mathbf{x}$ increase.

We already have representations of ω^{ω^β} from the previous section as sets of increasing sequences under the lexicographic ordering. The definition of those sets is recursive, so we fold these sets up into trees recursively. Specifically, the next definition uses the representations of G_{ω^β} detailed in Definition 9.10 and Remark 9.12.

10.4 Definition. Define by recursion on $\beta \le \omega$ a sequence of *folding maps*, $F_\beta : G_{\omega^\beta} \to \mathcal{T}$:

1. For $\tau = \langle k\rangle \in G_{\omega^0} = G_1$, set $F_0(\tau) := \{\langle k\rangle\}$.
2. For $\tau = \langle m\rangle^\frown\sigma_1{}^\frown\sigma_2{}^\frown\cdots{}^\frown\sigma_m \in G_{\omega^{n+1}}$, set
$$F_{n+1}(\tau) := \{\langle m\rangle\} \cup \bigcup\{\{\langle m\rangle\}^\frown F_n(\sigma_i) : 1 \le i \le m\}.$$
3. For $\tau = \langle m\rangle^\frown\sigma \in G_{\omega^\omega}$, set $F_\omega(\tau) := \{\langle m\rangle\} \cup \{\langle m\rangle\}^\frown F_m(\sigma)$.

Let $\mathcal{T}(\beta)$ be the range of F_β.

Prove the following lemmas by induction on β.

10.5 Lemma. *For each $\beta \le \omega$, the mapping F_β is one-to-one and $\tau = \bigcup F_\beta(\tau)$. Thus, $<_{\text{lex}}$ on G_{ω^β} induces an order $<$ on $\mathcal{T}(\beta)$.*

10.6 Lemma. *For all $\beta \le \omega$ and all infinite $H \subseteq \omega$, the collection of sequences in $G_{\omega^\beta} \cap [H]^{<\omega}$ has order type ω^{ω^β}, and hence so does the collection of trees in $\mathcal{T}(\beta, H) := \mathcal{T}(\beta) \cap \mathcal{P}([H]^{<\omega})$.*

Let $\mathcal{T}$ be the collection of all finite trees $(T, \sqsubseteq)$ of increasing sequences with the property that if $s, t \in T$ and as sets, $s \subseteq t$, then as sequences, $s \sqsubseteq t$. Identify each $t \in T \in \mathcal{T}$ with the set of its elements. Then $\sqsubseteq$ and $\subseteq$ coincide, so this identification permits one to use set operations on the nodes of T.

10.7 Lemma. *For all $\beta < \omega_1$, for all $T \in \mathcal{T}(\beta)$, the following conditions are satisfied:*

1. *(transitivity) $s \sqsubset t \in T$ implies $s \in T$;*
2. *(closure under intersection) for all $s, t \in T$, $s \cap t$ is an initial segment of both s and t;*
3. *(rooted) $(T, \sqsubseteq)$ is a rooted tree with $\emptyset \notin T$;*
4. *(node ordering) for all $s \neq t$ in T, exactly one of the following holds:*

(a) $s \sqsubset t$,

(b) $t \sqsubset s$,

(c) $s \leq_{\text{lex}} t$ *and* $s < t - (s \cap t)$,

(d) $t \leq_{\text{lex}} s$ *and* $t < s - (s \cap t)$.

10.8 Definition. For all $\beta < \omega_1$, for all $T \in \mathcal{T}(\beta)$, order the nodes of T by $u < v$ if and only if $u \sqsubset v$ or $u <_{\text{lex}} v$.

10.9 Lemma. *For all $\beta < \omega_1$, for all non-empty initial segments S, T of trees in $\mathcal{T}(\beta)$, $\bigcup S \sqsubset \bigcup T$ if and only if $S \sqsubset T$.*

Proof. By Lemma 10.7, if $\emptyset \neq S \sqsubset T \sqsubseteq T' \in \mathcal{T}(\beta)$, then $\bigcup S \sqsubset \bigcup T$. For $\beta = 0$, the reverse implication is trivially true, and for $\beta > 0$, it is true by definition of the fold map and the induction hypothesis. $\dashv$

10.10 Definition. For all $\beta \leq \omega$, define $e_\beta : [\omega]^{<\omega} \to \{-1\} \cup (\beta + 2)$ by recursion:

$$e_\beta(\emptyset) = \beta + 1;$$
$$e_\beta(\sigma^\frown\langle m\rangle) = \begin{cases} -1 & \text{if } e_\beta(\sigma) \leq 0, \\ e_\beta(\sigma) - 1 & \text{if } e_\beta(\sigma) > 0 \text{ successor}, \\ \max(\sigma) & \text{if } e_\beta(\sigma) = \omega \text{ limit}. \end{cases}$$

We refer to $e_\beta(x)$ as the *ordinal of* x.

Use induction on β, the definition of F_β, and the previous lemma to prove the next lemma.

10.11 Lemma. *For all $\beta \leq \omega$, for all $T \in \mathcal{T}(\beta)$, for all $t \in T$, $e_\beta(t) \geq 0$, and if $e_\beta(t) > 0$, then t has a proper extension $u \in T$.*

The following consequence of the recursive nature of Definition 10.10 is useful in induction proofs.

10.12 Lemma. *For all $\beta \leq \omega$, for all $\langle m\rangle^\frown\tau \in [\omega]^{<\omega}$, $e_\beta(\langle m\rangle) = \beta$ and if $\tau \neq \emptyset$ and $\gamma = e_\beta(\langle m, \max(\tau)\rangle) \geq 0$, then $e_\beta(\langle m\rangle^\frown\tau) = e_\gamma(\tau)$.*

10.13 Definition. Suppose $T \in \mathcal{T}$. For all $t \in T$, let $\sharp(t, T)$ be the number of successors of t in T.

10.14 Lemma. *For all $\beta \leq \omega$, for all $T \in \mathcal{T}(\beta)$, for all $t \in T$,*

$$\sharp(t, T) = \begin{cases} 0, & \text{if } e_\beta(t) = 0, \\ 1, & \text{if } e_\beta(t) = \omega \text{ is a limit}, \\ \max(t), & \text{if } e_\beta(t) \text{ is a successor}. \end{cases}$$

10.15 Lemma. *For all $\beta \leq \omega$, for all $T \subseteq [\omega]^{<\omega}$, $T \in \mathcal{T}(\beta)$ if and only if T satisfies the four conclusions of Lemma 10.7, and for all $t \in T$, $e_\beta(t) \geq 0$ and $\sharp(t, T)$ has the value specified in Lemma 10.14.*

Proof. By Lemmas 10.7, 10.11, and 10.14, if $(T, \sqsubseteq) \in \mathcal{T}(\beta)$, then it satisfies the given list of conditions.

To prove the other direction, work by induction on β to show that if $T \subseteq [\omega]^{<\omega}$ satisfies the given conditions for β, then $\bigcup T \in G_{\omega^\beta}$ and $T = F_\beta(\bigcup T) \in \mathcal{T}(\beta)$. ⊣

10.16 Definition. For $0 < \beta \leq \omega$ and $\emptyset \neq S \sqsubset T \in \mathcal{T}(\beta)$, the *critical node of S*, in symbols $\mathrm{cri}(S)$, is the largest $s \in S$ with $\sharp(s, S)$ smaller than the value predicted in Lemma 10.14. For notational convenience, let $\mathrm{cri}(\emptyset) = \emptyset$, and set $\mathrm{cri}(T) = \emptyset$ for $T \in \mathcal{T}(\beta)$.

The next lemma shows why the name was chosen.

10.17 Lemma. *For $0 \leq \beta \leq \omega$ and $S \sqsubseteq T \in \mathcal{T}(\beta)$, if $t := \min(T - S)$, then $t = \mathrm{cri}(S)^\frown\langle\max(t)\rangle$.*

Proof. Let $m < \omega$ be such that $\langle m\rangle \in T$. Then $\langle m\rangle$ is the least element of T. If $S = \emptyset$, then $t = \langle m\rangle = \mathrm{cri}(S)^\frown\langle\max(t)\rangle$ and the lemma follows. Otherwise, $\langle m\rangle$ must be in S, and because it is the root of T, $\langle m\rangle \sqsubset t := \min(T - S)$. Let $r = t - \{\max(t)\}$. Then $\langle m\rangle \sqsubseteq r \sqsubset t$, $\sharp(r, S) < \sharp(r, T)$, so r is an element of S with $\sharp(r, S)$ smaller than the value specified in Lemma 10.14.

If $p \in T$ and $p <_{\mathrm{lex}} t$, then $p \in S$, since $S \sqsubset T$ and $T = \min(T - S)$. Moreover, if $p <_{\mathrm{lex}} t$ and $p \sqsubset q \in T$, then $q <_{\mathrm{lex}} t$. Hence if $p <_{\mathrm{lex}} t$, then $\sharp(p, S) = \sharp(p, T)$ takes on the value specified in Lemma 10.14. Thus $\mathrm{cri}(S) \sqsubset t$, so $\mathrm{cri}(S) \sqsubseteq r$. It follows that $r = \mathrm{cri}(S)$ and $t = \mathrm{cri}(S)^\frown\langle\max(t)\rangle$ as required. ⊣

10.18 Lemma. *For all $\beta \leq \omega$, the set of initial segments of trees in $\mathcal{T}(\beta)$ is well-founded under $\sqsubset$.*

Proof. The proof is by induction on β. For $\beta = 0$, the lemma is clearly true, since the longest possible sequences are those of the form $\emptyset, \langle m\rangle$ for some $m < \omega$.

Next suppose the lemma is true for $k < \omega$ and $\beta = k+1$. Let $S_0, S_1, \ldots$ be an arbitrary $\sqsubset$-increasing sequence, and without loss of generality, assume it has at least two trees in it. Then there is some $m < \omega$ so that $\langle m\rangle \in S_1$. By the definition of the fold map F_k, it follows that for $i > 1$, the tree S_i satisfies $\bigcup S_i = \langle m\rangle^\frown\sigma_{i,1}{}^\frown \cdots {}^\frown\sigma_{i,n_i}$ for some $n_i \leq m$, where $F_k(\sigma_{i,j}) \in \mathcal{T}(k)$ for $j < n_i$, and for some $\sigma' \sqsupseteq \sigma_{i,n_i}$, $F_k(\sigma') \in \mathcal{T}(k)$, so $\sigma_{i,n_i} = \bigcup T_i$ for T_i an initial segment of a tree in $\mathcal{T}(k)$. If $i < \ell$ and T_i, T_ℓ are such that $n_i = n_\ell$, then for $j < n_i$, $\sigma_{i,j} = \sigma_{\ell,j}$. Thus by the induction hypothesis, for each n with $1 \leq n \leq m$, there can be at most finitely many trees in the sequence with $n_i = n$. Hence the sequence must be finite, and the lemma is true for $\beta = k+1$.

The proof for $\beta = \omega$ is similar, since for all initial segments S of trees in $\mathcal{T}(\omega)$, either $S = \emptyset$, $S = \{\langle m\rangle\}$, or $S = \{\langle m\rangle\}^\frown S'$ for some $m < \omega$ and some S' which is an initial segment of a tree in $\mathcal{T}(m)$. The details are left to the reader.

Therefore, by induction, the lemma holds for all $\beta \leq \omega$. ⊣

10.2. Node Labeled Trees

A typical proof of a positive partition relation for a countable ordinal for pairs includes a uniformization of an arbitrary 2-partition into 2 colors, but only for those pairs for which some easily definable additional information is also uniformized. We will introduce node labellings to provide that extra information, but before we do so, we examine convex partitions of disjoint trees and the partition nodes that determine them.

10.19 Definition. For trees S^0, S^1 from $\mathcal{T}(\beta)$ with $\bigcup S^0 \cap \bigcup S^1 = \emptyset$, call $t \in S^\varepsilon$ a *partition node* if $t < \max(S^\varepsilon)$ and there is some $u \in S^{1-\varepsilon}$ with $\max(t) < \max(u) < \min(\bigcup S^\varepsilon - (1 + \max(t))$.

For notational convenience, write $T(\emptyset, t]$ for the initial segment of T consisting of all nodes $s \leq t \in T$, and, for $t < u$ in T, write $T(t, u]$ for $\{s \in T : t < s \leq u\}$. With this notation in hand, we can state the lemma below justifying the label *partition nodes*. This lemma follows from Lemmas 10.7 and 10.9.

10.20 Lemma. *Suppose S^0, S^1 are in $\mathcal{T}(\beta)$ and $\bigcup S^0 \cap \bigcup S^1 = \emptyset$. Further suppose $t^0_0, t^0_1, \ldots, t^0_{k-1} \in S^0$ and $t^1_0, t^1_1, \ldots, t^1_{\ell-1} \in S^1$ are the partition nodes of these trees if any exist. Set $t^0_{-1} = t^1_{-1} = \emptyset$, $t^0_k = \max(S^0)$, $t^0_\ell = \max(S^1)$. Then every node of S^ε is in one and only one $S^\varepsilon(t^\varepsilon_{i-1}, t^\varepsilon_i]$, and the sets $\sigma^\varepsilon_i = \bigcup S^\varepsilon(t^\varepsilon_{i-1}, t^\varepsilon_i] - t^\varepsilon_{i-1}$ satisfy*

$$\sigma^0_0 < \sigma^1_0 < \sigma^0_1 < \sigma^1_1 < \cdots < \sigma^0_{\ell-1} < \sigma^1_{\ell-1} (< \sigma^0_{k-1}).$$

Now we introduce node labellings. For simplicity, this concept is given a general form.

10.21 Definition. Suppose $\beta \leq \omega$ and $N \subseteq \omega$ is infinite. For any initial segment $S \sqsubseteq T \in \mathcal{T}(\beta)$, a function C is a *node labeling of S into N* if $C : S \to [N]^{<\omega}$ satisfies $\max(C(s)) < \max(s)$ for all $s \in S$ with $C(s) \neq \emptyset$.

We carry over from $\mathcal{T}(\beta)$ the notions of extension, complete tree and trivial tree. In particular, call (T, D) a *(proper) extension of* (S, C), in symbols, $(S, C) \sqsubset (T, D)$, if $S \sqsubset T$ and $D{\restriction}S = C$. Call (T, D) *complete (for β)* if $T \in \mathcal{T}(\beta)$; call it *trivial* if $(T, D) = (\emptyset, \emptyset)$.

Call a pair S, T from $\mathcal{T}(\beta)$ *local* if S and T have a common root; otherwise it is global. Similarly, call (S, C), (T, D) *local* if S, T is local and otherwise call it global.

10.22 Definition. A pair $((S^0, C^0), (S^1, C^1))$ is *strongly disjoint* if (a) either $S^0 = \emptyset = S^1$ or $(\bigcup S^0 \cup \mathrm{ran}(C^0)) \cap (\bigcup S^1 \cup \mathrm{ran}(C^1)) = \emptyset$ and (b) for all $s, t \in S^0 \cup S^1$, whenever $\max(s) < \max(t)$ and $C^\varepsilon(t) \neq \emptyset$, then also $\max(s) < \min(C^\varepsilon(t))$.

10.23 Definition. Call a pair $((S^0, C^0), (S^1, C^1))$ of node labeled trees *clear* if $S^0 < S^1$, $((S^0, C^0), (S^1, C^1))$ is strongly disjoint, all partition nodes $t \in S^0 \cup S^1$ are leaf nodes ($e_\beta(t) = 0$), and if for all $\varepsilon < 2$ and all $s \in S^\varepsilon$,

- $C^\varepsilon(s) = \emptyset$ if $e_\beta(s) = 0$;
- $C^\varepsilon(s) = \{\sharp(s, S^\varepsilon(\emptyset, t]) : s \sqsubset t \in S^\varepsilon \text{ is a partition node}\}$ if $e_\beta(s)$ is a successor ordinal;
- $C^\varepsilon(s) = \{e_\beta(t) : s \sqsubset t \in S^\varepsilon \,\&\, |C^\varepsilon(t)| > 1\}$ if $e_\beta(s) = \omega$ is a limit ordinal.

Call a pair S^0, S^1 of trees from $\mathcal{T}(\beta)$ *clear* if it is local or if it is global and there are node labellings C^0, C^1 with $((S^0, C^0), (S^1, C^1))$ clear.

For $\beta > \omega$, the value of the node labeling for s with $e_\beta(s)$ limit is more complicated to describe.

Notice that for $2 \leq \beta \leq \omega$, if $(S^0, C^0), (S^1, C^1)$ is a global clear pair and neither C^0 nor C^1 is constantly the empty set, then all initial segments of partition nodes are identifiable: they are the root of the tree, successor nodes whose node label is non-empty, and nodes of ordinal 0 whose immediate predecessor has non-empty node label that identifies it as a successor which is a partition node.

From the definition of *clear*, if u is a partition node of one of a pair of trees, say (S, C) then for each initial segment s whose ordinal $e_\omega(s)$ is a successor, the node label $C(s)$ must have as a member the number of immediate successors of s which are less than or equal to u in the lexicographic order. If we index the immediate successors of s in S in increasing lexicographic order starting with 1, then this value is the *index* of the immediate successor of s which is an initial segment of u. This analysis motivates the next definition.

10.24 Definition. Consider a node labeled tree (S, C) with root $\langle m \rangle$. A non-root node t of (S, C) is a *prepartition node* if for all $s \sqsubset t$ with $e_\beta(s)$ a successor ordinal, $\sharp(s, S(\emptyset, t]) \in C(s)$, and if $e_\omega(s) \in C(\langle m \rangle)$ whenever $\beta = \omega$ and $|C(s)| > 1$ The root is a prepartition node if $S \in \mathcal{T}(0)$ or $C(\langle m \rangle) \neq \emptyset$ or (S, C) has a non-root prepartition node. Call (S, C) *relaxed* if $S \notin \mathcal{T}(0)$ and $\max(S)$ is a prepartition node of ordinal 0.

Node labeled trees, clear pairs, prepartition nodes and relaxed initial segments are used in the game introduced in the next section.

10.3. Game

In this section we develop the game $\mathcal{G}(h, N)$ in which two players collaborate to build a pair of node labeled trees.

Here is a brief description of the game. Player I, the architect, plays specifications for Player II, the builder, telling him (a) which tree to extend, (b) whether to complete the tree or to build it to the next decision point, and (c) what the size of the node label of the next node to be constructed is, if it is not already determined. In turn, the builder extends the designated tree by a series of steps, adding a node and node label at each step using elements of N, until he reaches the next decision point on the given tree, if he has been so directed, or until he completes the tree. The architect wins if the pair $((S, C), (T, D))$ created at the end of the play of the game is a global clear pair with $h(S, T) = 1$; otherwise the builder wins.

Before giving a detailed description of the general game, as a warm-up exercise, consider a 2-partition h into 2 colors, an infinite set N, and the game $\mathcal{G}_0(h, N)$ in which the architect plays the strategy σ_0 directing the builder to complete the first tree and then complete the second tree. The builder can use a fold map to fold an initial segment of N into a tree S and assign the constantly $\emptyset$ node labeling C to create his first response, (S, C). Then he can fold a segment of N starting above $\bigcup S$ into a tree T and assign the constantly $\emptyset$ node labeling D to create his second response, (T, D). By construction, the pair $((S, C), (T, D))$ is clear, since there are no partition nodes, so $\{S, T\}$ is a clear global pair. If all pairs $\{X, Y\}$ of trees created using nodes from N in this game have $h(X, Y) = 1$, then playing another game, starting with (T, D) as the initial move of the builder and ending with (U, E), one builds a triple $\{S, T, U\}$ each pair of which h takes to color 1. Thus if σ_0 is a winning strategy for the architect, then the architect can arrange for a triangle to be constructed.

As a second warm-up exercise, consider a 2-partition h into 2 colors, an infinite set N with $0 \notin N$, and the game $\mathcal{G}_1(h, N)$ in which the architect plays the strategy σ_1 directing the builder to build the first tree to the next decision point starting from a root node whose node label has 0 elements, to start and complete the second tree, and then to complete the first tree.

In response to the architect's first set of specifications, the builder uses the least element n_0 of N to build the root, $\langle n_0 \rangle$ and gives it the empty set as node label. He then uses the next two elements of N, namely n_1 and n_2 by setting $\langle n_0, n_2 \rangle$ as the immediate successor of the root with node label $C_0(\langle n_0, n_2 \rangle) = \{n_1\}$. He continues with successive elements of N, extending the critical node of the tree create to that point, giving the new node an empty label unless the node to be created is the successor of a prepartition node whose index is the sole element of the node label of the prepartition node, in which case he extends and labels it as he did the successor of the root. He continues until he has created and labeled a prepartition node u whose ordinal is $e_\omega(u) = 0$, and the pair (S_0, C_0) he has built is his response.

In response to the architect's second set of specifications, the builder uses elements of N larger than any used so far to build a tree T in $\mathcal{T}(\omega)$ and gives it the constantly $\emptyset$ labeling. Then he responds to the final set of specifications of the architect by completing S_0 to S in $\mathcal{T}(\omega)$ and extending C_0 to C with all new nodes receiving empty node labels.

In the brief description of the game, the architect was allowed to direct the builder to stop at the next decision point. The decision point is either when a partition node has been created and it is time to switch to the other tree or when the next node to be created is permitted to have a node label whose size is greater than 2. Notice that if the architect switches trees after the builder has created a prepartition node with ordinal 0, then that node becomes a partition node.

10.25 Definition. A *decision node* of (S, C) is a prepartition node t with ordinal $e_\omega(t)$ such that either $e_\omega(t) = 0$ or $e_\omega = \ell + 1$ is a successor ordinal with $\ell \in C(t\restriction 1)$, t is the critical node of S and $1+\sharp(t, S)$ is an element of $C(t)$.

In the game $\mathcal{G}_0(h, N)$, the final pair of trees S, T had the property that $\min(\bigcup S) < \min(\bigcup T)$ and $\max(\bigcup S) < \max(\bigcup T)$. Call such a pair an *outside* pair. In the game $\mathcal{G}_1(h, N)$, the final pair of trees S, T had the property that $\min(\bigcup S) < \min(\bigcup T)$ and $\max(\bigcup S) > \max(\bigcup T)$. Call such a pair an *inside* pair.

10.26 Definition. Suppose $N \subseteq \omega$ is infinite and h is a 2-partition of $\mathcal{T}(\omega)$ into 2 colors. Then $\mathcal{G}(h, N)$ is a two player game played in rounds. Player I is the architect who issues specifications, and Player II is the builder whose creates or extends one of a given pair of trees in round ℓ to $((S_\ell, C_\ell), (T_\ell, D_\ell))$. Note that if the second tree has not been started in round ℓ, then $T_\ell = D_\ell = \emptyset$.

The architect's moves: In the initial round, the architect declares the type of pair to be produced, either inside or outside. In round ℓ, the architect specifies the tree to be created or extended (first or second), specifies whether the extension is to completion with all new nodes receiving empty labels or to the point at which a decision node is created and labeled (completion or decision), and specifies the size of the label for the next node to be created. In her initial move, the architect must specify the first tree be created. She may not direct the builder to extend a tree which is complete.

The builder's moves: In round ℓ, the builder creates or extends the specified tree through a series of steps in which he adds one node and its label using elements of N larger than any used to that point. If he has been directed to continue to completion, he does so while assigning the empty set node label to all new nodes. Otherwise he adds nodes one at a time, until he creates the first decision node. He adds a node after determining the size of the node label, and choosing the node label, since all elements of the node label must be smaller than the single point used to extend the critical node. The size of the label of the first node to be created is specified by the architect's move. Otherwise, the builder determines if the node will be a prepartition node with non-zero ordinal. If so, its node label has one element and otherwise its node label is empty.

Stopping condition: Play stops at in round ℓ if both trees are complete.

Payoff set: The architect wins if both S_ℓ and T_ℓ are complete, the pair is inside or outside as specified at the onset, the pair $((S_\ell, C_\ell), (T_\ell, D_\ell))$ is a global clear pair and $h(S_\ell, T_\ell) = 1$; otherwise, the builder wins.

We are particularly interested in this game when we have a fixed 2-partition, $h : [\mathcal{T}(\beta)]^2 \to 2$, but the game may be modified to work with 2-partitions into more colors. This game may also be modified to require the builder to use an initial segment of an infinite sequence from N specified by the architect in her move or be modified to start with a specified pair of node labeled trees.

10.27 Lemma. *Suppose $N \subseteq \omega$ is infinite and h is a 2-partition of $\mathcal{T}(\omega)$ with 2 colors. Then every run of $\mathcal{G}(h, N)$ stops after finitely many steps.*

Proof. Use Lemma 10.18. ⊣

10.4. Uniformization

In this subsection, we prove the key dichotomy in which one or the other player has a winning strategy, at least up to some constraints on the play. Basically, we build a tree out of the plays of the game, show it is well-founded, and use recursion on the tree to define an infinite subset $H \subseteq \omega$ so that plays where the builder uses sufficiently large elements of H are uniform enough to allow us to prove the dichotomy.

10.28 Definition. Suppose $N \subseteq \omega$ is infinite, and h is a 2-partition of $\mathcal{T}(\omega)$ with 2 colors. Let $\mathcal{S}(N)$ be the set of sequences of consecutive moves in the game $\mathcal{G}(h, N)$, including the empty sequence.

10.29 Lemma. *For infinite $N \subseteq \omega$, $(\mathcal{S}(N), \sqsubset)$ is a rooted, well-founded tree.*

Proof. The root is the empty sequence. End-extension clearly is a tree order on $\mathcal{S}(N)$, and $\sqsubset$ is well-founded since every game is finite. ⊣

The basic idea for the builder is to use elements from a specified set and to always start high enough.

10.30 Definition. Suppose N is an infinite set with $1 < \min(N)$ and no two consecutive integers in N. Then a function $b : \mathcal{S}(N) \to \omega$ is a bounding function if $b(\emptyset) = 0$, and if $s \sqsubseteq t$, then $b(s) \leq b(t)$.

Use a bounding function and an infinite set to delineate *conservative* moves for the builder.

10.31 Definition. Suppose $H \subseteq N \subseteq \omega$ is infinite with $1 < \min(N)$ that b is a bounding function. If $\vec{R}$ is a position in the game $\mathcal{G}(h, N)$ ending with a move by the architect, then a move $((S_\ell, C_\ell), (T_\ell, D_\ell))$ for the builder is *conservative for b and H* if all new nodes and node labels are created using elements of H greater than $b(\vec{R})$.

10.32 Lemma (Ramsey Dichotomy). *Suppose $N \subseteq \omega$ is infinite, and h is a 2-partition of $\mathcal{T}(\omega)$ with 2 colors. Then there is an infinite subset $H \subseteq N$ and a bounding function b so that $1 < \min(H)$, no two consecutive integers are in H, and the following statements hold:*

1. *for every position $\vec{R} \in \mathcal{S}(N)$ ending in a play for the architect, there is a conservative (for b and H) move for the builder; and*
2. *either the architect has a strategy σ by which she wins $\mathcal{G}(h, N)$ if the builder plays conservatively, the builder wins every run of $\mathcal{G}(h, N)$ by playing conservatively (for b and H).*

Before we tackle the proof of the dichotomy, we introduce some preliminary definitions and lemmas.

10.33 Definition. Call a set $B \subseteq [\omega]^{<\omega}$ *thin* if no u from B is a proper initial segment of any other v from B. Call B a *block for $N \subseteq \omega$* if for every infinite set $H \subseteq N$, there is exactly one $u \in B$ which is an initial segment of H. Call it a *block* if it is a block for ω.

Note that if B is a block, then it is thin. A major tool of the proof of the dichotomy is the following theorem.

10.34 Theorem (Nash-Williams Partition Theorem). *Let $N \subseteq \omega$ be infinite. For any finite partition of a thin set $c : W \to n$, there is an infinite set $M \subseteq N$ so that c is constant on $W \restriction M$.*

For a proof see [45] or [23]. The terminology *thin* comes from [23].

Here are some easy examples of blocks.

10.35 Lemma. *The families $\{\emptyset\}$, and $[\omega]^k$ for $k < \omega$ are blocks.*

10.36 Lemma. *Suppose $w \subseteq \omega$ is an increasing sequence, and $B \subseteq [\omega]^{<\omega}$ is thin. Then there is at most one initial segment u of w with $u \in B$. If B is a block, then there is exactly one such initial segment.*

10.37 Lemma. *Suppose $H \subseteq N \subseteq \omega$ is infinite, h is a 2-partition of $\mathcal{T}(\omega)$ with 2 colors, and b is bounding function. For every position $\vec{R} \in \mathcal{S}(N)$ ending in a move by the architect, there is some $k \geq b(\vec{R})$ and a block $\mathcal{B}(\vec{R})$ for $H - k$ such that for all $B \in \mathcal{B}(\vec{R})$, the builder can build his responding move using all elements of B.*

Proof. Recall the architect may not direct the builder to extend a complete tree, so if the architect has just moved, the tree she directs the builder to extend is not complete. Thus the builder's individual steps are specified up to the choice of elements of N, and his stopping point is determined by his individual steps. Hence the set of sequences of new elements used is thin. Moreover, for any infinite increasing sequence w from H above $b(\vec{R})$ and above the largest element of N used in prior moves, the builder can create a move using an initial segment of w. Therefore the set of possible moves is a block. $\dashv$

At this point we are prepared to prove the main result of this section.

Proof of Ramsey Dichotomy 10.32. Without loss of generality, assume $1 < \min(N)$ and N has no two consecutive elements, since otherwise one can shrink N to an infinite set for which these conditions hold. These conditions assure that no decision node is an immediate successor of another decision node.

Let ρ^* be the rank of $\mathcal{S}(N)$. Use recursion on $\mu \leq \rho^*$ to define a sequence $\langle M_\mu \subseteq N : \mu < \rho^* \rangle$ and a valuation $v : \mathcal{S}(N) \to 2$.

For $\mu = 0$, the sequences $\vec{R}$ of rank 0 are ones in which the last move completes the play of the game. Let $M_0 = N$, and define $v(\vec{R}) = 0$ on a sequence of rank 0 if the game ends with a win for the architect and $v(\vec{R}) = 1$ otherwise.

Next suppose that $0 < \mu < \rho^*$, and v has been defined on all nodes of rank less than μ. Enumerate all the nodes of rank μ as $\vec{R}^0_\mu, \vec{R}^1_\mu, \ldots$ and let M^{-1}_μ be $M_{\mu-1}$ if μ is a successor ordinal and let M^{-1}_μ be a diagonal intersection of a sequence M_ν for a set of ν cofinal in μ otherwise.

Extend v to the nodes of rank μ and define sets M^i_μ by recursion. For the first case, suppose $\vec{R}^i_\mu$ ends with a move for the builder, and set $M^i_\mu = M^{i-1}_\mu$. If there is some move a^i_μ with $\vec{R}^i_\mu {}^\frown \langle a^i_\mu \rangle \in \mathcal{S}(N)$ and $v(\vec{R}^i_\mu {}^\frown \langle a^i_\mu \rangle) = 1$, then set $v(\vec{R}^i_\mu) = 1$, and otherwise set $v(\vec{R}^i_\mu) = 0$.

For the second case, assume $\vec{R}^i_\mu$ ends with an move for the architect. Let $\mathcal{B}(\vec{R}^i_\mu)$ be the block of Lemma 10.37 for the set M^{i-1}_μ and the position $\vec{R}^i_\mu$. Define $c : \mathcal{B}(\vec{R}^i_\mu) \to 2$ by $c(d) = v(\vec{R}^i_\mu {}^\frown \langle P(d) \rangle)$ where $P(d)$ is the unique approved move for the builder whose new elements are created using exactly the elements of d. Apply the Nash-Williams Partition Theorem 10.34 to c to get an infinite set $M^i_\mu \subseteq M^{i-1}_\mu$ and let $v(R^i_\mu)$ be the constant value of c on $\mathcal{B}(\vec{R}^i_\mu)$ restricted to M^i_μ.

Continue by recursion as long as possible, extending v to all nodes of rank μ. If there are only finitely many of them, let M_μ be M^i_μ where $\vec{R}^i_\mu$ is the last one. If there are infinitely many, let M_μ be a diagonal intersection of the sets M^i_μ.

Since every non-empty sequence of moves in the game $\mathcal{G}(N)$ extends the empty sequence, this root of $\mathcal{S}(N)$ has the largest rank of any element of

$\mathcal{S}(N)$, namely rank $\rho^* - 1$. Let $H = M_{\rho^*-1}$. Let $v(\emptyset)$ be 1 if there is some move a by the architect so that $v(\langle a\rangle) = 1$, and set $v(\emptyset) = 0$ otherwise.

Define b on $\mathcal{S}(N)$ by recursion. Let $b(\vec{R}) = 2$ for all $\vec{R} \in \mathcal{S}(N)$ with $|\vec{R}| \leq 1$. Continue by recursion on $|\vec{R}|$. For notational convenience, let $\vec{R}^-$ be obtained from $\vec{R} \in \mathcal{S}(N) - \{\emptyset\}$ by omission of the last entry. If $b(\vec{R}^-)$ has been defined and the last move in $\vec{R}$ is $\mathcal{B}_\ell = ((S_\ell, C_\ell), (T_\ell, D_\ell))$ for the builder, then let $b(\vec{R})$ be the least b greater than $b(\vec{R}^-)$ and any element of $\bigcup(S_\ell \cup \operatorname{ran}(C_\ell) \cup T_\ell \cup \operatorname{ran}(D_\ell))$. If $b(\vec{R}^-)$ has been defined, the last move in $\vec{R}$ is a_ℓ for the architect, and $\vec{R} = \vec{R}^i_\mu$, then let $b(\vec{R})$ be the least b greater than $b(\vec{R}^-)$ so that for all d in the restriction of $\mathcal{B}(\vec{R}^i_\mu)$ to subsets of H with $\min(d) > b$, there is a conservative move for the builder for position $\vec{R}$ with new elements d. The existence of a value for $b(\vec{R})$ in this latter case follows from the fact that $H \subseteq^* M^i_\mu$ by construction, and by Lemma 10.37.

Since all $\vec{R}$ in $\mathcal{S}(N)$ are finite, this recursion extends b to all of $\mathcal{S}(N)$. This definition of H and b guarantees that the builder can always respond with conservative moves to plays of the architect.

If $v(\emptyset) = 1$, then the strategy for the architect is to keep $v(\vec{R}) = 1$. Given the definition of v, the architect will always succeed, as long as the builder moves conservatively with H and b. If $v(\emptyset) = 0$, and the builder always moves conservatively with H and b, then he will win, again by the recursive definition of v and the definition of winning the game. ⊣

10.5. Triangles

For this section we assume that $h : [\mathcal{T}(\omega)]^2 \to 0$ is fixed and that an infinite set $H \subseteq \omega$ and a bounding function b are given so that the architect has a winning strategy σ for games of $\mathcal{G}(h, H)$ in which the builder plays conservatively for b and H. The goal is to outline how one uses the strategy of the architect to construct a triangle.

10.38 Lemma. *Suppose σ is a strategy for the architect with which she wins $\mathcal{G}(h, N)$ if the builder moves conservatively for H, b. Then there is a three element 1-homogeneous set for h.*

Proof. Consider the possibilities for $\sigma(\emptyset)$. The architect must declare the pair to be built will be inside or outside, the initial move is to complete the first tree or construct it to a decision point and must declare the size d of the node label of the initial node constructed. We construct our triangles by playing multiple interconnected games in which the architect uses σ, the builder plays conservatively for H and b, and plays sufficiently large that his plays work in all the relevant games. While technically we should report a pair of node labeled trees for each play of the builder, for simplicity, we frequently only mentioned the one just created or modified.

Case 1. Using σ, the architect specifies the builder constructs a complete tree in her initial move.

Then the architect must call for an outside pair and must set $d = 0$, since otherwise the pair constructed will not be clear. The builder responds via conservative play with a complete tree (S, C) whose node labeling is constantly the empty set. The strategy σ must then specify that the builder constructs a second complete tree whose initial node has a node label of size 0. The builder responds via conservative play with a complete tree (T, D) whose node labeling is constantly $\emptyset$. Since σ is a winning strategy, $h(S, T) = 1$.

Next the architect shifts to the game where the builder has responded to the opening move with (T, D), applies the strategy σ, to which the builder responds with (U, E), a (third) complete tree whose node labeling is constantly $\emptyset$ starting sufficiently large for this response to be appropriate for the game where the builder has responded to the opening move with (S, C). Since σ is a winning strategy, $h(T, U) = 1 = h(S, U)$. Thus $\{S, T, U\}$ is the required triangle.

Case 2. Using σ, the architect declares the pair will be an inside pair, and specifies the initial node label size $d = 0$ and that the builder constructs to a decision node.

The proof in this case is similar to the last, with the architect starting one game to which the builder responds with a first tree (S_0, C_0) where the decision node is a prepartition node of ordinal zero, since no levels were coded for introducing decision nodes with successor ordinals. Thus the next play for the architect is to direct the builder to create a complete tree all of whose nodes are labeled by $\emptyset$.

The architect stops moving on the first game and, using σ, starts a new game, directing the builder to start high enough that the tree constructed could be the beginning of his response in the first game. The builder responds with a tree (T_0, D_0) where the decision node is a prepartition node of ordinal zero The architect continues this game using σ and the builder responds with a complete tree (U, E) all of whose nodes are labeled with $\emptyset$. After the architect and builder each move a final time on this game, the builder has created a complete tree (T, D) extending (T_0, D_0). Since σ is a winning strategy, $h(T, U) = 1$.

Now return to the first game: the builder plays (T, D') where D' is the constantly empty set node labeling; The architect uses σ to respond and requires the builder to construct high enough that his response works in the game where the builder plays (U, E) as well as the one where the builder plays (T, D'). Since σ is a winning strategy, $h(S, T) = h(S, U)$, Thus $\{S, T, U\}$ is the required triangle.

Case 3. Using σ, the architect declares the pair will be an outside pair, and specifies the initial node label size $d = 0$ and that the builder constructs to a decision node.

The proof in this case is similar to the last, so only the list of subtrees to be constructed is given. Start with (S_0, C_0) and (T_0, D_0) as responses to the first two moves of the architect in the first game. Next build (U_0, E_0) and

(S, C) as second and third moves in a game where (S_0, C_0) is the first move, and (U_0, E_0) is started high enough to be a response in the game starting with (T_0, D_0). Finally build (T, D) and (U, E) in the game starting with responses (T_0, D_0) and (U_0, E_0) and continuing high enough that play using (S, C) in the appropriate games is conservative.

In the remaining two cases, we use σ and conservative play for the builder to create trees S, T, U with node labellings (S, C^1) , (S, C^2), (T, D^0), (T, D^1), (U, E^0) and (U, E^1) through plays $\mathcal{G}_{0,1}$, $\mathcal{G}_{0,2}$, $\mathcal{G}_{1,2}$ of the game $\mathcal{G}(h, H)$. We pay special attention to the creation of the initial segments up to the first partition nodes for each pair and to the terminal segments, after the last partition nodes. We refer to the remainder of the run as “the mid-game”.

Case 4. Using σ, the architect declares the pair will be an inside pair, and specifies the initial node label size $d > 0$ and directs the builder to construct the first tree to a decision node.

We start by displaying a schematic overview of the construction:

$$S \quad T \quad U \quad \boxed{T \quad U} \quad \boxed{S \quad U} \quad U \quad \boxed{S \quad T} \quad T \quad S$$

Next we outline the steps to be taken.

1. Choose from H codes for d levels for S and U; choose d larger levels for S and T; start the initial segment of S with respect to T; continue it to get the initial segment of S with respect to U (the difference is in the node labellings only), and apply σ to the results to determine the sizes d', d'' of node labels for the roots of T, U in $\mathcal{G}_{0,1}$, $\mathcal{G}_{0,2}$, respectively.

2. Choose d' levels for T's interaction with U; choose d larger levels for T's interaction with S; start the initial segment of T with respect to S; continue it to get the initial segment of T with respect to U; and apply σ to determine the size d''' of the node label of the root of U for $\mathcal{G}_{1,2}$.

3. Choose d''' levels for U's interaction with T; choose d'' larger levels for U's interaction with S; start the initial segment of U with respect to S; continue it to get the initial segment of U with respect to T.

4. Play the mid-game of $\mathcal{G}_{1,2}$ to the call for the completion of U.

5. The initial segments of T and U with respect to S are complete, so update the node labellings C^0 and C^1.

6. Play the mid-game of $\mathcal{G}_{0,2}$ until the architect calls for the completion of S. In particular, play until U is complete.

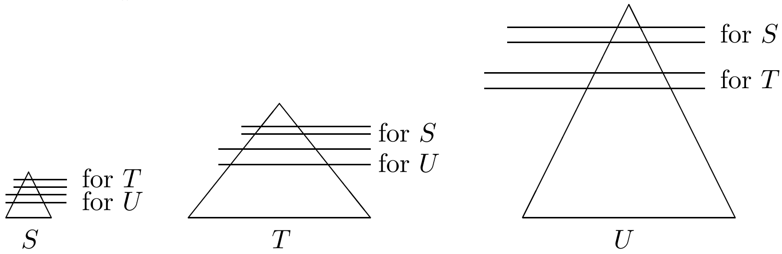
7. Update the node labeling E^1 for U by labeling all the new nodes by the empty set.

8. Complete the play of the game $\mathcal{G}_{0,1}$, starting by extending the part of S created in the play of the mid-game $\mathcal{G}_{0,2}$. Such a start is possible, since the levels of S for interaction with T are larger than those for interaction with U.

9. Update the node labellings C^2 for S and D^2 for T by labeling all the new nodes by the empty set.

Care must be taken to direct the builder to start high enough that all moves in the tree plays of $\mathcal{G}(h, H)$ are conservative. Since the construction of the initial segments calls for introducing levels, we describe the first such step in greater detail.

We know that we will need to choose *levels* for splitting of S with respect to T and U, and for splitting T with respect to U. Depending on the strategy σ, we may need to choose levels for the splitting of T with respect to S and for the splitting of U with respect to S and T. Here is a picture of the approach we plan to take on these splitting levels, in the general case where we need levels for all pairs.



To start the construction, choose $2d+1$ elements from H above $b(\langle\sigma(\emptyset)\rangle)$ ending in m^0, and use them to define $C^1(\langle m^0\rangle)$ and $C^2(\langle m^0\rangle)$ satisfying $C^2(\langle m^0\rangle) < C^1(\langle m^0\rangle)$.

Start playing a game $\mathcal{G}_{0,1}$ where the architect starts with $R_0^{0,1} = \sigma(\emptyset)$ and the builder must use the elements of $C^1(\langle m^0\rangle)$ and m^0 to start his initial move, $R_1^{0,1}$. Continue to play until the architect's last move $R_p^{0,1}$ before directing the builder to switch to the second tree. One can identify this point in the run of the game, since it is the first time the architect has stopped on a node, call it v_0, whose level is one more than $\min(C^1(\langle m^0\rangle))$. Let (S^1_{p-1}, C^1_{p-1}) be the tree paired with $(\emptyset, \emptyset)$ by the builder in his last move.

Let C^2 be the node labeling of S^1_{p-1} with the value of $C^2(\langle m^0\rangle)$ specified above, with the empty set assigned for nodes which are not initial segments of v_0, and for initial segments of v_0 longer than the root, are the singletons needed to guarantee that v_0 is a prepartition node. Then the architect directs the builder to extend this node labeled tree to a response $R_1^{0,2}$ to $\sigma(\emptyset)$ in the second game $\mathcal{G}_{0,2}$. The two players continue the game until the architect, in $R_q^{0,2}$, directs the builder to switch to the second tree to start with a node label of size d'' and to go to a decision node. Such a move is the only one that will lead to a clear pair. Let (S^2_{q-1}, C^2_{q-1}) be the tree played by the builder in his previous move.

Return to game $\mathcal{G}_{0,1}$ and require the builder to respond to $R_p^{0,1}$ with (S_{p+1}^1, C_{p+1}^1) for $S_{p+1}^1 = S_{q-1}^2$ and C_{p+1}^1 the node labeling where all new nodes that are not initial segments of the largest node are labeled with the empty set and initial segments of the largest node are labeled minimally so that it is a prepartition node. Let d' be the size of the node label for the root of the second tree determined by the architect's use of σ in response to this move of the builder.

The remaining details are left to the reader. The careful reader will note that there is one possibility in which the architect initially calls for $d = 1$, specifies a node label of size 2 at the first decision node, and after the completion of the first full segment, calls for an empty node label for the root of the second tree. The construction proceeds as above but is simpler, so these details are also left to the reader.

As in the previous cases, since σ is a winning strategy for the architect, the set $\{S, T, U\}$ we have constructed is the required triangle.

Case 5. Using σ, the architect declares the pair will be an outside pair, and specifies the initial node label size $d > 0$ and directs the builder to construct the first tree to a decision node.

This case is substantially like the previous one, so we give the schematic below to guide the reader and a few comments on how to move from one section to the next.

$$S \quad T \quad \boxed{S \quad T} \quad U \quad \boxed{S \quad U} \quad S \quad \boxed{T \quad U} \quad T \quad U$$

We start by building initial segments of S and T. We begin by choosing d small levels for the interaction of S with T and d larger levels for the interaction of S with U. We start to build the initial segment of S with respect to its convex partition by U, then extend that start to build the initial segment of S with respect to its convex partition by T. We obtain the size d' of the root node label of the second tree in $\mathcal{G}_{0,1}$ by applying σ, choose d' small levels for the interaction of T with S, and d larger levels for the interaction of T with U. We start building the initial segment of T with respect to U, then extend it to the initial segment of T with respect to S.

We play the mid-game of $\mathcal{G}_{0,1}$ until the architect calls for the completion of S. In the process we have completed the initial segments of S and T with respect to U, so we update C^2 and D^2, and apply σ to the current state of play of $\mathcal{G}_{0,2}$ to find d'' and to the current state of play of $\mathcal{G}_{1,2}$ to find d'''.

We choose d'' smaller levels for the interaction of U with respect to S and d''' larger levels for the interaction of U with respect to T. We start building the initial segment of U with respect to T, then extend it to the initial segment of U with respect to S.

We play the mid-game of $\mathcal{G}_{0,2}$ until the builder has completed the construction of S and the architect has called for the completion of U. In the process we have completed the initial segment of U with respect to T, and the final segment of S with respect to T so we update E^1 and C^1.

Then we play the mid-game of $\mathcal{G}_{1,2}$ and complete the play of that game with the final segments of T and U. Finally, we update D^0 and E^0 on the new elements of T and U which complete the games $\mathcal{G}_{0,1}$ and $\mathcal{G}_{0,2}$.

As in the previous cases, since σ is a winning strategy for the architect, the set $\{S, T, U\}$ we have constructed is the required triangle. $\dashv$

10.6. Free Sets

Our next goal is the construction of a subset of $\mathcal{T}(\omega)$ of order type ω^{ω^ω} which is 0-homogeneous for global pairs.

Recall the characterization of subsets of G_ω of order type at least ω^s that dates back to the late 1960's or early 1970's. (see [42, 41, 65]).

10.39 Definition. A non-empty set $S \subseteq \{\sigma \in G_\omega : \min(\sigma) = n\}$ is *free above coordinate* k if for every $\mathbf{x} = \langle x_0, x_1, \ldots, x_n\rangle \in S$, there is an infinite set $N \subseteq \omega$ so that for each $x' \in N$, the set of extensions of $\langle x_0, x_1, \ldots, x_k, x'\rangle$ in S is non-empty. The set S is *free in* s *coordinates* if there are s coordinates above which it is free.

10.40 Lemma (See Lemma 7.2.2 of [65]). *A set* $S \subseteq \{\sigma \in G_\omega : \min(\sigma) = n\}$ *has* $\mathrm{ot}(S) \geq \omega^s$ *if and only if there is a subset* $V \subseteq S$ *so that* V *is free in* s *coordinates.*

We would like to adapt this idea to sets of node labeled trees from $\mathcal{T}(\beta)$. By an abuse of notation, write $t \in (T, D) \in X$ to mean that $t \in T$ for some $(T, D) \in X$. The next definition facilitates our discussion. Recall that $e_\beta(s)$ is the ordinal of s.

10.41 Definition. For $\beta \leq \omega$ and any $s \in (S, C) \in \mathcal{T}^*(\beta)$, call s a *signal node* if either $|C(s)| > 1$ or $e_\beta(s)$ limit and $|C(s)| = 1$.

Recall Definition 10.24 of relaxed initial segments of trees in $\mathcal{T}(\beta)$. The first three parts of the next definition guarantee that locally Γ-free sets have nice regularity properties, and the last three guarantee (1) signal nodes are introduced whenever there is no constraint, (2) signal nodes are given large node labels, and (3) there are arbitrarily large starts for extensions of relaxed initial segments of trees in the collection. The definition of Γ-free from locally Γ-free guarantees that there are arbitrarily large new starts for trees as well.

10.42 Definition. Suppose $\beta \leq \omega$ and $0 \notin \Gamma \in [\beta + 1]^{<\omega}$. A non-empty set X of node labeled trees from $\mathcal{T}(\beta)$ is *locally* Γ*-free for* β if the following conditions are satisfied:

1. (commonality) if $\beta > 0$, then every tree in X has a proper relaxed initial segment and every local pair from X has a common proper relaxed initial segment and otherwise is disjoint;
2. (conformity) if $r \in (S, C) \in X$ and $k \in C(r) \neq \emptyset$, then there is some relaxed $(T, D) \sqsubseteq (S, C)$ so that $r \sqsubset \max(T)$ and if the ordinal of r is a successor, then $\sharp(r, T) = k$;

3. (Γ-signality) for any signal node $r \in (S, C) \in X$, either $e_\beta(r) \in \Gamma$ or for some $p \sqsubset r$ with $e_\beta(p) = \omega$, there is a $k \in C(p)$ so that $e_\beta(r) = k$;

4. (Γ-forecasting) for any relaxed $(S, C) \sqsubseteq (T, D) \in X$, if $\gamma_i \in \Gamma$, then there is some signal node $r \sqsubset \max(S)$ with $e_\beta(r) = \gamma_i$; and if $p \sqsubset \max(S)$ is a signal node, $k \in C(p)$, and $e_\beta(p) = \omega$ is a limit ordinal, then there is some signal node $r \sqsubset \max(S)$ with $e_\beta(r) = k$;

5. (signal size) for any signal node $r \in (S, C) \in X$, the inequality $|C(r)| < \max(r)$ holds, and $\max(t) < \max(r)$ implies $\max(t) < |C(r)|$ for all $t \in (T, D) \in X$;

6. (push-up) for every $k < \omega$ and every relaxed initial segment $(T, D) \sqsubset (U, E) \in X$, there is some complete extension $(V, F) \sqsupset (T, D)$ in X whose new elements start above k, i.e. $k < \min(\bigcup V \cup \operatorname{ran}(F) - \bigcup T \cup \operatorname{ran}(D))$.

We say X is Γ*-free for* β if it is locally Γ-free for β, and for all $k < \omega$, there is some $\langle m \rangle \in (S, C) \in X$ such that $k < |C(\langle m \rangle)|$ if $\beta \in \Gamma$ and $k < m$ otherwise.

By an abuse of notation, for a collection X of node labeled trees from $\mathcal{T}(\beta)$, we let $\operatorname{ot}(X) = \operatorname{ot}(\{S : \exists C (S, C) \in X\})$.

10.43 Lemma. *For all $\beta \leq \omega$, for all $0 \notin \Gamma \in [\beta + 1]^{<\omega}$, if X is Γ-free for β, then $\operatorname{ot}(X) \geq \zeta(\beta, \Gamma)$ where*

$$\zeta(\beta, \Gamma) := \begin{cases} \omega & \text{if } \beta = 0, \\ \omega^2 & \text{if } \beta > 0 \text{ and } \Gamma = \emptyset, \\ \omega^{\omega^{|\Gamma|}} & \text{if } \beta > 0 \text{ and } \omega \notin \Gamma \neq \emptyset, \text{ and} \\ \omega^{\omega^\omega} & \text{otherwise.} \end{cases}$$

Proof. Relaxed trees, especially with a specified node as an initial segment of the max, play an important role in the definition of free and locally free. Here is some notation to facilitate the discussion. For any set X of node labeled trees, define $X(t) := \{(T, D) \in X : t \in (T, D)\}$.

10.44 Claim. *If X is Γ-free for $\beta = 0$ and $0 \notin \Gamma \subseteq 1$, then $\operatorname{ot}(X) \geq \omega$.*

Proof. Since $0 \notin \Gamma \subseteq 1$, it follows that $\Gamma = \emptyset$. Since any Γ-free for $\beta = 0$ set X has arbitrarily large roots, it must have order type at least ω. $\dashv$

For $1 \leq \beta \leq \omega$, $\Gamma \subseteq \beta + 1$, Y a set of node labeled trees from $\mathcal{T}(\beta)$ and $m < \omega$, define $\rho(\beta, \Gamma, Y, m) := 0$ unless $Y(\langle m \rangle) \neq \emptyset$ is locally Γ-free for β and there is some $(S, C) \in Y$ with $\langle m \rangle \in (S, C)$, and in the latter case, set

$$\rho(\beta, \Gamma, Y, m) := \begin{cases} 1, & \text{if } \Gamma = \emptyset, \\ \omega^{\omega^\ell}, & \text{if } \Gamma \neq \emptyset \text{ and } \beta = \max(\Gamma) \text{ limit}, \\ \omega^{\omega^\mu \cdot \ell}, & \text{otherwise,} \end{cases}$$

where, for non-empty Γ, $\ell := |C(s)| - 1$ for s the least signal node of (S, C), $\mu := |\Gamma| - 1$. This function is well-defined, since if $Y(\langle m\rangle) \neq \emptyset$ is locally Γ-free for β with Γ non-empty, then all elements of $Y(\langle m\rangle)$ have a proper relaxed initial segment in common with (S, C) which must include the least signal node of (S, C).

Let $*(\beta, \Gamma)$ be the following statement.

$*(\beta,\Gamma)$ For all locally Γ-free for β sets Y, if $\langle m\rangle \in (S, C) \in Y$, then $\mathrm{ot}(Y(\langle m\rangle)) \geq \rho(\beta, \Gamma, Y, m)$.

10.45 Claim. *For all $\beta \geq 1$ and $0 \notin \Gamma \subseteq \beta + 1$, if X is Γ-free for β and $*(\beta, \Gamma)$ holds, then* $\mathrm{ot}(X) \geq \zeta(\beta, \Gamma)$.

Proof. Use induction on n to prove the claim for subsets $\Gamma \subseteq \omega$ of size n.

To start the induction, consider subsets of size 0. If X is $\emptyset$-free for $\beta \geq 1$, then by definition, $X(\langle m\rangle)$ is non-empty for infinitely many m, and by commonality and push-up, $\mathrm{ot}(X(\langle m\rangle)) \geq \omega$, so $\mathrm{ot}(X) \geq \omega^2 = \zeta(\beta, \emptyset)$.

Next assume the claim is true for subsets of size k and that $n = k + 1$. If X is Γ-free for $\beta \geq 1$ and $0 \notin \Gamma \subseteq \beta + 1$ satisfies $\omega \notin \Gamma$ and $|\Gamma| = k + 1$, then there are arbitrarily large ℓ for which there are $m \in (S, C) \in X$ with $\ell < |C(\langle m\rangle)|$ if $\beta \in \Gamma$ and with $\ell < m$ otherwise. In the latter case, by Γ-forecasting and by signal size, there are arbitrarily large ℓ for which the first signal node $s \in (S, C) \in X$ has $\ell < |C(s)|$. Since $*(\beta, \Gamma)$ holds, it follows that there are arbitrarily large $\ell < m$ with $\mathrm{ot}(X(\langle m\rangle)) \geq \omega^{\omega^k \ell}$ for $k = |\Gamma| - 1$, hence $\mathrm{ot}(X) \geq \omega^{\omega^{k+1}} = \zeta(\beta, \Gamma)$ as desired.

Therefore by induction, the claim holds for all finite subsets $\Gamma \subseteq \omega$.

To complete the proof, consider Γ with $\omega \in \Gamma$. Then $\beta = \omega$. Suppose X is Γ-free for ω and $\omega \in \Gamma$. Then the root node of every tree in X is a signal node. Also X has arbitrarily large values for $|C(\langle m\rangle)|$ by the definition of Γ-free for $\beta = \omega \in \Gamma$. Hence from $*(\omega, \Gamma)$ it follows that $\mathrm{ot}(X(\langle m\rangle)) \geq \omega^{\omega^\ell}$ for $\ell = |C(\langle m\rangle)| - 1$, so $\mathrm{ot}(X) = \omega^{\omega^\omega} = \zeta(\omega, \Gamma)$ as required. ⊣

10.46 Claim. *For all $\beta \geq 1$ and $0 \notin \Gamma \subseteq \beta+1$, the statement $*(\beta, \Gamma)$ holds.*

Proof. Suppose Y is locally $\emptyset$-free for $\beta \geq 1$ and $\langle m\rangle \in (S, C) \in Y$. Then by commonality and push-up, $\mathrm{ot}(Y(\langle m\rangle)) \geq \omega$, so $*(\beta, \emptyset)$ holds.

Use induction on β to show that for all non-empty $0 \notin \Gamma \subseteq \beta + 1$, the statement $*(\beta, \Gamma)$ holds. For the basis case, $\beta = 1$, the only case to be considered is $\Gamma = \{1\}$. Suppose Y is locally $\{1\}$-free and $\langle m\rangle \in (S, C) \in Y$. Then $\langle m\rangle$ is a signal node, and $Z := \{\bigcup T : (T, D) \in Y(\langle m\rangle)\}$ is free in $|C(\langle m\rangle)|$ coordinates in the sense of Definition 10.39 by conformity and push-up. Thus Z has order type $\omega^{|C(\langle m\rangle)|}$ by Lemma 10.40. Hence $Y(\langle m\rangle)$ has this order type as well, so $*(1, \{1\})$ holds.

For the induction step, assume $*(\beta')$ is true for all β' with $1 \leq \beta' < \beta$. Suppose Γ is non-empty with $0 \notin \Gamma \subseteq \beta + 1$, Y is locally Γ-free for β and $\langle m\rangle \in (S, C) \in Y$. It follows that $Y(\langle m\rangle)$ is also locally Γ-free for β. Let

(S^-, C^-) be the minimal proper relaxed initial segment of (S, C), required by commonality. Then (S^-, C^-) is a common initial segment of all trees in Y. Let $\langle m, m^-\rangle$ be the unique initial segment of $\max(S^-)$ of length 2.

Case 1. $\max(\Gamma) < \beta$ or $\max(\Gamma) = \beta = \omega$.

For each $(T, D) \in Y$, the *derived tree* $(\hat{T}, \hat{D})$ is defined by $\hat{t} \in \hat{T}$ if and only if $\langle m, m^-\rangle \sqsubseteq \langle m\rangle^\frown \hat{t} \in T$, and $\hat{D}(\hat{t}) = D(\langle m\rangle^\frown \hat{t})$.

Let Z be the collection of derived trees. Note that $\langle m^-\rangle$ is an element of every tree in Z. Let $\beta' = \beta - 1$ and $\Gamma' = \Gamma$ if β is finite, and let $\beta' = m$ and $\Gamma' = (\Gamma - \{\omega\}) \cup C(\langle m\rangle)$ otherwise. Then $Z = Z(\langle m^-\rangle)$ is locally Γ'-free for β'. Also, $\mathrm{ot}(Y(\langle m\rangle)) \geq \mathrm{ot}(Z(\langle m^-\rangle))$, so in this case, the desired inequality follows by the induction hypothesis.

Case 2. $\Gamma = \{\zeta + 1\}$.

Consider the set $E \subseteq \mathcal{T}(1)$ of $\langle m, k_1, k_2, \ldots, k_m\rangle$ such that there is a $(T, D) \in Y$ such that for all $1 \leq i \leq m$, $\langle m, k_i\rangle \in T$. By conformity and push-up, the set E is free in $\ell = |C(\langle m\rangle)| - 1$ many coordinates, so it has order type ω^ℓ, by Lemma 10.40. Thus $\mathrm{ot}(Y(\langle m\rangle)) \geq \mathrm{ot}(E) = \omega^\ell = \rho(\beta, \gamma, Y, m)$ as required.

Case 3. $\zeta + 1 \in \Gamma \neq \{\zeta + 1\}$.

Notice that every tree (T, D) in $Y(\langle m\rangle)$ may be thought of as a collection of m node labeled trees from $\mathcal{T}(\zeta)$ extending from the root $\langle m\rangle$.

Call an initial segment (T, D) of a tree in $Y(\langle m\rangle)$ *large* if $\max(T)$ is a prepartition node with ordinal 0 such that $\sharp(s, T) = \max(C(s))$ for all proper $s \sqsubset t$ with $|s| > 1$. Every element of $Y(\langle m\rangle)$ has exactly $|C(\langle m\rangle)|$ many large initial segments.

Let $\Gamma' = \Gamma - \{\zeta + 1\}$ and set $\mu = |\Gamma'|$. Fix attention on a large (T, D) for which $\sharp(\langle m\rangle, T) < \max(C(\langle m\rangle))$, and let k be the least element of $C(\langle m\rangle)$ greater than $\sharp(\langle m\rangle, T)$. Let $E(T, D)$ be the set of initial segments (T', D') of elements of Y extending (T, D) to a tree with root $\langle m\rangle$ extended by exactly k subtrees from $\mathcal{T}(\zeta)$. Then $E(T, D)$ has order type ω^{ω^μ}, since the collection of trees that occur for the kth slot are Γ'-free for ζ. In fact the set of maximal large initial segments of these trees also has order type ω^{ω^μ}, since each has exactly ω extensions in $E(T, D)$ and ω^{ω^μ} is multiplicatively indecomposable. From this analysis, it follows that $\mathrm{ot}(Y(\langle m\rangle)) \geq \omega^{\omega^\mu \cdot \ell}$, where $\ell = |C(\langle m\rangle)| - 1$, so $*(\beta, \Gamma)$ holds in this final case.

Therefore by induction on β, the claim follows. $\dashv$

Now the lemma follows from Claims 10.44, 10.45 and 10.46. $\dashv$

10.47 Lemma. *Suppose h is a 2-partition of $\mathcal{T}(\omega)$ with 2 colors and $N \subseteq \omega$ is infinite with $1 < \min(N)$ and no two consecutive integers are in N. Further suppose a bounding function b and $H \subseteq N$ infinite are such that the builder wins every run of $\mathcal{G}(h, N)$ by playing conservatively for b and H. Then there is a set $Y \subseteq \mathcal{T}(\omega)$ of order type ω^{ω^ω} so that $h(S, T) = 0$ for all global pairs from Y.*

Proof. We will use recursion to build a $\{\omega\}$-free for ω set X such that every global pair $((S,C),(T,D))$ from X has a coarsening $((S,C'),(T,D'))$ which is a final play in a run of $\mathcal{G}(h,N)$ in which the builder plays conservatively for b and H. (By a *coarsening*, we mean that $C'(s) \subseteq C(s)$ and $D'(t) \subseteq D(t)$ for all $s \in S$, $t \in T$.) Since the builder wins the game, $h(S,T) = 0$ for such pairs. Thus $Y = \{S : (\exists C)((S,C) \in X)\}$ is the desired set, since, by Lemma 10.43, Y has order type ω^{ω^ω}.

To start the recursion, let X_0 be the set with only $(\emptyset,\emptyset)$ in it. For positive $j < \omega$, we enumerate the node labeled trees in $\bigcup_{i<j} X_i$ which are proper initial segments, starting with $(\emptyset,\emptyset) = (S'_{j,0}, C'_{j,0})$ and ending with (S'_{j,n_j}, C'_{j,n_j}). Speaking generally, in stage j, for each $k \leq n_j$, we consider the kth initial segment, $(S'_{j,k}, C'_{j,k})$, use moves of the architect and builder in $\mathcal{G}(h,H)$ to create a relaxed or complete extension, $(S_{j,k}, C_{j,k})$, using elements of H larger than anything mentioned up to that point. Then we let X_k be the set of all $(S_{j,k}, C_{j,k})$ for $k \leq n_j$.

A simple induction shows that there are only finitely many proper initial segments to be considered in each stage and they fall into at most three types: *trivial* (i.e. $(\emptyset,\emptyset)$), *ready for completion* (i.e. a relaxed initial segment (T,D) such that for all $s \subseteq \max(T)$ whose ordinal is a successor, $\sharp(s,T) = \max(D(s))$), or relaxed but not ready for completion.

In stage j, for the trivial initial segment, one starts $\mathcal{G}(h,H)$ at the beginning. Otherwise, for the kth initial segment, one continues a game in which the first tree is $(S'_{j,k}, C'_{j,k})$ and the second tree is the relaxed initial segment constructed to extend $(\emptyset,\emptyset)$ in this stage, namely $(S_{j,0}, C_{j,0})$.

In the games played, the architect uses the following strategy. She always directs the builder to create or extend the first tree. If the architect is making her first move on the kth initial segment and it is relaxed, then she declares the next node label size to be 0 and calls for completion if $(S'_{j,k}, C'_{j,k})$ is ready for completion, and for decision otherwise. Recall that if the architect calls for completion, then the node label of new elements is the empty set. Otherwise, the architect uses the least element of H larger than any used to that point as the size of the next node label, and calls for construction to the next decision node.

The builder always responds conservatively for H, b, and always plays large enough to have the play remain conservative for any possible game that could be constructed using coarsenings of the given trees.

Play stops at the end of the first move by the builder in which he creates a tree $(S_{j,k}, C_{j,k})$ which is relaxed or complete.

In any stage, with any starting initial segment, after finitely many steps of the game, the builder has constructed the required relaxed or complete extension. Since there are only finitely many trees to extend in a given round, eventually each round is finished. Therefore, the construction stops after ω rounds with a set $\overline{X} = \bigcup X_j$ of trees. Let X be the set of complete trees in $\overline{X}$. By construction, X is $\{\omega\}$-free, so by Lemma 10.43, the set $Y := \{S : (\exists C)((S,C) \in X)\}$ has order type ω^{ω^ω}.

To check that Y is the required set, suppose that $((S^0, C^0), (S^1, C^1))$ is a global pair from the set X with $(S^0, C^0) < (S^1, C^1)$. By the construction, every partition node of $(S^\varepsilon, C^\varepsilon)$ is the maximum of some relaxed segment of $(S^\varepsilon, C^\varepsilon)$, and every splitting node r has $e_\beta(r)$ in $C(\langle m^\varepsilon\rangle)$, where a *splitting node* $r \in S^\varepsilon$ is one of the form $s \cap t$ for distinct partition nodes $s, t \in S^\varepsilon$. Hence there are coarsenings (S^0, D^0) and (S^1, D^1) so that for all $r \in S^\varepsilon$,

$$D^\varepsilon(r) = \begin{cases} \{\sharp(r, S^\varepsilon(\emptyset, s]) : r \sqsubset s \text{ partition node}\} & e_\omega(r) \text{ successor,} \\ \{e_\omega(t) : r \sqsubset t \text{ splitting node}\} & e_\omega(r) \text{ limit,} \\ \emptyset & \text{otherwise.} \end{cases}$$

Thus $((S^0, D^0), (S^1, D^1))$ satisfies Definition 10.23 and is a global clear pair. If $\max(\bigcup S^0) > \max(\bigcup S^1)$, then the pair is inside, and otherwise it is outside. Use this knowledge in the architect's initial move; use the values of $|D^\varepsilon(r)|$ for the sizes of the node labels in the architect's moves; and orchestrate her moves to create the pair of node labeled trees when the builder is required to use the elements of $\bigcup S^0 \cup \operatorname{ran}(D^0) \cup \bigcup S^1 \cup \operatorname{ran}(D^1)$. Since the architect has no winning strategy, and the builder's plays were large enough for any coarsening, it follows that this run of the game is a win for the builder. Thus $h(S^0, S^1) = 0$ as desired. $\dashv$

10.7. Completion of the Proof

In this subsection, we complete the proof that $\omega^{\omega^\omega} \to (\omega^{\omega^\omega}, 3)^2$ by assembling the appropriate lemmas. We start with $h : [\mathcal{T}(\omega)]^2 \to 2$. We apply the Ramsey Dichotomy 10.32 to h and $N = \omega$ to get $H \subseteq \omega$ infinite, a bounding function b and a favored player.

If the architect has a winning strategy by which she wins $\mathcal{G}(h, N)$ when the builder plays conservatively, then there is a 1-homogeneous triangle by Lemma 10.38.

Otherwise, the builder wins every run of $\mathcal{G}(h, N)$ by playing conservatively, so by Lemma 10.47, there is a set Y of order type ω^{ω^ω} so that all global pairs get color 0. Partition Y into sets Y_n so that $Y_0 < Y_1 < \cdots$, all pairs from Y_n are local, and $\operatorname{ot}(Y_n) \geq \omega^{\omega^{1+2n}}$. Apply Corollary 9.3 to each Y_n. If for some n, the result is a 1-homogeneous triangle, we are done. Otherwise, we get 0-homogeneous sets $Z_n \subseteq Y_n$ of order type $\omega^{\omega^{1+n}}$, and $Z = \bigcup Z_n$ is the 0-homogeneous set required for completion of the proof of the theorem.

A transfinite sequence $C_\xi \subseteq \xi$ $(\xi < \theta)$ of sets may have a number of "coherence properties" and the purpose of this chapter is to study some of them, as well as some of their uses. Here, "coherence" usually means that the C_ξ's are chosen in some canonical way, beyond the natural requirement that C_ξ be closed and unbounded in ξ for all ξ. For example, choosing a canonical "fundamental sequence" of sets $C_\xi \subseteq \xi$ for $\xi < \varepsilon_0$ relying on the specific properties of the Cantor normal form for ordinals below the first ordinal satisfying the equation $x = x^x$ is a basis for a number of important results in proof theory. In set theory, one is interested in longer sequences as well and usually has a different perspective in applications, so one is naturally led to use some other tools beside the Cantor normal form. It turns out that the sets C_ξ can not only be used as "ladders" for climbing up in recursive constructions but also as tools for "walking" from an ordinal to a smaller one. This notion of a "walk" and the corresponding "distance functions" constitute the main body of study in this chapter. We show that the resulting "metric theory of ordinals" not only provides a unified approach to a number of classical problems in set theory but also has its own intrinsic interest. For example, from this theory one learns that the triangle inequality of an ultrametric

$$e(\alpha, \gamma) \leq \max\{e(\alpha, \beta), e(\beta, \gamma)\}$$

has three versions, depending on the natural ordering between the ordinals α, β and γ, that are of a quite different character and are occurring in quite different places and constructions in set theory. The most frequent occurrence is the case $\alpha < \beta < \gamma$ when the triangle inequality becomes something that one can call the "transitivity" of e. Considerably more subtle is the case $\alpha < \gamma < \beta$ of this inequality. It is this case of the inequality that captures most of the coherence properties found in this chapter. Another thing one learns from this theory is the special role of the first uncountable ordinal in this theory. Any natural coherence requirement on the sets C_ξ $(\xi < \theta)$ that one finds in this theory is satisfiable in the case $\theta = \omega_1$. The first uncountable cardinal is the only cardinal on which the theory can be carried out without relying on additional axioms of set theory. The first uncountable cardinal is the place where the theory has its deepest applications as well as its most important open problems. This special role can perhaps be explained by the fact that many set-theoretical problems, especially those coming from other fields of mathematics, are usually concerned only about the duality between the countable and the uncountable rather than some intricate relationship between two or more uncountable cardinalities. This is of course not to say that an intricate relationship between two or more uncountable cardinalities may not be a profitable detour in the course of solving such a problem. In fact, this is one of the reasons for our attempt to develop the metric theory of ordinals without restricting ourselves only to the realm of countable ordinals.

The chapter is organized as a discussion of five basic distance functions on ordinals, $\rho, \rho_0, \rho_1, \rho_2$ and ρ_3, and the reader may choose to follow the analysis of any of these functions in various contexts. The distance functions will naturally lead us to many other derived objects, most prominent of which is the "square-bracket operation" that gives us a way to transfer the quantifier "for every unbounded set" to the quantifier "for every closed and unbounded set". This reduction of quantifiers has proven to be quite useful in constructions of various mathematical structures, some of which have been mentioned or reproduced here.

I wish to thank Bernhard König, Piotr Koszmider, Justin Moore and Christine Härtl for help in the preparation of the manuscript.

1. The Space of Countable Ordinals

This is by far the most interesting space considered in this chapter. There are many mathematical problems whose combinatorial essence can be reformulated as a problem about ω_1, the smallest uncountable structure. What we mean by "structure" is ω_1 together with a system C_α $(\alpha < \omega_1)$ of fundamental sequences, i.e. a system with the following two properties:

(a) $C_{\alpha+1} = \{\alpha\}$,

(b) C_α is an unbounded subset of α of order-type ω, whenever α is a countable limit ordinal > 0.

Such a sequence we shall simply call a *C-sequence*, here and when we generalize to ω_1 replaced by a general regular κ and C_α is a closed unbounded subset of α for limit $\alpha < \kappa$.

Despite its simplicity, this structure can be used to derive virtually all other known structures that have been defined so far on ω_1. There is a natural recursive way of picking up the fundamental sequences C_α, a recursion that refers to the Cantor normal form which works well for, say, ordinals $< \varepsilon_0$.[1] For longer fundamental sequences one typically relies on some other principles of recursive definition and one typically works with fundamental sequences with as few extra properties as possible. We shall see that the following assumption is what is frequently needed and will therefore be implicitly assumed whenever necessary:

(c) If α is a limit ordinal, then C_α does not contain limit ordinals.

1.1 Definition. A *step* from a countable ordinal β towards a smaller ordinal α is the minimal point of C_β that is $\geq \alpha$. The cardinality of the set $C_\beta \cap \alpha$, or better to say the order-type of this set, is the *weight* of the step.

1.2 Definition. A *walk* (or a *minimal walk*) from a countable ordinal β to a smaller ordinal α is the sequence $\beta = \beta_0 > \beta_1 > \cdots > \beta_n = \alpha$ such that for each $i < n$, the ordinal β_{i+1} is the step from β_i towards α.

[1] One is tempted to believe that the recursion can be stretched all the way up to ω_1 and this is probably the way P.S. Alexandroff found his famous Pressing Down Lemma (see [1] and [2, appendix]).

Analysis of this notion leads to several two-place functions on ω_1 that give a rich structure with many applications. So let us describe some of these functions.

1.3 Definition. The *full code* of the walk is the function $\rho_0 : [\omega_1]^2 \longrightarrow \omega^{<\omega}$ defined recursively by

$$\rho_0(\alpha, \beta) = \langle |C_\beta \cap \alpha| \rangle^\frown \rho_0(\alpha, \min(C_\beta \setminus \alpha)),$$

where $\rho_0(\alpha, \alpha) = 0$,[2] and the symbol $^\frown$ refers to the sequence obtained by concatenating the one-term sequence $\langle |C_\beta \cap \alpha| \rangle$ with the already known finite sequence $\rho_0(\alpha, \min(C_\beta \setminus \alpha)$ of integers. Clearly, knowing $\rho_0(\alpha, \beta)$ and the ordinal β one can reconstruct the (*upper*) trace

$$\mathrm{Tr}(\alpha, \beta) = \{\beta_0, \dots, \beta_n\},$$

remembering that $\beta = \beta_0 > \beta_1 > \cdots > \beta_n = \alpha$, of the walk from β to α. The *lower trace* is defined to be

$$\mathrm{L}(\alpha, \beta) = \{\lambda_0, \lambda_1, \dots, \lambda_{n-1}\},$$

where $\lambda_i = \max(\bigcup_{j=0}^{i} C_{\beta_j} \cap \alpha)$ for $i < n$ and so $\lambda_0 \leq \lambda_1 \leq \cdots \leq \lambda_{n-1}$.

1.4 Definition. The *full lower trace* of the minimal walk is the function $\mathrm{F} : [\omega_1]^2 \longrightarrow [\omega_1]^{<\omega}$ defined recursively by

$$\mathrm{F}(\alpha, \beta) = \mathrm{F}(\alpha, \min(C_\beta \setminus \alpha)) \cup \bigcup_{\xi \in C_\beta \cap \alpha} \mathrm{F}(\xi, \alpha),$$

where $\mathrm{F}(\gamma, \gamma) = \{\gamma\}$ for all γ.

Clearly, $\mathrm{F}(\alpha, \beta) \supseteq \mathrm{L}(\alpha, \beta)$ but $\mathrm{F}(\alpha, \beta)$ is considerably larger than $\mathrm{L}(\alpha, \beta)$ as it includes also the traces of walks between any two ordinals $\leq \alpha$ that have ever been referred to during the walk from β to α. The following two properties of the full lower trace are straightforward to check (see [66]).

1.5 Lemma. *For all $\alpha \leq \beta \leq \gamma$,*

(a) $\mathrm{F}(\alpha, \gamma) \subseteq \mathrm{F}(\alpha, \beta) \cup \mathrm{F}(\beta, \gamma)$,

(b) $\mathrm{F}(\alpha, \beta) \subseteq \mathrm{F}(\alpha, \gamma) \cup \mathrm{F}(\beta, \gamma)$.

1.6 Lemma. *For all $\alpha \leq \beta \leq \gamma$,*

(a) $\rho_0(\alpha, \beta) = \rho_0(\min(\mathrm{F}(\beta, \gamma) \setminus \alpha), \beta)^\frown \rho_0(\alpha, \min(\mathrm{F}(\beta, \gamma) \setminus \alpha))$,

(b) $\rho_0(\alpha, \gamma) = \rho_0(\min(\mathrm{F}(\beta, \gamma) \setminus \alpha), \gamma)^\frown \rho_0(\alpha, \min(\mathrm{F}(\beta, \gamma) \setminus \alpha))$.

[2] Technically speaking, ρ_0 operates on $[\omega_1]^2$ so $\rho_0(\alpha, \alpha) = 0$ makes no sense. What we mean is that whenever the formal recursive definition of $\rho_0(\alpha, \beta)$ involves the term $\rho_0(\alpha, \alpha)$ we take it to be equal to 0. This will be applied frequently in this chapter, not always in explicit form.

1.7 Definition. The ordering $<_c$ on ω_1 is defined as follows:

$$\alpha <_c \beta \quad \text{iff} \quad \rho_0(\xi,\alpha) <_r \rho_0(\xi,\beta),$$

where $\xi = \Delta(\alpha,\beta) = \min\{\eta \leq \min\{\alpha,\beta\} : \rho_0(\eta,\alpha) \neq \rho_0(\eta,\beta)\}$. Here $<_r$ refers to the *right lexicographical ordering* on $\omega^{<\omega}$ defined by letting $s <_r t$ iff s is an end-extension of t or $s(i) < t(i)$ for $i = \min\{j : s(j) \neq t(j)\}$.

1.8 Lemma. *The Cartesian square of the total ordering $<_c$ of ω_1 is the union of countably many chains.*

Proof. It suffices to decompose the set of all pairs (α,β) where $\alpha < \beta$. To each such pair we associate a hereditarily finite set $p(\alpha,\beta)$ which codes the finite structure obtained from $\mathrm{F}(\alpha,\beta)\cup\{\beta\}$ by adding relations that describe the way ρ_0 acts on it. To show that this parametrization works, suppose we are given two pairs (α,β) and (γ,δ) such that

$$p(\alpha,\beta) = p(\gamma,\delta) = p \quad \text{and} \quad \alpha <_c \gamma.$$

We must show that $\beta \leq_c \delta$. Let

$$\begin{aligned} \xi_{\alpha\beta} &= \min(\mathrm{F}(\alpha,\beta) \setminus \Delta(\alpha,\gamma)) \quad \text{and} \\ \xi_{\gamma\delta} &= \min(\mathrm{F}(\gamma,\delta) \setminus \Delta(\alpha,\gamma)). \end{aligned}$$

Note that $\mathrm{F}(\alpha,\beta)\cap\Delta(\alpha,\gamma) = \mathrm{F}(\gamma,\delta)\cap\Delta(\alpha,\gamma)$ so $\xi_{\alpha\beta}$ and $\xi_{\gamma\delta}$ correspond to each other in the isomorphism of the (α,β) and (γ,δ) structures. It follows that:

$$\begin{aligned} \rho_0(\xi_{\alpha\beta},\alpha) &= \rho_0(\xi_{\gamma\delta},\gamma)(= t_{\alpha,\gamma}), \\ \rho_0(\xi_{\alpha\beta},\beta) &= \rho_0(\xi_{\gamma\delta},\delta)(= t_{\beta,\delta}). \end{aligned}$$

Applying Lemma 1.6 we get:

$$\begin{aligned} \rho_0(\Delta(\alpha,\gamma),\alpha) &= t_{\alpha\gamma}{}^\frown\rho_0(\Delta(\alpha,\gamma),\xi_{\alpha\beta}), \\ \rho_0(\Delta(\alpha,\gamma),\gamma) &= t_{\alpha\gamma}{}^\frown\rho_0(\Delta(\alpha,\gamma),\xi_{\gamma\delta}). \end{aligned}$$

It follows that $\rho_0(\Delta(\alpha,\gamma),\xi_{\alpha\beta}) \neq \rho_0(\Delta(\alpha,\gamma),\xi_{\gamma\delta})$. Applying Lemma 1.6 for β and δ and the ordinal $\Delta(\alpha,\gamma)$ we get:

$$\rho_0(\Delta(\alpha,\gamma),\beta) = t_{\beta\delta}{}^\frown\rho_0(\Delta(\alpha,\gamma),\xi_{\alpha\beta}), \tag{3.1}$$

$$\rho_0(\Delta(\alpha,\gamma),\delta) = t_{\beta\delta}{}^\frown\rho_0(\Delta(\alpha,\gamma),\xi_{\gamma\delta}). \tag{3.2}$$

It follows that $\rho_0(\Delta(\alpha,\gamma),\beta) \neq \rho_0(\Delta(\alpha,\gamma),\delta)$. This shows $\Delta(\alpha,\gamma) \geq \Delta(\beta,\delta)$. A symmetric argument shows the other inequality $\Delta(\beta,\delta) \geq \Delta(\alpha,\gamma)$. It follows that

$$\Delta(\alpha,\gamma) = \Delta(\beta,\delta)(= \bar{\xi}).$$

Our assumption is that $\rho_0(\bar{\xi},\alpha) <_r \rho_0(\bar{\xi},\gamma)$ and since these two sequences have $t_{\alpha\gamma}$ as common initial part, this reduces to

$$\rho_0(\bar{\xi},\xi_{\alpha\beta}) <_r \rho_0(\bar{\xi},\xi_{\gamma\delta}). \tag{3.3}$$

On the other hand $t_{\beta\delta}$ is a common initial part of $\rho_0(\bar{\xi},\beta)$ and $\rho_0(\bar{\xi},\delta)$, so their lexicographical relationship depends on their tails which by (3.1) and (3.2) are equal to $\rho_0(\bar{\xi},\xi_{\alpha\beta})$ and $\rho_0(\bar{\xi},\xi_{\gamma\delta})$ respectively. Referring to (3.3) we conclude that indeed $\rho_0(\bar{\xi},\beta) <_r \rho_0(\bar{\xi},\delta)$, i.e. $\beta <_c \delta$. ⊣

1.9 Notation. *Well-ordered sets of rationals.* The set $\omega^{<\omega}$ ordered by the right lexicographical ordering $<_r$ is a particular copy of the rationals of the interval $(0,1]$ which we are going to denote by $\mathbb{Q}_r$ or simply by $\mathbb{Q}$. The next lemma shows that for a fixed α, $\rho_0(\xi,\alpha)$ is a strictly increasing function of ξ from α into $\mathbb{Q}_r$. Let $(\rho_0)_\alpha$ denote this function which we identify with its range, i.e. view as a member of the tree $\sigma\mathbb{Q}_r$ of all well-ordered subsets of $\mathbb{Q}_r$, ordered by end-extension.

1.10 Lemma. *$\rho_0(\alpha,\gamma) <_r \rho_0(\beta,\gamma)$ whenever $\alpha<\beta<\gamma$.*

At this point we recall several standard concepts for trees of height ω_1, concepts that generally figure in what follows: A tree of height ω_1 is an *Aronszajn tree* if all of its levels and chains are countable. A tree of height ω_1 is a *special Aronszajn tree* if it is an Aronszajn tree that admits a decomposition into countably many antichains or, equivalently, admits a strictly increasing map into the rationals. Finally, a tree of height ω_1 is a *Souslin tree* if all of its chains and antichains countable.

The sequence $(\rho_0)_\alpha$ $(\alpha<\omega_1)$ of members of $\sigma\mathbb{Q}_r$ naturally determines the subtree

$$T(\rho_0) = \{(\rho_0)_\beta \restriction \alpha : \alpha \le \beta < \omega_1\}.$$

Note that for a fixed α, the restriction $(\rho_0)_\beta\restriction\alpha$ is determined by the way $(\rho_0)_\beta$ acts on the finite set $\mathrm{F}(\alpha,\beta)$. This is the content of Lemma 1.6. Hence all levels of $T(\rho_0)$ are countable, and therefore $T(\rho_0)$ is a particular example of an Aronszajn tree. We shall now see that $T(\rho_0)$ is in fact a special Aronszajn tree. The proof of this will depend on the following straightforward fact.

1.11 Lemma. *$\{\xi<\beta : \rho_0(\xi,\beta)=\rho_0(\xi,\gamma)\}$ is a closed subset of β whenever $\beta<\gamma$.*

It follows that $T(\rho_0)$ does not branch at limit levels. From this we can conclude that $T(\rho_0)$ is a special subtree of $\sigma\mathbb{Q}$ since this is easily seen to be so for any subtree of $\sigma\mathbb{Q}$ which is finitely branching at limit nodes.

1.12 Definition. Identifying the power set of $\mathbb{Q}$ with the particular copy $2^{\mathbb{Q}}$ of the Cantor set, define for every countable ordinal α,

$$G_\alpha = \{x\in 2^{\mathbb{Q}} : x \text{ end-extends no } (\rho_0)_\beta\restriction\alpha \text{ for } \beta\ge\alpha\}.$$

1.13 Lemma. *G_α ($\alpha < \omega_1$) is an increasing sequence of proper G_δ-subsets of the Cantor set whose union is equal to the Cantor set.*

1.14 Lemma. *The set $X = \{(\rho_0)_\beta : \beta < \omega_1\}$ considered as a subset of the Cantor set $2^{\mathbb{Q}}$ has universal measure zero.*

Proof. Let μ be a given non-atomic Borel measure on $2^{\mathbb{Q}}$. For $t \in T(\rho_0)$, set

$$P_t = \{x \in 2^{\mathbb{Q}} : x \text{ end-extends } t\}.$$

Note that each P_t is a perfect subset of $2^{\mathbb{Q}}$ and therefore is μ-measurable. Let

$$S = \{t \in T(\rho_0) : \mu(P_t) > 0\}.$$

Then S is a downward closed subtree of $\sigma\mathbb{Q}$ with no uncountable antichains. By an old result of Kurepa (see [55]), no Souslin tree admits a strictly increasing map into the reals (as for example $\sigma\mathbb{Q}$ does). It follows that S must be countable and so we are done. ⊣

1.15 Definition. The *maximal weight* of the walk is the two-place function $\rho_1 : [\omega_1]^2 \longrightarrow \omega$ defined recursively by

$$\rho_1(\alpha, \beta) = \max\{|C_\beta \cap \alpha|, \rho_1(\alpha, \min(C_\beta \setminus \alpha))\},$$

where we stipulate that $\rho_1(\alpha, \alpha) = 0$ for all $\alpha < \omega_1$.[3] Thus $\rho_1(\alpha, \beta)$ is simply the maximal integer appearing in the sequence $\rho_0(\alpha, \beta)$.

1.16 Lemma. *For all $\alpha < \beta < \omega_1$ and $n < \omega$,*

(a) $\{\xi \leq \alpha : \rho_1(\xi, \alpha) \leq n\}$ is finite,

(b) $\{\xi \leq \alpha : \rho_1(\xi, \alpha) \neq \rho_1(\xi, \beta)\}$ is finite.

Proof. The proof is by induction. To prove (a) it suffices to show that for every $n < \omega$ and every $A \subseteq \alpha$ of order-type ω there is a $\xi \in A$ such that $\rho_1(\xi, \alpha) > n$. Let $\eta = \sup(A)$. If $\eta = \alpha$ one chooses arbitrary $\xi \in A$ with the property that $|C_\alpha \cap \xi| > n$, so let us consider the case $\eta < \alpha$. Let $\alpha_1 = \min(C_\alpha \setminus \eta)$. By the inductive hypothesis there is a $\xi \in A$ such that:

$$\xi > \max(C_\alpha \cap \eta) \quad \text{and} \quad \rho_1(\xi, \alpha_1) > n.$$

Note that $\rho_0(\xi, \alpha) = \langle |C_\alpha \cap \eta| \rangle^\frown \rho_0(\xi, \alpha_1)$, and therefore

$$\rho_1(\xi, \alpha) \geq \rho_1(\xi, \alpha_1) > n.$$

To prove (b) we show by induction that for every $A \subseteq \alpha$ of order-type ω there exists a $\xi \in A$ such that $\rho_1(\xi, \alpha) = \rho_1(\xi, \beta)$. Let $\eta = \sup(A)$ and let $\beta_1 = \min(C_\beta \setminus \eta)$. Let $n = |C_\beta \cap \eta|$ and let

$$B = \{\xi \in A : \xi > \max(C_\beta \cap \eta) \quad \text{and} \quad \rho_1(\xi, \beta_1) > n\}.$$

[3] This is another use of the convention $\rho_1(\alpha, \alpha) = 0$ that is necessary for the recursive definition to work.

Then B is infinite, so by the induction hypothesis we can find $\xi \in B$ such that $\rho_1(\xi,\alpha) = \rho_1(\xi,\beta_1)$. Then

$$\rho_1(\xi,\beta) = \max\{n, \rho_1(\xi,\beta_1)\} = \rho_1(\xi,\beta_1),$$

so we are done. $\dashv$

1.17 Remark. Define $(\rho_1)_\alpha$ from ρ_1 just as $(\rho_0)_\alpha$ was defined from ρ_0 above. It follows that the sequence

$$(\rho_1)_\alpha : \alpha \longrightarrow \omega \ (\alpha < \omega_1)$$

of finite-to-one functions is *coherent* in the sense that $(\rho_1)_\alpha =^* (\rho_1)_\beta \restriction \alpha$ whenever $\alpha \leq \beta$. (Here $=^*$ for functions denotes agreement on all but finitely many arguments.) The corresponding tree

$$T(\rho_1) = \{t : \alpha \longrightarrow \omega : \alpha < \omega_1 \text{ and } t =^* (\rho_1)_\alpha\}$$

is a homogeneous, special Aronszajn tree with many other interesting properties, some of which we are going to describe here. For example, we have the following fact whose proof (see [66]) is quite analogous to that of Lemma 1.8.

1.18 Lemma. *The Cartesian square of $T(\rho_1)$ ordered lexicographically is the union of countably many chains.*

1.19 Definition. Consider the following extension of $T(\rho_1)$:

$$\widetilde{T}(\rho_1) = \{t : \alpha \longrightarrow \omega : \alpha < \omega_1 \text{ and } t\restriction\xi \in T(\rho_1) \text{ for all } \xi < \alpha\}.$$

If we order $\widetilde{T}(\rho_1)$ by the right lexicographical ordering $<_r$ we get a complete linearly ordered set. It is not continuous, as it contains jumps of the form

$$[t^\frown\langle m\rangle, t^\frown\langle m+1\rangle^\frown\vec{0}\,],$$

where $t \in T(\rho_1)$ and $m < \omega$. Removing the right-hand points from all the jumps we get a linearly ordered continuum which we denote by $\widetilde{A}(\rho_1)$ For the proof of the following, see [66].

1.20 Lemma. *$\widetilde{A}(\rho_1)$ is a homogeneous non-reversible ordered continuum that can be represented as the union of an increasing ω_1-sequence of Cantor sets.*

1.21 Definition. The set $\widetilde{T}(\rho_1)$ has another natural structure, a topology generated by the family of sets of the form

$$\widetilde{V}_t = \{u \in \widetilde{T}(\rho_1) : t \subseteq u\},$$

for t a node of $T(\rho_1)$ of successor length as a clopen subbase. Let $T^0(\rho_1)$ denote the set of all nodes of $T(\rho_1)$ of successor length. Then $\widetilde{T}(\rho_1)$ can be regarded as the set of all downward closed chains of the tree $T^0(\rho_1)$ and the topology on $\widetilde{T}(\rho_1)$ is simply the topology one obtains from identifying the power set of $T^0(\rho_1)$ with the cube $\{0,1\}^{T^0(\rho_1)}$ with its Tychonoff topology.[4] $\widetilde{T}(\rho_1)$ being a closed subset of the cube is compact. In fact $\widetilde{T}(\rho_1)$ has some very strong topological properties such as the property that closed subsets of $\widetilde{T}(\rho_1)$ are its retracts.

1.22 Lemma. *$\widetilde{T}(\rho_1)$ is a homogeneous compactum whose function space $\mathcal{C}(\widetilde{T}(\rho_1))$ is generated by a weakly compact subset.*[5]

Proof. The proof that $\widetilde{T}(\rho_1)$ is homogeneous is quite similar to the corresponding part of the proof of the Lemma 1.20. To see that $\widetilde{T}(\rho_1)$ is an Eberlein compactum, i.e. that the function space $\mathcal{C}(\widetilde{T}(\rho_1))$ is weak compactly generated, let $\{X_n\}$ be a countable antichain decomposition of $T(\rho_1)$ and consider the set $K = \{2^{-n}\chi_{\widetilde{V}_t} : n < \omega, t \in X_n\} \cup \{\chi_\emptyset\}$. Note that K is a weakly compact subset of $\mathcal{C}(\widetilde{T}(\rho_1))$ which separates the points of $\widetilde{T}(\rho_1)$. $\dashv$

The coherent sequence $(\rho_1)_\alpha : \alpha \longrightarrow \omega$ $(\alpha < \omega_1)$ of finite-to-one maps can easily be turned into a coherent sequence of maps that are actually one-to-one. For example, one way to achieve this is via the following formula:

$$\bar{\rho}_1(\alpha, \beta) = 2^{\rho_1(\alpha,\beta)} \cdot (2 \cdot |\{\xi \leq \alpha : \rho_1(\xi, \beta) = \rho_1(\alpha, \beta)\}| + 1).$$

Define $(\bar{\rho}_1)_\alpha$ from $\bar{\rho}_1$ just as $(\rho_1)_\alpha$ was defined from ρ_1; then the $(\bar{\rho}_1)_\alpha$'s are one-to-one. From ρ_1 one has a natural sequence r_α $(\alpha < \omega_1)$ of elements of ω^ω defined as follows:

$$r_\alpha(n) = |\{\xi \leq \alpha : \rho_1(\xi, \alpha) \leq n\}|.$$

Note that r_β eventually dominates r_α whenever $\alpha + \omega < \beta$.

1.23 Definition. The sequences $e_\alpha = (\bar{\rho}_1)_\alpha$ $(\alpha < \omega_1)$ and r_α $(\alpha < \omega_1)$ can be used in describing a functor $G \longmapsto G^*$, which to every graph G on ω_1 associates another graph G^* on ω_1 as follows:

$$\{\alpha, \beta\} \in G^* \quad \text{iff} \quad \{e_\alpha^{-1}(l), e_\beta^{-1}(l)\} \in G$$

for all $l < \Delta(r_\alpha, r_\beta)$ for which these preimages are both defined and different.

The proof of the following lemma can be found in [66].

1.24 Lemma. *Suppose that every uncountable family $\mathcal{F}$ of pairwise disjoint finite subsets of ω_1 contains two sets A and B such that $A \otimes B \subseteq G$.*[6] *Then the same is true about G^* provided the uncountable family $\mathcal{F}$ consists of finite cliques*[7] *of G^*.*

---

[4] This is done by identifying a subset V of $T^0(\rho_1)$ with its characteristic function $\chi_V : T^0(\rho_1) \longrightarrow 2$.

[5] Compacta K with this property of their function spaces $\mathcal{C}(K)$ are known in the literature under the name of *Eberlein compacta*.

[6] Here, $A \otimes B = \{\{\alpha, \beta\} : \alpha \in A, \beta \in B, \alpha \neq \beta\}$.

[7] A *clique* of G^* is a subset C of ω_1 with the property that $[C]^2 \subseteq G^*$.

1.25 Lemma. *If there is an uncountable $\Gamma \subseteq \omega_1$ such that $[\Gamma]^2 \subseteq G^*$ then ω_1 can be decomposed into countably many sets Σ such that $[\Sigma]^2 \subseteq G$.*

Proof. Fix an uncountable $\Gamma \subseteq \omega_1$ such that $[\Gamma]^2 \subseteq G^*$. For a finite binary sequence s of length equal to some $l+1$, set

$$\Gamma_s = \{\xi < \omega_1 : e(\xi, \alpha) = l \text{ for some } \alpha \text{ in } \Gamma \text{ with } s \subseteq r_\alpha\}.$$

Then the sets Γ_s cover ω_1 and $[\Gamma_s]^2 \subseteq G$ for all s. ⊣

1.26 Remark. Let G be the comparability graph of some Souslin tree T. Then for every uncountable family $\mathcal{F}$ of pairwise disjoint cliques of G (finite chains of T) there exist $A \neq B$ in $\mathcal{F}$ such that $A \cup B$ is a clique of G (a chain of T). However, it is not hard to see that G^* fails to have this property (i.e. the conclusion of Lemma 1.24). This shows that some assumption on the graph G in Lemma 1.24 is necessary. There are indeed many graphs that satisfy the hypothesis of Lemma 1.24. Many examples appear when one is trying to apply Martin's Axiom to some Ramsey-theoretic problems. Note that the conclusion of Lemma 1.24 is simply saying that the poset of all finite cliques of G^* is c.c.c. while its hypothesis is a bit stronger than the fact that the poset of all finite cliques of G is c.c.c. in all of its finite powers. Applying Lemma 1.25 to the case when G is the incomparability graph of some Aronszajn tree, we see that the statement saying that all Aronszajn trees are special is a purely Ramsey-theoretic statement in the same way Souslin's Hypothesis, that there are no Souslin trees, is.

2. Subadditive Functions

In this section we describe a metric feature of the space ω_1 of countable ordinals. One first encounters this feature by analyzing properties of the following function.

2.1 Definition. The *rho-function* $\rho : [\omega_1]^2 \longrightarrow \omega$ is defined recursion follows:

$$\rho(\alpha, \beta) = \max\{|C_\beta \cap \alpha|, \rho(\alpha, \min(C_\beta \setminus \alpha)), \rho(\xi, \alpha) : \xi \in C_\beta \cap \alpha\},$$

where we stipulate that $\rho(\alpha, \alpha) = 0$ for all $\alpha < \omega_1$.

2.2 Lemma. *For all $\alpha < \beta < \gamma < \omega_1$ and $n < \omega$,*

(a) $\{\xi \leq \alpha : \rho(\xi, \alpha) \leq n\}$ *is finite,*

(b) $\rho(\alpha, \gamma) \leq \max\{\rho(\alpha, \beta), \rho(\beta, \gamma)\}$,

(c) $\rho(\alpha, \beta) \leq \max\{\rho(\alpha, \gamma), \rho(\beta, \gamma)\}$.

Proof. Note that $\rho(\alpha,\beta) \geq \rho_1(\alpha,\beta)$, so (a) follows from the corresponding property of ρ_1. The proof of (b) and (c) is simultaneous by induction on α, β and γ:

To prove (b), consider $n = \max\{\rho(\alpha,\beta), \rho(\beta,\gamma)\}$, and let

$$\xi_\alpha = \min(C_\gamma \setminus \alpha) \quad \text{and} \quad \xi_\beta = \min(C_\gamma \setminus \beta).$$

We have to show that $\rho(\alpha,\gamma) \leq n$.

Case 1^b. $\xi_\alpha = \xi_\beta$. Then by the inductive hypothesis,

$$\rho(\alpha,\xi_\alpha) \leq \max\{\rho(\alpha,\beta), \rho(\beta,\xi_\beta)\}.$$

From the definition of $\rho(\beta,\gamma) \leq n$ we get that $\rho(\beta,\xi_\beta) \leq \rho(\beta,\gamma)$, so replacing $\rho(\beta,\xi_\beta)$ by $\rho(\beta,\gamma)$ in the above inequality we get $\rho(\alpha,\xi_\alpha) \leq n$. Consider a $\xi \in C_\gamma \cap \alpha = C_\gamma \cap \beta$. By the inductive hypothesis

$$\rho(\xi,\alpha) \leq \max\{\rho(\xi,\beta), \rho(\alpha,\beta)\}.$$

From the definition of $\rho(\beta,\gamma)$ we see that $\rho(\xi,\beta) \leq \rho(\beta,\gamma)$, so replacing $\rho(\xi,\beta)$ with $\rho(\beta,\gamma)$ in the last inequality we get that $\rho(\xi,\alpha) \leq n$. Since $|C_\gamma \cap \alpha| = |C_\gamma \cap \beta| \leq \rho(\beta,\gamma) \leq n$, referring to the definition of $\rho(\alpha,\gamma)$ we conclude that $\rho(\alpha,\gamma) \leq n$.

Case 2^b. $\xi_\alpha < \xi_\beta$. Then $\xi_\alpha \in C_\gamma \cap \beta$, so

$$\rho(\xi_\alpha,\beta) \leq \rho(\beta,\gamma) \leq n.$$

By the inductive hypothesis

$$\rho(\alpha,\xi_\alpha) \leq \max\{\rho(\alpha,\beta), \rho(\xi_\alpha,\beta)\} \leq n.$$

Similarly, for every $\xi \in C_\gamma \cap \alpha \subseteq C_\gamma \cap \beta$,

$$\rho(\xi,\alpha) \leq \max\{\rho(\xi,\beta), \rho(\alpha,\beta)\} \leq n.$$

Finally $|C_\gamma \cap \alpha| \leq |C_\gamma \cap \beta| \leq \rho(\beta,\gamma) \leq n$. Combining these inequalities we get the desired conclusion $\rho(\alpha,\gamma) \leq n$.

To prove (c), consider now $n = \max\{\rho(\alpha,\gamma), \rho(\beta,\gamma)\}$. We have to show that $\rho(\alpha,\beta) \leq n$. Let ξ_α and ξ_β be as above and let us consider the same two cases as above.

Case 1^c. $\xi_\alpha = \xi_\beta = \bar{\xi}$. Then by the inductive hypothesis

$$\rho(\alpha,\beta) \leq \max\{\rho(\alpha,\bar{\xi}), \rho(\beta,\bar{\xi})\}.$$

This gives the desired bound $\rho(\alpha,\beta) \leq n$, since $\rho(\alpha,\xi_\alpha) \leq \rho(\alpha,\gamma) \leq n$ and $\rho(\beta,\xi_\beta) \leq \rho(\beta,\gamma) \leq n$.

Case 2^c. $\xi_\alpha < \xi_\beta$. Applying the inductive hypothesis again we get

$$\rho(\alpha,\beta) \leq \max\{\rho(\alpha,\xi_\alpha), \rho(\xi_\alpha,\beta)\} \leq n.$$

This completes the proof. $\dashv$

The following simple consequence shows that the function ρ has a considerably finer coherence property than ρ_1.

2.3 Lemma. *If $\alpha < \beta < \gamma$ and $\rho(\alpha, \beta) > \rho(\beta, \gamma)$, then $\rho(\alpha, \gamma) = \rho(\alpha, \beta)$.*

2.4 Definition. Define $\bar{\rho} : [\omega_1]^2 \longrightarrow \omega$ as follows

$$\bar{\rho}(\alpha, \beta) = 2^{\rho(\alpha,\beta)} \cdot (2 \cdot |\{\xi \leq \alpha : \rho(\xi, \alpha) \leq \rho(\alpha, \beta)\}| + 1).$$

Using the properties of ρ one easily checks the following facts about its stretching $\bar{\rho}$.

2.5 Lemma. *For all $\alpha < \beta < \gamma < \omega_1$,*

(a) $\bar{\rho}(\alpha, \gamma) \neq \bar{\rho}(\beta, \gamma)$,

(b) $\bar{\rho}(\alpha, \gamma) \leq \max\{\bar{\rho}(\alpha, \beta), \bar{\rho}(\beta, \gamma)\}$,

(c) $\bar{\rho}(\alpha, \beta) \leq \max\{\bar{\rho}(\alpha, \gamma), \bar{\rho}(\beta, \gamma)\}$.

The following property of $\bar{\rho}$ is also sometimes useful (see [66]).

2.6 Lemma. *Suppose $\eta_\alpha \neq \eta_\beta < \min\{\alpha, \beta\}$ and $\bar{\rho}(\eta_\alpha, \alpha) = \bar{\rho}(\eta_\beta, \beta) = n$. Then $\bar{\rho}(\eta_\alpha, \beta), \bar{\rho}(\eta_\beta, \alpha) > n$.*

2.7 Definition. For $p \in \omega^{<\omega}$ define a binary relation $<_p$ on ω_1 by letting $\alpha <_p \beta$ iff $\alpha < \beta$, $\bar{\rho}(\alpha, \beta) \in |p|$, and

$$p(\bar{\rho}(\xi, \alpha)) = p(\bar{\rho}(\xi, \beta))$$

for any $\xi < \alpha$ such that $\bar{\rho}(\xi, \alpha) < |p|$.

2.8 Lemma.

(a) $<_p$ *is a tree ordering on* ω_1 *of height* $\leq |p| + 1$,

(b) $p \subseteq q$ *implies* $<_p \subseteq <_q$.

Proof. This follows immediately from Lemma 2.5. ⊣

2.9 Definition. For $x \in \omega^\omega$, set

$$<_x = \bigcup\{<_{x \restriction n} : n < \omega\}.$$

The proof of the following lemma can also be found in [66].

2.10 Lemma. *For every $p \in \omega^{<\omega}$ there is a partition of ω_1 into finitely many pieces such that if $\alpha < \beta$ belong to the same piece then there is a $q \supseteq p$ in $\omega^{<\omega}$ such that $\alpha <_q \beta$.*

2.11 Theorem. *For every infinite subset $\Gamma \subseteq \omega_1$, the set*

$$G_\Gamma = \{x \in \omega^\omega : \alpha <_x \beta \text{ for some } \alpha, \beta \in \Gamma\}$$

is a dense open subset of the Baire space.

Proof. This is an immediate consequence of Lemma 2.10. ⊣

2.12 Definition. For $\alpha < \beta < \omega_1$, let $\alpha <_{\bar\rho} \beta$ denote the fact that $\bar\rho(\xi,\alpha) = \bar\rho(\xi,\beta)$ for all $\xi < \alpha$. Then $<_{\bar\rho}$ is a tree ordering on ω_1 obtained by identifying α with the member $\bar\rho(\cdot,\alpha)$ of the tree $T(\bar\rho)$. Note that $<_{\bar\rho} \subseteq <_x$ for all $x \in \omega^\omega$ and that there exists an $x \in \omega^\omega$ such that $<_x = <_{\bar\rho}$ (e.g., one such x is the identity map $\mathrm{id} : \omega \longrightarrow \omega$).

The following result is an analogue of Lemma 2.10 for the incomparability relation, though its proof is considerably simpler.

2.13 Lemma. *If Γ is an infinite $<_{\bar\rho}$-antichain, the set*

$$H_\Gamma = \{x \in \omega^\omega : \alpha \not<_x \beta \textit{ for some } \alpha < \beta \textit{ in } \Gamma\}$$

is a dense open subset of Baire space.

2.14 Definition. For a family $\mathcal{F}$ of infinite $<_{\bar\rho}$-antichains, we say that a real $x \in \omega^\omega$ is $\mathcal{F}$-*Cohen* if $x \in G_\Gamma \cap H_\Gamma$ for all $\Gamma \in \mathcal{F}$. We say that x is $\mathcal{F}$-*Souslin* if no member of $\mathcal{F}$ is a $<_x$-chain or a $<_x$-antichain. We say that a real $x \in \omega^\omega$ is *Souslin* if the tree ordering $<_x$ on ω_1 has no uncountable chains nor antichains, i.e. when x is $\mathcal{F}$-Souslin for $\mathcal{F}$ equal to the family of all uncountable subsets of ω_1.

Note that since every uncountable subset of ω_1 contains an uncountable $<_{\bar\rho}$-antichain, if a family $\mathcal{F}$ refines the family of all uncountable $<_{\bar\rho}$-antichains, then every $\mathcal{F}$-Souslin real is Souslin. The following fact summarizes Theorems 2.11 and 2.13 and connects the two kinds of reals.

2.15 Theorem. *If $\mathcal{F}$ is a family of infinite $<_{\bar\rho}$-antichains, then every $\mathcal{F}$-Cohen real is $\mathcal{F}$-Souslin.*

2.16 Corollary. *If the density of the family of all uncountable subsets of ω_1 is smaller than the number of nowhere dense sets needed to cover the real line, then there is a Souslin tree.*

2.17 Remark. Recall that the *density* of a family $\mathcal{F}$ of infinite subsets of some set S is the minimal size of a family $\mathcal{F}_0$ of infinite subsets of S with the property that every member of $\mathcal{F}$ is refined by a member of $\mathcal{F}_0$. A special case of Corollary 2.16, when the density of the family of all uncountable subsets of ω_1 is equal to $\aleph_1$, was first observed by Miyamoto (unpublished).

2.18 Corollary. *Every Cohen real is Souslin.*

Proof. Every uncountable subset of ω_1 in the Cohen extension contains an uncountable subset from the ground model. So it suffices to consider the family $\mathcal{F}$ of all infinite $<_{\bar\rho}$-antichains from the ground model. ⊣

If ω_1 is a successor cardinal in the constructible universe, then $\bar{\rho}$ can be chosen to be coanalytic and so the transformation $x \longmapsto <_x$ will transfer combinatorial notions of Souslin, Aronszajn or special Aronszajn trees into the corresponding classes of reals that lie in the third level of the projective hierarchy. This transformation has been explored in several places in the literature (see e.g. [3, 21]).

2.19 Remark. We have just seen how the combination of the subadditivity properties (2.5(b),(c)) of the coherent sequence $\bar{\rho}_\alpha : \alpha \longrightarrow \omega$ ($\alpha < \omega_1$) of one-to-one mappings can be used in controlling the finite disagreement between them. It turns out that in many contexts the coherence and the subadditivities are essentially equivalent restrictions on a given sequence $e_\alpha : \alpha \longrightarrow \omega$ ($\alpha < \omega_1$). For example, the following construction shows that this is so for any sequence of finite-to-one mappings $e_\alpha : \alpha \longrightarrow \omega$ ($\alpha < \omega_1$).

2.20 Definition. Given a coherent sequence $e_\alpha : \alpha \longrightarrow \omega$ ($\alpha < \omega_1$) of finite-to-one mappings, define $\tau_e : [\omega_1]^2 \longrightarrow \omega$ as follows

$$\tau_e(\alpha, \beta) = \max\{\max\{e(\xi, \alpha), e(\xi, \beta)\} : \xi \leq \alpha \text{ and } e(\xi, \alpha) \neq e(\xi, \beta)\}.$$

2.21 Lemma. *For every $\alpha < \beta < \gamma < \omega_1$,*

(a) $\tau_e(\alpha, \beta) \geq e(\alpha, \beta)$,

(b) $\tau_e(\alpha, \gamma) \leq \max\{\tau_e(\alpha, \beta), \tau_e(\beta, \gamma)\}$,

(c) $\tau_e(\alpha, \beta) \leq \max\{\tau_e(\alpha, \gamma), \tau_e(\beta, \gamma)\}$.

Proof. Since (a) is true if $e(\alpha, \beta) = 0$, let us assume $e(\alpha, \beta) > 0$. By our convention, $e(\alpha, \alpha) = 0$ and so $e(\alpha, \alpha) \neq e(\alpha, \beta) = 0$. It follows that $\tau_e(\alpha, \beta) \geq \max\{\max\{e(\alpha, \alpha), e(\alpha, \beta)\} = e(\alpha, \beta)$. This shows (a).

To show (b), let $n = \max\{\tau_e(\alpha, \beta), \tau_e(\beta, \gamma)\}$. Suppose $\tau_e(\alpha, \gamma) > n$. Then we can choose $\xi \leq \alpha$ such that $e(\xi, \alpha) > n$ or $e(\xi, \gamma) > n$. If $e(\xi, \alpha) > n$ then $e(\xi, \beta) = e(\xi, \alpha) > n$ and so $e(\xi, \beta) \neq e(\xi, \gamma)$. It follows that $\tau_e(\beta, \gamma) \geq e(\xi, \beta) > n$, a contradiction. If $e(\xi, \gamma) > n$ then $e(\xi, \beta) = e(\xi, \gamma) > n$. In particular, $e(\xi, \alpha) \neq e(\xi, \beta)$. It follows that $\tau_e(\beta, \gamma) \geq e(\xi, \beta) > n$, a contradiction.

The proof of (c) is similar. ⊣

2.22 Definition. A mapping $a : [\omega_1]^2 \longrightarrow \omega$ is *transitive* if

$$a(\alpha, \gamma) \leq \max\{a(\alpha, \beta), a(\beta, \gamma)\}$$

for all $\alpha < \beta < \gamma < \omega_1$.

Transitive maps occur quite frequently in set-theoretic constructions. For example, given a sequence A_α ($\alpha < \omega_1$) of subsets of ω that increases relative to the ordering $\subseteq^*$ of inclusion modulo a finite set, the mapping $a : [\omega_1]^2 \longrightarrow \omega$ defined by

$$a(\alpha, \beta) = \min\{n : A_\alpha \setminus n \subseteq A_\beta\}$$

is a transitive map. The transitivity condition by itself is not nearly as useful as its combination with the other subadditivity property (2.5(c)). Fortunately, there is a general procedure that produces a subadditive dominant to every transitive map.

2.23 Definition. For a transitive $a : [\omega_1]^2 \longrightarrow \omega$ define $\rho_a : [\omega_1]^2 \longrightarrow \omega$ recursively as follows:

$$\rho_a(\alpha, \beta) = \max\{|C_\beta \cap \alpha|, a(\min(C_\beta \setminus \alpha), \beta), \\ \rho_a(\alpha, \min(C_\beta \setminus \alpha)), \rho_a(\xi, \alpha) : \xi \in C_\beta \cap \alpha\}.$$

2.24 Lemma. *For all $\alpha < \beta < \gamma < \omega_1$ and $n < \omega$,*

(a) $\{\xi \leq \alpha : \rho_a(\xi, \alpha) \leq n\}$ is finite,

(b) $\rho_a(\alpha, \gamma) \leq \max\{\rho_a(\alpha, \beta), \rho_a(\beta, \gamma)\}$,

(c) $\rho_a(\alpha, \beta) \leq \max\{\rho_a(\alpha, \gamma), \rho_a(\beta, \gamma)\}$,

(d) $\rho_a(\alpha, \beta) \geq a(\alpha, \beta)$.

Proof. The proof of (a), (b), (c) is quite similar to the corresponding part of the proof of Lemma 2.2. This comes of course from the fact that the definition of ρ and ρ_a are closely related. The occurrence of the factor $a(\min(C_\beta \setminus \alpha), \beta)$ complicates a bit the proof that ρ_a is subadditive, and the fact that a is transitive is quite helpful in getting rid of the additional difficulty. The details are left to the interested reader. Given $\alpha < \beta$, for every step $\beta_n \to \beta_{n+1}$ of the minimal walk $\beta = \beta_0 > \beta_1 > \cdots > \beta_k = \alpha$, we have $\rho_a(\alpha, \beta) \geq \rho_a(\beta_n, \beta_{n+1}) \geq a(\beta_n, \beta_{n+1})$ by the very definition of ρ_a. Applying the transitivity of a to this path of inequalities we get the conclusion (d). $\dashv$

2.25 Lemma. *$\rho_a(\alpha, \beta) \geq \rho_a(\alpha + 1, \beta)$ whenever $0 < \alpha < \beta$ and α is a limit ordinal.*

Proof. Recall the assumption (c) about the fixed C-sequence C_ξ $(\xi < \omega_1)$ on which all our definitions are based: if ξ is a limit ordinal > 0, then no point of C_ξ is a limit ordinal. It follows that if $0 < \alpha < \beta$ and α is a limit ordinal, then the minimal walk $\beta \to \alpha$ must pass through $\alpha + 1$ and therefore $\rho_a(\alpha, \beta) \geq \rho_a(\alpha + 1, \beta)$. $\dashv$

Let us now give an application of ρ_a to a classical phenomenon of occurrence of gaps in the quotient algebra $\mathcal{P}(\omega)/\mathrm{fin}$.

2.26 Definition. A *Hausdorff gap* in $\mathcal{P}(\omega)/\mathrm{fin}$ is a pair of sequences A_α $(\alpha < \omega_1)$ and B_α $(\alpha < \omega_1)$ such that

(a) $A_\alpha \subseteq^* A_\beta \subseteq^* B_\beta \subseteq^* B_\alpha$ whenever $\alpha < \beta$, but

(b) there is no C such that $A_\alpha \subseteq^* C \subseteq^* B_\alpha$ for all α.

The following straightforward reformulation shows that a Hausdorff gap is just another instance of a nontrivial coherent sequence

$$f_\alpha : A_\alpha \longrightarrow 2 \ \ (\alpha < \omega_1),$$

where the domain A_α of f_α is not the ordinal α itself but a subset of ω and that the corresponding sequence of domains A_α $(\alpha < \omega_1)$ is a realization of ω_1 inside $\mathcal{P}(\omega)/\text{fin}$ in the sense that $A_\alpha \subseteq^* A_\beta$ whenever $\alpha < \beta$.

2.27 Lemma. *A pair of ω_1-sequences A_α $(\alpha < \omega_1)$ and B_α $(\alpha < \omega_1)$ form a Hausdorff gap iff the pair of ω_1-sequences $\bar{A}_\alpha = A_\alpha \cup (\omega \setminus B_\alpha)$ $(\alpha < \omega_1)$ and $\bar{B}_\alpha = \omega \setminus B_\alpha$ $(\alpha < \omega_1)$ has the following three properties:*

(a) $\bar{A}_\alpha \subseteq^* \bar{A}_\beta$ whenever $\alpha < \beta$,

(b) $\bar{B}_\alpha =^* \bar{B}_\beta \cap \bar{A}_\alpha$ whenever $\alpha < \beta$,

(c) there is no B such that $\bar{B}_\alpha =^* B \cap \bar{A}_\alpha$ for all α.

From now on we fix a strictly $\subseteq^*$-increasing chain A_α $(\alpha < \omega_1)$ of infinite subsets of ω and let $a : [\omega_1]^2 \longrightarrow \omega$ be defined by

$$a(\alpha, \beta) = \min\{n : A_\alpha \setminus n \subseteq A_\beta\}.$$

Let $\rho_a : [\omega_1]^2 \longrightarrow \omega$ be the corresponding subadditive dominant of a defined above. For $\alpha < \omega_1$, set

$$D_\alpha = A_{\alpha+1} \setminus A_\alpha.$$

2.28 Lemma. *The sets $D_\alpha \setminus \rho_a(\alpha, \gamma)$ and $D_\beta \setminus \rho_a(\beta, \gamma)$ are disjoint whenever $0 < \alpha < \beta < \gamma$ and α and β are limit ordinals.*

Proof. This follows immediately from Lemmas 2.24 and 2.25. ⊣

We are in a position to define a partial mapping $m : [\omega_1]^2 \longrightarrow \omega$ by

$$m(\alpha, \beta) = \min(D_\alpha \setminus \rho_a(\alpha, \beta)),$$

whenever $\alpha < \beta$ and α is a limit ordinal.

2.29 Lemma. *The mapping m is coherent, i.e., $m(\alpha, \beta) = m(\alpha, \gamma)$ for all but finitely many limit ordinals $\alpha < \min\{\beta, \gamma\}$.*

Proof. This is by the coherence of ρ_a and the fact that $\rho_a(\alpha, \beta) = \rho_a(\alpha, \gamma)$ already implies $m(\alpha, \beta) = m(\alpha, \gamma)$. ⊣

2.30 Lemma. *$m(\alpha, \gamma) \neq m(\beta, \gamma)$ whenever $\alpha \neq \beta < \gamma$ and α, β are limit ordinals.*

Proof. This follows from Lemma 2.28. ⊣

For $\beta < \omega_1$, set

$$B_\beta = \{m(\alpha, \beta) : \alpha < \beta \text{ and } \alpha \text{ limit}\}.$$

2.31 Lemma. *$B_\beta =^* B_\gamma \cap A_\beta$ whenever $\beta < \gamma$.*

Proof. By the coherence of m. ⊣

Note the following immediate consequence of Lemma 2.28 and the definition of m.

2.32 Lemma. *$m(\alpha, \beta) = \max(B_\beta \cap D_\alpha)$ whenever $\alpha < \beta$ and α is a limit ordinal.*

2.33 Lemma. *There is no $B \subseteq \omega$ such that $B \cap A_\beta =^* B_\beta$ for all β.*

Proof. Suppose that such a B exists and for a limit ordinal α let us define $g(\alpha) = \max(B \cap D_\alpha)$. Then by Lemma 2.32, $g(\alpha) = m(\alpha, \beta)$ for all $\beta < \omega_1$ and all but finitely many limit ordinals $\alpha < \beta$. By Lemma 2.30, it follows that g is a finite-to-one map, a contradiction. ⊣

2.34 Theorem. *For every strictly $\subset^*$-increasing chain A_α $(\alpha < \omega_1)$ of subsets of ω, there is a sequence B_α $(\alpha < \omega_1)$ of subsets of ω such that:*

(a) $B_\alpha =^* B_\beta \cap A_\alpha$ whenever $\alpha < \beta$,

(b) there is no B such that $B_\alpha =^* B \cap A_\alpha$ for all α.

3. Steps and Coherence

3.1 Definition. The *number of steps* of the minimal walk is the function $\rho_2 : [\omega_1]^2 \longrightarrow \omega$ defined recursively by

$$\rho_2(\alpha, \beta) = \rho_2(\alpha, \min(C_\beta \setminus \alpha)) + 1,$$

with the convention that $\rho_2(\gamma, \gamma) = 0$ for all γ.

This is an interesting mapping which is particularly useful on higher cardinalities and especially in situations where the more informative mappings ρ_0, ρ_1 and ρ lack their usual coherence properties. Here is a typical property of this mapping which will be explained in much more general terms in later sections of this chapter.

3.2 Lemma. $\sup_{\xi<\alpha}|\rho_2(\xi, \alpha) - \rho_2(\xi, \beta)| < \infty$ *for all $\alpha < \beta < \omega_1$.*

In this section we use ρ_2 only to succinctly express the following mapping.

3.3 Definition. The *last step function* of the minimal walk is the map $\rho_3 : [\omega_1]^2 \longrightarrow 2$ defined by letting

$$\rho_3(\alpha, \beta) = 1 \quad \text{iff} \quad \rho_0(\alpha, \beta)(\rho_2(\alpha, \beta) - 1) = \rho_1(\alpha, \beta).$$

In other words, we let $\rho_3(\alpha, \beta) = 1$ just in case the last step of the walk $\beta \to \alpha$ comes with the maximal weight.

3.4 Lemma. $\{\xi < \alpha : \rho_3(\xi, \alpha) \neq \rho_3(\xi, \beta)\}$ *is finite for all* $\alpha < \beta < \omega_1$.

Proof. It suffices to show that for every infinite $\Gamma \subseteq \alpha$ there exists a $\xi \in \Gamma$ such that $\rho_3(\xi, \alpha) = \rho_3(\xi, \beta)$. Shrinking Γ we may assume that for some fixed $\bar{\alpha} \in F(\alpha, \beta)$ and all $\xi \in \Gamma$:

(1) $\bar{\alpha} = \min(F(\alpha, \beta) \setminus \xi)$,

(2) $\rho_1(\xi, \alpha) = \rho_1(\xi, \beta)$,

(3) $\rho_1(\xi, \alpha), \rho_1(\xi, \beta) > \max\{\rho_1(\bar{\alpha}, \alpha), \rho_1(\bar{\alpha}, \beta)\}$.

It follows (see Lemma 1.6) that for every $\xi \in \Gamma$:

$$\rho_0(\xi, \alpha) = \rho_0(\bar{\alpha}, \alpha)^\frown \rho_0(\xi, \bar{\alpha}),$$
$$\rho_0(\xi, \beta) = \rho_0(\bar{\alpha}, \beta)^\frown \rho_0(\xi, \bar{\alpha}).$$

So for any $\xi \in \Gamma$, $\rho_3(\xi, \alpha) = 1$ iff the last term of $\rho_0(\xi, \bar{\alpha})$ is its maximal term iff $\rho_3(\xi, \beta) = 1$. ⊣

The sequence $(\rho_3)_\alpha : \alpha \longrightarrow 2$ $(\alpha < \omega_1)$[8] is therefore coherent in the sense that $(\rho_3)_\alpha =^* (\rho_3)_\beta \restriction \alpha$ whenever $\alpha < \beta$. We need to show that the sequence is not trivial, i.e. that it cannot be uniformized by a single total map from ω_1 into 2. In other words, we need to show that ρ_3 still contains enough information about the C-sequence C_α $(\alpha < \omega_1)$ from which it is defined. For this it will be convenient to assume that C_α $(\alpha < \omega_1)$ satisfies the following natural condition:

(d) If α is a limit ordinal > 0 and if ξ occupies the nth place in the increasing enumeration of C_α (that starts with $\min(C_\alpha)$ on its 0th place), then $\xi = \lambda + n + 1$ for some limit ordinal λ (possibly 0).

3.5 Definition. Let Λ denote the set of all countable limit ordinals and for an integer $n \in \omega$, let $\Lambda + n = \{\lambda + n : \lambda \in \Lambda\}$.

The assumption (d) about the C-sequence is behind the following property of ρ_3.

3.6 Lemma. $\rho_3(\lambda + n, \beta) = 1$ *for all but finitely many* n *with* $\lambda + n < \beta$.

[8] Recall the way one always defines the fiber-functions from a two-variable function applied to the context of ρ_3: $(\rho_3)_\alpha(\xi) = \rho_3(\xi, \alpha)$.

3.7 Lemma. *For all $\beta < \omega_1$, $n < \omega$, the set $\{\lambda \in \Lambda : \lambda + n < \beta$ and $\rho_3(\lambda + n, \beta) = 1\}$ is finite.*

Proof. Given an infinite subset Γ of $(\Lambda+n)\cap\beta$ we need to find a $\lambda+n \in \Gamma$ such that $\rho_3(\lambda+n, \beta) = 0$. Shrinking Γ if necessary assume that $\rho_1(\lambda+n, \beta) > n+2$ for all $\lambda+n \in \Gamma$. So if $\rho_3(\lambda+n, \beta) = 1$ for some $\lambda+n \in \Gamma$ then the last step of $\beta \rightarrow \lambda+n$ would have to be of weight$> n+2$ which is impossible by our assumption (d) about C_α $(\alpha < \omega_1)$. $\dashv$

The meaning of these properties of ρ_3 perhaps is easier to comprehend if we reformulate them in a way that resembles the original formulation of the existence of Hausdorff gaps.

3.8 Lemma. *Let $B_\alpha = \{\xi < \alpha : \rho_3(\xi, \alpha) = 1\}$ for $\alpha < \omega_1$. Then:*

(1) $B_\alpha =^* B_\beta \cap \alpha$ for $\alpha < \beta$,

(2) $(\Lambda + n) \cap B_\beta$ is finite for all $n < \omega$ and $\beta < \omega_1$,

(3) $\{\lambda + n : n < \omega\} \subseteq^* B_\beta$ whenever $\lambda + \omega \leq \beta$.

In particular, there is no uncountable $\Gamma \subseteq \omega_1$ such that $\Gamma \cap \beta \subseteq^* B_\beta$ for all $\beta < \omega_1$. On the other hand, the P-ideal[9] $\mathfrak{I}$ generated by B_β $(\beta < \omega_1)$ is large as it contains all intervals of the form $[\lambda, \lambda + \omega)$. The following general dichotomy about P-ideals shows that here indeed we have quite a canonical example of a P-ideal on ω_1.

3.9 Definition. *The P-ideal dichotomy:* For every P-ideal $\mathfrak{I}$ of countable subsets of some set S either:

(1) there is an uncountable $X \subseteq S$ such that $[X]^\omega \subseteq \mathfrak{I}$, or

(2) S can be decomposed into countably many sets orthogonal to $\mathfrak{I}$.

3.10 Remark. It is known that the P-ideal dichotomy is a consequence of the Proper Forcing Axiom and moreover that it does not contradict the Continuum Hypothesis (see [64]). This is an interesting dichotomy which will be used in this article for testing various notions of coherence as we encounter them. For example, let us consider the following notion of coherence, already encountered above at several places, and see how it is influenced by the P-ideal dichotomy.

3.11 Definition. A mapping $a : [\omega_1]^2 \longrightarrow \omega$ is *coherent* if for every $\alpha < \beta < \omega_1$ there exist only finitely many $\xi < \alpha$ such that $a(\xi, \alpha) \neq a(\xi, \beta)$, or in other words, $a_\alpha =^* a_\beta \restriction \alpha$.[10] We say that a is *nontrivial* if there is no $h : \omega_1 \longrightarrow \omega$ such that $h \restriction \alpha =^* a_\alpha$ for all $\alpha < \omega_1$.

---

[9] Recall that an ideal $\mathfrak{I}$ of subsets of some set S is a *P-ideal* if for every sequence A_n $(n < \omega)$ of elements of $\mathfrak{I}$ there is a B in $\mathfrak{I}$ such that $A_n \setminus B$ is finite for all $n < \omega$. A set X is *orthogonal* to $\mathfrak{I}$ if $X \cap A$ is finite for all A in $\mathfrak{I}$.

[10] A mapping $a : [\omega_1]^2 \longrightarrow \omega$ is naturally identified with a sequence a_α $(\alpha < \omega_1)$, where $a_\alpha : \alpha \longrightarrow \omega$ is defined by $a_\alpha(\xi) = a(\xi, \alpha)$.

Note that the existence of a coherent and nontrivial $a : [\omega_1]^2 \longrightarrow 2$ (such as, for example, the function ρ_3 defined above) is something that corresponds to the notion of a Hausdorff gap (cf. the previous lemma) in this context. Notice moreover, that this notion is also closely related to the notion of an Aronszajn tree since

$$T(a) = \{t : \alpha \longrightarrow \omega : \alpha < \omega_1 \text{ and } t =^* a_\alpha\}$$

is such an Aronszajn tree whenever $a : [\omega_1]^2 \longrightarrow \omega$ is coherent and nontrivial.[11] In fact, we shall call an arbitrary Aronszajn tree T *coherent* if T is isomorphic to $T(a)$ for some coherent and nontrivial $a : [\omega_1]^2 \longrightarrow \omega$. In case the range of the map a is actually smaller than ω, e.g. equal to some integer k, then it is natural to let $T(a)$ be the collection of all $t : \alpha \longrightarrow k$ such that $\alpha < \omega_1$ and $t =^* a_\alpha$. This way, we have coherent binary, ternary, etc. Aronszajn trees rather than only ω-ary coherent Aronszajn trees.

3.12 Definition. The *support* of a map $a : [\omega_1]^2 \longrightarrow \omega$ is the sequence $\mathrm{supp}(a_\alpha) = \{\xi < \alpha : a(\xi, \alpha) \neq 0\}$ $(\alpha < \omega_1)$ of subsets of ω_1. A set Γ is *orthogonal* to a if $\mathrm{supp}(a_\alpha) \cap \Gamma$ is finite for all $\alpha < \omega_1$. We say that $a : [\omega_1]^2 \longrightarrow \omega$ is *nowhere dense* if there is no uncountable $\Gamma \subseteq \omega_1$ such that $\Gamma \cap \alpha \subseteq^* \mathrm{supp}(a_\alpha)$ for all $\alpha < \omega_1$.

Note that ρ_3 is an example of a nowhere dense coherent map for the simple reason that ω_1 can be covered by countably many sets $\Lambda + n$ $(n < \omega)$ that are orthogonal to ρ_3. The following immediate fact shows that ρ_3 is indeed a prototype of a nowhere dense and coherent map $a : [\omega_1]^2 \longrightarrow \omega$.

3.13 Proposition. *Under the P-ideal dichotomy, for every nowhere dense and coherent map $a : [\omega_1]^2 \longrightarrow \omega$ the domain ω_1 can be decomposed into countably many sets orthogonal to a.*

3.14 Notation. To every $a : [\omega_1]^2 \longrightarrow \omega$ associate the corresponding Δ-function $\Delta_a : [\omega_1]^2 \longrightarrow \omega$ as follows:

$$\Delta_a(\alpha, \beta) = \min\{\xi < \alpha : a(\xi, \alpha) \neq a(\xi, \beta)\}$$

with the convention that $\Delta_a(\alpha, \beta) = \alpha$ whenever $a(\xi, \alpha) = a(\xi, \beta)$ for all $\xi < \alpha$. Given this notation, it is natural to let

$$\Delta_a(\Gamma) = \{\Delta_a(\alpha, \beta) : \alpha, \beta \in \Gamma, \alpha < \beta\}$$

for an arbitrary set $\Gamma \subseteq \omega_1$.

The following simple fact reveals a crucial property of coherent trees.

[11] Similarities between the notion of a Hausdorff gap and the notion of an Aronszajn tree have been further explained recently in the two papers of Talayco [53, 54], where it is shown that they naturally correspond to first cohomology groups over a pair of very similar spaces.

3.15 Lemma. *Suppose that $a : [\omega_1]^2 \longrightarrow \omega$ is nontrivial and coherent and that every uncountable subset of $T(a)$ contains an uncountable antichain. Then for every pair Σ,Ω of uncountable subsets of ω_1 there exists an uncountable subset Γ of ω_1 such that $\Delta_a(\Gamma) \subseteq \Delta_a(\Sigma) \cap \Delta_a(\Omega)$.*

3.16 Notation. For $a : [\omega_1]^2 \longrightarrow \omega$, set

$$\mathcal{U}(a) = \{A \subseteq \omega_1 : A \supseteq \Delta_a(\Gamma) \text{ for some uncountable } \Gamma \subseteq \omega_1\}.$$

By Lemma 3.15, $\mathcal{U}(a)$ is a uniform filter on ω_1 for every nontrivial coherent $a : [\omega_1]^2 \longrightarrow \omega$ for which $T(a)$ contains no Souslin subtrees. It turns out that under some very mild assumption, $\mathcal{U}(a)$ is in fact a uniform ultrafilter on ω_1. The proof of this can be found in [66].

3.17 Theorem. *Under MA_{ω_1}, the filter $\mathcal{U}(a)$ is an ultrafilter for every nontrivial and coherent $a : [\omega_1]^2 \longrightarrow \omega$.*

3.18 Remark. One may find Theorem 3.17 a bit surprising in view of the fact that it gives us an ultrafilter $\mathcal{U}(a)$ on ω_1 that is Σ_1-definable over the structure $(H_{\omega_2}, \in)$. It is well-known that there is no ultrafilter on ω that is Σ_1-definable over the structure $(H_{\omega_1}, \in)$.

It turns out that the transformation $a \longmapsto \mathcal{U}(a)$ captures some of the essential properties of the corresponding and more obvious transformation $a \longmapsto T(a)$. To state this we need some standard definitions.

3.19 Definition. For two trees S and T, by $S \leq T$ we denote the fact that there is a strictly increasing map $f : S \longrightarrow T$. Let $S < T$ whenever $S \leq T$ and $T \not\leq S$ and let $S \equiv T$ whenever $S \leq T$ and $T \leq S$. In general, the equivalence relation $\equiv$ on trees is very far from the finer relation $\cong$, the isomorphism relation. However, the following fact shows that in the realm of trees $T(a)$, these two relations may coincide and moreover, that the mapping $T(a) \longmapsto \mathcal{U}(a)$ reduces $\equiv$ and $\cong$ to the equality relation among ultrafilters on ω_1 (see [65]).

The following fact reveals in particular that the class of coherent trees has the Schroeder-Bernstein property. Its proof can again be found in [66].

3.20 Theorem. *Assuming MA_{ω_1}, for every pair of coherent and nontrivial mappings $a : [\omega_1]^2 \longrightarrow \omega$ and $b : [\omega_1]^2 \longrightarrow \omega$, the trees $T(a)$ and $T(b)$ are isomorphic iff $T(a) \equiv T(b)$ iff $\mathcal{U}(a) = \mathcal{U}(b)$.*

3.21 Definition. The *shift* of $a : [\omega_1]^2 \longrightarrow \omega$ is defined to be the mapping $a^{(1)} : [\omega_1]^2 \longrightarrow \omega$ determined by the equation $a^{(1)}(\alpha, \beta) = a(\alpha + 1, \hat{\beta})$, where $\hat{\beta} = \min\{\lambda \in \Lambda : \lambda \geq \beta\}$. The n-fold iteration of the shift operation is defined recursively by the formula $a^{(n+1)} = (a^{(n)})^{(1)}$.

The following fact, whose proof can be found in [66], shows that Aronszajn trees are not well-quasi-ordered under the quasi-ordering $\leq$ (see also [65]).

3.22 Theorem. *If a is nontrivial, coherent and orthogonal to Λ, then $T(a) > T(a^{(1)})$.*

3.23 Corollary. *If a is nontrivial, coherent and orthogonal to $\Lambda + n$ for all $n < \omega$, then $T(a^{(n)}) > T(a^{(m)})$ whenever $n < m < \omega$.*

Proof. Note that if a is orthogonal to $\Lambda + n$ for all $n < \omega$, then so is every of its finite shifts $a^{(m)}$. ⊣

3.24 Corollary. $T(\rho_3^{(n)}) > T(\rho_3^{(m)})$ *whenever $n < m < \omega$.*

Somewhat unexpectedly, with very little extra assumptions we can say much more about $\leq$ in the domain of coherent Aronszajn trees (for proofs see [65] and [66]).

3.25 Theorem. *Under MA_{ω_1}, the family of coherent Aronszajn trees is totally ordered under $\leq$.*

3.26 Remark. While under MA_{ω_1}, the class of coherent Aronszajn trees is totally ordered by $\leq$, Corollary 3.24 gives us that this chain of trees is not well-ordered. This should be compared with an old result of Ohkuma [39] that the class of all scattered trees is well-ordered by $\leq$ (see also [32]). It turns out that the class of all Aronszajn trees is not totally ordered under $\leq$, i.e. there exist Aronszajn trees S and T such that $S \not\leq T$ and $T \not\leq S$. The reader is referred to [65] and [66] for more information on this and other related results that we chose not to reproduce here.

4. The Trace and the Square-Bracket Operation

Recall the notion of a *minimal walk* from a countable ordinal β to a smaller ordinal α along the fixed C-sequence C_ξ $(\xi < \omega_1)$: $\beta = \beta_0 > \beta_1 > \cdots > \beta_n = \alpha$ where $\beta_{i+1} = \min(C_{\beta_i} \setminus \alpha)$. Recall also the notion of a *trace*

$$\mathrm{Tr}(\alpha, \beta) = \{\beta_0, \beta_1, \ldots, \beta_n\},$$

the finite set of places visited in the minimal walk from β to α. The following simple fact about the trace lies at the heart of all known definitions of square-bracket operations not only on ω_1 but also at higher cardinalities.

4.1 Lemma. *For every uncountable subset Γ of ω_1 the union of $\mathrm{Tr}(\alpha, \beta)$ for $\alpha < \beta$ in Γ contains a closed and unbounded subset of ω_1.*

Proof. It suffices to show that the union of traces contains every countable limit ordinal δ such that $\sup(\Gamma \cap \delta) = \delta$. Pick an arbitrary $\beta \in \Gamma \setminus \delta$ and let

$$\beta = \beta_0 > \beta_1 > \cdots > \beta_k = \delta$$

be the minimal walk from β to δ. Let $\gamma < \delta$ be an upper bound of all sets of the form $C_{\beta_i} \cap \delta$ for $i < k$. By the choice of δ there is an $\alpha \in \Gamma \cap \delta$ above γ. Then the minimal walk from β to α starts as $\beta_0 > \beta_1 > \cdots > \beta_k$, so in particular δ belongs to $\mathrm{Tr}(\alpha, \beta)$. ⊣

We shall now see that it is possible to pick a single place $[\alpha\beta]$ in $\mathrm{Tr}(\alpha,\beta)$ so that Lemma 4.1 remains valid with $[\alpha\beta]$ in place of $\mathrm{Tr}(\alpha,\beta)$. Recall that by Lemma 1.11,

$$\Delta(\alpha,\beta) = \min\{\xi \leq \alpha : \rho_0(\xi,\alpha) \neq \rho_0(\xi,\beta)\}$$

is a successor ordinal. We shall be interested in its predecessor,

4.2 Definition. $\sigma(\alpha,\beta) = \Delta(\alpha,\beta) - 1$.

Thus, if $\xi = \sigma(\alpha,\beta)$, then $\rho_0(\xi,\alpha) = \rho_0(\xi,\beta)$ and so there is a natural isomorphism between $\mathrm{Tr}(\xi,\alpha)$ and $\mathrm{Tr}(\xi,\beta)$. We shall define $[\alpha\beta]$ by comparing the three sets $\mathrm{Tr}(\alpha,\beta), \mathrm{Tr}(\xi,\alpha)$ and $\mathrm{Tr}(\xi,\beta)$.

4.3 Definition. The *square-bracket operation* on ω_1 is defined as follows:

$$[\alpha\beta] = \min(\mathrm{Tr}(\alpha,\beta) \cap \mathrm{Tr}(\sigma(\alpha,\beta),\beta)) = \min(\mathrm{Tr}(\sigma(\alpha,\beta),\beta) \setminus \alpha).$$

Next, recall the function $\rho_0 : [\omega_1]^2 \to \omega^{<\omega}$ defined from the C-sequence C_ξ $(\xi < \omega_1)$ and the corresponding tree $T(\rho_0)$. For $\gamma < \omega_1$ let $(\rho_0)_\gamma$ be the fiber-mapping : $\gamma \to \omega^{<\omega}$ defined by $(\rho_0)_\gamma(\alpha) = \rho_0(\alpha,\gamma)$.

4.4 Lemma. *For every uncountable subset Γ of ω_1 the set of all ordinals of the form $[\alpha\beta]$ for some $\alpha < \beta$ in Γ contains a closed and unbounded subset of ω_1.*

Proof. For $t \in T(\rho_0)$ let $\Gamma_t = \{\gamma \in \Gamma : (\rho_0)_\gamma \text{ end-extends } t\}$. Let S be the collection of all $t \in T(\rho_0)$ for which Γ_t is uncountable. Clearly, S is a downward closed uncountable subtree of T. The lemma is established once we prove that every countable limit ordinal $\delta > 0$ with the following two properties can be represented as $[\alpha\beta]$ for some $\alpha < \beta$ in Γ:

(1) $\sup(\Gamma_t \cap \delta) = \delta$ for every $t \in S$ of length $< \delta$,

(2) every $t \in S$ of length $< \delta$ has two incomparable successors in S both of length $< \delta$.

Fix such a δ and choose $\beta \in \Gamma \setminus \delta$ such that $(\rho_0)_\beta \restriction \delta \in S$ and consider the minimal walk from β to δ:

$$\beta = \beta_0 > \beta_1 > \cdots > \beta_k = \delta.$$

Let $\gamma < \delta$ be an upper bound of all sets of the form $C_{\beta_i} \cap \delta$ for $i < k$. Since the restriction $t = (\rho_0)_\beta \restriction \gamma$ belongs to S, by (2) we can find one of its end-extensions s in S which is incomparable with $(\rho_0)_\beta$. It follows that for $\alpha \in \Gamma_s$, the ordinal $\sigma(\alpha,\beta)$ has the fixed value

$$\xi = \min\{\xi < |s| : s(\xi) \neq \rho_0(\xi,\beta)\} - 1.$$

Note that $\xi \geq \gamma$, so the walk $\beta \to \delta$ is a common initial part of walks $\beta \to \xi$ and $\beta \to \alpha$ for every $\alpha \in \Gamma_s \cap \delta$. Hence if we choose $\alpha \in \Gamma_s \cap \delta$

above $\min(C_\delta \setminus \xi)$ (which we can by (1)), we get that the walks $\beta \to \xi$ and $\beta \to \alpha$ never meet after δ. In other words for any such α, the ordinal δ is the minimum of $\mathrm{Tr}(\alpha, \beta) \cap \mathrm{Tr}(\xi, \beta)$, or equivalently δ is the minimum of $\mathrm{Tr}(\xi, \beta) \setminus \alpha$. $\dashv$

It should be clear that the above argument can easily be adjusted to give us the following slightly more general fact about the square-bracket operation.

4.5 Lemma. *For every uncountable family A of pairwise disjoint finite subsets of ω_1, all of the same size n, the set of all ordinals of the form $[a(1)b(1)] = [a(2)b(2)] = \cdots = [a(n)b(n)]$ for some $a \neq b$ in A contains a closed and unbounded subset of ω_1.*[12]

It turns out that the square-bracket operation can be used in constructions of various mathematical objects of complex behavior where all known previous constructions needed the Continuum Hypothesis or stronger enumeration principles. The usefulness of $[\cdot\cdot]$ in these constructions is based on the fact that $[\cdot\cdot]$ reduces the quantification over uncountable subsets of ω_1 to the quantification over closed unbounded subsets of ω_1. For example composing $[\cdot\cdot]$ with a unary operation $* : \omega_1 \longrightarrow \omega_1$ which takes each of the values stationary many times one gets the following fact about the mapping $c(\alpha, \beta) = [\alpha\beta]^*$.

4.6 Theorem. *There is a mapping $c : [\omega_1]^2 \longrightarrow \omega_1$ which takes all the values from ω_1 on any square $[\Gamma]^2$ of some uncountable subset Γ of ω_1.*

Note that the basic C-sequence C_α ($\alpha < \omega_1$) which we have fixed at the beginning of this chapter can be used to actually define a unary operation $* : \omega_1 \longrightarrow \omega_1$ which takes each of the ordinals from ω_1 stationarily many times. So the projection $[\alpha\beta]^*$ can actually be defined in our basic structure $(\omega_1, \omega, \vec{C})$. We are now at the point to see that our basic structure is actually rigid.

4.7 Lemma. *The algebraic structure $(\omega_1, [\cdot\cdot], *)$ has no nontrivial automorphisms.*

Proof. Let h be a given automorphism of $(\omega_1, [\cdot\cdot], *)$. If the set Γ of fixed points of h is uncountable, h must be the identity map. To see this, consider a $\xi < \omega_1$. By the property of the map $c(\alpha, \beta) = [\alpha\beta]^*$ stated in Theorem 4.6 there exists a $\gamma < \delta$ in Γ such that $[\gamma\delta]^* = \xi$. Applying h to this equation we get

$$h(\xi) = h([\gamma\delta]^*) = (h([\gamma\delta]))^* = [h(\gamma)h(\delta)]^* = [\gamma\delta]^* = \xi.$$

It follows that $\Delta = \{\delta < \omega_1 : h(\delta) \neq \delta\}$ is in particular uncountable. Shrinking Δ and replacing h by h^{-1}, if necessary, we may safely assume

[12] For a finite set x of ordinals of size n we use the notation $x(1), x(2), \ldots, x(n)$ or $x(0), x(1), \ldots, x(n-1)$, depending on the context, for the enumeration of x according to the natural ordering on the ordinals.

that $h(\delta) > \delta$ for all $\delta \in \Delta$. Consider a $\xi < \omega_1$ and let S_ξ be the set of all $\alpha < \omega_1$ such that $\alpha^* = \xi$. By our choice of $*$ the set S_ξ is stationary. By Lemma 4.5 applied to the family $A = \{\{\delta, h(\delta)\} : \delta \in \Delta\}$ we can find $\gamma < \delta$ in Δ such that $[\gamma\delta] = [h(\gamma)h(\delta)]$ belongs to S_ξ, or in other words,

$$[\gamma\delta]^* = [h(\gamma)h(\delta)]^* = \xi.$$

Since $[h(\gamma)h(\delta)]^* = h([\gamma\delta]^*)$ we conclude that $h(\xi) = \xi$. Since ξ was an arbitrary countable ordinal, this shows that h is the identity map. $\dashv$

We give now an application of this rigidity result to a problem in model theory about the quantifier Qx = "there exist uncountably many x" and its higher dimensional analogues $Q^n x_1 \cdots x_n$ = "there exist an uncountable n-cube many $x_1, \ldots, x_n$". By a result of Ebbinghaus and Flum [15] (see also [40]) every model of every sentence of $L(Q)$ has nontrivial automorphisms. However we shall now see that this is no longer true about the quantifier Q^2.

4.8 Example. *A sentence of $L(Q^2)$ with only rigid models.* The sentence ϕ will talk about one unary relation N, one binary relation $<$ and two binary functional symbols C and E. It is the conjunction of the following seven sentences

(ϕ_1) $Qx\ x = x$,

(ϕ_2) $\neg Qx\ N(x)$,

(ϕ_3) $<$ is a total ordering,

(ϕ_4) E is a symmetric binary operation,

(ϕ_5) $\forall x < y\ N(E(x, y))$,

(ϕ_6) $\forall x < y < z\ E(x, z) \neq E(y, z)$,

(ϕ_7) $\forall x \forall n \{N(n) \rightarrow \neg Q^2 uv[\exists u' < u \exists v' < v(u' \neq v' \wedge E(u', u) = E(v', v) = n) \wedge \forall u' < u\ \forall v' < v(E(u', u) = E(v', v) = n \rightarrow (C(u', v') \neq x \vee C(u, v) \neq x))]\}$.

The model of ϕ that we have in mind is the model $(\omega_1, \omega, <, c, e)$ where $c(\alpha, \beta) = [\alpha\beta]^*$ and $e : [\omega_1]^2 \longrightarrow \omega$ is any mapping such that $e(\alpha, \gamma) \neq e(\beta, \gamma)$ whenever $\alpha < \beta < \gamma$ (e.g. we can take $e = \bar{\rho}_1$ or $e = \bar{\rho}$). The sentence ϕ_7 is simply saying that for every $\xi < \omega_1$ and every uncountable family A of pairwise disjoint unordered pairs of countable ordinals there exist $a \neq b$ in A such that

$$c(\min a, \min b) = c(\max a, \max b) = \xi.$$

This is a consequence of Lemma 4.5 and the fact that $S_\xi = \{\alpha : \alpha^* = \xi\}$ is a stationary subset of ω_1. These are the properties of $[\cdot\cdot]$ and $*$ which we have used in the proof of Lemma 4.7 in order to prove that $(\omega_1, [\cdot\cdot], *)$ is a rigid structure. So a quite analogous proof will show that any model $(M, N, <, C, E)$ of ϕ must be rigid.

The crucial property of $[\cdot\cdot]$ stated in Lemma 4.5 can also be used to provide a negative answer to the basis problem for uncountable graphs by constructing a large family of pairwise orthogonal uncountable graphs.

4.9 Definition. For a subset Γ of ω_1, let $\mathcal{G}_\Gamma$ be the graph whose vertex-set is ω_1 and whose edge-set is equal to $\{\{\alpha,\beta\} : [\alpha\beta] \in \Gamma\}$.

4.10 Lemma. *If the symmetric difference between Γ and Δ is a stationary subset of ω_1, then the corresponding graphs $\mathcal{G}_\Gamma$ and $\mathcal{G}_\Delta$ are orthogonal to each other, i.e. they do not contain uncountable isomorphic subgraphs.*

We have seen above that comparing $[\cdot\cdot]$ with a map $\pi : \omega_1 \longrightarrow I$ where I is some set of mathematical objects/requirements in such a way that each object/requirement is given a stationary preimage, gives us a way to meet each of these objects/requirements in the square of any uncountable subset of ω_1. This observation is the basis of all known applications of the square-bracket operation. A careful choice of I and $\pi : \omega_1 \longrightarrow I$ gives us a projection of the square-bracket operation that can be quite useful. So let us illustrate this on yet another example.

4.11 Definition. Let $\mathcal{H}$ be the collection of all maps $h : 2^n \longrightarrow \omega_1$ where n is a positive integer denoted by $n(h)$. Choose a mapping $\pi : \omega_1 \longrightarrow \mathcal{H}$ which takes each value from $\mathcal{H}$ stationarily many times. Choose also a one-to-one sequence r_α $(\alpha < \omega_1)$ of elements of the Cantor set 2^ω. Note that both these objects can actually be defined in our basic structure $(\omega_1, \omega, \vec{C})$. Consider the following projection of the square-bracket operation:

$$[\![\alpha\beta]\!] = \pi([\alpha\beta])(r_\alpha \restriction n(\pi([\alpha\beta]))).$$

It is easily checked that the property of $[\cdot\cdot]$ stated in Lemma 4.5 corresponds to the following property of the projection $[\![\alpha\beta]\!]$:

4.12 Lemma. *For every uncountable family A of pairwise disjoint finite subsets of ω_1, all of the same size n, and for every n-sequence $\xi_1, \dots, \xi_n$ of countable ordinals there exist a and b in A such that $[\![a(i)b(i)]\!] = \xi_i$ for $i = 1, \dots, n$.*

This projection of $[\cdot\cdot]$ leads to an interesting example of a Banach space with "few" operators, which we will now describe.

4.13 Theorem. *There is a nonseparable reflexive Banach space E with the property that every bounded linear operator $T : E \longrightarrow E$ can be expressed as $T = \lambda I + S$ where λ is a scalar, I the identity operator of E, and S an operator with separable range.*

Proof. Let $I = 3 \times [\omega_1]^{<\omega}$ and let us identify the index-set I with ω_1, i.e. pretend that $[\![\cdot\cdot]\!]$ takes its values in I rather than ω_1. Let $[\![\cdot\cdot]\!]_0$ and $[\![\cdot\cdot]\!]_1$ be the two projections of $[\![\cdot\cdot]\!]$.

$$\mathcal{G} = \{G \in [\omega_1]^{<\omega} : [\![\alpha\beta]\!]_0 = 0 \text{ for all } \{\alpha,\beta\} \in [G]^2\},$$
$$\mathcal{H} = \{H \in [\omega_1]^{<\omega} : [\![\alpha\beta]\!]_0 = 1 \text{ for all } \{\alpha,\beta\} \in [H]^2\}.$$

Let $\mathcal{K}$ be the collection of all finite sets $\{\{\alpha_i, \beta_i\} : i < k\}$ of pairs of countable ordinals such that for all $i < j < k$:

(i) $\max\{\alpha_i, \beta_i\} < \min\{\alpha_j, \beta_j\}$,

(ii) $[\![\alpha_i\alpha_j]\!]_0 = [\![\beta_i\beta_j]\!]_0 = 2$,

(iii) $[\![\alpha_i\alpha_j]\!]_1 = [\![\beta_i\beta_j]\!]_1 = \{\alpha_l : l < i\} \cup \{\beta_l : l < i\}$.

The following properties of $\mathcal{G}, \mathcal{H}$ and $\mathcal{K}$ should be clear:

(1) $\mathcal{G}$ and $\mathcal{H}$ contain all the singletons, are closed under subsets and they are 1-orthogonal to each other in the sense that $\mathcal{G} \cap \mathcal{H}$ contains no doubleton.

(2) $\mathcal{G}$ and $\mathcal{H}$ are both 2-orthogonal to the family of the unions of members of $\mathcal{K}$.

(3) If K and L are two distinct members of $\mathcal{K}$, then there are no more than 5 ordinals α such that $\{\alpha, \beta\} \in K$ and $\{\alpha, \gamma\} \in L$ for some $\beta \neq \gamma$.

(4) For every sequence $\{\alpha_\xi, \beta_\xi\}$ $(\xi < \omega_1)$ of pairwise disjoint pairs of countable ordinals there exist arbitrarily large finite sets $\Gamma, \Delta \subseteq \omega_1$ such that $\{\alpha_\xi : \xi \in \Gamma\} \in \mathcal{G}$, $\{\beta_\xi : \xi \in \Gamma\} \in \mathcal{H}$ and $\{\{\alpha_\xi, \beta_\xi\} : \xi \in \Delta\} \in \mathcal{K}$.

For a function x from ω_1 into $\mathbb{R}$, set

$$\|x\|_{\mathcal{H},2} = \sup\left\{ \left(\textstyle\sum_{\alpha \in H} x(\alpha)^2\right)^{\frac{1}{2}} : H \in \mathcal{H} \right\},$$
$$\|x\|_{\mathcal{K},2} = \sup\left\{ \left(\textstyle\sum_{\{\alpha,\beta\} \in K} (x(\alpha) - x(\beta))^2\right)^{\frac{1}{2s}} : K \in \mathcal{K} \right\}.$$

Let $\|\cdot\| = \max\{\|\cdot\|_\infty, \|\cdot\|_{\mathcal{H},2}, \|\cdot\|_{\mathcal{K},2}\}$ and define $\bar{E}_2 = \{x : \|x\| < \infty\}$. Let 1_α be the characteristic function of $\{\alpha\}$. Finally, let E_2 be the closure of the linear span of $\{1_\alpha : \alpha \in \omega_1\}$ inside $(\bar{E}_2, \|\cdot\|)$. The following facts about the norm $\|\cdot\|$ are easy to establish using the properties of the families $\mathcal{G}, \mathcal{H}$ and $\mathcal{K}$ listed above.

(i) If x is supported by some $G \in \mathcal{G}$, then $\|x\| \leq 2 \cdot \|x\|_\infty$.

(ii) If x is supported by $\bigcup K$ for some K in $\mathcal{K}$, then $\|x\| \leq 10 \cdot \|x\|_\infty$.

The role of the seminorm $\|\cdot\|_{\mathcal{H},2}$ is to ensure that every bounded operator $T : E_2 \longrightarrow E_2$ can be expressed as $D + S$, where D is a diagonal operator relative to the basis[13] 1_α $(\alpha < \omega_1)$ and where S has separable range.

Note that $\|x\| \leq 2\|x\|_2$ for all $x \in \ell_2(\omega_1)$. It follows that $\ell_2(\omega_1) \subseteq E_2$ and the inclusion is a bounded linear operator. Note also that $\ell_2(\omega_1)$ is a dense subset of E_2. Therefore E_2 is a weak compactly generated space. For

[13] Indeed it can be shown that 1_α $(\alpha < \omega_1)$ is a "transfinite basis" of E_2 in the sense of [51]. So every vector x of E_2 has a unique representation as $\Sigma_{\alpha<\omega_1} x(\alpha)1_\alpha$ and the projection operators $P_\beta : E_2 \to E_2 \restriction \beta$ $(\beta < \omega_1)$ are uniformly bounded.

example, $W = \{x \in \ell_2(\omega_1) : \|x\|_2 \leq 1\}$ is a weakly compact subset of E_2 and its linear span is dense in E_2. To get a reflexive example out of E_2 one uses an interpolation method of Davis, Figiel, Johnson and Pelczynski [9] as follows. Let p_n be the Minkowski functional of the set $2^n W + 2^{-n}\mathrm{Ball}(E_2)$.[14] Let

$$E = \left\{x \in E_2 : \|x\|_E = \left(\textstyle\sum_{n=0}^{\infty} p_n(x)^2\right)^{\frac{1}{2}} < \infty\right\}.$$

By [9, Lemma 1], E is a reflexive Banach space and $\ell_2(\omega_1) \subseteq E \subseteq E_2$ are continuous inclusions. Note that $p_n(x) < r$ iff $x = y + z$ for some $y \in E_2$ and $z \in \ell_2(\omega_1)$ such that $\|y\| < 2^{-n} r$ and $\|z\|_2 < 2^n r$. Then the reflexive version of the space also has the property that every bounded operator $T : E \longrightarrow E$ has the form $\lambda I + S$. $\dashv$

4.14 Remark. The above example is reproduced from Wark [70] who based his example on a previous construction due to Shelah and Steprans [50]. The reader is referred to these sources and to [66] for more information.

We only mention yet another interesting application of the square-bracket operation, given recently by Erdős, Jackson and Mauldin [17]:

4.15 Theorem. *For every positive integer n there exist collections $\mathcal{H}$ and X of hyperplanes and points of $\mathbb{R}^n$, respectively, and a coloring $P : \mathcal{H} \longrightarrow \omega$ such that:*

(1) any n hyperplanes of distinct colors meet in at most one point,

(2) there is no coloring $Q : X \longrightarrow \omega$ such that for every $H \in \mathcal{H}$ there exists at most $n-1$ points x in $X \cap H$ such that $Q(x) = P(H)$.

Let us now introduce yet another projection of the square-bracket operation which has some universality properties.

4.16 Definition. Let $\mathcal{H}$ now be the collection of all maps $h : 2^n \times 2^n \longrightarrow \omega_1$ where $n = n(h) < \omega$ and let π be a mapping from ω_1 onto $\mathcal{H}$ that takes each of the values stationarily many times. Define a new operation on ω_1 by

$$|\alpha\beta| = \pi([\alpha\beta])(r_\alpha \restriction n(\pi([\alpha\beta])), r_\beta \restriction n(\pi([\alpha\beta]))).$$

4.17 Lemma. *For every positive integer n, every uncountable subset Γ of ω_1 and every symmetric $n \times n$-matrix M of countable ordinals there is a one-to-one $\phi : n \longrightarrow \Gamma$ such that $|\phi(i)\phi(j)| = M(i,j)$ for $i, j < n$.*

[14] I.e. $p_n(x) = \inf\{\lambda > 0 : x \in \lambda B\}$, where B denotes this set.

5. A Square-Bracket Operation on a Tree

In this section we try to show that the basic idea of the square-bracket operation on ω_1 can perhaps be more easily grasped by working on an arbitrary special Aronszajn tree rather than $T(\rho_0)$. So let $T = \langle T, <_T \rangle$ be a fixed special Aronszajn tree and let $a : T \longrightarrow \omega$ be a fixed map witnessing this, i.e. a mapping with the property that $a^{-1}(\{n\})$ is an antichain of T for all $n < \omega$. We shall assume that for every $s, t \in T$ the greatest lower bound $s \wedge t$ exists in T. For $t \in T$ and $n < \omega$, set

$$F_n(t) = \{s \leq_T t : s = t \text{ or } a(s) \leq n\}.$$

Finally, for $s, t \in T$ with $\mathrm{ht}(s) \leq \mathrm{ht}(t)$, let

$$[st]_T = \min\{v \in F_{a(s \wedge t)}(t) : \mathrm{ht}(v) \geq \mathrm{ht}(s)\}.$$

(If $\mathrm{ht}(s) \geq |ht(t)$ we let $[st]_T = [ts]_T$.)

The following fact corresponds to Lemma 4.4 when $T = T(\rho_0)$.

5.1 Lemma. *If X is an uncountable subset of T, the set of nodes of T of the form $[st]_T$ for some $s, t \in X$ intersects a closed and unbounded set of levels of T.*

We do not give a proof of this fact as it is almost identical to the proof of Lemma 4.4 which deals with the special case $T = T(\rho_0)$. But one can go further and show that $[\cdot\cdot]_T$ shares all the other properties of the square-bracket operation $[\cdot\cdot]$ described in the previous section. Some of these properties, however, are easier to visualize and prove in the general context. For example, consider the following fact which in the case $T = T(\rho_0)$ is the essence of Lemma 4.

5.2 Lemma. *Suppose $A \subseteq T$ is an uncountable antichain and that for each $t \in A$ be given a finite set F_t of its successors. Then for every stationary set $\Gamma \subseteq \omega_1$ there exists an arbitrarily large finite set $B \subseteq A$ such that the height of $[xy]_T$ belongs to Γ whenever $x \in F_s$ and $y \in F_t$ for some $s \neq t$ in B.*

Let us now examine in more detail the collection of graphs $\mathcal{G}_\Gamma(\Gamma \subseteq \omega_1)$ of 4.9 but in the present more general context.

5.3 Definition. For $\Gamma \subseteq \omega_1$, let $K_\Gamma = \{\{s, t\} \in [T]^2 : \mathrm{ht}([st]_T) \in \Gamma\}$.

Working as in Lemma 4.10 one shows that (T, K_Γ) and (T, K_Δ) have no isomorphic uncountable subgraph whenever the symmetric difference between Γ and Δ is a stationary subset of ω_1, i.e. whenever they represent different members of the quotient algebra $\mathcal{P}(\omega_1)/\mathrm{NS}$. In particular, K_Γ contains no square $[X]^2$ of an uncountable set $X \subseteq T$ whenever Γ contains no closed and unbounded subset of ω_1. The following fact is a sort of converse to this. Its proof can be found in [66].

5.4 Lemma. *If Γ contains a closed and unbounded subset of ω_1 then there is a proper forcing notion introducing an uncountable set $X \subseteq T$ such that $[X]^2 \subseteq K_\Gamma$.*

5.5 Corollary. *The graph K_Γ contains the square of some uncountable subset of T in some ω_1-preserving forcing extension if and only if Γ is a stationary subset of ω_1.*

Proof. If Γ is disjoint from a closed and unbounded subset then in any ω_1-preserving forcing extension its complement $\Delta = \omega_1 \setminus \Gamma$ will be a stationary subset of ω_1. So by the basic property Lemma 5.1 of the square-bracket operation no such a forcing extension will contain an uncountable set $X \subseteq T$ such that $[X]^2 \subseteq K_\Gamma$. On the other hand, if Γ is a stationary subset of ω_1, going first to some standard ω_1-preserving forcing extension in which Γ contains a closed and unbounded subset of ω_1 and then applying Lemma 5.4, we get an ω_1-preserving forcing extension having an uncountable set $X \subseteq T$ such that $[X]^2 \subseteq K_\Gamma$. $\dashv$

5.6 Remark. Corollary 5.5 gives us a further indication of the extreme complexity of the class of graphs on the vertex-set ω_1. It also bears some relevance to the recent work of Woodin [74] who, working in his $\mathbb{P}_{\max}$-forcing extension, was able to associate a stationary subset of ω_1 to any partition of $[\omega_1]^2$ into two pieces. So one may view Corollary 5.5 as some sort of converse to this since in the $\mathbb{P}_{\max}$-extension one is able to get a sufficiently generic filter to the forcing notion $\mathbb{P} = \mathbb{P}_\Gamma$ of Lemma 5.4 that would give us an uncountable $X \subseteq T$ such that $[X]^2 \subseteq K_\Gamma$. In other words, under a bit of PFA or Woodin's axiom $(*)$, a set $\Gamma \subseteq \omega_1$ contains a closed and unbounded subset of ω_1 if and only if K_Γ contains $[X]^2$ for some uncountable $X \subseteq T$.

6. Special Trees and Mahlo Cardinals

One of the most basic questions frequently asked about set-theoretical trees is the question whether they contain any *cofinal branch*, a branch that intersects each level of the tree. The fundamental importance of this question has already been realized in the work of Kurepa [31] and then later in the works of Erdős and Tarski in their respective attempts to develop the theory of partition calculus and large cardinals (see [16]). A tree T of height equal to some regular cardinal θ may not have a cofinal branch for a very special reason as the following definition indicates.

6.1 Definition. For a tree $T = \langle T, <_T \rangle$, a function $f : T \to T$ is *regressive* if $f(t) <_T t$ for every $t \in T$ that is not a minimal node of T. A tree T of height θ is *special* if there is a regressive map $f : T \longrightarrow T$ with the property that the f-preimage of every point of T can be written as the union of $< \theta$ antichains of T.

This definition in case $\theta = \omega_1$ reduces indeed to the old definition of special tree, a tree that can be decomposed into countably many antichains. More generally we have the following:

6.2 Lemma. *If θ is a successor cardinal then a tree T of height θ is special if and only if T is the union of fewer than θ antichains.*

The new definition, however, seems to be the right notion of specialness as it makes sense even if θ is a limit cardinal.

6.3 Definition. A tree T of height θ is *Aronszajn* if T has no cofinal branches and if every level of T has size $< \theta$.

Recall the well-known characterization of weakly compact cardinals due to Tarski and his collaborators: a strongly inaccessible cardinal θ is weakly compact if and only if there are no Aronszajn trees of height θ. We supplement this with the following:

6.4 Theorem. *The following are equivalent for a strongly inaccessible cardinal θ:*

(1) θ is Mahlo,

(2) there are no special Aronszajn trees of height θ.

Proof. Suppose θ is a Mahlo cardinal and let T be a given tree of height θ all of whose levels have size $< \theta$. To show that T is not special let $f : T \longrightarrow T$ be a given regressive mapping. By our assumption of θ there is an elementary submodel M of some large enough structure H_κ such that $T, f \in M$ and $\lambda = M \cap \theta$ is a regular cardinal $< \theta$. Note that $T \restriction \lambda$ is a subset of M and since this tree of height λ is clearly not special, there is an $t \in T \restriction \lambda$ such that the preimage $f^{-1}(\{t\})$ is not the union of $< \lambda$ antichains. Using the elementarity of M we conclude that $f^{-1}(\{t\})$ is actually not the union of $< \theta$ antichains.

The proof that (2) implies (1) uses the method of minimal walks in a rather crucial way. So suppose to the contrary that our cardinal contains a closed and unbounded subset C consisting of singular strong limit cardinals. Using C, we choose a C-sequence C_α $(\alpha < \theta)$ such that: $C_{\alpha+1} = \{\alpha\}$, $C_\alpha = (\bar{\alpha}, \alpha)$ for α limit such that $\bar{\alpha} = \sup(C \cap \alpha) < \alpha$ but if $\alpha = \sup(C \cap \alpha)$ then take C_α such that:

(a) $\mathrm{tp}(C_\alpha) = \mathrm{cf}(\alpha) < \min(C_\alpha)$,

(b) $\xi = \sup(C_\alpha \cap \xi)$ implies $\xi \in C$,

(c) $\xi \in C_\alpha$ and $\xi > \sup(C_\alpha \cap \xi)$ imply that $\xi = \eta + 1$ for some $\eta \in C$.

Given the C-sequence C_α $(\alpha < \theta)$ we have the notion of minimal walk along the sequence and various distance functions defined above. In this proof we are particularly interested in the function ρ_0 from $[\theta]^2$ into the set $\mathbb{Q}_\theta$ of all finite sequences of ordinals from θ:

$$\rho_0(\alpha,\beta) = \langle \mathrm{tp}(C_\beta \cap \alpha)\rangle^\frown \rho_0(\alpha, \min(C_\beta \setminus \alpha))$$

where we stipulate that $\rho_0(\gamma,\gamma) = 0$ for all $\gamma < \theta$. We would like to show that the tree

$$T(\rho_0) = \{(\rho_0)_\beta \restriction \alpha : \alpha \le \beta < \theta\}$$

is a special Aronszajn tree of height θ. Note that the size of the αth level $(T(\rho_0))_\alpha$ of $T(\rho_0)$ is controlled in the following way:

$$|(T(\rho_0))_\alpha| \le |\{C_\beta \cap \alpha : \alpha \le \beta < \theta\}| + |\alpha + \omega|. \tag{3.4}$$

So under the present assumption that θ is a strongly inaccessible cardinal, all levels of $T(\rho_0)$ do indeed have size $< \theta$. It remains to define the regressive map

$$f : T(\rho_0) \longrightarrow T(\rho_0)$$

that will witness specialness of $T(\rho_0)$. Note that it really suffices defining f on all levels whose index belong to our club C of singular cardinals. So let $t = (\rho_0)_\beta \restriction \alpha$ be a given node of T such that $\alpha \in C$ and $\alpha \le \beta < \theta$. Note that by our choice of the C-sequence every term of the finite sequence of ordinals $\rho_0(\alpha,\beta)$ is strictly smaller than α. So, if we let $f(t) = t \restriction \ulcorner \rho_0(\alpha,\beta) \urcorner$, where $\ulcorner \cdot \urcorner$ is a standard coding of finite sequences of ordinals by ordinals, we get a regressive map. To show that f is one-to-one on chains of $T(\rho_0)$, which would be more than sufficient, suppose $t_i = (\rho_0)_{\beta_i} \restriction \alpha_i$ $(i < 2)$ are two nodes such that $t_0 \subsetneqq t_1$. Our choice of the C-sequence allows us to deduce the following general fact about the corresponding ρ_0-function as in the case $\theta = \omega_1$ dealt with above in Lemma 1.11.

> If $\alpha \le \beta \le \gamma$, α is a limit ordinal, and if $\rho_0(\xi,\beta) = \rho_0(\xi,\gamma)$ for all $\xi < \alpha$, then $\rho_0(\alpha,\beta) = \rho_0(\alpha,\gamma)$.

Applying this to the triple of ordinals α_0, β_0 and β_1 we conclude that $\rho_0(\alpha_0,\beta_0) = \rho_0(\alpha_0,\beta_1)$. Now observe another fact about the ρ_0-function whose proof is identical to that of $\theta = \omega_1$ dealt with above in Lemma 1.10.

$$\text{If} \quad \alpha \le \beta \le \gamma \quad \text{then} \quad \rho_0(\alpha,\gamma) <_r \rho_0(\beta,\gamma).$$

Applying this to the triple $\alpha_0 < \alpha_1 \le \beta_1$ we in particular have that $\rho_0(\alpha_0,\beta_1) \ne \rho_0(\alpha_1,\beta_1)$. Combining this with the above equality gives us that $\rho_0(\alpha_0,\beta_0) \ne \rho_0(\alpha_1,\beta_1)$ and therefore that $f(t_0) \ne f(t_1)$. $\dashv$

A similar argument gives us the following characterization of Mahlo cardinals due to Hajnal, Kanamori and Shelah [20] which improves a bit an earlier characterization of this sort due to Schmerl [46]. Its proof can also be found in [66].

6.5 Theorem. *A cardinal θ is a Mahlo cardinal if and only if every regressive map f defined on a cube $[C]^3$ of a closed and unbounded subset of θ has an infinite min-homogeneous set $X \subseteq C$.*[15]

Starting from the case $n = 1$ one can now easily deduce the following characterization also due to Hajnal, Kanamori and Shelah [20].

6.6 Theorem. *The following are equivalent for an uncountable cardinal θ and a positive integer n:*

(1) θ is n-Mahlo,

(2) Every regressive map defined on $[C]^{n+2}$ for some closed and unbounded subset C of θ has an infinite min-homogeneous subset.

The proof of Theorem 6.4 gives us the following well-known fact, first established by Silver (see [36]) when θ is a successor of a regular cardinal, which we are going to reprove now.

6.7 Theorem. *If θ is a regular uncountable cardinal which is not Mahlo in the constructible universe, then there is a constructible special Aronszajn tree of height θ.*

Proof. Working in L we choose a closed and unbounded subset C of θ consisting of singular ordinals and a C-sequence C_α $(\alpha < \theta)$ such that $C_{\alpha+1} = \{\alpha\}$, $C_\alpha = (\bar{\alpha}, \alpha)$ when $\bar{\alpha} = \sup(C \cap \alpha) < \alpha$, while if α is a limit point of C we take C_α to have the following properties:

(i) $\xi = \sup(C_\alpha \cap \xi)$ implies $\xi \in C$,

(ii) $\xi > \sup(C_\alpha \cap \xi)$ implies $\xi = \eta + 1$ for some $\eta \in C$.

We choose the C-sequence to also have the following crucial property:

(iii) $|\{C_\alpha \cap \xi : \xi \leq \alpha < \theta\}| \leq |\xi| + \aleph_0$ for all $\xi < \theta$.

It is clear then that the tree $T(\rho_0)$, where ρ_0 is the ρ_0-function of C_α $(\alpha < \theta)$, is a constructible special Aronszajn tree of height θ. ⊣

We are also in a position to deduce the following well-known fact.

6.8 Theorem. *The following are equivalent for a successor cardinal θ:*

(a) There is a special Aronszajn tree of height θ.

(b) There is a C-sequence C_α $(\alpha < \theta)$ such that $\mathrm{tp}(C_\alpha) \leq \theta^-$ for all α and such that $\{C_\alpha \cap \xi : \alpha < \theta\}$ has size $\leq \theta^-$ for all $\xi < \theta$.

[15] Recall, that X is min-homogeneous for f if $f(\alpha, \beta, \gamma) = f(\alpha', \beta', \gamma')$ for every pair $\alpha < \beta < \gamma$ and $< \alpha' < \beta' < \gamma'$ of triples of elements of X such that $\alpha = \alpha'$.

Proof. If C_α $(\alpha < \theta)$ is a C-sequence satisfying (b) and if ρ_0 is the associated ρ_0-function then $T(\rho_0)$ is a special Aronszajn tree of height θ. Suppose $<_T$ is a special Aronszajn tree ordering on θ such that $[\theta^- \cdot \alpha, \theta^- \cdot (\alpha+1))$ is its αth level. Let C be the club of ordinals $< \theta$ divisible by θ^-. Let $f : \theta \longrightarrow \theta^-$ be such that the f-preimage of every ordinal $< \theta^-$ is an antichain of the tree $(\theta, <_T)$. We choose a C-sequence C_α $(\alpha < \theta)$ such that $C_{\alpha+1} = \{\alpha\}$, $C_\alpha = (\bar{\alpha}, \alpha)$ for α limit with the property that $\bar{\alpha} = \sup(C \cap \alpha) < \alpha$, but if α is a limit point of C we take C_α more carefully as follows: $C_\alpha = \{\alpha_\xi : \xi < \eta\}$ where

$$\begin{aligned}
\alpha_\lambda = {} & \sup\{\alpha_\xi : \xi < \lambda\} \text{ for } \lambda \text{ limit} < \eta,\\
\alpha_0 = {} & \text{the } <_T\text{-predecessor of } \alpha \text{ with minimal } f\text{-image},\\
\alpha_{\xi+1} = {} & \text{the } <_T\text{-predecessor of } \alpha \text{ with minimal } f\text{-image subject}\\
& \text{to the requirement that } f(\alpha_{\xi+1}) > f(\alpha_{\zeta+1}) \text{ for all } \zeta < \xi,\\
\eta = {} & \text{the limit ordinal} \leq \theta^- \text{ where the process stops, i.e.}\\
& \sup\{f(\alpha_{\xi+1}) : \xi < \eta\} = \theta^-.
\end{aligned}$$

Note that if α and β are two limit points of C and if $\gamma <_T \alpha, \beta$ then $C_\alpha \cap \gamma = C_\beta \cap \gamma$. From this one concludes that the C-sequence is locally small, i.e. that $\{C_\alpha \cap \gamma : \gamma \leq \alpha < \theta\}$ has size $\leq \theta^-$ for all $\gamma < \theta$. ⊣

6.9 Corollary. *If $\theta^{<\theta} = \theta$ then there exists a special Aronszajn tree of height θ^+.*

6.10 Corollary. *In the constructible universe, special Aronszajn trees of any regular uncountable non-Mahlo height exist.*

6.11 Remark. In a large portion of the literature on this subject the notion of a special Aronszajn tree of height equal to some successor cardinal θ^+ is somewhat weaker, equivalent to the fact that the tree can be embedded inside the tree $\{f : \alpha \longrightarrow \theta : \alpha < \theta \ \&\ f \text{ is } 1-1\}$. One would get our notion of specialness by restricting the tree on successor ordinals losing thus the frequently useful property of a tree that different nodes of the same limit height have different sets of predecessors. The result 6.9 in this weaker form is due to Specker [52], while the result 6.10 is essentially due to Jensen [23].

7. The Weight Function on Successor Cardinals

In this section we assume that $\theta = \kappa^+$ and we fix a C-sequence C_α $(\alpha < \kappa^+)$ such that

$$\mathrm{tp}(C_\alpha) \leq \kappa \quad \text{for all } \alpha < \kappa^+.$$

Let $\rho_1 : [\kappa^+]^2 \longrightarrow \kappa$ be defined recursively by

$$\rho_1(\alpha, \beta) = \max\{\mathrm{tp}(C_\beta \cap \alpha), \rho_1(\alpha, \min(C_\beta \setminus \alpha))\},$$

where we stipulate that $\rho_1(\gamma,\gamma) = 0$ for all $\gamma < \kappa^+$.

7.1 Lemma. $|\{\xi \leq \alpha : \rho_1(\xi,\alpha) \leq \nu\}| \leq |\nu| + \aleph_0$ *for all* $\alpha < \kappa^+$ *and* $\nu < \kappa$.

Proof. Let ν^+ be the first infinite cardinal above the ordinal ν. The proof of the conclusion is by induction on α. So let $\Gamma \subseteq \alpha$ be a given set of order-type ν^+. We need to find a $\xi \in \Gamma$ such that $\rho_1(\xi,\alpha) > \nu$. This will clearly be true if there is a $\xi \in \Gamma$ such that $\mathrm{tp}(C_\alpha \cap \xi) > \nu$. So, we may assume that $\mathrm{tp}(C_\alpha \cap \xi) \leq \nu$ for all $\xi \in \Gamma$. Then there must be an ordinal $\alpha_1 \in C_\alpha$ such that $\Gamma_1 = \{\xi \in \Gamma : \alpha_1 = \min(C_\alpha \setminus \xi)\}$ has size ν^+. By the inductive hypothesis there is a $\xi \in \Gamma_1$ such that, $\rho_1(\xi,\alpha_1) > \nu \geq \mathrm{tp}(C_\alpha \cap \xi)$. It follows that

$$\rho_1(\xi,\alpha) = \max\{\mathrm{tp}(C_\alpha \cap \xi), \rho_1(\xi,\alpha_1)\} = \rho_1(\xi,\alpha_1) > \nu.$$

This finishes the proof. ⊣

7.2 Lemma. *If* κ *is regular, then* $\{\xi \leq \alpha : \rho_1(\xi,\alpha) \neq \rho_1(\xi,\beta)\}$ *has size* $< \kappa$ *for all* $\alpha < \beta < \kappa^+$.

Proof. The proof is by induction on α and β. Let $\Gamma \subseteq \alpha$ be a given set of order-type κ. We need to find $\xi \in \Gamma$ such that $\rho_1(\xi,\alpha) = \rho_1(\xi,\beta)$. Let $\gamma = \sup(\Gamma)$, $\gamma_0 = \max(C_\beta \cap \gamma)$, and $\beta_0 = \min(C_\beta \setminus \gamma)$. Note that by our assumption on κ and the C-sequence, these two ordinals are well-defined and

$$\gamma_0 < \gamma \leq \beta_0 < \beta.$$

By Lemma 7.1 and the inductive hypothesis there is an ξ in $\Gamma \cap (\gamma_0,\gamma)$ such that

$$\rho_1(\xi,\alpha) = \rho_1(\xi,\beta_0) > \mathrm{tp}(C_\beta \cap \gamma).$$

It follows that $C_\beta \cap \gamma = C_\beta \cap \xi$ and $\beta_0 = \min(C_\beta \setminus \xi)$, and so

$$\rho_1(\xi,\beta) = \max\{\mathrm{tp}(C_\beta \cap \xi), \rho_1(\xi,\beta_0)\} = \rho_1(\xi,\beta_0) = \rho_1(\xi,\alpha).$$

⊣

7.3 Remark. The assumption about the regularity of κ in Lemma 7.2 is essential. For example, it can be seen (see [5, p. 72]) that the conclusion of this lemma fails if κ is a singular limit of supercompact cardinals.

7.4 Definition. For κ regular, define $\bar{\rho}_1 : [\kappa^+]^2 \longrightarrow \kappa$ by

$$\bar{\rho}_1(\alpha,\beta) = 2^{\rho_1(\alpha,\beta)} \cdot (2 \cdot \mathrm{tp}\{\xi \leq \alpha : \rho_1(\xi,\beta) = \rho_1(\alpha,\beta)\} + 1).$$

7.5 Lemma. *If* κ *is a regular cardinal then*

(a) $\bar{\rho}_1(\alpha,\gamma) \neq \bar{\rho}_1(\beta,\gamma)$ *whenever* $\alpha < \beta < \gamma < \kappa^+$,

(b) $|\{\xi \leq \alpha : \bar{\rho}_1(\xi,\alpha) \neq \bar{\rho}_1(\xi,\beta)\}| < \kappa$ *whenever* $\alpha < \beta < \kappa^+$.

7.6 Remark. Note that Lemma 7.5 gives an alternative proof of Corollary 6.9 since under the assumption $\kappa^{<\kappa} = \kappa$ the tree $T(\bar{\rho}_1)$ will have levels of size at most κ. It should be noted that the coherent sequence $(\bar{\rho})_\alpha$ $(\alpha < \kappa^+)$ of one-to-one mappings is an object of independent interest which can be particularly useful in stepping-up combinatorial properties of κ to κ^+. It is also an object that has interpretations in such areas as the theory of Čech-Stone compactifications of discrete spaces (see, e.g. [71, 8, 43, 30, 13]). We have already noted that if κ is singular then we may no longer have the coherence property of Lemma 7.2. To get this property, one needs to make some additional assumption on the C-sequence C_α $(\alpha < \kappa^+)$, an assumption about the coherence of the C-sequence. This will be subject of some of the following chapters where we will concentrate on the finer function ρ rather than ρ_1.

8. The Number of Steps

The purpose of this section is to isolate a condition on C-sequences C_α $(\alpha < \theta)$ on regular uncountable cardinals θ as weak as possible subject to a requirement that the corresponding function

$$\rho_2(\alpha, \beta) = \rho_2(\alpha, \min(C_\beta \setminus \alpha)) + 1$$

is in some sense nontrivial, and in particular, far from being constant. Without doubt the C-sequence $C_\alpha = \alpha$ $(\alpha < \theta)$ is the most trivial choice and the corresponding ρ_0-function gives no information about the cardinal θ. The following notion of the triviality of a C-sequence on θ seems to be only marginally different.

8.1 Definition. A C-sequence C_α $(\alpha < \theta)$ on a regular uncountable cardinal θ is *trivial* if there is a closed and unbounded set $C \subseteq \theta$ such that for every $\alpha < \theta$ there is a $\beta \geq \alpha$ with $C \cap \alpha \subseteq C_\beta$.

The proof of the following fact can be found in [66].

8.2 Theorem. *The following are equivalent for any C-sequence C_α $(\alpha < \theta)$ on a regular uncountable cardinal θ and the corresponding function ρ_2:*

(i) C_α $(\alpha < \theta)$ is nontrivial.

(ii) For every family A of θ pairwise disjoint finite subsets of θ and every integer n there is a subfamily B of A of size θ such that $\rho_2(\alpha, \beta) > n$ for all $\alpha \in a$, $\beta \in b$ and $a \neq b$ in B.

8.3 Corollary. *Suppose that C_α $(\alpha < \theta)$ is a nontrivial C-sequence and let $T(\rho_0)$ be the corresponding tree (see Sect. 6 above). Then every subset of $T(\rho_0)$ of size θ contains an antichain of size θ.*

Proof. Consider a subset K of $[\theta]^2$ of size θ which gives us a subset of $T(\rho_0)$ of size θ as follows: $\{(\rho_0)_\beta\restriction(\alpha+1)\colon \{\alpha,\beta\} \in K\}$. Here, we are assuming without loss of generality that the set consists of successor nodes of $T(\rho_0)$. Clearly, we may also assume that the set takes at most one point from a given level of $T(\rho_0)$. Shrinking K further, we obtain that ρ_2 is constant on K. Let n be the constant value of $\rho_2\restriction K$. Applying Theorem 8.2(ii) to K and n, we get $K_0 \subseteq K$ of size θ such that $\rho_2(\alpha,\delta) > n$ for all $\{\alpha,\beta\}$ and $\{\gamma,\delta\}$ from K_0 with properties $\alpha < \beta$, $\gamma < \delta$ and $\alpha < \gamma$. Then $\{(\rho_0)_\beta\restriction(\alpha+1)\colon \{\alpha,\beta\} \in K_0\}$ is an antichain in $T(\rho_0)$. ⊣

8.4 Remark. It should be clear that nontrivial C-sequences exist on any successor cardinal. Indeed, with very little extra work one can show that nontrivial C-sequences exist for some inaccessible cardinals quite high in the Mahlo hierarchy. To show how close this is to the notion of weak compactness, we state an interesting characterization of it, proved in [66], which is of independent interest.[16]

8.5 Theorem. *The following are equivalent for an inaccessible cardinal θ:*

(i) θ is weakly compact.

(ii) For every C-sequence C_α $(\alpha < \theta)$ there is a closed and unbounded set $C \subseteq \theta$ such that for all $\alpha < \theta$ there is a $\beta \geq \alpha$ with $C_\beta \cap \alpha = C \cap \alpha$.

We have already remarked that every successor cardinal $\theta = \kappa^+$ admits a nontrivial C-sequence C_α $(\alpha < \theta)$. It suffices to take the C_α's to be all of order-type $\leq \kappa$. It turns out that for such a C-sequence the corresponding ρ_2-function has a property that is considerably stronger than Theorem 8.2(ii). The proof of this can again be found in [66].

8.6 Theorem. *For every infinite cardinal κ there is a C-sequence on κ^+ such that the corresponding ρ_2-function has the following unboundedness property: for every family A of κ^+ pairwise disjoint subsets of κ^+, all of size $< \kappa$, and for every $n < \omega$ there exists a $B \subseteq A$ of size κ^+ such that $\rho_2(\alpha,\beta) > n$ whenever $\alpha \in a$ and $\beta \in b$ for some $a \neq b$ in B.*

Theorems 8.2 and 8.6 admit the following variation.

8.7 Theorem. *Suppose that a regular uncountable cardinal θ supports a nontrivial C-sequence and let ρ_2 be the associated function. Then for every integer n and every pair of θ-sized families A_0 and A_1, where the members of A_0 are pairwise disjoint bounded subsets of θ and the members of A_1 are pairwise disjoint finite subsets of θ, there exist $B_0 \subseteq A_0$ and $B_1 \subseteq A_1$ of size θ such that $\rho_2(\alpha,\beta) > n$ whenever $\alpha \in a$ and $\beta \in b$ for some $a \in B_0$ and $b \in B_1$ such that* $\sup(a) < \min(b)$.

[16] It turns out that every C-sequence on θ being trivial is not quite as strong as the weak compactness of θ. As pointed out to us by Donder and König, one can show this using a model of Kunen [29, §3].

9. Square Sequences

9.1 Definition. A C-sequence C_α $(\alpha < \theta)$ is a *square sequence* if and only if it is *coherent*, i.e. it has the property that $C_\alpha = C_\beta \cap \alpha$ whenever α is a limit point of C_β.

Note that the nontriviality conditions appearing in Definition 8.1 and Theorem 8.5 coincide in the realm of square sequences:

9.2 Lemma. *A square sequence C_α $(\alpha < \theta)$ is trivial if and only if there is a closed and unbounded subset C of θ such that $C_\alpha = C \cap \alpha$ whenever α is a limit point of C.*

To a given square sequence C_α $(\alpha < \theta)$ one naturally associates a tree ordering $<^2$ on θ as follows by letting $\alpha <^2 \beta$ if and only if α is a limit point of C_β. The triviality of C_α $(\alpha < \theta)$ is then equivalent to the statement that the tree $(\theta, <^2)$ has a chain of size θ. In fact, one can characterize the tree orderings $<_T$ on θ for which there exists a square sequence C_α $(\alpha < \theta)$ such that for all $\alpha < \beta < \theta$,

$$\alpha <_T \beta \text{ if and only if } \alpha \text{ is a limit point of } C_\beta. \tag{3.5}$$

9.3 Lemma. *A tree ordering $<_T$ on θ admits a square sequence C_α $(\alpha < \theta)$ satisfying (3.5) if and only if*

(i) $\alpha <_T \beta$ can hold only for limit ordinals α and β such that $\alpha < \beta$,

(ii) $P_\beta = \{\alpha : \alpha <_T \beta\}$ is a closed subset of β, which is unbounded in β whenever $\mathrm{cf}(\beta) > \omega$ and

(iii) minimal as well as successor nodes of the tree $<_T$ on θ are ordinals of cofinality ω.

Proof. For each ordinal $\alpha < \theta$ of countable cofinality we fix a subset $S_\alpha \subseteq \alpha$ of order-type ω cofinal with α. Given a tree ordering $<_T$ on θ with properties (i)–(iii), for a limit ordinal $\beta < \theta$ let P^+_β be the set of all successor nodes from $P_\beta \cup \{\beta\}$ including the minimal one. For $\alpha \in P^+_\beta$ let α^- be its immediate predecessor in P_β. Finally, set

$$C_\beta = P_\beta \cup \bigcup\{S_\alpha \cap [\alpha^-, \alpha) : \alpha \in P^+_\beta\}.$$

It is easily checked that this defines a square sequence C_β $(\beta < \theta)$ with the property that $\alpha <_T \beta$ holds if and only if α is a limit point of C_β. ⊣

9.4 Remark. It should be clear that the proof of Lemma 9.3 shows that the exact analogue of this result is true for any cofinality $\kappa < \theta$ rather than just for the cofinality ω.

The most important result about square sequences is of course the following well-known result of Jensen [23].

9.5 Theorem. *If a regular uncountable cardinal θ is not weakly compact in the constructible universe then there is a nontrivial square sequence on θ which is moreover constructible.*

9.6 Corollary. *If a regular uncountable cardinal θ is not weakly compact in the constructible universe then there is a constructible Aronszajn tree on θ.*

Proof. Let C_α $(\alpha < \theta)$ be a fixed nontrivial square sequence which is constructible. Changing the C_α's a bit, we may assume that if β is a limit ordinal with $\alpha = \min C_\beta$ or if $\alpha \in C_\beta$ but $\sup(C_\beta \cap \alpha) < \alpha$ then α must be a successor ordinal in θ. Consider the corresponding function $\rho_0 : [\theta]^2 \longrightarrow \mathbb{Q}_\theta$

$$\rho_0(\alpha, \beta) = \mathrm{tp}(C_\beta \cap \alpha)^\frown \rho_0(\alpha, \min(C_\beta \setminus \alpha)),$$

where $\rho_0(\gamma, \gamma) = \emptyset$ for all $\gamma < \theta$. Consider the tree

$$T(\rho_0) = \{(\rho_0)_\beta \restriction \alpha : \alpha \le \beta < \theta\}.$$

Clearly $T(\rho_0)$ is constructible. By (3.4) the αth level of $T(\rho_0)$ is bounded by the size of the set $\{C_\beta \cap \alpha : \beta \ge \alpha\}$. Since the intersection of the form $C_\beta \cap \alpha$ is determined by its maximal limit point modulo a finite subset of α, we conclude that the αth level of $T(\rho_0)$ has size $\le |\alpha| + \aleph_0$. Since the sequence C_α $(\alpha < \theta)$ is nontrivial, the proof of Theorem 8.5 shows that $T(\rho_0)$ has no cofinal branches. $\dashv$

9.7 Lemma. *Suppose C_α $(\alpha < \theta)$ is a square sequence on θ, $<^2$ the associated tree ordering on θ and $T(\rho_0) = \{(\rho_0)_\beta \restriction \alpha : \alpha \le \beta < \theta\}$ where $\rho_0 : [\theta]^2 \longrightarrow \mathbb{Q}_\theta$ is the associated ρ_0-function. Then $\alpha \longmapsto (\rho_0)_\alpha$ is a strictly increasing map from the tree $(\theta, <^2)$ into the tree $T(\rho_0)$.*

Proof. If α is a limit point of C_β then $C_\alpha = C_\beta \cap \alpha$ so the walks $\alpha \to \xi$ and $\beta \to \xi$ for $\xi < \alpha$ get the same code $\rho_0(\xi, \alpha) = \rho_0(\xi, \beta)$. $\dashv$

The purpose of this section, however, is to analyze a family of ρ-functions associated with a square sequence C_α $(\alpha < \theta)$ on some regular uncountable cardinal θ, both fixed from now on. Recall that an ordinal α *divides* an ordinal γ if there is a β such that $\gamma = \alpha \cdot \beta$, i.e. γ can be written as the union of an increasing β-sequence of intervals of type α. Let $\kappa \le \theta$ be a fixed infinite regular cardinal. Let $\Lambda_\kappa : [\theta]^2 \longrightarrow \theta$ be defined by

$$\Lambda_\kappa(\alpha, \beta) = \max\{\xi \in C_\beta \cap (\alpha + 1) : \kappa \text{ divides } \mathrm{tp}(C_\beta \cap \xi)\}.$$

Finally, we are ready to define the main object of study in this section:

$$\rho_\kappa : [\theta]^2 \longrightarrow \kappa$$

defined recursively by

$$\rho_\kappa(\alpha, \beta) = \sup\{\mathrm{tp}(C_\beta \cap [\Lambda_\kappa(\alpha, \beta), \alpha)), \rho_\kappa(\alpha, \min(C_\beta \setminus \alpha)),$$
$$\rho_\kappa(\xi, \alpha) : \xi \in C_\beta \cap [\Lambda_\kappa(\alpha, \beta), \alpha)\},$$

where we stipulate that $\rho_\kappa(\gamma,\gamma)=0$ for all γ.

The following consequence of the coherence property of C_α $(\alpha<\theta)$ will be quite useful.

9.8 Lemma. *If α is a limit point of C_β then $\rho_\kappa(\xi,\alpha)=\rho_\kappa(\xi,\beta)$ for every $\xi<\alpha$.*

Note that ρ_κ is something that corresponds to the function $\rho:[\omega_1]^2\longrightarrow\omega$ considered in Definition 2.1 (see also Sect. 11) and that the ρ_κ's are simply various *local versions* of the key definition. It turns out that they all have the crucial subadditive properties (see [66]).

9.9 Lemma. *If $\alpha<\beta<\gamma<\theta$ then*

(a) $\rho_\kappa(\alpha,\gamma)\leq\max\{\rho_\kappa(\alpha,\beta),\rho_\kappa(\beta,\gamma)\}$,

(b) $\rho_\kappa(\alpha,\beta)\leq\max\{\rho_\kappa(\alpha,\gamma),\rho_\kappa(\beta,\gamma)\}$.

The following is an immediate consequence of the fact that the definition of ρ_κ is closely tied to the notion of a walk along the fixed square sequence.

9.10 Lemma. *$\rho_\kappa(\alpha,\gamma)\geq\rho_\kappa(\alpha,\beta)$ whenever $\alpha\leq\beta\leq\gamma$ and β belongs to the trace of the walk from γ to α.*

9.11 Lemma. *Suppose $\beta\leq\gamma<\theta$ and that β is a limit ordinal >0. Then $\rho_\kappa(\alpha,\gamma)\geq\rho_\kappa(\alpha,\beta)$ for coboundedly many $\alpha<\beta$.*

Proof. Let $\gamma=\gamma_0>\gamma_1>\cdots>\gamma_{n-1}>\gamma_n=\beta$ be the trace of the walk from γ to β. Let $\bar\gamma=\gamma_{n-1}$ if β is a limit point of $C_{\gamma_{n-1}}$, otherwise let $\bar\gamma=\beta$. Note that by Lemma 9.8, in any case we have that

$$\rho_\kappa(\alpha,\beta)=\rho_\kappa(\alpha,\bar\gamma)\quad\text{for all }\alpha<\beta.\tag{3.6}$$

Let $\bar\beta<\beta$ be an upper bound of all $C_{\gamma_i}\cap\beta$ $(i<n)$ which are bounded in β. Then $\bar\gamma$ is a member of the trace of any walk from γ to some ordinal α in the interval $[\bar\beta,\beta)$. Applying Lemma 9.10 to this fact gives us

$$\rho_\kappa(\alpha,\gamma)\geq\rho_\kappa(\alpha,\bar\gamma)\quad\text{for all }\alpha\in[\bar\beta,\beta).$$

Since $\rho_\kappa(\alpha,\bar\gamma)=\rho_\kappa(\alpha,\beta)$ for all $\alpha<\beta$ (see (3.6)), this gives us the conclusion of the lemma. ⊣

The proof of the following lemma can be found in [66].

9.12 Lemma. *The set $P^\kappa_\nu(\beta)=\{\xi<\beta:\rho_\kappa(\xi,\beta)\leq\nu\}$ is a closed subset of β for every $\beta<\theta$ and $\nu<\kappa$.*

For $\alpha<\beta<\theta$ and $\nu<\kappa$ set

$$\alpha<^\kappa_\nu\beta\quad\text{if and only if}\quad\rho_\kappa(\alpha,\beta)\leq\nu.$$

9.13 Lemma.

(1) $<^\kappa_\nu$ *is a tree ordering on* θ*,*

(2) $<^\kappa_\nu \subseteq <^\kappa_\mu$ *whenever* $\nu < \mu < \kappa$*,*

(3) $\in \restriction (\theta \times \theta) = \bigcup_{\nu<\kappa} <^\kappa_\nu$*.*

Proof. This follows immediately from Lemma 9.9. $\dashv$

Recall the notion of a special tree of height θ from Sect. 6, a tree T for which one can find a T-regressive map $f : T \longrightarrow T$ with the property that the preimage of any point is the union of $< \theta$ antichains. By a *tree on* θ we mean a tree of the form $(\theta, <_T)$ with the property that $\alpha <_T \beta$ implies $\alpha < \beta$.

9.14 Lemma. *If a tree* T *naturally placed on* θ *is special, then there is an ordinal-regressive map* $f : \theta \longrightarrow \theta$ *and a closed and unbounded set* $C \subseteq \theta$ *such that* f *is one-to-one on all chains separated by* C*.*

Proof. Let $g : \theta \longrightarrow \theta$ be a T-regressive map such that for each $\xi < \theta$ the preimage $g^{-1}(\{\xi\})$ can be written as a union of a sequence $A_\delta(\xi)$ $(\delta < \lambda_\xi)$ of antichains, where $\lambda_\xi < \theta$. Let C be the collection of all limit $\alpha < \theta$ with the property that $\lambda_\xi < \alpha$ for all $\xi < \alpha$. Choose an ordinal-regressive $f : \theta \longrightarrow \theta$ as follows. If there is a $\delta \in C$ such that $g(\alpha) < \delta \leq \alpha$, then $f(\alpha)$ is smaller than the minimal member of C above $g(\alpha)$, $f(\alpha)$ codes in some standard way the ordinal $g(\alpha)$ as well as the index δ of the antichain $A_\delta(g(\alpha))$ to which α belongs, and $f(\alpha) \notin C$. If no member of C separates $g(\alpha)$ and α, let $f(\alpha)$ be the maximal member of C that is smaller than α. $\dashv$

By Lemma 9.13 we have a sequence $<^\kappa_\nu$ $(\nu < \kappa)$ of tree orderings on θ. The following lemma tells us that they are frequently quite large orderings.

9.15 Lemma. *If* $\theta > \kappa$ *is not a successor of a cardinal of cofinality* κ *then there must be a* $\nu < \kappa$ *such that* $(\theta, <^\kappa_\nu)$ *is a nonspecial tree on* θ*.*

Proof. Suppose to the contrary that all trees are special. By Lemma 9.14 we may choose ordinal-regressive maps $f_\nu : \theta \longrightarrow \theta$ for all $\nu < \kappa$ and a single closed and unbounded set $C \subseteq \theta$ such that each of the maps f_ν is one-to-one on $<^\kappa_\nu$-chains separated by C. Using the Pressing Down Lemma we find a stationary set Γ of cofinality κ^+ ordinals $< \theta$ and $\lambda < \theta$ such that $f_\nu(\gamma) < \lambda$ for all $\gamma \in \Gamma$ and $\nu < \kappa$. If $|\lambda|^+ < \theta$, let $\Delta = \lambda$, $\Gamma = \Gamma_0$ and if $|\lambda|^+ = \theta$, represent λ as the increasing union of a sequence Δ_ξ $(\xi < \mathrm{cf}(|\lambda|))$ of sets of size $< |\lambda|$. Since $\kappa \neq \mathrm{cf}(|\lambda|)$ there is a $\bar{\xi} < \mathrm{cf}(|\lambda|)$ and a stationary $\Gamma_0 \subseteq \Gamma$ such that for all $\gamma \in \Gamma_0$, $f_\nu(\gamma) \in \Delta_{\bar{\xi}}$ for κ many $\nu < \kappa$. Let $\Delta = \Delta_{\bar{\xi}}$. This gives us subsets Δ and Γ_0 of θ such that

(1) $|\Delta|^+ < \theta$ and Γ_0 is stationary in θ,

(2) $\Sigma_\gamma = \{\nu < \kappa : f_\nu(\gamma) \in \Delta\}$ is unbounded in κ for all $\gamma \in \Gamma_0$.

Let $\bar\theta = \kappa^+ \cdot |\Delta|^+$. Then $\bar\theta < \theta$ and so we can find $\beta \in \Gamma_0$ such that $\Gamma_0 \cap C \cap \beta$ has size $\bar\theta$. Then there will be $\nu_0 < \kappa$ and $\Gamma_1 \subseteq \Gamma_0 \cap C \cap \beta$ of size $\bar\theta$ such that $\rho_\kappa(\alpha, \beta) \leq \nu_0$ for all $\alpha \in \Gamma_1$. By (2) we can find $\Gamma_2 \subseteq \Gamma_1$ of size $\bar\theta$ and $\nu_1 \geq \nu_0$ such that $f_{\nu_1}(\alpha) \in \Delta$ for all $\alpha \in \Gamma_2$. Note that Γ_2 is a $<^\kappa_{\nu_1}$-chain separated by C, so f_{ν_1} is one-to-one on Γ_2. However, this gives us the desired contradiction since the set Δ, in which f_{ν_1} embeds Γ_2 has size smaller than the size of Γ_2. This finishes the proof. ⊣

It is now natural to ask the following question: under which assumption on the square sequence C_α $(\alpha < \theta)$ can we conclude that neither of the trees $(\theta, <^\kappa_\nu)$ will have a branch of size θ?

9.16 Lemma. *If the set $\Gamma_\kappa = \{\alpha < \theta : \mathrm{tp}(C_\alpha) = \kappa\}$ is stationary in θ, then none of the trees $(\theta, <^\kappa_\nu)$ has a branch of size θ.*

Proof. Assume that B is a $<^\kappa_\nu$-branch of size θ. By Lemma 9.12, B is a closed and unbounded subset of θ. Pick a limit point β of B which belongs to Γ_κ. Pick $\alpha \in B \cap \beta$ such that $\mathrm{tp}(C_\beta \cap \alpha) > \nu$. By definition of $\rho_\kappa(\alpha, \beta)$ we have that $\rho_\kappa(\alpha, \beta) \geq \mathrm{tp}(C_\beta \cap \alpha) > \nu$ since clearly $\Lambda_\kappa(\alpha, \beta) = 0$. This contradicts the fact that $\alpha <^\kappa_\nu \beta$ and finishes the proof. ⊣

9.17 Definition. A square sequence on θ is *special* if the corresponding tree $(\theta, <^2)$ is special, i.e. there is a $<^2$-regressive map $f : \theta \longrightarrow \theta$ with the property that the f-preimage of every $\xi < \theta$ is the union of $< \theta$ antichains of $(\theta, <^2)$.

9.18 Theorem. *Suppose $\kappa < \theta$ are regular cardinals such that θ is not a successor of a cardinal of cofinality κ. Then to every square sequence C_α $(\alpha < \theta)$ for which there exist stationarily many α such that $\mathrm{tp}(C_\alpha) = \kappa$, one can associate a sequence $C_{\alpha\nu}$ $(\alpha < \theta, \nu < \kappa)$ such that:*

- *(i) $C_{\alpha\nu} \subseteq C_{\alpha\mu}$ for all α and $\nu \leq \mu$,*
- *(ii) $\alpha = \bigcup_{\nu<\kappa} C_{\alpha\nu}$ for all limit α,*
- *(iii) $C_{\alpha\nu}$ $(\alpha < \theta)$ is a nonspecial (and nontrivial) square sequence on θ for all $\nu < \kappa$.*

Proof. Fix $\nu < \kappa$ and define $C_{\alpha\nu}$ by induction on $\alpha < \theta$. So suppose β is a limit ordinal $< \theta$ and that $C_{\alpha\nu}$ is defined for all $\alpha < \beta$. If $P^\kappa_\nu(\beta)$ is bounded in β, let $\bar\beta$ be the maximal limit point of $P^\kappa_\nu(\beta)$ ($\bar\beta = 0$ if the set has no limit points) and let

$$C_{\beta\nu} = C_{\bar\beta\nu} \cup P^\kappa_\nu(\beta) \cup (C_\beta \cap [\max(P^\kappa_\nu(\beta)), \beta)).$$

If $P^\kappa_\nu(\beta)$ is unbounded in β, let

$$C_{\beta\nu} = P^\kappa_\nu(\beta) \cup \bigcup\{C_{\alpha\nu} : \alpha \in P^\kappa_\nu(\beta) \text{ and } \alpha = \sup(P^\kappa_\nu(\beta) \cap \alpha)\}.$$

By Lemmas 9.9 and 9.12, $C_{\beta\nu}$ $(\beta < \theta)$ is well defined and it forms a square sequence on θ. The properties (i) and (ii) are also immediate. To see that for each $\nu < \kappa$ the sequence $C_{\beta\nu}$ $(\beta < \theta)$ is nontrivial, one uses Lemma 9.16 and the fact that if α is a limit point of $C_{\beta\nu}$ occupying a place in $C_{\beta\nu}$ that is divisible by κ, then $\alpha <_\nu^\kappa \beta$. By Lemma 9.15, or rather its proof, we conclude that there is a $\bar{\nu} < \kappa$ such that $C_{\beta\nu}$ $(\beta < \theta)$ is nonspecial for all $\nu \geq \bar{\nu}$. This finishes the proof. ⊣

The following facts whose proof can be found in [66] gives us a square sequence satisfying the hypothesis of Lemma 9.18.

9.19 Lemma. *For every pair of regular cardinals $\kappa < \theta$, every special square sequence C_α $(\alpha < \theta)$ can be refined to a square sequence $\bar{C}_\alpha$ $(\alpha < \theta)$ with the property that* $\mathrm{tp}(\bar{C}_\alpha) = \kappa$ *for stationarily many $\alpha < \theta$.*

Finally we can state the main result of this section which follows from Theorem 9.18 and Lemma 9.19.

9.20 Theorem. *A regular uncountable cardinal $\theta \neq \omega_1$ carries a nontrivial square sequence iff it also carries such a sequence which is moreover nonspecial.*

9.21 Corollary. *If a regular uncountable cardinal $\theta \neq \omega_1$ is not weakly compact in the constructible universe then there is a nonspecial Aronszajn tree of height θ.*

Proof. By Theorem 9.5, θ carries a nontrivial square sequence C_α $(\alpha < \theta)$. By Theorem 9.20 we may assume that the sequence is moreover nonspecial. Let ρ_0 be the associated ρ_0-function and consider the tree $T(\rho_0)$. As in Corollary 9.6 we conclude that $T(\rho_0)$ is an Aronszajn tree of height θ. By Lemma 9.7 there is a strictly increasing map from $(\theta, <^2)$ into $T(\rho_0)$, so $T(\rho_0)$ must be nonspecial. ⊣

9.22 Remark. The assumption $\theta \neq \omega_1$ in Theorem 9.20 is essential as there is always a nontrivial square sequence on ω_1 but it is possible to have a situation where all Aronszajn trees on ω_1 are special. For example MA_{ω_1} implies this. In [33], Laver and Shelah have shown that any model with a weakly compact cardinal admits a forcing extension satisfying CH and the statement that all Aronszajn trees on ω_2 are special. A well-known open problem in this area asks whether one can have GCH rather than CH in a model where all Aronszajn trees on ω_2 are special.

10. The Full Lower Trace of a Square Sequence

In this section θ is a regular uncountable cardinal and C_α $(\alpha < \theta)$ is a nontrivial square sequence on θ. Recall the function $\Lambda = \Lambda_\omega : [\theta]^2 \longrightarrow \theta$:

$$\Lambda(\alpha, \beta) = \text{maximal limit point of } C_\beta \cap (\alpha + 1).$$

($\Lambda(\alpha,\beta)=0$ if $C_\beta\cap(\alpha+1)$ has no limit points.)

The purpose of this section is to study the following recursive trace formula, describing a mapping $\mathrm{F}:[\theta]^2\longrightarrow[\theta]^{<\omega}$:

$$\mathrm{F}(\alpha,\beta)=\mathrm{F}(\alpha,\min(C_\beta\setminus\alpha))\cup\bigcup\{\mathrm{F}(\xi,\alpha):\xi\in C_\beta\cap[\Lambda(\alpha,\beta),\alpha)\},$$

where $\mathrm{F}(\gamma,\gamma)=\{\gamma\}$ for all γ.

As in the case $\theta=\omega_1$, the full lower trace has the following two properties (see [66]).

10.1 Lemma. *For all $\alpha\leq\beta\leq\gamma$,*

(a) $\mathrm{F}(\alpha,\gamma)\subseteq\mathrm{F}(\alpha,\beta)\cup\mathrm{F}(\beta,\gamma)$,

(b) $\mathrm{F}(\alpha,\beta)\subseteq\mathrm{F}(\alpha,\gamma)\cup\mathrm{F}(\beta,\gamma)$.

10.2 Lemma. *For all $\alpha\leq\beta\leq\gamma$,*

(a) $\rho_0(\alpha,\beta)=\rho_0(\min(\mathrm{F}(\beta,\gamma)\setminus\alpha),\beta)^\frown\rho_0(\alpha,\min(\mathrm{F}(\beta,\gamma)\setminus\alpha))$,

(b) $\rho_0(\alpha,\gamma)=\rho_0(\min(\mathrm{F}(\beta,\gamma)\setminus\alpha),\gamma)^\frown\rho_0(\alpha,\min(\mathrm{F}(\beta,\gamma)\setminus\alpha))$.

Recall the function $\rho_2:[\theta]^2\longrightarrow\omega$ which counts the number of steps in the walk along the fixed C-sequence C_α $(\alpha<\theta)$ which in this section is assumed to be moreover a square sequence:

$$\rho_2(\alpha,\beta)=\rho_2(\alpha,\min(C_\beta\setminus\alpha))+1,$$

where we let $\rho_2(\gamma,\gamma)=0$ for all γ. Thus $\rho_2(\alpha,\beta)+1$ is simply equal to the cardinality of the trace $\mathrm{Tr}(\alpha,\beta)$ of the minimal walk from β to α.

10.3 Lemma. $\sup_{\xi<\alpha}|\rho_2(\xi,\alpha)-\rho_2(\xi,\beta)|<\infty$ *for all $\alpha<\beta<\theta$.*

Proof. By Lemma 10.2, $\sup_{\xi<\alpha}|\rho_2(\xi,\alpha)-\rho_2(\xi,\beta)|$ is less than or equal than $\sup_{\xi\in F(\alpha,\beta)}|\rho_2(\xi,\alpha)-\rho_2(\xi,\beta)|$. ⊣

10.4 Definition. Set $\mathcal{I}$ to be the set of all countable $\Gamma\subseteq\theta$ such that $\sup_{\xi\in\Delta}\rho_2(\xi,\alpha)=\infty$ for all $\alpha<\theta$ and infinite $\Delta\subseteq\Gamma\cap\alpha$.

10.5 Lemma. *$\mathcal{I}$ is a P-ideal of countable subsets of θ.*

Proof. Let Γ_n $(n<\omega)$ be a given sequence of members of $\mathcal{I}$ and fix $\beta<\theta$ such that $\Gamma_n\subseteq\beta$ for all n. For $n<\omega$ set $\Gamma_n^*=\{\xi\in\Gamma_n:\rho_2(\xi,\beta)\geq n\}$. Since Γ_n belongs to $\mathcal{I}$, Γ_n^* is a cofinite subset of Γ_n. Let $\Gamma_\infty=\bigcup_{n<\omega}\Gamma_n^*$. Then Γ_∞ is a member of $\mathcal{I}$ such that $\Gamma_n\setminus\Gamma_\infty$ is finite for all n. ⊣

10.6 Theorem. *The P-ideal dichotomy implies that a nontrivial square sequence can exist only on $\theta=\omega_1$.*

Proof. Applying the P-ideal dichotomy on $\mathcal{I}$ from Definition 10.4 we get the two alternatives (see Definition 3.9):

(1) there is an uncountable $\Delta \subseteq \theta$ such that $[\Delta]^\omega \subseteq \mathcal{I}$, or

(2) there is a decomposition $\theta = \bigcup_{n<\omega} \Sigma_n$ such that $\Sigma_n \perp \mathcal{I}$ for all n.

By Lemma 10.3, if (1) holds, then $\Delta \cap \alpha$ must be countable for all $\alpha < \theta$ and so the cofinality of θ must be equal to ω_1. Since we are working only with regular uncountable cardinals, we see that (1) gives us that $\theta = \omega_1$ must hold. Suppose now (2) holds and pick $k < \omega$ such that Σ_k is unbounded in θ. Since $\Sigma_k \perp \mathcal{I}$ we have that $(\rho_2)_\alpha$ is bounded on $\Sigma_k \cap \alpha$ for all $\alpha < \theta$. So there is an unbounded set $\Gamma \subseteq \theta$ and an integer n such that for each $\alpha \in \Gamma$ the restriction of $(\rho_2)_\alpha$ on $\Sigma_k \cap \alpha$ is bounded by n. By Theorem 8.2 we conclude that the square sequence C_α $(\alpha < \theta)$ we started with must be trivial. ⊣

10.7 Definition. By S_θ we denote the *sequential fan* with θ edges, i.e. the space on $(\theta \times \omega) \cup \{*\}$ with $*$ as the only nonisolated point, while a typical neighborhood of $*$ has the form $\mathcal{U}_f = \{(\alpha, n) : n \geq f(\alpha)\} \cup \{*\}$ where $f : \theta \longrightarrow \omega$.

The *tightness* of a point x in a space X is equal to θ if θ is the minimal cardinal such that, if a set $W \subseteq X \setminus \{x\}$ accumulates to x, then there is a subset of W of size $\leq \theta$ that accumulates to x.

10.8 Theorem. *If there is a nontrivial square sequence on θ then the square of the sequential fan S_θ has tightness equal to θ.*

The proof will be given after a sequence of definitions and lemmas.

10.9 Definition. Given a square sequence C_α $(\alpha < \theta)$ and its number of steps function $\rho_2 : [\theta]^2 \longrightarrow \omega$ we define $d : [\theta]^2 \longrightarrow \omega$ by letting

$$d(\alpha, \beta) = \sup_{\xi \leq \alpha} |\rho_2(\xi, \alpha) - \rho_2(\xi, \beta)|.$$

10.10 Lemma. *For all $\alpha \leq \beta \leq \gamma$,*

(a) $\rho_2(\alpha, \beta) \leq d(\alpha, \beta)$,

(b) $d(\alpha, \gamma) \leq d(\alpha, \beta) + d(\beta, \gamma)$,

(c) $d(\alpha, \beta) \leq d(\alpha, \gamma) + d(\beta, \gamma)$.

Proof. The conclusion (a) follows from the fact that we allow $\xi = \alpha$ in the definition of $d(\alpha, \beta)$. The conclusions (b) and (c) are consequences of the triangle inequalities of the ℓ_∞-norm and the fact that in both inequalities we have that the domain of functions on the left-hand side is included in the domain of functions on the right-hand side. ⊣

10.11 Definition. For $\gamma \leq \theta$, let

$$W_\gamma = \{((\alpha, d(\alpha, \beta)), (\beta, d(\alpha, \beta))) : \alpha < \beta < \gamma\}.$$

The following lemma establishes that the tightness of the point $(*,*)$ of S^2_θ is equal to θ, giving us the proof of Theorem 10.8.

10.12 Lemma. $(*,*) \in \bar{W}_\theta$ *but* $(*,*) \notin \bar{W}_\gamma$ *for all* $\gamma < \theta$.

Proof. To see that W_θ accumulates to $(*,*)$, let $\mathcal{U}^2_f$ be a given neighborhood of $(*,*)$. Fix an unbounded set $\Gamma \subseteq \theta$ on which f is constant. By Theorem 8.2 and Lemma 10.10(a) there exists an $\alpha < \beta$ in Γ such that $d(\alpha,\beta) \geq f(\alpha) = f(\beta)$. Then $((\alpha, d(\alpha,\beta)), (\beta, d(\alpha,\beta)))$ belongs to the intersection $W_\theta \cap \mathcal{U}^2_f$. To see that for a given $\gamma < \theta$ the set W_γ does not accumulate to $(*,*)$, choose $g : \theta \longrightarrow \omega$ such that

$$g(\alpha) = 2d(\alpha,\gamma) + 1 \quad \text{for } \alpha < \gamma.$$

Suppose $W_\gamma \cap \mathcal{U}^2_g$ is nonempty and choose $((\alpha, d(\alpha,\beta)), (\beta, d(\alpha,\beta)))$ from this set. Then

$$d(\alpha,\beta) \geq 2d(\alpha,\gamma) + 1 \quad \text{and} \quad d(\alpha,\beta) \geq 2d(\beta,\gamma) + 1,$$

and so, $d(\alpha,\beta) \geq d(\alpha,\gamma) + d(\beta,\gamma) + 1$, contradicting Lemma 10.10(c). $\dashv$

Since $\theta = \omega_1$ admits a nontrivial square sequence, Theorem 10.8 leads to the following result of Gruenhage and Tanaka [19].

10.13 Corollary. *The square of the sequential fan with* ω_1 *edges is not countably tight.*

10.14 Question. What is the tightness of the square of the sequential fan with ω_2 edges?

10.15 Corollary. *If a regular uncountable cardinal* θ *is not weakly compact in the constructible universe then the square of the sequential fan with* θ *edges has tightness equal to* θ.

11. Special Square Sequences

The following well-known result of Jensen [23] supplements the corresponding result for weakly compact cardinals listed above as Theorem 9.5.

11.1 Theorem. *If a regular uncountable cardinal* θ *is not Mahlo in the constructible universe then there is a special square sequence on* θ *which is moreover constructible.*

Today we know many more inner models with sufficient amount of fine structure necessary for building special square sequences. So the existence of special square sequences, especially at successors of strong-limit singular cardinals, is tied to the existence of some other large cardinal axioms. The reader is referred to the relevant chapters of this Handbook for the specific information. In this section we give the combinatorial analysis of walks along special square sequences and the corresponding distance functions. Let us start by restating some results of Sect. 9.

11.2 Theorem. *Suppose $\kappa < \theta$ are regular cardinals and that θ carries a special square sequence. Then there exist $C_{\alpha\nu}$ $(\alpha < \theta, \nu < \kappa)$ such that:*

(1) $C_{\alpha\nu} \subseteq C_{\alpha\mu}$ for all α and $\nu < \mu$,

(2) $\alpha = \bigcup_{\nu<\kappa} C_\alpha$ for all limit α,

(3) $C_{\alpha\nu}$ $(\alpha < \theta)$ is a nontrivial square sequence on θ for all $\nu < \kappa$.

Moreover, if θ is not a successor of a cardinal of cofinality κ then each of the square sequences can be chosen to be nonspecial.

11.3 Theorem. *Suppose $\kappa < \theta$ are regular cardinals and that θ carries a special square sequence. Then there exist $<_\nu$ $(\nu < \kappa)$ such that:*

(i) $<_\nu$ is a closed tree ordering of θ for each $\nu < \kappa$,

(ii) $\in\restriction(\theta \times \theta) = \bigcup_{\nu<\kappa} <_\nu$,

(iii) no tree $(\theta, <_\nu)$ has a chain of size θ.

11.4 Lemma. *The following are equivalent when θ is a successor of some cardinal κ:*

(1) there is a special square sequence on θ,

(2) there is a square sequence C_α $(\alpha < \theta)$ such that $\mathrm{tp}(C_\alpha) \le \kappa$ for all $\alpha < \theta$.

Proof. Let D_α $(\alpha < \kappa^+)$ be a given special square sequence. By Lemma 6.2 the corresponding tree $(\kappa^+, <^2)$ can be decomposed into κ antichains so let $f : \kappa^+ \longrightarrow \kappa$ be a fixed map such that $f^{-1}(\{\xi\})$ is a $<^2$-antichain for all $\xi < \kappa$. Let $\alpha < \kappa^+$ be a given limit ordinal. If D_α has a maximal limit point $\bar{\alpha} < \alpha$, let $C_\alpha = D_\alpha \setminus \bar{\alpha}$. Suppose now that $\{\xi : \xi <^2 \alpha\}$ is unbounded in α and define a strictly increasing continuous sequence $c_\alpha(\xi)$ $(\xi < \nu(\alpha))$ of its elements as follows. Let $c_\alpha(0) = \min\{\xi : \xi <^2 \alpha\}$, $c_\alpha(\eta) = \sup_{\xi<\eta} c_\alpha(\xi)$ for η limit, and $c_\alpha(\xi+1)$ is the minimal $<^2$-predecessor γ of α such that $\gamma > c_\alpha(\xi)$ and has the minimal f-image among all $<^2$-predecessors that are $> c_\alpha(\xi)$. The ordinal $\nu(\alpha)$ is defined as the place where the process stops, i.e. when $\alpha = \sup_{\xi<\nu(\alpha)} c_\alpha(\xi)$. Let $C_\alpha = \{c_\alpha(\xi) : \xi < \nu(\alpha)\}$. It is easily checked that this gives a square sequence C_α $(\alpha < \kappa^+)$ with the property that $\mathrm{tp}(C_\alpha) \le \kappa$ for all $\alpha < \kappa^+$. $\dashv$

Square sequences C_α $(\alpha < \kappa^+)$ that have the property $\mathrm{tp}(C_\alpha) \le \kappa$ for all $\alpha < \kappa^+$ are usually called $\square_\kappa$-sequences. So let C_α $(\alpha < \kappa^+)$ be a $\square_\kappa$-sequence fixed from now on. Let

$$\Lambda(\alpha, \beta) = \text{maximal limit point of } C_\beta \cap (\alpha + 1)$$

when such a limit point exists; otherwise $\Lambda(\alpha,\beta)=0$. The purpose of this section is to analyze the following distance function:

$$\rho : [\kappa^+]^2 \longrightarrow \kappa$$

defined recursively by

$$\begin{aligned}\rho(\alpha,\beta) = \max\{&\mathrm{tp}(C_\beta \cap \alpha), \rho(\alpha, \min(C_\beta \setminus \alpha)),\\ &\rho(\xi,\alpha) : \xi \in C_\beta \cap [\Lambda(\alpha,\beta),\alpha)\},\end{aligned}$$

where we stipulate that $\rho(\gamma,\gamma)=0$ for all $\gamma<\kappa^+$. Clearly $\rho(\alpha,\beta)\geq\rho_1(\alpha,\beta)$, so by Lemma 7.1 we have

11.5 Lemma. $|\{\xi\leq\alpha : \rho(\xi,\alpha)\leq\nu\}|\leq|\nu|+\aleph_0$ *for* $\alpha<\kappa^+$ *and* $\nu<\kappa$.

The following two crucial subadditive properties of ρ have proofs that are almost identical to the proofs of the corresponding properties of, say, the function ρ_ω discussed above in Sect. 9.

11.6 Lemma. *For all* $\alpha\leq\beta\leq\gamma$,

(a) $\rho(\alpha,\gamma)\leq\max\{\rho(\alpha,\beta),\rho(\beta,\gamma)\}$,

(b) $\rho(\alpha,\beta)\leq\max\{\rho(\alpha,\gamma),\rho(\beta,\gamma)\}$.

The following immediate fact will also be quite useful.

11.7 Lemma. *If* α *is a limit point of* C_β, *then* $\rho(\xi,\alpha)=\rho(\xi,\beta)$ *for every* $\xi<\alpha$.

The following as well is an immediate consequence of the fact that the definition of ρ is closely tied to the notion of a minimal walk along the square sequence.

11.8 Lemma. $\rho(\alpha,\gamma)\geq\max\{\rho(\alpha,\beta),\rho(\beta,\gamma)\}$ *whenever* $\alpha\leq\beta\leq\gamma$ *and* β *belongs to the trace of the walk from* γ *to* α.

Using Lemmas 11.7 and 11.8 one proves the following fact exactly as in the case of ρ_κ of Sect. 9 (the proof of Lemma 9.11).

11.9 Lemma. *If* $0<\beta\leq\gamma$ *and* β *is a limit ordinal, then there is a* $\bar\beta<\beta$ *such that* $\rho(\alpha,\gamma)\geq\rho(\alpha,\beta)$ *for all* α *in the interval* $[\bar\beta,\beta)$.

The proof of the following fact is also completely analogous to the proof of the corresponding fact for the local version ρ_κ considered above in Sect. 9 (the proof of Lemma 9.12).

11.10 Lemma. $P_\nu(\gamma)=\{\beta<\gamma : \rho(\beta,\gamma)\leq\nu\}$ *is a closed subset of* γ *for all* $\gamma<\kappa^+$ *and* $\nu<\kappa$.

The discussion of $\rho : [\kappa^+]^2 \longrightarrow \kappa$ now splits naturally into two cases depending on whether κ is a regular or a singular cardinal (with the case $\mathrm{cf}(\kappa)=\omega$ of special importance).

12. Successors of Regular Cardinals

In this section, κ is a fixed regular cardinal, C_α ($\alpha < \kappa^+$) a fixed $\square_\kappa$-sequence and $\rho : [\kappa^+]^2 \longrightarrow \kappa$ the corresponding ρ-function. For $\nu < \kappa$ and $\alpha < \beta < \kappa^+$ set

$$\alpha <_\nu \beta \quad \text{if and only if} \quad \rho(\alpha, \beta) \leq \nu.$$

The following is an immediate consequence of the analysis of ρ given in the previous section.

12.1 Lemma.

(a) $<_\nu$ *is a closed tree ordering of* κ^+ *of height* $\leq \kappa$ *for all* $\nu < \kappa$*,*

(b) $<_\nu \subseteq <_\mu$ *whenever* $\nu \leq \mu < \kappa$*,*

(c) $\in \restriction (\kappa^+ \times \kappa^+) = \bigcup_{\nu<\kappa} <_\nu$*.*

The following result shows that these trees have some properties of smallness not covered by statements of Lemma 12.1.

12.2 Lemma. *If* $\kappa > \omega$*, then no tree* $(\kappa^+, <_\nu)$ *has a branch of size* κ*.*

Proof. Suppose towards a contradiction that some tree $(\kappa^+, <_\nu)$ does have a branch of size κ and let B be one such fixed branch (maximal chain). By Lemmas 11.5 and 11.10, if $\gamma = \sup(B)$ then B is a closed and unbounded subset of γ of order-type κ. Since κ is regular and uncountable, $C_\gamma \cap B$ is unbounded in C_γ, so in particular we can find $\alpha \in C_\gamma \cap B$ such that $\mathrm{tp}(C_\gamma \cap \alpha) > \nu$. Reading off the definition of $\rho(\alpha, \gamma)$ we conclude that $\rho(\alpha, \beta) = \mathrm{tp}(C_\gamma \cap \alpha) > \nu$. Similarly we can find a $\beta > \alpha$ belonging to the intersection of $\lim(C_\gamma)$ and B. Then $C_\beta = C_\gamma \cap \beta$ so $\alpha \in C_\beta$ and therefore $\rho(\alpha, \beta) = \mathrm{tp}(C_\beta \cap \alpha) > \nu$ contradicting the fact that $\alpha <_\nu \beta$. ⊣

A tree of height κ is *Souslin* if all of its chains and antichains are of cardinality less than κ.

12.3 Lemma. *If* $\kappa > \omega$*, then no tree* $(\kappa^+, <_\nu)$ *has a tree of height* κ *which is Souslin subtree.*

Proof. Forcing with subtree of $(\kappa^+, <_\nu)$ of height κ which is Souslin would produce an ordinal γ of cofinality κ and a closed and unbounded subset B of C_γ forming a chain of the tree $(\kappa^+, <_\nu)$. It is well-known that in this case B would contain a ground model subset of size κ, contradicting Lemma 12.2. ⊣

12.4 Lemma. *If* $\kappa > \omega$ *then for every* $\nu < \kappa$ *and every family* A *of* κ *pairwise disjoint finite subsets of* κ^+ *there exists an* $A_0 \subseteq A$ *of size* κ *such that for all* $a \neq b$ *in* A_0 *and all* $\alpha \in a$*,* $\beta \in b$ *we have* $\rho(\alpha, \beta) > \nu$*.*

Proof. We may assume that for some n and all $a \in A$ we have $|a| = n$. Let $a(0), \ldots, a(n-1)$ enumerate a given element a of A increasingly. By Lemma 12.3, shrinking A we may assume that $a(i)$ $(a \in A)$ is an antichain of $(\kappa^+, <_\nu)$ for all $i < n$. Going to a subfamily of A of equal size we may assume to have a well-ordering $<_w$ of A with the property that if $a <_w b$ then no node from a is above a node from b in the tree ordering $<_\nu$. Define $f : [A]^2 \longrightarrow \{0\} \cup (n \times n)$ by letting $f(a, b) = 0$ if $a \cup b$ is an $<_\nu$-antichain; otherwise, assuming $a <_w b$, let $f(a, b) = (i, j)$ where (i, j) is the minimal pair such that $a(i) <_\nu b(j)$. By the Dushnik-Miller partition theorem [14], either there exists an $A_0 \subseteq A$ of size κ such that f is constantly equal to 0 on $[A_0]^2$ or there exist $(i, j) \in n \times n$ and an infinite $A_1 \subseteq A$ such that f is constantly equal to (i, j) on $[A_1]^2$. The first alternative is what we want, so let us see that the second one is impossible. Otherwise, choose $a <_w b <_w c$ in A_1. Then $a(i)$ and $b(i)$ are both $<_\nu$-dominated by $c(j)$, so they must be $<_\nu$-comparable, contradicting our initial assumption about A. This completes the proof. ⊣

The unboundedness property of Lemma 12.4 can be quite useful in designing forcing notions satisfying good chain conditions. Having such applications in mind, we now state a further refinement of this kind of unboundedness property of the ρ-function. Its tedious proof can be found for example in [66].

12.5 Lemma. *Suppose $\kappa > 0$, let $\gamma < \kappa^+$ and let $\{\alpha_\xi, \beta_\xi\}$ $(\xi < \kappa)$ be a sequence of pairwise disjoint elements of $[\kappa^+]^{\leq 2}$. Then there is an unbounded set $\Gamma \subseteq \kappa$ such that $\rho\{\alpha_\xi, \beta_\eta\} \geq \min\{\rho\{\alpha_\xi, \gamma\}, \rho\{\beta_\eta, \gamma\}\}$ for all $\xi \neq \eta$ in Γ.*[17]

This lemma allows a further refinement as follows (see [66]). A cardinal κ is *λ-inaccessible* if $\nu^\tau < \kappa$ for all $\nu < \kappa$ and $\tau < \lambda$.

12.6 Lemma. *Suppose κ is λ-inaccessible for some $\lambda < \kappa$ and that A is a family of size κ of subsets of κ^+, all of size $< \lambda$. Then for every ordinal $\nu < \kappa$ there is a subfamily B of A of size κ such that for all a and b in B:*

(a) $\rho\{\alpha, \beta\} > \nu$ for all $\alpha \in a \setminus b$ and $\beta \in b \setminus a$.

(b) $\rho\{\alpha, \beta\} \geq \min\{\rho\{\alpha, \gamma\}, \rho\{\beta, \gamma\}\}$ for all $\alpha \in a \setminus b$, $\beta \in b \setminus a$ and $\gamma \in a \cap b$.

12.7 Definition. The set-mapping $D : [\kappa^+]^2 \longrightarrow [\kappa^+]^{<\kappa}$ is defined by

$$D(\alpha, \beta) = \{\xi \leq \alpha : \rho(\xi, \alpha) \leq \rho(\alpha, \beta)\}.$$

(Note that $D(\alpha, \beta) = \{\xi \leq \alpha : \rho(\xi, \beta) \leq \rho(\alpha, \beta)\}$, so we could take the formula

$$D\{\alpha, \beta\} = \{\xi \leq \min\{\alpha, \beta\} : \rho(\xi, \alpha) \leq \rho\{\alpha, \beta\}\}$$

as our definition of $D\{\alpha, \beta\}$ when there is no implicit assumption about the ordering between α and β as there is whenever we write $D(\alpha, \beta)$.)

[17] Here, and everywhere else later in this chapter, the convention is that, $\rho\{\alpha, \beta\}$ is meant to be equal to $\rho(\alpha, \beta)$ if $\alpha < \beta$, equal to $\rho(\beta, \alpha)$ if $\beta < \alpha$, and equal to 0 if $\alpha = \beta$.

12.8 Lemma. *If κ is λ-inaccessible for some $\lambda < \kappa$, then for every family A of size κ of subsets of κ^+, all of size $< \lambda$, there exists a $B \subseteq A$ of size κ such that for all a and b in B and all $\alpha \in a \setminus b$, $\beta \in b \setminus a$ and $\gamma \in a \cap b$:*

$$
\begin{aligned}
&(a)\ \alpha, \beta > \gamma \implies D\{\alpha, \gamma\} \cup D\{\beta, \gamma\} \subseteq D\{\alpha, \beta\},\\
&(b)\quad\ \ \beta > \gamma \implies D\{\alpha, \gamma\} \subseteq D\{\alpha, \beta\},\\
&(c)\quad\ \ \alpha > \gamma \implies D\{\beta, \gamma\} \subseteq D\{\alpha, \beta\},\\
&(d)\ \gamma > \alpha, \beta \implies D\{\alpha, \gamma\} \subseteq D\{\alpha, \beta\} \text{ or } D\{\beta, \gamma\} \subseteq D\{\alpha, \beta\}.
\end{aligned}
$$

Proof. Choose $B \subseteq A$ of size κ satisfying the conclusion (b) of Lemma 12.6. Pick $a \neq b$ in B and consider $\alpha \in a \setminus b$, $\beta \in b \setminus a$ and $\gamma \in a \cap b$. By the conclusion of 12.6(b), we have

$$\rho\{\alpha, \beta\} \geq \min\{\rho\{\alpha, \gamma\}, \rho\{\beta, \gamma\}\}. \tag{3.7}$$

- **a.** Suppose $\alpha, \beta > \gamma$. Note that in this case a single inequality $\rho(\gamma, \alpha) \leq \rho\{\alpha, \beta\}$ or $\rho(\gamma, \beta) \leq \rho\{\alpha, \beta\}$ given to us by (3.7) implies that we actually have both inequalities simultaneously holding. The subadditivity of ρ gives us $\rho(\xi, \alpha) \leq \rho\{\alpha, \beta\}$, or equivalently $\rho(\xi, \beta) \leq \rho\{\alpha, \beta\}$ for any $\xi \leq \gamma$ with $\rho(\xi, \gamma) \leq \rho(\gamma, \alpha)$ or $\rho(\xi, \gamma) \leq \rho(\gamma, \beta)$. This is exactly the conclusion of Lemma 12.8(a).

- **b.** Suppose that $\beta > \gamma > \alpha$. Using the subadditivity of ρ we see that in both cases given to us by (3.7) we have that $\rho(\alpha, \gamma) \leq \rho\{\alpha, \beta\}$. So the inclusion $D\{\alpha, \gamma\} \subseteq D\{\alpha, \beta\}$ follows immediately.

- **c.** Suppose that $\alpha > \gamma > \beta$. The conclusion $D\{\beta, \gamma\} \subseteq D\{\alpha, \beta\}$ follows from the previous case by symmetry.

- **d.** Suppose that $\gamma > \alpha, \beta$. Then $\rho(\alpha, \gamma) \leq \rho\{\alpha, \beta\}$ gives $D\{\alpha, \gamma\} \subseteq D\{\alpha, \beta\}$ while $\rho(\beta, \gamma) \leq \rho\{\alpha, \beta\}$ gives us $D\{\beta, \gamma\} \subseteq D\{\alpha, \beta\}$.

This completes the proof. $\dashv$

12.9 Remark. Note that $\min\{x, y\} \in D\{x, y\}$ for every $\{x, y\} \in [\kappa^+]^2$, so the conclusion (a) of Lemma 12.8 in particular means that $\gamma < \min\{\alpha, \beta\}$ implies $\gamma \in D\{\alpha, \beta\}$. In applications, one usually needs this consequence of Lemma 12.8(a) rather than Lemma 12.8(a) itself.

12.10 Definition. The Δ-*function* of some family $\mathcal{F}$ of subsets of some ordinal κ (respectively, a family of functions with domain κ) is the function $\Delta : [\mathcal{F}]^2 \longrightarrow \kappa$ defined by $\Delta(f, g) = \min(f \triangle g)$, (respectively, $\Delta(f, g) = \min\{\xi : f(\xi) \neq g(\xi)\}$).

Note the following property of Δ:

12.11 Lemma. $\Delta(f, g) \geq \min\{\Delta(f, h), \Delta(g, h)\}$ *for all* $\{f, g, h\} \in [\mathcal{F}]^3$.

12.12 Remark. This property can be very useful when transferring objects that live on κ to objects on $\mathcal{F}$. This is especially interesting when $\mathcal{F}$ is of size larger than κ while all of its restrictions $\mathcal{F}\restriction\nu = \{f \cap \nu : f \in \mathcal{F}\}$ ($\nu < \kappa$) have size $< \kappa$, i.e. when $\mathcal{F}$ is a *Kurepa family* (see for example [10]). We shall now see that it is possible to have a Kurepa family $\mathcal{F} = \{f_\alpha : \alpha < \kappa^+\}$ whose Δ-function is dominated by ρ, i.e. $\Delta(f_\alpha, f_\beta) \leq \rho(\alpha, \beta)$ for all $\alpha < \beta < \kappa^+$.

12.13 Theorem. *If $\Box_\kappa$ holds and κ is λ-inaccessible then there is a λ-closed κ-c.c. forcing notion $\mathcal{P}$ that introduces a Kurepa family on κ.*

Proof. Put p in $\mathcal{P}$, if p is a one-to-one function from a subset of κ^+ of size $< \lambda$ into the family of all subsets of κ of size $< \lambda$ such that for all α and β in $\mathrm{dom}(p)$:

$$p(\alpha) \cap p(\beta) \text{ is an initial part of } p(\alpha) \text{ and of } p(\beta), \tag{3.8}$$

$$\Delta(p(\alpha), p(\beta)) \leq \rho(\alpha, \beta) \text{ provided that } \alpha \neq \beta. \tag{3.9}$$

Let $p \leq q$ whenever $\mathrm{dom}(p) \supseteq \mathrm{dom}(q)$ and $p(\alpha) \supseteq q(\alpha)$ for all $\alpha \in \mathrm{dom}(q)$. Clearly $\mathcal{P}$ is a λ-closed forcing notion. The proof that $\mathcal{P}$ satisfies the κ-chain condition, depends heavily on the properties of the set-mapping D and can be found in [66]. $\dashv$

Recall that a poset satisfies *property K* (for Knaster) if every uncountable subset has a further uncountable subset consisting of pairwise compatible elements. Note that in the case $\kappa = \omega_1$ the proof of the previous theorem shows that the corresponding poset has the property K rather just the c.c.c.

12.14 Corollary. *If $\Box_{\omega_1}$ holds, and so in particular if ω_2 is not a Mahlo cardinal in the constructible universe, then there is a property K poset, forcing the Kurepa hypothesis.*

12.15 Remark. This is a variation on a result of Jensen, namely that under $\Box_{\omega_1}$ there is a c.c.c. poset forcing the Kurepa hypothesis. Veličković [67] was the first to use the function ρ to reprove Jensen's result though his proof works only in case $\kappa = \omega_1$ and produces only a c.c.c. poset rather than a property K poset. It should also be noted that Jensen also proved (see [24]) that in the Levy collapse of a Mahlo cardinal to ω_2 there is no c.c.c. poset forcing the Kurepa hypothesis. We shall now see that ρ provides sufficient ground for another well-known forcing construction, the forcing construction of Baumgartner and Shelah [4] of a locally compact scattered topology on ω_2 all of whose Cantor-Bendixson ranks are countable.

12.16 Theorem. *If $\Box_{\omega_1}$ holds then there is a property K forcing notion that introduces a locally compact scattered topology on ω_2 all of whose Cantor-Bendixson ranks are countable.*

Proof. Let $\mathcal{P}$ be the set of all $p = \langle D_p, \leq_p, M_p\rangle$ where D_p is a finite subset of ω_2, where $\leq_p$ is a partial ordering of D_p compatible with the well-ordering and $M_p : [D_p]^2 \longrightarrow [\omega_2]^{<\omega}$ has the following properties:

(i) $M_p\{\alpha,\beta\} \subseteq D\{\alpha,\beta\} \cap D_p$,

(ii) $M_p\{\alpha,\beta\} = \{\alpha\}$ if $\alpha \leq_p \beta$ and $M_p\{\alpha,\beta\} = \{\beta\}$ if $\beta \leq_p \alpha$,

(iii) $\gamma \leq_p \alpha,\beta$ for all $\gamma \in M_p\{\alpha,\beta\}$,

(iv) for every $\delta \leq_p \alpha,\beta$ there is a $\gamma \in M_p\{\alpha,\beta\}$ such that $\delta \leq_p \gamma$.

We let $p \leq q$ if and only if $D_p \supseteq D_q$, $\leq_p \restriction D_q = \leq_q$ and $M_p \restriction [D_q]^2 = M_q$. To verify that $\mathcal{P}$ satisfies property K one again relies heavily on the properties of the function D. Full details about this can be found for example in [66]. $\dashv$

12.17 Remark. A function $f : [\omega_2]^2 \longrightarrow [\omega_2]^{\leq\omega}$ has *property* Δ if for every uncountable set A of finite subsets of ω_2 there exist a and b in A such that for all $\alpha \in a \setminus b$, $\beta \in b \setminus a$ and $\gamma \in a \cap b$, $\alpha, \beta > \gamma$ implies $\gamma \in f\{\alpha,\beta\}$, if $\beta > \gamma$ implies $f\{\alpha,\gamma\} \subseteq f\{\alpha,\beta\}$, and if $\alpha > \gamma$ implies $f\{\beta,\gamma\} \subseteq f\{\alpha,\beta\}$. This definition is due to Baumgartner and Shelah [4] who used it in their forcing construction of the scattered topology on ω_2. They were also able to force a function with the property Δ using a σ-closed ω_2-c.c. poset. This part of their result was reproved by Veličković (see [4, p.129]) who showed that the function $D\{\alpha,\beta\} = \{\xi \leq \min\{\alpha,\beta\} : \rho(\xi,\alpha) \leq \rho\{\alpha,\beta\}\}$ has property Δ. We have seen above that D has many more properties of independent interest which are likely to be needed in similar forcing constructions. The reader is referred to papers of Koszmider [27] and Rabus [41] for further work in this area.

13. Successors of Singular Cardinals

In the previous section we saw that the function $\rho : [\kappa^+]^2 \longrightarrow \kappa$ defined from a $\Box_\kappa$-sequence C_α $(\alpha < \kappa^+)$ can be quite a useful tool in stepping-up objects from κ to κ^+. In this section we analyze the stepping-up power of ρ under the assumption that κ is a singular cardinal of cofinality ω. So let κ_n $(n < \omega)$ be a strictly increasing sequence of regular cardinals converging to κ fixed from now on. This immediately gives rise to a rather striking tree decomposition $<_n$ $(n < \omega)$ of the $\in$-relation on κ^+:

$$\alpha <_n \beta \quad \text{if and only if} \quad \rho(\alpha,\beta) \leq \kappa_n. \tag{3.10}$$

13.1 Lemma.

(1) $\in \restriction (\kappa^+ \times \kappa^+) = \bigcup_{n<\omega} <_n$,

(2) $<_n \subseteq <_{n+1}$,

(3) $(\kappa^+, <_n)$ *is a tree of height* $\leq \kappa_n^+$.

13.2 Definition. Let $F_n(\alpha) = \{\xi \leq \alpha : \rho(\xi,\alpha) \leq \kappa_n\}$, and let $f_\alpha(n) = \mathrm{tp}(F_n(\alpha))$ for $\alpha < \kappa^+$ and $n < \omega$. Let $L = \{f_\alpha : \alpha < \kappa^+\}$, considered as a linearly ordered set with the lexicographical ordering.

Since L is a subset of ${}^{\omega}\kappa$, it has an order-dense subset of size κ, so in particular it contains no well-ordered subset of size κ^+. The following result shows, however, that every subset of L of smaller size is the union of countably many well-ordered subsets.

13.3 Lemma. *For each $\beta < \kappa^+$, $L_\beta = \{f_\alpha : \alpha < \beta\}$ can be decomposed into countably many well-ordered subsets.*

Proof. Let $L_{\beta n} = \{f_\alpha : \alpha \in F_n(\beta)\}$ for $n < \omega$. Note that the projection $f \longmapsto f\restriction(n+1)$ is one-to-one on $L_{\beta n}$ so each $L_{\beta n}$ is lexicographically well-ordered. ⊣

13.4 Remark. Note that $\mathcal{K} = \{\{(n, f_\alpha(n)) : n < \omega\} : \alpha < \kappa^+\}$ is a family of countable subsets of $\omega \times \kappa$ which has the property that $\mathcal{K}\restriction X = \{K \cap X : K \in \mathcal{K}\}$ has size $\leq |X| + \aleph_0$ for every $X \subseteq \omega \times \kappa$ of size $< \kappa$. We shall now see that with a bit more work a considerably finer such a family can be constructed.

13.5 Definition. If a family $\mathcal{K} \subseteq [S]^\omega$ is at the same time locally countable and cofinal in $[S]^\omega$ then we call it a *cofinal Kurepa family* (*cofinal K-family* for short). Two cofinal K-families $\mathcal{H}$ and $\mathcal{K}$ are *compatible* if $H \cap K \in \mathcal{H} \cap \mathcal{K}$ for all $H \in \mathcal{H}$ and $K \in \mathcal{K}$. We say that $\mathcal{K}$ *extends* $\mathcal{H}$ if they are compatible and if $\mathcal{H} \subseteq \mathcal{K}$.

13.6 Remark. Note that the size of any cofinal K-family $\mathcal{K}$ on a set S is equal to the cofinality of $[S]^\omega$. Note also that for every $X \subseteq S$ there is a $Y \supseteq X$ of size $\mathrm{cf}([X]^\omega)$ such that $K \cap Y \in \mathcal{K}$ for all $K \in \mathcal{K}$.

13.7 Definition. Define $\mathrm{CK}(\theta)$ to be the statement that every sequence $\mathcal{K}_n$ $(n < \omega)$ of comparable cofinal K-families with domains included in θ which are closed under $\cup$, $\cap$ and $\setminus$ can be extended to a single cofinal K-family on θ, which is also closed under these three operations.

13.8 Lemma. $\mathrm{CK}(\omega_1)$ *is true and if* $\mathrm{CK}(\theta)$ *is true for some θ such that* $\mathrm{cf}([\theta]^\omega) = \theta$ *then* $\mathrm{CK}(\theta^+)$ *is also true.*

Proof. The easy proof of $\mathrm{CK}(\omega_1)$ is left to the reader.

Suppose $\mathrm{CK}(\theta)$ and let $\mathcal{K}_n$ $(n < \omega)$ be a given sequence of compatible cofinal K-families as in the hypothesis of $\mathrm{CK}(\theta^+)$. By Remark 13.6 there is a strictly increasing sequence δ_ξ $(\xi < \theta^+)$ of ordinals $< \theta$ such that $\mathcal{K}_n\restriction\delta_\xi \subseteq \mathcal{K}_n$ for all $\xi < \theta^+$ and $n < \omega$. Recursively on $\xi < \theta^+$ we construct a chain $\mathcal{H}_\xi$ $(\xi < \theta^+)$ of cofinal K-families as follows. If $\xi = 0$ or $\xi = \eta + 1$ for some η, using $\mathrm{CK}(\delta_\xi)$ we can find a cofinal K-family $\mathcal{H}_\xi$ on δ_ξ extending $\mathcal{H}_{\xi-1}$ and $\mathcal{K}_n\restriction\delta_\xi$ $(n < \omega)$. If ξ has uncountable cofinality then the union of $\bar{\mathcal{H}}_\xi = \bigcup_{\eta<\xi} \mathcal{H}_\eta$ is a cofinal K-family with domain included in δ_ξ, so using $\mathrm{CK}(\delta_\xi)$ we can find a cofinal K-family $\mathcal{H}_\xi$ on δ_ξ extending $\bar{\mathcal{H}}_\xi$ and $\mathcal{K}_n\restriction\delta_\xi$ $(n < \omega)$. If ξ has countable cofinality, pick a sequence $\{\xi_n\}$ converging to ξ and use $\mathrm{CK}(\delta_\xi)$ to find a cofinal K-family $\mathcal{H}_\xi$ on δ_ξ extending $\mathcal{H}_{\xi_n}$ $(n < \omega)$ and $\mathcal{K}_n$ $(n < \omega)$.

When the recursion is done, set $\mathcal{H} = \bigcup_{\xi<\theta^+} \mathcal{H}_\xi$. Then $\mathcal{H}$ is a cofinal K-family on θ^+ extending $\mathcal{K}_n$ $(n < \omega)$. $\dashv$

13.9 Corollary. *For each $n < \omega$ there is a cofinal Kurepa family on ω_n.*

13.10 Definition. Let κ be a cardinal of cofinality ω. A *Jensen matrix* on κ^+ is a matrix $\mathrm{J}_{\alpha n}$ $(\alpha < \kappa^+, n < \omega)$ of subsets of κ with the following properties, where κ_n $(n < \omega)$ is some increasing sequence of cardinals converging to κ:

(1) $|\mathrm{J}_{\alpha n}| \leq \kappa_n$ for all $\alpha < \kappa^+$ and $n < \omega$,

(2) for all $\alpha < \beta$ and $n < \omega$ there is an $m < \omega$ such that $\mathrm{J}_{\alpha n} \subseteq \mathrm{J}_{\beta m}$,

(3) $\bigcup_{n<\omega}[\mathrm{J}_{\beta n}]^\omega = \bigcup_{\alpha<\beta}\bigcup_{n<\omega}[\mathrm{J}_{\alpha n}]^\omega$ whenever $\mathrm{cf}(\beta) > \omega$,

(4) $[\kappa^+]^\omega = \bigcup_{\alpha<\kappa^+}\bigcup_{n<\omega}[\mathrm{J}_{\alpha n}]^\omega$.

13.11 Remark. The notion of a Jensen matrix is the combinatorial essence behind Silver's proof of Jensen's model-theoretic two-cardinal transfer theorem in the constructible universe (see [23, appendix]), so the matrix could equally well be called "Silver matrix". It has been implicitly or explicitly used in several places in the literature. The reader is referred to the paper of Foreman and Magidor [18] which gives quite a complete discussion of this notion and its occurrence in the literature.

13.12 Lemma. *Suppose some cardinal κ of countable cofinality carries a Jensen matrix $\mathrm{J}_{\alpha n}$ $(\alpha < \kappa^+, n < \omega)$ relative to some sequence of cardinals κ_n $(n < \omega)$ that converge to κ. If $\mathrm{CK}(\kappa_n)$ holds for all $n < \omega$ then $\mathrm{CK}(\kappa^+)$ is also true.*

Proof. Let $\mathcal{K}_n$ $(n < \omega)$ be a given sequence of compatible cofinal K-families with domains included in κ^+. Given $\mathrm{J}_{\alpha n}$, there is a natural continuous chain $\mathrm{J}^\xi_{\alpha n}$ $(\xi < \omega_1)$ of subsets of κ^+ of size $\leq \kappa_n$ such that $\mathrm{J}^0_{\alpha n} = \mathrm{J}_{\alpha n}$ and $\mathrm{J}^{\xi+1}_{\alpha n}$ equal to the union of all $K \in \bigcup_{n<\omega}\mathcal{K}_n$ which intersect $\mathrm{J}^\xi_{\alpha n}$. Let $\mathrm{J}^*_{\alpha n} = \bigcup_{\xi<\omega_1}\mathrm{J}^\xi_{\alpha n}$. It is easily seen that $\mathrm{J}^*_{\alpha n}$ $(\alpha < \kappa^+, n < \omega)$ is also a Jensen matrix. By recursion on α and n we define a sequence $\mathcal{H}_{\alpha n}$ $(\alpha < \kappa^+, n < \omega)$ of compatible cofinal K-families as follows. If $\alpha = \beta + 1$ or $\alpha = 0$ and $n < \omega$ using $\mathrm{CK}(\kappa_n)$ we can find a cofinal K-family $\mathcal{H}_{\alpha n}$ with domain $\mathrm{J}^*_{\alpha n}$ compatible with $\mathcal{H}_{\alpha m}$ $(m < n)$, $\mathcal{H}_{(\alpha-1)m}$ $(m < \omega)$ and $\mathcal{K}_m \restriction \mathrm{J}^*_{\alpha n}$ $(m < \omega)$. If $\mathrm{cf}(\alpha) = \omega$ let α_n $(n < \omega)$ be an increasing sequence of ordinals converging to α. Using $\mathrm{CK}(\kappa_n)$ we can find a cofinal K-family $\mathcal{H}_{\alpha n}$ which extends $\mathcal{H}_{\alpha m}$ $(m < n)$, $\mathcal{K}_m \restriction \mathrm{J}^*_{\alpha n}$ $(m < \omega)$ and each of the families $\mathcal{H}_{\alpha_i k}$ $(i < \omega, k < \omega$ and $\mathrm{J}^*_{\alpha_i k} \subseteq \mathrm{J}^*_{\alpha n})$. Finally, suppose that $\mathrm{cf}(\alpha) > \omega$. For $n < \omega$, set

$$\mathcal{H}_{\alpha n} = [\mathrm{J}^*_{\alpha n}]^\omega \cap \big(\bigcup_{\xi<\alpha}\bigcup_{m<\omega}\mathcal{H}_{\xi m}\big).$$

Using the properties of the Jensen matrix (especially (3)) as well as the compatibility of $\mathcal{H}_{\xi m}$ $(\xi < \alpha, m < \omega)$ one easily checks that $\mathcal{H}_{\alpha n}$ is a cofinal

K-family with domain $\mathrm{J}^*_{\alpha n}$ which extends each member of $\mathcal{H}_{\alpha m}$ $(m < n)$ and $\mathcal{K}_m\lceil\mathrm{J}^*_{\alpha n}$ $(m < \omega)$ and which is compatible with all of the previously constructed families $\mathcal{H}_{\xi m}$ $(\xi < \alpha, m < \omega)$. When the recursion is done we set

$$\mathcal{H} = \bigcup_{\alpha<\kappa^+}\bigcup_{n<\omega}\mathcal{H}_{\alpha n}.$$

Using the property (4) of $\mathrm{J}^*_{\alpha n}$ $(\alpha < \kappa^+, n < \omega)$, it follows easily that $\mathcal{H}$ is a cofinal K-family on κ^+ extending $\mathcal{K}_n$ $(n < \omega)$. ⊣

13.13 Theorem. *If a Jensen matrix exists on any successor of a cardinal of cofinality ω, then a cofinal Kurepa family exists on any domain.*

The ρ-function $\rho : [\kappa^+]^2 \longrightarrow \kappa$ associated with a $\Box_\kappa$-sequence C_α $(\alpha < \kappa^+)$ for some singular cardinal κ of cofinality ω leads to the matrix

$$F_n(\alpha) = \{\xi < \alpha : \rho(\xi, \alpha) \leq n\}(\alpha < \kappa^+, n < \omega) \tag{3.11}$$

which has the properties (1)–(3) of Definition 13.10 as well as some other properties not captured by the definition of a Jensen matrix. If one additionally has a sequence a_α $(\alpha < \kappa^+)$ of countable subsets of κ^+ that is cofinal in $[\kappa^+]^\omega$ one can extend the matrix (3.11) as follows:

$$M_{\beta n} = \bigcup_{\alpha<_n\beta}(a_\alpha \cup \{\alpha\})\ (\beta < \kappa^+, n < \omega).$$

(Recall that $<_n$ is the tree ordering on κ^+ defined by the formula $\alpha <_n \beta$ iff $\rho(\alpha, \beta) \leq \kappa_n$ where κ_n is a fixed increasing sequence of cardinals converging to κ.) The matrix $M_{\beta n}$ $(\beta < \kappa^+, n < \omega)$ has properties not captured by Definition 13.10 that are of independent interest.

13.14 Lemma.

(1) $\alpha <_n \beta$ implies $M_{\alpha n} \subseteq M_{\beta n}$,

(2) $M_{\alpha m} \subseteq M_{\alpha n}$ whenever $m < n$,

(3) if $\beta = \sup\{\alpha : \alpha <_n \beta\}$ then $M_{\beta n} = \bigcup_{\alpha<_n\beta} M_{\alpha n}$,

(4) every countable subset of κ^+ is covered by some $M_{\beta n}$,

(5) $\mathcal{M} = \{M_{\beta n} : \beta < \kappa^+, n < \omega\}$ is a locally countable family if we have started with a locally countable $\mathcal{K} = \{a_\alpha : \alpha < \kappa^+\}$.

13.15 Remark. One can think of the matrix $\mathcal{M} = \{M_{\beta n} : \beta < \kappa^+, n < \omega\}$ as a version of a "morass" for the singular cardinal κ (see [68]). It would be interesting to see how far one can go in this analogy. We give a few applications just to illustrate the usefulness of the families we have constructed so far.

13.16 Definition. A *Bernstein decomposition* of a topological space X is a function $f : X \longrightarrow 2^{\mathbb{N}}$ with the property that f takes all the values from $2^{\mathbb{N}}$ on any subset of X homeomorphic to the Cantor set.

13.17 Remark. The classical construction of Bernstein [6] can be interpreted by saying that every space of size at most continuum admits a Bernstein decomposition. For larger spaces one must assume Hausdorff's separation axiom, a result of Nešetril and Rődl (see [38]). In this context Malykhin was able to extend Bernstein's result to all spaces of size $< \mathfrak{c}^{+\omega}$ (see [35]). To extend this to all Hausdorff spaces, some use of square sequences seems natural. In fact, the first Bernstein decompositions of an arbitrary Hausdorff space have been constructed using $\square_\kappa$ and $\kappa^\omega = \kappa^+$ for every $\kappa > \mathfrak{c}$ of cofinality ω by Weiss [72] and Wolfsdorf [73]. We shall now see that cofinal K-families are quite natural tools in constructions of Bernstein decompositions. The proof of this result can be found for example in [66].

13.18 Theorem. *Suppose every regular $\theta > \mathfrak{c}$ supports a cofinal Kurepa family of size θ. Then every Hausdorff space admits a Bernstein decomposition.*

It is interesting that various less pathological classes of spaces admit a local version of Theorem 13.18 (see [66]).

13.19 Theorem. *Every metric space that carries a cofinal Kurepa family admits a Bernstein decomposition.*

13.20 Definition. Recall the notion of a *coherent family* of partial functions indexed by some ideal $\mathfrak{I}$, a family of the form $f_a : a \longrightarrow \omega$ $(a \in \mathfrak{I})$ with the property that $\{x \in a \cap b : f_a(x) \neq f_b(x)\}$ is finite for all $a, b \in \mathfrak{I}$.

It can be seen (see [64]) that the P-ideal dichotomy (see Definition 3.9) has a strong influence on such families provided $\mathfrak{I}$ is a P-ideal of countable subsets of some set Γ.

13.21 Theorem. *Assuming the P-ideal dichotomy, for every coherent family of functions $f_a : a \longrightarrow \omega$ $(a \in \mathfrak{I})$ indexed by some P-ideal $\mathfrak{I}$ of countable subsets of some set Γ, either*

(1) there is an uncountable $\Delta \subseteq \Gamma$ such that $f_a \restriction \Delta$ is finite-to-one for all $a \in \mathfrak{I}$, or

(2) there is a $g : \Gamma \longrightarrow \omega$ such that $g \restriction a =^* f_a$ for all $a \in \mathfrak{I}$.

Proof. Let $\mathfrak{L}$ be the family of all countable subsets b of Γ for which one can find an a in $\mathfrak{I}$ such that $b \setminus a$ is finite and f_a is finite-to-one on b. To see that $\mathfrak{L}$ is a P-ideal, let $\{b_n\}$ be a given sequence of members of $\mathfrak{L}$ and for each n fix a member a_n of $\mathfrak{I}$ such that f_{a_n} is finite-to-one on b_n. Since $\mathfrak{I}$ is a P-ideal, we can find $a \in \mathfrak{I}$ such that $a_n \setminus a$ is finite for all n. Note that for all n, $b_n \setminus a$ is finite and that f_a is finite-to-one on b_n. For $n < \omega$, let

$$b_n^* = \{\xi \in b_n \cap a : f_a(\xi) > n\}.$$

Then b_n^* is a cofinite subset of b_n for each n, so if we set b to be equal to the union of the b_n^*'s, we get a subset of a which almost includes each b_n and on which f_a is finite-to-one. It follows that b belongs to $\mathfrak{L}$. This completes the proof that $\mathfrak{L}$ is a P-ideal. Applying the P-ideal dichotomy to $\mathfrak{L}$, we get the two alternatives that translate into the alternatives (1) and (2) of the theorem. ⊣

This leads to the natural question whether for any set Γ one can construct a family $\{f_a : a \longrightarrow \omega\}$ of finite-to-one mappings indexed by $[\Gamma]^\omega$. This question was answered by Koszmider [26] using the notion of a Jensen matrix discussed above. We shall present Koszmider's result using the notion of a cofinal Kurepa family instead.

13.22 Theorem. *If Γ carries a cofinal Kurepa family then there is a coherent family $f_a : a \longrightarrow \omega$ $(a \in [\Gamma]^\omega)$ of finite-to-one mappings.*

Proof. Let $\mathcal{K}$ be a fixed well-founded cofinal K-family on Γ and let $<_w$ be a well-ordering of $\mathcal{K}$ compatible with $\subseteq$. It suffices to produce a coherent family of finite-to-one mappings indexed by $\mathcal{K}$. This is done by induction on $<_w$. Suppose $K \in \mathcal{K}$ and $f_H : H \longrightarrow \omega$ is determined for all $H \in \mathcal{K}$ with $H <_w K$. Let H_n $(n < \omega)$ be a sequence of elements of $\mathcal{K}$ that are $<_w K$ and have the property that for every $H \in \mathcal{K}$ with $H <_w K$ there is an $n < \omega$ such that $H \cap K =^* H_n \cap K$. So it suffices to construct a finite-to-one $f_K : K \longrightarrow \omega$ which coheres with each f_{H_n} $(n < \omega)$, a straightforward task. ⊣

13.23 Corollary. *For every nonnegative integer n there is a coherent family $f_a : a \longrightarrow \omega$ $(a \in [\omega_n]^\omega)$ of finite-to-one mappings.*

13.24 Remark. It is interesting that "finite-to-one" cannot be replaced by "one-to-one" in these results. For example, there is no coherent family of one-to-one mappings $f_a : a \longrightarrow \omega$ $(a \in [\mathfrak{c}^+]^\omega)$. We finish this section with a typical application of coherent families of finite-to-one mappings discovered by Scheepers [44].

13.25 Theorem. *If there is a coherent family $f_a : a \longrightarrow \omega$ $(a \in [\Gamma]^\omega)$ of finite-to-one mappings, then there is an $F : [[\Gamma]^\omega]^2 \longrightarrow [\Gamma]^{<\omega}$ with the property that for every strictly $\subseteq$-increasing sequence a_n $(n < \omega)$ of countable subsets of Γ, the union of $F(a_n, a_{n+1})$ $(n < \omega)$ covers the union of a_n $(n < \omega)$.*

Proof. For $a \in [\Gamma]^\omega$ let $x_a : \omega \longrightarrow \omega$ be defined by letting $x_a(n) = |\{\xi \in a : f_a(\xi) \leq n\}|$. Note that x_a is eventually dominated by x_b whenever a is a proper subset of b. Choose $\Phi : \omega^\omega \longrightarrow \omega^\omega$ with the property that $x <^* y$ implies $\Phi(y) <^* \Phi(x)$, where $<^*$ is the ordering of eventual dominance on ω^ω (i.e. $x <^* y$ if $x(n) < y(n)$ for all but finitely many n's). Define another family of functions $g_a : a \longrightarrow \omega$ $(a \in [\Gamma]^\omega)$ by letting

$$g_a(\xi) = \Phi(x_a)(f_a(\xi)).$$

Note the following interesting property of g_a $(a \in [\Gamma]^\omega)$:

$$F(a, b) = \{\xi \in a : g_b(\xi) \geq g_a(\xi)\} \text{ is finite for all } a \subsetneqq b \text{ in } [\Gamma]^\omega.$$

So if a_n $(n < \omega)$ is a strictly $\subseteq$-increasing sequence of countable subsets of Γ and $\bar{\xi}$ belongs to some $a_{\bar{n}}$ then the sequence of integers $g_{a_n}(\bar{\xi})$ $(\bar{n} \le n < \omega)$ must have some place $n \ge \bar{n}$ with the property that $g_{a_n}(\bar{\xi}) < g_{a_{n+1}}(\bar{\xi})$, i.e. a place $n \ge \bar{n}$ such that $\xi \in F(a_n, a_{n+1})$. $\dashv$

13.26 Remark. Note that if κ is a singular cardinal of cofinality ω with the property that $\mathrm{cf}([\theta]^\omega) < \kappa$ for all $\theta < \kappa$, then the existence of a cofinal Kurepa family on κ^+ implies the existence of a Jensen matrix on κ^+. So these two notions appear to be quite close to each other. The three basic properties of the function $\rho : [\kappa^+] \longrightarrow \kappa$ (Lemmas 11.5 and 11.6(a),(b)) seem much stronger in view of the fact that the linear ordering as in Lemma 13.3 cannot exist for κ above a supercompact cardinal and the fact that Foreman and Magidor [18] have produced a model with a supercompact cardinal that carries a Jensen matrix on any successor of a singular cardinal of cofinality ω. The "Chang's conjecture" $(\kappa^+, \kappa) \twoheadrightarrow (\omega_1, \omega)$ is the model-theoretic transfer principle asserting that every structure of the form $(\kappa^+, \kappa, <, \ldots)$ with a countable signature has an uncountable elementary submodel B with the property that $B \cap \omega_1$ is countable. Note that $(\kappa^+, \kappa) \twoheadrightarrow (\omega_1, \omega)$ for some singular κ of cofinality ω implies that every locally countable family $\mathcal{K} \subseteq [\kappa]^\omega$ must have size $\le \kappa$. So, one of the models of set theory that has no cofinal K-family on, say $\aleph_{\omega+1}$, is the model of Levinski, Magidor and Shelah [34], in which $(\aleph_{\omega+1}, \aleph_\omega) \twoheadrightarrow (\omega_1, \omega)$ holds. It seems still unknown whether the conclusion of Theorem 13.25 can be proved without additional set-theoretic assumptions.

14. The Oscillation Mapping

In what follows, θ will be a fixed regular infinite cardinal.

$$\mathrm{osc} : \mathcal{P}(\theta)^2 \longrightarrow \mathrm{Card}$$

is defined by

$$\mathrm{osc}(x, y) = |x \setminus (\sup(x \cap y) + 1)/ \sim |,$$

where $\sim$ is the equivalence relation on $x \setminus (\sup(x \cap y) + 1)$ defined by letting $\alpha \sim \beta$ iff the closed interval determined by α and β contains no point from y. So, if x and y are disjoint, $\mathrm{osc}(x, y)$ is simply the number of convex pieces the set x is split by the set y. The oscillation mapping has proven to be a useful device in various schemes for coding information. It usefulness in a given context depend very much of the corresponding "oscillation theory", a set of definitions and lemmas that disclose when it is possible to achieve a given number as oscillation between two sets x and y in a given family $\mathcal{X}$. The following definition reveals the notion of largeness relevant to the oscillation theory that we develop in this section.

14.1 Definition. A family $\mathcal{X} \subseteq \mathcal{P}(\theta)$ is *unbounded* if for every closed and unbounded subset C of θ there exist $x \in \mathcal{X}$ and an increasing sequence

$\{\delta_n : n < \omega\} \subseteq C$ such that $\sup(x \cap \delta_n) < \delta_n$ and $[\delta_n, \delta_{n+1}) \cap x \neq \emptyset$ for all $n < \omega$.

This notion of unboundedness has proven to be the key behind a number of results asserting the complex behavior of the oscillation mapping on $\mathcal{X}^2$. The case $\theta = \omega$ seems to contain the deeper part of the oscillation theory known so far (see [58], [59, §1] and [63]), though in this section we shall only consider the case $\theta > \omega$. We shall also restrict ourselves to the family $\mathcal{K}(\theta)$ of all closed bounded subsets of θ rather than the whole power-set of θ. Our next lemma is the basic result about the behavior of the oscillation mapping in this context. Its proof can again be found in [66].

14.2 Lemma. *If $\mathcal{X}$ is an unbounded subfamily of $\mathcal{K}(\theta)$ then for every positive integer n there exist x and y in $\mathcal{X}$ such that* $\operatorname{osc}(x, y) = n$.

Lemma 14.2 also has a rectangular form.

14.3 Lemma. *If $\mathcal{X}$ and $\mathcal{Y}$ are two unbounded subfamilies of $\mathcal{K}(\theta)$ then for all but finitely many positive integers n there exist $x \in \mathcal{X}$ and $y \in \mathcal{Y}$ such that* $\operatorname{osc}(x, y) = n$.

Recall the notion of a nontrivial C-sequence C_α $(\alpha < \theta)$ on θ from Sect. 8, a C-sequence with the property that for every closed and unbounded subset C of θ there is a limit point δ of C such that $C \cap \delta \nsubseteq C_\alpha$ for all $\alpha < \theta$.

14.4 Definition. For a subset D of θ let $\lim(D)$ denote the set of all $\alpha < \theta$ with the property that $\alpha = \sup(D \cap \alpha)$. A subsequence C_α $(\alpha \in \Gamma)$ of some C-sequence C_α $(\alpha < \theta)$ is *stationary* if the union of all $\lim(C_\alpha)$ $(\alpha \in \Gamma)$ is a stationary subset of θ.

14.5 Lemma. *A stationary subsequence of a nontrivial C-sequence on θ is an unbounded family of subsets of θ.*

Proof. Let C_α $(\alpha \in \Gamma)$ be a given stationary subsequence of a nontrivial C-sequence on θ. Let C be a given closed and unbounded subset of θ. Let Δ be the union of all $\lim(C_\alpha)$ $(\alpha \in \Gamma)$. Then Δ is a stationary subset of θ. For $\xi \in \Delta$ choose $\alpha_\xi \in \Gamma$ such that $\xi \in \lim(C_{\alpha_\xi})$. Applying the assumption that C_α $(\alpha \in \Gamma)$ is a nontrivial C-subsequence, we can find a $\xi \in \Delta \cap \lim(C)$ such that

$$C \cap [\eta, \xi) \nsubseteq C_{\alpha_\xi} \quad \text{for all } \eta < \xi. \tag{3.12}$$

If such a ξ cannot be found using the stationarity of the set $\Delta \cap \lim(C)$ we would be able to use the Pressing Down Lemma on the regressive mapping that would give us an $\eta < \xi$ violating (3.12) and get that a tail of C trivializes C_α $(\alpha \in \Gamma)$. Using (3.12) and the fact that $C_{\alpha_\xi} \cap \xi$ is unbounded in ξ we can find a strictly increasing sequence δ_n $(n < \omega)$ of elements of $(C \cap \xi) \setminus C_{\alpha_\xi}$ such that $[\delta_n, \delta_{n+1}) \cap C_{\alpha_\xi} \neq \emptyset$ for all n. So the set C_{α_ξ} satisfies the conclusion of Definition 14.1 for the given closed and unbounded set C. ⊣

Recall that $\mathbb{Q}_\theta$ denotes the set of all finite sequences of ordinals $< \theta$ and that we consider it ordered by the right lexicographical ordering. We need the following two further orderings on $\mathbb{Q}_\theta$: $s \sqsubseteq t$ if and only if s is an initial segment of t, and $s \sqsubset t$ if and only if s is a proper initial part of t.

14.6 Definition. Given a C-sequence C_α $(\alpha < \theta)$ we can define an *action* $(\alpha, t) \longmapsto \alpha_t$ of $\mathbb{Q}_\theta$ on θ recursively on the ordering $\sqsubseteq$ of $\mathbb{Q}_\theta$ as follows: $\alpha_\emptyset = \alpha$, $\alpha_{\langle\xi\rangle}$ is equal to the ξth member of C_α if $\xi < \operatorname{tp}(C_\alpha)$; otherwise $\alpha_{\langle\xi\rangle} = \alpha$, and finally, $\alpha_{t^\frown\langle\xi\rangle} = (\alpha_t)_{\langle\xi\rangle}$.

14.7 Remark. Note that if $\rho_0(\alpha, \beta) = t$ for some $\alpha < \beta < \theta$ then $\beta_t = \alpha$. In fact, if $\beta = \beta_0 > \cdots > \beta_n = \alpha$ is the walk from β to α along the C-sequence, each member of the trace $\operatorname{Tr}(\alpha, \beta) = \{\beta_0, \beta_1, \ldots, \beta_n\}$ has the form β_s where s is the uniquely determined initial part of t. Note, however, that in general $\beta_t = \alpha$ does not imply that $\rho_0(\alpha, \beta) = t$.

14.8 Notation. Given a C-sequence C_α $(\alpha < \theta)$ on θ we shall use $\operatorname{osc}(\alpha, \beta)$ to denote $\operatorname{osc}(C_\alpha, C_\beta)$.

The proof of the following result can be found in [66].

14.9 Theorem. *If C_α $(\alpha < \theta)$ is a nontrivial C-sequence on θ, then for every unbounded set $\Gamma \subseteq \theta$ and positive integer n there exist $\alpha < \beta$ in Γ and $t \sqsubseteq \rho_0(\alpha, \beta)$ such that $\operatorname{osc}(\alpha_t, \beta_t) = n$, but $\operatorname{osc}(\alpha_s, \beta_s) = 1$ for all $s \sqsubset t$.*

14.10 Corollary. *Suppose a regular uncountable cardinal θ carries a nontrivial C-sequence. Then there is an $f : [\theta]^2 \longrightarrow \omega$ which takes all the values from ω on any set of the form $[\Gamma]^2$ for an unbounded subset of θ.*

Proof. Given $\alpha < \beta < \theta$, if there is a $t \sqsubseteq \rho_0(\alpha, \beta)$ satisfying the conclusion of 14.9, put $f(\alpha, \beta) = \operatorname{osc}(\alpha_t, \beta_t) - 2$; otherwise put $f(\alpha, \beta) = 0$. ⊣

14.11 Remark. The class of all regular cardinals θ that carry a nontrivial C-sequence is quite extensive. It includes not only all successor cardinals but also some inaccessible as well as hyperinaccessible cardinals such as for example, the first inaccessible cardinal or the first Mahlo cardinal. In view of the well-known Ramsey-theoretic characterization of weak compactness, Corollary 14.10 leads us to the following natural question.

14.12 Question. Can the weak compactness of a strong limit regular uncountable cardinal be characterized by the fact that for every $f : [\theta]^2 \longrightarrow \omega$ there exists an unbounded set $\Gamma \subseteq \theta$ such that $f``[\Gamma]^2 \neq \omega$? This is true when ω is replaced by 2, but can any other number beside 2 be used in this characterization?

15. The Square-Bracket Operation

In this section we show that the basic idea of the square-bracket operation on ω_1 introduced in Definition 4.3 extends to a general setting on an arbitrary uncountable regular cardinal θ that carries a nontrivial C-sequence C_α

($\alpha < \theta$). The basic idea is based on the oscillation map defined in the previous section and, in particular, on the property of this map described in Theorem 14.9: for $\alpha < \beta < \theta$ we set

$$[\alpha\beta] = \beta_t, \text{ where } t \sqsubseteq \rho_0(\alpha,\beta) \text{ is such that } \operatorname{osc}(\alpha_t,\beta_t) \geq 2 \text{ but } \operatorname{osc}(\alpha_s,\beta_s) = 1 \text{ for all } s \sqsubset t\text{; if such a } t \text{ does not exist, we let } [\alpha\beta] = \alpha. \tag{3.13}$$

Thus, $[\alpha\beta]$ is the first place visited by β on its walk to α where a nontrivial oscillation with the corresponding step of α occurs. What Theorem 14.9 is telling us is that the nontrivial oscillation indeed happens most of the time. Results that would say that the set of values $\{[\alpha\beta] : \{\alpha,\beta\} \in [\Gamma]^2\}$ is in some sense large no matter how small the unbounded set $\Gamma \subseteq \theta$ is, would correspond to the results of Lemmas 4.4–4.5 about the square-bracket operation on ω_1. It turns out that this is indeed possible and to describe it we need the following definition.

15.1 Definition. A C-sequence C_α ($\alpha < \theta$) on θ *avoids* a given subset Δ of θ if $C_\alpha \cap \Delta = \emptyset$ for all limit ordinals $\alpha < \theta$.

The proof of the following lemma is quite similar to the proof of the corresponding fact in case $\theta = \omega_1$ considered above though its full proof can be found in [66].

15.2 Lemma. *Suppose C_α ($\alpha < \theta$) is a given C-sequence on θ that avoids a set $\Delta \subseteq \theta$. Then for every unbounded set $\Gamma \subseteq \theta$, the set of elements of Δ not of the form $[\alpha\beta]$ for some $\alpha < \beta$ in Γ is nonstationary in θ.*

A similar proof gives the following more general result.

15.3 Lemma. *Suppose C_α ($\alpha < \theta$) avoids $\Delta \subseteq \theta$ and let A be a family of size θ consisting of pairwise disjoint finite sets, all of some fixed size n. Then the set of all elements of Δ that are not of the form $[a(1)b(1)] = [a(2)b(2)] = \cdots = [a(n)b(n)]$ for some $a \neq b$ in A is nonstationary in θ.*

Since $[\alpha\beta]$ belongs to the trace $\operatorname{Tr}(\alpha,\beta)$ of the walk from β to α it is not surprising that $[\cdot\cdot]$ strongly depends on the behavior of Tr. The following is one of the results which brings this out.

15.4 Lemma. *The set $\Omega \setminus \{[\alpha\beta] : \{\alpha,\beta\} \in [\Gamma]^2\}$ is not stationary in θ if and only if the set $\Omega \setminus \bigcup\{\operatorname{Tr}(\alpha,\beta) : \{\alpha,\beta\} \in [\Gamma]^2\}$ is not stationary in θ.*

This fact suggests the following definition.

15.5 Definition. The *trace filter* of a given C-sequence C_α ($\alpha < \theta$) is the normal filter on θ generated by sets of the form $\bigcup\{\operatorname{Tr}(\alpha,\beta) : \{\alpha,\beta\} \in [\Gamma]^2\}$ where Γ is an unbounded subset of θ.

15.6 Remark. Having a proper (i.e. $\neq \mathcal{P}(\theta)$) trace filter is a strengthening of the nontriviality requirement on a given C-sequence C_α $(\alpha < \theta)$. For example, if a C-sequence avoids a stationary set $\Omega \subseteq \theta$, then its trace filter is nontrivial and in fact no stationary subset of Γ is a member of it. Note the following analogue of Lemma 15.4: the trace filter of a given C-sequence is the normal filter generated by sets of the form $\{[\alpha\beta] : \{\alpha, \beta\} \in [\Gamma]^2\}$ where Γ is an unbounded subset of θ. So to obtain the analogues of the results of Sect. 4 about the square-bracket operation on ω_1 one needs a C-sequence C_α $(\alpha < \theta)$ on θ whose trace filter is not only nontrivial but also not θ-saturated, i.e. it allows a family of θ pairwise disjoint positive sets. It turns out that the hypothesis of Lemma 15.2 is sufficient for both of these conclusions.

15.7 Lemma. *If a C-sequence on θ avoids a stationary subset of θ, then there exist θ pairwise disjoint subsets of θ that are positive with respect to its trace filter.*[18]

Proof. This follows from the well-known fact (see [25]) that if there is a normal, nontrivial and θ-saturated filter on θ, then for every stationary $\Omega \subseteq \theta$ there exists a $\lambda < \theta$ such that $\Omega \cap \lambda$ is stationary in λ (and the fact that the stationary set which is avoided by the C-sequence does not reflect in this way). ⊣

15.8 Corollary. *If a regular cardinal θ admits a nonreflecting stationary subset then there is a $c : [\theta]^2 \longrightarrow \theta$ which takes all the values from θ on any set of the form $[\Gamma]^2$ for some unbounded set $\Gamma \subseteq \theta$.*

To get such a c, one composes the square-bracket operation of some C-sequence, that avoids a stationary subset of θ, with a mapping $* : \theta \longrightarrow \theta$ with the property that the $*$-preimage of each point from θ is positive with respect to the trace filter of the square sequence. In other words, c is equal to the composition of $[\cdot\cdot]$ and $*$, i.e. $c(\alpha, \beta) = [\alpha\beta]^*$. Note that, as in Sect. 4, the property of the square-bracket operation from Lemma 15.3 leads to the following rigidity result which corresponds to Lemma 4.7.

15.9 Lemma. *The algebraic structure $(\theta, [\cdot\cdot], *)$ has no nontrivial automorphisms.*

15.10 Remark. Note that every θ which is a successor of a regular cardinal κ admits a nonreflecting stationary set. For example, $\Omega = \{\delta < \theta : \mathrm{cf}(\delta) = \kappa\}$ is such a set. Thus any C-sequence on θ that avoids Ω leads to a square bracket operation which allows analogues of all the results from Sect. 4 about the square-bracket operation on ω_1. The reader is urged to examine these analogues.

Let us now introduce a useful projection of the square-bracket operation, the analogue of Definition 4.11 considered above. This concerns the case

[18] A subset A of the domain of some filter $\mathcal{F}$ is *positive* with respect to $\mathcal{F}$ if $A \cap F \neq \emptyset$ for every $F \in \mathcal{F}$.

when θ is the successor of some regular cardinal κ and when the square-bracket operation is based on a fixed C-sequence C_α $(\alpha < \kappa^+)$ on κ^+ such that $\mathrm{tp}(C_\alpha) \leq \kappa$ for all α, or equivalently, such that C_α $(\alpha < \kappa^+)$ avoids the set $\Omega_\kappa = \{\delta < \kappa^+ : \mathrm{cf}(\delta) = \kappa\}$. Let $[\cdot\cdot]$ be the corresponding square-bracket operation. Let λ be the minimal cardinal such that $2^\lambda \geq \kappa^+$. Choose a sequence r_ξ $(\xi < \kappa^+)$ of distinct subsets of λ. Let $\mathcal{H}$ be the collection of all maps $h : \mathcal{P}(D(h)) \longrightarrow \kappa^+$ where $D(h)$ is a finite subset of λ. Let $\pi : \kappa^+ \longrightarrow \mathcal{H}$ be a map with the property that $\pi^{-1}(\{h\}) \cap \Omega_\kappa$ is stationary for all $h \in \mathcal{H}$. Finally, define an operation $[\![\cdot\cdot]\!]$ on κ^+ as follows:

$$[\![\alpha\beta]\!] = \pi([\alpha\beta])(r_\alpha \cap D(\pi([\alpha\beta]))).$$

The following is a simple consequence of the property Lemma 15.3 of the square-bracket operation.

15.11 Lemma. *For every family A of size κ^+ consisting of pairwise disjoint finite subsets of κ^+ all of some fixed size n and every sequence $\xi_0, \ldots, \xi_{n-1}$ of ordinals $< \kappa^+$ there exist $a \neq b$ in A such that $[\![a(i)b(i)]\!] = \xi_i$ for all $i < n$.*

For sufficiently large cardinals θ we have the following variation on the theme first encountered above in Theorem 8.2 and the reader can find its full proof in [66].

15.12 Theorem. *Suppose θ is bigger than the continuum and carries a C-sequence avoiding a stationary set Γ of cofinality $> \omega$ ordinals in θ. Let A be a family of θ pairwise disjoint finite subsets of θ, all of some fixed size n. Then for every stationary $\Gamma_0 \subseteq \Gamma$ there exist $s, t \in \omega^n$ and a positive integer k such that for every $l < \omega$ there exist $a < b$* [19] *in A and $\delta_0 > \delta_1 > \cdots > \delta_l$ in $\Gamma_0 \cap (\max(a), \min(b))$ such that:*

(1) $\rho_2(\delta_{i+1}, \delta_i) = k$ *for all* $i < l$,

(2) $\rho_0(a(i), b(j)) = \rho_0(\delta_0, b(j))^\frown \rho_0(\delta_1, \delta_0)^\frown \cdots {}^\frown \rho_0(\delta_l, \delta_{l-1})^\frown \rho_0(a(i), \delta_l)$ *for all* $i, j < n$,

(3) $\rho_2(\delta_0, b(j)) = t_j$ *and* $\rho_2(a(i), \delta_l) = s_i$ *for all* $i, j < n$.

From now on, θ is assumed to be a fixed cardinal satisfying the hypotheses of Theorem 15.12. It turns out that Theorem 15.12 gives us a way to define another square-bracket operation which has complex behavior not only on squares of unbounded subsets of θ but also on rectangles formed by two unbounded subsets of θ. To define this new operation we choose a mapping $h : \omega \longrightarrow \omega$ such that:

$$\text{for every } k, m, n, p < \omega \text{ and } s \in \omega^n \text{ there is an } l < \omega \text{ such that } h(m + l \cdot k + s(i)) = m + p \text{ for all } i < n. \tag{3.14}$$

[19] Recall that if a and b are two sets of ordinals, then the notation $a < b$ means that $\max(a) < \min(b)$.

15.13 Definition. $[\cdot\cdot]_h : [\theta]^2 \longrightarrow \theta$ is defined by letting $[\alpha\beta]_h = \beta_t$ where $t = \rho_0(\alpha,\beta)\restriction h(\rho_2(\alpha,\beta))$.

Thus, $[\alpha\beta]_h$ is the $h(\rho_2(\alpha,\beta))$th place that β visits on its walk to α. It is clear that Theorem 15.12 and the choice of h in (3.14) give us the following conclusion.

15.14 Lemma. *Let A be a family of θ pairwise disjoint finite subsets of θ, all of some fixed size n, and let Ω be an unbounded subset of θ. Then almost every $\delta \in \Gamma$ has the form $[a(0)\beta]_h = [a(1)\beta]_h = \cdots = [a(n-1)\beta]_h$ for some $a \in A$, $\beta \in \Omega$, $a < \beta$.*[20]

In fact, one can get a projection of this square-bracket operation with seemingly even more complex behavior. Keeping the notation of Theorem 15.12, pick a function $\xi \longmapsto \xi^*$ from θ to ω such that $\{\xi \in \Gamma : \xi^* = n\}$ is stationary for all n. This gives us a way to consider the following projection of the trace function $\mathrm{Tr}^* : [\theta]^2 \longrightarrow \omega^{<\omega}$:

$$\mathrm{Tr}^*(\alpha,\beta) = \langle \min(C_\beta \setminus \alpha)^* \rangle^\frown \mathrm{Tr}^*(\alpha, \min(C_\beta \setminus \alpha)),$$

where we stipulate that $\mathrm{Tr}^*(\gamma,\gamma) = \langle \gamma^* \rangle$ for all $\gamma < \theta$. It is clear that the proof of Theorem 15.12 allows us to add the following conclusions:

15.12* Theorem. *Under the hypothesis of Theorem 15.12, its conclusion can be extended by adding the following two new statements:*

(4) $\mathrm{Tr}^*(\delta_1,\delta_0) = \cdots = \mathrm{Tr}^*(\delta_l,\delta_{l-1})$,

(5) The maximal term of the sequence $\mathrm{Tr}^*(\delta_1,\delta_0) = \cdots = \mathrm{Tr}^*(\delta_l,\delta_{l-1})$ *is bigger than the maximal term of any of the sequences* $\mathrm{Tr}^*(\delta_0, b(j))$ *or* $\mathrm{Tr}^*(a(i),\delta_l)$ *for $i, j < n$.*

15.15 Definition. For $\alpha < \beta < \theta$, let $[\alpha\beta]^* = \beta_t$ for t the minimal initial part of $\rho_0(\alpha,\beta)$ such that $\beta_t^* = \max(\mathrm{Tr}^*(\alpha,\beta))$.

Thus $[\alpha\beta]^*$ is the first place in the walk from β to α where the function $*$ reaches its maximum among all other places visited during the walk. Note that combining the conclusions (1)–(5) of Theorem 15.12$^{(*)}$ we get:

15.12** Theorem. *Under the hypothesis of Theorem 15.12, its conclusion can be extended by adding the following:*

(6) $[a(i)b(j)]^* = [\delta_1\delta_0]^*$ *for all $i, j < n$.*

Having in mind the property of $[\cdot\cdot]_h$ stated in Lemma 15.14, the following variation is now quite natural.

15.16 Definition. $[\alpha\beta]_h^* = [\alpha[\alpha\beta]^*]_h$ for $\alpha < \beta < \theta$.

[20] Here "almost every" is to be interpreted by "all except a nonstationary set".

Using Theorem 15.12$^{(**)}$(1)–(6) one easily gets the following conclusion.

15.17 Lemma. *Let A be a family of θ pairwise disjoint finite subsets of θ, all of some fixed size n. Then for all but nonstationarily many $\delta \in \Gamma$ one can find $a < b$ in A such that $[a(i)b(j)]^*_h = \delta$ for all $i, j < n$.*

15.18 Remark. Composing $[\cdot\cdot]^*_h$ with a mapping $\pi : \theta \longrightarrow \theta$ with the property that $\pi^{-1}(\{\xi\}) \cap \Gamma$ is stationary for all $\xi < \theta$, one gets a projection of $[\cdot\cdot]^*_h$ for which the conclusion of Lemma 15.17 is true for *all* $\delta < \kappa$. Assuming that θ is moreover a successor of a regular cardinal κ (of size at least continuum), in which case Γ can be taken to be $\{\delta < \kappa^+ : \mathrm{cf}(\delta) = \kappa\}$, and proceeding as in 15.11 above we get a projection $[\![\cdot\cdot]\!]^*_h$ with the following property:

15.19 Lemma. *For every family A of pairwise disjoint finite subsets of κ^+ all of some fixed size n and for every $q : n \times n \longrightarrow \kappa^+$ there exist $a < b$ in A such that $[\![a(i)b(j)]\!]^*_h = q(i, j)$ for all $i, j < n$.*

15.20 Remark. The first example of a cardinal with such a complex binary operation was given by the author [58] using the oscillation mapping described above in Sect. 14. It was the cardinal $\mathfrak{b}$, the minimal cardinality of an unbounded subset of ω^ω under the ordering of eventual dominance. The oscillation mapping restricted to some well-ordered unbounded subset W of ω^ω is perhaps still the most interesting example of this kind due to the fact that its properties are preserved in forcing extensions that do not change the unboundedness of W (although they can collapse cardinals and therefore destroy the properties of the square-bracket operations on them). This absoluteness of osc is the key feature behind its applications in various coding procedures (see e.g. [61]).

15.21 Theorem. *For every regular cardinal κ of size at least the continuum, the κ^+-chain condition is not productive, i.e. there exist two partially ordered sets $\mathcal{P}_0$ and $\mathcal{P}_1$ satisfying the κ^+-chain condition but their product $\mathcal{P}_0 \times \mathcal{P}_1$ fails to have this property.*

Proof. Fix two disjoint stationary subsets Γ_0 and Γ_1 of $\{\delta < \kappa^+ : \mathrm{cf}(\delta) = \kappa\}$. Let $\mathcal{P}_i$ be the collection of all finite subsets p of κ^+ with the property that $[\alpha\beta]^*_h \in \Gamma_i$ for all $\alpha < \beta$ in p. By Lemma 15.17, $\mathcal{P}_0$ and $\mathcal{P}_1$ are κ^+-c.c. posets. Their product $\mathcal{P}_0 \times \mathcal{P}_1$, however, contains a family $\langle\{\alpha\}, \{\alpha\}\rangle$ $(\alpha < \kappa^+)$ of pairwise incomparable conditions. $\dashv$

15.22 Remark. Theorem 15.21 is due to Shelah [48] who proved it using similar methods. The first ZFC examples of non-productiveness of the κ^+-chain condition were given by the author in [57] using what is today known under the name pcf theory. After the full development of pcf theory it became apparent that the basic construction from [57] applies to every successor of a singular cardinal [49]. A quite different class of cardinals θ with θ-c.c. non-productive was given by the author in [56]. For example, $\theta = \mathrm{cf}(\mathfrak{c})$ is one of these cardinals. For an overview of recent advances in this area, the reader is referred to [37]. The following problem seems still open:

15.23 Question. Suppose that θ is a regular strong limit cardinal and the θ-chain condition is productive. Is θ necessarily a weakly compact cardinal?

16. Unbounded Functions on Successors of Regular Cardinals

In this section, κ is a regular cardinal and C_α $(\alpha < \kappa^+)$ is a fixed sequence with $\mathrm{tp}(C_\alpha) \leq \kappa$ for all $\alpha < \kappa^+$. Define $\rho^* : [\kappa^+]^2 \longrightarrow \kappa$ by

$$\rho^*(\alpha, \beta) = \sup\{\mathrm{tp}(C_\beta \cap \alpha), \rho^*(\alpha, \min(C_\beta \setminus \alpha)), \rho^*(\xi, \alpha) : \xi \in C_\beta \cap \alpha\}, \quad (3.15)$$

where we stipulate that $\rho^*(\gamma, \gamma) = 0$ for all $\gamma < \kappa^+$. Since $\rho^*(\alpha, \beta) \geq \rho_1(\alpha, \beta)$ for all $\alpha < \beta < \kappa^+$ by Lemma 7.1 we have the following:

16.1 Lemma. *For $\nu < \kappa$, $\alpha < \kappa^+$ the set $P_\nu(\alpha) = \{\xi \leq \alpha : \rho^*(\xi, \alpha) \leq \nu\}$ has size no more than $|\nu| + \aleph_0$.*

The proof of the following subadditivity properties of ρ^* is very similar to the proof of the corresponding fact for the function ρ from Sect. 11.

16.2 Lemma. *For all $\alpha \leq \beta \leq \gamma$,*

(a) $\rho^*(\alpha, \gamma) \leq \max\{\rho^*(\alpha, \beta), \rho^*(\beta, \gamma)\}$,

(b) $\rho^*(\alpha, \beta) \leq \max\{\rho^*(\alpha, \gamma), \rho^*(\beta, \gamma)\}$.

We mention a typical application of this function to the problem of the existence of partial square sequences which, for example, have some applications in pcf theory (see [7]).

16.3 Theorem. *For every regular uncountable cardinal $\lambda < \kappa$ and stationary $\Gamma \subseteq \{\delta < \kappa^+ : \mathrm{cf}(\delta) = \lambda\}$, there is a stationary set $\Sigma \subseteq \Gamma$ and a sequence C_α $(\alpha \in \Sigma)$ such that:*

(1) C_α is a closed and unbounded subset of α,

(2) $C_\alpha \cap \xi = C_\beta \cap \xi$ for every $\xi \in C_\alpha \cap C_\beta$.

Proof. For each $\delta \in \Gamma$, choose $\nu = \nu(\delta) < \kappa$ such that the set $P_{<\nu}(\delta) = \{\xi < \delta : \rho^*(\xi, \delta) < \nu\}$ is unbounded in δ and closed under taking suprema of sequences of size $< \lambda$. Then there are $\bar{\nu}, \bar{\mu} < \kappa$ and stationary $\Sigma \subseteq \Gamma$ such that $\nu(\delta) = \bar{\nu}$ and $\mathrm{tp}(P_{<\bar{\nu}}(\delta)) = \bar{\mu}$ for all $\delta \in \Sigma$. Let C be a fixed closed and unbounded subset of $\bar{\mu}$ of order-type λ. Finally, for $\delta \in \Gamma$ set

$$C_\delta = \{\alpha \in P_{<\bar{\nu}}(\delta) : \mathrm{tp}(P_{<\bar{\nu}}(\alpha)) \in C\}.$$

Using Lemma 16.2, one easily checks that C_α $(\alpha \in \Sigma)$ satisfies the conditions (1) and (2). $\dashv$

Another application concerns the fact described above in Sect. 13, that the inequalities from Lemma 16.2(a),(b) are particularly useful when κ has cofinality ω. Also consider the well-known phenomenon first discovered by Prikry (see [25]), that in some cases, the cofinality of a regular cardinal κ can be changed to ω, while preserving all cardinals.

16.4 Theorem. *In any cardinal-preserving extension of the universe which has no new bounded subsets of κ, but in which κ has a cofinal ω-sequence diagonalizing the filter of closed and unbounded subsets of κ restricted to the ordinals of cofinality $> \omega$, there is a sequence $C_{\alpha n}(\alpha \in \lim(\kappa^+), n < \omega)$ such that for all $\alpha < \beta$ in $\lim(\kappa^+)$:*

(1) $C_{\alpha n}$ is a closed subset of α for all n,

(2) $C_{\alpha n} \subseteq C_{\alpha m}$, whenever $n \le m$,

(3) $\alpha = \bigcup_{n<\omega} C_{\alpha n}$,

(4) $\alpha \in \lim(C_{\beta n})$ implies $C_{\alpha n} = C_{\beta n} \cap \alpha$.

Proof. For $\alpha < \kappa^+$, let D_α be the collection of all $\nu < \kappa$ for which $P_{<\nu}(\alpha)$ is σ-closed, i.e. closed under suprema of bounded countable subsets. Clearly, D_α contains a closed unbounded subset of κ, restricted to cofinality $> \omega$ ordinals. Note that $\nu \in D_\beta$ and $\rho^*(\alpha, \beta) < \nu$ imply that $\nu \in D_\alpha$. In the extended universe, pick a strictly increasing sequence ν_n $(n < \omega)$ which converges to κ and has the property that for each $\alpha < \kappa^+$ there is an $n < \omega$ such that $\nu_m \in D_\alpha$ for all $m \ge n$. Let $n(\alpha)$ be the minimal integer n with this property.

Given $\alpha < \kappa^+$ and $n < \omega$, we define $C_{\alpha n}$ according to the following cases. If there is a $\gamma \ge \alpha$ such that $n \ge n(\gamma)$ and $\sup P_{\nu_n}(\gamma) \cap \alpha = \alpha$, let $\gamma(\alpha, n)$ be the minimal such γ and let $C_{\alpha n} = \overline{P_{\nu_n}(\gamma(\alpha, n))} \cap \alpha$. If there is no such $\gamma \ge \alpha$, we let $C_{\alpha n} = \emptyset$ for $n < n(\alpha)$ and $C_{\alpha n} = \overline{P_{\nu_n}(\alpha)} \cap \alpha$ for $n \ge n(\alpha)$.

Then one can easily verify that $C_{\alpha n}$ $(\alpha < \kappa^+, n < \omega)$ satisfies the conditions (1), (2), (3) and (4). Detailed checking of this, however, can be found in [66]. ⊣

16.5 Remark. The combinatorial principle appearing in the statement of Theorem 16.4 is a member of a family of square principles that has been studied systematically by Schimmerling and others (see e.g. [45]). It is definitely a principle sufficient for all of the applications of $\square_\kappa$ appearing in Sect. 13 above.

16.6 Definition. A function $f : [\kappa^+]^2 \longrightarrow \kappa$ is *unbounded* if $f``[\Gamma]^2$ is unbounded in κ for every $\Gamma \subseteq \kappa^+$ of size κ. We shall say that such an f is *strongly unbounded* if for every family A of size κ^+, consisting of pairwise disjoint finite subsets of κ^+, and every $\nu < \kappa$ there exists an $A_0 \subseteq A$ of size κ such that $f(\alpha, \beta) > \nu$ for all $\alpha \in a$, $\beta \in b$ and $a \ne b$ in A_0.

16.7 Lemma. *If $f : [\kappa^+]^2 \longrightarrow \kappa$ is unbounded and subadditive (i.e. it satisfies the two inequalities 16.2(a),(b)), then f is strongly unbounded.*

Proof. For $\alpha < \beta < \kappa^+$, set $\alpha <_\nu \beta$ if and only if $f(\alpha, \beta) \leq \nu$. Then our assumption about f satisfying Lemma 16.2(a) and (b) reduces to the fact that each $<_\nu$ is a tree ordering on κ^+ compatible with the usual ordering on κ^+. Note that the unboundedness property of f is preserved by any forcing notion satisfying the κ-chain condition, so in particular no tree $(\kappa^+, <_\nu)$ can contain a subtree of height κ which is Souslin. In the proof of Lemma 12.4 above we have seen that this property of $(\kappa^+, <_\nu)$ alone is sufficient to conclude that every family A of κ many pairwise disjoint subsets of κ^+ contains a subfamily A_0 of size κ such that for every $a \neq b$ in A_0 every $\alpha \in a$ is $<_\nu$-incomparable to every $\beta \in b$, which is exactly the conclusion of f being strongly unbounded. ⊣

The following useful facts whose proof can be found in [66] relates the notions of unboundedness and subadditivity.

16.8 Lemma. *The following are equivalent:*

(1) There is a structure $(\kappa^+, \kappa, <, R_n)_{n<\omega}$ with no substructure B of size κ such that $B \cap \kappa$ is bounded in κ.

(2) There is an unbounded function $f : [\kappa^+]^2 \longrightarrow \kappa$.

(3) There is a strongly unbounded, subadditive function $f : [\kappa^+]^2 \longrightarrow \kappa$.

16.9 Remark. Recall that *Chang's Conjecture* is the model-theoretic transfer principle asserting that every structure of the form $(\omega_2, \omega_1, <, \ldots)$ with a countable signature has an uncountable elementary submodel B with the property that $B \cap \omega_1$ is countable. This principle shows up in many considerations including the first two uncountable cardinals ω_1 and ω_2. For example, it is known that it is preserved by c.c.c. forcing extensions, that it holds in the Silver collapse of an ω_1-Erdős cardinal, and that it in turn implies that ω_2 is an ω_1-Erdős cardinal in the core model of Dodd and Jensen (see e.g. [12, 25]).

16.10 Corollary. *The negation of Chang's Conjecture is equivalent to the statement that there exists an $e : [\omega_2]^2 \longrightarrow \omega_1$ such that:*

(a) $e(\alpha, \gamma) \leq \max\{e(\alpha, \beta), e(\beta, \gamma)\}$ whenever $\alpha \leq \beta \leq \gamma$,

(b) $e(\alpha, \beta) \leq \max\{e(\alpha, \gamma), e(\beta, \gamma)\}$ whenever $\alpha \leq \beta \leq \gamma$,

(c) For every uncountable family A of pairwise disjoint finite subsets of ω_2 and every $\nu < \omega_1$ there exists an uncountable $A_0 \subseteq A$ such that $e(\alpha, \beta) > \nu$ whenever $\alpha \in a$ and $\beta \in b$ for every $a \neq b \in A_0$.

16.11 Remark. Note that if a mapping $e : [\omega_2]^2 \longrightarrow \omega_1$ has properties (a), (b) and (c) of Corollary 16.10, then $D_e : [\omega_2]^2 \longrightarrow [\omega_2]^{\aleph_0}$ defined by $D_e\{\alpha, \beta\} = \{\xi \leq \min\{\alpha, \beta\} : e(\xi, \alpha) \leq e\{\alpha, \beta\}\}$ satisfies the weak form of the Baumgartner-Shelah definition of a Δ-function considered above, where only the first condition is kept. It could be shown, however, that all three properties of a Δ-function cannot be achieved assuming only the negation of Chang's Conjecture. This shows that the function ρ, based on a $\square_{\omega_1}$-sequence, is a considerably deeper object than an $e : [\omega_2]^2 \longrightarrow \omega_1$ satisfying Corollary 16.10(a),(b),(c).

Recall that the successor of the continuum is characterized as the minimal cardinal θ with the property that every $f : [\theta]^2 \longrightarrow \omega$ is constant on the square of some infinite set. We shall now see that in slightly weakening the partition property by replacing squares by rectangles one gets a characterization of a quite different sort. To see this, let us use the arrow notation

$$\binom{\theta}{\theta} \longrightarrow \binom{\omega}{\omega}^{1,1}_{\omega}$$

to succinctly express the statement that for every map $f : \theta \times \theta \longrightarrow \omega$, there exist infinite sets $A, B \subseteq \theta$ such that f is constant on their product. Let θ_2 be the minimal θ which fails to satisfy this property. Note that $\omega_1 < \theta_2 \leq \mathfrak{c}^+$. The following result whose proof can be found in [66] shows that θ_2 can have the minimal possible value ω_2, as well as that θ_2 can be considerably smaller than the continuum.

16.12 Theorem. *Chang's Conjecture is equivalent to the statement that*

$$\binom{\omega_2}{\omega_2} \longrightarrow \binom{\omega}{\omega}^{1,1}_{\omega}$$

holds in every c.c.c. forcing extension.

16.13 Remark. The relative size of θ_2 (or its higher-dimensional analogues $\theta_3, \theta_4, \ldots$) in comparison to the sequence of cardinals $\omega_2, \omega_3, \omega_4, \ldots$ is of considerable interest, both in set theory and model theory (see e.g. [47, 60, 62]). On the other hand, even the following most simple questions, left open by Theorem 16.12, are still unanswered.

16.14 Question. Can one prove any of the bounds like $\theta_2 \leq \omega_3$, $\theta_3 \leq \omega_4$, $\theta_4 \leq \omega_5$, etc. without appealing to additional axioms?

Note that by Corollary 16.10, Chang's Conjecture is equivalent to the statement that within every decomposition of the usual ordering on ω_2 as an increasing chain of tree orderings, one of the trees has an uncountable chain. Is it possible to have decompositions of $\in\restriction(\omega_2 \times \omega_2)$ into an increasing ω_1-chain of tree orderings of countable heights? It turns out that the answer to this question is equivalent to a different well-known combinatorial statement about ω_2 rather than Chang's Conjecture itself. Recall that $f : [\kappa^+]^2 \longrightarrow \kappa$ is *transitive* if $f(\alpha, \gamma) \leq \max\{f(\alpha, \beta), f(\beta, \gamma)\}$ whenever $\alpha \leq \beta \leq \gamma$. Given a transitive map $f : [\kappa^+]^2 \longrightarrow \kappa$, one defines $\rho_f : [\kappa^+]^2 \longrightarrow \kappa$ recursively on $\alpha \leq \beta < \kappa^+$ as follows

$$\rho_f(\alpha, \beta) = \sup\{f(\min(C_\beta \setminus \alpha), \beta), \mathrm{tp}(C_\beta \cap \alpha), \\ \rho_f(\alpha, \min(C_\beta \setminus \alpha)), \rho_f(\xi, \alpha) : \xi \in C_\beta \cap \alpha\},$$

where we stipulate that $\rho_f(\alpha, \alpha) = 0$ for all $\alpha < \kappa^+$.

16.15 Lemma. *For every transitive map $f : [\kappa^+]^2 \longrightarrow \kappa$ the corresponding $\rho_f : [\kappa^+]^2 \longrightarrow \kappa$ has the following properties:*

(a) $\rho_f(\alpha, \gamma) \leq \max\{\rho_f(\alpha, \beta), \rho_f(\beta, \gamma)\}$ whenever $\alpha \leq \beta \leq \gamma$,

(b) $\rho_f(\alpha, \beta) \leq \max\{\rho_f(\alpha, \gamma), \rho_f(\beta, \gamma)\}$ whenever $\alpha \leq \beta \leq \gamma$,

(c) $|\{\xi \leq \alpha : \rho_f(\xi, \alpha) \leq \nu\}| \leq |\nu| + \aleph_0$ for $\nu < \kappa$ and $\alpha < \kappa^+$,

(d) $\rho_f(\alpha, \beta) \geq f(\alpha, \beta)$ for all $\alpha < \beta < \kappa^+$.

Transitive maps are frequently used combinatorial objects, especially when one works with quotient structures. Adding the extra subadditivity condition Lemma 16.15(b), one obtains a considerably more subtle object which is much less understood. For example, let $f_\alpha : \kappa \longrightarrow \kappa$ $(\alpha < \kappa^+)$ be a given sequence of functions such that $f_\alpha <^* f_\beta$ whenever $\alpha < \beta$.[21] Then the corresponding transitive map $f : [\kappa^+]^2 \longrightarrow \kappa$ is defined by $f(\alpha, \beta) = \min\{\mu < \kappa : f_\alpha(\nu) < f_\beta(\nu)$ for all $\nu \geq \mu\}$. Let ρ_f be the corresponding ρ-function that dominates this particular f and for $\nu < \kappa$ let $<^f_\nu$ be the corresponding tree ordering of κ^+, i.e., $\alpha <^f_\nu \beta$ if and only if $\rho_f(\alpha, \beta) \leq \nu$.

16.16 Lemma. *Suppose $f_\alpha \leq g$ for all $\alpha < \kappa^+$ where $\leq$ is the ordering of everywhere dominance. Then for every $\nu < \kappa$ the tree $(\kappa^+, <^f_\nu)$ has height $\leq g(\nu)$.*

Proof. Let P be a maximal chain of $(\kappa^+, <^f_\nu)$. $f(\alpha, \beta) \leq \rho_f(\alpha, \beta) \leq \nu$ for every $\alpha < \beta$ in P. It follows that $f_\alpha(\nu) < f_\beta(\nu) \leq g(\nu)$ for all $\alpha < \beta$ in P. So P has order-type $\leq g(\nu)$. ⊣

Note that if we have a function $g : \kappa \longrightarrow \kappa$ which bounds the sequence f_α $(\alpha < \kappa^+)$ in the ordering $<^*$ of eventual dominance, then the new sequence $\bar{f}_\alpha = \min\{f_\alpha, g\}$ $(\alpha < \kappa^+)$ is still strictly $<^*$-increasing but now bounded by g even in the ordering of everywhere dominance. So this proves the following result of Galvin (see [22, 42]).

16.17 Corollary. *The following two conditions are equivalent for every regular cardinal κ.*

[21] Here, $f_\alpha <^* f_\beta$ whenever $\{\nu < \kappa : f_\alpha(\nu) \geq f_\beta(\nu)\}$ is bounded in κ.

(1) There is a sequence $f_\alpha : \kappa \longrightarrow \kappa$ $(\alpha < \kappa^+)$ which is strictly increasing and bounded in the ordering of eventual dominance.

(2) The usual order-relation of κ^+ can be decomposed into an increasing κ-sequence of tree orderings of heights $< \kappa$.

16.18 Remark. The assertion that every strictly $<^*$-increasing κ^+-sequence of functions from κ to κ is $<^*$-unbounded is strictly weaker than Chang's Conjecture and in the literature it is usually referred to as *weak Chang's Conjecture*. This statement still has considerable large cardinal strength (see [11]). Also note the following consequence of Corollary 16.17 which can be deduced from Lemmas 16.1 and 16.2 above as well.

16.19 Corollary. *If κ is a regular limit cardinal (e.g. $\kappa = \omega$), then the usual order-relation of κ^+ can be decomposed into an increasing κ-sequence of tree orderings of heights $< \kappa$.*

17. Higher Dimensions

The reader must have noticed already that in this chapter so far, we have only considered functions of the form $f : [\theta]^2 \longrightarrow I$ or equivalently sequences $f_\alpha : \alpha \longrightarrow I$ $(\alpha < \theta)$ of one-place functions. To obtain analogous results about functions defined on higher-dimensional cubes $[\theta]^n$ one usually develops some form of *stepping-up procedure* that lifts a function of the form $f : [\theta]^n \longrightarrow I$ to a function of the form $g : [\theta^+]^{n+1} \longrightarrow I$. The basic idea seems quite simple. One starts with a coherent sequence $e_\alpha : \alpha \longrightarrow \theta$ $(\alpha < \theta^+)$ of one-to-one mappings and wishes to define $g : [\theta^+]^{n+1} \longrightarrow I$ as follows:

$$g(\alpha_0, \alpha_1, \ldots, \alpha_n) = f(e_{\alpha_n}(\alpha_0), \ldots, e_{\alpha_n}(\alpha_{n-1})). \tag{3.16}$$

In other words, we use e_{α_n} to send $\{\alpha_0, \ldots, \alpha_{n-1}\}$ to the domain of f and then apply f to the resulting n-tuple. The problem with such a simple-minded definition is that for a typical subset Γ of θ^+, the sequence of restrictions $e_\delta \restriction (\Gamma \cap \delta)$ $(\delta \in \Gamma)$ may not cohere, so we cannot produce a subset of θ that would correspond to Γ and on which we would like to apply some property of f. It turns out that the definition (3.16) is basically correct except that we need to replace e_{α_n} by $e_{\tau(\alpha_{n-2},\alpha_{n-1},\alpha_n)}$, where $\tau : [\theta^+]^3 \longrightarrow \theta^+$ is defined as follows (see Definition 14.6):

$$\tau(\alpha, \beta, \gamma) = \gamma_t, \quad \text{where } \ t = \rho_0(\alpha, \gamma) \cap \rho_0(\beta, \gamma). \tag{3.17}$$

The function ρ_0 to which (3.17) refers is of course based on some C-sequence C_α $(\alpha < \theta^+)$ on θ^+. The following result shows that if the C-sequence is carefully chosen, the function τ will serve as a stepping-up tool. The following lemma whose proof can be found in [66] gives the basic idea behind this.

17.1 Lemma. *Suppose ρ_0 and τ are based on some $\square_\theta$-sequence C_α $(\alpha < \theta^+)$ and let κ be a regular uncountable cardinal $\leq \theta$. Then every set $\Gamma \subseteq \theta^+$ of order-type κ contains a cofinal subset Δ such that, if $\varepsilon = \sup(\Gamma) = \sup(\Delta)$, then $\rho_0(\xi, \varepsilon) = \rho_0(\xi, \tau(\alpha, \beta, \gamma))$ for all $\xi < \alpha < \beta < \gamma$ in Δ.*

Recall that for a given C-sequence C_α $(\alpha < \theta^+)$ such that $\mathrm{tp}(C_\alpha) \leq \theta$ for all $\alpha < \theta^+$, the range of ρ_0 is the collection of all finite sequences of ordinals $< \theta$. There is a natural way to identify $\mathbb{Q}_\theta$ with θ itself via the well-ordering of $\mathbb{Q}_\theta$ of length θ: $s <_w t$ if and only if $\max(s) < \max(t)$, or $\max(s) = \max(t)$ and $t \subseteq s$, or $\max(s) = \max(t)$ and $s(i) \neq t(i)$ for some i in the common domain of s and t and $s(i) < t(i)$ for the minimal such i. This identification gives us a way to define a lift-up of an arbitrary map $f : [\theta]^n \longrightarrow I$ (really, $f : [\mathbb{Q}_\theta]^n \longrightarrow I$) to a map $f^+ : [\theta^+]^{n+1} \longrightarrow I$ by the following formula:

$$f^+(\alpha_0, \ldots, \alpha_{n-1}, \alpha_n) = f(\rho_0(\alpha_0, \varepsilon), \ldots, \rho_0(\alpha_{n-1}, \varepsilon)), \tag{3.18}$$

where $\varepsilon = \tau(\alpha_{n-2}, \alpha_{n-1}, \alpha_n)$.

Let us examine how this stepping-up procedure works on a particular example, a combinatorial property of a function f which has been stepped up by Velleman [69] from $n = 3$ to $n = 4$ using his version of the gap-2 morass.

17.2 Theorem. *Suppose θ is an arbitrary cardinal for which $\square_\theta$ holds. Suppose further that for some regular $\kappa > \omega$ and integer $n \geq 2$ there is a map $f : [\theta]^n \longrightarrow [[\theta]^{<\kappa}]^{<\kappa}$ such that:*

(1) $A \subseteq \min(a)$ for all $a \in [\theta]^n$ and $A \in f(a)$.

(2) For all $\nu < \kappa$ and $\Gamma \subseteq \theta$ of size κ there exist $a \in [\Gamma]^n$ and $A \in f(a)$ such that $\mathrm{tp}(A) \geq \nu$ and $A \subseteq \Gamma$.

Then θ^+ and κ satisfy the same combinatorial property, but with $n+1$ in place of n.

Proof. Identifying $\mathbb{Q}_\theta$ with θ using the wellordering $<_w$ defined above, we assume that actually $f : [\mathbb{Q}_\theta]^n \longrightarrow [[\mathbb{Q}_\theta]^{<\kappa}]^{<\kappa}$. Apply the idea of (3.18) and define $g : [\theta^+]^n \longrightarrow [[\theta^+]^{<\kappa}]^{<\kappa}$ by the formula

$$g(\alpha_0, \ldots, \alpha_{n-1}, \alpha_n) = (\rho_0)_\varepsilon^{-1}(f(\rho_0(\alpha_0, \varepsilon), \ldots, \rho_0(\alpha_{n-1}, \varepsilon))),$$

where $\varepsilon = \tau(\alpha_{n-2}, \alpha_{n-1}, \alpha_n)$ and where τ is based on a fixed $\square_\theta$-sequence.

Note that the transformation $(\rho_0)_\varepsilon^{-1}$ does not necessarily preserve (1), so we intersect each member of a given $g(a)$ with $\min(a)$ in order to satisfy this condition. To check (2), let $\Gamma \subseteq \theta^+$ be a given set of size κ. By Lemma 17.1, shrinking Γ we may assume that Γ has order-type κ and that if $\varepsilon = \sup(\Gamma)$, then

$$\rho_0(\xi, \varepsilon) = \rho_0(\xi, \tau(\alpha, \beta, \gamma)) \quad \text{for all } \alpha < \beta < \gamma \text{ in } \Gamma. \tag{3.19}$$

It follows that g restricted to $[\Gamma]^{n+1}$ satisfies the formula

$$g(\alpha_0,\dots,\alpha_{n-1},\alpha_n) = (\rho_0)_\varepsilon^{-1}(f(\rho_0(\alpha_0,\varepsilon),\dots,\rho_0(\alpha_{n-1},\varepsilon))). \tag{3.20}$$

Shrinking Γ further we assume that the mapping $(\rho_0)_\varepsilon : (\varepsilon,\in) \longrightarrow (\mathbb{Q}_\theta,<_w)$ is strictly increasing, when restricted to Γ. Given an ordinal $\nu<\kappa$, we apply (2) for f to the set $\Delta=\{\rho_0(\alpha,\varepsilon):\alpha\in\Gamma\}$ and find $a\in[\Delta]^n$ and $A\in f(a)$ such that $\mathrm{tp}(A)\geq\nu$ and $A\subseteq\Delta$. Let $\{\alpha_0,\dots,\alpha_{n-1}\}$ be the increasing enumeration of the preimage $(\rho_0)_\varepsilon^{-1}(a)$ and pick $\alpha_n\in\Gamma$ above α_{n-1}. Let B be the preimage $(\rho_0)_\varepsilon^{-1}(A)$. Then $B\in g(\alpha_0,\dots,\alpha_{n-1},\alpha_n)$, $\mathrm{tp}(B)\geq\nu$ and $B\subseteq\Gamma$. This completes the proof. ⊣

If we apply this stepping-up procedure to the projection $[\![\cdot\cdot]\!]$ of the square-bracket operation defined in Definition 4.11, one obtains analogues of families $\mathcal{G},\mathcal{H}$ and $\mathcal{K}$ of Theorem 4.13 for ω_2 instead of ω_1. This will give us the following result whose proof can be found in [66].

17.3 Theorem. *Assuming $\square_{\omega_1}$, there is a reflexive Banach space E with a transitive basis of type ω_2 with the property that every bounded operator $T:E\longrightarrow E$ can be written as a sum of an operator with a separable range and a diagonal operator (relative to the basis) with only countably many changes of constants.*

17.4 Remark. In [28], Koszmider has shown that such a space cannot be constructed on the basis of the usual axioms of set theory. We refer the reader to that paper for more details about these kinds of examples of Banach spaces.

For the rest of this section we shall examine the stepping-up method with fewer restrictions on the given C-sequence C_α $(\alpha<\theta^+)$ on which it is based.

17.5 Theorem. *The following are equivalent for a regular cardinal θ such that* $\log\theta^+=\theta$.[22]

(1) There is a substructure of the form $(\theta^{++},\theta^+,<,\dots)$ with no substructure B of size θ^+ with $B\cap\theta^+$ of size θ.

(2) There is an $f:[\theta^{++}]^3\longrightarrow\theta^+$ which takes all the possible values on the cube of any subset Γ of θ^{++} of size θ^+.

Proof. To prove the nontrivial direction from (1) to (2), we use Lemma 16.8 and choose a strongly unbounded and subadditive $e:[\theta^{++}]^2\longrightarrow\theta^+$. We also choose a C-sequence C_α $(\alpha<\theta^+)$ such that $\mathrm{tp}(C_\alpha)\leq\theta$ for all $\alpha<\theta^+$ and consider the corresponding function $\rho^*:[\theta^+]^2\longrightarrow\theta$ defined above in (3.15). Finally, we choose a one-to-one sequence r_α $(\alpha<\theta^{++})$ of elements of $\{0,1\}^{\theta^+}$ and consider the corresponding function $\Delta:[\theta^{++}]^2\longrightarrow\theta^+$:

$$\Delta(\alpha,\beta)=\Delta(r_\alpha,r_\beta)=\min\{\nu:r_\alpha(\nu)\neq r_\beta(\nu)\}. \tag{3.21}$$

[22] $\log\kappa=\min\{\lambda:2^\lambda\geq\kappa\}$.

The definition of $f : [\theta^{++}]^3 \longrightarrow \theta$ is given according to the following two rules applied to a given triple $x = \{\alpha, \beta, \gamma\} \in [\theta^{++}]^3$ ($\alpha < \beta < \gamma$):

Rule 1. If $\Delta(r_\alpha, r_\beta) < \Delta(r_\beta, r_\gamma)$ and $r_\alpha <_{\text{lex}} r_\beta <_{\text{lex}} r_\gamma$ or $r_\alpha >_{\text{lex}} r_\beta >_{\text{lex}} r_\gamma$, let

$$f(\alpha, \beta, \gamma) = \min(P_\nu(\Delta(\beta, \gamma)) \setminus \Delta(\alpha, \beta)),$$

where $\nu = \rho^*(\min\{\xi \leq \Delta(\alpha, \beta) : \rho^*(\xi, \Delta(\alpha, \beta)) \neq \rho^*(\xi, \Delta(\beta, \gamma))\}, \Delta(\beta, \gamma))$.

Rule 2. If $\alpha \in x$ is such that r_α is lexicographically between the other two r_ξ's for $\xi \in x$, if $\beta \in x \setminus \{\alpha\}$ is such that $\Delta(r_\alpha, r_\beta) > \Delta(r_\alpha, r_\gamma)$, where γ is the remaining element of x and if x does not fall under Rule 1, let

$$f(\alpha, \beta, \gamma) = \min(P_\nu(e(\beta, \gamma)) \setminus e(\alpha, \beta)),$$

where $\nu = \rho^*\{\Delta(\alpha, \beta), e(\beta, \gamma)\}$.

The proof of the theorem is complete once we show the following: for every stationary set Σ of cofinality θ ordinals $< \theta^+$ and every $\Gamma \subseteq \theta^{++}$ of size θ^+ there exist $\alpha < \beta < \gamma$ in Γ such that $f(\alpha, \beta, \gamma) \in \Sigma$. The details of this can again be found in [66]. ⊣

17.6 Theorem. *If θ is a regular strong limit cardinal carrying a nonreflecting stationary set, then there is an $f : [\theta^+]^3 \longrightarrow \theta$ which takes all the values from θ on the cube of any subset of θ^+ of size θ.*

Proof. This is really a corollary of the proof of Theorem 17.5, so let us only indicate the adjustments. By Corollary 16.19 and Lemma 16.7, we can choose a strongly unbounded subadditive map $e : [\theta^+]^2 \longrightarrow \theta$. By the assumption about θ we can choose a C-sequence C_α ($\alpha < \theta$) avoiding a stationary set $\Sigma \subseteq \theta$ and consider the corresponding notion of a walk, trace, ρ_0-function and the square-bracket operation $[\cdot\cdot]$ as defined in (3.13) in Sect. 15. As in the proof of Theorem 17.5, we choose a one-to-one sequence r_α ($\alpha < \theta^+$) of elements of $\{0, 1\}^\theta$ and consider the corresponding function $\Delta : [\theta^+]^2 \longrightarrow \theta$:

$$\Delta(\alpha, \beta) = \Delta(r_\alpha, r_\beta) = \min\{\nu < \theta : r_\alpha(\nu) \neq r_\beta(\nu)\}.$$

The definition of $f : [\theta^+]^3 \longrightarrow \theta$ is given according to the following rules, applied to a given $x \in [\theta^+]^3$.

Rule 1. If $x = \{\alpha < \beta < \gamma\}$, $\Delta(r_\alpha, r_\beta) < \Delta(r_\beta, r_\gamma)$ and $r_\alpha <_{\text{lex}} r_\beta <_{\text{lex}} r_\gamma$, or $r_\alpha >_{\text{lex}} r_\beta >_{\text{lex}} r_\gamma$, let

$$f\{\alpha, \beta, \gamma\} = [\Delta(\alpha, \beta)\Delta(\beta, \gamma)].$$

Rule 2. If $\alpha \in x$ is such that r_α is lexicographically between the other two r_ξ's for $\xi \in x$, if $\beta \in x \setminus \{\alpha\}$ is such that $\Delta(r_\alpha, r_\beta) > \Delta(r_\alpha, r_\gamma)$, where γ is the remaining element of x, and they do not satisfy the conditions of Rule 1, set

$$f\{\alpha, \beta, \gamma\} = \min(\mathrm{Tr}(\Delta(\alpha, \beta), e\{\beta, \gamma\}) \setminus e\{\alpha, \beta\}),$$

i.e. $f\{\alpha,\beta,\gamma\}$ is the minimal point on the trace of the walk from $e\{\beta,\gamma\}$ to $\Delta(\alpha,\beta)$ above the ordinal $e\{\alpha,\beta\}$; if such a point does not exist, set $f\{\alpha,\beta,\gamma\}=0$.

Then it suffices to show that for every stationary $\Omega\subseteq\Sigma$ and every $\Gamma\subseteq\theta^+$ of size θ, there exists an $x\in[\Gamma]^3$ such that $f(x)\in\Omega$. The details of this are given in [66]. ⊣

Since $\log\omega_1=\omega$, we get the following consequence of Theorem 17.5.

17.7 Theorem. *Chang's Conjecture is equivalent to the statement that for every $f:[\omega_2]^3\longrightarrow\omega_1$ there is an uncountable $\Gamma\subseteq\omega_2$ such that $f``[\Gamma]^3\neq\omega_1$.*

17.8 Remark. Since this same statement is stronger for functions from higher dimensional cubes $[\omega_2]^n$ into ω_1 Theorem 17.7 shows that they are all equivalent to Chang's Conjecture. Note also that $n=3$ is the minimal dimension for which this equivalence holds, since the case $n=2$ follows from the Continuum Hypothesis, which has no relationship to Chang's Conjecture.

For the rest of this section we examine the stepping-up procedure without the assumption that some form of Chang's Conjecture is false. So let θ be a given regular uncountable cardinal and let C_α $(\alpha<\theta^+)$ be a fixed C-sequence such that $\mathrm{tp}(C_\alpha)\leq\kappa$ for all $\alpha<\theta^+$. Let $\rho^*:[\theta^+]^2\longrightarrow\theta$ be the ρ^*-function defined above in (3.15). Recall that, in case C_α $(\alpha<\theta^+)$ is a $\Box_\theta$-sequence, the key to our stepping-up procedure was the function $\tau:[\theta^+]^3\longrightarrow\theta^+$ defined by the formula (3.17). Without the assumption of C_α $(\alpha<\theta^+)$ being a $\Box_\theta$-sequence, the following related function turns out to be a good substitute: $\chi:[\theta^+]^3\longrightarrow\omega$ defined by

$$\chi(\alpha,\beta,\gamma)=|\rho_0(\alpha,\gamma)\cap\rho_0(\beta,\gamma)|.$$

Thus $\chi(\alpha,\beta,\gamma)$ is equal to the length of the common part of the walks $\gamma\to\alpha$ and $\gamma\to\beta$.

17.9 Definition. A subset Γ of θ^+ is *stable* if χ is bounded on $[\Gamma]^3$.

The following result whose proof can be found in [66] relates this notion to the unboundedness property of ρ^*.

17.10 Lemma. *Suppose that Γ is a stable subset of θ^+ of size θ. Then $\{\rho^*(\alpha,\beta):\{\alpha,\beta\}\in[\Omega]^2\}$ is unbounded in θ for every $\Omega\subseteq\Gamma$ of size θ.*

17.11 Definition. The 3-*dimensional version of the oscillation mapping*, $\mathrm{osc}:[\theta^+]^3\longrightarrow\omega$ is defined on the basis of the 2-dimensional version of Sect. 14 as follows

$$\mathrm{osc}(\alpha,\beta,\gamma)=\mathrm{osc}(C_{\beta_s}\setminus\alpha,C_{\gamma_t}\setminus\alpha),$$

where $s=\rho_0(\alpha,\beta)\restriction\chi(\alpha,\beta,\gamma)$ and $t=\rho_0(\alpha,\gamma)\restriction\chi(\alpha,\beta,\gamma)$.

In other words, we let n be the length of the common part of the two walks $\gamma \to \alpha$ and $\gamma \to \beta$, then we consider the walks $\gamma = \gamma_0 > \cdots > \gamma_k = \alpha$ and $\beta = \beta_0 > \cdots > \beta_l = \alpha$ from γ to α and β to α respectively; if both k and l are bigger than n, i.e. if γ_n and β_n are both defined, we let $\operatorname{osc}(\alpha, \beta, \gamma)$ be equal to the oscillation of the two sets $C_{\beta_n} \setminus \alpha$ and $C_{\gamma_n} \setminus \alpha$. If $\min\{k, l\} < n$, we let $\operatorname{osc}(\alpha, \beta, \gamma) = 0$. The proof of the following basic fact about the three-dimensional oscillation mapping can again be found in [66].

17.12 Lemma. *Suppose that Γ is a subset of θ^+ of size κ, a regular uncountable cardinal, and that every subset of Γ of size κ is unstable. Then for every integer $n \geq 1$, there exist $\alpha < \beta < \gamma$ in Γ such that $\operatorname{osc}(\alpha, \beta, \gamma) = n$.*

Applying the last two lemmas to the subsets of θ^+ of size θ, we get an interesting dichotomy:

17.13 Lemma. *Every $\Gamma \subseteq \theta^+$ of size θ can be refined to a subset Ω of size θ such that either:*

(1) ρ^* is unbounded and therefore strongly unbounded on Ω, or

(2) the oscillation mapping takes all possible values on the cube of Ω.

We finish the section with a typical application of this dichotomy.

17.14 Theorem. *Suppose θ is a regular cardinal such that $\log \theta^+ = \theta$. Then there is an $f : [\theta^{++}]^3 \longrightarrow \omega$ which takes all the values from ω on the cube of any subset of θ^{++} of size θ^+.*

Proof. We choose two C-sequences C_α ($\alpha < \theta^+$) and C^+_α ($\alpha < \theta^{++}$) on θ^+ and θ^{++} respectively, such that $\operatorname{tp}(C_\alpha) \leq \theta$ for all $\alpha < \theta^+$ and $\operatorname{tp}(C^+_\alpha) \leq \theta^+$ for all $\alpha < \theta^{++}$. Let $\rho^* : [\theta^+]^2 \longrightarrow \theta$ and $\rho^{*+} : [\theta^{++}]^2 \longrightarrow \theta^+$ be the corresponding ρ^*-functions defined above in Lemma 3.15. Also choose a one-to-one sequence r_α ($\alpha < \theta^{++}$) of elements of $\{0,1\}^{\theta^+}$ and consider the corresponding function $\Delta : [\theta^{++}]^2 \longrightarrow \theta^+$ defined in (3.21). We define $f : [\theta^{++}]^3 \longrightarrow \theta^+$ according to the following two cases for a given triple $\alpha < \beta < \gamma$ of elements of θ^{++}.

Case 1. $(C_{\beta_s} \cap C_{\gamma_t}) \setminus \alpha \neq \emptyset$, where $s = \rho_0(\alpha, \beta) \restriction \chi(\alpha, \beta, \gamma)$ and $t = \rho_0(\alpha, \gamma) \restriction \chi(\alpha, \beta, \gamma)$ assuming of course that $\rho_0(\alpha, \beta)$ has length $\geq \chi(\alpha, \beta, \gamma)$.

Rule 1. If $\Delta(r_\alpha, r_\beta) < \Delta(r_\beta, r_\gamma)$ and $r_\alpha <_{\text{lex}} r_\beta <_{\text{lex}} r_\gamma$ or $r_\alpha >_{\text{lex}} r_\beta >_{\text{lex}} r_\gamma$, set

$$f(\alpha, \beta, \gamma) = \min(P_\nu(\Delta(\beta, \gamma)) \setminus \Delta(\alpha, \beta)),$$

where $\nu = \rho^*(\min\{\xi \leq \Delta(\alpha, \beta) : \rho^*(\xi, \Delta(\alpha, \beta)) \neq \rho^*(\xi, \Delta(\beta, \gamma))\}, \Delta(\beta, \gamma))$.

Rule 2. If $\bar{\alpha} \in \{\alpha, \beta, \gamma\}$ is such that $r_{\bar{\alpha}}$ is lexicographically between the other two r_ξ's for $\xi \in \{\alpha, \beta, \gamma\}$, if $\bar{\beta} \in \{\alpha, \beta, \gamma\} \setminus \{\bar{\alpha}\}$ is such that $\Delta(r_{\bar{\alpha}}, r_{\bar{\beta}}) > \Delta(r_{\bar{\alpha}}, r_{\bar{\gamma}})$, where $\bar{\gamma}$ is the remaining member of $\{\alpha, \beta, \gamma\}$, and if $\{\alpha, \beta, \gamma\}$ does not fall under Rule 1, let

$$f(\alpha, \beta, \gamma) = \min(P_\nu(\rho^{*+}\{\bar{\beta}, \bar{\gamma}\}) \setminus \rho^{*+}(\alpha, \beta)),$$

where $\nu = \rho^*\{\Delta(\alpha,\beta), \rho^{*+}(\beta,\gamma)\}$.

Case 2. $(C_{\beta_s} \cap C_{\gamma_t}) \setminus \alpha = \emptyset$, where $s = \rho_0(\alpha,\beta)\restriction\chi(\alpha,\beta,\gamma)$ and $t = \rho_0(\alpha,\gamma)\restriction\chi(\alpha,\beta,\gamma)$ assuming of course that $\rho_0(\alpha,\beta)$ has length $\geq \chi(\alpha,\beta,\gamma)$. Let

$$f(\alpha,\beta,\gamma) = \mathrm{osc}(\alpha,\beta,\gamma).$$

If a given triple $\alpha < \beta < \gamma$ does not fall into one of these two cases, let $f(\alpha,\beta,\gamma) = 0$.

Then it suffices to show that for every $\Gamma \subseteq \theta^{++}$ of size θ^+, the image $f``[\Gamma]^3$ either contains all positive integers or almost all ordinals $< \theta^+$ of cofinality θ. The details of this are given in [66]. $\dashv$

17.15 Corollary. *There is an $f : [\omega_2]^3 \longrightarrow \omega$ which takes all the values on the cube of any uncountable subset of ω_2.*

17.16 Remark. Note that the dimension 3 in this corollary cannot be lowered to 2 as long as one does not use some additional axioms to construct such f. Note also that the range ω cannot be replaced by a set of bigger size, as this would contradict Chang's Conjecture. We have seen above that Chang's Conjecture is equivalent to the statement that for every $f : [\omega_2]^3 \longrightarrow \omega_1$ there is an uncountable set $\Gamma \subseteq \omega_2$ such that $f``[\Gamma]^3 \neq \omega_1$. Is there a similar reformulation of the Continuum Hypothesis? More precisely, one can ask the following question.

17.17 Question. Is CH equivalent to the statement that for every $f : [\omega_2]^2 \longrightarrow \omega$ there exists an uncountable $\Gamma \subseteq \omega_2$ with $f``[\Gamma]^2 \neq \omega$?

M. Foreman, A. Kanamori (eds.), *Handbook of Set Theory*,
DOI 10.1007/978-1-4020-5764-9_5,

This chapter is setting out to achieve an impossibility, namely to survey the rapidly exploding field of Borel equivalence relations as found in descriptive set theory and the connections with areas entirely outside logic. The choice of content and emphasis is inevitably molded by this author's own prejudices and research history; others may have a radically different vision of the subject. For instance I have somewhat arbitrarily chosen to say nothing about the study of equivalence relations arising in Borel ideals, as found in papers such as [64, 51, 11], or the parallel theory of Borel linear orderings as found in say [49, 30], or the still unpublished work of Hugh Woodin's and of Richard Ketchersid's on the cardinality of certain Borel equivalence relations under strong determinacy assumptions, the work on general $\underset{\sim}{\Sigma}^1_1$ equivalence relations as found in [4], or the topological Vaught conjecture as discussed in [60, 45, 5, 37]. Moreover the discussion of Borel equivalence relations is organized around the Borel reducibility order, $\leq_B$, rather than notions such as orbit equivalence, as found in say [22, 20, 23, 59, 40], or notions of isomorphism, as discussed in [9]. Without a super-human effort to the contrary, it is easy to slip in to discussing what I know best, which, regretfully perhaps, are the papers I have written. Finally I should admit to being much more conversant with the mathematics of the subject than the history, and since my main concern is to communicate the most vibrant ideas with a certain immediacy undoubtedly some important citations have been overlooked.

Thus I stand impeached with prejudice, ignorance, arbitrariness, arrogance, and discourtesy.

But as unfortunate as these failings may be, they are inevitable, and I say all of this simply so the reader will understand that this is a project doomed to at least partial failure and nevertheless worth pursuing in the hope of partial success. A similar but rather different point of view can be found [52]. The reader might also look at [6] for a closer examination of some of the issues surrounding actions induced by Polish group actions, or at [37] for a discussion of the Vaught conjecture, or [58] for orbit equivalence. Another survey is given in [39], but in fact I am unable to even point to any small set of papers which would be fully adequate.

1. Definitions

Before moving on to the theory of Borel equivalence relations it would be helpful to discuss Borel sets in general. A thorough and more complete account can be found in [50].

1.1 Definition. A *Polish space* is a separable topological space which admits a compatible complete metric. The *Borel* subsets of a Polish space are those appearing in the σ-algebra generated by the open sets—that is to say, if we begin with the open sets and continue applying the operations of countable union, countable intersection, and complementation, then the Borel sets are those appearing in the collection which thereby arises.

Inside the Borel sets we make further distinctions. Thus a set is $\underset{\sim}{\Sigma}^0_1$ if it is open, and after that we define recursively a set to be $\underset{\sim}{\Pi}^0_\alpha$ if its complement is $\underset{\sim}{\Sigma}^0_\alpha$, and to be $\underset{\sim}{\Sigma}^0_\alpha$ if it is a countable union of Borel sets each of which are $\underset{\sim}{\Pi}^0_\beta$ for some $\beta < \alpha$. It is easily shown that $\underset{\sim}{\Pi}^0_\alpha \subseteq \underset{\sim}{\Sigma}^0_{\alpha+1}$ and every Borel set will be $\underset{\sim}{\Sigma}^0_\alpha$ for some $\alpha < \omega_1$. At the bottom level of this hierarchy there is alternate notations used by analysts—for instance a $\underset{\sim}{\Pi}^0_2$ set is also called G_δ and a $\underset{\sim}{\Sigma}^0_2$ set is also called F_σ.

For much of the time we are unconcerned with the topological structure of a Polish space, focusing instead on its Borel structure. Accordingly, a set X equipped with a σ-algebra $\mathcal{B}$ is a *standard Borel space* if there is some Polish topology on X which gives rise to $\mathcal{B}$ as the collection of Borel sets.

1.2 Examples.

1. $\mathbb{R}$ and $\mathbb{C}$ are Polish. Any compact metric space is Polish.

2. There is a natural way to think of the collection of all subsets of the natural numbers as a Polish space. By associating with each set its characteristic function, or indicator function, we can identify the power set of $\mathbb{N}$, denoted by $\mathcal{P}(\mathbb{N})$, with
$$\{0,1\}^{\mathbb{N}} =_{\mathrm{df}} 2^{\mathbb{N}},$$
which is a compact space in the product topology. Similarly $\mathcal{P}(\mathbb{N}\times\mathbb{N})$ or $\mathcal{P}(S)$ any countable set S.

3. Any Borel subset of a Polish space is a standard Borel space in the inherited Borel structure (see [55, 13.4], [50]).

4. The Borel probability measures on a standard Borel space themselves again form a standard Borel space (this ultimately follows from the Riesz representation theorem; compare [50, 17.23]).

5. Consider the collection of subsets of $\mathbb{N}\times\mathbb{N}\times\mathbb{N}$ which form the graph of a function
$$\bullet : \mathbb{N}\times\mathbb{N}\to\mathbb{N}$$
providing a finite rank torsion-free abelian group structure on $\mathbb{N}$. This collection in the natural Borel structure is a standard Borel space, since it is a Borel subset of the Polish space $\mathbb{N}\times\mathbb{N}\times\mathbb{N}$.

6. Given a countable language we can form two possible Polish topologies on the space of $\mathcal{L}$-structures on $\mathbb{N}$. For simplicity assume the language is relational, though the more general case of $\mathcal{L}$ having function symbols is only slightly more complicated. We let $\mathrm{Mod}(\mathcal{L})$ be the set of all $\mathcal{L}$-structures with the natural numbers as their underlying set.

The first of the topologies is τ_{qf}. For $\psi(\vec{x})$ a formula in $\mathcal{L}$ and $\vec{a} = (a_1, \ldots, a_n)$ a sequence in $\mathbb{N}$, we let $U(\psi(\vec{x}), \vec{a})$ be the collection of all $\mathcal{N} \in \mathrm{Mod}(\mathcal{L})$ with

$$\mathcal{N} \models \psi(\vec{a}),$$

and then τ_{qf} is the collection the topology with basis consisting of all the sets of the form $U(\psi(\vec{x}), \vec{a})$, as ψ ranges over the quantifier-free formulas. If $\mathcal{L}$ consists of relations $R_1, R_2, \ldots$, each R_i and $n(i)$-ary relation, then it is easily seen that $(\mathrm{Mod}(\mathcal{L}), \tau_{qf})$ is isomorphic to $\prod_{i\in\mathbb{N}} 2^{\mathbb{N}^{n(i)}}$ in the product topology. Since the class of Polish spaces is closed under product (see [36, §2.1]) we have that $(\mathrm{Mod}(\mathcal{L}), \tau_{qf})$ is Polish.

The more subtle topology is τ_{fo}, with basis consisting of all $U(\psi(\vec{x}), \vec{a})$ as ψ ranges over first-order formulas. This is a again a Polish topology, though the proof of this, say as found at [36, 2.42], is less obvious.

While these are divergent choices in topology, there is really one reasonable choice of *Borel structure* on this space. Since $\tau_{fo} \supseteq \tau_{qf}$ and both are Polish topologies, they give rise to the same Borel structure. (This follows from [50, 18.10, 18.14].)

1.3 Definition. Given a Polish space X, we let $\mathcal{F}(X)$ be the collection of all closed subsets of X, equipped with the σ-algebra generated by sets of the form $\{F \in \mathcal{F}(X) : U \cap F \neq \emptyset\}$ for U open.

This is known as the *Effros Borel structure* on the closed subsets of X. It is not hard to show that $\mathcal{F}(X)$ equipped with this Borel structure is indeed a standard Borel space—see for instance [36, §2] or [50].

The reader should definitely consult [50] for a more reasonable introduction to the theory of Borel sets. This is the smallest sketch.

1.4 Definition. A function

$$f : X \to Y$$

is said to be *Borel* if $f^{-1}[B]$ is Borel for any Borel set $B \subseteq Y$.

An equivalence relation E on X is said to be *Borel* if it is Borel as subset of $X \times X$. We then use $[x]_E$ to denote the equivalence class of x for any $x \in X$—that is to say, the set $\{y \in X : x\, E\, y\}$.

1.5 Definition. Given E and F Borel equivalence relations on standard Borel X and Y, we write

$$E \leq_B F,$$

E is *Borel reducible to* F, if there is a Borel $f : X \to Y$ such that for all $x_1, x_2 \in X$

$$x_1\, E\, x_2 \iff f(x_1)\, F\, f(x_2);$$

in other words, f pushes down to an injective map

$$\bar{f} : X/E \to Y/F$$

between the quotient spaces.

After this we naturally set $E <_B F$ if there is a Borel reduction from E to F but not F to E. We set $E \sim_B F$ if each is Borel reducible to the other. Note that the order $\leq_B$ is transitive, since the composition of two Borel functions is again Borel.

The above definition is only for Borel f, but one can of course consider more general classes of functions if this seems too stingy—for instance, C-measurable functions, projective functions, $L(\mathbb{R})$ functions. In virtually all cases this makes no difference—the failures of reducibility for Borel functions persist to these wider classes. Indeed, appropriately understood most of the theorems about Borel equivalence relations turn into theorems about cardinality in $L(\mathbb{R})$. See Sect. 4 below.

It should also be admitted that there are other ways in which we can compare Borel equivalence relations, for instance asking that there be isomorphisms of the underlying spaces that conjugate the relations, or in the presence of a measure we can ask for measure preserving isomorphisms between the spaces which conjugate the equivalence relations almost everywhere; indeed this second notion is the subject of extensive study in areas such as operator algebras (for instance [59]), geometric group theory (for instance [22, 62]), and the rigidity theory in the sense of Zimmer [70]. For the purposes of descriptive set theory, I incline to the view that $\leq_B$ is the central notion. Indeed some kind of defense of the philosophical significance of $\leq_B$ is given in Sect. 4.

1.6 Examples.

1. For X a Polish space, we let $\mathrm{id}(X)$ be the identity relation on the space X. Since any two uncountable standard Borel spaces are isomorphic [50, 15.6], it follows that for any uncountable X we have
$$\mathrm{id}(X) \leq_B \mathrm{id}(\mathbb{R}).$$
2. We let E_0 be the equivalence relation of eventual agreement on infinite binary sequences. Thus for $\vec{x} = (x_0, x_1, \ldots), \vec{y} = (y_0, y_1, \ldots) \in 2^{\mathbb{N}}$, we set
$$\vec{x} \, E_0 \, \vec{y}$$
if and only if there exists some $N \in \mathbb{N}$ with
$$\forall n > N (x_n = y_n).$$
Here we have
$$\mathrm{id}(2^{\mathbb{N}}) <_B E_0.$$
To see that there is a Borel reduction from $\mathrm{id}(2^{\mathbb{N}})$ to E_0 is routine. It follows simply because there is perfect set in Cantor space consisting of mutually generic reals.

The failure of reducibility in the other direction is more subtle. First one observes that E_0 is given by the continuous action of the countable group

$$\bigoplus_{\mathbb{N}} \mathbb{Z}/2\mathbb{Z}$$

with $(g_0, g_2, \ldots) \cdot (x_0, x_1, \ldots) = (g_0 + x_0 \mod 2, g_1 + x_1 \mod 2, \ldots)$. Then given a supposed Borel reduction f of E_0 to the identity relation on $2^{\mathbb{N}}$ we can find a comeager set C on which f is continuous. Then we can take

$$\bigcap_{\vec{g} \in \bigoplus \mathbb{Z}/2\mathbb{Z}} \vec{g} \cdot C,$$

which will still be comeager and now invariant. Taking any $\vec{x}$ in this set we obtain that f will be constant on $[\vec{x}]_{E_0}$. Since this equivalence class is dense, f will constant on the entire set $\bigcap_{\vec{g}} \vec{g} \cdot C$. Since this set is uncountable, it contains many equivalence classes with a contradiction. (For a more detailed and general argument, see [36, 3.2].)

3. We let E_1 be the equivalence relation of eventual agreement on infinite sequences of reals. Here one has

$$E_0 <_B E_1.$$

(See [53], or even [36].)

4. Given a countable group Γ, we let 2^Γ be the collection of all functions

$$f : \Gamma \to \{0, 1\}$$

with the product topology. We let Γ act on 2^Γ with

$$\gamma \cdot f(\delta) = f(\gamma^{-1}\delta),$$

the left shift action. We then let E_G be the resulting equivalence relation.

In the case that we start with $G = \mathbb{F}_2$, the free group on two generators, one has

$$E_0 <_B E_{\mathbb{F}_2}.$$

(See for instance Appendix A of [44] for a survey of stronger and more general results one can prove in this direction.)

5. An example of historical importance is the *Vitali equivalence relation*, E_v. For $r, s \in \mathbb{R}$ set

$$r \, E_v \, s$$

if and only if

$$r - s \in \mathbb{Q}.$$

The classical argument that this equivalence relation has no measurable selector can be modified to show that $\mathrm{id}(\mathbb{R}) <_B E_v$; alternatively one may appeal to a variation of the Baire category argument at example 2 just above.

On the other hand, at the level of Borel reducibility there is no distinction between E_0 and E_v. (See for instance the argument after [35, 1.5] for a short proof that $E_0 \sim_B E_v$.)

6. Let X_2 be the space of all $h \in 2^{\mathbb{N}\times\mathbb{N}}$, where at each $n \neq m$ there exists a k with $h(n,k) \neq h(m,k)$. In other words, if we set $h_n \in 2^{\mathbb{N}}$ to be given by $h_n(k) = h(n,k)$ then for $n \neq m$ we have $h_n \neq h_m$.

   Then define $\mathcal{T}_2$ on X_2 by $h^1 \mathcal{T}_2 h^2$ if and only if the corresponding countable sets in $2^{\mathbb{N}}$ are equal—that is to say,

$$\{h^1_n : n \in \mathbb{N}\} = \{h^2_n : n \in \mathbb{N}\}.$$

   Thus if we let S_∞ be the group all permutations of $\mathbb{N}$, acting on X_2 by

$$\sigma \cdot h(n,k) = h(\sigma^{-1}(n), k),$$

   then $\mathcal{T}_2$ is the resulting equivalence relation.

   It is well-known that for any E_G as above, arising from a countable group G acting on 2^G, one has

$$E_G <_B \mathcal{T}_2.$$

   (See for instance [36, 2.64].)

1.7 Definition. An equivalence relation E on standard Borel X is said to be *smooth* or *tame* if $E \leq_B \mathrm{id}(\mathbb{R})$.

Smoothness amounts to asserting the existence of a countable algebra $\{B_n : n \in \mathbb{N}\}$ of E-invariant Borel sets which separates points—which is to say

$$x\,E\,y \quad\Longleftrightarrow\quad \forall n(x \in B_n \iff y \in B_n).$$

This in turn is equivalent to saying that $X/E = \{[x]_E : x \in X\}$ in the quotient Borel structure consisting of all E-invariant Borel sets is a subset of a standard Borel space. (See [29, 48].)

1.8 Definition. A Borel equivalence relation E on a standard Borel space X is said to be *countable* if every equivalence class is countable. It is *essentially countable* if there is some other countable Borel equivalence relation F with $E \leq_B F$.

1.9 Example. Let $\mathbb{F}_2$ be the free group on two generators and let E_∞ arise from action of $\mathbb{F}_2$ on $2^{\mathbb{F}_2}$. Then this is countable, since the responsible group is countable.

It is known from [48] that this equivalence relation is *universal* among the countable equivalence relations, in the sense that for every countable Borel equivalence relation E one has

$$E \leq_B E_\infty.$$

We will not get ensnared in the details of this argument here, but it might be helpful to point out that the proof depends on the Feldman-Moore theorem, which in some sense reduces to the study of countable Borel equivalence relations to the study of the orbit equivalence relations induced by countable groups.

1.10 Theorem (Feldman-Moore [15, 16]). *If E is a countable Borel equivalence relation on X, then there is a Borel group of automorphisms whose orbits equal the E-equivalence classes.*

Proof. With the Luzin-Novikov Uniformization Theorem [50, 18.10, 18.15] we can find a sequence of Borel functions $(f_n)_{n\in\mathbb{N}}$ such that $[x]_E$ always equals $\{f_n(x) : n \in \mathbb{N}\}$. We can find Borel sets B_n consisting of exactly the points on which $f_n(x) \neq x$. We can then find a partition of B_n into Borel sets $\{C_{n,i} : i \in \mathbb{N}\}$ with $f_n[C_{n,i}]$ disjoint from $C_{n,i}$ and $f|_{C_{n,i}}$ one-to-one. We then let $g_{n,i}$ be the function which is the identity off of $f_n[C_{n,i}] \cup C_{n,i}$, equal to f_n on $C_{n,i}$, and to f_n^{-1} on $f[C_{n,i}]$. It follows by Luzin-Novikov again that each $g_{n,i}$ is Borel.

Letting G be the countable group of automorphisms generated by $\{g_{n,i} : i, n \in \mathbb{N}\}$ we obtain $E = E_G$, the orbit equivalence relation induced by G. $\dashv$

1.11 Lemma. *A countable Borel equivalence relation is smooth if and only if it has a Borel selector—that is to say, a Borel set which meets every equivalence class in exactly one point.*

Proof. This follows rapidly from the Luzin-Novikov Uniformization Theorem. See for instance [48], or [7] for far more general results. $\dashv$

This lemma fails for general equivalence relations. For instance if we take $C \subseteq \mathbb{N}^\mathbb{N} \times \mathbb{N}^\mathbb{N}$ with the projection $\{x : \exists y((x, y) \in C)\}$ non-Borel, and set $(x, y)E(x', y')$ on C exactly when $x = x'$, then a Borel selector would result in the projection being Borel, since the one-to-one image of any Borel set under a Borel function is Borel.

1.12 Definition. An equivalence relation E is *hyperfinite* if there is a sequence of Borel equivalence relations, $(F_n)_{n\in\mathbb{N}}$, with each F_n having all its equivalence classes finite, each $F_n \subseteq F_{n+1}$, and $E = \bigcup_{n\in\mathbb{N}} F_n$.

1.13 Lemma (See [48]). *A countable Borel equivalence relation E on X is hyperfinite if and only if $E \leq_B E_0$.*

1.14 Definition. An equivalence relation E on a standard Borel space X is *treeable* if its classes form the components of a Borel treeing on X—that is to say, there is $\mathcal{T} \subseteq X \times X$ which is Borel with respect to the product Borel structure, is symmetric, acyclic, loopless, and for which we have $x\,E\,y$ if and only if there is a finite chain $x_0 = x, x_1, x_2, \ldots, x_n = y$, each $(x_i, x_{i+1}) \in \mathcal{T}$. (So here one has in mind the notion of tree prevalent in certain branches of combinatorics or computer science, rather than descriptive set theory—an acyclic graph, with no distinguished root in the various connected components).

1.15 Definition. Let $\mathbb{F}_2$ be the free group on two generators. Let $F(2^{\mathbb{F}_2})$ be the free part of the shift action of $\mathbb{F}_2$ on $2^{\mathbb{F}_2}$—that is to say, the set of $h : \mathbb{F}_2 \to \{0, 1\}$ such that for all $\sigma \in \mathbb{F}_2$ there exists τ with $h(\sigma^{-1}\tau) \neq h(\tau)$, equipped with the action $(\sigma \cdot h)(\gamma) = h(\sigma^{-1}\gamma)$. We then let $E_{\mathcal{T}\infty}$ be the orbit equivalence arising from this action of $\mathbb{F}_2$ on $F(2^{\mathbb{F}_2})$.

In most cases treeable equivalence relations have been studied simply in the case that E is already countable. Here one has an analogue of Lemma 1.13.

1.16 Lemma (See [48] or [41]). *A countable equivalence relation is treeable if and only if it is Borel reducible to* $E_{\mathcal{T}\infty}$.

Although this survey is primarily concerned with Borel equivalence relations, one must naturally connect this study with the analysis of those lying just outside this class.

1.17 Definition. A subset of a standard Borel space is *analytic* or $\utilde{\Sigma}^1_1$ if it is the image under a Borel function of a Borel set.

1.18 Definition. A *Polish group* is a topological group which is Polish as a space. Given a Polish group G, a *Polish G-space* is a Polish space equipped with a continuous action of G; a *standard Borel G-space* is a standard Borel space equipped with a Borel action by G.

In either case, if X is the space we use E^X_G, or even just E_G when there is no doubt to X, to denote the resulting orbit equivalence relation, and $[x]_G$ to denote the orbit of a point x.

The equivalence relations arising from the Borel action of a Polish group are always $\utilde{\Sigma}^1_1$, but frequently non-Borel. As noted in [6], for any such E^X_G we can write X as an $\aleph_1$ union of invariant Borel sets,

$$X = \bigcup_{\alpha<\omega_1} X_\alpha,$$

and E^X_G restricted to each X_α Borel.

1.19 Examples.

1. Let S_∞ be the group of all infinite permutations of the natural numbers equipped with the topology of pointwise convergence—that is to say,

a basic open set has the form $\{\sigma \in S_\infty : \sigma(n_0) = k_0, \ldots, \sigma(n_\ell) = k_\ell\}$. For $\mathcal{L}$ a countable language we let S_∞ act on $\mathrm{Mod}(\mathcal{L})$ in the natural way:

$$(\sigma \cdot \mathcal{M}) \models R(n_0, \ldots, n_\ell)$$

if and only if

$$\mathcal{M} \models R(\sigma^{-1}(n_0), \ldots, \sigma^{-1}(n_\ell)).$$

The resulting equivalence relation is nothing other than isomorphism on this class of structure, and for any reasonably rich one has that E_{S_∞} is $\undertilde{\Sigma}^1_1$ but non-Borel.

2. Given $\mathcal{L}$ as above, and $\varphi \in \mathcal{L}_{\omega_1,\omega}$, a countably infinitary formula, we let $\mathrm{Mod}(\varphi)$ be the structures in $\mathrm{Mod}(\mathcal{L})$ which satisfy φ. Since this is a Borel subset of a Polish space, it is a standard Borel space in its own right, and in the induced action a standard Borel S_∞-space.

   Here one should see [6] for further details. The first paper to consider these examples seriously from the point of the view of the $\leq_B$ ordering is [18].

3. Given a Polish group G we can let it act on itself by conjugation

$$\sigma \cdot \rho = \sigma^{-1} \rho \sigma.$$

   In many cases this corresponds naturally to some kind of classification problem. For instance, if M_∞ is the group of all measure-preserving transformations of the unit interval considered up to agreement almost everywhere, then this group is indeed Polish in the natural topology and the equivalence relation arising from its conjugation action is the equivalence relation of isomorphism of measure-preserving transformations. Or if we let U_∞ be the unitary group on infinite dimensional Hilbert space, we are find ourselves confronted with the classification up to unitary equivalence of unitary operators. Or one may consider $\mathrm{Hom}([0,1])$, the homeomorphism group of the unit interval, for the classification problem for homeomorphisms of the unit interval up to topological similarity. All these examples are discussed at length in [36].

2. A Survey of Structure Theorems

2.1. Structure

At the base level of the $\leq_B$ there is a sharp structure. The first of these results is due to Jack Silver. Although it was proved sometime prior to the general study of Borel equivalence relations, it may be paraphrased in modern terminology as follows.

2.1 Theorem (Silver [63]). *If E is a Borel equivalence relation, then exactly one of the following holds:*

(I) $E \leq_B \mathrm{id}(\mathbb{N})$*; or*

(II) $\mathrm{id}(\mathbb{R}) \leq_B E$.

In some ways this belongs to the prehistory of the subject. Momentum developed only after the seminal dichotomy theorem of Leo Harrington, Alexander Kechris, and Alain Louveau. This is sometimes known as the *Glimm-Effros dichotomy*, since forerunners of this theorem were proved by Glimm and then later Effros, who had the result in the case that E is an F_σ equivalence relation induced by the continuous action of a Polish group.

2.2 Theorem (Harrington-Kechris-Louveau [29]). *If E is a Borel equivalence relation, then exactly one of the following holds:*

(I) $E \leq_B \mathrm{id}(\mathbb{R})$*; or*

(II) $E_0 \leq_B E$.

Sketch of Proof. We describe some of the combinatorics under the drastic assumption that E is a *countable* Borel equivalence relation. This is misleading as to the difficulty of the proof, since then the vast majority of the mathematical issues simply evaporate. It should also be pointed out that the theorem in this case was already known to Glimm [28] and Effros [10].

First we can appeal to Theorem 1.10 to obtain a countable group G acting by Borel transformations on the Polish space X with $E_G = E$. Applying a change of topology argument, as found in say [50, §13], we may assume G acts by homeomorphisms.

Now there are two possibilities.

First of all we may have that for any $x \neq y \in X$ we have the closures of their orbits, $\overline{[x]_G}, \overline{[y]_G}$, distinct. In that case one defines a map

$$X \to \mathcal{F}(X),$$

$$x \mapsto \overline{[x]_G},$$

from X to the space of all closed subsets of X with the standard Borel structure. It is easily seen that this map is Borel, and so we obtain a reduction of E to $\mathrm{id}(\mathcal{F}(X))$. Since any two uncountable Borel spaces are Borel isomorphic, this is as good as a reduction to $\mathrm{id}(\mathbb{R})$.

The other case is that there are distinct orbits with the same closure. We will now work entirely inside some $X_0 \subseteq X$ consisting of all y with $\overline{[y]_G} = C$ for some closed C. X_0 is a G_δ subset of X, and hence Polish in its own right. (See for instance [36, §2.1].) At this stage we are assuming that X_0 contains more than one orbit for the purpose of deriving a contradiction. We let $\{g_n : n \in \mathbb{N}\}$ enumerate the group G. Now note that E_G is F_σ, and our assumptions on X_0 imply that both it and its complement are dense in $X_0 \times X_0$.

We then construct non-empty open neighborhoods $(U_s)_{s \in 2^{<\mathbb{N}}}$ in X_0 and $(g_s)_{s \in 2^{<\mathbb{N}}}$ so that:

(i) $\overline{U_s} \subseteq U_t$ for s a strict extension of t;

(ii) with respect to a compatible complete metric on X_0, the diameter of each U_s is less than 2^{-n} for $s \in 2^n$;

(iii) $g_{s^\frown 0} = g_s$; $g_{s^\frown 1} = g_s g_{\langle 0,0,\ldots,0\rangle^\frown 1}$; $g_{\langle 0,0,\ldots,0\rangle} = e$, the identity of the group;

(iv) $g_s \cdot U_{\langle 0,0,\ldots,0\rangle} = U_s$, where $\langle 0,0,\ldots,0\rangle$ is the constantly zero sequence of the same length as s;

(v) if $s, t \in 2^{n+1}$ and $s(n) \neq t(n)$, then for all $i \leq n$ we have $g_i \cdot U_s \cap U_t = \emptyset$.

Assuming we can effect this elaborate arrangement, the conclusion is brief. (iv) will guarantee that for each $s, t \in 2^n$ we have

$$g_t g_s^{-1} \cdot U_s = U_t,$$

and then repeated applications of (iii) ensures for any $w \in 2^{<\mathbb{N}}$

$$g_t g_s^{-1} \cdot U_{s^\frown w} = U_{t^\frown w}.$$

Thus for any $x \in 2^{\mathbb{N}}$ there will be a unique point

$$\theta(x) \in \bigcap U_{x|_n},$$

and if $x(n) = y(n)$ all $n \geq N$, then

$$g_{x|_n} g_{y|_n}^{-1}(\theta(y)) = \theta(x),$$

whilst if $x(n) \neq y(n)$ for infinitely many n then (v) guarantees E_G-inequivalence.

So suppose we have done this up through $(U_s)_{s \in 2^n}, (g_s)_{s \in 2^n}$. By the density of the complement of E_G we can find some $x, y \in U_{\langle 0,0,\ldots,0\rangle}$ which are inequivalent. We can then let $x_s = g_s \cdot x$, $y_s = g_s \cdot y$. We form small enough open sets W, V around x, y so that if $W_s = g_s \cdot W$, $V_s = g_s \cdot V$, then $g_i \cdot V_s \cap W_t = \emptyset$, $g_i^{-1} \cdot V_s \cap W_t = \emptyset$.

We then find a point $x' \in [x]_G \cap V_{\langle 0,0,\ldots,0\rangle}$ by the density of the orbits. We let $g_{\langle 0,0,\ldots,0\rangle^\frown 1}$ be a group element moving x to x'. We let $g_{s^\frown 1}$ be $g_s g_{\langle 0,0,\ldots,0\rangle^\frown 1}$. We then build a sufficiently small set $U^* \subseteq W$ so that if we let $U_t = g_t \cdot U^*$ for each $t \in 2^{n+1}$ then for $i \leq n$ we have ensured (i), (ii), and (v). $\dashv$

The argument for general Borel E is far harder, and uses the Gandy-Harrington topology. There is no known proof of Theorem 2.2 which does not use ideas from logic.

Therefore at the base of the picture one obtains the Borel equivalence relations with finitely many classes, followed by any Borel equivalence relation with exactly $\aleph_0$ many classes, then the identity relation on the reals, and then E_0, or, equivalently when considered up to Borel reducibility, the Vitali equivalence relation.

It should be mentioned that Harrington-Kechris-Louveau implies Silver's theorem. If $f : 2^{\mathbb{N}} \to X$ witnesses $E_0 \leq_B E$ then we can find a comeager set on which this function is continuous, and then inside this comeager we can find a compact perfect set of E_0-inequivalent reals. On the other hand if $E \leq \mathrm{id}(\mathbb{R})$ then the equivalence classes of E can be identified with a $\undertilde{\Sigma}^1_1$ subset of a Polish space, whereupon Silver's theorem reduces to the perfect set theorem for $\undertilde{\Sigma}^1_1$ sets.

Immediately after this one obtains a splintering. It is known from [53] that there are no other Borel equivalence relations E such that for any other Borel F one has either $E \leq_B F$ or $F \leq_B E$. Instead we have:

2.3 Theorem (Kechris-Louveau [53]). *Let E be a Borel equivalence relation with $E \leq_B E_1$. Then exactly one of the following holds:*

(I) $E \leq_B E_0$; or

(II) $E_1 \leq_B E$.

2.4 Definition. Let $E_0^{\mathbb{N}}$ be the equivalence relation on $(2^{\mathbb{N}})^{\mathbb{N}}$ given by

$$\vec{x}\, E_0^{\mathbb{N}}\, \vec{y}$$

if and only if

$$\forall n (x_n\, E_0\, y_n);$$

that is to say, we have E_0-equivalence at every coordinate.

2.5 Theorem (Hjorth-Kechris [43]). *Let E be a Borel equivalence relation with $E \leq_B E_0^{\mathbb{N}}$. Then exactly one of the following holds:*

(I) $E \leq_B E_0$; or

(II) $E_0^{\mathbb{N}} \leq_B E$.

There are no other known immediate successors to E_0, but Ilijas Farah [12] has proposed a continuum of plausible examples which are inspired by ideas in Banach space theory. What he does show is that these examples are incomparable, and that any equivalence relation strictly below any of them is essentially countable. The gnawing technical difficulty at the end of his argument is our inability to determine which countable equivalence relations are hyperfinite. Very recently, in a spectacular and unpublished piece of work, Su Gao and Steve Jackson showed all equivalence relations arising from the Borel actions of countable abelian groups are hyperfinite, and on this basis we might hope for further clarification in the coming years.

Although we are at a loss to provide further global dichotomy theorems, there is something more that can be said if we restrict ourselves to the region of equivalence relations which are below isomorphism of countable structures.

2.6 Definition. For $\mathcal{L}$ a countable language, we let $\cong_{\mathrm{mod}(\mathcal{L})}$ be isomorphism on the standard Borel space of $\mathcal{L}$-structures with underlying set $\mathbb{N}$. For $\psi \in \mathcal{L}_{\omega_1,\omega}$ we let $\cong_{\mathrm{mod}(\psi)}$ be the restriction of this equivalence relation to models of ψ.

2.7 Lemma (Becker-Kechris [6]). *Let E be Borel. Then the following are equivalent:*

(I) $E \leq_B \cong_{\mathrm{mod}(\mathcal{L})}$ for some countable language $\mathcal{L}$.

(II) $E \leq_B E_{S_\infty}$, where E_{S_∞} arises from the continuous action of a S_∞ on a Polish space.

2.8 Definition. If either of these equivalent conditions hold, then we say that E *admits classification by countable structures.*

In the still unpublished [31] a dichotomy theorem was recently announced for equivalence relations admitting classification by countable structures. It should be emphasized that this proof is long and has not been refereed, and accordingly the result has a provisional status.

2.9 Theorem (Hjorth [31]). *Let E be a Borel equivalence relation admitting classification by countable structures. Then exactly one of the following holds:*

(I) $E \leq E_\infty$, that is to say, E is essentially countable; or

(II) $E_0^{\mathbb{N}} \leq_B E$.

2.2. Anti-Structure

The last section represented the good news. Now for the evil.

Refining an earlier result of Woodin's, Louveau and Boban Velickovic embedded $\mathcal{P}(\mathbb{N})/\mathrm{Fin}$ into the Borel equivalence relations considered up to Borel reducibility.

2.10 Theorem (Louveau-Velickovic [56]). *There is an assignment*

$$A \mapsto E_A$$

of $\underset{\sim}{\Pi}^0_3$ equivalence relations to subsets of $\mathbb{N}$ such that

$$E_{A_1} \leq_B E_{A_2}$$

if and only if $A_2 \setminus A_1$ is finite.

Therefore there is no global structure theorem for the $\leq_B$ ordering.

Given the dichotomy theorems of [53] and [43] we might at least hope for some kind of basis of immediate successors to E_0, but even this seems unlikely. In [13] Farah obtains an infinite descending chain in $\leq_B$ which is *unlikely* to be above an immediate successor to E_0. I say unlikely, though it is hard to make a fast guess at this point. Literally Farah obtains the existence of a sequence $(F_n)_{n\in\mathbb{N}}$ with each $F_{n+1} <_B F_n$, none of them essentially countable, and with the further property that any equivalence relation $E \leq_B F_n$ at every n must be essentially countable. Since the F_n's arise in a very simple form, in particular the continuous action of an abelian Polish group, there is some grounds for thinking the only countable equivalence relations reducible to one of these will be reducible to E_0.

Farah's work also disproves the existence of a dichotomy theorem for being classifiable by countable structures in many dramatic ways. For instance he obtains an uncountable sequence of Borel equivalence relations, $(E_x)_{x\in 2^{\mathbb{N}}}$, which are not classifiable by countable structures, and such that for any $x \neq y$ and Borel E with

$$E \leq_B E_x, E_y$$

we have E classifiable by countable structures.

2.3. Beyond Good and Evil

There are slender few candidates for outright Borel dichotomy theorems in the style of Theorems 2.2 and 2.10 and the later results of Farah would seem to rush hopes for a global analysis of the $\leq_B$ ordering. On the other hand it still seems that there are results which would help us understand when equivalence relations fall on some side of a key divide.

A distinction of philosophical interest is when we can classify by countable structures, which has clear parallels in broader mathematical practice. Here one has in mind for instance certain branches of topology, where one seeks complete algebraic invariants, and in effect one is trying to classify a certain equivalence relation by a countable algebraic structure considered up to isomorphism. The introduction of [36] surveys several examples along these lines from a variety of different mathematical areas.

2.11 Definition. Let G be a Polish group and X a Polish G-space. For $U \subseteq G$ an open neighborhood of the identity, $V \subseteq X$ an open neighborhood of a point x, the *local U-V-orbit of* x, written $\mathcal{O}(x, U, V)$, is the set of all y such that there exists a finite sequence of points $x_0 = x, x_1, x_2, \ldots, x_n = y$ in U with each $x_{i+1} \in V \cdot x_i$—that is to say, we can move from x_i to x_{i+1} using some group element in V. Then we say that the action of G on X is *turbulent* if the following three things hold:

(i) every orbit $[x]_G$ is dense in X;

(ii) every orbit $[x]_G$ is meager in X;

(iii) given $x, y \in X$, U an open neighborhood of y, V an open neighborhood of the identity in G, there is some $x' \in [x]_G \cap U$ with y in the closure of the local orbit $\mathcal{O}(x', U, V)$.

2.12 Theorem (Hjorth [36]). *If E_G arises from a turbulent action of G on the Polish G-space X and $\mathcal{L}$ is a countable language, then E_G is not Borel reducible to $\cong_{\mathrm{mod}(\mathcal{L})}$.*

Sketch of Proof. We present the argument in a simple case with a number of simplifying assumptions. Consider the example of an S_∞ action given before, where the space is X_2, consisting of all $h \in 2^{\mathbb{N}\times\mathbb{N}}$, where at each $n \neq m$ there exists a k with $h(n,k) \neq h(m,k)$. Then define $\mathcal{T}_2$ on X_2 by $h^1 \mathcal{T}_2 h^2$ if and only if the corresponding countable sets in $2^{\mathbb{N}}$ are equal. This is the orbit equivalence relation arising from the S_∞ action

$$(\sigma \cdot h)(m,n) = h(\sigma^{-1}(m), n).$$

We assume toward a contradiction that $\theta : X \to X_2$ witnesses $E_G \leq_B \mathcal{T}_2$.

Every Borel function is continuous on a comeager set, so let us actually make the simplifying assumption that θ is continuous everywhere.

Claim: For any n there is a comeager collection of $x \in X$ which have some basic open neighborhood $V_{x,n}$ of the identity in S_∞ for which there is a comeager collection of $\sigma \in V_{x,n}$ having

$$(\theta(x))(n,\cdot) = (\theta(\sigma \cdot x))(n,\cdot).$$

Proof of Claim: For each individual point x and m we consider the Borel function

$$f_x^m : G \to \mathbb{N}$$

which assigns to $g \in G$ the natural number $f(g)$ with $\theta(x)(m,\cdot) = \theta(g \cdot x)(f(g),\cdot)$. Each Borel set has the property of Baire, hence we can find open sets $(O_n^m)_{n\in\mathbb{N}}$ with dense union in G such that $O_n \Delta f^{-1}(n)$ is meager at every n. Then for any

$$g \in \bigcap_m \bigcup_n O_n^m$$

we have at each ℓ some basic open $V \subseteq G$ such that for a comeager collection of $h \in V$

$$\theta(g \cdot x)(\ell,\cdot) = \theta(hg \cdot x)(\ell,\cdot).$$

Thus we have show that inside each orbit the collection of $g \in G$ for which $g \cdot x$ has the required property is comeager. Now the conclusion of the claim follows by the Kuratowski-Ulam Theorem (see [50]).

Let us make the additional and rather radical assumption that

$$x \mapsto V_{x,n}$$

is defined everywhere, and "continuous" in the sense that given any basic open V and n the collection of x with $V_{x,n} = V$ is open.

Let $x, y \in X$. Consider some n. It suffices to show that there is a representative of the orbit of x,

$$x' \in [x]_G,$$

which has $\theta(x')(n, \cdot) = \theta(y)(n, \cdot)$. By the above simplifying assumptions we can find a basic open neighborhood of U of y and V a basic open neighborhood of the identity in the group which has

$$(\theta(z))(n, \cdot) = (\theta(\sigma \cdot z))(n, \cdot)$$

all $z \in U, \sigma \in V$.

Now if we take $x' \in [x]_G$ with

$$y \in \overline{\mathcal{O}(x', U, V)}$$

then we can find a sequence of points $(z_i)_{i \in \mathbb{N}}$, each $z_i \in \mathcal{O}(x', U, V)$ with

$$z_i \to y.$$

By the assumptions on U and V we have $\theta(z_i)(n, \cdot) = \theta(x')(n, \cdot)$ at all n, and hence $\theta(x')(n, \cdot) = \theta(y)(n, \cdot)$, as required. ⊣

As a practical matter [36] suggests turbulence to be the key phenomena in determining whether an equivalence relation is classifiable by countable structures. This has been supported in various examples and practical investigations, such as [26, 54], as well as some partial results given in [36]. The correct theorem was not established until a few years later.

2.13 Theorem (Hjorth [38]). *Let G be a Polish group and X a Polish G-space. Suppose E_G^X is Borel. Then exactly one of the following hold:*

(I) E_G^X admits classification by countable structures; or

(II) there is a turbulent Polish G-space Y with $E_G^Y \leq E_G^X$.

3. Countable Borel Equivalence Relations

The subject of countable Borel equivalence relations is notable for its interactions with such diverse fields as geometric group theory, the ergodic theory of non-amenable groups, operator algebras, and superrigidity in the sense of Zimmer. There is a sense in which this interaction has been largely one way, since one finds logicians borrowing from these other fields rather than these areas being serviced by logic.

In the course of this period it is perhaps unsurprising that logicians have made a few notable contributions to the benefit of the other fields. However in almost every case the applications do not consist in applying deep ideas from logic, as found in say the work of Hrushovski [47], but rather the natural result of mathematicians from one field rethinking the problems from another and approaching with a different point of view.

3.1. The Global Structure

In some form or another almost every argument which distinguishes countable Borel equivalence relations in the $\leq_B$ ordering uses measure theory. At the very base level we can use Baire category arguments to show $\mathrm{id}(\mathbb{R}) <_B E_0$ but beyond this there is a fundamental obstruction.

3.1 Theorem (Sullivan-Weiss-Wright [65]). *Let E be a countable Borel equivalence relation on a Polish space X. Then there is a comeager set on which E is hyperfinite.*

Sketch of Proof. (This draws on Segal's thesis [61]; see also [58].) E is induced by a countable group G acting by Borel automorphisms. Let us make the simplifying assumptions that G acts by homeomorphisms and the space is zero-dimensional—these assumptions are harmless, but we will skip over this point in the interest of keeping the argument short.

Let $\mathcal{B}$ be a countable basis for X consisting of clopen sets. Let $(g_n)_{n\in\mathbb{N}}$ enumerate the countable group G.

At each n let Y_n be the collection of sequences

$$\vec{A} = (A_0, A_1, \ldots, A_n),$$

where each A_i is a finite subset of $\mathcal{B}$. Given such a sequence we let $R_{\vec{A}}$ be the graph on X given by

$$x \, R_{\vec{A}} \, x'$$

if there is some $i \leq n$, $V, V' \in A_i$, with $x \in V, x' \in V'$ and

$$g_i \cdot x = x'.$$

We let $E_{\vec{A}}$ be the equivalence relation arising from the connected components of $R_{\vec{A}}$.

We then let Y_n^* be the subset of Y_n for which the induced equivalence relation $E_{\vec{A}}$ has all its equivalence classes finite. Given $\vec{A} = (A_0, \ldots, A_n) \in Y_n^*$, $\vec{B} = (B_0, \ldots, B_m) \in Y_n^*$ where $m \geq n$, we say that $\vec{B}$ *extends* $\vec{A}$ if every at every $i \leq n$

$$A_i \subseteq B_i.$$

Claim: Given any x, $y = g_i \cdot x$, $n \geq i$ and

$$\vec{A} \in Y_n^*$$

we can find an extension $\vec{B} \in Y_n^*$ with

$$x \, R_{\vec{B}} \, y.$$

Proof of Claim: The point is that we can add to A_i a small enough open set W around x that will specify x with sufficient exactness to ensure that for any $x' \in W$, the $E_{\vec{A}}$ equivalence class of x consists of $\{h_i \cdot x' : i \leq \ell\}$ for some finite sequence $h_0, \ldots, h_{\ell-1}$ of group elements. (This is where we use zero-dimensionality.) Then we can find $V \in \mathcal{B}$ that specifies x with sufficient precision to ensure that for any $x' \in V$ and $z \, E_{\vec{A}} \, x'$ we have either $z = x'$ or $z \notin V$. Similarly we can do the same for y with some V'. Then if we were to take the simple extension $\vec{B}$ which has $B_i = A_i \cup \{V, V'\}$ but $B_j = A_j$ at $j \neq i$, then $E_{\vec{A}}$ has index at most two in $E_{\vec{B}}$. (Claim ⊣)

We then let Y be the space of all infinite sequences

$$(\vec{A}^n)_{n\in\mathbb{N}} \in \prod_{n\in\mathbb{N}} Y_n^*$$

where each $\vec{A}^{n+1}$ extends A_n. Any such $(\vec{A}^n)_{n\in\mathbb{N}} \in Y$ gives rise to an increasing sequence of Borel equivalence relations with finite classes, taking $F_n^{(\vec{A}^n)_{n\in\mathbb{N}}}$ to be $E_{\vec{A}^n}$. $\prod_{n\in\mathbb{N}} Y_n^*$ comes with a natural product topology, under which it is Polish. Y is a closed subset of this product space, and hence Polish in its own right. The above claim shows that for all $x \in X$ there is a comeager collection of $(\vec{A}^n)_{n\in\mathbb{N}} \in Y$ with

$$[x]_E = \bigcup_{n\in\mathbb{N}} [x]_{F_n^{(\vec{A}^n)_{n\in\mathbb{N}}}}.$$

Thus by Kuratowski-Ulam (see [50]), there is a comeager collection of $(\vec{A}^n)_{n\in\mathbb{N}} \in Y$ for which there is a comeager collection of x with $[x]_E = \bigcup_{n\in\mathbb{N}} [x]_{F_n^{(\vec{A}^n)_{n\in\mathbb{N}}}}$. Taking any such $(\vec{A}^n)_{n\in\mathbb{N}} \in Y$ and corresponding comeager set, we are done. ⊣

On the other hand the subject of countable Borel equivalence relations considered up to Borel reducibility might collapse into a kind of death by heat dispersal if all these examples were hyperfinite. It turns that in the presence of an invariant probability measure, *non-amenable* groups give rise to equivalence relations which are not hyperfinite.

3.2 Definition. A countable group Γ is *amenable* if for any finite $F \subseteq \Gamma$ and $\epsilon > 0$ there is a finite, non-empty $A \subseteq \Gamma$ such that for all $\sigma \in F$

$$\frac{|A \Delta \sigma A|}{|A|} < \epsilon.$$

As a word on the notation, we use $|B|$ to denote the cardinality of the set B and $B \Delta C$ to denote the symmetric difference of the sets B and C. Thus amenability amounts to the existence of something like "almost invariant" subsets of the group—given any finite collection of group elements, any tolerance ($\epsilon > 0$), we can find a finite set which when translated by any of the group elements differs from its original position on a relatively small number of elements.

3.3 Examples.

1. $\mathbb{Z}$ is amenable. Given $F = \{k_1, \ldots, k_\ell\}$ in the group and $\epsilon > 0$, we let $k = \max(|k_1|, \ldots, |k_\ell|)$, the max of the absolute values, and then let

$$N > \frac{2(k+1)}{\epsilon}.$$

The set $A = \{-N, -N+1, -N+2, \ldots, 0, 1, \ldots, N-1, N\}$ is as required.

2. On the other hand, $\mathbb{F}_2 = \langle a, b \rangle$, the free group on two generators, is most famously non-amenable. Just take $\epsilon = 1/10$, $F = \{a, b, a^{-1}, b^{-1}\}$. We can see this by dividing the non-identity elements of $\mathbb{F}_2$ into four regions, $C_a, C_b, C_{a^{-1}}, C_{b^{-1}}$, where a (reduced) word is in the region C_u if it begins with u.

Consider some putative set A that is trying to witness amenability for $1/10$ and $\{a, b, a^{-1}, b^{-1}\}$. For $u = a, b, a^{-1}$, or b^{-1}, $n \in \mathbb{N}$, if at least n of A's elements are *not* in $C_{a^{-1}}, C_{b^{-1}}, C_a$, or C_b, respectively, then at least n of $u \cdot A$'s elements are in $C_a, C_b, C_{a^{-1}}$, or $C_{b^{-1}}$, respectively. Therefore we can clearly find two distinct u_1, u_2 with at least three fifths of $u_i \cdot A$'s elements in C_{u_i}. One of these sets must differ from A by at least $\frac{1}{10}|A|$.

Note that there is nothing special here about the use of *almost invariant* sets in $\mathbb{F}_2$. We would obtain a similar contradiction if we considered almost invariant *functions* in $\ell^1(\mathbb{F}_2)$. Given $f \in \ell^1(\mathbb{F}_2)$ and $u \in \{a, b, a^{-1}, b^{-1}\}$ we could look at the norm of the corresponding f_u defined by $f_u(\sigma) = f(\sigma)$ if $\sigma \in C_u$, $f_u(\sigma) = 0$ otherwise.

3.4 Definition. A *standard Borel probability space* is a standard Borel space X equipped with an atomless σ-additive probability measure μ on its Borel sets.

3.5 Theorem. *Let Γ be a countable non-amenable group. Suppose Γ acts freely and by measure preserving transformations on a standard Borel probability space (X, μ). Then E_Γ is not hyperfinite.*

Proof. We sketch the argument just in the case that $G = \mathbb{F}_2$.

For a contradiction suppose $E_{\mathbb{F}_2} = \bigcup_{n \in \mathbb{N}} F_n$, where each F_n is finite, Borel, and has $F_n \subseteq F_{n+1}$. At each $x \in X$ we define

$$f_{n,x} : \mathbb{F}_2 \to \mathbb{R}$$

with

$$f_{n,x}(\sigma) = \frac{1}{|[x]_{F_n}|}$$

if $\sigma^{-1} \cdot x F_n x$,

$$f_{n,x}(\sigma) = 0$$

otherwise. Let

$$f_n(\sigma) = \int_X f_{n,x}(\sigma)\, d\mu.$$

For any x we have $\|f_{n,x}\|_{\ell^1} = 1$, and so certainly $\|f_n\|_{\ell^1} = 1$, and in fact for any measurable set $A \subseteq X$

$$\sum_\sigma \int_A f_{n,x}(\sigma)\, d\mu \leq \mu(A).$$

Claim: For any $\gamma \in \mathbb{F}_2$, as $n \to \infty$

$$\|f_n - \gamma \cdot f_n\|_{\ell^1} \to 0.$$

Proof of Claim: Note that if $xF_n\gamma \cdot x$ then

$$\gamma \cdot f_{n,x} = f_{n,\gamma\cdot x},$$

since for any σ we have

$$\gamma \cdot f_{n,x}(\sigma) = f_{n,x}(\gamma^{-1}\sigma) = \frac{1}{|[x]_{F_n}|}\left(= \frac{1}{|[\gamma \cdot x]_{F_n}|}\right)$$

if and only if $\sigma^{-1}\gamma \cdot xF_n x$, which, by the assumption $xF_n\gamma \cdot x$, amounts to saying if and only if

$$f_{n,\gamma\cdot x}(\sigma) = \frac{1}{|[\gamma \cdot x]_{F_n}|}.$$

Thus if we let $A_{n,\gamma} = \{x \in X : xF_n\gamma \cdot x\}$, then

$$\int_{A_{n,\gamma}} \gamma \cdot f_{n,x}(\sigma)\, d\mu = \int_{\gamma\cdot A_{n,\gamma}} f_{n,x}(\sigma)\, d\mu,$$

and hence

$$\begin{aligned}\|f_n - \gamma \cdot f_n\|_{\ell^1} &\leq 2\sum_\sigma \int_{X\setminus A_{n,\gamma}} f_{n,x}(\sigma) = 2\int_{X\setminus A_{n,\gamma}} \sum_\sigma f_{n,x}(\sigma) \\ &= 2\mu(X \setminus A_{n,\gamma}).\end{aligned}$$

Since $\mu(A_{n,\gamma}) \to 1$ as $n \to \infty$, we are done. (Claim $\dashv$)

Now we have established the existence of almost invariant functions in $\ell^1(\mathbb{F}_2)$, and this can be refuted by the same kind of argument as used to show the non-amenability of $\mathbb{F}_2$. $\dashv$

For the longest while there was only a small finite number of countable Borel equivalence relations known to be distinct in the $\leq_B$ ordering. It was a notorious open problem to establish even the existence of $\leq_B$-incomparable examples. This was finally settled by:

3.6 Theorem (Adams-Kechris [2]). *There exists an assignment of countable Borel equivalence relations to Borel subsets of* $\mathbb{R}$*,*

$$B \mapsto E_B,$$

such that $E_B \leq_B E_C$ *if and only if* $B \subseteq C$*.*

Formally their result relied on the superrigidity theory of Zimmer [70] for lattices in higher rank Lie groups, and thus in turn had connections with earlier work of Margulis and Mostow. I will say nothing about Zimmer's work as such, but instead try to describe some of the engine which drives the theory.

3.7 Definition. For a compact metric space K we let $M(K)$ denote the probability measures on K. By the Riesz representation theorem this can be identified with a closed subset of the dual of $C(K)$, and thus is a Polish space in its own right. Note that the homeomorphism group of K acts on $M(K)$ in a natural way:

$$(\psi \cdot \mu)(f) = \mu(\psi^{-1} \cdot f),$$

where $\psi^{-1} \cdot f$ is defined by $(\psi^{-1} \cdot f)(x) = f(\psi(x))$.

3.8 Definition. Given a group Γ acting on a space X and another group H we say that

$$\alpha : \Gamma \times X \to H$$

is a *cocycle* if for all $\gamma_1, \gamma_2 \in \Gamma, x \in X$

$$\alpha(\gamma_2, \gamma_1 \cdot x)\alpha(\gamma_1, x) = \alpha(\gamma_1\gamma_2, x).$$

Here is a typical situation in which a cocycle arises. Given Γ a group of Borel automorphisms of standard Borel space X, H a countable group acting freely and in a Borel manner on a standard Borel space Y, if

$$\theta : X \to Y$$

witnesses $E_\Gamma^X \leq_B E_H^Y$, then we obtain a Borel cocycle by letting $\alpha(\gamma, x)$ be unique $h \in H$ with

$$h \cdot \theta(x) = \theta(\gamma \cdot x).$$

3.9 Lemma (Furstenberg [21], Zimmer [70]). *If* Δ *is a countable amenable group acting in a Borel manner on a standard Borel probability space* (X, μ) *and*

$$\alpha : \Delta \times X \to \mathrm{Hom}(K)$$

is a cocycle into the homeomorphism group of a compact metric space K*, then we can find a measurable assignment of measures*

$$x \mapsto \nu_x,$$

$$X \to M(K),$$

which is almost everywhere equivariant, that is to say

$$\forall^\mu x \forall \gamma (\alpha(\gamma, x) \cdot \nu_x) = \nu_{\gamma \cdot x}.$$

The applications of this lemma and its forerunners are much too involved to be discussed here. Some understanding of what is going on can be given by the following simple lemma. In fact, the hypotheses of the lemma can never be realized, and indeed the real theorem is that equivalence relations of the form $E^X_{\Gamma\times\mathbb{Z}}$ are never treeable, but I simply want to give a short illustration of some key ideas.

3.10 Lemma. *Suppose* Γ *is a non-amenable countable group. Let* $X = \{0,1\}^{\Gamma\times\mathbb{Z}}$ *and let* μ *be the product measure on this space. Let* $\Gamma \times \mathbb{Z}$ *act in the natural way on this space:*

$$\sigma \cdot f(\tau) = f(\sigma^{-1}\tau)$$

for any $f \in X$, $\sigma, \tau \in \Gamma \times \mathbb{Z}$.

Suppose $\mathbb{F}_2$ *acts freely and by Borel automorphisms on standard Borel probability space* Y. *Suppose*

$$\theta : X \to Y$$

witnesses $E^X_{\Gamma\times\mathbb{Z}} \leq_B E^Y_{\mathbb{F}_2}$.

Then there is homomorphism $\rho : \Gamma \to \mathbb{F}_2$ *and an alternative reduction*

$$\hat{\theta} : X \to Y,$$

which is equivalent in the sense that

$$\hat{\theta}(x) \, E^Y_{\mathbb{F}_2} \, \theta(x)$$

for all $x \in X$ *and whose resulting cocycle accords with* ρ *almost everywhere, in the sense that*

$$\forall^\mu x \forall \gamma (\rho(\gamma) \cdot \hat{\theta}(x)) = \hat{\theta}(\gamma \cdot x).$$

Sketch of Proof. Let

$$\alpha : (\Gamma \times \mathbb{Z}) \times X \to \mathbb{F}_2$$

be the induced cocycle.

Let $\partial(\mathbb{F}_2)$ denote the *infinite* reduced words from $\{a, b, a^{-1}, b^{-1}\}$. This is a compact metric space on which $\mathbb{F}_2$ acts by homeomorphisms. (See [44, Appendix C].) Following Lemma 3.9 we can find a measurable assignment

$$X \to M(\partial(\mathbb{F}_2)),$$

$$x \mapsto \mu_x,$$

with

$$\alpha(e,\ell)\cdot\mu_x=\mu_{(e,\ell)\cdot x}$$

for all $\ell\in\mathbb{Z}$ and a.e. $x\in X$. (We will use e for the identity in Γ and 0 for the identity in $\mathbb{Z}$.)

Claim: We can choose this assignment so that the measures μ_x concentrate almost everywhere on more than two points.

Proof of Claim: (Sketch only; see [44, Appendix C] for a completely precise argument for a more general claim.) Suppose instead that every such $\mathbb{Z}$-equivariant assignment of measures concentrates on at most two points.

The key observation here is that if

$$x\mapsto\mu_x$$

is such an assignment of measures then for any $\gamma\in\Gamma$ so is

$$x\mapsto\alpha(\gamma,0)^{-1}\cdot\mu_{(\gamma,0)\cdot x}.$$

Thus to prevent a situation in which we could simply pile on more and more of these measures, passing from say $x\mapsto\mu_x$ to

$$x\mapsto\frac{\mu_x+\alpha(\gamma,0)^{-1}\cdot\mu_{(\gamma,0)\cdot x}}{2}$$

we must be able to obtain an assignment which is actually Γ-equivariant.

Using certain strong ergodicity properties of the shift action of Γ on X (see [44, Appendix A]) and the hyperfiniteness of the action of $\mathbb{F}_2$ on $\partial(\mathbb{F}_2)$ (see [44, Appendix C]) we obtain that there is a single measure ν_0 such that for almost all x we have some $\sigma_x\in\mathbb{F}_2$ with

$$\sigma_x\cdot\mu_x=\nu_0.$$

Thus replacing θ with the reduction

$$\hat\theta:x\mapsto\sigma_x\cdot\theta(x)$$

we obtain a reduction of $E^X_{\Gamma\times\mathbb{Z}}$ to E^X_H where H is the subgroup of $\mathbb{F}_2$ corresponding which stabilizes the measure ν_0. This subgroup will be amenable (see [44, Appendix C]), which in turn provides a contradiction to the non-amenability of $\Gamma\times\mathbb{Z}$ (see [44, Appendix A] again). (Claim $\dashv$)

So now we obtain an assignment of measures that concentrates on at least three points almost everywhere. Here an observation of Russ Lyons (the rough idea is that a measure on $\partial(\mathbb{F}_2)$ concentrating on more than three points can be assigned a *center* in an $\mathbb{F}_2$-equivariant manner—again, see [44, Appendix C]) gives us a measurable map

$$\eta:X\to\mathbb{F}_2$$

such that
$$\eta((e,\ell)\cdot x) = \alpha((e,\ell),x)\cdot\eta(x)$$
almost everywhere. Replacing $\theta : X \to Y$ by
$$\hat{\theta} : X \to Y,$$
$$x \mapsto \eta(x)^{-1}\cdot\theta(x)$$
we obtain a reduction with an induced cocycle
$$\hat{\alpha} : (\Gamma\times\mathbb{Z})\times X \to \mathbb{F}_2$$
with $\hat{\alpha}((e,\ell),x) = e$ almost everywhere.

Then, as at the proof of [44, 2.2], the ergodicity of the action of $\mathbb{Z}$ on X gives that for any $\gamma\in\Gamma$,
$$x \mapsto \hat{\alpha}((\gamma,0),x)$$
is a.e. invariant. From this it is easily seen that we obtain the required homomorphism into $\mathbb{F}_2$. ⊣

Arguments of this form can be found very clearly in papers by Scott Adams such as [1], though in truth the ideas trace back to Margulis and Mostow by way of Zimmer [70].

Hjorth and Kechris [44] give a self-contained proof of the existence of many $\le_B$-incomparable countable Borel equivalence relations using arguments along these lines, but something similar is implicit in the superrigidity results of [70] to which Adams and Kechris appeal in the course of proving Theorem 3.6. In that case one is dealing not with the compact space $\partial(\mathbb{F}_2)$ but certain compact quotients of an algebraic group (see for instance [70, p. 88]) or the measures on projective space over a locally compact field (see [70, 3.2.1]). The appearance of product group actions is more subtle, but present; superrigidity typically on works for groups of matrices of rank greater than two, when we can hope to find a subgroup which indeed has the form $\Gamma\times\mathbb{Z}$ for Γ non-amenable.

In passing it should also be mentioned that there are applications of Furstenberg's lemma to the theory of the homeomorphism group of the circle. In [27] the combinatorial properties of $M(S^1)$ play a role in understanding what kinds of homomorphisms are possible into $\mathrm{Homeo}(S^1)$.

3.2. Treeable Equivalence Relations

The situation with the countable Borel equivalence relations can in some sense be viewed as resolved. It is a giant mess, with many incomparable examples, but we know it to be the ghastly mess that it is. The situation with treeable countable Borel equivalence relations is far different.

It is well-known that not all treeable equivalence relations are hyperfinite. If one take the free part of the shift action of $\mathbb{F}_2$ on $2^{\mathbb{F}_2}$ then the resulting equivalence relation, $E_{\mathcal{T}\infty}$, is treeable—we define a Borel treeing by $x\,\mathcal{T}\,x'$ if there is a generator of $\mathbb{F}_2$ which moves x to x'. The equivalence relation is not hyperfinite, as shown for instance in [44], since the product measure concentrates on the free part and is $\mathbb{F}_2$-invariant.

It is also known that there is a maximal countable treeable equivalence relation. [48] shows that for any treeable countable Borel equivalence relation E one has $E \leq_B E_{\mathcal{T}\infty}$.

After that precious little is known. Reference [40] gives the existence of a treeable equivalence relation E with $E_0 <_B E <_B E_{\mathcal{T}\infty}$, but at the time of writing it is still open whether there are exactly two non-hyperfinite treeable countable Borel equivalence relations up to Borel reducibility.

3.3. Hyperfiniteness

One of the enduring problems in this field is to determine which countable Borel equivalence relations are hyperfinite. Nowadays this is almost always asked in the Borel context, since the measure theoretic setting is completely understood.

3.11 Theorem (Connes-Feldman-Weiss [8]). *Let G be a countable amenable group acting by measure preserving transformations on a standard Borel probability space (X, μ). Then there is a conull set on which the orbit equivalence relation is hyperfinite.*

Equivalently, we can find a *measurable* reduction of E_G to E_0.

Even this result for very simple groups remains excruciatingly difficult in the Borel setting.

3.12 Theorem (Jackson-Kechris-Louveau [48]). *Let G be a finitely generated group with a nilpotent subgroup H with $[G : H]$, the index of H in G, finite. If G acts by Borel automorphisms on a standard Borel space X, then the resulting equivalence relation E_G is hyperfinite.*

There was a considerable pause until quite recently it was shown:

3.13 Theorem (Gao-Jackson [25]). *Let G be a countable abelian group. If G acts by Borel automorphisms on a standard Borel space X, then the resulting equivalence relation E_G is hyperfinite.*

To give an idea of how difficult these problems have proved, it was not until Theorem 3.13, despite considerable efforts, we even knew that the commensurability equivalence relation on $\mathbb{R} \setminus \{0\}$,

$$r \, E_c \, s \quad \Longleftrightarrow \quad r/s \in \mathbb{Q}$$

was hyperfinite.

It would be natural to conjecture all E_G's arising from the Borel action of an countable amenable group on a standard Borel space are hyperfinite. This conjecture is presently far out of reach, and actually has little in the way of supporting evidence.

4. Effective Cardinality

One way in which to look at the theory of Borel reducibility is as a kind of theory of *Borel cardinality*, and in this sense there are definitely roots in papers by Harvey Friedman such as [17]. If we were to truly embrace a mathematical ontology consisting solely of Borel objects, then we would also be naturally led to consider certain kinds of quotients arising from Borel equivalence relations and to make any comparison along the lines of *cardinality* it seems we would use something like Borel reducibility.

In this sense I am more inclined to consider the theory of $\leq_B$ as something like a theory of cardinality, as opposed to a theory of reducibility of information, as one finds in the theory of Turing reducibility. In fact there are close parallels between the structure of the $\leq_B$-ordering on Borel equivalence relations and the cardinality theory of $L(\mathbb{R})$ under suitable determinacy assumptions.

4.1 Definition. For $A, B \in L(\mathbb{R})$ write

$$|A|_{L(\mathbb{R})} \leq |B|_{L(\mathbb{R})},$$

the $L(\mathbb{R})$ *cardinality of A does not exceed that of B*, if there is an injection

$$i : A \hookrightarrow B$$

in $L(\mathbb{R})$.

4.2 Lemma (Folklore, but see [32]). *Assume* $\mathrm{AD}^{L(\mathbb{R})}$. *Let E, F be Borel equivalence relations on $\mathbb{R}$. If*

$$|\mathbb{R}/E|_{L(\mathbb{R})} \leq |\mathbb{R}/F|_{L(\mathbb{R})}$$

then there is a function

$$f : \mathbb{R} \to \mathbb{R}$$

in $L(\mathbb{R})$ with for all $x_1, x_2 \in \mathbb{R}$

$$x_1 \, E \, x_2 \iff f(x_1) \, F \, f(x_2).$$

Then in parallel to Silver's theorem Woodin has shown:

4.3 Theorem (Woodin). *Let $A \in L(\mathbb{R})$. Then exactly one of the following holds:*

(I) There is an ordinal α with $|A|_{L(\mathbb{R})} \leq |\alpha|_{L(\mathbb{R})}$—in other words, A is well-orderable; or

(II) $|\mathbb{R}|_{L(\mathbb{R})} \leq |A|_{L(\mathbb{R})}$.

And for Harrington-Kechris-Louveau:

4.4 Theorem (Hjorth [33]). *Assume* $\mathrm{AD}^{L(\mathbb{R})}$. *Let* $A \in L(\mathbb{R})$. *Then exactly one of the following holds:*

(I) There is an ordinal α *with* $|A|_{L(\mathbb{R})} \leq |2^\alpha|_{L(\mathbb{R})}$*—in other words,* A *has a well-orderable separating family; or*

(II) $|\mathbb{R}/E_v|_{L(\mathbb{R})} \leq |A|_{L(\mathbb{R})}$.

In (II) we can equivalently say that $\mathcal{P}(\omega)/\mathrm{Fin}$ embeds into A.

The theory of effective cardinality, whether we choose to explicate it using Borel functions and objects or the more joyously playful world of $L(\mathbb{R})$, can also be compared with the idea of *classification difficulty*. If the effective cardinality of A is below that of B, then any objects which succeed as complete invariants for B do as well for A. Here one could even begin certain kinds of wild speculations, to the effect that subconsciously part of the mathematical activity of vaguely searching for some kind of ill-defined *classification theorem* for a class of objects is in fact a query as to its effective cardinality.

Even if circumspection draws us back from grand fantasies along these lines, calculations of Borel cardinality undoubtedly say *something* about classification difficulty. A non-reduction result, saying E not Borel reducible to F, will inform as to which kinds of objects would be *insufficient*, in the Borel category at least, to act as complete invariants for E.

Finally, in the context of $L(\mathbb{R})$ there is a curious refinement of the usual Borel hierarchy theorem.

4.5 Theorem (Hjorth [34]). *Assume* $\mathrm{AD}^{L(\mathbb{R})}$. *Then for every* $\alpha < \beta < \omega_1$

$$|\utilde{\Pi}^0_\alpha|_{L(\mathbb{R})} < |\utilde{\Pi}^0_\beta|_{L(\mathbb{R})}.$$

Thus, not only is $\utilde{\Pi}^0_\alpha$ strictly included in $\utilde{\Pi}^0_\beta$, it is also smaller in effective cardinality. Sharper results are possible here. Andretta et al. [3] determines the exact levels of the Wadge degrees which provide new cardinals in $L(\mathbb{R})$.

5. Classification Problems

Until this point our discussion has largely been concerned with the *structural* properties of the $\leq_B$ ordering. However in the sum total of papers on the subject, the majority deal not with the abstract issues of this partial order, but instead with the specific problems of placing certain naturally occurring equivalence relations in this hierarchy.

Here one pictures specific levels of classification difficulty, and for an example "from the wild" we ask whether it is *smooth*, or *classifiable by countable structures*, or *universal for countable Borel equivalence relations*, and so on.

5.1. Smooth versus Non-Smooth

At the very base, we have the distinction between smooth and non-smooth. If $E \leq_B \mathrm{id}(\mathbb{R})$ then we can classify the E-classes by points in a concrete space.

The very first writings dealing at all with attempting to understand the classification difficulty of mathematical problems as a kind of science in and of itself are due to George Mackey, for instance in [57]. Very specifically he was concerned with understanding which groups have *smooth duals*. Here given $U(\mathcal{H})$, the unitary group of a separable Hilbert space, and irreducible representations

$$\sigma_1, \sigma_2 : \Gamma \to U(\mathcal{H}),$$

we set $\sigma_1 \sim \sigma_2$ if there is some unitary $T \in U(\mathcal{H})$ with

$$T^{-1} \circ \sigma_1(\gamma) \circ T = \sigma_2(\gamma)$$

all $\gamma \in \Gamma$. For Γ countable, the space of unitary representations is a Polish space, since it is a closed subset of

$$U(\mathcal{H})^{\Gamma},$$

and then the irreducible representations form a G_δ subset of those, and hence again Polish in the subspace topology (see for instance [10]). We say that the group Γ has *smooth dual* if the equivalence relation $\sim$ on the irreducibles is smooth. Ultimately it was determined in [66] that the countable groups with smooth duals are exactly the abelian by finite.

Another example is the equivalence relation of matrices over $\mathbb{C}$ considered up to similarity. As remarked in [29], this equivalence relation is smooth, since we can assign to a matrix its canonical Jordan form as a complete invariant.

Some authors following on from this have drawn out from Mackey's writings the entirely general view that in all branches of mathematics the dividing line between classifiable and non-classifiable is given by the smooth versus non-smooth distinction. Indeed the author of [10] appears to flirt with such a opinion. For a rather different take one might look at the introduction of [36]; indeed this work cites many apparent classification theorems—Baer's analysis of rank one torsion free abelian groups, the von Neumann-Halmos analysis of discrete spectrum transformations, the spectral theorem for infinite dimensional unitary operators—for equivalence relations which are non-smooth.

5.2. Universal for Polish Group Actions

It is a well-known result—probably first due to Leo Harrington, but for a proof see [46]—that there is no *universal* Borel equivalence relation: For every Borel equivalence relation E there is another Borel equivalence relation F which does not Borel reduce to E. On the other hand there is a universal

Σ^1_1 equivalence relation, which we might in some sense think of as sitting on the throne above all our examples.

As a practical matter almost all the equivalence relations which seem to have independent interest arise as, or are reducible to, orbit equivalence relations induced by the continuous action of a Polish group on a Polish space. *Among these* there is an uppermost example: $E^{X_\infty}_{G_\infty}$, induced by the continuous action of a Polish group G_∞ on a Polish space X_∞. Although we are stepping slightly outside the subject of Borel equivalence relations as such, $E^{X_\infty}_{G_\infty}$ can be viewed as a kind of extreme, at the opposite end to $\mathrm{id}(\mathbb{R})$, of an equivalence relation with maximal complexity.

In unpublished work Kechris and Solecki showed that in the natural Borel structure compact metric spaces considered up to homeomorphism are $\sim_B$ with, bi-Borel reducible with, $E^{X_\infty}_{G_\infty}$. A recent and published example is given by [26], where they show that complete separable metric spaces considered up to isometry is $\sim_B$ to $E^{X_\infty}_{G_\infty}$, as are closed subsets of the Urysohn space under the orbit equivalence relation induced by the isometry group of this space.

5.3. Universal for S_∞

As shown in [6], for each Polish group G there is a corresponding Polish G-space X with E^X_G universal for orbit equivalence relations of G, moreover in the case of $G = S_\infty$ we can take X to be $\mathrm{Mod}(\mathcal{L})$ for any $\mathcal{L}$ which contains at least one relation of arity two or higher. For future reference let us fix some such universal space for S_∞ orbit equivalence relations and denote the corresponding equivalence relation by $E_{\infty S_\infty}$. Again this is Σ^1_1 but not Borel.

The study of which equivalence relations lie at the level of $E_{\infty S_\infty}$ go right back to the first work of logicians on the $\leq_B$ ordering.[1] One finds $\leq_B$ defined independently, quite by accident with the exact same notation and terminology, in [29] and [18]. The first of these papers deals with the structural result of Theorem 2.2, and the second almost entirely with specific issues of which classes of isomorphism are $\sim_B$ with $E_{\infty S_\infty}$. More generally, given any E which admits classification by countable structures, we automatically have $E \leq_B E_{\infty S_\infty}$ and we can go on to ask when in fact the reverse $\geq_B$ holds as well.

Friedman and Stanley [18] demonstrate, among other examples, that isomorphism of countable groups, countable fields, and countable linear orderings, are all $\sim_B$ $E_{\infty S_\infty}$. (In general, given any $\psi \in \mathcal{L}_{\omega_1,\omega}$, the set of $\mathcal{M} \in \mathrm{Mod}(\mathcal{L})$ satisfying ψ is Borel, and hence forms a standard Borel space in its own right.) More recently [24] show countable boolean algebras up to isomorphism are universal in this class.

[1] I choose these words warily. Although the notion of $\leq_B$ does not appear explicitly in the writings of Mackey, and was first formally isolated in the late 1980s, in some form the idea is already implicit, both in Mackey and in other authors such as [14].

In general most of the questions in this area which can be reasonably posed have been answered. However one wound remains with us from [18]:

Question (Friedman-Stanley). Is isomorphism on countable torsion free abelian groups $\sim_B$ to $E_{\infty S_\infty}$?

This question remains open despite several efforts to give it closure.

5.4. E_∞

If E is a countable equivalence relation then Theorem 1.10 shows E is induced by the Borel action of a countable group, G. Any countable group is realizable as a closed subgroup of S_∞, and so by [6] we have that E admits classification by countable structures.

Thus the countable Borel equivalence relations form a subclass of the equivalence relations admitting classification by countable structures, with a top most example E_∞. The subclass is proper, since $\mathcal{T}_2$ from our earlier examples, corresponding to equality on countable sets of reals, is $<_B$ above E_∞. In fact, the lesson we take away from say [46] is that the countable Borel equivalence relations are only a tiny part of the totality of equivalence relations admitting classification by countable structures.

Nevertheless many important examples lie in the class of countable Borel equivalence relations, and on the whole this has proved to be one of the hardest and most exciting parts of the discipline. In general terms a class of countable structures tends to be $\leq_B E_\infty$, that is to say, *essentially countable*, if there is some notion of finite rank.

Simon Thomas and Velickovic, [69], in answer to questions raised in [42], show that isomorphism on finitely generated groups and fields of finite transcendence degree are $\sim_B E_\infty$.

5.5. E_0

If the diagram has a well-described bottom, $\mathrm{id}(\mathbb{R})$, then it equally has a well-defined second rung, that of E_0. Implicitly in the classical literature on this subject there is a classification theorem in terms of hyperfiniteness.

5.1 Theorem (Baer, in effect; see [19]). *Isomorphism on rank one torsion free abelian groups is hyperfinite.*

In fact, Baer's original result dates back to the 1920s and is not stated in this form. Rather he explicitly associates to each rank one torsion free group a kind of *type*, consisting of a description of orders considered up to finite difference, and goes on to show that the type is a complete invariant. This has generally been considered a satisfactory classification of the rank one torsion free groups, and Fuchs in [19] asks the vague but earnest question whether the rank two torsion free abelian groups can be "classified".

5.2 Definition. For each n let S_n be the subgroups of $(\mathbb{Q}^n, +)$. Let $\cong_n$ be the isomorphism relation on these groups.

Every rank n torsion free abelian group appears as a subgroup of $\mathbb{Q}^n$, and in turn these subgroups all have rank $\leq n$. Moreover two subgroups of $\mathbb{Q}^n$ are isomorphic if and only if there is a linear transformation over the rationals which sends one to the other, and thus the equivalence relation $\cong_n$ has countable classes—and thus $\leq_B E_\infty$.

The authors of [42] observe that Baer had implicitly shown $\cong_1 \leq_B E_0$ and went on to suggest as a possible explication of Fuchs' question whether $\cong_2 \leq_B E_0$. With absolutely no evidence, and armed only with the arrogance of ignorance, [42] conjectured that $\cong_2 \sim_B E_\infty$.

This conjecture was refuted by Thomas in a spectacular sequence of papers. There are several papers around the subject of isomorphism on finite rank torsion free abelian groups, most of which are surveyed in [67].

5.3 Theorem (Thomas [68]). *At every n*

$$\cong_n <_B \cong_{n+1} .$$

1. Introduction

It is sometimes the case that new concepts not only widen our horizons, but also bring difficult old results into main stream and within common knowledge. Properness, introduced and developed by Saharon Shelah, is such a concept and the wealth of results, both old and new, that it provides justifies its early introduction into advanced set theory courses. My aim is to provide an introductory exposition of the theory of proper forcing which will also give some of its interesting applications, to the point where the reader can continue with research papers and with the more advanced material in Shelah's book [15]. I assume that the reader has some knowledge of axiomatic set theory and is familiar with the basics of the forcing method, including some iterated forcing (the consistency proof of Martin's Axiom is sufficient).

We deal here with countable support iteration. This type of iteration appeared in Jensen's consistency proof of the Continuum Hypothesis with the Souslin Hypothesis, and it also appeared in Laver's work on Borel's Conjecture (see [3] and [10]). (These two outstanding results will not be treated here. They have now simpler proofs in which the theory of proper forcing is used to concentrate on the single step of the iteration.)

The chapter contains four parts. First: preservation of properness in countable support iteration. Second: preservation of the ${}^{\omega}\omega$-bounding property, and an application concerning non-isomorphism of ultrapowers of elementarily equivalent structures. Third: preservation of unboundedness, and an application concerning two cardinal invariants, the bounding number and the splitting number. Fourth: Dee-completeness, forcings that add no countable sets of ordinals. These results are all due to Shelah, and most of them appear in Chapters V and VI of his proper forcing book [15], but are presented here at a more concrete level, and sometimes with simpler proofs. (Theorem 5.8, concerning the chromatic number of Hajnal-Máté graphs, is due to the author.)

Our notations follow a standard usage, and the introduction describes them and reviews some elementary facts about forcing. Note that $a \leq b$ in a forcing poset denotes here that b carries more information than a. We say then that b extends a.

A *preorder* is a transitive and reflexive relation on a set (its domain). If $\leq$ is a preorder on A and $a \leq b$ then we say that b *extends* a. We say that $a, b \in A$ are *compatible* if there exists some $x \in A$ that extends a and b. Otherwise, a and b are *incompatible*, and a set of pairwise incompatible elements is called an *antichain*. A set $D \subseteq A$ is *dense* iff

$$\forall a \in A \exists d \in D \ (a \leq d),$$

and D is predense iff

$$\forall a \in A \exists d \in D \ (a \text{ and } d \text{ are compatible}).$$

A preorder is *separative* iff whenever b does not extend a there is an extension of b that is incompatible with a. We say that $P = (A, \leq)$ is a *forcing poset* iff $\leq$ is a separative preorder on A with a minimal element 0_P. We often write $\leq_P$ for the preordering of P. In the context of iteration, preorderings are more convenient than (antisymmetric) orderings, because this is what one naturally obtains. (The reader who prefers orderings can remain with posets of course, but at the price of taking quotients with their notational burden.)

Let $P = (A, \leq)$ be a forcing poset. We say that $G \subseteq A$ is a *filter* iff G is downwards closed: $\forall x \leq y\ (y \in G \longrightarrow x \in G)$, and any two members of G are compatible in G. We say that G is (V, P)*-generic* iff G is a filter over P that meets (has a non-empty intersection with) every dense set of P that lies in V. It is convenient to employ (V, P)-generic filters and to be able to speak about actual generic extensions $V[G]$. I assume that the reader knows how to avoid such ontological commitments.

V^P is the class of all P forcing names in V. If $a \in V^P$ and G is (V, P)-generic, then $a[G]$ (or a^G) denotes the interpretation of a in $V[G]$. It is convenient to define the interpretation of names in such a way that every set in V can be interpreted as a name: $a[G] = \{y[G] \mid \exists p \in G(\langle p, y\rangle \in a)\}$. Usually for a set $a \in V$, $\check{a}$ denotes the (canonical) name of a. However, often a rather than $\check{a}$ is written here in forcing formulas, for graphical clarity and since this is very rarely a source of confusion. If φ is a forcing formula then "φ holds in V^P" means that $0_P \Vdash_P \varphi$. Often $\Vdash_P \varphi$ is written instead of $0_P \Vdash_P \varphi$. Also, I seldom put quotation marks around forcing formulas. The canonical name of the (V, P)-generic filter is denoted $\underset{\sim}{G}$.

The reason for employing separative posets is the following characterization: P is separative iff for any $p, q \in P$, $p \Vdash_P q \in \underset{\sim}{G}$ implies $q \leq p$. Notice that $p, q \in P$ is written rather than the more accurate $p, q \in A$. A poset may be used as a name for its own universe.

The relation $P \lhd Q$ on forcing posets P and Q means that there is a function (projection) $\pi : Q \to P$ such that

1. π is order-preserving (that is, $q_1 \leq_Q q_2$ implies $\pi(q_1) \leq_P \pi(q_2)$), π is onto P, and $\pi(0_Q) = 0_P$.

2. For every $q \in Q$ and $p' \in P$ such that $p' \geq \pi(q)$ there is a $q' \geq q$ in Q such that $\pi(q') = p'$.

If $P \lhd Q$ and $D \subseteq P$ is dense, then $\pi^{-1}(D)$ is dense in Q. Hence, if H is a (V, Q)-generic filter, then its image π“H generates a (V, P)-generic filter.

We say that π is a *trivial* projection iff $\pi(q_1) = \pi(q_2)$ implies that q_1, q_2 are compatible in Q. It can be seen that π is trivial iff for any (V, P)-generic filter G, $\pi^{-1}(G)$ is a (V, Q)-generic filter.

In many applications the projection of $P \lhd Q$ satisfies a stronger property than 2: for any $p \in P$ and $q \in Q$, if $p \geq \pi(q)$ then q has an extension $q_1 \in Q$, denoted $p + q$, such that

1. $\pi(q_1) = p$, and

2. if $r \in Q$ is such that $r \geq q$ and $\pi(r) \geq p$, then $r \geq q_1$.

If this additional property holds then every $p \in P$ can be identified with $i(p) = p + 0_Q$. (That is, P can be assumed to be a subposet of Q.)

If $Q \in V^P$ is a forcing poset (that is, by our convention, forced by the zero condition to be a forcing poset), then $P * Q$, the two-step iteration, is the forcing poset defined as follows. First, some sufficiently large set V_α is chosen so that if $b \in V^P$ is any name then there is already a name $a \in V_\alpha$ such that for any $p \in P$, if $p \Vdash_P b \in Q$, then $p \Vdash_P b = a$. (V_α here is the set of all sets of rank $< \alpha$.) Now form $P * Q$ as the set of all pairs (p, q) such that $p \in P$, $q \in V_\alpha \cap V^P$ and $p \Vdash_P q \in Q$. The preordering $\leq = \leq_{P*Q}$ is defined by

$$(p, q) \leq (p', q') \quad \text{iff} \quad p \leq_P p' \quad \text{and} \quad p' \Vdash_P q \leq_Q q'.$$

The map $\pi(p, q) = p$ is a projection. Usually one does not bother to define the set V_α from which the names q are taken and $P * Q$ is presented as a class.

I will summarize (without proofs) some basic facts about two-step iterations. The two notions, projection and two-step iteration, are closely related. If $P \lhd R$ with projection $\pi : R \to P$, and if G_0 is a (V, P)-generic filter, then form in $V[G_0]$ the following set

$$Q = R/G_0 = \{r \in R \mid \pi(r) \in G_0\}$$

and define a partial, separative preorder $\leq = \leq_{R/G_0}$ on Q by

$$\begin{aligned} r_1 \leq r_2 \quad \text{iff} \quad & \text{every } \leq_R \text{ extension of } r_2 \text{ in } R/G_0 \text{ is} \\ & \leq_R\text{-compatible with } r_1 \text{ in } R/G_0. \end{aligned} \tag{5.1}$$

Equivalently,

$$r_1 \leq r_2 \quad \text{iff} \quad r_1 \leq_R g + r_2 \text{ for some } g \in G_0 \text{ with } \pi(r_2) \leq_P g. \tag{5.2}$$

It follows that $r_1 \leq r_2$ iff for any $g_1, g_2 \in G_0$, $g_1 + r_1 \leq g_2 + r_2$. Sometimes, we write $R/\underset{\sim}{G}_0$, or even R/P, for the V^P name of $Q = R/G_0$.

1.1 Lemma. *Assume $P \lhd R$ as above and G_0 is a (V, P)-generic filter. Suppose that in $V[G_0]$ we have a sequence $\langle r_i \mid i \in \omega\rangle$ such that $r_i \in R/G_0$ and $r_i \leq_{R/G_0} r_{i+1}$. Then there is a sequence $\langle s_i \mid i \in \omega\rangle$ such that each s_i has the form $s_i = g_i + r_i$ for some $g_i \in G_0$ and $s_i \leq_R s_{i+1}$.*

Proof. Suppose that $g_i \in G_0$ is defined. Since $r_i \leq_{R/G_0} r_{i+1}$, there exists a $g \in G_0$ such that $r_i \leq_R g + r_{i+1}$. We may take $g \geq g_i$. Since $\pi(g + r_{i+1}) = g$, we get $g_i + r_i \leq_R g + r_{i+1}$. So that $g_{i+1} = g$ works. $\dashv$

Now let $\underset{\sim}{Q}$ be the name of Q in V^P and form the two-step iteration $P * \underset{\sim}{Q}$. Then R with its original ordering $\leq_R$ is isomorphic to a dense subset of $P * \underset{\sim}{Q}$. Namely, the map $r \mapsto (\pi(r), \check{r})$ is that embedding (where $\check{r}$ is the V^P name of r). Thus R itself can be viewed as a two-step iteration: the projection P followed by the quotient poset whose name is denoted by $R/\underset{\sim}{G}_0$.

Suppose now that some forcing poset $Q \in V^P$ is given and $R = P * Q$ is formed. Then $P \lhd R$, with projection $\pi(p, q) = p$. The stronger property of projections holds here, and we can identify $p \in P$ with $(p, \underset{\sim}{0}) \in P * Q$. Let G_0 be (V, P)-generic, and form R/G_0 as above. $R/G_0 = \{(p, q) \in P * Q \mid p \in G_0\}$ ordered as in (5.1). Then the following holds for $(p_1, q_1), (p_2, q_2) \in R/G_0$

$$(p_1, q_1) \leq_{R/G_0} (p_2, q_2) \quad \text{iff} \quad \exists p \in G_0\ ((p_1, q_1) \leq_{P*Q} (p, q_2)).$$

In $V[G_0]$, both R/G_0 and $Q[G_0]$ can be formed. ($Q[G_0]$ is the interpretation of Q in $V[G_0]$.) These are essentially the same poset. That is, the map

$$i : (p, q) \mapsto q[G_0]$$

taking $(p, q) \in R/G_0$ into the interpretation of q is a trivial projection.

Let P and R be any posets such that $P \lhd R$. We have said that if H is a (V, R)-generic filter, then $G_0 = \pi``H$ is (V, P)-generic, and clearly $H \subseteq R/G_0$. In fact, H is a $(V[G_0], R/G_0)$-generic filter.

On the other hand, if G_0 is (V, P)-generic, and if G_1 is $(V[G_0], R/G_0)$-generic, then $G_1 \subseteq R$ is a (V, R) generic filter and $\pi``G_1 = G_0$.

Now, given a poset P, suppose that $Q \in V^P$ is a poset and $R = P * Q$ is formed. Let G_0 be (V, P)-generic, and G_1 be $(V[G_0], Q[G_0])$-generic, where $Q[G_0]$ is the interpretation of Q in $V[G_0]$. Define in $V[G_0]$ the trivial projection $i : R/G_0 \to Q[G_0]$ as above, and define $H = i^{-1}(G_1)$ in $V[G_0][G_1]$. That is,

$$H = \{(p, q) \in P * Q \mid p \in G_0 \wedge q[G_0] \in G_1\}.$$

Then H is an $(R/G_0, V[G_0])$-generic filter (the pre-image of a trivial projection). Hence (by the preceding paragraph) H is also $(V, P * Q)$-generic, and $\pi``H = G_0$. Abusing the product notation we write $H = G_0 * G_1$.

Let $R = P * Q$. I want to explain the equation $V^R = (V^P)^Q$. We shall define a function

$$\rho : V^R \to V^P$$

from the R-names into the P-names such that the following holds for every (V, R)-generic filter H and $G_0 = \pi``H$ its projection.

1. As we have seen, $G_0 = \pi``H = \{p \in P \mid (p, q) \in R \text{ for some } q \in H\}$ is (V, P)-generic, and H is $(V[G_0], R/G_0)$-generic.

2. For every $a \in V^R$, $a[H] = (\rho(a)[G_0])[H]$. That is, the interpretation $a[H]$ of a in $V[H]$ can be obtained in two steps: first interpret $\rho(a)$ in $V[G_0]$, as a name, and then interpret this name in the remaining forcing over R/G_0.

Usually, we write a/G_0 instead of $\rho(a)[G_0]$ (without mentioning ρ) and then $a/\underset{\sim}{G}_0$ is written for $\rho(a)$.

To define ρ let pair : $V^P \times V^P \to V^P$ be a (definable) map such that for any $\tau_1, \tau_2 \in V^P$, $\text{pair}(\tau_1, \tau_2)[G_0] = \langle \tau_1[G_0], \tau_2[G_0] \rangle$. In plain words, $\text{pair}(\tau_1, \tau_2)$ is a canonical name for the pair formed from (the interpretations of) τ_1 and τ_2. Define now ρ by rank induction so that for any $a \in V^R$

$$\rho(a) = \{\langle \pi(r), \text{pair}(\check{r}, \rho(y)) \rangle \mid r \in R \text{ and } \langle r, y \rangle \in a\},$$

where $\check{r}$ is the canonical P-name for r. Suppose now that H is (V, R)-generic and G_0 is (V, P)-generic through the projection $G_0 = \pi``H$. For any $a \in V^R$

$$\begin{aligned} \rho(a)[G_0] &= \{\text{pair}(\check{r}, \rho(y))[G_0] \mid (r, y) \in a \wedge \pi(r) \in G_0\} \\ &= \{\langle r, \rho(y)[G_0] \rangle \mid (r, y) \in a \wedge r \in R/G_0\}. \end{aligned}$$

Now the required equality

$$\rho(a)[G_0][H] = a[H]$$

is established by the following equalities:

$$\begin{aligned} \rho(a)[G_0][H] &= \{\rho(y)[G_0][H] \mid \exists r \in H((r, y) \in a \wedge r \in R/G_0)\} \\ &= \{y[H] \mid \exists r \in H\ (r, y) \in a\} \\ &= a[H]. \end{aligned}$$

The function ρ can be defined as above whenever $P \lhd R$.

The following lemma is often used.

1.2 Lemma. *Assume that $P \lhd R$, and $D \subseteq R$ is dense. Let G be a (V, P)-generic filter. Then the following holds in $V[G]$: Every $q \in R$ with $\pi(q) \in G$ has an extension $d \in D$ with $\pi(d) \in G$. In other words, $D \cap R/G$ is dense in R/G.*

Proof. Suppose that $p \in P$ forces that $\pi(q) \in \underset{\sim}{G}$. Then $\pi(q) \leq_P p$, and hence there is an extension q_1 of q with $\pi(q_1) = p$. Now extend further q_1 to a condition $d \in D$, and then $\pi(d)$ forces $d \in D \cap R/G$ as required. ⊣

We will encounter the following situation in Sect. 3.

1.3 Lemma. *$Q_0 \lhd Q_1 \lhd Q_2$ are posets with projections $\pi_{i,j} : Q_i \to Q_j$ for $0 \leq j < i \leq 2$. The projections commute: $\pi_{2,0} = \pi_{1,0} \circ \pi_{2,1}$. Suppose G_0 is a (V, Q_0)-generic filter, and form $Q_1' = Q_1/G_0$ and $Q_2' = Q_2/G_0$. Then $\pi_{2,1} : Q_2' \to Q_1'$ is a projection and the quotient Q_2'/Q_1' can be seen to be exactly Q_2/Q_1.*

Let $\underset{\sim}{G}_{(Q_1/G_0)}$ be the canonical name in $V[G_0]$ of the Q_1/G_0 generic filter. Then

$$(Q_2/G_0)/\underset{\sim}{G}_{(Q_1/G_0)} \in V[G_0]^{Q_1/G_0}.$$

If G_1 is a $(V[G_0], Q_1/G_0)$-generic filter, then the interpretation of that name, $(Q_2/G_0)/G_1$, is equal to Q_2/G_1. In addition, G_1 is (V, Q_1)-generic and if $\underset{\sim}{f} \in V^{Q_2}$ then $(\underset{\sim}{f}/G_0) \in V[G_0]^{Q_1/G_0}$ and $(\underset{\sim}{f}/G_0)/G_1$ is $\underset{\sim}{f}/G_1$.

1.1. Countable Support Iterations

We deal here only with countable support iterations. An iteration of length γ (an ordinal) is defined by induction. For this, one needs a scheme to produce the next poset in the iteration. Suppose that this scheme is given by some function F (a formula that defines a function) such that for every forcing poset P, $F(P) = Q$ is in V^P a forcing poset. Then the iteration $\langle P_\alpha \mid \alpha \leq \gamma \rangle$ is defined so that:

1. Members of P_α are functions defined on α.
2. If $\alpha < \gamma$ then $P_\alpha = \{f \restriction \alpha \mid f \in P_\gamma\}$.
3. Every $f \in P_\gamma$ has a countable support, which is a set $S_f = S \subseteq \gamma$ such that f is trivial outside of S, that is, $f(\xi)$ is the P_ξ name of the zero condition for $\xi \in \gamma \setminus S$.

The definition of the iteration is as follows.

1. P_0 is the trivial poset consisting of the minimal condition $\emptyset$ alone, and V^{P_0} is (or is isomorphic to) V. If P_α is already defined and $\alpha < \gamma$, then $P_{\alpha+1}$ is defined as the set of all functions f defined on $\alpha + 1$ such that $f \restriction \alpha \in P_\alpha$, $f(\alpha) \in V^{P_\alpha}$ and
$$f \restriction \alpha \Vdash_{P_\alpha} f(\alpha) \in Q,$$
where $Q = F(P_\alpha)$. We define $f_1 \leq f_2$ iff $f_1 \restriction \alpha \leq f_2 \restriction \alpha$ and $f_2 \restriction \alpha \Vdash_{P_\alpha} f_1(\alpha) \leq f_2(\alpha)$. It is evident that $P_{\alpha+1}$ is defined to be isomorphic to $P_\alpha * Q$. (Since we want $P_{\alpha+1}$ to be a set, we must limit the possible values of $f(\alpha)$.)
2. If $\delta \leq \gamma$ is a limit ordinal and P_i is defined for every $i < \delta$, then P_δ is the set of all countably supported functions f defined on δ and such that for every $\alpha < \delta$, $f \restriction \alpha \in P_\alpha$. Thus for every $\alpha < \delta$, $f(\alpha) \in V^{P_\alpha}$ and f has a countable support. Define $f_1 \leq f_2$ iff for every $\alpha < \delta$, $f_1 \restriction \alpha \leq_{P_\alpha} f_2 \restriction \alpha$.

We assume that the reader knows the basic properties of these countable support iterations: first, that they form forcing posets, and then, that if $\gamma_0 < \gamma$ then $\pi : P_\gamma \to P_{\gamma_0}$ defined by $\pi(p) = p \restriction \gamma_0$ is a projection of P_γ onto P_{γ_0}. If $q \in P_{\gamma_0}$ and $q \geq \pi(p)$, then $p_1 = q + p$ is defined in P_γ by the requirement that

$$p_1(\xi) = q(\xi) \quad \text{for } \xi < \gamma_0 \quad \text{and} \quad p_1(\xi) = p(\xi) \quad \text{for } \xi \geq \gamma_0. \tag{5.3}$$

Strictly speaking P_{γ_0} is not a subset of P_γ, but in practice we identify $f \in P_{\gamma_0}$ with $f + 0_\gamma$ which is the trivial extension of f on γ. The ordering on P_γ is denoted $\leq_{P_\gamma}$ or just $\leq_\gamma$ for clarity. We shall often write $\Vdash_\gamma$ instead of $\Vdash_{P_\gamma}$.

The poset name $F(P_\alpha) = Q_\alpha$ is called "the αth iterand". In complex consistency proofs, the exact definition of F, and even its existence, is often passed over in silence. The term "bookkeeping device" is often invoked to refer to that part of the construction which is omitted.

2. Properness and Its Iteration

In this section we define *properness* and prove that the countable support iteration of proper forcing is proper. A slightly different proof can be read in [4].

In discussing proper forcing, the phrase "let λ be a sufficiently large cardinal, and H_λ the collection of sets of cardinality hereditarily $< \lambda$" appears so often that it deserves a remark. The role of H_λ is to encapsulate enough of the universe of sets V to reflect the statements in which we are interested. So the exact meaning of "sufficiently large" depends on the circumstances, and other reflecting sets such as V_λ can replace H_λ (but less naturally). When dealing with a forcing poset of cardinality κ, any cardinal $\lambda > 2^\kappa$ is sufficiently large for our purposes. We will be interested in countable elementary substructures of $\langle H_\lambda, \in, <, \text{etc.}\rangle$, where $<$ is some fixed well-ordering of H_λ, and etc. may include the poset P, the forcing relation, and other relevant parameters. The role of the well-ordering $<$ is to allow for inductive constructions. For notational clarity we just write $M \prec H_\lambda$, and omit the $\in$ relation, the well-order and the other parameters. We often say "$M \prec H_\lambda$ is as usual" to indicate that H_λ refers to a richer structure and the reader may have to include in M all those parameters that are relevant.

So let P be a poset, $M \prec H_\lambda$ be countable, with $P \in M$, as usual, and let G be (V, P)-generic. Define $M[G] = \{a[G] \mid a \in M\}$. So $M[G]$ is the set of all interpretations of names that lie in M. Since the forcing relation is (definable) in M (by virtue of the largeness of λ) the Forcing Theorem implies that $M[G] \prec H_\lambda[G]$ (for details, see [15, Theorem 2.11]). However $M[G]$ is not necessarily a generic extension of M. What does it mean that $M[G]$ is a generic extension of M? This is a delicate question because of the special status of the members of M: on one account they are just points with no other meaning than that provided by the structure M itself, and on the other hand, they are bona fide members of H_λ and carry information of which M is not aware. By collapsing M onto a transitive structure only the local properties remain and we are no longer confused by this double role. So let $\pi : M \to \bar{M}$ be the transitive collapsing of M, and let $\pi``G = \bar{G}$ be the image of G. Then genericity of G over M means that $\bar{G}$ is $\bar{M}$-generic over $\pi(P)$. That is, $\bar{G}$ has a non empty intersection with every dense subset of $\pi(P)$ that lies in $\bar{M}$. I find that collapsing is illuminating, but of course one can give a more direct definition: G is (M, P)*-generic* iff for any $D \subseteq P$ dense in P such that $D \in M$, $G \cap D \neq \emptyset$.

Properness of P, as we shall see in a moment, ensures that this is the normal situation. A good example for a non-proper forcing is the forcing P that collapses ω_1 to ω. (The "conditions", the members of P, are finite functions from ω into ω_1 and the ordering is extension.) Here it is obvious that the generic function $g : \omega \to \omega_1$ onto ω_1 is not $\bar{M}$-generic, since it involves ordinals not in $\bar{M}$.

To define properness, we need the concept of an (M, P)-generic condition.

Let P be a poset and $M \prec H_\lambda$, with $P \in M$, be an elementary substructure. A condition $q \in P$ is said to be (M,P)-*generic* iff for every dense subset $D \subseteq P$ such that $D \in M$, $D \cap M$ is predense above q, i.e., for any $q_1 \geq q$, there is a $q_2 \geq q_1$ extending some $d \in D \cap M$. Sometimes, when the identity of P is clear from the context, we just say that q is an "M-generic" condition.

In the proof of the properness preservation theorem we shall employ the following

2.1 Lemma. *A condition q is (M,P)-generic iff for every $D \in M$ dense in P there is a name $\underset{\sim}{p} \in V^P$ such that*

$$q \Vdash_P \underset{\sim}{p} \in M \cap D \cap \underset{\sim}{G}.$$

2.2 Definition. A poset P is called *proper* iff for any $\lambda > 2^{|P|}$ and countable $M \prec H_\lambda$ with $P \in M$, every $p \in P \cap M$ has an extension $q \geq p$ that is an (M,P)-generic condition.

Properness, and genericity of a condition have the following equivalent property which is often used. A condition q is (M,P)-generic iff

$$q \Vdash_P M[\underset{\sim}{G}] \cap \mathrm{On} = M \cap \mathrm{On}.$$

Assuming a predicate V that denotes the ground model, we can replace this by

$$q \Vdash_P M[\underset{\sim}{G}] \cap V = M \cap V.$$

Thus P is proper iff for any $\lambda > 2^{|P|}$ and countable $M \prec H_\lambda$ with $P \in M$, every $p \in P \cap M$ has an extension $q \geq p$ such that for every $\tau \in M \cap V^P$ and every $q' \geq q$, if $q' \Vdash_P \tau \in V$, then $q' \Vdash_P \tau \in M$.

We will prove that in the definition of properness, the quantification "for any $\lambda > 2^{|P|}$ and every countable $M \prec H_\lambda$" can be weakened to "for $\lambda = (2^{|P|})^+$ (or, for some $\lambda > 2^{|P|}$) and for a closed unbounded set of $M \prec H_\lambda \ldots$", and the resulting definition is equivalent to the original. (See also [15, Chap. III].)

One of the first consequences of properness is the following. If P is proper, and G a (V,P)-generic filter, then $\aleph_1$ is not collapsed in $V[G]$. Moreover, every countable set of ordinals in $V[G]$ is included in an old countable set (from V). Indeed, if q is (M,P)-generic and $\tau \in M$ is a name for an ordinal, then q forces τ to be in M. (By the alternative definition, or argue as follows. The set D of conditions that determine the value of τ is dense in P and is in M, and hence $D \cap M$ is dense above q which implies that every extension of q can be further extended to force $\tau = \alpha$ for some $\alpha \in M$.) It follows from this observation that if P is proper and forcing with P introduces no new subsets of ω, then forcing with P adds no new countable sets of ordinals.

The simplest examples of proper forcing posets are the countably closed posets and the c.c.c. posets. It is illuminating to realize that despite the obvious difference between these two families of posets, they have (at some level of abstraction) the same reason for not collapsing ω_1—namely their properness. If P is c.c.c., then *any* condition is (M, P)-generic, and if P is countably closed then any upper bound of an (M, P)-complete sequence is (M, P)-generic. For an arbitrary proper poset, finding generic conditions is usually the main burden of the proof.

A large family of posets was defined by Baumgartner [1], and called Axiom A posets. It turns out that they are all proper.

2.3 Definition. A poset $(P, \leq)$ *satisfies* Axiom A iff there are partial orders $\langle \leq_i \mid i < \omega \rangle$ on P, with $\leq_0 = \leq$, such that:

1. For $i < j$, $\leq_j \subseteq \leq_i$.
2. For every $p \in P$, dense $D \subseteq P$, and $n < \omega$, there are $p' \in P$ and countable $D_0 \subseteq D$ such that $p \leq_n p'$ and D_0 is predense above p' (i.e., if $p'' \geq p'$ then p'' is compatible with some condition in D_0).
3. If $\langle p_i \in P \mid i \in \omega \rangle$ is a sequence such that $p_i \leq_i p_{i+1}$, then there is a $p \in P$ (called the *fusion* of the sequence) such that for every i, $p_i \leq_i p$.

A poset $(P, \leq)$ *satisfies* Axiom A^* iff in addition the D_0 above can be taken to be finite.

The Sacks-Spector conditions (subtrees of $2^{<\omega}$ with arbitrarily high splitting) satisfies Axiom A^*.

It is easy to prove that any Axiom A forcing is proper (see Baumgartner [1]). In fact, if $M \prec H_\lambda$ is countable with $P \in M$ and $p_0 \in P \cap M$, then for any i there is an (M, P)-generic condition p such that $p_0 \leq_i p$.

The projection of a proper poset is also proper. That is, if $P \lhd Q$ and Q is proper, then P is proper. In fact, if $M \prec H_\lambda$ and $q \in Q$ is (M, Q)-generic, then $\pi(q)$ is (M, P)-generic.

Another equivalent definition of when a condition is (M, P)-generic can be obtained from the following lemma.

2.4 Lemma. *Let P be a poset, $M \prec H_\lambda$ countable with $P \in M$ (where $\lambda > 2^{|P|}$ so that $\mathcal{P}(P) \in H_\lambda$) and suppose that $p \in P$ is some (M, P)-generic condition. If $x, y \in M \cap V^P$ are such that $p \Vdash x \in y$, then for some $p_1 \geq p$ and $(a, b) \in y \cap M$, where $a \in P$ and $b \in V^P$, $a \leq p_1$ and $p_1 \Vdash x = b$ hold.*

Proof. In order to illustrate in a simple setting two possible approaches, we give two proofs for this lemma. It follows immediately from the definition of forcing that there is an extension of p (denoted p_1) and a pair $(a, b) \in y$ such that $p_1 \geq a$ and $p_1 \Vdash x = b$. The point of the lemma, however, is to get such a pair (a, b) in M whenever p is (M, P)-generic. Consider the set

$$E = \{p_0 \in P \mid \exists (a, b) \in y \ (a \leq p_0 \text{ and } p_0 \Vdash x = b)\}.$$

Note that $E \in M$ is an open subset of P that is dense above p. Let $F \subseteq P$ be the set of all conditions that are in E or else are incompatible with every condition in E. Then $F \in M$ is dense (open) and so p is compatible with some $p_0 \in F \cap M$. Since E is dense above p, $p_0 \in E \cap M$ and hence the defining clause applies to p_0. But M is an elementary substructure, and hence there is a pair $(a, b) \in y \cap M$ with $a \le p_0$ and such that $p_0 \Vdash x = b$. This proves the lemma.

For the second proof, let $\pi_0 : M \to \bar{M}$ be the transitive collapse. Let G be an arbitrary (V, P)-generic filter containing p. Define $G_0 = \pi_0 “G \cap M$. Then G_0 is a $(\bar{M}, \pi_0(P))$-generic filter and π_0 can be extended to $\pi_1 : M[G] \to \bar{M}[G_0]$. For every $m \in M \cap V^P$, $\pi_1(m[G]) = \pi_1(m)[G_0]$. We have $M[G] \prec H_\lambda[G]$, so that π_1^{-1} is an elementary embedding of $\bar{M}[G_0]$ into $H_\lambda[G]$.

Since $p \Vdash x \in y$, $x[G] \in y[G]$. Hence $\pi_1(x[G]) \in \pi_1(y[G]) = \pi_1(y)[G_0]$. So there are $(a_0, b_0) \in \pi_1(y)$ such that $a_0 \in G_0$ and $\pi_1(x[G]) = b_0[G_0]$. Hence, for $(a, b) = \pi_1^{-1}(a_0, b_0)$, $(a, b) \in y \cap M$ and we have $a \in G$ and $x[G] = \pi_1^{-1}(b_0[G_0]) = b[G]$.

Back in V, let $p_1 \ge p$ be an extension that forces these facts about (a, b). Thus, $p_1 \Vdash a \in \utilde{G}$ (so that $p_1 \ge a$) and $p_1 \Vdash x = b$, as required. $\dashv$

The next lemma is used in the proof that the two-step iteration of proper posets is proper.

2.5 Lemma. *Let P be a forcing poset, and $Q \in V^P$ a forcing poset in V^P. Let $M \prec H_\lambda$ be countable with $P, Q \in M$, and suppose that λ is sufficiently large. Then $(p, q) \in P * Q$ is $(M, P * Q)$-generic iff*

$$p \text{ is } (M, P)\text{-generic}$$

and

$$p \Vdash_P q \text{ is } (M[\utilde{G}_0], Q)\text{-generic},$$

where $\utilde{G}_0$ is the canonical name for the (V, P)-generic filter.

Now we prove that the iteration of two proper posets is again proper, and in fact the following stronger claim holds which we establish for later use.

2.6 Lemma. *Suppose that P_0 is proper, and P_1 is proper in V^{P_0} (that is, P_1 is a P_0-name and 0_{P_0} forces it to be proper). Let $R = P_0 * P_1$ be the two-step iteration, and let $\pi : R \longrightarrow P_0$ be the projection defined by $\pi(p, \utilde{q}) = p$. Suppose that $M \prec H_\lambda$ is countable with $R \in M$. Then every $r \in R \cap M$ an M-generic extension. Moreover, the following holds: Suppose that $p_0 \in P_0$ is an (M, P_0)-generic condition. For any name $\utilde{r} \in V^{P_0}$ if*

$$p_0 \Vdash_{P_0} \utilde{r} \in M \cap R \quad \text{and} \quad \pi(\utilde{r}) \in \utilde{G}_0 \tag{5.4}$$

($\utilde{G}_0$ is the canonical name of the generic filter over P_0) then there is some $\utilde{p_1} \in V^{P_0}$ such that $(p_0, \utilde{p_1})$ is an M-generic condition and

$$(p_0, \utilde{p_1}) \Vdash_R \utilde{r} \in \utilde{G}.$$

(Being a P_0-name, $\utilde{r}$ is also an R-name and it may appear in R-forcing formulas. $\utilde{G}$ is the canonical name of the (V, R)-generic filter.)

Proof. Let G_0 be any (V, P_0)-generic filter containing p_0. The name $\underset{\sim}{r}$ is not necessarily in M, but by (5.4) it is interpreted as some condition r in $M \cap R$ such that $\pi(r) \in G_0$. Say $r = (r_0, \underset{\sim}{r_1})$ where $\underset{\sim}{r_1}$ is a P_0 name for a condition in P_1. In $M[G_0]$, $\underset{\sim}{r_1}$ is interpreted as a condition r_1 in (the G_0 interpretation of) P_1. Since P_1 is proper, there is an extension p_1 of r_1 that is $M[G_0]$-generic. Let $\underset{\sim}{p_1}$ be a name of p_1 forced to have all of these properties. In particular,

$$p_0 \Vdash_{P_0} \underset{\sim}{p_1} \text{ extends the second component of } \underset{\sim}{r} \text{ in } P_1.$$

Then $u = (p_0, \underset{\sim}{p_1})$ is as required. Firstly, Lemma 2.5 gives that

$$u \text{ is } (M, R)\text{-generic.}$$

Secondly,

$$u \Vdash_R \underset{\sim}{r} \in \underset{\sim}{G} \tag{5.5}$$

is proved as follows. Observe that $\underset{\sim}{r}$ is not a condition, but a V^{P_0} name and hence a V^R name of a condition in R. However, any condition above p_0 can be extended to decide the value of $\underset{\sim}{r}$ as a condition in R. Suppose any $u' \in R$ that extends u and determines for some $r \in R$ that

$$u' \Vdash \underset{\sim}{r} = r,$$

where $r \in R$ is of the form $r = (r_0, \underset{\sim}{r_1})$. To prove (5.5) we will show that $u' \Vdash r \in \underset{\sim}{G}$. Assume that $u' = (u'_0, \underset{\sim}{u'_1})$. Since $u'_0 \Vdash_{P_0} \pi(\underset{\sim}{r}) \in \underset{\sim}{G}_0$, and as P_0 is separative, $r_0 \leq u'_0$. But

$$u'_0 \Vdash \underset{\sim}{p_1} \text{ extends } \underset{\sim}{r_1} \text{ (the second component of } \underset{\sim}{r}\text{)},$$

and this implies $r \leq u'$ in R. Thus $u' \Vdash r \in \underset{\sim}{G}$. Since u' is an arbitrary extension of u that identifies $\underset{\sim}{r}$, $u \Vdash_R \underset{\sim}{r} \in \underset{\sim}{G}$. ⊣

2.1. Preservation of Properness

We prove here that the countable support iteration of proper forcing posets is proper. The expression "$\langle P_\alpha \mid \alpha \leq \gamma \rangle$ is an iteration of posets that satisfy property X" (such as properness) means that each successor stage $P_{\alpha+1}$ is isomorphic to some $P_\alpha * Q_\alpha$ formed with an iterand $Q_\alpha \in V^{P_\alpha}$ that satisfies property X in V^{P_α}.

2.7 Theorem. *Let δ be a limit ordinal. Suppose that $\langle P_\alpha \mid \alpha \leq \delta \rangle$ is a countable support iteration of proper forcings. Then P_δ is proper.*

We assume that δ is a limit ordinal, since the successor case was handled by Lemma 2.6. The inductive proof of the theorem is a paradigm for all preservation theorems given here, but first an intuitive (yet incorrect) overview of the proof is given. Let be given a countable structure $M \prec H_\lambda$

with $P_\delta \in M$ and a specified condition $p_0 \in P_\delta \cap M$. We are required to extend p_0 to an (M, P_δ)-generic condition. This is done in ω steps. Fix an increasing ω-sequence $\gamma_i \in \delta \cap M$, unbounded in $\delta \cap M$. (The sequence itself is not assumed to be in M, only its members.) At the n-th step we want to define $q_n \in P_{\gamma_n}$ that is (M, P_{γ_n})-generic, and is an extension of $p_0 \restriction \gamma_n$. We also require that $q_{n+1} \restriction \gamma_n = q_n$. The final condition $q = \bigcup_{n<\omega} q_n$ is in P_δ, and it extends the given condition p_0 since each initial condition does. Now at the n-th step we must also take care of D_n, the n-th dense set of P_δ in M in some pre-fixed enumeration of all the dense subsets of P_δ that are in M. It follows that we need at this step an auxiliary condition $p_n \in P_\delta \cap M \cap D_{n-1}$ that extends p_{n-1} and such that q_n extends $p_n \restriction \gamma_n$. We will first extend p_n to some $p_{n+1} \in D_n$ and then commit all the following q_m's to extend $p_{n+1} \restriction \gamma_m$ as well. Surely we cannot succeed in such a construction, for if we do, then $q \in \bigcap_{n\in\omega} D_n$ and this is too much (unless no reals are added, but this is a different story). So where did we go astray? When we claimed that p_{n+1} with $p_{n+1} \restriction \gamma_n \le q_n$ can be found in D_n. We could do that only in case $\{r \in P_{\gamma_n} \cap M \mid r \le q_n\}$ is a generic filter over M. Otherwise, we may only have a *name* for such a p_{n+1}. It turns out that this is enough for the proof, but we must formulate a slightly more involved inductive assumption.

2.8 Lemma (The Properness Extension Lemma). *Let $\langle P_\alpha \mid \alpha \le \gamma\rangle$ be a countable support iteration of proper forcing posets. Let λ be a sufficiently large cardinal. Let $M \prec H_\lambda$ be countable, with $\gamma, P_\gamma \in M$ etc. For any $\gamma_0 \in \gamma \cap M$, and $q_0 \in P_{\gamma_0}$ that is (M, P_{γ_0})-generic the following holds. If $\underset{\sim}{p_0} \in V^{P_{\gamma_0}}$ is such that*

$$q_0 \Vdash_{P_{\gamma_0}} \underset{\sim}{p_0} \in P_\gamma \cap M \quad \textit{and} \quad \underset{\sim}{p_0} \restriction \gamma_0 \in \underset{\sim}{G}_0$$

where $\underset{\sim}{G}_0$ is the canonical name for the generic filter over P_{γ_0}, then there is an (M, P_γ)-generic condition q such that $q \restriction \gamma_0 = q_0$ and

$$q \Vdash_{P_\gamma} \underset{\sim}{p_0} \in \underset{\sim}{G} \tag{5.6}$$

where $\underset{\sim}{G}$ is the canonical name of the generic filter over P_γ, and we view $\underset{\sim}{p_0}$ as a name in V^{P_γ}.

An equivalent formulation of (5.6) is that for every $q' \ge q$, if q' identifies $\underset{\sim}{p_0}$ (that is, $q' \Vdash_{p_\gamma} \underset{\sim}{p_0} = p_0$, for some $p_0 \in P_\gamma$), then $p_0 \le q'$.

We emphasize that $\underset{\sim}{p_0}$ is not necessarily in M, but it is forced by q_0 to be a condition in $P_\gamma \cap M$.

Proof of Theorem 2.7. Given $M \prec H_\lambda$ and $p_0 \in P_\delta$, we apply the lemma with $\lambda_0 = 0$ and p_0 viewed as a name in the trivial poset $P_0 = \{\emptyset\}$. $\dashv$

Proof of Lemma 2.8. The proof of the lemma is by induction on γ. For γ a successor, the lemma was essentially stated as Lemma 2.6. (There are two subcases here. $\gamma_0 + 1 = \gamma$, and $\gamma_0 + 1 < \gamma$. The first subcase is essentially stated as Lemma 2.6, and the second subcase is reduced to the first by the inductive hypothesis.)

So assume that γ is a limit ordinal. Pick an increasing sequence $\langle \gamma_i \mid i \in \omega \rangle$ cofinal in $\gamma \cap M$, with $\gamma_i \in M$ and where γ_0 is the given ordinal. (Note that γ may well be uncountable but $\gamma \cap M$ is a countable set of ordinals.) Fix an enumeration $\{D_i \mid i \in \omega\}$ of all the dense subsets of P_γ that are in M.

We will define by induction on $n < \omega$ conditions $q_n \in P_{\gamma_n}$ and names $\underset{\sim}{p}_n$ in $V^{P_{\gamma_n}}$ such that:

1. $q_0 \in P_{\gamma_0}$ is the given condition; $q_n \in P_{\gamma_n}$ is (M, P_{γ_n})-generic; and $q_{n+1} \restriction \gamma_n = q_n$.

2. $\underset{\sim}{p}_0$ is given. $\underset{\sim}{p}_n$ is a P_{γ_n}-name such that

$$q_n \Vdash_{P_{\gamma_n}} \quad \underset{\sim}{p}_n \text{ is a condition in } P_\gamma \cap M \text{ such that:}$$

(a) $\underset{\sim}{p}_n \restriction \gamma_n \in \underset{\sim}{G}_{\gamma_n}$,

(b) $\underset{\sim}{p}_{n-1} \leq_\gamma \underset{\sim}{p}_n$,

(c) $\underset{\sim}{p}_n$ is in D_{n-1} (for $n > 0$).

(Here and subsequently $\Vdash_\gamma$ may be written instead of $\Vdash_{P_\gamma}$ and $\leq_\gamma$ instead of $\leq_{P_\gamma}$.) To see where we are going, suppose that q_n, $\underset{\sim}{p}_n$ have already been constructed for all $n \in \omega$. Then let $q = \bigcup_n q_n$. We claim that for every n:

$$q \Vdash_\gamma \underset{\sim}{p}_n \in \underset{\sim}{G}_\gamma. \tag{5.7}$$

It can be seen that this claim implies that q is (M, P_γ)-generic (because $\underset{\sim}{p}_n$ is forced to be in $D_{n-1} \cap M$, and by Lemma 2.1).

To prove the claim in (5.7), note first that by 2(b), for every $n < m$,

$$q \Vdash_\gamma \underset{\sim}{p}_n \leq_\gamma \underset{\sim}{p}_m.$$

By 2(a), for every m,

$$q \Vdash_\gamma \underset{\sim}{p}_m \restriction \gamma_m \in \underset{\sim}{G}_{\gamma_m}.$$

Hence, for every m and n such that $m \geq n$

$$q \Vdash_\gamma \underset{\sim}{p}_n \restriction \gamma_m \in \underset{\sim}{G}_{\gamma_m}.$$

This implies that for every n

$$q \Vdash_\gamma \underset{\sim}{p}_n \in \underset{\sim}{G}_\gamma.$$

Indeed, for any q' extending q in P_γ, if $q' \Vdash \underset{\sim}{p}_n = p$, for some $p \in P_\gamma$, then

$$q' \Vdash_\gamma p \in P_\gamma \cap M \quad \text{and} \quad p \restriction \gamma_m \in \underset{\sim}{G}_{\gamma_m}, \quad \text{for } m \geq n.$$

Since the posets P_{γ_n} are separative, it follows that $p\restriction\gamma_m \le q'$ for every m. Hence $p \le q'$, because $p \in M$ and thus $\mathrm{dom}(p) \subseteq \gamma \cap M$, so that $\mathrm{dom}(p) \subseteq \sup\{\gamma_m \mid m < \omega\}$. So $q' \Vdash p \in \underset{\sim}{G}_\gamma$. This holds for any extension q' of q that determines $\underset{\sim}{p_n}$, and hence $q \Vdash \underset{\sim}{p_n} \in \underset{\sim}{G}_\gamma$.

Returning now to the inductive construction, assume that q_n and $\underset{\sim}{p_n}$ have been constructed. We will first define $\underset{\sim}{p_{n+1}}$ in $V^{P_{\gamma_n}}$, and then q_{n+1}. Imagine a generic extension $V[G_n]$, made via P_{γ_n}, such that $q_n \in G_n$. Then $\underset{\sim}{p_n}[G_n]$, the realization of $\underset{\sim}{p_n}$, is some condition p_n in $P_\gamma \cap M$ such that $p_n\restriction\gamma_n \in G_n$. Since q_n is (M, P_{γ_n})-generic, $G_n \cap M$ intersects every dense subset of P_{γ_n} that lies in M. An easy density argument now gives a condition $p_{n+1} \in D_n \cap M$, extending p_n, such that $p_{n+1}\restriction\gamma_n \in G_n$. (Argue in the collapsed structure $\bar{M}$ and use Lemma 1.2.) We let $\underset{\sim}{p_{n+1}}$ be a P_{γ_n}-name of p_{n+1}, forced by q_n to satisfy all of these properties of p_{n+1}. That is,

$$q_n \Vdash_{\gamma_n} \underset{\sim}{p_{n+1}} \in D_n \cap M, \quad \underset{\sim}{p_n} \le_\gamma \underset{\sim}{p_{n+1}}, \quad \text{and} \quad \underset{\sim}{p_{n+1}}\restriction\gamma_n \in \underset{\sim}{G}_{\gamma_n}.$$

Now that $\underset{\sim}{p_{n+1}}$ is defined, apply the inductive assumption of this lemma to $\gamma_n < \gamma_{n+1}$, q_n, and $\underset{\sim}{p_{n+1}}\restriction\gamma_{n+1}$. This gives $q_{n+1} \in P_{\gamma_{n+1}}$ that satisfies the required inductive assumptions. ⊣

We draw two further conclusions from the Properness Extension Lemma.

2.9 Corollary. *Let $\langle P_i \mid i \le \delta\rangle$ be a countable support iteration of proper forcings.*

1. *Suppose that $\mathrm{cf}(\delta) > \omega$. Then any real (or countable set of ordinals) in V^{P_δ} already appears in V^{P_i} for some $i < \delta$.*
2. *Suppose that $\mathrm{cf}(\delta) = \omega$ and $\langle\gamma_i \mid i \in \omega\rangle$ is increasing and cofinal in δ. Then for every name $\underset{\sim}{f} \in V^{P_\delta}$ of a countable sequence of ordinals and every condition $p_0 \in P_\delta$, there is an extension $p \ge p_0$ such that for every $n \in w$, there is a P_{γ_n} name c_n such that $p \Vdash_\delta \underset{\sim}{f}(n) = c_n$.*

Proof. Let $\underset{\sim}{f} \in V^{P_\delta}$ be a real. Find a countable $M \prec H_\lambda$ with $\underset{\sim}{f} \in M$, and let $q \in P_\delta$ be some (M, P_δ)-generic condition (given by the lemma). If $i = \sup(M \cap \delta)$ then $i < \delta$. The support of any condition in $P_\delta \cap M$ is included in i and $\underset{\sim}{f} \cap M$ can be viewed as a V^{P_i} name forced by q to be equal to $\underset{\sim}{f}$.

For item 2, let $M \prec H_\lambda$ be countable, containing all relevant parameters (including the name of the real). Repeat the proof of the Extension Lemma with $\langle\gamma_i \mid i \in \omega\rangle$ as the cofinal sequence and instead of dealing with all dense sets let D_{n-1} be the set of conditions that determine $\underset{\sim}{f}(n-1)$. Let p be the resulting (M, P_δ)-generic condition. ⊣

2.2. The $\aleph_2$-Chain Condition

In almost all applications given here, we assume the Continuum Hypothesis (CH) in the ground model, and iterate ω_2 proper forcings, each of size $\aleph_1$.

To conclude that $\aleph_2$ and higher cardinals are not collapsed, the following theorem can be invoked. More general chain condition theorems (which deal with bigger posets) can be found in Shelah's book ([15, Chap. VIII] on the p.i.c. condition, for example) and in Sect. 5.4.

2.10 Theorem. *Assume* CH. *Let $\langle P_i \mid i \leq \delta\rangle$ be a countable support iteration of length $\delta \leq \omega_2$ of proper forcings of size $\aleph_1$. Then P_δ satisfies the $\aleph_2$-c.c.*

Proof. The assumption is that each iterand Q_α has size $\aleph_1$ in V^{P_α}, but the posets P_i themselves may be large ($2^{\aleph_1}$, because of the names involved). In any family $\{r_\xi \mid \xi \in \omega_2\} \subseteq P_\delta$, we must find two compatible conditions. Fixing a large λ, pick for every $\xi \in \omega_2$ a countable $M_\xi \prec H_\lambda$ such that $r_\xi \in M_\xi$. Look at the isomorphism types of the countable structures M_ξ. Since CH holds, there is a set $I \subseteq \omega_2$ of size $\aleph_2$ such that all M_ξ for $\xi \in I$ are pairwise isomorphic. But the transitive collapse is determined by the isomorphism type, and hence there is a single transitive structure $\bar{M}$ to which all M_ξ for $\xi \in I$ are collapsed. In addition, we may form a Δ-system for the countable sets $M_\xi \cap \omega_2$ (again by CH). This leads to the following assumptions on I.

1. For some fixed transitive structure $\bar{M}$, $h_\xi : M_\xi \to \bar{M}$, where h_ξ are the collapsing functions for $\xi \in I$.

2. The countable sets $M_\xi \cap \omega_2$ form a Δ-system: For some countable $C \subseteq \omega_2$,
$$M_{\zeta_1} \cap M_{\zeta_2} \cap \omega_2 = C \quad \text{for all } \zeta_1 \neq \zeta_2 \text{ in } I.$$
   Moreover, C is an initial segment of $M_\xi \cap \omega_2$, and there is no interleaving of the $M_\xi \cap \omega_2 \setminus C$ parts. That is, if we define $\mu_\xi = \min(M_\xi \cap \omega_2 \setminus C)$ then for $\xi_1 < \xi_2$ in I, $\sup(C) < \mu_{\xi_1}$, and $\sup(M_{\xi_1} \cap \omega_2) < \mu_{\xi_2}$. We also assume that $h_\xi(r_\xi)$ does not depend on ξ and is a fixed member of $\bar{M}$.

We now claim that any two conditions with indices in I are compatible. Given $\xi_1, \xi_2 \in I$, it suffices to show that $r_1 = r_{\xi_1} \restriction \mu_{\xi_1} = r_{\xi_1} \restriction \sup(C)$ and $r_2 = r_{\xi_2} \restriction \mu_{\xi_2}$ are compatible. Because then, if $r \in P_{\sup(C)}$ extends r_1 and r_2, then $p = r \cup r_{\xi_1} \restriction (\omega_2 \setminus C) \cup r_{\xi_2} \restriction (\omega_2 \setminus C)$ extends the two given conditions. The fact that C is an initial segment of $M_\xi \cap \delta$ and hence that p is a function in P_δ is used in the proof (if the iteration were of length $\delta > \omega_2$ then $\aleph_2$ may indeed be collapsed).

Let $\mu = \mu_{\xi_1}$, and let $h : M_{\xi_1} \to M_{\xi_2}$ be an isomorphism of the two structures. Then h is the identity on $\mu \cap M_{\xi_1} = h(\mu) \cap M_{\xi_2}$, and $h(r_1) = r_2$. We shall prove that if p is any (M_{ξ_1}, P_μ)-generic condition extending r_1, then p extends r_2, and hence r_1 and r_2 are compatible as required. The iterands are of power $\aleph_1$ and we may assume that their universe is always ω_1. Then for every α in its domain, $r_1(\alpha)$ is forced by $r_1 \restriction \alpha$ to be a countable ordinal. A similar statement holds for r_2. However, $r_1(\alpha)$ is not necessarily the same name as $r_2(\alpha)$.

The following lemma therefore suffices.

2.11 Lemma. *Let M_1 and M_2 be two isomorphic countable elementary substructures of H_λ. Let $h : M_1 \to M_2$ be an isomorphism, and $\mu \in M_1 \cap \omega_2$ be such that h is the identity on $\mu \cap M_1$. (We do not require that $h(\mu) \neq \mu$, but this is possible.) If $p \in P_\mu$ is any (M_1, P_μ)-generic condition then for any condition $r \in P_\mu \cap M_1$, $p \geq r$ implies $p \geq h(r)$. (Hence any (M_1, P_μ)-generic condition is also $(M_2, P_{h(\mu)})$-generic.)*

Proof. The proof is by induction on μ.

Case 1. μ is a limit ordinal. Note that, for any $r \in P_\mu \cap M_1$, r and $h(r)$ have the same support, since h is the identity on μ and the support is countable. Assume that $p \in P_\mu$ is (M_1, P_μ)-generic and $r \in P_\mu \cap M_1$, $p \geq r$ as in the lemma. In order to prove that $p \geq h(r)$, it suffices to prove for every $\mu' \in \mu \cap M_1$ that $p\restriction\mu' \geq h(r)\restriction\mu'$. This follows from the inductive assumption, because $p\restriction\mu'$ is $(M_1, P_{\mu'})$-generic, and $p\restriction\mu' \geq r\restriction\mu'$ implies that $p\restriction\mu' \geq h(r\restriction\mu') = h(r)\restriction\mu'$.

Case 2. $\mu = \mu' + 1$. As $p \geq r$ in $P_{\mu'+1}$ $(= P_{\mu'} * Q_{\mu'})$, $p\restriction\mu'$ extends $r\restriction\mu'$ and

$$p\restriction\mu' \Vdash p(\mu') \quad \text{extends} \quad r(\mu') \text{ in } Q_{\mu'}. \tag{5.8}$$

By Lemma 2.5, $p\restriction\mu'$ is $(M_1, P_{\mu'})$-generic, and the inductive condition implies that $p\restriction\mu'$ extends $h(r)\restriction\mu'$. We want to prove that

$$p\restriction\mu' \Vdash p(\mu') \quad \text{extends} \quad h(r)(\mu') \text{ in } Q_{\mu'}.$$

Consider any t in $P_{\mu'}$ that extends $p\restriction\mu'$, and we shall find an extension t' of t in $P_{\mu'}$ forcing $r(\mu') = h(r)(\mu')$. Thus

$$t' \Vdash p(\mu') \quad \text{extends} \quad h(r)(\mu')$$

follows from (5.8) as required. The set of conditions that "know" the value of $r(\mu')$ (as an ordinal in ω_1) is dense above $r\restriction\mu'$ and is in M_1. Hence, by genericity of t, t is compatible with some $s \in P_{\mu'} \cap M_1$, $s \geq r\restriction\mu'$, such that

$$s \Vdash_{\mu'} r(\mu') = \alpha$$

for some $\alpha < \omega_1$. Since $h(\mu') = \mu'$, and $h(\alpha) = \alpha$, this implies that

$$h(s) \Vdash_{\mu'} h(r)(\mu') = \alpha.$$

Let $t' \in P_{\mu'}$ be a common extension of t and s. By the inductive assumption, t' extends $h(s)$ as well and so $t' \Vdash_{\mu'} r(\mu') = \alpha = h(r)(\mu')$.

$\dashv$

This completes the proof of Theorem 2.10. $\dashv$

Knowing the $\aleph_2$-c.c. we can prove by induction on $\delta \le \omega_2$ that $|P_\delta| \le 2^{\aleph_1}$. This helps in defining iterations of length ω_2 of proper forcing posets of size $\aleph_1$ each, when we want to ensure that every $A \subseteq \omega_1$ in $V^{P_{\omega_2}}$ has had its chance to be considered at some successor stage of the iteration.

A useful consequence of the previous lemma is the following

2.12 Theorem. *Assume* CH. *Let $\langle P_i \mid i \le \delta\rangle$ be a countable support iteration of length $\delta < \omega_2$ of proper forcings of size $\aleph_1$. Then* CH *holds in V^{P_δ}.*

Proof. Write P for P_δ. Let $x \in V^P$ be a name forced by $p_0 \in P$ to be a function from ω_2 into $\mathcal{P}(\omega)$ (the power set of ω). We shall find an extension p_1 of p_0 and two indexes $\xi_0 \ne \xi_1$ such that $p_1 \Vdash x(\xi_0) = x(\xi_1)$.

As above, we define countable $M_\xi \prec H_\lambda$ with $P, x, \xi \in M_\xi$ for $\xi < \omega_2$. By CH, there are $\xi_1 \ne \xi_2$ with an isomorphism $h : M_{\xi_1} \to M_{\xi_1}$ taking ξ_1 to ξ_2 and such that $M_{\xi_1} \cap \delta = M_{\xi_2} \cap \delta$. Let p_2 be an (M_{ξ_1}, P)-generic condition extending p_1. Then p_2 is also (M_{ξ_2}, P)-generic by the lemma, and hence

$$p_2 \Vdash x(\xi_1) = x(\xi_2)$$

follows from $h(\xi_1) = \xi_2$. $\dashv$

2.3. Equivalent Formulations

Suppose that Q is a non-proper poset and P is a proper poset. Then, in V^P, Q remains non-proper. To prove this basic result we need an equivalent formulation of properness in terms of preservation of stationary subsets of $\mathcal{P}_{\aleph_1}(A)$. Here, $\mathcal{P}_{\aleph_1}(A) = [A]^{<\aleph_1}$ is the collection of all countable subsets of A. We refer the reader to Jech's chapter on stationary sets for basic properties of the closed unbounded filter on $\mathcal{P}_{\aleph_1}(A)$. We shall rely on the following facts for any uncountable set A. (1) The collection of closed unbounded sets generates a countably closed and normal filter over $\mathcal{P}_{\aleph_1}(A)$. (2) For any closed unbounded set $C \subseteq \mathcal{P}_{\aleph_1}(A)$ there is a function $f : [A]^{<\aleph_0} \to A$ such that if $x \in \mathcal{P}_{\aleph_1}(A)$ is closed under f, then $x \in C$. (3) If $A_1 \subseteq A_2$ and $C \subseteq \mathcal{P}_{\aleph_1}(A_2)$ is closed unbounded, then $\{x \cap A_1 \mid x \in C\}$ contains a closed unbounded subset of $\mathcal{P}_{\aleph_1}(A_1)$. (4) A subset S of $\mathcal{P}_{\aleph_1}(A)$ is said to be stationary if it has non-empty intersection with every closed unbounded set. If S is stationary and f is a function such that $f(x) \in x$ for every non-empty $x \in S$, then for some $a \in A$, the set $\{x \in S \mid f(x) = a\}$ is stationary.

Let P be a poset and $p \in P$ a condition. We say that $D \subseteq P$ is *pre-dense above* p if $\forall p' \ge p \exists d \in D$ (p' and d are compatible in P). Equivalently, D is pre-dense above p if the set D' of all extensions of members of D is dense above p.

Given any poset P, form $A = P \cup \mathcal{P}(P)$, a disjoint union of the poset universe with its power set. The "test-set" for P is the collection of all $a \in \mathcal{P}_{\aleph_1}(A)$ such that, for any $p_0 \in P \cap a$ there exists an extension $p \in P$ such that, for every $D \in a \cap \mathcal{P}(P)$, if D is dense in P then $D \cap a$ is pre-dense above p. We can say that p is "generic" for a, and then the test-set is the collection of all a, countable subsets of A, that have generic conditions extending each member of $P \cap a$.

If $T \subseteq \mathcal{P}_{\aleph_1}(A)$ is the test-set of P then its complement $\mathcal{P}_{\aleph_1}(A) \setminus T$ is called the "failure set" for P.

2.13 Theorem (Properness Equivalents). *For any poset P the following are equivalent.*

1. *P is proper (as in Definition 2.2).*
2. *For some $\lambda > 2^{|P|}$ and any countable $M \prec H_\lambda$ with $P \in M$, every $p_0 \in P \cap M$ has an extension $p \geq p_0$ that is an M-generic condition.*
3. *For every uncountable λ, P preserves stationary subsets of $\mathcal{P}_{\aleph_1}(\lambda)$. That is, if $S \subseteq \mathcal{P}_{\aleph_1}(\lambda)$ is stationary, then it remains so in any generic extension via P.*
4. *For $\lambda_0 = 2^{|P|}$, P preserves stationary subsets of $\mathcal{P}_{\aleph_1}(\lambda_0)$.*
5. *The test set for P, as defined above, contains a closed unbounded subset of $\mathcal{P}_{\aleph_1}(A)$.*

Proof. Clearly, *1* $\Rightarrow$ *2*. We prove that *1* $\Rightarrow$ *3*. So assume that P is proper, and let $S \subseteq \mathcal{P}_{\aleph_1}(\lambda)$ be a stationary set. To prove that S remains stationary in any extension via P, we take any $f \in V^P$ such that $p_0 \Vdash f : [\lambda]^{<\aleph_0} \to \lambda$, and we shall find an extension $p \in P$ so that some $x \in S$ is forced by p be closed under f. Pick a sufficiently large cardinal κ and a countable $M \prec H_\kappa$ with $\lambda, P, p_0, f \in M$ and such that $M \cap \lambda \in S$. We can find one since the collection of intersections $M \cap \lambda$ for structures M as above contains a closed unbounded subset of $\mathcal{P}_{\aleph_1}(\lambda)$. As P is assumed proper, there is an extension $p \geq p_0$ that is (M, P)-generic. The genericity of p then implies that $p \Vdash M \cap \lambda$ is closed under f.

3 $\Rightarrow$ *4* is trivial, and *2* $\Rightarrow$ *4* is just like *1* $\Rightarrow$ *3*. We prove now that *4* $\Rightarrow$ *5*.

Assume that P preserves stationarity of subsets of $\mathcal{P}_{\aleph_1}(\lambda_0)$ for $\lambda_0 = 2^{|P|}$. Define $A = P \cup \mathcal{P}(P)$. Then $|A| = \lambda_0$. Suppose that S, the failure set for P as defined above, is stationary, and we shall derive a contradiction. By normality, we may assume that the failure is due to the same $p_0 \in a$ for $a \in S$. Let $G \subseteq P$ be a (V, P)-generic filter containing p_0. Then S is stationary in $V[G]$ since P preserves stationarity. Define a function $g : A \to A$ so that if D is dense in P then $g(D) \in G$. Since S is stationary, there is an $x \in S$ closed under g. If $p \geq p_0$ forces this fact about x, then p shows that x is in fact in the test set for P.

Finally we prove *5* $\Rightarrow$ *1*. Suppose that $\lambda > 2^{|P|}$, $M \prec H_\lambda$ is countable, and $P \in M$. Then $A = P \cup \mathcal{P}_{\aleph_1}(P) \in H_\lambda$ and $A \in M$. The test set for P is also in M. Assuming that this set contains a closed unbounded set, we may find such a closed unbounded set C in M. This implies that $M \cap A \in C$, and hence there exists an (M, P)-generic condition above any condition in $M \cap P$. ⊣

3. Preservation of ${}^{\omega}\omega$-Boundedness

The set of functions from ω to ω is denoted ${}^{\omega}\omega$ (the "reals"). For $f,\ g \in {}^{\omega}\omega$ and $k < \omega$ define $f <_k g$ iff $\forall n \geq k(f(n) \leq g(n))$. $<^* = \bigcup_k <_k$ is the *bounding* (also called eventual bounding) relation: If $f <^* g$, then g *bounds* (or *dominates*) f, and if $f <_0 g$ then g *totally bounds* f. A basic fact is that any countable $F \subseteq {}^{\omega}\omega$ is bounded by some $g \in {}^{\omega}\omega$.

A forcing poset P is said to be ${}^{\omega}\omega$*-bounding* iff for every generic filter $G \subseteq P$, $V \cap {}^{\omega}\omega$ bounds $V[G] \cap {}^{\omega}\omega$, i.e., for every $g \in {}^{\omega}\omega \cap V[G]$ there is an $h \in {}^{\omega}\omega \cap V$ with $g <^* h$ (we could equivalently require $g <_0 h$). Our aim is to prove that the countable support iteration of proper ${}^{\omega}\omega$-bounding posets is ${}^{\omega}\omega$-bounding.

Let P be a poset and $\underset{\sim}{f} \in V^P$ a name of a real (i.e., a name forced by 0_P to be a real). We say that an increasing sequence $\bar{p} = \langle p_i \mid i \in \omega \rangle$ of conditions in P *interprets* $\underset{\sim}{f}$ *as* $f^* \in {}^{\omega}\omega$ iff for every $n < \omega$ p_n forces $\underset{\sim}{f} \restriction n = f^* \restriction n$. We write in this case $f^* = \mathrm{intp}(\bar{p}, \underset{\sim}{f})$.

3.1 Definition. Let P be a forcing poset and $\underset{\sim}{f} \in V^P$ a name of a real. Suppose that $\bar{p} = \langle p_i \mid i \in \omega \rangle$ is an increasing sequence of conditions in P that interprets $\underset{\sim}{f}$. We say that $\bar{p}$ *respects* $g \in {}^{\omega}\omega$ iff

$$\mathrm{intp}(\bar{p}, \underset{\sim}{f}) <_0 g. \tag{5.9}$$

The following surprising property turns out to be important for the preservation theorem.

3.2 Theorem. *If P is ${}^{\omega}\omega$-bounding, then P satisfies the following ostensibly stronger property: Let $\underset{\sim}{f} \in V^P$ be a name of a real and let $M \prec H_\kappa$ be countable, with $P, \underset{\sim}{f} \in M$. Suppose that $g \in {}^{\omega}\omega$ dominates all the reals of M, and $\bar{p} \in M$ is an increasing sequence of conditions in P that interprets $\underset{\sim}{f}$ and respects g. Then, for some $p \in P \cap M$ and $h \in M$, $h <_0 g$ and $p \Vdash_P \underset{\sim}{f} \leq_0 h$. So that*

$$p \Vdash_P \underset{\sim}{f} <_0 g.$$

Proof. The point of the theorem is this. As P is ${}^{\omega}\omega$-bounding, every condition in M can be extended to force that $\underset{\sim}{f}$ is bounded by some real in M and hence that $\underset{\sim}{f} <^* g$, but it takes the theorem to find $p \in M$ that forces $\underset{\sim}{f} <_0 g$.

Work in M. By assumption $\bar{p} = \langle p_i \mid i \in \omega \rangle$ is an increasing sequence of conditions in P that interprets $\underset{\sim}{f}$ as f^*, and $f^* <_0 g$. For each n, that P is ${}^{\omega}\omega$-bounding and $p_n \Vdash \underset{\sim}{f} \restriction n = f^* \restriction n$ implies that there is an extension p'_n of p_n and an $h_n \in {}^{\omega}\omega \cap M$ such that:

1. $p'_n \Vdash \underset{\sim}{f} \leq_0 h_n$.
2. $h_n \restriction n = f^* \restriction n$.

Let $u \in {}^{\omega}\omega$ be defined by

$$u(m) = \max\{h_i(m) \mid i \leq m\}.$$

Then $u \in M$, and is hence bounded by g; say $u <_\ell g$. This implies that $h_\ell <_0 g$ by the following argument. For $k < \ell$, $h_\ell(k) = f^*(k) < g(k)$, and for $k \geq \ell$ $h_\ell(k) \leq u(k) < g(k)$. Now p'_ℓ is as required: it forces $\underset{\sim}{f} <_0 g$ since it forces $\underset{\sim}{f} \leq_0 h_\ell$.

Remark that we can require that p extends any given condition in the sequence $\bar{p}$. ⊣

A main tool in the preservation proof is the notion of a *derived sequence*. Let Q_1 and Q_2 be two forcing posets such that $Q_1 \lhd Q_2$, and let $\pi : Q_2 \to Q_1$ be the related projection. Let $\underset{\sim}{f}$ be a Q_2-name forced by 0_{Q_2} to be a real, and let $\bar{r} = \langle r_i \mid i \in \omega \rangle$ be an increasing sequence of conditions in Q_2 that interprets $\underset{\sim}{f}$. Fix a well-ordering of Q_2. Suppose that G_1 is a (V, Q_1)-generic filter. Recall that $Q_2/G_1 = \{q \in Q_2 \mid \pi(q) \in G_1\}$. We shall define in $V[G_1]$ an increasing sequence $\bar{s} = \langle s_i \mid i \in \omega \rangle$ of conditions in Q_2/G_1 that interprets $\underset{\sim}{f}$ by the following induction.

1. If $\pi(r_i) \in G_1$ then $s_i = r_i$. (In this case $\pi(r_k) \in G_1$ for every $k < i$ and $s_k = r_k$.)

2. If $\pi(r_i) \notin G_1$, then let s_i be the first Q_2-extension of s_{i-1} that is in Q_2/G_1 and determines the value of $\underset{\sim}{f} \restriction i$.

Thus, if $\pi(r_i) \in G_1$ for all $i \in \omega_1$, then $s_i = r_i$ for all i, but if n is the first index such that $\pi(r_n) \notin G_1$, then $s_i = r_i$ for $i < n$, and for $i \geq n$ we define $s_i \in Q_2$ as the first extension of s_{i-1} with $\pi(s_i) \in G_1$ and such that s_i determines $\underset{\sim}{f} \restriction i$ in the forcing relation $\Vdash_{Q_2}$.

We say that the sequence $\bar{s}$ defined above in $V[G_1]$ is "derived" from $\bar{r}$, G_1, and $\underset{\sim}{f}$. We write $\delta_{G_1}(\bar{r}, \underset{\sim}{f})$ to denote this derived sequence in Q_2/G_1. The V^{Q_1}-name of the derived sequence is denoted $\underset{\sim}{\delta}_{Q_1}(\bar{r}, \underset{\sim}{f})$.

3.3 Lemma. *Let $Q_1 \lhd Q_2$ be posets with projection $\pi : Q_2 \to Q_1$, and suppose that Q_1 is ${}^{\omega}\omega$-bounding (no such assumption is made about Q_2). Suppose that:*

1. $\underset{\sim}{f} \in V^{Q_2}$ is forced by every condition to be a real.

2. $\bar{r} = \langle r_i \mid i < \omega \rangle$ is an increasing sequence of conditions in Q_2 (above some given $p \in Q_2$) that interprets $\underset{\sim}{f}$.

3. $M \prec H_\kappa$ is countable with $Q_1, Q_2, \underset{\sim}{f}, \bar{r}, p \in M$.

4. $g \in {}^{\omega}\omega$ bounds all the reals of M, and $\mathrm{int}(\bar{r}, \underset{\sim}{f}) <_0 g$. *That is, $\bar{r}$ respects g in its interpretation of $\underset{\sim}{f}$.*

Then some condition $s \in Q_1 \cap M$ extends $\pi(p)$ and forces that the derived sequence $\underset{\sim}{\delta}_{Q_1}(\bar{r}, \underset{\sim}{f})$ respects g in its interpretation of $\underset{\sim}{f}$ and is above p in the Q_2 ordering.

Proof. Let $\underset{\sim}{\delta} = \underset{\sim}{\delta}_{Q_1}(\bar{r}, \underset{\sim}{f})$ be the name of the derived sequence, $\underset{\sim}{\delta} \in V^{Q_1}$. Define a name of a real, $\underset{\sim}{h} \in V^{Q_1}$, by

$$\underset{\sim}{h} = \mathrm{int}(\underset{\sim}{\delta}, \underset{\sim}{f}).$$

That is, if G_1 is a (V, Q_1)-generic filter, let $\delta_{G_1}(\bar{r}, \underset{\sim}{f})$ be the resulting derived sequence, a Q_2-increasing sequence of conditions in Q_2/G_1 interpreting $\underset{\sim}{f}$, and let $\underset{\sim}{h}[G_1]$ be that interpretation.

Define $p_i = \pi(r_i) \in Q_1$ for $i \in \omega$. Then $\langle p_i \mid i \in \omega \rangle \in M$ and $p_i \Vdash_{Q_1} r_i = \underset{\sim}{\delta}(i)$. That is, as $p_i \Vdash_{Q_1} r_i \in Q_1/\underset{\sim}{G}_1$, p_i "knows" that r_i is the i-th member of the derived sequence. Consequently, p_i determines $\underset{\sim}{h} \restriction i$ (in Q_1 forcing) as r_i determines $\underset{\sim}{f} \restriction i$ (in Q_2 forcing). Namely

$$\mathrm{int}(\langle p_i \mid i \in \omega \rangle, \underset{\sim}{h}) = \mathrm{int}(\bar{r}, \underset{\sim}{f}).$$

Hence, $\mathrm{int}(\langle p_i \mid i \in \omega \rangle, \underset{\sim}{h}) <_0 g$, and so by the surprising theorem there exists a $s \geq p_0$ in $Q_1 \cap M$ so that $s \Vdash_{Q_1} \underset{\sim}{h} <_0 g$. That is,

$$s \Vdash_{Q_1} \mathrm{int}(\underset{\sim}{\delta}_{Q_1}(\bar{r}, \underset{\sim}{f}), \underset{\sim}{f}) <_0 g.$$

Since $s \geq p_0$, s forces that r_0 is the first member of the derived sequence, and hence that all members of the derived sequence extend p in Q_2. $\dashv$

In the following we shall apply the previous lemma in a slightly more complex situation in which the discussion is not in V, but rather in V^{Q_0}, where $Q_0 \lhd Q_1 \lhd Q_2$. We will use $\underset{\sim}{G}_0$ and $\underset{\sim}{G}_1$ as canonical names for the generic filters Q_0 and Q_1.

3.4 Lemma. *Suppose that $Q_0 \lhd Q_1 \lhd Q_2$ are posets with commuting projections $\pi_{i,j} : Q_i \to Q_j$, for $0 \leq j < i \leq 2$. Assume that Q_1 (and hence Q_0) is proper and ${}^\omega\omega$-bounding. Suppose that:*

1. *$\underset{\sim}{f} \in V^{Q_2}$ is a name of a real.*

2. *$M \prec H_\kappa$ is countable with $Q_0, Q_1, Q_2, \underset{\sim}{f} \in M$. Let $q_0 \in Q_0$ be an (M, Q_0)-generic condition. Assume that $g \in {}^\omega\omega$ bounds all the reals of M.*

3. *$\underset{\sim}{p} \in V^{Q_0}$ is given such that $q_0 \Vdash_{Q_0} \underset{\sim}{p} \in (Q_2/\underset{\sim}{G}_0) \cap M$.*

4. *q_0 forces that there is in $M[\underset{\sim}{G}_0]$ a Q_2-increasing sequence of conditions in $Q_2/\underset{\sim}{G}_0$ that interprets $\underset{\sim}{f}$, respects g, and is above $\underset{\sim}{p}$ in the Q_2 ordering.*

Then there is an (M, Q_1)-generic condition q_1 such that

(a) $\pi_{1,0}(q_1) = q_0$.

(b) $q_1 \Vdash_{Q_1} \pi_{2,1}(\underset{\sim}{p}) \in \underset{\sim}{G}_1$.

(c) *q_1 forces that there is in $M[\underset{\sim}{G}_1]$ a Q_2-increasing sequence of conditions in $Q_2/\underset{\sim}{G}_1$ that interprets $\underset{\sim}{f}$ and respects g, and is above $\underset{\sim}{p}$ in the Q_2 ordering.*

Proof. Observe that what the lemma does is to push the situation described in *4* from $\underset{\sim}{G}_0$ to $\underset{\sim}{G}_1$. That is, the basic object that interests us is a sequence of conditions in Q_2-increasing in the ordering of Q_2 and interpreting $\underset{\sim}{f}$ (in $\Vdash_{Q_2}$) as a function that respects g. The assumed sequence (in *4*) is compatible with $\underset{\sim}{G}_0$, and the resulting sequence is compatible with $\underset{\sim}{G}_1$.

Let G_0 be some (V, Q_0)-generic filter containing q_0. Work in $M[G_0] \prec H_\kappa[G_0]$ and apply the previous lemma as follows. Observe first that g dominates all the reals in $M[G_0]$, since q_0 is (M, Q_0)-generic. Observe also that $\pi_{2,1} : Q_2/G_0 \to Q_1/G_0$ is a projection (see Lemma 1.3). Then $\underset{\sim}{f}/G_0 \in V[G_0]^{Q_2/G_0}$ is a name of a real. Following *4*, let $\bar{r} \in M[G_0]$ be an increasing sequence of conditions in Q_2/G_0 that interprets $\underset{\sim}{f}/G_0$ (since it interprets $\underset{\sim}{f}$) and respects g (and is above $\underset{\sim}{p}[G_0]$ in $\leq_{Q_2}$). We apply the previous lemma to Q_2/G_0, Q_1/G_0, and $\underset{\sim}{f}/G_0$ in $V[G_0]$. Thus by that lemma some condition $s \in (Q_1/G_0) \cap M[G_0]$ exists which extends $\pi_{2,1}(\underset{\sim}{p}[G_0])$ and forces in Q_1/G_0 that the derived sequence $\underset{\sim}{\delta}_{Q_1/G_0}(\bar{r}, \underset{\sim}{f}/G_0)$ respects g in its interpretation of $\underset{\sim}{f}/G_0$, and is above $\underset{\sim}{p}[G_0]$ in Q_2/G_0.

Now let $\underset{\sim}{s} \in V^{Q_0}$ be a name of s, forced to have all the properties of s described above. (Observe that $\underset{\sim}{s}$ is not in M since its definition involves g, but it is forced to become a condition in M.) By the Properness Extension Lemma there is a $q_1 \in Q_1$ that is (M, Q_1)-generic such that $\pi_{1,0}(q_1) = q_0$ and $q_1 \Vdash_{Q_1} \underset{\sim}{s} \in \underset{\sim}{G}_1$. So $q_1 \Vdash_{Q_1} \pi_{2,1}(\underset{\sim}{p}) \in \underset{\sim}{G}_1$. We claim that q_1 is as required.

Let G be any (V, Q_1)-generic filter containing q_1. Then $G_0 = \pi_{1,0}$"G is (V, Q_0)-generic and $p = \underset{\sim}{p}[G_0]$, $s = \underset{\sim}{s}[G_0]$ can be formed. Since $q_1 \in G$ and $q_1 \Vdash \underset{\sim}{s} \in \underset{\sim}{G}_1$, $s \in G$. Now G is also $(V[G_0], Q_1/G_0)$-generic, and we write $G_1 = G$ to emphasize that $G_1 \subseteq Q_1/G_0$. Since $s \in G_1$, whatever s forces holds in $V[G_1]$. Namely, there is in $M[G_1]$ a Q_2/G_0 increasing sequence in $(Q_2/G_0)/G_1 = Q_2/G_1$ that respects g in its interpretation of $\underset{\sim}{f}/G_0$ and is above p in the ordering of Q_2/G_0. If p_n is the n-th member of this sequence, then for some finite function e we have $p_n \Vdash_{Q_2/G_0} (\underset{\sim}{f}/G_0)\restriction n = e$. So there is some $g \in G_0$ such that $g + p_n \Vdash_{Q_2} \underset{\sim}{f}\restriction n = e$. Using Lemma 1.1, we can amend the derived sequence (that is, replace conditions p with conditions of the form $g + p$ where $g \in G_0$) and obtain a sequence of conditions in Q_2/G_1 that is increasing in Q_2 and respects g in its interpretation of $\underset{\sim}{f}$ (in Q_2 forcing) and is above p in Q_2. $\dashv$

3.5 Theorem. *Let $\langle P_i \mid i \leq \delta \rangle$ be a countable support iteration of proper ${}^\omega\omega$-bounding posets. Then P_δ is (proper and) ${}^\omega\omega$-bounding.*

Proof. We know that P_δ is proper, and the ${}^\omega\omega$-bounding property of P_δ is proved by induction on δ. The successor case is obvious and so we assume that δ is a limit ordinal. Let $\underset{\sim}{f}$ be a P_δ-name of a real; we must find a condition (extending a given condition $p_0 \in P_\delta$) that forces $\underset{\sim}{f} <_0 g$ for some ground model $g \in {}^\omega\omega$. Pick $M \prec H_\kappa$, countable, with $P_\delta, \underset{\sim}{f}, p_0 \in M$. Let $\gamma_n \in \delta \cap M$ for $n \in \omega$ be increasing and cofinal in $M \cap \delta$. For simplicity, start with $\gamma_0 = 0$.

Find in M an increasing sequence $\bar{r} = \langle r_i \mid i \in \omega \rangle$ of conditions in P_δ that interprets $\underset{\sim}{f}$ as $f^* \in {}^\omega\omega$, starting with the given condition p_0. Find $g \in {}^\omega\omega$ that bounds the reals of M, and such that $f^* <_0 g$. To prove the theorem, we will find $q \in P_\delta$ (extending p_0) that forces $\underset{\sim}{f} <_0 g$.

We intend to define by induction on $n \in \omega$ conditions $q_n \in P_{\gamma_n}$, and names $\underset{\sim}{p_n} \in V^{P_{\gamma_n}}$, that satisfy the following four properties (the first two are as in the Properness Extension Lemma 2.8 but the dense sets are not needed).

1. $q_0 \in P_0$ is the trivial condition; $q_n \in P_{\gamma_n}$ is (M, P_{γ_n})-generic; and $q_{n+1} \restriction \gamma_n = q_n$.

2. $\underset{\sim}{p_0} = p_0$ is given in P_δ, and $\underset{\sim}{p_n}$ is a P_{γ_n}-name such that: $q_n \Vdash_{P_{\gamma_n}}$ "$\underset{\sim}{p_n}$ is a condition in $P_\delta \cap M$ with $\underset{\sim}{p_n} \restriction \gamma_n \in \underset{\sim}{G}_{\gamma_n}$ and $\underset{\sim}{p_{n-1}} \leq_\delta \underset{\sim}{p_n}$."

3. $q_n \Vdash_{\gamma_n}$ "$\underset{\sim}{p_n}$ determines $\underset{\sim}{f} \restriction n$ in P_δ-forcing to be totally bounded by $g \restriction n$."

4. $q_n \Vdash_{\gamma_n}$ "some $r \in M[\underset{\sim}{G}_{\gamma_n}]$ is a P_δ-increasing sequence of conditions in $P_\delta / \underset{\sim}{G}_{\gamma_n}$ that interprets $\underset{\sim}{f}$, respects g, and is above $\underset{\sim}{p_n}$."

In words, this last asserts that if G is a (V, P_{γ_n})-generic filter containing q_n, then there is in $M[G]$ a P_δ-increasing sequence r of conditions in P_δ / G that interpret $\underset{\sim}{f}$ (in P_δ forcing) and respect g, and are all above $\underset{\sim}{p_n}[G]$ in P_δ.

If we succeed in this and define $q = \bigcup_n q_n$, then $q \Vdash_\delta \underset{\sim}{p_n} \in \underset{\sim}{G}_\delta$, as in (5.7). So 3. implies that $q \Vdash \underset{\sim}{f} <_0 g$.

To start the induction observe that $\bar{r}$ respects g so that 4. holds for $n = 0$. Suppose that $q_n \in P_{\gamma_n}$, and $\underset{\sim}{p_n} \in V^{P_{\gamma_n}}$ are defined. We first define $\underset{\sim}{p_{n+1}}$ and then q_{n+1}.

Let G be a (V, P_{γ_n})-generic filter containing q_n. Then by 4. there is in $M[G]$ a P_δ-increasing sequence r of conditions in P_δ / G that interpret $\underset{\sim}{f}$, respect g, and are above $\underset{\sim}{p_n}[G]$. Let p_{n+1} be $r(n+1)$, the $(n+1)$-th member of r, which determines $\underset{\sim}{f} \restriction (n+1) = v$ for some $v : n+1 \to \omega$ with $v <_0 g \restriction (n+1)$. Then $\underset{\sim}{p_{n+1}}$ is defined to be a $V^{P_{\gamma_n}}$ name of p_{n+1}.

Now for $Q_0 = P_{\gamma_n}$, $Q_1 = P_{\gamma_{n+1}}$, $Q_2 = P_\delta$, Lemma 3.4 can be applied to q_n (as $q_0 \in Q_0$) and $\underset{\sim}{p_{n+1}}$ (as $\underset{\sim}{p} \in V^{Q_0}$). So there exists some $q_{n+1} \in P_{\gamma_{n+1}}$ that is $(M, P_{\gamma_{n+1}})$-generic with $q_n = \pi(q_{n+1})$ and such that the required inductive assumptions hold. $\dashv$

3.1. Application: Non-Isomorphism of Ultrapowers

The significance of Theorem 3.7 proved in this section is clarified by comparing the following two theorems of Keisler and of Shelah concerning the notion of elementary equivalence (see the book by Comfort and Negrepontis [2]).

3.6 Theorem (Keisler [9]). *If $2^\lambda = \lambda^+$ and $\mathcal{A}, \mathcal{B}$ are structures of size $\leq \lambda^+$ in a language of size λ, then $\mathcal{A} \equiv \mathcal{B}$ implies that $\mathcal{A}$ and $\mathcal{B}$ have isomorphic ultrapowers,*

$$\mathcal{A}^\lambda/p \cong \mathcal{B}^\lambda/p$$

obtained by some ultrafilter p on λ.

Keisler also showed that it is not possible to obtain this result if the language has size λ^+.

The following was proved by Shelah [12]:

> If $\mathcal{A} \equiv \mathcal{B}$ are both of size $\leq \kappa$, then $\mathcal{A}^\alpha/p \cong \mathcal{B}^\alpha/p$ for some ultrafilter p on $2^\kappa = \alpha$.

In particular, for countable elementarily equivalent structures, Shelah's theorem provides an ultrafilter on a set of size $2^{\aleph_0}$ that makes their ultrapowers isomorphic, and Keisler's theorem obtains an ultrafilter on ω, provided that $2^{\aleph_0} = \aleph_1$. The theorem proved in this section shows that CH is indeed necessary for obtaining the ultrafilter to be on ω (see Shelah [14]).

3.7 Theorem. *Assuming* CH*, there are two countable elementarily equivalent structures $\mathcal{A} \equiv \mathcal{B}$ and there is a generic extension in which $2^{\aleph_0} = \aleph_2$ and for any ultrafilters p, q on ω*

$$\mathcal{A}^\omega/p \ncong \mathcal{B}^\omega/q.$$

To prove this theorem, we will consider two propositions, P_1 and P_2, show that they imply the existence of $\mathcal{A} \equiv \mathcal{B}$ as in the theorem, and then establish their consistency.

Let DP (Diverging and Positive) denote the set of functions $h \in {}^\omega\omega$ diverging to infinity with $h(n) > 0$ for every n. If $\langle A_n \mid n \in \omega\rangle$ is a sequence of finite (non-empty) sets, then $\Pi_{n<\omega} A_n$ is the set of all functions f defined on ω with $f(n) \in A_n$ for every n.

(P_1) If $\langle A_n \mid n \in \omega\rangle$ is a sequence of finite sets, and $\{f_\alpha \mid \alpha \in \omega_1\} \subseteq \Pi_{n<\omega} A_n$, then, for every $h \in$ DP, there is a choice of subsets $H_n \subseteq A_n$, $n \in \omega$, such that

  (a) $|H_n| \leq h(n)$ for all n,

  (b) $\forall \alpha < \omega_1 \exists n_0 \forall n \geq n_0\ (f_\alpha(n) \in H_n)$.

(P_2) $({}^\omega\omega, <^*)$ has a cofinal sequence of length ω_1.

It is left as an exercise to prove that Martin's Axiom + $2^{\aleph_0} > \aleph_1$ implies P_1 but negates P_2, and CH implies P_2 but negates P_1.

Our aim now is to prove the following theorem.

3.8 Theorem. *$P_1 \wedge P_2$ implies the existence of two countable elementarily equivalent structures that have no isomorphic ultrapowers with ultrafilters on ω.*

We first investigate a consequence of P_2 concerning the structure of ultrapowers of a certain type of graph. Let Δ be the bipartite graph obtained by taking U and V to be two copies of ω, with edges such that every $n \in V$ is connected exactly to those k in U such that $k \le n$. Let p be any nonprincipal ultrafilter over ω, and form the ultrapower $P = \Delta^\omega/p$. Consider the cofinal sequence $\langle f_\alpha \mid \alpha \in \omega_1 \rangle$ from P_2, and form for every f_α an element a_α of U^P obtained by viewing $f_\alpha(n) \in U$ (and taking the equivalence class of f_α). The fact that the sequence of functions is cofinal in ${}^\omega\omega$ implies the following property of P (expressed with U and V as predicates):

There is a sequence $a_i \in U$, $i \in \omega_1$ such that there is no $b \in V$ edge connected with every a_i. (5.10)

Indeed, any $[b] \in V^P$ is the equivalence class of some function $n \mapsto b(n)$, and there is some f_α that bounds b. Hence b is not connected to f_α in the ultrapower.

In fact, we can redo this argument even in the following slightly more general situation. Suppose that Δ is a bipartite graph built on two copies U and V of ω, just as before, but now we know that the following holds.

For every finite set $X \subseteq V$ there is some $u \in U$ such that no $x \in X$ is connected with u. (5.11)

Then define a sequence $u_n \in U$ by induction on n such that u_n is not connected to any one of the first n nodes of V. Here too (5.10) holds in any ultrapower. That is, in Δ^ω/p there is a set of ω_1 members of U such that there is no $b \in V$ that is connected to all of them. In fact, this result on ultrapowers can be generalized to ultraproducts of countable bipartite graphs that satisfy property (5.11) above. These ultraproducts must satisfy (5.10).

Define $\Gamma_{k,\ell}$ to be the finite bipartite graph with two disjoint sets of vertices U and V, where $|U| = k$, and the vertices in V are obtained by associating with every $x \subseteq U$ of size $\le \ell$ a vertex a_x in V that is edge connected exactly with the vertices of x.

We are particularly interested in graphs of the form $\Gamma_{n^2+1,n}$ because they have the following property: for any $X \subseteq V$ with cardinality $\le n$ there is some $a \in U$ that is not connected to any $x \in X$.

Let Γ be the disjoint union of the graphs $G_n = \Gamma_{n^2+1,n}$ for $2 \le n < \omega$. The language of the structure Γ includes not only the edge relation but also the predicates U and V, and a partial order $<_\Gamma$ that puts the vertices of G_n below those of G_m for $n < m$. The nodes in G_n are incomparable in $<_\Gamma$.

The connected components of the graph Γ are the copies of the $\Gamma_{n^2+1,n}$. (Because for $n \ge 2$, $\Gamma_{k,n}$ is connected. In fact, any two nodes that are in the same G_n are connected by a sequence of at most four edges.) So the connected components of Γ are exactly the maximal antichains of $<_\Gamma$ and this fact can be expressed by a single sentence.

Let Γ_{NS} be some countable nonstandard elementary extension of Γ. Then $\Gamma_{NS} \equiv \Gamma$, but Γ_{NS} also contains infinite connected components. The connected components of Γ_{NS} are, again, its $<_\Gamma$ antichains. Assuming P_1

and P_2, we are going to prove that Γ_{NS} and Γ have no isomorphic ultrapowers on ω. Observe that any non-standard (infinite) component of Γ_{NS} has property (5.11). Hence the following statement is true in any nonprincipal ultrapower $(\Gamma_{NS})^\omega/q$. The set of components C that satisfy the following property is cofinal in the ordering $<_\Gamma$.

There are $a_i \in C \cap U$ for $i \in \omega_1$ such that there is no $b \in V$ edge connected with every a_i. (5.12)

Indeed, the set of components that are in fact ultraproducts of nonstandard components of Γ_{NS} is such a cofinal set in the ordering $<_\Gamma$ of all components.

On the other hand no ultrapower of Γ over ω can satisfy this property, because the following holds in any ultrapower Γ^ω/p. There is a complement of an initial set of components C in the $<_\Gamma$ ordering for which:

If $a_i \in C \cap U$ for $i \in \omega_1$, then there is some $b \in V$ connected to all the a_i's. (5.13)

It is easy to establish (5.13) for Γ^ω/p once the following observation is made. Suppose that $h \in \mathrm{DP}$, p is a nonprincipal ultrafilter on ω, and $G = (\Pi_n G_{h(n)})/p$. Then (P_1) implies that G is a bipartite graph with the following property.

If $a_i \in G \cap U$, for $i \in \omega_1$, then there is a $b \in G \cap V$ connected to all the a_i's. (5.14)

This follows by applying P_1 to $A_n = h(n)^2 + 1$, $\{a_\alpha \mid \alpha \in \omega_1\}$, and h.

Now we turn to the consistency result itself.

3.9 Theorem. *Let $\langle A_n \mid n \in \omega\rangle$ be a sequence of finite sets. Let $h \in \mathrm{DP}$ (diverging to ∞ with $h(n) \geq 1$). Then there is a proper, ${}^\omega\omega$-bounding forcing poset P, of size $2^{\aleph_0}$, such that in any generic extension $V[G]$ via P the following holds.*

> *There is in $V[G]$ a sequence $\langle H_n \mid n \in \omega\rangle$, with $H_n \subseteq A_n$ and $|H_n| \leq h(n)$, that eventually bounds every ground-model $f \in \Pi_n A_n$. That is, if $f \in V \cap \Pi_{n<\omega} A_n$, then for some k and for all $n \geq k$, $f(n) \in H_n$.*

To obtain the desired model where P_1 and P_2 hold, assume $\mathrm{CH} + 2^{\aleph_1} = \aleph_2$ and iterate with countable support ω_2 many posets as in the theorem. By CH, the resulting poset satisfies the $\aleph_2$-c.c. (Theorem 2.10). This ensures P_1, since any parameters for P_1 appears in an initial segment of the iteration, so that a suitable bookkeeping device takes care of all possible sequences. P_2 is a consequence of the fact that the resulting poset is ${}^\omega\omega$-bounding and hence the ground reals give a bounding sequence of length ω_1 (by the preservation theorem). We turn to the proof of the theorem.

For any finite set A let $\mathcal{P}(A)$ be the power set of A, and $\mathcal{P}_m(A)$ be the collection of subsets of A of cardinality $\leq m$. We say that $E \subseteq \mathcal{P}(A)$ is a

k-cover (k a natural number) if for every $x \subseteq A$ of size $\leq k$, for some $e \in E$, $x \subseteq e$.

Referring to the given DP function h, define

$$S = \bigcup_{\ell<\omega} \prod_{0 \leq i < \ell} \mathcal{P}_{h(i)}(A_i).$$

That is, $\eta \in S$ iff η is a finite sequence such that for $i \in \mathrm{dom}(\eta)$, $\eta(i)$ is a subset of A_i of size $\leq h(i)$. S forms a tree under extension (inclusion). We will force with infinite subtrees of S that are good in the following sense.

Let $T \subseteq S$ be a subtree (that is, a collection of sequences in S closed under initial segments). We make the following definitions.

1. If $\eta \in T$ then the number $\mathrm{dom}(\eta)$ is also called the *height* of the node η. Let $T\restriction m$ be the collection of all nodes in T of height $< m$.

2. We say that $\eta \in T$ is the *stem* of T if η is comparable to all nodes of T (under inclusion), and η is maximal with this property.

3. A node $\eta \in T$ is said to be *k-covering in T* iff its (immediate) successors in T form a k-cover of the appropriate A_i ($i = \mathrm{dom}(\eta)$). That is, $\{\mu(i) \mid \mu \in T \text{ extends } \eta\}$ is a k-cover of A_i.

Let P be the poset (under inclusion) of all infinite subtrees $T \subseteq S$ that have a stem $\sigma(T)$, and each node $\eta \in T$ is at least 1-covering (except the nodes below the stem which are not 1-covering), and such that, for every k, except for finitely many nodes, all nodes of T are k-covering.

In any forcing extension via P, the generic sequence of stems provides a sequence $H_n \subseteq A_n$ with $|H_n| \leq h(n)$. A density argument shows that every ground model $f \in \Pi_n A_n$ is eventually bounded by the H_n's. In this argument, use the obvious remark that if $E \subseteq P_m(A)$ is a k-cover, and $a \in A$, then the collection of $e \in E$ such that $a \in e$ form a $(k-1)$-cover of A. Both properness and the ${}^\omega\omega$-bounding property follow once we prove that P satisfies Axiom A^* of Baumgartner (see Definition 2.3). For this we define relations $\leq_k$, for $0 \leq k < \omega$, on the trees in P.

$\leq_0$ is just the poset ordering (inverse inclusion).

Define $T_1 \leq_1 T_2$ iff T_2 is a pure extension of T_1: that is, T_2 extends T_1, and they have the same stem.

Define $T_1 \leq_k T_2$ for $k > 1$ iff $T_1 \leq_1 T_2$, $T_1\restriction k = T_2\restriction k$ and for every $i \leq k$, for any $\eta \in T_2$, if η is i-covering in T_1 then η remains i-covering in T_2. The following is a direct consequence of the definitions.

3.10 Lemma. *$\leq_k$ is transitive, and $k < \ell$ implies that $\leq_\ell \subseteq \leq_k$.*

3.11 Lemma. *If $T_1 \leq_1 T_2 \leq_2, \ldots, T_n \leq_n T_{n+1}, \ldots,$ then a fusion $T \in P$ can be defined such that $T_i \leq_i T$ for all i.*

Proof. Indeed, $T = \bigcup_{1 \leq i < \omega} T_i\restriction i$ works. $\dashv$

Given a name $\underset{\sim}{\tau}$ of an ordinal we must show that every $T \in P$ has a $\leq_k$ extension that decides $\underset{\sim}{\tau}$ up to finitely many possibilities. (This can be seen to be an equivalent formulation of item 2 in Definition 2.3.)

Say that a tree T is *m-covering* if every node in T (not below the stem) is m-covering. For any $T \in P$ and $\eta \in T$, let $T(\eta)$ be the subtree of T obtained by letting η to be the stem. The following lemma suffices to prove Axiom A^*.

3.12 Lemma. *Let $\underset{\sim}{\tau}$ be a P-name of an ordinal. If $m \geq 2k$ and T is m-covering, then T has a pure extension T' that is k-covering and such that for some finite set B of ordinals, $T' \Vdash \underset{\sim}{\tau} \in B$.*

Proof. A node η of T is *good* iff $T(\eta)$ has a pure, k-covering extension that decides $\underset{\sim}{\tau}$ up to finitely many possibilities. η is *bad* if it is not good. So, the lemma says that the stem of T is good.

Let X be a set of successors of some η in T; we say that X is a *majority set* if X is k-covering. More formally, X is a majority set if for $i = |\eta|$ the collection $\{\mu(i) \mid \mu \in X\}$ is a k-cover of A_i.

Observe that since any $\eta \in T$ is m-covering and $m \geq 2k$, if the set of successors of η is given as a union $X_1 \cup X_2$, then X_1 or X_2 is a majority set. (For otherwise there are sets $x_1, x_2 \subseteq A_i$ of size k each such that x_1 is not covered by the nodes of X_1 and x_2 is not covered by the nodes of X_2. But then $x_1 \cup x_2$ is of size $\leq m$ and is not covered by any successor of η!) Hence if $\eta \in T$ is bad, then the bad successors of η form a majority set.

For any trees T_1, T_2 we say that T_2 is a majority extension of T_1 if $T_2 \geq T_1$ is obtained by taking only majority sets of successors in T_1. Equivalently, T_2 is a pure extension of T_1 which is k-covering.

Now if the lemma does not hold and the stem is bad, then there is a majority extension T' of T consisting entirely of bad nodes. This is impossible: pick any $T'' \geq T'$ that decides $\underset{\sim}{\tau}$, and find in T'' a node η such that $T(\eta)$ is k-covering. Then η must be good (already in T). $\dashv$

4. Preservation of Unboundedness

This section is adapted from [13] (reworked in [15, Chap. VI]). A forcing poset P is said to be *weakly ${}^{\omega}\omega$-bounding* if the old reals are not bounded in the extension. That is, the following holds in every extension $V[G]$ via P: for any $f \in {}^{\omega}\omega \cap V[G]$ there is a $g \in V$ such that $\{n \mid f(n) \leq g(n)\}$ is infinite. For example, the Cohen-real forcing is weakly ${}^{\omega}\omega$-bounding. (Given $f \in V^P$, let $\{c_n \mid n \in \omega\}$ enumerate all Cohen conditions, and define $g(n)$ so that some extension of c_n forces that $g(n) = \underset{\sim}{f}(n)$.)

4.1 Theorem. *The weak ${}^{\omega}\omega$-bounding property is preserved by the limit of a countable support iteration of proper posets if each initial part of the iteration is weakly ${}^{\omega}\omega$-bounding.*

Thus, if δ is a limit and $\langle P_i \mid i \leq \delta\rangle$ is a countable support iteration of proper posets and every P_i for $i < \delta$ is weakly ${}^{\omega}\omega$-bounding, then P_δ is weakly ${}^{\omega}\omega$-bounding as well.

Observe the difference between the formulation of this theorem and that of Theorem 3.5: here we speak about initial parts of the iteration—not about the iterands. In the next subsection we will explain why the iteration of weakly ${}^{\omega}\omega$-bounding posets is not necessarily weakly ${}^{\omega}\omega$-bounding, and we will define the notion of almost bounding and show that the iteration of almost bounding posets is weakly ${}^{\omega}\omega$-bounding.

Theorem 4.1 is proved by induction on δ. Let $\underset{\sim}{f}$ be a name for a real in V^{P_δ}, and $p_0 \in P_\delta$ an arbitrary condition. Pick $M \prec H_\kappa$ countable, with $P_\delta, p_0, \underset{\sim}{f} \in M$ as usual. Fix an increasing sequence $\gamma_i \in \delta \cap M$ converging to $\sup(\delta \cap M)$. Let $g \in {}^{\omega}\omega$ $<^*$-dominate all the reals of M. We will find in P_δ an extension q of p_0 that forces

$$\{n \in \omega \mid \underset{\sim}{f}(n) \leq g(n)\} \quad \text{is infinite.}$$

As before, we define by induction conditions $q_n \in P_{\gamma_n}$ that are (M, P_{γ_n})-generic, and names $\underset{\sim}{p_n} \in V^{P_{\gamma_n}}$ such that:

1. $q_{n+1} \restriction \gamma_n = q_n$.
2. $q_n \Vdash_{\gamma_n}$ "$\underset{\sim}{p_n}$ is in $P_\delta \cap M$ and extends $\underset{\sim}{p_{n-1}}$, and $\underset{\sim}{p_n} \restriction \gamma_n \in \underset{\sim}{G_n}$ (the generic filter over P_{γ_n})".
3. $q_n \Vdash_{\gamma_n}$ "$\underset{\sim}{p_n} \Vdash_\delta$ for some $k \geq n$, $\underset{\sim}{f}(k) \leq g(k)$".

When done, $q = \bigcup_n q_n$ is in P_δ, and for every n

$$q \Vdash_\delta \underset{\sim}{p_n} \in G_\delta$$

(we have seen that in proving the Properness Extension Lemma 2.8). Hence q "knows" what every interpretation of $\underset{\sim}{p_n}$ knows, i.e., $q \Vdash_\delta$ for some $k \geq n$, $\underset{\sim}{f}(k) \leq g(k)$. This holds for every n. Hence q is as required.

We now turn to the inductive definition. To begin with, $\underset{\sim}{p_0}$ is in fact a condition—the given p_0—and $q_0 \in P_{\gamma_0}$ is an (M, P_{γ_0})-generic condition extending $p_0 \restriction \gamma_0$.

Suppose that q_n and $\underset{\sim}{p_n}$ are defined; we shall obtain $\underset{\sim}{p_{n+1}}$ and then q_{n+1}. Imagine a generic extension $V[G_n]$, where $q_n \in G_n \subseteq P_{\gamma_n}$. Then $\underset{\sim}{p_n}$ is realized as some condition $p_n \in P_\delta \cap M$ such that $p_n \restriction \gamma_n \in G_n$.

In $M[G_n]$, define an increasing sequence $\langle r_i \mid i \in \omega\rangle$ beginning with $r_0 = p_n$, of conditions in P_δ that decide the values of $\underset{\sim}{f}$, and such that $r_i \restriction \gamma_n \in G_n$ (use Lemma 1.2). Let f^* be the real thus interpreted; so for every $k < \omega$, r_k forces (in P_δ forcing) that $\underset{\sim}{f} \restriction k = f^* \restriction k$. Obviously $f^* \in M[G_n]$.

Since P_{γ_n} is weakly ${}^{\omega}\omega$-bounding, for some $h \in {}^{\omega}\omega \cap M$, $h(i)$ is above $f^*(i)$ for infinitely many i's. But $h <^* g$, and hence for some $i_0 \geq n+1$, $f^*(i_0) < g(i_0)$. For $j = i_0 + 1$, r_j fixes the value of $\underset{\sim}{f}(i_0)$ to be $f^*(i_0)$. Now define $\underset{\sim}{p}_{n+1}$ to be a P_{γ_n}-name of r_j. Finally, q_{n+1} is defined by the Properness Extension Lemma to be a condition in $P_{\gamma_{n+1}}$ such that $q_{n+1}\restriction\gamma_n = q_n$ and

$$q_{n+1} \Vdash_{\gamma_{n+1}} \underset{\sim}{p}_{n+1}\restriction\gamma_{n+1} \in \underset{\sim}{G}_{n+1}.$$

The proof is finished, but it is worth remarking that the definition of $\underset{\sim}{p}_{n+1}$ depends on g, the function that dominates M, hence $\underset{\sim}{p}_{n+1}$ cannot be defined in M. But of course it is always realized as some condition in M.

4.1. The Almost Bounding Property

The successor case, which causes no problem for the ${}^\omega\omega$-bounding property, is not obvious at all for the weakly ${}^\omega\omega$-bounding property. In fact, it is possible to have Q_1 weakly ${}^\omega\omega$-bounding, $Q_2 \in V$ weakly ${}^\omega\omega$-bounding in V^{Q_1}, yet $Q_1 \times Q_2$ adds a dominating real. For example, add $\aleph_1$ many Cohen reals (this is Q_1), and then do the Hechler forcing with conditions from V. (Hechler [6] posets adds a generic function in ${}^\omega\omega$ by giving finite information on the generic function, and a function in ${}^\omega\omega$ which the generic must from now on dominate. See also Jech [7].) Now, though Q_2 adds a dominating real to V, it is an exercise to see that Q_2 is weakly ${}^\omega\omega$-bounding in V^{Q_1}, because the Q_2-name of any real is already in $V^{Q_1\restriction\alpha}$ for some countable α.

In order to tackle the successor stage, we introduce a notion that is of intermediate strength between weakly ${}^\omega\omega$-bounding and ${}^\omega\omega$-bounding—*almost* ${}^\omega\omega$-bounding.

4.2 Definition. A poset Q is called *almost ${}^\omega\omega$-bounding* iff for every Q-name, $\underset{\sim}{f} \in {}^\omega\omega$, and condition $q \in Q$, there exists $g \in {}^\omega\omega$ such that

For every infinite $A \subseteq \omega$, there is a $q' \geq q$ such that: $(*)$

$$q' \Vdash \text{for infinitely many } n \in A,\ \underset{\sim}{f}(n) \leq g(n). \tag{5.15}$$

Notice the order of quantification: $\exists g \in {}^\omega\omega \forall A \subseteq \omega$. If it is reversed, then (for proper posets) this property becomes the weak ${}^\omega\omega$-bounding property.

4.3 Lemma. *If P is weakly ${}^\omega\omega$-bounding, and $Q \in V^P$ is almost ${}^\omega\omega$-bounding (in V^P), then $P * Q$ is weakly ${}^\omega\omega$-bounding.*

Proof. Let $\underset{\sim}{f}$ be a $P * Q$-name, and $(p, q) \in P * Q$ a condition that forces $\underset{\sim}{f} \in {}^\omega\omega$. We will find a generic extension via $P * Q$ with a filter containing (p, q) in which $\underset{\sim}{f}$ is weakly bounded by some function in V. First take a (V, P)-generic G with $p \in G$. Working in $V[G]$, $\underset{\sim}{f}$ "becomes" a name in Q-forcing of a real, and we continue to denote this name by $\underset{\sim}{f}$. Q "is" now an almost ${}^\omega\omega$-bounding forcing poset, and $q \in Q$ a condition. By definition, there is in $V[G]$ a function $g \in {}^\omega\omega$ such that $(*)$ (in Definition 4.2) holds. Since P is weakly ${}^\omega\omega$-bounding, g is weakly bounded, say by $h \in V$, and

$$A = \{n \mid g(n) \leq h(n)\}$$

is infinite, in $V[G]$. So there is an extension q' of q in Q for which (5.15) of $(*)$ holds. If the second generic extension is done with q' in the generic filter, then for an infinite subset $A_0 \subseteq A$, $f(n) \leq g(n)$ holds for $n \in A_0$. Thus $\underset{\sim}{f}$ is weakly dominated by $h \in V$. $\dashv$

By combining Theorem 4.1 and Lemma 4.3 we get the following theorem.

4.4 Theorem. *The iteration of almost ${}^{\omega}\omega$-bounding, proper posets is weakly ${}^{\omega}\omega$-bounding.*

4.2. Application to Cardinal Invariants

This section deals with two cardinal invariants $\mathfrak{b}$ and $\mathfrak{s}$ of the continuum. For additional information on these cardinals the reader may consult Blass's chapter in this Handbook. Following [13] we will establish here the consistency of

$$\text{bounding number} < \text{splitting number}.$$

The bounding number $\mathfrak{b}$ is the smallest cardinality of an unbounded subset of ${}^{\omega}\omega$ (in the eventual dominance ordering $<^*$). In what follows, $[\omega]^\omega$ denotes the set of infinite subsets of ω, and $\subseteq^*$ between members of $[\omega]^\omega$ denotes eventual inclusion, i.e. $A \subseteq^* B$ *iff* $A \setminus B$ is finite.

The splitting number $\mathfrak{s}$ is the smallest cardinality of a "splitting" set $S \subseteq [\omega]^\omega$, where S is splitting iff for every infinite $A \subseteq \omega$, some $B \in S$ splits A, that is, both $A \cap B$ and $A \setminus B$ are infinite. In other words, say that $A \subseteq \omega$ *makes an ultrafilter on* $S \subseteq [\omega]^\omega$ if for every $B \in S$ either $A \subseteq^* B$ or $A \subseteq^* \omega \setminus B$. Thus S is splitting iff no A makes an ultrafilter on S.

4.5 Theorem. *Assume* CH. *There is a generic extension in which $2^{\aleph_0} = \aleph_2$, cardinals are not collapsed, and $\mathfrak{b} < \mathfrak{s}$.*

The general structure of the consistency proof for this theorem is to iterate ω_2 almost ${}^{\omega}\omega$-bounding proper forcings that "kill" the old reals as a splitting family. Finally, by Theorem 4.4, the reals of the ground model are still not dominated, and hence $\mathfrak{b} = \aleph_1$, but $s = \aleph_2$ because no set of size $\aleph_1$ can be splitting. This is so because every set of reals of size $\aleph_1$ is included in some stage $\gamma < \omega_2$ of the iteration and hence was "killed" at the following stage (by introducing some A that makes an ultrafilter on $\mathcal{P}(\omega) \cap V_\gamma$). Thus we only need the following.

4.6 Theorem. *There is a proper, almost ${}^{\omega}\omega$-bounding poset Q of size $2^{\aleph_0}$ such that in V^Q:*

> *There is an infinite set $A \subseteq \omega$ such that for every $B \subseteq \omega$ from V, $A \subseteq^* B$ or $A \subseteq^* \omega \setminus B$.*

Proof. The first forcing notion that comes to mind is Mathias forcing [11]. It consists of pairs (u, E) where u is a finite and E an infinite subset of ω.

Extension is defined by $(u_1, E_1) \leq (u_2, E_2)$ iff $E_2 \subseteq E_1$, u_2 is an end-extension of u_1, and $u_2 \setminus u_1 \subseteq E_1$. If G is a generic filter, then $U = \bigcup\{u \mid (u, E) \in G$ for some $E\}$ makes an ultrafilter on $\mathcal{P}(\omega) \cap V$ (it is not split by any subset of ω in the ground model). However, this forcing introduces a dominating real—the enumeration of the generic subset—and hence we must search for another solution.

The conditions in Q will be pairs (u, T) such that $u \subseteq \omega$ is finite, and $T = \langle t_i \mid i \in \omega \rangle$ is a sequence of "logarithmic measures". Each t_i consists of a finite subset s_i of ω, also denoted $\mathrm{int}(t_i)$, and a finite measure, specified below, defined on all subsets of $\mathrm{int}(t_i)$ and taking natural number values. We have that $\max(u) < \min(s_i) \leq \max(s_i) < \min(s_{i+1})$. Define $\mathrm{int}(T) = \bigcup_i \mathrm{int}(t_i)$; this is an infinite set of numbers in ω above u, and the order on Q will be such that if $(u_1, T_1) \leq (u_2, T_2)$ holds, then $(u_1, \mathrm{int}(T_1)) \leq (u_2, \mathrm{int}(T_2))$ as Mathias conditions. The reason that the reals in V do not split the generic real $U = \bigcup\{u \mid \exists T (u, T) \in G\}$ is the same as for the Mathias forcing: it will be shown that if $(u_1, T_1) \in Q$ then whenever $\mathrm{int}(T_1) = x \cup y$, there is an extension (u_2, T_2) of (u_1, T_1) in Q such that $\mathrm{int}(T_2) \subseteq x$ or $\mathrm{int}(T_2) \subseteq y$. To define Q we need first the notion of "logarithmic measure".

A *logarithmic measure* on $S \subseteq \omega$ (S is usually finite) is a function $h : \mathcal{P}_\omega(S) \to \omega$ (where $\mathcal{P}_\omega(S)$ is the collection of all *finite* subsets of S) and such that if $A \cup B \subseteq S$ is finite and $h(A \cup B) \geq \ell + 1$ then $h(A) \geq \ell$ or $h(B) \geq \ell$. It follows that if $h(A_0 \cup \cdots \cup A_{n-1}) > \ell$ then $h(A_j) \geq \ell - j$ for some $0 \leq j < n$.

When h is a logarithmic measure on S and S is finite, then $h(S)$ is called the level of h, and is denoted $\mathrm{level}(h)$.

Actually, our measures will all be induced by a collection of positive sets as follows: Given a collection $P \subseteq \mathcal{P}_\omega(S)$ that is closed upwards ($a \in P$ and $a \subseteq b$ imply $b \in P$), a logarithmic measure h *induced by* P is inductively defined as follows on $\mathcal{P}_\omega(S)$:

1. $h(e) \geq 0$ for every $e \in \mathcal{P}_\omega(S)$.
2. $h(e) > 0$ iff $e \in P$.
3. For $\ell \geq 1$, $h(e) \geq \ell + 1$ iff $|e| > 1$ and whenever $e = e_1 \cup e_2$ then $h(e_1) \geq \ell$ or $h(e_2) \geq \ell$.

Then $h(e) = \ell$ iff ℓ is the maximal natural number such that $h(e) \geq \ell$ (there has to be such ℓ and $h(e) < \infty$).

We have, for measures defined by positive sets, that if $h(e) = k$ and $e \subseteq a$ then $h(a) \geq k$.

For example, if the positive sets are those containing at least two points, then $h(X)$ is the least i for which $|X| \leq 2^i$. We will use the following observation.

4.7 Lemma. *Let $P \subseteq \mathcal{P}_\omega(\omega)$ be an upwards closed collection (of finite non-empty sets). The following condition implies that the measure h induced by P on $\mathcal{P}_\omega(\omega)$ has arbitrarily high values:*

For every decomposition $\omega = A_1 \cup \cdots \cup A_n$ into finitely many sets, for some i, $\mathcal{P}_\omega(A_i) \cap P \neq \emptyset$.

Assuming this condition, for every $k < \omega$ and decomposition $\omega = \bigcup_{i<n} A_i$ into $n < \omega$ sets, for some $i < n$, $h(e) \geq k$ for some $e \subseteq A_i$.

Proof. Suppose that P satisfies the condition of the lemma, and we shall prove by induction on $k < \omega$ the required conclusion.

For $k = 1$, this is just the assumed condition. Assume the claim for $k = \ell$, and let us prove it for $\ell + 1$. Let $\omega = \bigcup_{i<n} A_i$ be a decomposition such that (contrary to our lemma) for every $j < \omega$, for all $i < n$, $h(A_i \cap j) \not\geq \ell + 1$. Thus for every $i < n$ there are e_1 and e_2 such that $A_i \cap j = e_1 \cup e_2$ and both $h(e_1) \not\geq \ell$ and $h(e_2) \not\geq \ell$. Kőnig's lemma can be used to find a decomposition $A_i = E^i_1 \cup E^i_2$ such that there is no x with $h(x) \geq \ell$ included in E^i_1 or in E^i_2. Hence a decomposition of ω into $2n$ sets contradicts the inductive assumption for ℓ. ⊣

To prove Theorem 4.6, we define the poset Q which was informally described above. Q consists of all pairs $p = (u, T)$ where

1. $u \subseteq \omega$ is finite (called the *stem* of p) and
2. $T = \langle t_i \mid i \in \omega \rangle$ is a sequence of measures $t_i = (s_i, h_i)$ where h_i is a logarithmic measure on s_i, a finite subset of ω ($s_i = \mathrm{int}(t_i)$), such that
   (a) $\max(u) < \min(s_0)$.
   (b) $\max(s_i) < \min(s_{i+1})$.
   (c) The level of the measures diverges to infinity, and, moreover, $\mathrm{level}(h_i) < \mathrm{level}(h_{i+1})$. (We defined $\mathrm{level}(h_i) = h_i(s_i)$.)

Recall that $\mathrm{int}(T) = \bigcup\{s_i \mid i \in \omega\}$. For convenience, we write $p = (u, T)$ even when $\max(u)$ is not below $\min(s_0)$. This p refers then to the condition obtained by throwing away sufficiently many t_i's, that is, $p = (u, \langle t_i \mid i \geq k \rangle)$ where k is first such that $\max(u) < \min(s_k)$.

The extension relation for Q is defined by:

$$(u_1, T_1) \leq (u_2, T_2),$$

where $T_\ell = \langle t^\ell_i \mid i \in \omega \rangle, t^\ell_i = (s^\ell_i, h^\ell_i)$ for $\ell = 1, 2$, if and only if

1. u_2 is an end extension of u_1, and $u_2 \setminus u_1 \subseteq \mathrm{int}(T_1)$.
2. $\mathrm{int}(T_2) \subseteq \mathrm{int}(T_1)$. Moreover, there is a sequence of finite subsets of ω, $\langle B_i \mid i \in \omega \rangle$ with $\max(B_i) < \min(B_{i+1})$ and $\max(u_2) < \min(s^1_j)$ for $j = \min(B_0)$, such that $s^2_i \subseteq \bigcup\{s^1_j \mid j \in B_i\}$.
3. For every i: if $e \subseteq s^2_i$ is h^2_i-positive (i.e., $h^2_i(e) > 0$), then for some j, $e \cap s^1_j$ is h^1_j-positive.

The reader may check that this defines an order on Q. An extension that does not change the stem is called a *pure extension.* Observe that if (w, R) extends (v, T) then (w, R) extends (w, T) as well. That is, any extension can be formed by first extending the stem and then taking a pure extension. We shall prove that Q is proper and almost ${}^\omega\omega$-bounding.

For properness, Axiom A will be shown to hold. The $\leq_n$ relations needed are defined as follows. $<_0$ is the extension relation on Q just defined. For $n > 0$,

$$(u_1, T_1) \leq_n (u_2, T_2) \quad \text{iff} \quad \begin{array}{l}(u_2, T_2) \text{ is a pure extension of} \\ (u_1, T_1) \text{ and for } 0 \leq i < n-1,\ h_i^1 = h_i^2.\end{array}$$

That is, the stem and the first $n-1$ measures (and sets) are the same in both conditions. In particular $(u_1, T_1) \leq_1 (u_2, T_2)$ iff (u_2, T_2) is a pure extension of (u_1, T_1).

We can check the fusion property. Suppose that $p_0 \leq_1 p_1 \leq_2 \cdots \leq_{i-1} p_{i-1} \leq_i p_i \ldots$ is a fusion sequence, where $p_\ell = (u_\ell, \langle t_i^\ell \mid i \in \omega\rangle)$. Then set $p = (u, T)$ by $u = u_0$, and $T = \langle t_i \mid i \in \omega\rangle$ defined as $t_i = t_i^{i+1}$ (p takes the common stem u, and the measure t_i that is common to all the conditions with indices above i) then $p \in Q$ and $p_i \leq_i p$ for all i.

To verify Axiom A, we have to prove that for any $n \in \omega$, $p = (u, T)$, and dense open set D, there are a countable $D_0 \subseteq D$ and an extension $p \leq_n p_0$, such that D_0 is predense above p_0.

We say that a condition (u, T) (with $T = \langle t_i \mid i \in \omega\rangle$) is *preprocessed* for D and i iff for every $v \subseteq i$ that is an end extension of u, if $(v, \langle t_j \mid j \geq i\rangle)$ has a pure extension in D, then $(v, \langle t_j \mid j \geq i\rangle)$ is already in D. The following can be easily proved:

1. If (u, T) is preprocessed for D and i, then any extension is also preprocessed for D and i.

2. Any given condition has a $\leq_{i+1}$ extension that is preprocessed for D and i.

3. Hence by taking the fusion of a sequence, one may obtain an extension of any given condition that is preprocessed for every i.

Now if $p_0 = (u, T)$ is preprocessed for every i and D_0 is the set of all conditions in D of the form $(v, \langle t_j \mid j \geq i\rangle)$, then D_0 is predense above p_0. Thus Axiom A holds.

The almost ${}^\omega\omega$-bounding property of Q is of course the main point.

4.8 Lemma (Main Lemma). *Let $\underset{\sim}{f}$ be a Q-name for a function in ${}^\omega\omega$, and $q \in Q$ a condition. There is a pure extension $p \geq q$, $p = (u, T)$, $T = \langle t_i \mid i \in \omega\rangle$, with the following property:*

> *For any i and $s \subseteq \mathrm{int}(t_i)$ that is t_i-positive, if $v \subseteq i$ then for some $w \subseteq s$, $((v \cup w), T)$ determines the value of $\underset{\sim}{f}(i)$.*

We first show how this lemma implies the almost bounding property (Definition 4.2). Given $\underset{\sim}{f}$ and q, let $p \in Q$ be as in the lemma. For each i, define

$$g(i) = \max\{k \mid \text{for some } v \subseteq i \text{ and } w \subseteq \operatorname{int}(t_i),\ (v \cup w, T) \Vdash \underset{\sim}{f}(i) = k\}.$$

Now let $A \subseteq \omega$ be any infinite set. Put $p' = (u, \langle t_i \mid i \in A\rangle)$. Then p' extends p and

$$p' \Vdash \text{ for infinitely many } i \in A,\ \underset{\sim}{f}(i) \leq g(i).$$

To see this, let p'' be any extension of p' and k an arbitrarily high integer. Say $p'' = (v, R)$ where $R = \langle r_i \mid i \in \omega\rangle$. Find $i > k$, $i \in A$, such that $v \subseteq i$, and $\operatorname{int}(R) \cap \operatorname{int}(t_i)$ is t_i-positive (there is such an i by the definition of extension in Q). Using the property of the Main Lemma for $s = \operatorname{int}(R) \cap \operatorname{int}(t_i)$, let $w \subseteq s$ be such that $(v \cup w, T)$ decides the value of $\underset{\sim}{f}(i)$. Then $(v \cup w, R)$ extends p'' and makes the same decision because it is also an extension of $(v \cup w, T)$.

Now we turn to the proof of the Main Lemma. The required condition p is obtained as a fusion of a sequence defined inductively in ω steps. At the ith step we have a condition $p_i = (u, \langle t_j \mid j \in \omega\rangle)$ and we define p_{i+1} so that $p_i \leq_{i+1} p_{i+1}$. That is, u and $t_0, \dots, t_{i-1}$ are not touched in the extension. We start with $T = \langle t_j \mid j \geq i\rangle$ and apply the following lemma 2^i times, considering each $v \subseteq i$ in turn.

4.9 Lemma. *Let $(\emptyset, T)$ be a condition, $\underset{\sim}{f}$ a name for a function in ${}^{\omega}\omega$, and i any natural number. Fix $v \subseteq i$. There is a pure extension $(\emptyset, R)$ of $(\emptyset, T)$ with $R = \langle r_\ell \mid \ell \in \omega\rangle$ such that for every ℓ and r_ℓ-positive $s \subseteq \operatorname{int}(r_\ell)$, for some $w \subseteq s$, $(v \cup w, \langle r_m \mid m > \ell\rangle)$ determines the value of $\underset{\sim}{f}(i)$. (Observe that any further pure extension of $(\emptyset, R)$ retains this property.)*

Proof. We may assume that $(\emptyset, T)$ (and thence any extension) is preprocessed for $\underset{\sim}{f}(i)$: If an extension (w, R) determines the value of $\underset{\sim}{f}(i)$, then already (w, T) determines that value.

Define a measure h on $\operatorname{int}(T)$ induced by the following positive sets. A finite set $x \subseteq \operatorname{int}(T)$ is *positive* iff

1. For some l, $x \cap \operatorname{int}(t_l)$ is t_l-positive. (t_l are the measures composing T.)

2. For some $w \subseteq x$, $(v \cup w, T)$ determines the value of $\underset{\sim}{f}(i)$.

1. ensures that if $(\emptyset, R)$ is obtained by taking a sequence of subsets of $\operatorname{int}(T)$ with increasing h-measures, then $(\emptyset, R)$ is an extension of $(\emptyset, T)$. 2. ensures that this extension has the required properties.

It remains to check that the basic property required to obtained arbitrarily high values of h holds (Lemma 4.7). So let $\operatorname{int}(T) = A_0 \cup \cdots \cup A_{n-1}$ be a partition, and we will find some A_ℓ that contains a positive set. Because the measures t_i are logarithmic and increasing to infinity, for some $\ell < n$ there exists an infinite index set $I \subseteq \omega$ such that the t_i-measures of $A_\ell \cap \mathrm{int}(t_i)$ for $i \in I$ are diverging to infinity. (Otherwise, for every $\ell < n$ there is a finite bound on the t_i measures of $A_\ell \cap \mathrm{int}(t_i)$ for $i \in \omega$, and hence there is a bound k on the measures of $A_\ell \cap \mathrm{int}(t_i)$ where $\ell < n$ and $i \in \omega$. But this is impossible when the measure of t_i is greater than $k + n$.) We may thus find an extension of (v, T) of form (v, R) such that $\mathrm{int}(R) \subseteq A_\ell$. Now pick any extension $(v \cup w, R')$ of (v, R) that decides the value of $\underset{\sim}{f}(i)$. Then already $(v \cup w, T)$ decides that value. This shows the existence of a positive subset of A_ℓ, namely a finite union x of $\mathrm{int}(r_m)$'s such that $w \subseteq x$. $\dashv$

This completes the proof of Theorem 4.6. $\dashv$

5. No New Reals

This last section deals with proper posets that add no new reals, that is, introduce no new subsets of ω in any generic extension. (Such posets add no countable sequences of ordinals either, but the shorter expression is the customary description.) It follows from the work of Jensen and Johnsbråten [8] that the countable support iteration of forcing posets that add no new reals may well add a new real. This shows the need for more complex schemes for iterating posets that add no new reals, and the notion of Dee-completeness is simpler than any other scheme introduced by Shelah for that purpose. The preservation proof that we present here uses the notion of α-properness, and we therefore begin with this notion (following Shelah [15, Chap. V]). Our aim is to explain Dee-completeness by means of a simple example (in Sect. 5.2), and then to give a rather detailed proof of the Dee-completeness Iteration Theorem 5.17.

5.1. α-Properness

Let $\alpha > 0$ be a countable ordinal and $\bar{M} = \langle M_i \mid i < \alpha \rangle$ a sequence of countable, elementary substructures of H_λ (where λ is some fixed regular cardinal). We say that $\bar{M}$ is an *α-tower* iff

1. For every limit $\delta < \alpha$, $M_\delta = \bigcup_{i<\delta} M_i$.
2. For every $j < \alpha$, $\langle M_i \mid i \leq j \rangle \in M_{j+1}$.

Since λ is regular (or, at least, $\mathrm{cf}(\lambda) > \aleph_0$) if $M \subseteq H_\lambda$ is countable then $M \in H_\lambda$. Thus, for $j < \alpha$, $\langle M_i \mid i \leq j \rangle \in H_\lambda$ so that 2. makes sense.

5.1 Definition. Let $\alpha > 0$ be a countable ordinal. A forcing poset P is *α-proper* iff for sufficiently large λ and every α-tower $\bar{M} = \langle M_i \mid i < \alpha \rangle$ of countable, elementary substructures of H_λ such that $P \in M_0$, the following holds: Every $p \in P \cap M_0$ has an extension $q \geq p$ that is (M_i, P)-generic for every $i < \alpha$. We say that q is $(\bar{M}, P)$-generic in this case.

Clearly, properness is 1-properness. We say that P is *$<\omega_1$-proper* if it is α-proper for every countable ordinal α.

Any c.c.c. poset is $<\omega_1$-proper. Any countably closed poset is $<\omega_1$-proper. In proving this, one sees why each successor structure in the tower needs to contain the sequence of structures up to that point.

Another example is given by Axiom A posets (Definition 2.3). Let P be an Axiom A poset and prove by induction on $\alpha < \omega_1$ that P is α-proper. For $\alpha = \omega$ we argue as follows. Let $\bar{M} = \langle M_i \mid i < \omega \rangle$ be a tower of countable, elementary substructures of H_λ with $P \in M_0$, and let $p_0 \in P \cap M_0$ be a given condition. Construct by induction conditions $p_i \in P$ such that:

$$p_i \leq_i p_{i+1}, \quad \text{and} \quad p_{i+1} \in M_{i+1} \text{ is } (M_i, P)\text{-generic.}$$

Let q be the fusion condition, satisfying $p_i \leq_i q$ for all i. Then $p_i \leq q$ and q is thence (M_i, P)-generic.

It is not difficult to check that if P is α-proper then it is $(\alpha+1)$-proper. So properness implies n-properness for every $n < \omega$. It does not imply ω-properness. If $\alpha = \beta_1 + \beta_2$ is a sum of two smaller ordinals, then any poset that is both β_1 and β_2 proper is also α proper. So, for α-properness, the values that really count are indecomposable countable ordinals.

Equivalent Definition

As for properness, it is useful to know that if P and Q are posets, P is α-proper and Q is α-proper in V^P, then Q is α-proper already in V. A suitable notion of closed unbounded sets is introduced which is the basis for an equivalent definition of α-properness, from which that useful fact follows. Recall that $\mathcal{P}_{\aleph_1}(A)$ is the collection of all countable subsets of A.

5.2 Definition. Let A be an uncountable set and α a countable ordinal.

1. $P^\alpha_{\aleph_1}(A)$ is the set of all increasing and continuous sequences $\langle a_i \mid i < \alpha \rangle$ where $a_i \in \mathcal{P}_{\aleph_1}(A)$ for all $i < \alpha$. (The sequence is increasing if $a_i \subseteq a_j$ for $i < j$, and it is continuous if for limit $\delta < \alpha$, $a_\delta = \bigcup_{i<\delta} a_i$.)

2. Let $F : (\bigcup_{\beta<\alpha} P^\beta_{\aleph_1}(A)) \times [A]^{<\aleph_0} \to \mathcal{P}_{\aleph_1}(A)$ be given. We say that F is an *α-function.* A sequence $\langle a_i \mid i < \alpha \rangle \in P^\alpha_{\aleph_1}(A)$ is said to be *closed* under F if for every $\beta < \alpha$ that is a successor ordinal or zero, for every $x \in [a_\beta]^{<\aleph_0}$, $F(\langle a_i \mid i < \beta \rangle, x) \subseteq a_\beta$. So a_0 is closed under the function taking $x \in [a_0]^{<\aleph_0}$ to $F(\emptyset, x)$; a_1 is closed under the function taking $x \in [a_1]^{<\aleph_0}$ to $F(\langle a_0 \rangle, x)$, and so forth.

3. Let $G(F) \subseteq P^\alpha_{\aleph_1}(A)$ be the collection of all α-sequences that are closed under F. Then $\{G(F) \mid F \text{ is an } \alpha\text{-function}\}$ generates a countably closed filter on $P^\alpha_{\aleph_1}(A)$, which is denoted $\mathcal{D}^\alpha_{\aleph_1}(A)$.

4. We say that $S \subseteq P^\alpha_{\aleph_1}(A)$ is *stationary* if its complement is not in $\mathcal{D}^\alpha_{\aleph_1}(A)$.

Useful examples of $\mathcal{D}^{\alpha}_{\aleph_1}(A)$ sets are the following:

1. The collection of all α-towers $\langle M_i \mid i < \alpha\rangle$ of countable elementary substructures of H_λ. Here A is the set H_λ, and M_i refers to the universe of that structure.

2. For a closed unbounded set $C \subseteq \mathcal{P}_{\aleph_1}(A)$, collect all sequences $\langle a_i \mid i < \alpha\rangle \in P^{\alpha}_{\aleph_1}(A)$ such that $a_i \in C$ for all i.

In a sense, $\mathcal{D}^{\alpha}_{\aleph_1}(A)$ is normal. If $g : \mathcal{P}_{\aleph_1}(A) \to A$ is a choice function (namely $g(x) \in x$ whenever x is non-empty) and $S \subseteq P^{\alpha}_{\aleph_1}(A)$ is stationary, then for some fixed $v \in A$, $\{\langle a_i \mid i < \alpha\rangle \in S \mid g(a_0) = v\}$ is stationary.

The following is standard.

5.3 Lemma. *Suppose that $A_0 \subseteq A_1$ are uncountable and $C_1 \in \mathcal{D}^{\alpha}_{\aleph_1}(A_1)$. Define $C_0 = \{\langle a_i \cap A_0 \mid i < \alpha\rangle \mid \langle a_i \mid i < \alpha\rangle \in C_1\}$. Then $C_0 \in \mathcal{D}^{\alpha}_{\aleph_1}(A_0)$.*

The proof of the following theorem resembles that of the Properness Equivalents Theorem 2.13.

5.4 Theorem. *For any poset P and countable ordinal α the following are equivalent.*

1. *P is α-proper (as in Definition 5.1).*

2. *For some $\lambda > 2^{|P|}$, for every α-tower $\bar{M}$ of countable elementary substructures of H_λ, any condition in M_0 has an extension that is $(\bar{M}, P)$-generic.*

3. *For every uncountable λ, P preserves stationary subsets of $P^{\alpha}_{\aleph_1}(\lambda)$.*

4. *For $\lambda_0 = 2^{|P|}$, P preserves stationary subsets of $P^{\alpha}_{\aleph_1}(\lambda_0)$.*

5. *The α-test set for P, as defined below, is in $\mathcal{D}^{\alpha}_{\aleph_1}(A)$.*

   Form $A = P \cup \mathcal{P}(P)$. Then $\langle a_i \mid i < \alpha\rangle \in P^{\alpha}_{\aleph_1}(A)$ is in the α-test set for P iff for every $p_0 \in a_0 \cap P$ there is a $p \in P$ that is a_i-generic for every $i < \alpha$. (That is, for every $D \in a_i \cap \mathcal{P}(P)$, if D is dense in P, then D is pre-dense above p.)

Preservation of α-Properness

We shall prove the following.

5.5 Theorem. *Let $\alpha < \omega_1$ be a countable ordinal and $\langle P_i \mid i \leq \gamma\rangle$ a countable support iteration of α-proper posets. Then the limit P_γ is α-proper.*

The theorem is obtained as a particular case of the α-Extension Lemma which is proved by induction on α. As the case $\alpha = \omega$ involves almost all the essential ideas of the general case, the reader may concentrate on ω-properness.

5.6 Lemma (The α-Extension Lemma). *Let α be any countable ordinal and $\langle P_i \mid i \leq \gamma \rangle$ a countable support iteration of α-proper posets. Let λ be a sufficiently large cardinal, and let $\bar{M} = \langle M_\xi \mid \xi \leq \alpha \rangle$ be an $(\alpha+1)$-tower of countable elementary substructures of H_λ, with $\gamma, P_\gamma, \alpha \in M_0$. For every $\gamma_0 \in \gamma \cap M_0$ and $q_0 \in P_{\gamma_0}$ that is $(\bar{M}, P_{\gamma_0})$-generic, the following holds:*

If $\underset{\sim}{p_0} \in V^{P_{\gamma_0}}$ is such that

$$q_0 \Vdash_{\gamma_0} \underset{\sim}{p_0} \in P_\gamma \cap M_0 \wedge \underset{\sim}{p_0} \restriction \gamma_0 \in \underset{\sim}{G_0}$$

(where $\underset{\sim}{G_0}$ is the canonical name for the (V, P_{γ_0})-generic filter), then there is an $(\bar{M}, P_\gamma)$-generic condition q such that

$$q \restriction \gamma_0 = q_0 \quad \textit{and} \quad q \Vdash_\gamma \underset{\sim}{p_0} \in \underset{\sim}{G}$$

(where $\underset{\sim}{G}$ is the canonical name for the (V, P_γ)-generic filter, and the name $\underset{\sim}{p_0} \in V^{P_{\gamma_0}}$ is now viewed as member of V^{P_γ}).

Proof. The proof is by induction on $\alpha < \omega_1$ and for any fixed α by induction on γ. We begin with $\alpha = \alpha' + 1$ a successor ordinal. We are given a tower $\bar{M} = \langle M_\xi \mid \xi \leq \alpha' + 1 \rangle$, a condition q_0, and a name $\underset{\sim}{p_0}$ as in the lemma. We intend to define a name $\underset{\sim}{r} \in V^{P_{\gamma_0}}$ such that q_0 forces (in P_{γ_0}) the following sentences.

1. $\underset{\sim}{r} \in M_\alpha \cap P_\gamma$ is $\langle M_\xi \mid \xi \leq \alpha' \rangle$-generic.
2. $\underset{\sim}{r} \restriction \gamma_0 \in \underset{\sim}{G_0}$, and $\underset{\sim}{p_0} <_{P_\gamma} \underset{\sim}{r}$.

Then, using the Properness Extension Lemma 2.8, we can find a $q \in P_\gamma$ that is (M_α, P_γ)-generic and such that $q \restriction \gamma_0 = q_0$ and $q \Vdash \underset{\sim}{r} \in \underset{\sim}{G}$. It follows that q is as required.

To define $\underset{\sim}{r}$, let G_0 be a (V, P_{γ_0})-generic filter with $q_0 \in G_0$, and we shall describe $\underset{\sim}{r}[G_0]$. Let $p_0 \in P_\gamma \cap M_0$ be the interpretation of $\underset{\sim}{p_0}$. Then $p_0 \restriction \gamma_0 \in G_0$ and we can find a $q_0' \in G_0$ that extends both q_0 and $p_0 \restriction \gamma_0$. Now we can apply the inductive assumption on α' to the tower $\langle M_\xi \mid \xi \leq \alpha' \rangle$, to q_0' and to p_0, and we find a $q' \in P_\gamma$ such that $q' \restriction \gamma_0 = q_0'$, q' is $(\langle M_\xi \mid \xi \leq \alpha' \rangle, P_\gamma)$-generic, and $p_0 <_{P_\gamma} q'$. Since $M_\alpha[G_0] \prec H_\lambda[G_0]$, we can find a $q^* \in M_\alpha[G_0]$ with similar properties as q'. Namely, $q^* \in P_\gamma$ (and so $q^* \in M_\alpha$, as $M_\alpha[G_0] \cap V = M_\alpha$), $q^* \restriction \gamma_0 \in G_0$, $p_0 <_{P_\gamma} q^*$, and q^* is $(\langle M_\xi \mid \xi \leq \alpha' \rangle, P_\gamma)$-generic. Let $\underset{\sim}{r}$ be a name of q^* forced by q_0 to have these properties. Then $\underset{\sim}{r}$ is as required.

Assume now that α is a limit ordinal. In case γ is a successor ordinal, we can inductively apply the following two-step iteration lemma, whose proof is similar to the corresponding case of proper forcing (and is hence not given here).

5.7 Lemma. *Suppose that P_0 is α-proper and $P_1 \in V^{P_0}$ is α-proper in V^{P_0}. Then $R = P_0 * P_1$ is α-proper, and the following holds. Suppose that $\bar{M} \prec H_\lambda$ is an α-tower and $R \in M_0$. Let $\underset{\sim}{r} \in V^{P_0}$ be a name, and $p_0 \in P_0$ be an $(\bar{M}, P_0)$-generic condition such that*

$$p_0 \Vdash_{P_0} \underset{\sim}{r} \in M_0 \cap R \quad \textit{and} \quad \pi(\underset{\sim}{r}) \in \underset{\sim}{G_0}$$

where $\pi : R \to P_0$ is the projection (taking $(a,b) \in R$ to a), and $\underset{\sim}{G}_0$ is the canonical name for the (V, P_0)-generic filter. Then there is a name $\underset{\sim}{p}_1 \in V^{P_0}$ such that

1. *$(p_0, \underset{\sim}{p}_1)$ is $(\bar{M}, R)$-generic, and*
2. *$(p_0, \underset{\sim}{p}_1) \Vdash_R \underset{\sim}{r} \in \underset{\sim}{G}$*

where $\underset{\sim}{G}$ is the canonical name for the (V, R)-generic filter.

Continuing the proof of the α-Extension Lemma for α a limit ordinal, assume now that γ is a limit ordinal. We fix a sequence $\langle \alpha_n \mid n \in \omega \rangle$ increasing and cofinal in α, and a sequence $\langle \gamma_i \mid i \in \omega \rangle$ increasing in γ and such that $\gamma_n \in M_{\alpha_n}$ with γ_0 the given ordinal. (If $\mathrm{cf}(\gamma) = \omega$, let $\langle \gamma_i \mid i \in \omega \rangle$ be an increasing, cofinal in γ sequence in $M_0 \cap \gamma$, with γ_0 as given. If $\mathrm{cf}(\gamma) > \omega$, define $\gamma_n = \sup(\gamma \cap M_{\alpha_{n-1}})$ for $n \geq 1$.) We intend to define by induction on $n < \omega$ conditions $q_n \in P_{\gamma_n}$ and names $\underset{\sim}{p}_n \in V^{P_{\gamma_n}}$ such that:

1. $q_0 \in P_{\gamma_0}$ is the given condition. And for $n > 0$, $q_n \in P_{\gamma_n}$ is $(\langle M_\xi \mid \alpha_n < \xi \leq \alpha \rangle, P_{\gamma_n})$-generic and $q_{n+1} \restriction \gamma_n = q_n$. (In fact, q_n is generic for the complete tower, but this follows from item 2 below.)
2. $\underset{\sim}{p}_0$ is given. $\underset{\sim}{p}_n$ is a P_{γ_n}-name such that

$$q_n \Vdash_{\gamma_n} \underset{\sim}{p}_n \text{ is a condition in } P_\gamma \cap M_{\alpha_n+1} \text{ such that:}$$

   (a) $\underset{\sim}{p}_n \restriction \gamma_n \in \underset{\sim}{G}_{\gamma_n}$,

   (b) $\underset{\sim}{p}_{n-1} \leq_\gamma \underset{\sim}{p}_n$,

   (c) $\underset{\sim}{p}_n$ is an $(\langle M_\xi \mid \xi \leq \alpha_n \rangle, P_\gamma)$-generic condition (when $n > 0$).

When this sequence is defined, $q = \bigcup_n q_n$ is a condition in P_γ and

$$q \Vdash_\gamma \underset{\sim}{p}_n \in \underset{\sim}{G}_\gamma$$

as we have seen in the proof of the Properness Extension Lemma. But as q forces that $\underset{\sim}{p}_n$ is $(\langle M_\xi \mid \xi \leq \alpha_n \rangle, P_\gamma)$-generic, q itself is $(\langle M_\xi \mid \xi \leq \alpha_n \rangle, P_\gamma)$-generic for every $n \in \omega$, and the proof of the lemma is concluded since q is then $(\langle M_\xi \mid \xi < \alpha \rangle, P_\gamma)$ and hence $(\bar{M}, P_\gamma)$-generic (as α is a limit ordinal).

We turn now to the inductive construction. Suppose that q_n and $\underset{\sim}{p}_n$ are defined. As before, we shall first define $\underset{\sim}{p}_{n+1}$ and then q_{n+1}.

We define $\underset{\sim}{p}_{n+1}$ as a P_{γ_n}-name by the following requirements. If G is any (V, P_{γ_n})-generic filter containing q_n, form

$$M_{\alpha_{n+1}+1}[G] \prec H_\lambda[G], \tag{5.16}$$

and let $p \in P_\gamma$ be the interpretation of $\underset{\sim}{p}_n$. Then $p \in P_\gamma \cap M_{\alpha_n+1}$ and $p \restriction \gamma_n \in G$. As $q_n, p \restriction \gamma_n \in P_{\gamma_n}$ are in G, there is a $q_n' \in G$ that extends both q_n and $p\restriction\gamma_n$. By the α_{n+1}-Properness Extension Lemma applied to q'_n and p there is a $q^*_n \in P_\gamma$ such that $q^*_n\restriction\gamma_n = q'_n$, $p \leq_\gamma q^*_n$, and q^*_n is $(\langle M_\xi \mid \alpha_n+1 \leq \xi \leq \alpha_{n+1}\rangle, P_\gamma)$-generic. It follows from (5.16) that (similarly to q^*_n) there is in $M_{\alpha_{n+1}+1}$ a condition $q^* \in P_\gamma$ such that $q^*\restriction\gamma_n \in G$, $p \leq_\gamma q^*$, and q^* is $(\langle M_\xi \mid \alpha_n+1 \leq \xi \leq \alpha_{n+1}\rangle, P_\gamma)$-generic. Then we define the interpretation of $\underset{\sim}{p}_{n+1}$ in $V[G]$ to be q^*.

Clearly q_n forces that $\underset{\sim}{p}_{n+1}$ is in $P_\gamma \cap M_{\alpha_{n+1}+1}$ and

1. $\underset{\sim}{p}_{n+1}\restriction\gamma_n \in \underset{\sim}{G}_{\gamma_n}$,
2. $\underset{\sim}{p}_n \leq \underset{\sim}{p}_{n+1}$ in P_γ,
3. $\underset{\sim}{p}_{n+1}$ is $(\langle M_\xi \mid \alpha_n+1 \leq \xi \leq \alpha_{n+1}\rangle, P_\gamma)$-generic (and so by item 2 it is $(\langle M_\xi \mid \xi \leq \alpha_{n+1}\rangle, P_\gamma)$-generic).

Now $\underset{\sim}{p}_{n+1}\restriction\gamma_{n+1}$ is forced by q_n to be in $M_{\alpha_{n+1}+1}$ and the inductive assumption for γ_{n+1} can be applied to yield a condition $q_{n+1} \in P_{\gamma_{n+1}}$ that is $(\langle M_\xi \mid \alpha_{n+1} < \xi \leq \alpha\rangle, P_{\gamma_{n+1}})$-generic and such that

$$q_{n+1} \Vdash_{\gamma_{n+1}} \underset{\sim}{p}_{n+1}\restriction\gamma_{n+1} \in \underset{\sim}{G}_{\gamma_{n+1}}.$$

Hence q_{n+1} is also $(\langle M_\xi \mid \xi \leq \alpha_{n+1}\rangle, P_{\gamma_{n+1}})$-generic. This completes the proof of the α-Extension Lemma, and hence of the α-properness preservation theorem. $\dashv$

5.2. A Coloring Problem

The definitions needed for Dee-completeness are quite complex and they can be better understood with an example. Hence, before presenting the general definition of Dee-completeness (in Sect. 5.3) we discuss a particular case. The simplest that I know is a problem of Hajnal and Máté concerning the chromatic number of graphs in a certain family of graphs on ω_1 described below. (There is also a nostalgic reason for discussing this example: Theorem 5.8 is my first result in set theory.) The *chromatic number* of any (non-directed) graph $g = (V, E)$ is the least cardinal κ such that there is a function $f : V \to \kappa$ from the set of vertices V into κ such that for every $\alpha \neq \beta$ in V, if $\alpha\, E\, \beta$ then $f(\alpha) \neq f(\beta)$.

Hajnal and Máté investigated in [5] the following family of graphs $g = (V, E)$ with set of vertices $V = \omega_1$, and in which for any limit $\delta \in \omega_1$ the set $\chi^g_\delta = \{\alpha \mid \alpha \in \delta \text{ and } \alpha\, E\, \delta\}$ forms an ω-sequence cofinal in δ (and for non-limit $\beta \in \omega_1$ there is no $\alpha < \beta$ such that $\alpha\, E\, \beta$). We shall call such graphs *Hajnal-Máté graphs*. They had shown that if the diamond principle $\diamondsuit$ holds, then there is an Hajnal-Máté graph of chromatic number $\aleph_1$, and if MA + $2^{\aleph_0} > \aleph_1$ holds, then every Hajnal-Máté graph has countable chromatic number. They had suggested that Jensen's method [3] for proving the consistency of CH + "there are no Souslin trees" may lead to a consistency proof for CH + "the chromatic number of every Hajnal-Máté graph is $\aleph_0$". This turned out to be true.

5.8 Theorem. *Assume $2^{\aleph_0} = \aleph_1$ and $2^{\aleph_1} = \aleph_2$. There is a generic extension that adds no new reals, collapses no cardinals, and such that every Hajnal-Máté graph in the extension has a countable chromatic number and $2^{\aleph_1} = \aleph_2$.*

Let $g = (V, E)$ be a Hajnal-Máté graph. Define P_g as the poset for making the chromatic number of g countable. That is, $h \in P_g$ iff for some countable ordinal γ, $h : \gamma + 1 \to \omega$ is such that whenever $\alpha < \beta \leq \gamma$ and $\alpha E \beta$ then $h(\alpha) \neq h(\beta)$. So the domain, $\mathrm{dom}(h)$, of a condition in P_g is always a countable successor ordinal.

The ordering on P_g is extension.

Clearly if $h \in P_g$ and $\gamma' < \gamma = \mathrm{dom}(h)$ is a successor ordinal then $h \restriction \gamma' \in P_g$. It is easy to check that any condition in P_g has extensions with arbitrarily high domain in ω_1.

If $h \in P_g$ and x is a finite function from $\mathrm{dom}(x) \subseteq \omega_1$ to ω, we say that x is compatible with h if $h \cup x$ is a function that assigns distinct values (in ω) to connected vertices.

5.9 Lemma. *If $h \in P_g$ and $\gamma + 1 = \mathrm{dom}(h)$, then for every countable μ above γ there is some condition $h' > h$ with $\mu + 1 = \mathrm{dom}(h')$. Moreover, for any finite x that is compatible with h there is an extension h' of $h \cup x$ in P_g.*

Thus if G is generic over P_g then $\bigcup G$ is defined on ω_1 and the chromatic number of g in the extension is countable.

We plan to prove that P_g is proper, α-proper for every countable α, and show how to iterate P_g forcings without adding new reals. Then $2^{\aleph_1} = \aleph_2$ implies that an iteration of length ω_2 suffices to ensure that all Hajnal-Máté graphs produced are taken care of, and the theorem can be established.

5.10 Lemma. *P_g is proper. Moreover, if $M \prec H_\lambda$ is countable, $P_g \in M$, and $h_0 \in P_g \cap M$, then for any finite x compatible with h_0 there is an (M, P_g)-generic condition h compatible with x. (x is not necessarily in M.)*

Proof. Given $h_0 \in P_g \cap M$ with $\mathrm{dom}(h_0) = \gamma_0 + 1$, list all dense sets $\langle D_i \mid i \in \omega \rangle$ that are in M. Let $\delta = M \cap \omega_1$ and let χ^g_δ be the ω-sequence of ordinals that are connected in g to δ. Our aim is to define an increasing sequence of conditions $h_n \in M$ so that $h_{n+1} \in D_n$ and then to define $h = \bigcup_{n \in \omega} h_n$ and to extend h on δ as well, in order to obtain an (M, P_g)-generic condition. The problem, of course, is that h may map χ^g_δ onto ω and leave no place for the value of δ, or that it assigns a value that is incompatible with x. The solution is based on the fact that δ "is" ω_1 for M.

We make an observation. Given a condition $f \in P_g$, and v, a finite function compatible with f, let $H_f(v)$ be the first (in some well-ordering) condition in P_g that extends $f \cup v$.

5.11 Claim. *Let $D \subseteq P_g$ be dense. For any $f \in P_g$ there is a closed unbounded set $C_f \subseteq \omega_1$ such that for every $\gamma \in C$ and finite function v defined on a subset of γ and compatible with f, if $h = H_f(v)$, then h has an extension $h' \in D$ such that $\mathrm{dom}(h') < \gamma$.*

This claim is not difficult to prove.

Consider the given finite function x compatible with h_0. We may assume that $\delta \in \mathrm{dom}(x)$ (or else extend x). Let $x_0 = x \cap M$ and $x_1 = x \setminus M$ be the lower and upper parts of x. By further extending h_0 in M we may assume that $x_0 \subseteq h_0$. We can also assume that if $\alpha < \delta$ and α is connected in the graph to some point in the domain of x_1 above δ then $\alpha \in \mathrm{dom}(h_0)$ (as there are only finitely many such αs). So, in fact, in defining h_n's we must only be careful to avoid $k = x(\delta)$ on χ^g_δ. This k is "reserved" as the value for δ. Assume that $h_n \in M$ is defined and $k \notin h_n$"χ^g_δ. For $f = h_n$ and $D = D_n$ there is an unbounded set $C_f \subseteq \omega_1$ as in the claim above. As C_f is definable, $C_f \in M$. Let γ be the first member of C_f above $\mathrm{dom}(h_n)$. Let $u = \chi^g_\delta \cap \gamma \setminus \mathrm{dom}(h_n)$. Then u is finite since $\gamma < \delta$. Let v be a function defined on u, compatible with h_n, and avoiding the value k. Then $h = H_f(v)$ has an extension $h' = h_{n+1} \in D_n$ that lives in γ, so that $\{\langle \delta, k \rangle\}$ is still compatible with h_{n+1}. Finally $h = \bigcup_{n \in \omega} h_n \cup \{\langle \delta, k \rangle\}$ is (M, P_g)-generic. This completes the properness proof for P_g. ⊣

The generic condition h thus obtained is a "completely generic" condition, which means that it actually defines an (M, P_g)-generic filter. This shows that P_g adds no new reals.

5.12 Definition. If $P \in M$ is a poset, then $q \in P$ is *completely* (M, P)*-generic* iff $\{p \in P \cap M \mid p \leq q\}$ is an (M, P)-generic filter. We say that G is *bounded by* q and also that q *induces* G.

A poset P is *completely proper* iff P is proper and the properness definition applies to P with "completely generic condition" replacing "generic condition".

Clearly, completely proper posets do not add new reals. In fact, P is completely proper iff P is proper and adds no new reals. (If the latter condition holds and M is as in the definition of properness, find q that is (M, P)-generic and then further extend it to some condition that determines $\underset{\sim}{G} \cap M$.)

Thus we know that P_g adds no new reals, and now we prove by induction on $\alpha < \omega_1$ that

5.13 Lemma. *P_g is α-proper. In fact, if $\langle M_\xi \mid \xi \leq \alpha \rangle$ is any α tower of countable elementary submodels of H_λ with $P_g \in M_0$ and $h_0 \in M_0$ is any condition, then for every finite x compatible with h_0 there is an extension $h \in P_g$ that is completely (M_ξ, P_g)-generic for every $\xi \leq \alpha$ and is compatible with x.*

Proof. The proof of the lemma is by induction on $\omega \leq \alpha < \omega_1$. Using the properness Lemma 5.10 we assume that α is a limit ordinal, and pick an increasing and cofinal sequence α_n. We define an increasing sequence h_n of conditions compatible with x such that $h_{n+1} \in M_{\alpha_{n+1}+1}$ is $\langle M_\xi \mid \xi \leq \alpha_{n+1} \rangle$. Then $\bigcup_{n \in \omega} h_n \cup \{\langle \delta, x(\delta) \rangle\}$ is as required. ⊣

Now we make a crucial observation which is the key to the proof that the iteration of P_g posets adds no new reals. Let $M \prec H_\lambda$ be a countable elementary substructure with $P_g \in M$, and let $p_0 \in P_g \cap M$ be given. Recall that $G^* \subseteq P_g \cap M$ is an (M, P_g)-generic filter if it is a filter over $P_g \cap M$ that intersects every dense set in M. Define

$$\mathrm{Gen}_{p_0}(M, P_g)$$

to be the set of all (M, P_g)-generic filters containing p_0. An (M, P_g)-generic G^* is *extendible* to a condition in P_g iff for some $q \in P_g$, $G^* = \{p \in P_g \cap M \mid p < q\}$. We say in this case that q bounds G^*. Clearly G^* is extendible to a condition in P_g iff its range of values on χ^g_δ (where $\delta = \omega_1 \cap M$) is not all of ω. For any ω-sequence x cofinal in δ, we shall say that G^* is *appropriate* for x iff $\bigcup G^* \restriction x$ omits at least one value. So G^* is extendible to a condition in P_g iff G^* is appropriate for χ^g_δ.

For an ω-sequence x cofinal in $\delta = \omega_1 \cap M$ define

$$A^{p_0}_x = \{G^* \in \mathrm{Gen}_{p_0}(M, P_g) \mid G^* \text{ is appropriate for } x\}.$$

Thus $A^{p_0}_{\chi^g_\delta}$ is the collection of all $G^* \in \mathrm{Gen}_{p_0}(M, P_g)$ extendible to a condition in P_g.

We claim that (for a fixed p_0) the collection

$$\{A^{p_0}_x \mid x \subseteq \delta \ \text{ is a cofinal } \omega \text{ sequence}\}$$

has the countable intersection property. That is, if $X = \{x_i \mid i \in \omega\}$ is some countable collection of ω-sequences cofinal in $\delta = \omega_1 \cap M$, then there is some G^* in $\bigcap_{i\in\omega} A^{p_0}_{x_i}$. To prove this, find some ω-sequence x converging to δ and such that $\mathrm{range}(x_i) \setminus \mathrm{range}(x)$ is finite for every i. It is easy to define such x that almost contains each x_i by induction. If G^* is some (M, P_g)-generic filter containing p_0 that omits infinitely many values on x (and now we can easily define such a filter), then $G^* \in A^{p_0}_{x_i}$ for every i.

We describe in general terms what is involved in proving that the iteration adds no new reals. In proving that the iteration of P_g-like forcings does not add any new real we will be asked to produce a completely generic condition for some $M \prec H_\lambda$ without knowing the value of χ^g_δ. This ω-sequence of ordinals connected to δ will only be given as a name. So instead of χ_δ we will be offered a countable collection $\{x_i \mid i \in \omega\}$ of ω-sequences with the assurance that χ^g_δ is forced to be among them. We will still be able to find G^* by taking into consideration all the x_i's as was shown above. The essence of this argument is embodied in the following lemma.

5.14 Lemma. *Suppose that $M_0 \prec M_1 \prec H_\lambda$ are countable elementary substructures with $M_0 \in M_1$. Suppose that $P \in M_0$ is a poset that adds no new reals, and that $g \in V^P \cap M_0$ is a name for some Hajnal-Máté graph. Let $G_0 \in M_1$ be some (M_0, P)-generic filter. Then there exists an $(M_0, P * P_g)$-generic filter G_1 extending G_0, and there exists a name $\underset{\sim}{r} \in V^P$ such that the following holds.*

If $q \in P$ is a (plain) (M_1, P)-generic condition that bounds G_0 (and is hence completely (M_0, P)-generic), then the condition $(q, \underset{\sim}{r}) \in P * P_g$ bounds G_1.

In fact, both the filter G_1 and the name $\underset{\sim}{r}$ are definable from parameters in M_1 and a countable enumeration of M_1. Thus, if $M_1 \in M_2 \prec H_\lambda$ then $G_1, \underset{\sim}{r} \in M_2$.

Proof. Let $\mu : M_0 \to N_0$ be the Mostowski collapsing function of M_0 onto a transitive structure N_0. Then $N_0 \in M_1$. Let $\mathcal{G}_0 = \mu$“$G_0 \subseteq \mu(P)$ be the image of G_0 under the collapsing map. Forming $N_0[\mathcal{G}_0]$ as a generic extension, $\mu(g)[\mathcal{G}_0]$ is a Hajnal-Máté graph there denoted h. This graph is clearly on $\delta = \omega_1 \cap M_0$. As $\mathcal{G}_0 \in M_1$, $N_0[\mathcal{G}_0] \in M_1$.

Let $X = \{x_i \mid i \in \omega\}$ be an enumeration (the least in some global well order) of all ω-sequences x in M_1 that are cofinal in δ. We know how to find an $(N_0[\mathcal{G}_0], P_h)$-generic filter H that is appropriate for every x_i. Now form $\mathcal{G}_1 = \mathcal{G}_0 * H$. Then $\mathcal{G}_1$ is an N_0-generic filter extending $\mathcal{G}_0$. The required filter G_1 is the μ pre-image of $\mathcal{G}_1$.

The name $\underset{\sim}{r} \in V^P$ is defined by the following requirement as a condition in P_g with domain $\delta + 1$. It is easier to describe the interpretation of $\underset{\sim}{r}$ in (V, P)-generic extensions $V[G]$. If $\bigcup H$ (which is a function on δ that lies in V) can be extended (by assigning a value to δ) to a condition in $P_{g[G]}$, then let $\underset{\sim}{r}[G]$ be that condition.

Assume now that $q \in P$ is as in the lemma, a bound of $G_0 = \mu^{-1}$“$\mathcal{G}_0$ that is also an (M_1, P)-generic condition. Since P adds no new countable sequences, there exists in M_1 a dense set of conditions in P that determine the value of χ^g_δ in V. Thus $q \Vdash \chi^g_\delta \in M_1$, and hence $q \Vdash \exists i \in \omega\ (\chi^g_\delta = x_i)$. Hence $q \Vdash H$ is bounded by $\underset{\sim}{r}$. ⊣

Observe that $\underset{\sim}{r}$ is a name of a function defined on $\delta + 1$. Although $\underset{\sim}{r} \upharpoonright \delta$ is, in a sense, $\bigcup H$, $\underset{\sim}{r}(\delta)$ is just a name and any specific value for $\underset{\sim}{r}(\delta)$ may conflict with some x_i. Only after determining (generically) χ^g_δ can we assign a compatible value to $\underset{\sim}{r}(\delta)$.

In applications we need a slightly stronger version of this lemma, in which a condition $(p_0, p_1) \in P * P_g \cap M_0$ is also given, and $p_0 < q$ is assumed. Then $\underset{\sim}{r}$ is also required to satisfy $q \Vdash_P \underset{\sim}{r} > p_1$, so that the given condition (p_0, q_0) is in the (M_0, P)-generic filter determined by $(q, \underset{\sim}{r})$.

The final model of CH + “every Hajnal-Máté graph has countable chromatic number” is obtained through an iteration with countable support of posets of the form P_g, done over a ground model in which CH holds. Since each P_g has size $\aleph_1$ the iteration satisfies the $\aleph_2$-c.c., and a suitable book-keeping device ensures that every possible Hajnal-Máté graph is dealt with.

As a preparation for the final iteration we prove here that P_ω (the iteration of the first $\aleph_0$ posets) adds no new reals. So let P_n be defined by $P_{n+1} \equiv P_n * P_{g_n}$ where g_n is a name for some Hajnal-Máté graph. Specifically, the members of P_n are functions defined on n and P_ω is the countable support limit.

Let $M_0 \prec H_\lambda$ be some countable elementary substructure with $P_\omega \in M_0$, and $p_0 \in P_\omega \cap M_0$ a given condition. It suffices to find an extension of p_0 that is completely (M_0, P_ω)-generic. Let $\langle D_n \mid n \in \omega \rangle$ be an enumeration of all dense subsets of P_ω that are in M_0.

Starting with M_0 build a tower $\langle M_n \mid n \in \omega \rangle$ of countable elementary substructures of H_λ. We plan to define a sequence of conditions $q_n \in P_n$ and $p_n \in P_\omega \cap M_0$ such that

1. $q_n \in P_n$ is completely (M_0, P_n)-generic, and it is (M_k, P_n)-generic for every $k \geq n$,
2. $p_n \restriction n \leq q_n$, and $q_n = q_{n+1} \restriction n$,
3. $p_n \leq p_{n+1}$ in P_ω, and $p_{n+1} \in D_n \cap M_0$.

When the construction is done, define $q = \bigcup_n q_n$. Then $q \geq p_k \restriction n$ for every n and hence $q \geq p_k$ for every k. This shows that $q \in P_\omega$ is completely (M_0, P_ω)-generic, because the p_k's visit every dense set in M_0.

Suppose that p_n and q_n are defined. The assumption that q_n is completely (M_0, P_n)-generic means that

$$G_0 = \{p \in P_n \cap M_0 \mid p \leq q_n\}$$

is (M_0, P_n)-generic. Use Lemma 1.2 to find $p_{n+1} \geq p_n$ with $p_{n+1} \in D_n \cap M_0$ and such that $p_{n+1} \restriction n \leq q_n$.

Notice that $G_0 \in M_n$ because the set D of conditions $q \in P_n$ that are completely (M_0, P_n)-generic is pre-dense above q_n. Since $D \in M_n$, q_n is compatible with a member q of $D \cap M_n$ and, in the definition of G_0, q can replace q_n.

The previous lemma is applicable to $M_0 \in M_n \in M_{n+1}$ and to $P = P_n$. So there is a name $\underset{\sim}{r} \in M_{n+1}$ such that $(q_n, \underset{\sim}{r}) \in P_{n+1}$ is completely (M_0, P_{n+1})-generic and $p_{n+1} \restriction n+1 \leq (q_n, \underset{\sim}{r})$. As P_{g_n} is (forced to be) ω-proper, there is a name $r' \in V^{P_n}$ such that

$$q_n \Vdash \underset{\sim}{r} < r' \,\&\, r' \text{ is } (\langle M_i[\underset{\sim}{G}_{P_n}] \mid i \geq n+1 \rangle, P_{g_n})\text{-generic.}$$

Define $q_{n+1} = q_n {}^\frown \langle r' \rangle$. Then $q_{n+1} \in P_{n+1}$ is tower generic for $\langle M_k \mid k \geq n+1 \rangle$, $q_n = q_{n+1} \restriction n$, and $q_{n+1} \geq p_{n+1} \restriction n+1$.

5.3. Dee-Completeness

The aim of Dee-completeness is to provide a framework for obtaining models of CH. It allows countable support iteration of a large family of posets that add no new countable sets. Our definitions here are slightly different from those originally given by Shelah [15, Chap. V], but we have kept the original names believing that our interpretation of the basic ideas is accurate.

A *completeness system* is a three-argument function $\mathbb{D}(N, P, p_0)$ defined when

1. N is a countable transitive model of ZFC$^-$ (ZFC minus the Power Set Axiom),

2. $P \in N$ is a forcing poset in N, and

3. $p_0 \in P$.

$\mathbb{D}(N, P, p_0)$ is consequently a non-empty collection of non-empty subsets of $\mathrm{Gen}_{p_0}(N, P)$. That is, if $A \in \mathbb{D}(N, P, p_0)$ then every $G \in A$ is a filter over P containing p_0 and intersecting every dense subset of P in N.

For example, if $g \in N$ is some Hajnal-Máté graph and $P = P_g$ is in N the poset for coloring g with countably many colors, then we define $\mathbb{D}(N, P, p_0) = \{A_X \mid X \subseteq N\}$ where $A_X \subseteq \mathrm{Gen}_{p_0}(N, P)$ is defined as follows. In case X is an ω-sequence cofinal in ω_1^N, then $G \in A_X$ iff $G \in \mathrm{Gen}_{p_0}(N, P)$ is such that $\bigcup G \restriction X$ omits infinitely many colors. If X is not as above, then $A_X = \mathrm{Gen}_{p_0}(N, P)$. It is reasonable to have g as a parameter, although in our case it is reconstructible from P.

We apply $\mathbb{D}$ to non-transitive structures as well: if $M \prec H_\lambda$ is a countable elementary submodel, $P \in M$ a poset, and $p_0 \in P \cap M$, then we let $\pi : M \to N$ be the transitive collapsing isomorphism and for each $X \in \mathbb{D}(N, \pi(P), \pi(p_0))$ we define $\pi^{-1}(X) = \{\pi^{-1}``G \mid G \in X\}$. This yields $\mathbb{D}(M, P, p_0) = \{\pi^{-1}(X) \mid X \in \mathbb{D}(N, \pi(P), \pi(p_0))\}$. In simple terms, $\mathbb{D}(M, P, p_0)$ is defined by viewing the argument (M, P, p_0) as a representation of its isomorphism type.

We say that a poset P is *Dee-complete* (or just *complete*, for brevity) *with respect to a completeness system* $\mathbb{D}$ if for sufficiently large λ, for every countable $M \prec H_\lambda$ with $P \in M$ and every $p_0 \in P \cap M$, there is an $X \in \mathbb{D}(M, P, p_0)$ such that every $G \in X$ is bounded in P. (Thus P is completely proper.)

Repeating this definition, now with transitive structures, we obtain that P is Dee-complete with respect to $\mathbb{D}$ if the following holds for every countable $M \prec H_\lambda$ with $P \in M$:

For any $p_0 \in P \cap M$, if $\pi : M \to N$ is the transitive collapse, there is an $X \in \mathbb{D}(N, \pi(P), \pi(p_0))$ such that (5.17)

$$\text{for every } \mathcal{G} \in X,\ \pi^{-1}``\mathcal{G} \text{ is bounded in } P.$$

We say that a completeness system is *countably complete* iff whenever $A_i \in \mathbb{D}(N, P, p)$ for $i \in \omega$ then $\bigcap_{i \in \omega} A_i \neq \emptyset$. We have seen that for every Hajnal-Máté graph g the system defined above is countably complete. Thus every P_g is Dee-complete with respect to a countably complete system.

It is sometimes convenient to add a parameter to $\mathbb{D}$. We shall say that $\mathbb{D}$ is a completeness system with a parameter if $\mathbb{D}$ is a four argument function: $\mathbb{D}(N, P, p_0, c)$ is defined when N, P, p_0 are as in the definition given above, and $c \in N$ is the parameter. As before, $\mathbb{D}(N, P, p_0, c)$ is a non-empty collection of non-empty subsets of $\mathrm{Gen}_{p_0}(N, P)$. We say that a poset P is

Dee-complete with respect to a completeness system $\mathbb{D}$ *with parameter* iff for sufficiently large λ there is a $c \in H_\lambda$ such that:

$$\text{for every countable } M \prec H_\lambda \text{ with } P, c \in M \text{ and every } p_0 \in P \cap M, \text{ if } \pi : M \to N \text{ is the transitive collapse, then there is an } X \in \mathbb{D}(N, \pi(P), \pi(p_0), \pi(c)) \text{ such that, for every } \mathcal{G} \in X,\ \pi^{-1}``\mathcal{G} \text{ is bounded in } P. \tag{5.18}$$

In fact, the parameters are dispensable by the following lemma. Recall that by H_λ we mean the structure $(H_\lambda, \in, <)$ where $<$ is a fixed well-ordering of H_λ.

5.15 Lemma. *Let* P *be a poset that is Dee-complete with respect to some countably complete completeness system* $\mathbb{D}$ *with parameter. Then* P *is also Dee-complete with respect to some three-argument countably complete completeness system* $\mathbb{D}'$*.*

Proof. Let λ be sufficiently large so that H_λ with parameter $c \in H_\lambda$ shows the completeness of P with respect to $\mathbb{D}$ (as in (5.18)). Then, for $\lambda' > \lambda^{<\lambda} + 2^{2^{\mathfrak{c}}}$, $H_\lambda \in H_{\lambda'}$ and $\mathbb{D} \in H_{\lambda'}$ (since $\mathbb{D}$ is a function from $H_{\aleph_1}$ to $\mathcal{P}\mathcal{P}(H_{\aleph_1})$). So $H_{\lambda'}$ satisfies the statement $\psi(P, \lambda, c, \mathbb{D})$ saying that λ is a cardinal with $P, c \in H_\lambda$ and $\mathbb{D}$ is a four-argument system such that (5.18) holds.

Using the assumed well-ordering of $H_{\lambda'}$, let λ_0, c_0, and $\mathbb{D}_0$ be minimal such objects for which $\psi(P, \lambda_0, c_0, \mathbb{D}_0)$ holds. If $M \prec H_{\lambda'}$ is any countable elementary substructure with $P \in M$, then $\lambda_0, c_0, \mathbb{D}_0 \in M$ since they are definable in $H_{\lambda'}$, and moreover, these objects are minimal in M to satisfy $\psi(P, \lambda_0, c_0, \mathbb{D}_0)$. Observe that $H^M_{\lambda_0} = M \cap H_{\lambda_0} \prec H_{\lambda_0}$, and also that if $D \in M$ is a subset of P then $D \in H^M_{\lambda_0}$.

Let $\pi : M \to N$ be the collapse onto a transitive structure. Then $\pi_0 = \pi \restriction H_{\lambda_0}$ is the collapse of a countable elementary substructure of H_{λ_0}, namely $H^M_{\lambda_0}$ onto $H^N_{\pi(\lambda_0)} = N_0$.

So $\mathbb{D}_0(N_0, \pi(P), \pi(p_0), \pi(c_0))$ has the required good properties, and in particular each $G \in X \in \mathbb{D}_0(N_0, \pi(P), \pi(p_0), \pi(c_0))$ is generic not only over N_0 but also over N. This leads to the following definition of $\mathbb{D}'$ as required by the lemma.

If N is any countable transitive structure, $R \in N$ a poset and $r \in R$, define $\mathbb{D}'(N, R, r)$ as follows. Look for λ'_0, c'_0, that are minimal to satisfy $\exists D \psi(R, \lambda'_0, c'_0, D)$ in N, and apply $\mathbb{D}_0(H^N_{\lambda'_0}, R, r, c'_0)$. If there is no such λ'_0, then $\mathbb{D}'(N, R, r)$ is arbitrarily defined. $\dashv$

The definition of Dee-completeness has the form "for λ sufficiently large etc.". It is not difficult to see that if there is a completeness system that works for one λ, there is one that works for all larger λ as well. We are going to argue now that it is always possible in this case to take $\lambda = (2^{|P|})^+$ (Shelah, personal communication).

5.16 Lemma. *If a poset P is complete with respect to a countably complete completeness system $\mathbb{D}$ then there is a countably complete (four-argument) completeness system $\mathbb{D}'$ so that already $\lambda_0 = (2^{|P|})^+$ suffices to demonstrate the completeness of P. That is, for some $c \in H_{\lambda_0}$, (5.18) holds.*

Proof. The definition of $\mathbb{D}'$ is simple. For any countable transitive structure N, poset $R \in N$, condition $r \in R$, and parameter $p \in N$, define

$$\mathbb{D}'(N, R, r, p) = \mathbb{D}(p, R, r)$$

if this makes sense, that is, if p is transitive, $R, r \in p$ and $\mathbb{D}(p, R, r)$ is indeed a collection of sets of (N, R)-generic filters as required. In case this definition does not make sense, let $\mathbb{D}'(N, R, r, p)$ be defined as an arbitrary collection of subsets of $\mathrm{Gen}_r(N, R)$ with the countable intersection property. We must define a good parameter $c \in H_{\lambda_0}$ that will work.

Let λ be sufficiently large so that for every countable $M \prec H_\lambda$ with $P \in H_\lambda$ (5.17) holds. Let $\kappa = |P|$ be the cardinality of P, and assume for simplicity that κ is the universe of P. We may assume that $\lambda > \lambda_0 = (2^\kappa)^+$ (or else there is nothing to show). Let K be an elementary substructure of H_λ of cardinality 2^κ (containing all subsets of κ). Clearly, every elementary substructure of K is also an elementary substructure of H_λ, so that if we let $\pi : K \to \bar{K}$ be the transitive collapse of K then, for every $M \prec \bar{K}$, the transitive collapse of M is the transitive collapse of an elementary substructure of K, namely the pre-image of M.

We claim that $c = \bar{K} \in H_{\lambda_0}$ works. Let $M \prec H_{\lambda_0}$ be countable with $P, \bar{K} \in M$, and $p_0 \in P \cap M$ be given. Then $M \cap \bar{K} \prec \bar{K}$. Let $\pi : M \to N$ be the collapsing function onto a transitive structure. $\pi(\bar{K})$ is the transitive collapse of $M \cap \bar{K}$, and $\mathbb{D}'(N, \pi(P), \pi(p_0), \pi(\bar{K})) = \mathbb{D}(\pi(\bar{K}), \pi(P), \pi(p_0))$. The point is that if $G \in X \in \mathbb{D}(\pi(\bar{K}), \pi(P), \pi(p_0))$, then G is not only $(\pi(P), \pi(\bar{K}))$-generic filter but also (N, P)-generic, since any subset of $\pi(\kappa)$ in N is already in $\pi(\bar{K})$ (as any subset of κ in M is already in $M \cap \bar{K}$). $\dashv$

Our aim is to prove the following

5.17 Theorem (Dee-Completeness Iteration Theorem). *The countable support iteration of any length γ of $<\omega_1$-proper posets, each Dee-complete with respect to some countably complete system in the ground model, does not add any new reals.*

Note the inductive character of this theorem. For $Q_i \in V^{P_i}$ to be Dee-complete with respect to a system that lies in V, one needs that P_i adds no new countable sets—so that every countable transitive set in V^{P_i} is in V.

To prove the theorem we shall first define for each countable $M \prec H_\lambda$ (with $P_\gamma \in M$) an (M, P_γ)-generic filter G_γ. Then we will prove that G_γ is bounded in P_γ. That is, we will find a condition in P_γ that is completely (M, P_γ)-generic. The definition of G_γ is by induction, and we shall actually have to define for every $\gamma_0 < \gamma$ and G_{γ_0} that is (M, P_{γ_0})-generic, a filter G_γ that extends G_{γ_0}. There will be two main cases in this definition: γ successor and γ limit, and likewise there will be two cases in the proof that G_γ is bounded. We start with what is needed for the successor case.

Two-Step Iteration

Let P be a poset and $\underset{\sim}{Q} \in V^P$ a name forced (by 0_P) to be a poset. Let λ be sufficiently large and $M_0 \prec H_\lambda$ be a countable elementary submodel such that $P, \underset{\sim}{Q} \in M_0$. We want to find a criterion for when a condition $(q_0, q_1) \in P * \underset{\sim}{Q}$ is completely $(M_0, P * \underset{\sim}{Q})$-generic. A first guess is: q_0 is completely (M_0, P)-generic and q_0 forces that q_1 is completely $(M_0[\underset{\sim}{G}], \underset{\sim}{Q})$-generic. But a moment's reflection reveals that this is not sufficient for (q_0, q_1) to determine, in V, an $(M_0, P * \underset{\sim}{Q})$-generic filter. So we need a finer criterion.

Let $\pi : M_0 \to N_0$ be the transitive collapsing map. Suppose that $q_0 \in P$ is completely (M_0, P)-generic and let $G_P \subseteq P \cap M_0$ be the (M_0, P)-generic filter induced by q_0. Then $\mathcal{G}_0 = \pi$“G_P is an $(N_0, \pi(P))$-generic filter and we can form the (transitive) extension $N_0^* = N_0[\mathcal{G}_0]$. In N_0, $\pi(\underset{\sim}{Q})$ is a name, and its interpretation $Q_0^* = \pi(\underset{\sim}{Q})[\mathcal{G}_0]$ is a poset in N_0^*.

Let $\underset{\sim}{G} \in V^P$ be the canonical name of the generic filter over P. If F is any (V, P)-generic filter containing q_0, then $M_0[F] \prec H_\lambda[F]$ can be formed and the collapsing map π on M_0 can be extended to collapse $M_0[F]$ onto N_0^*. Let $\underset{\sim}{\pi}$ be the name of this extended collapse. Then $q_0 \Vdash_P \underset{\sim}{\pi} : M_0[\underset{\sim}{G}] \to N_0^*$. We phrase now the desired criterion but omit the routine proof.

5.18 Lemma. *With the above notation,* (q_0, q_1) *is completely* $(M_0, P * \underset{\sim}{Q})$*-generic iff*

1. q_0 *is completely* (M_0, P)*-generic, and*

2. *for some* (N_0^*, Q_0^*)*-generic* $\mathcal{G}_1 \subseteq Q_0^*$, $q_0 \Vdash \underset{\sim}{\pi}^{-1}$“$\mathcal{G}_1$ *is bounded by* q_1.

In this case, the filter induced by (q_0, q_1) *over* $M_0 \cap P * \underset{\sim}{Q}$ *is* π^{-1}“$\mathcal{G}_0 * \mathcal{G}_1$.

Given a countable $M_0 \prec H_\lambda$ such that the two-step iteration $P * \underset{\sim}{Q}$ is in M_0, our aim (under some assumptions stated in the following definition) is to extend each (M_0, P)-generic filter G_0 to an $(M_0, P * \underset{\sim}{Q})$-generic filter. This definition depends not only on M_0, but also on another countable elementary submodel $M_1 \prec H_\lambda$ such that $M_0 \in M_1$. In addition, we assume some $p_0 \in P * \underset{\sim}{Q}$ which we want to include in the extended filter. All of this leads to a five place function $\mathbb{E}(M_0, M_1, P * \underset{\sim}{Q}, G_0, p_0)$ that we define now.

5.19 Definition. Let P be a poset that adds no new countable sets of ordinals, and suppose that $\underset{\sim}{Q}, \underset{\sim}{\mathbb{D}} \in V^P$ are such that

$$\Vdash_P \quad \begin{array}{l} \underset{\sim}{\mathbb{D}} \in V \text{ is a countably complete system} \\ \text{and } \underset{\sim}{Q} \text{ is Dee-complete with respect to } \underset{\sim}{\mathbb{D}}. \end{array}$$

Let λ be sufficiently large, and $M_0 \prec M_1 \prec H_\lambda$ be countable elementary submodels with $M_0 \in M_1$ and $P, \underset{\sim}{Q}, \underset{\sim}{\mathbb{D}} \in M_0$. Let $G_0 \subseteq M_0 \cap P$ be (M_0, P)-generic and suppose that $G_0 \in M_1$. Let $p_0 \in (P * \underset{\sim}{Q}) \cap M_0$ be given, $p_0 = (a, \underset{\sim}{b})$ with $a \in G_0$. Then we define

$$G = \mathbb{E}(M_0, M_1, P * \underset{\sim}{Q}, G_0, p_0), \tag{5.19}$$

an $(M_0, P * \underset{\sim}{Q})$-generic filter containing p_0, by the following procedure.

Let $\pi : M_0 \to N_0$ be the transitive collapse, and $\mathcal{G}_0 = \pi``G_0$. Form $N_0^* = N_0[\mathcal{G}_0]$. Observe that $N_0^* \in M_1$. Let $Q_0^* = \pi(\underset{\sim}{Q})[\mathcal{G}_0]$, and $\mathbb{D}_0 = \pi(\underset{\sim}{\mathbb{D}})[\mathcal{G}_0]$. Then $\mathbb{D}_0 \in N_0$ because it is forced to be in the ground model. So $\mathbb{D}_0 = \pi(\mathbb{D})$ where $\mathbb{D} \in M_0$ is a countably complete completeness system. Thus $\mathbb{D}(N_0^*, Q_0^*, b^*)$ is defined in M_1 where $b^* = \pi(\underset{\sim}{b})[\mathcal{G}_0]$ is a condition in Q_0^*. Since $M_1 \cap \mathbb{D}(N_0^*, Q_0^*, b^*)$ is countable, $\exists \mathcal{G}_1 \in \bigcap(M_1 \cap \mathbb{D}(N_0^*, Q_0^*, b^*))$. $\mathcal{G}_1$ is (N_0^*, Q_0^*)-generic and $b^* \in \mathcal{G}_1$.

Form $\mathcal{G}_0 * \mathcal{G}_1 = \mathcal{G}$, an $(N_0, \pi(P * \underset{\sim}{Q}))$-generic filter. Then $\pi(p_0) \in \mathcal{G}$. Finally, set

$$\mathbb{E}(M_0, M_1, P * \underset{\sim}{Q}, G_0, p_0) = \pi^{-1}``\mathcal{G}.$$

This completes Definition 5.19.

In fact, we want to define a formula ψ so that

$$H_\lambda \models \psi(G, M_0, M_1, P * \underset{\sim}{Q}, G_0, p_0)$$

iff (5.19) holds. That is, we want to define $\mathbb{E}$ in H_λ. We cannot take the above definition literally because it relies on the assumption that M_0 and M_1 are elementary substructures of H_λ, something which is not expressible in H_λ itself. So we redo that definition for any countable subsets M_0 and M_1 of H_λ (or models of ZF$^-$). Whenever Definition 5.19 above relies on some fact that happens not to hold, we let G have an arbitrary value. For example, if N_0^* is not in M_1 or if $M_1 \cap \mathbb{D}(N_0^*, Q_0^*, b^*)$ is empty, then we let G be some arbitrary fixed $(M_0, P * \underset{\sim}{Q})$-generic filter.

The following is a main lemma which exhibits the crux of the argument (compare with Lemma 5.14). It analyzes the iteration of two posets when the second is Dee-complete.

5.20 Lemma (The Gambit Lemma). *Let P be a poset and suppose that $\underset{\sim}{Q}, \underset{\sim}{\mathbb{D}} \in V^P$ are such that*

$$\Vdash_P \quad \begin{array}{l} \underset{\sim}{\mathbb{D}} \in V \text{ is a countably complete system} \\ \text{and } \underset{\sim}{Q} \text{ is Dee-complete with respect to } \underset{\sim}{\mathbb{D}}. \end{array}$$

Let λ be sufficiently large, and $M_0 \prec M_1 \prec H_\lambda$ be countable elementary submodel with $M_0 \in M_1$ and $P, \underset{\sim}{Q}, \underset{\sim}{\mathbb{D}} \in M_0$. Suppose that $q_0 \in P$ is (M_1, P)-generic as well as completely (M_0, P)-generic, and let $G_0 \subseteq M_0 \cap P$ be the M_0 filter over $M_0 \cap P$ induced by q_0. Let $p_0 \in P * \underset{\sim}{Q}$, $p_0 \in M_0$ be given so that $p_0 = (a, \underset{\sim}{b})$ and $a \in G_0$. Then there is a $q_1 \in V^P$ so that (q_0, q_1) is completely $(M_0, P * \underset{\sim}{Q})$-generic and $p_0 < (q_0, q_1)$. In fact, (q_0, q_1) bounds $G = \mathbb{E}(M_0, M_1, P * \underset{\sim}{Q}, G_0, p_0)$.

Proof. Notice that $G_0 \in M_1$ by the following argument. Let R be the collection of all conditions $r \in P$ that are completely (M_0, P)-generic. Then $R \in M_1$ and $q_0 \in R$. Since q_0 is (M_1, P)-generic it follows that it is compatible with some $r \in R \cap M_1$. But any two compatible conditions in R induce the same filter, and hence G_0 is the filter induced by r.

As in Definition 5.19, let $\pi : M_0 \to N_0$ be the transitive collapse, and $\mathcal{G}_0 = \pi``G_0$. We recall the definition of $\mathbb{E}(M_0, M_1, P * \underset{\sim}{Q}, G_0, p_0)$. Form $N_0^* = N_0[\mathcal{G}_0]$. Let $Q_0^* = \pi(\underset{\sim}{Q})[\mathcal{G}_0]$, and $\mathbb{D}_0 = \pi(\underset{\sim}{\mathbb{D}})[\mathcal{G}_0]$. $\mathbb{D}_0 \in N_0$ and $\mathbb{D}_0 = \pi(\mathbb{D})$ where $\mathbb{D} \in M_0$ is a countably complete completeness system. Thus $\mathbb{D}(N_0^*, Q_0^*, b^*)$ is defined in M_1 where $b^* = \pi(\underset{\sim}{b})[\mathcal{G}_0]$ is a condition in Q_0^*. Since $M_1 \cap \mathbb{D}(N_0^*, Q_0^*, b^*)$ is countable and non-empty, we were able to pick $\mathcal{G}_1 \in \bigcap(M_1 \cap \mathbb{D}(N_0^*, Q_0^*, b^*))$, (N_0^*, Q_0^*)-generic with $b^* \in \mathcal{G}_1$. We defined $\mathcal{G} = \mathcal{G}_0 * \mathcal{G}_1$, and defined $G = \mathbb{E}(M_0, M_1, P * \underset{\sim}{Q}, G_0, p_0)$ as $\pi^{-1}``\mathcal{G}$.

Let $\underset{\sim}{G} \in V^P$ be the canonical name of the generic filter over P. Then q_0 forces that π can be extended to a collapse $\underset{\sim}{\pi}$ which is onto N_0^*: that is,

$$q_0 \Vdash_P \underset{\sim}{\pi} : M_0[\underset{\sim}{G}] \to N_0^*.$$

The conclusion of our lemma follows if we show that

$$q_0 \Vdash_P \underset{\sim}{\pi}^{-1}``\mathcal{G}_1 \text{ is bounded in } \underset{\sim}{Q}. \tag{5.20}$$

In this case, if we define $q_1 \in V^P$ so that $q_0 \Vdash_P q_1$ bounds $\underset{\sim}{\pi}^{-1}``\mathcal{G}_1$, then the previous lemma (5.18) implies that the $(M_0, P * \underset{\sim}{Q})$-generic filter induced by $(q_0, q_1)$ is $\pi^{-1}``\mathcal{G}_0 * \mathcal{G}_1$.

So let F be (V, P)-generic with $q_0 \in F$. $\underset{\sim}{\pi}[F]$ collapses $M_0[F]$ onto N_0^*, and there is a set $X \in \mathbb{D}(N_0^*, Q_0^*, b^*)$ so that if $\mathcal{H} \in X$ is any filter then $\underset{\sim}{\pi}^{-1}``\mathcal{H}$ is bounded in $\underset{\sim}{Q}[F]$. As $M_1[F] \prec H_\lambda[F]$, we can have $X \in M_1[F]$. But since $\mathbb{D}$ is in the ground model, $X \in M_1$. Thus $\mathcal{G}_1 \in X$, where $\mathcal{G}_1$ is the filter defined above. This proves (5.20). $\dashv$

Proof of Theorem 5.17

Let P_γ be a countable support iteration of length γ, obtained by iterating $Q_i \in V^{P_i}$ as in the theorem. That is, each Q_i is Dee-complete in V^{P_i} for some countably complete system taken from V. Let λ be a sufficiently large cardinal. To prove the theorem we first describe a machinery for obtaining generic filters over countable submodels of H_λ. We define a function $\mathbb{E}$ that takes five arguments $\mathbb{E}(M_0, \bar{M}, P_\gamma, G_0, p_0)$, of the following types.

1. $M_0 \prec H_\lambda$ is countable, $P_\gamma \in M_0$ (so $\gamma \in M_0$), and $p_0 \in P_\gamma \cap M_0$.

2. For some $\gamma_0 \in M_0 \cap \gamma$, G_0 is an (M_0, P_{γ_0})-generic filter such that $p_0 \restriction \gamma_0 \in G_0$. We assume that $G_0 \in M_1$.

3. The order type of $M_0 \cap [\gamma_0, \gamma)$ is α.

4. $\bar{M} = \langle M_\xi \mid 1 \le \xi \le \alpha \rangle$ is a tower of countable elementary submodels of H_λ, and $M_0 \in M_1$. It will be clear later why we separate M_0 from the rest of the tower.

The value returned, $G_\gamma = \mathbb{E}(M_0, \bar{M}, P_\gamma, G_0, p_0)$ is an (M_0, P_γ)-generic filter that extends G_0 and contains p_0. Formally, in saying that G_γ extends G_0 we mean that the restriction projection takes G_γ onto G_0. The definition of $\mathbb{E}(M_0, \bar{M}, P_\gamma, G_0, p_0)$ is by induction on $\alpha < \omega_1$.

Assume that $\alpha = \alpha' + 1$ is a successor ordinal. Then $\gamma = \gamma' + 1$ is also a successor. Assume first that $\gamma_0 = \gamma'$. Then $\alpha = 1$ and we have only two structures: M_0 and M_1. Since P_γ is isomorphic to $P_{\gamma_0} * Q_{\gamma_0}$, we can define G_γ by Definition 5.19. So

$$G_\gamma = \mathbb{E}(M_0, M_1, P_{\gamma_0} * Q_{\gamma_0}, G_0, p_0).$$

Assume next that $\gamma_0 < \gamma'$. Then

$$G_{\gamma'} = \mathbb{E}(M_0, \langle M_\xi \mid 1 \le \xi \le \alpha' \rangle, P_{\gamma'}, G_0, p_0 \restriction \gamma')$$

is defined and is an $(M_0, P_{\gamma'})$-generic filter that extends G_0 and contains $p_0 \restriction \gamma'$. Moreover, we assume that $G_{\gamma'} \in M_\alpha$, for otherwise the inductive definition stops. (When we finish this definition, it will be evident that it continues through every $\alpha < \omega_1$ since $M_\alpha \prec H_\lambda$ and the parameters are all in M_α.)

This brings us to the previous case and we define

$$G_\gamma = \mathbb{E}(M_0, M_\alpha, P_{\gamma'} * Q_{\gamma'}, G_{\gamma'}, p_0). \tag{5.21}$$

Now suppose that α is a limit ordinal, and let $\langle \alpha_n \mid n \in \omega \rangle$ be an increasing and cofinal sequence with $\alpha_0 = 0$. Let $\gamma_n \in M_0$ be the corresponding increasing and cofinal in γ sequence (so that α_n is the order-type of $M_0 \cap [\gamma_0, \gamma_n)$). Let $\langle D_n \mid n \in \omega \rangle$ be an enumeration of all dense subsets of P_γ that are in M_0.

We define $G_\gamma = \mathbb{E}(M_0, \bar{M}, P_\gamma, G_0, p_0)$ as follows. We define by induction on $n \in \omega$ a condition $p_n \in P_\gamma \cap M_0$ and an (M_0, P_{γ_n})-generic filter $G_n \in M_{\alpha_n + 1}$ such that:

1. G_0 and p_0 are given. $p_n \restriction \gamma_n \in G_n$.

2. $p_n \le p_{n+1}$ and $p_{n+1} \in D_n$.

Suppose that G_n and p_n are defined. First, we can easily find a $p_{n+1} \in D_n \cap M_0$ such that $p_{n+1} \restriction \gamma_n \in G_n$. Now define

$$G_{n+1} = \mathbb{E}(M_0, \langle M_\xi \mid \alpha_n + 1 \le \xi \le \alpha_{n+1} \rangle, P_{\gamma_{n+1}}, G_n, p_{n+1} \restriction \gamma_{n+1}). \tag{5.22}$$

Finally, let G_γ be the generic filter generated by $\{p_n \mid n \in \omega\}$. This completes the definition of $\mathbb{E}(M_0, \bar{M}, P_\gamma, G_0, p_0)$.

Theorem 5.17 is a direct consequence of the following lemma.

5.21 Lemma (Dee-Properness Extension Lemma). *Let $\langle P_i \mid i \leq \gamma\rangle$ be a countable support iteration of forcing posets (γ is any ordinal) where each iterand Q_i satisfies the following in V^{P_i}:*

1. *Q_i is α-proper for every countable α.*
2. *Q_i is Dee-complete with respect to some countably complete completeness system in the ground model V.*

Suppose that $M_0 \prec H_\lambda$ is countable, $P_\gamma \in M_0$ and $p_0 \in P_\gamma \cap M_0$. For any $\gamma_0 \in \gamma \cap M_0$, if α is the order-type of $M_0 \cap [\gamma_0, \gamma)$ and $\bar{M} = \langle M_k \mid k \leq \alpha\rangle$ is a tower of countable elementary substructures (starting with the given M_0) then the following holds. For any $q_0 \in P_{\gamma_0}$ that is completely (M_0, P_{γ_0})-generic as well as $(\bar{M}, P_{\gamma_0})$-generic, if $p_0 \restriction \gamma_0 < q_0$ then there is some $q \in P_\gamma$ such that $q_0 = q \restriction \gamma_0$, $p_0 < q$ and q is completely (M_0, P_γ)-generic. In fact, the filter induced by q is $\mathbb{E}(M_0, \langle M_\xi \mid 1 \leq \xi \leq \alpha\rangle, P_\gamma, G_0, p_0)$ where $G_0 \subseteq P_{\gamma_0} \cap M_0$ is the filter induced by q_0.

Proof. Let $G_0 \subseteq P_{\gamma_0} \cap M_0$ be the (M_0, P_{γ_0})-generic filter induced by q_0. Observe that $G_0 \in M_1$ follows from the assumption that q_0 is (also) M_1-generic. We shall prove by induction on α (the order-type of $M_0 \cap [\gamma_0, \gamma)$) that q can be found which bounds $G_\gamma = \mathbb{E}(M_0, \langle M_\xi \mid 1 \leq \xi \leq \alpha\rangle, P_\gamma, G_0, p_0)$.

Suppose first that $\alpha = \alpha' + 1$ and consequently $\gamma = \gamma' + 1$ are successor ordinals. Define, in M_α, $X \subseteq P_{\gamma_0}$ a maximal antichain of conditions r such that

1. r bounds G_0.
2. r is $\langle M_\xi \mid 1 \leq \xi \leq \alpha'\rangle$-generic.

Then $X \in M_\alpha$ is pre-dense above q_0. By our inductive assumption every $r_0 \in X$ has a prolongation $r_1 \in P_{\gamma'}$ that bounds $G_{\gamma'} = \mathbb{E}(M_0, \langle M_\xi \mid 1 \leq \xi \leq \alpha'\rangle, P_{\gamma'}, G_0, p_0 \restriction \gamma')$. Since all the parameters are in M_α, we get that $G_{\gamma'} \in M_\alpha$. Since $M_\alpha \prec H_\lambda$, we can choose $r_1 \in M_\alpha$ whenever $r_0 \in X \cap M_\alpha$. This defines a name $\underset{\sim}{r_1} \in V^{P_{\gamma_0}}$, forced by q_0 to be in $M_\alpha \cap P_{\gamma'}$. Namely, if G is any (V, P_{γ_0})-generic filter containing q_0, then $X \cap G$ contains a unique condition r_0, and we let $\underset{\sim}{r_1}[G] = r_1$. By the Properness Extension Lemma we can find a $q_1 \in P_{\gamma'}$ with $q_1 \restriction \gamma_0 = q_0$ so that q_1 is $(M_\alpha, P_{\gamma'})$-generic, and $q_1 \Vdash \underset{\sim}{r_1}$ is in the generic filter. It follows that q_1 bounds $G_{\gamma'}$. We must define $q_2 \in P_\gamma$ such that $q_2 \restriction \gamma' = q_1$ and q_2 bounds G_γ. In order to define $q_2(\gamma')$ use Lemma 5.20 and (5.21).

Now assume that α is a limit ordinal. We follow the definition of G_γ (see (5.22)). Recall that we had an ω-sequence $\langle \alpha_n \mid n \in \omega\rangle$ cofinal in α, and we defined γ_n cofinal in γ as the resulting sequence. We defined by induction $p_n \in P_\gamma \cap M_0$ and filters $G_n \subseteq P_{\gamma_n}$, $G_n \in M_{\alpha_n+1}$, and defined G_γ as the filter generated by the p_n's. We shall define now $q_n \in P_{\gamma_n}$ by induction on $n \in \omega$ so that the following hold.

1. q_n bounds G_n.

2. $p_n \restriction \gamma_n < q_n$.

3. $q_n = q_{n+1} \restriction \gamma_n$.

4. q_n is $\langle M_\xi \mid \alpha_n + 1 \leq \xi \leq \alpha \rangle$ generic over P_{γ_n}.

Thus, as q_n gains in length, it loses its status as an M_ξ generic condition for $0 < \xi \leq \alpha_n$. So, finally, $q = \bigcup_{n \in \omega} q_n$ is not M_ξ-generic for any $\xi > 0$. But these M_ξ's are not needed anymore as q gained its complete genericity over M_0.

Suppose that q_n is defined. Let X in $M_{\alpha_{n+1}+1}$ be a maximal antichain in P_{γ_n} of conditions r that induce G_n and are $\langle M_\xi \mid \alpha_n + 1 \leq \xi \leq \alpha_{n+1} \rangle$-generic over P_{γ_n}. Observe that X is pre-dense above q_n. For each $r_0 \in X$ find a $r_1 \in P_{\gamma_{n+1}}$ such that r_1 bounds G_{n+1}, $p_{n+1} \restriction \gamma_{n+1} < r_1$, and $r_1 \restriction \gamma_n = r_0$ (use the inductive assumption). If $r_0 \in X \cap M_{\alpha_{n+1}+1}$ then r_1 is taken from $M_{\alpha_{n+1}+1}$. Now view $\{r_1 \mid r_0 \in X\}$ as a name $\underset{\sim}{r}$ for a condition forced by q_n to lie in $M_{\alpha_{n+1}+1}$. By the α-Extension Lemma define q_{n+1} that satisfies 2–4 above and such that $q_{n+1} \Vdash \underset{\sim}{r} \in \underset{\sim}{G}$. Then q_{n+1} bounds G_{n+1} and is as required. $\dashv$

Simple Completeness Systems

An important chapter in the theory of forcing is the study of forcing axioms. These are axioms in the spirit of Martin's Axiom, and the best known among those related to proper forcing is probably the Proper Forcing Axiom (PFA) which uses a supercompact cardinal for its consistency. PFA is due to Baumgartner, and [1] contains many applications and a consistency proof. (The reader can also read a consistency proof in Cummings's chapter in this Handbook.) Chapters VII, VIII, XVII of [15] discuss many of these proper forcing axioms, and we shall restrict our attention here to just one axiom: a variant of Axiom II of Chap. VII which is used to obtain consistency results with CH. This will motivate the notion of *simple* completeness systems and will lead to the p.i.c.

Assume that κ is a supercompact cardinal in the ground model V. Define a countable support iteration P_γ, for $\gamma \leq \kappa$ of $<\omega_1$-proper posets, of cardinality $< \kappa$ each, that are Dee-complete for countably complete completeness systems from V. The actual choice of the iterand is done by some "Laver diamond" function.

Let $P = P_\kappa$ be the resulting countable support iteration. It follows by arguments that are very similar to those used for the PFA consistency result that if G is (V, P)-generic, then $V[G]$ satisfies the following axiom, formulated with the ground model V as a predicate:

> GCH holds. V is a ZFC subuniverse containing all reals, and such that the following holds. Let P be any poset such that
>
> 1. P is $<\omega_1$-proper.

2. P is Dee-complete with respect to some countably complete completeness system from V.

Then for any sequence $D_\alpha \subseteq P$ of dense subsets of P for $\alpha < \omega_1$, there is some filter $G \subseteq P$ such that $G \cap D_\alpha \neq \emptyset$ for every $\alpha < \omega_1$.

It can be maintained that an axiom should not relate to a subuniverse V in its formulation, and that a more local axiom is required. For this the notion of simplicity is introduced, and we bring here an axiom which is a variant of the original formulation of Shelah [15].

Let HC $= (H_{\aleph_1}, \in)$ be the structure consisting of the universe of all hereditarily countable sets together with the membership relation $\in$. We say that a completeness system $\mathbb{D}$ is *simple over* HC if there is a first-order formula $\psi(y_0, \dots, y_4)$ in the $\in$ language such that for every transitive and countable model N of ZFC$^-$, poset $P \in N$, and $p \in P$

$$\mathbb{D}(N, P, p) = \{A_X \mid X \in H_{\aleph_1}\}$$

where

$$A_X = \{G \in \mathrm{Gen}_p(N, P) \mid \mathrm{HC} \models \psi(G, X, N, P, p)\}. \tag{5.23}$$

For example, $\psi(G, X, N, P, p)$ could say the following.

Assume that:

1. In N, g is a Hajnal-Mátė graph, $P = P_g$, and $p \in P$.

2. X is an unbounded ω-sequence in ω_1^N.

Then $G \subseteq P$ is (N, P)-generic, $p \in G$, and the restriction of $\bigcup G$ to X omits infinitely many colors. If the above assumptions do not hold, then G is any (N, P)-generic filter containing p.

Now the axiom that can be used to obtain results that are consistent with CH is the following (PFA for countably complete simple completeness systems).

> CH holds. If P is any $<\omega_1$-proper poset that is Dee-complete for some countably complete completeness system that is simple over HC, and if $\{D_i \mid i \in \omega_1\}$ is a collection of dense subsets of P, then there is a filter $G \subseteq P$ that meets all of the D_i's. (5.24)

As mentioned, the consistency of this axiom relies on a supercompact cardinal in the ground model, yet in many of the specific applications of this axiom, the supercompact cardinal is not needed. For example, the Souslin hypothesis (which says there are no Souslin trees) is a consequence of the axiom, and in fact the axiom implies that every Aronszajn tree is special. For every Aronszajn tree T, there is a $<\omega_1$-proper poset which is Dee-complete with respect to some countably complete *simple* over HC system, and which specializes T (see Shelah [15, Chap. V]). Hence the axiom quoted above implies this strong form of the Souslin hypothesis. Yet, to get the consistency with CH of "every Aronszajn tree is special" no large cardinal is needed—this is the result of Jensen [3]. We may, without any large cardinal assumption, iterate such specializing posets (by the Dee-Completeness Iteration Theorem) and obtain the same consistency result. If we do so, we encounter a small difficulty which is discussed in the following subsection, namely that the specializing posets have size $2^{\aleph_1}$ each and so it is unclear, at this stage, that the iteration satisfies the $\aleph_2$-c.c. Although we shall not describe the specializing posets, it turns out that they satisfy the $\aleph_2$-p.i.c. (a strong form of the chain condition described below) and hence the $\aleph_2$-c.c of the iteration follows. Another use of the $\aleph_2$-p.i.c. (which is the one that will be exemplified) is to obtain extensions in which $2^{\aleph_1} > \aleph_2$.

5.4. The Properness Isomorphism Condition

Using the iteration scheme of the previous section we know how to obtain models of ZFC + CH + $2^{\aleph_1} = \aleph_2$ + "Every Hajnal-Máté graph has countable chromatic number". In this section we modify a little the construction in order to obtain such models with $2^{\aleph_1}$ arbitrarily large. To obtain this, Shelah uses the following simple idea. Starting with $2^{\aleph_1}$ already large, form a countable support *product* of all posets of the form P_g that are in the ground model. This takes care of all Hajnal-Máté graphs in V. Now iterate such large products ω_2 times, and obtain a model of ZFC + CH + $2^{\aleph_1}$ large + "Every Hajnal-Máté graph has countable chromatic number". The main technical problem in this approach is to prove that the iteration satisfies the $\aleph_2$-c.c. After we prove that this is the case, we will argue that every Hajnal-Máté graph in the extension already appears in some intermediate stage and hence acquired a countable chromatic number at the following stage. To establish the $\aleph_2$-c.c. we will use the condition named $\aleph_2$-p.i.c. (for Properness Isomorphism Condition), introduced in [15, Chap. VIII] exactly for such applications in mind.

We employ the following terminology. Suppose $M_0, M_1 \prec H_\lambda$ are countable, isomorphic, elementary submodels, and $\aleph_2 \leq \kappa < \lambda$ is a regular cardinal such that $\kappa \in M_0 \cap M_1$; typically $\kappa = \aleph_2$. We say that M_0 and M_1 are in *standard situation* (with respect to κ) iff

1. The sets $A = M_0 \cap M_1 \cap \kappa$, $B = (M_0 \setminus M_1) \cap \kappa$, and $C = (M_1 \setminus M_0) \cap \kappa$ are arranged $A < B < C$ (where $X < Y$ means that $\forall x \in X \forall y \in Y (x < y)$).

2. The isomorphism, denoted $h : M_0 \to M_1$, is the identity function on $M_0 \cap M_1$ (so in particular on A).

5.22 Definition. Let M_0 and M_1 be in standard situation with $h : M_0 \to M_1$ the isomorphism. Suppose that $P \in M_0 \cap M_1$ is a poset. We say that a condition $q \in P$ is *simultaneously* (M_0, P)*- and* (M_1, P)*-generic* iff

1. q is both (M_0, P)- and (M_1, P)-generic,
2. $$q \Vdash_P (\forall r \in M_0 \cap P)\ r \in \underset{\sim}{G} \quad \text{iff} \quad h(r) \in \underset{\sim}{G} \tag{5.25}$$
   where $\underset{\sim}{G}$ is the name of the P generic filter.

Equivalently, (5.25) can be stated as: for every $q' \geq q$ and $r \in M_0 \cap P$, if $r < q'$ then $h(r) < q'$. Yet another equivalent formulation is that p forces that h can be extended to an isomorphism of $M_0[\underset{\sim}{G}]$ onto $M_1[\underset{\sim}{G}]$.

Note that the requirement in 1. that q be (M_1, P)-generic is dispensable, since it follows from 2. when q is (M_0, P)-generic.

5.23 Definition. Let κ be an uncountable regular cardinal. A poset P *satisfies the* κ-p.i.c. if the following holds for sufficiently large cardinals λ and any two isomorphic countable elementary submodels $M_0, M_1 \prec H_\lambda$ with $P \in M_0 \cap M_1$ that are in standard situation. For any $p \in M_0 \cap P$ there is a $q > p$ in P that is simultaneously (M_0, P)- and (M_1, P)-generic. (Hence, in particular, $q > h(p)$.)

This definition is phrased so that the κ-p.i.c. of P implies its properness (take $M_0 = M_1$), but for clarity we shall use the expression "P is a proper κ-p.i.c. poset".

For example, any proper poset of size $\aleph_1$ is $\aleph_2$-p.i.c. because $M_0 \cap P = M_1 \cap P$. So our discussion here generalizes Sect. 2.2. In fact, if P is proper and $|P| < \kappa$ then P satisfies the κ-p.i.c. (see [15, Chap. VIII]), but $\mu^{\aleph_0} < \kappa$ for $\mu < \kappa$ is needed for the lemma that derives the κ chain condition (see below). The Cohen forcing poset for adding $\aleph_2$ reals (with finite conditions), while c.c.c., is not $\aleph_2$-p.i.c. In contrast, the poset for adding subsets of ω_1 with countable conditions is $\aleph_2$-p.i.c.

5.24 Lemma. *If κ is a regular cardinal such that $\mu^{\aleph_0} < \kappa$ for every $\mu < \kappa$, then any κ-p.i.c. poset satisfies the usual κ-c.c.*

Proof. In fact, every collection $\{p_i \mid i < \kappa\} \subseteq P$ contains a subcollection of size κ of pairwise compatible conditions. For each $i < \kappa$ pick some countable $M_i \prec H_\lambda$ with $p_i \in M_i$. Since $\mu^{\aleph_0} < \kappa$ for every $\mu < \kappa$, a standard Δ-system argument yields a set $I \subseteq \kappa$ of cardinality κ such that $\{M_i \cap \kappa \mid i \in I\}$ form a Δ-system. So for $i, j \in I$ with $i < j$, M_i and M_j are in standard situation. We may also assume that (M_i, p_i) and (M_j, p_j) are isomorphic (so $h : M_i \to M_j$ is an isomorphism such that $h(p_i) = p_j$). Now the κ-p.i.c. implies that some $q \in P$ extends both p_i and p_j. ⊣

We shall prove now the main theorem using a short argument followed by a series of lemmas which are brought without proof or with a short proof since they resemble those of Sect. 2.

5.25 Theorem. *Suppose that κ is a regular cardinal and $\mu^{\aleph_0} < \kappa$ for every $\mu < \kappa$.*

1. *If P_κ is a countable support iteration of length κ of proper κ-p.i.c. posets, then P_κ satisfies the κ-c.c.*

2. *If P_γ is a countable support iteration of length $\gamma < \kappa$ of proper κ-p.i.c. posets, then P_γ satisfies the κ-p.i.c. (For this we do not need the assumption on $\mu^{\aleph_0}$.)*

Proof. To prove the first part, consider a collection $\{p_i \mid i < \kappa\} \subseteq P_\kappa$. Use Fodor's Theorem to fix a bound $i_0 < \kappa$ on $\sup(i \cap \mathrm{dom}(p_i))$ on a stationary set of indices i's with uncountable cofinality, so that $\mathrm{dom}(p_i)$ form a Δ-system. This shows that it suffices to prove that P_{i_0}, the iteration of the first $i_0 < \kappa$ posets, is κ-c.c. In fact it is κ-p.i.c. as the second part of the theorem shows. The proof of this part is in the following sequence of lemmas. ⊣

5.26 Lemma. *Let P be a poset and $Q \in V^P$ a name of a poset. Form $R = P * Q$. Then for any countable $M_0, M_1 \prec H_\lambda$ in standard situation and such that $R \in M_0 \cap M_1$ we have the following characterization: $(p, q) \in R$ is simultaneously (M_0, R)- and (M_1, R)-generic iff*

1. *$p \in P$ is simultaneously (M_0, P)- and (M_1, P)-generic; and*

2. *$p \Vdash_P q$ is simultaneously $(M_0[\underset{\sim}{G}_P], Q)$and $(M_1[\underset{\sim}{G}_P], Q)$-generic.*

For the proof, use Lemma 2.5 and the equivalent statement following (5.25).

5.27 Lemma. *Suppose that P is a κ-p.i.c. poset and $Q \in V^P$ is (forced to be) κ-p.i.c. there. Then $R = P * Q$ is also κ-p.i.c. and the following stronger form of Lemma 2.5 holds.*

Suppose that

1. *$M_0, M_1 \prec H_\lambda$ with $R \in M_0 \cap M_1$ are countable elementary submodels in standard situation.*

2. *$p_0 \in P$ is a simultaneously (M_0, P)- and (M_1, P)-generic.*

3. *$\underset{\sim}{r} \in V^P$ is a name such that*

$$p_0 \Vdash_P \underset{\sim}{r} \in M_0 \cap R \quad \textit{and} \quad \pi(\underset{\sim}{r}) \in \underset{\sim}{G}_0$$

where $\pi : P * Q \to P$ is the projection, and $\underset{\sim}{G}_0$ is the canonical name for the P-generic filter.

Then there is some $q_0 \in V^P$ such that (p_0, q_0) is simultaneously (M_0, R)- and (M_1, R)-generic and

$$(p_0, q_0) \Vdash_R \underset{\sim}{r} \in \underset{\sim}{G}.$$

So also

$$(p_0, q_0) \Vdash_R h(\underset{\sim}{r}) \in \underset{\sim}{G}.$$

The following lemma completes the proof of the second item of Theorem 5.25.

5.28 Lemma (Extension of p.i.c.). *Let P_γ be a countable support iteration of length $\gamma < \kappa$ of proper posets that are κ-p.i.c. Let λ be sufficiently large and $M_0, M_1 \prec H_\lambda$ be countable with $P_\gamma \in M_0 \cap M_1$ and that are in standard situation. For any $\gamma_0 \in \gamma \cap M_0$ and $q_0 \in P_{\gamma_0}$ that is simultaneously (M_0, P_{γ_0})- and (M_1, P_{γ_0})-generic the following holds. If $\underset{\sim}{p_0} \in V^{P_{\gamma_0}}$ is such that*

$$q_0 \Vdash_{\gamma_0} \underset{\sim}{p_0} \in P_\gamma \cap M_0 \quad \textit{and} \quad \underset{\sim}{p_0} \restriction \gamma_0 \in \underset{\sim}{G}_0$$

(where $\underset{\sim}{G}_0$ is the name of the P_{γ_0} generic filter) then there is a condition $q \in P_\gamma$ such that $q \restriction \gamma_0 = q_0$, q is simultaneously (M_0, P_γ)- and (M_1, P_γ)-generic, and $q \Vdash_\gamma \underset{\sim}{p_0} \in \underset{\sim}{G}$. (Thus also $q \Vdash_\gamma h(\underset{\sim}{p_0}) \in \underset{\sim}{G}$.)

The proof follows the same steps of the Properness Extension Lemma 2.8.

The following discussion can help to clarify some of the definitions and statements described above. Let HM be the collection of all Hajnal-Máté graphs. Recall that for any $g \in HM$, P_g is the poset for making the chromatic number of g countable. Let $P = \Pi^{\aleph_0}_{g \in HM} P_g$ be the countable support product of all ground model P_g's. That is, $f \in P$ iff f is a function defined on HM with $f(g) \in P_g$ and such that $f(g) = \emptyset$ for all but countably many g's. The ordering is coordinate wise extension.

The reader can go over the corresponding steps for P_g and prove that P is

1. proper,
2. α-proper for every $\alpha < \omega_1$,
3. Dee-complete for a countably complete completeness system $\mathbb{D}$,
4. an $\aleph_2$-p.i.c. poset.

Acknowledgments

I wish to thank James Cummings and Robert Solovay for discussions and comments that improved earlier versions of the chapter. The referee and editor clarified the text in many places and my thanks are extended to them as well.

1. Introduction

The first theorem about cardinal characteristics of the continuum is Cantor's classical result [38] that the cardinality $\mathfrak{c} = 2^{\aleph_0}$ of the continuum is strictly larger than the cardinality $\aleph_0$ of a countably infinite set. The distinction between $\aleph_0$ and $\mathfrak{c}$ was soon put to good use, especially in real analysis, where countable sets were shown to have many useful properties that cannot be extended to sets of cardinality $\mathfrak{c}$. Here are a few familiar examples; more examples are implicit throughout this chapter.

- Countably many nowhere dense sets cannot cover the real line. (The Baire Category Theorem.)
- If countably many sets each have Lebesgue measure zero then so does their union.
- Given countably many sequences of real numbers, there is a single sequence that eventually dominates each of the given ones.
- Let countably many bounded sequences $S_k = \langle x_{k,n} \rangle_{n\in\omega}$ of real numbers be given. There is an infinite subset A of ω such that all the corresponding subsequences $S_k \restriction A = \langle x_{k,n} \rangle_{n\in A}$ converge.

Each of these results becomes trivially false if the hypothesis of countability is weakened to allow cardinality $\mathfrak{c}$. It is natural to ask whether the hypothesis can be weakened at all and, if so, by how much. For which uncountable cardinals, if any, do these results remain correct?

If the Continuum Hypothesis (CH) is assumed, the answer is trivial. The results are false already for $\aleph_1$ because $\aleph_1 = \mathfrak{c}$. But the Continuum Hypothesis, though not refutable from the usual (ZFC) axioms of set theory, is also not provable from them, so one can reasonably ask what happens if CH is false. Then there are cardinals strictly between $\aleph_0$ and $\mathfrak{c}$, and it is not evident whether the results cited above remain valid when "countable" is replaced by one of these cardinals.

Not only is it not evident, but it is not decidable in ZFC. For example, it is consistent with ZFC that $\mathfrak{c} = \aleph_2$ and all the cited results remain correct for $\aleph_1$, but it is also consistent that $\mathfrak{c} = \aleph_2$ and all the cited results fail for $\aleph_1$. It may seem that this undecidability prevents us from saying anything useful about extending the results above to higher cardinals. Fortunately, though little can be said about extending any one of these results, there are surprising and deep connections between extensions of different results. For example, if the Lebesgue measure result quoted above remains true for a cardinal κ, then so do the results about Baire category and about eventual domination.

A major goal of the theory of cardinal characteristics of the continuum is to understand relationships of this sort, either by proving implications like the one just cited or by showing that other implications are unprovable in ZFC. The cardinal characteristics are simply the smallest cardinals for which various results, true for $\aleph_0$, become false. (The characteristics corresponding to the four results cited above are called $\mathbf{cov}(\mathcal{B})$, $\mathbf{add}(\mathcal{L})$, $\mathfrak{b}$, and $\mathfrak{s}$, respectively, so the implication at the end of the preceding paragraph would be expressed by the inequalities $\mathbf{add}(\mathcal{L}) \leq \mathbf{cov}(\mathcal{B})$ and $\mathbf{add}(\mathcal{L}) \leq \mathfrak{b}$.) We shall be concerned here only with results about $\aleph_0$ that are false for $\mathfrak{c}$, so the characteristics we consider lie in the interval from $\aleph_1$ to $\mathfrak{c}$, inclusive.

A second goal of the theory, which we touch on only briefly here, is to find situations, in set theory or other branches of mathematics, where cardinal characteristics arise naturally. Wherever a result involves a countability hypothesis, one can ask whether it extends to some uncountable cardinals. Quite often, one can extend it to all cardinals below some previously studied characteristic. (Of course, if the result fails for $\mathfrak{c}$, one can simply use it to define a new characteristic, but this is of little value unless one can relate it to more familiar characteristics or at least give a simple, combinatorial description of it.) Such applications are fairly common in set-theoretic topology—notice that the two standard survey articles on cardinal characteristics, [42] and [111], appeared in topology books. They are becoming more common in other branches of mathematics as these branches come up against set-theoretic independence results.

We digress for a moment to comment on the meaning of "continuum" in the name of our subject. In principle, "continuum" refers to the real line $\mathbb{R}$ or to an interval like $[0, 1]$ in $\mathbb{R}$, regarded as a topological space. It is, however, common practice in set theory to apply the word also to spaces like ${}^\omega 2$, ${}^\omega\omega$ and $[\omega]^\omega$. Here ${}^\omega X$ means the space of ω-sequences of elements of X, topologized as a product of discrete spaces. Thus, ${}^\omega 2$ consists of sequences of zeros and ones; it may be identified with the power set $\mathcal{P}\omega$ of ω. $[\omega]^\omega$ is the subspace of $\mathcal{P}\omega$ consisting of the infinite sets. All these spaces are equivalent for many purposes, since any two become homeomorphic after removal of suitable countable subsets. We remark in particular that there is a continuous bijection from ${}^\omega\omega$ to $[0, 1)$, whose inverse is continuous except at dyadic rationals. This bijection, which takes the sequence $(a_0, a_1, \dots) \in {}^\omega\omega$ to the number whose binary expansion is a_0 ones, a zero, a_1 ones, a zero, …, also behaves nicely with respect to measure. Lebesgue measure on $[0, 1)$ corresponds to the product measure on ${}^\omega\omega$ obtained from the measure on ω giving each point n the measure 2^{-n-1}. Similarly, the obvious "binary notation" map from ${}^\omega 2$ onto $[0, 1]$, which fails to be one-to-one only over the dyadic rationals, makes Lebesgue measure correspond to the product measure on ${}^\omega 2$ obtained from the uniform measure on 2. In view of correspondences like these, we shall, without further explanation, apply cardinal characteristics like $\mathbf{cov}(\mathcal{B})$ and $\mathbf{add}(\mathcal{L})$ to all these versions of the continuum (with the corresponding measures), although they were defined in terms of $\mathbb{R}$ (with Lebesgue measure).

Another aspect of our subject's name also deserves a brief digression. Are these cardinals really characteristics of the continuum, or do they depend on more of the set-theoretic universe? Of course they depend on the class of cardinals; a characteristic that ceases to be a cardinal in some forcing extension will obviously cease to be a characteristic there also. So a more reasonable question would be whether the characteristics are determined by the continuum and the cardinals. More specifically, can cardinal characteristics of the continuum be changed by a forcing that neither adds reals nor collapses cardinals? Mildenberger [78] has shown that, for certain characteristics, such changes are possible but only in the presence of inner models with large cardinals.

As a final comment on the name of the subject, we mention that the traditional terminology was "invariants" rather than "characteristics"; see for example [99]. The alternative name "characteristics" was introduced because the invariants varied; indeed, much of the theory is about what sorts of variation are possible. Nevertheless, "invariant" is still in very common use—for example in Bartoszyński's chapter in this Handbook and [115].

We adopt the following standard notations for dealing with "modulo finite" notions on the natural numbers. First, $\forall^\infty x$ means "for all but finitely many x"; here x will always range over natural numbers, so the quantifier is equivalent to "for all sufficiently large x". Similarly $\exists^\infty x$ means "for infinitely many x" or equivalently "there exist arbitrarily large x such that". Notice that these quantifiers stand in the same duality relation as simple $\forall$ and $\exists$, namely $\neg\forall^\infty x$ is equivalent to $\exists^\infty x\neg$. An asterisk is often used to indicate a weakening from "for all" to "for all but finitely many". In particular, for subsets X and Y of ω, we write $X \subseteq^* Y$ to mean that X is almost included (or included modulo finite) in Y, i.e., $\forall^\infty x\ (x \in X \implies x \in Y)$. Similarly, for functions $f, g \in {}^\omega\omega$, we write $f \leq^* g$ to mean $\forall^\infty x\ (f(x) \leq g(x))$. We often use "almost" to mean modulo finite sets. For example, an almost decreasing sequence of sets is one where $X_m \supseteq^* X_n$ whenever $m < n$.

We use the standard abbreviations (some already mentioned above): ZFC for Zermelo-Fraenkel set theory including the axiom of choice, CH for the Continuum Hypothesis ($\mathfrak{c} = \aleph_1$), and GCH for the Generalized Continuum Hypothesis ($2^{\aleph_\alpha} = \aleph_{\alpha+1}$ for all cardinals $\aleph_\alpha$).

2. Growth of Functions

The ordering $\leq^*$ on ${}^\omega\omega$ provides two simple but frequently useful cardinal characteristics, the dominating and (un)bounding numbers.

2.1 Definition. A family $\mathcal{D} \subseteq {}^\omega\omega$ is *dominating* if for each $f \in {}^\omega\omega$ there is $g \in \mathcal{D}$ with $f \leq^* g$. The *dominating number* $\mathfrak{d}$ is the smallest cardinality of any dominating family, $\mathfrak{d} = \min\{|\mathcal{D}| : \mathcal{D} \text{ dominating}\}$.

2.2 Definition. A family $\mathcal{B} \subseteq {}^\omega\omega$ is *unbounded* if there is no single $f \in {}^\omega\omega$ such that $g \leq^* f$ for all $g \in \mathcal{B}$. The *bounding number* $\mathfrak{b}$ (sometimes called the *unbounding number*) is the smallest cardinality of any unbounded family.

2.3 Remark. Had we used the "everywhere" ordering ($f \leq g$ if $\forall x\,(f(x) \leq g(x))$) instead of the "almost everywhere" ordering, $\mathfrak{d}$ would be unchanged, as any dominating $\mathcal{D}$ could be made dominating in the new sense by adding all finite modifications of its members. But $\mathfrak{b}$ would drop down to $\aleph_0$, as the constant functions form an unbounded family in the new sense.

Both $\mathfrak{b}$ and $\mathfrak{d}$ would be unchanged if in their definitions we replaced ${}^\omega\omega$ with ${}^\omega\mathbb{R}$ or with the set of sequences from any linear ordering of cofinality ω.

The following theorem gives all the constraints on $\mathfrak{b}$ and $\mathfrak{d}$ that are provable in ZFC.

2.4 Theorem. $\aleph_1 \leq \mathrm{cf}(\mathfrak{b}) = \mathfrak{b} \leq \mathrm{cf}(\mathfrak{d}) \leq \mathfrak{d} \leq \mathfrak{c}$.

Proof. That $\aleph_1 \leq \mathfrak{b}$ means that, for every countably many functions $g_n : \omega \to \omega$, there is a single $f \geq^* $ all of them. Such an f is given by $f(x) = \max_{n \leq x} g_n(x)$.

To prove that $\mathfrak{b} \leq \mathrm{cf}(\mathfrak{d})$, let $\mathcal{D}$ be a dominating family of size $\mathfrak{d}$, and let it be decomposed into the union of $\mathrm{cf}(\mathfrak{d})$ subfamilies $\mathcal{D}_\xi$ of cardinalities $< \mathfrak{d}$. So there is, for each ξ, some f_ξ not dominated by any $g \in \mathcal{D}_\xi$. There can be no f dominating all the f_ξ, for such an f would not be dominated by any $g \in \mathcal{D}$. So $\{f_\xi : \xi < \mathrm{cf}(\mathfrak{d})\}$ is unbounded.

The proof that $\mathrm{cf}(\mathfrak{b}) = \mathfrak{b}$ is similar, and the rest of the theorem is obvious. $\dashv$

Hechler [57] has shown that, if P is a partially ordered set in which every countable subset has an upper bound, then P can consistently be isomorphic to a cofinal subset of $({}^\omega\omega, \leq^*)$. More precisely, given any such P, Hechler constructs a c.c.c. forcing extension of the universe where there is a strictly order-preserving, cofinal embedding of P into $({}^\omega\omega, \leq^*)$. (Hechler's proof, done soon after the invention of forcing, has been reworked, using a more modern formulation, by Talayco in [109, Chap. 4] and by Burke in [36].) Hechler's result implies that the preceding theorem is optimal in the following sense.

2.5 Theorem. *Assume* GCH, *and let* $\mathfrak{b}'$, $\mathfrak{d}'$, *and* $\mathfrak{c}'$ *be any three cardinals satisfying*

$$\aleph_1 \leq \mathrm{cf}(\mathfrak{b}') = \mathfrak{b}' \leq \mathrm{cf}(\mathfrak{d}') \leq \mathfrak{d}' \leq \mathfrak{c}'$$

and $\mathrm{cf}(\mathfrak{c}') > \aleph_0$. *Then there is a c.c.c. forcing extension of the universe satisfying* $\mathfrak{b} = \mathfrak{b}'$, $\mathfrak{d} = \mathfrak{d}'$, *and* $\mathfrak{c} = \mathfrak{c}'$.

Proof. Apply Hechler's theorem to $P = [\mathfrak{d}']^{<\mathfrak{b}'}$ partially ordered by inclusion. The regularity of $\mathfrak{b}'$ implies that any $< \mathfrak{b}'$ elements in P have an upper bound, but some $\mathfrak{b}'$ elements (e.g., distinct singletons) do not. From $\mathrm{cf}(\mathfrak{d}') \geq \mathfrak{b}'$ and GCH we get that $|P| = \mathfrak{d}'$. Fewer than $\mathfrak{d}'$ elements of P cannot be cofinal, for their union (as sets) has cardinality smaller than $\mathfrak{d}'$. These observations imply that $\mathfrak{b} = \mathfrak{b}'$ and $\mathfrak{d} = \mathfrak{d}'$ in the forcing extension given by Hechler's theorem. Finally, to get $\mathfrak{c} = \mathfrak{c}'$, adjoin $\mathfrak{c}'$ random reals; these will not damage

$\mathfrak{b}$ or $\mathfrak{d}$, as the ground model's ${}^\omega\omega$ is cofinal in the ${}^\omega\omega$ of any random real extension. ⊣

To see that $\mathfrak{b} < \mathfrak{d}$ is consistent, it is not necessary to invoke Hechler's theorem. The original Cohen models [40] for the negation of CH have $\mathfrak{b} = \aleph_1$ and $\mathfrak{d} = \mathfrak{c}$. In fact, if one adjoins $\kappa \geq \aleph_1$ Cohen reals (by the usual product forcing) to any model of set theory, then the resulting model has $\mathfrak{b} = \aleph_1$ while $\mathfrak{d}$ becomes at least κ.

The contrary situation, that $\mathfrak{b} = \mathfrak{d}$, has the following useful characterization.

2.6 Theorem. $\mathfrak{b} = \mathfrak{d}$ *if and only if there is a scale in* ${}^\omega\omega$, *i.e., a dominating family well-ordered by* $\leq^*$.

Proof. If $\mathcal{D} = \{f_\xi : \xi < \mathfrak{b}\}$ is a dominating family of size $\mathfrak{b}$, then we obtain a scale $\{g_\xi : \xi < \mathfrak{b}\}$ by choosing each g_ξ to dominate f_ξ and all previous g_η ($\eta < \xi$); this can be done because we need to dominate fewer than $\mathfrak{b}$ functions at a time.

Conversely, if there is a scale, choose one and let $\mathcal{B}$ be an unbounded family of size $\mathfrak{b}$. By increasing each element of $\mathcal{B}$ if necessary, we can arrange for $\mathcal{B}$ to be a subset of our scale. But then, being unbounded, it must be cofinal in the well-ordering $\leq^*$ of the scale. Therefore it is a dominating family. ⊣

There are several alternative ways of looking at $\mathfrak{b}$ and $\mathfrak{d}$. We present two of them here and refer to [42, 56, 58] for others.

The first of these involves the "standard" characteristics of an ideal, defined as follows.

2.7 Definition. Let $\mathcal{I}$ be a proper ideal of subsets of a set X, containing all singletons from X.

- The *additivity* of $\mathcal{I}$, $\mathbf{add}(\mathcal{I})$, is the smallest number of sets in $\mathcal{I}$ with union not in $\mathcal{I}$.
- The *covering number* of $\mathcal{I}$, $\mathbf{cov}(\mathcal{I})$, is the smallest number of sets in $\mathcal{I}$ with union X.
- The *uniformity* of $\mathcal{I}$, $\mathbf{non}(\mathcal{I})$, is the smallest cardinality of any subset of X not in $\mathcal{I}$.
- The *cofinality* of $\mathcal{I}$, $\mathbf{cof}(\mathcal{I})$ is the smallest cardinality of any subset $\mathcal{B}$ of $\mathcal{I}$ such that every element of $\mathcal{I}$ is a subset of an element of $\mathcal{B}$. Such a $\mathcal{B}$ is called a *basis* for $\mathcal{I}$.

It is easy to check that both $\mathbf{cov}(\mathcal{I})$ and $\mathbf{non}(\mathcal{I})$ are $\geq \mathbf{add}(\mathcal{I})$ and $\leq \mathbf{cof}(\mathcal{I})$. In fact, $\mathbf{add}(\mathcal{I})$ is a lower bound for the cofinalities $\mathrm{cf}(\mathbf{non}(\mathcal{I}))$ and $\mathrm{cf}(\mathbf{cof}(\mathcal{I}))$ also. In this chapter, $\mathcal{I}$ will always be a σ-ideal, so its additivity (and therefore the other three characteristics) will be uncountable. Furthermore, $\mathcal{I}$ will have a basis consisting of Borel sets; since there are only

$\mathfrak{c}$ Borel sets, the cofinality (and therefore the other three characteristics) will be $\leq \mathfrak{c}$. (That the other three characteristics are $\leq \mathfrak{c}$ follows already from the simpler fact that the underlying set X is the continuum.)

The ideal relevant to the present section is the σ-ideal $\mathcal{K}_\sigma$ generated by the compact subsets of ${}^\omega\omega$, i.e., the ideal of sets coverable by countably many compact sets. Its connection with $\leq^*$ was pointed out by Rothberger in [91].

2.8 Theorem. $\mathbf{add}(\mathcal{K}_\sigma) = \mathbf{non}(\mathcal{K}_\sigma) = \mathfrak{b}$ *and* $\mathbf{cov}(\mathcal{K}_\sigma) = \mathbf{cof}(\mathcal{K}_\sigma) = \mathfrak{d}$.

Proof. Since a subset of the discrete space ω is compact if and only if it is finite, the Tychonoff theorem implies that a subset of ${}^\omega\omega$ is compact if and only if it is closed and included in a product of finite subsets of ω. There is no loss of generality in taking the finite subsets to be initial segments, so we find that all sets of the form

$$\{f \in {}^\omega\omega : f \leq g\} = \textstyle\prod_{n\in\omega}[0, g(n)]$$

are compact and every compact set is included in one of this form. It follows that all sets of the form $\{f \in {}^\omega\omega : f \leq^* g\}$ (with $\leq^*$ instead of $\leq$) are in $\mathcal{K}_\sigma$ and every set in $\mathcal{K}_\sigma$ is a subset of one of these. (The last uses that $\mathfrak{b} \geq \aleph_1$ to show that countably many bounds g for countably many compact sets are all $\leq^*$ a single bound.)

This connection between $\mathcal{K}_\sigma$ and $\leq^*$ easily implies the theorem. $\dashv$

Recalling that ${}^\omega\omega$ is homeomorphic, via continued fraction expansions, to the space of irrational numbers $\mathbb{R}-\mathbb{Q}$ (topologized as a subspace of $\mathbb{R}$), we see that the theorem remains valid if we interpret $\mathcal{K}_\sigma$ as the σ-ideal generated by the compact subsets of $\mathbb{R} - \mathbb{Q}$. In particular, $\mathfrak{d}$ is characterized as the minimum number of compact sets whose union is $\mathbb{R} - \mathbb{Q}$. (Here the choice of "continuum" is important. The corresponding cardinals for the spaces ${}^\omega 2$, $[0, 1]$, and $\mathbb{R}$ are clearly 1, 1, and $\aleph_0$, respectively.)

Yet another way of looking at the ordering $\leq^*$ and the associated cardinals $\mathfrak{b}$ and $\mathfrak{d}$ involves partitions of ω into finite intervals. (The earliest reference I know for this idea is Solomon's [103].)

2.9 Definition. An *interval partition* is a partition of ω into (infinitely many) finite intervals I_n $(n \in \omega)$. We always assume that the intervals are numbered in the natural order, so that, if i_n is the left endpoint of I_n then $i_0 = 0$ and $I_n = [i_n, i_{n+1})$. We say that the interval partition $\{I_n : n \in \omega\}$ *dominates* another interval partition $\{J_n : n \in \omega\}$ if $\forall^\infty n\, \exists k\ (J_k \subseteq I_n)$. We write IP for the set of all interval partitions.

2.10 Theorem. $\mathfrak{d}$ *is the smallest cardinality of any family of interval partitions dominating all interval partitions.* $\mathfrak{b}$ *is the smallest cardinality of any family of interval partitions not all dominated by a single interval partition.*

Proof. We prove only the first statement, as the second can be proved similarly or deduced from the proof of the first using the duality machinery of Sect. 4.

Suppose first that we have a family $\mathcal{F}$ of interval partitions dominating all interval partitions. To each of the partitions $\{I_n = [i_n, i_{n+1}) : n \in \omega\}$ in $\mathcal{F}$, associate the function $f : \omega \to \omega$ defined by letting $f(x)$ be the right endpoint of the interval after the one containing x; thus if $x \in I_n$ then $f(x) = i_{n+2} - 1$. We shall show that these functions f form a dominating family, so $\mathfrak{d} \leq |\mathcal{F}|$. Given any $g \in {}^\omega\omega$, the required f dominating g is obtained as follows. Form an interval partition $\{J_n = [j_n, j_{n+1}) : n \in \omega\}$ such that whenever $x \leq j_n$ then $g(x) < j_{n+1}$; it is trivial to do this by choosing the j_n inductively. Let $\{I_n = [i_n, i_{n+1}) : n \in \omega\}$ in $\mathcal{F}$ dominate this $\{J_n : n \in \omega\}$, and let f be the function associated to $\{I_n : n \in \omega\}$. To see that $g(x) \leq f(x)$ for all sufficiently large x, we chase through the definitions as follows. Let n be the index such that $x \in I_n$ and let (since x is sufficiently large) k be an index such that $J_k \subseteq I_{n+1}$. Then as $x \leq j_k$, we have $g(x) \leq j_{k+1} - 1 \leq i_{n+2} - 1 = f(x)$. This completes the proof that $\mathfrak{d} \leq |\mathcal{F}|$.

To produce a dominating family of interval partitions of cardinality $\mathfrak{d}$, we begin with a dominating family $\mathcal{D}$ of cardinality $\mathfrak{d}$ in ${}^\omega\omega$, and we associate to each $g \in \mathcal{D}$ an interval partition $\{J_n = [j_n, j_{n+1}) : n \in \omega\}$ exactly as in the preceding paragraph. To show that the resulting family of $\mathfrak{d}$ interval partitions dominates all interval partitions, let an arbitrary interval partition $\{I_n = [i_n, i_{n+1}) : n \in \omega\}$ be given, associate to it an $f \in {}^\omega\omega$ as in the preceding paragraph, and let $g \in \mathcal{D}$ be $\geq^* f$. We shall show that the $\{J_n : n \in \omega\}$ associated to this g dominates $\{I_n : n \in \omega\}$. For any sufficiently large n, we have $f(j_n) \leq g(j_n) \leq j_{n+1} - 1$. By virtue of the definition of f, this means that the next I_k after the one containing j_n lies entirely in J_n. ⊣

3. Splitting and Homogeneity

In this section, we treat several characteristics related to the "competition" between partitions trying to split sets and sets trying to be homogeneous for partitions. We begin with a combinatorial definition of a characteristic already mentioned, from an analytic point of view, in the introduction.

3.1 Definition. A set $X \subseteq \omega$ *splits* an infinite set $Y \subseteq \omega$ if both $Y \cap X$ and $Y - X$ are infinite. A *splitting family* is a family $\mathcal{S}$ of subsets of ω such that each infinite $Y \subseteq \omega$ is split by at least one $X \in \mathcal{S}$. The *splitting number* $\mathfrak{s}$ is the smallest cardinality of any splitting family.

Having defined $\mathfrak{s}$ differently in the introduction, we hasten to point out that the definitions are equivalent.

3.2 Theorem. *$\mathfrak{s}$ is the minimum cardinality of any family of bounded ω-sequences $S_\xi = \langle x_{\xi,n} \rangle_{n\in\omega}$ of real numbers such that for no infinite $Y \subseteq \omega$ do all the corresponding subsequences $S_\xi \restriction Y = \langle x_{\xi,n} \rangle_{n\in Y}$ converge. The same is true if we consider only sequences consisting of just zeros and ones.*

Proof. The second assertion, where all S_ξ are in ${}^\omega 2$, is a trivial rephrasing of the definition of $\mathfrak{s}$; just regard the sequences S_ξ as the characteristic functions of the sets in a splitting family. The key point is that, for the characteristic function of X, convergence means eventual constancy, and so convergence of its restriction to Y means that Y is not split by X.

Half of the first assertion follows immediately from the second. To prove the other half of the first assertion, use the fact that a bounded sequence of real numbers converges if (though not quite only if) for each k the sequence of kth binary digits converges. $\dashv$

The last part of the preceding proof implicitly used the fact that $\mathfrak{s}$ is uncountable. We omit the easy, direct proof of this, because it will also follow from results to be proved later ($\aleph_1 \leq \mathfrak{t} \leq \mathfrak{h} \leq \mathfrak{s}$; see Sect. 6).

Theorem 2.10 makes it easy to relate $\mathfrak{s}$ to $\mathfrak{d}$.

3.3 Theorem. $\mathfrak{s} \leq \mathfrak{d}$.

Proof. By Theorem 2.10, fix a family of $\mathfrak{d}$ interval partitions dominating all interval partitions. To each partition $\Pi = \{I_n : n \in \omega\}$ in this family, associate the union $\varphi(\Pi) = \bigcup_n I_{2n}$ of its even-numbered intervals. We shall show that these $\mathfrak{d}$ sets $\varphi(\Pi)$ constitute a splitting family. To this end, consider an arbitrary infinite subset X of ω. Associate to it an interval partition $\psi(X)$ in which every interval contains at least one member of X. Our dominating family of interval partitions contains a Π that dominates $\psi(X)$. But then each interval of Π, except for finitely many, includes an interval of $\psi(X)$ and therefore contains a point of X. It follows immediately that both $\varphi(\Pi)$ and its complement (the union of the odd-numbered intervals) contain infinitely many points of X. So $\varphi(\Pi)$ splits X. $\dashv$

We record for future reference the basic property of the constructions φ and ψ that makes the preceding proof work: For any interval partition Π and any infinite $X \subseteq \omega$,

$$\Pi \text{ dominates } \psi(X) \quad \Longrightarrow \quad \varphi(\Pi) \text{ splits } X.$$

The inequality in the theorem can consistently be strict. For example, if one adds $\kappa > \aleph_0$ Cohen reals to a model of set theory, then in the resulting model $\mathfrak{d} \geq \kappa$ (as remarked earlier) while $\mathfrak{s} = \aleph_1$ because any $\aleph_1$ of the added Cohen reals constitute a splitting family.

The splitting number is the simplest of a family of characteristics defined in terms of structures that are not simultaneously homogeneous (modulo finite) on any one infinite set. For $\mathfrak{s}$, the "structures" are two-valued functions and "homogeneous" simply means constant. Other notions of structure and homogeneity are suggested by various partition theorems. We shall characterize the analog of $\mathfrak{s}$ arising from Ramsey's Theorem and briefly mention a few other analogs afterward.

3.4 Definition. A set $H \subseteq \omega$ is *homogeneous* for a function $f : [\omega]^n \to k$ (a partition of $[\omega]^n$ into k pieces) if f is constant on $[H]^n$. H is *almost* *homogeneous* for f if there is a finite set F such that $H - F$ is homogeneous for f. $\mathfrak{par}_n$ is the smallest cardinality of any family of partitions of $[\omega]^n$ into two pieces such that no single infinite set is almost homogeneous for all of them simultaneously.

We note that $\mathfrak{par}_1$ is simply $\mathfrak{s}$ and that the definition of $\mathfrak{par}_n$ would be unchanged if we allowed partitions into any finite number of pieces (for any such partition could be replaced with the finitely many coarser partitions into two pieces). We note also that the use of *almost* homogeneity in the definition is essential; it is easy to produce countably many partitions with no common infinite homogeneous set.

3.5 Theorem. *For all integers $n \geq 2$, $\mathfrak{par}_n = \min\{\mathfrak{b}, \mathfrak{s}\}$.*

Proof. Notice first that $\mathfrak{par}_n \leq \mathfrak{par}_m$ if $n \geq m$, because any partition $[\omega]^m \to 2$ can be regarded as a partition of $[\omega]^n$ ignoring the last $n - m$ elements of its input. In particular, we have $\mathfrak{par}_n \leq \mathfrak{s}$, and if we show $\mathfrak{par}_2 \leq \mathfrak{b}$ then the $\leq$ direction of the theorem will be proved. For the $\geq$ direction, we must consider arbitrary n, but in fact we shall confine attention to $n = 2$ since the general case is longer but not harder.

To show $\mathfrak{par}_2 \leq \mathfrak{b}$, let $\mathcal{B} \subseteq {}^\omega\omega$ be an unbounded family of size $\mathfrak{b}$, assume without loss of generality that each $g \in \mathcal{B}$ is monotone increasing, and associate to each such g the partition of $[\omega]^2$ that puts a pair $\{x < y\}$ into class 0 if $g(x) < y$ and into class 1 otherwise. We shall show that no infinite $H \subseteq \omega$ is almost homogeneous for all these partitions simultaneously. Notice first that a homogeneous set of class 1 must be finite since, if x is its first element, then all the other elements are majorized by $g(x)$. So suppose, toward a contradiction, that H is infinite and almost homogeneous of class 0 for all the partitions associated to the functions $g \in \mathcal{B}$. Consider the function h sending each natural number x to the second member of H above x. For each x, we have $x < y < h(x)$ with both y and $h(x)$ in H. By almost homogeneity of H, we have, for each $g \in \mathcal{B}$ and for all sufficiently large x, $g(y) < h(x)$ and thus, by monotonicity of g, $g(x) < h(x)$. Thus, $g \leq^* h$ for all $g \in \mathcal{B}$, contrary to our choice of $\mathcal{B}$.

To show $\mathfrak{par}_2 \geq \min\{\mathfrak{b}, \mathfrak{s}\}$, suppose we are given a family of $\kappa < \min\{\mathfrak{b}, \mathfrak{s}\}$ partitions $f_\xi : [\omega]^2 \to 2$; we must find an infinite set almost homogeneous for all of them. First, consider the functions

$$f_{\xi,n} : \omega \to 2 : x \mapsto f_\xi\{n, x\}.$$

(This is undefined for $x = n$; define it arbitrarily there.) Since the number of these functions is $\kappa \cdot \aleph_0 < \mathfrak{s}$, there is an infinite $A \subseteq \omega$ on which they are almost constant; say $f_{\xi,n}(x) = j_\xi(n)$ for all $x \geq g_\xi(n)$ in A. Furthermore, since $\kappa < \mathfrak{s}$ we can find an infinite $B \subseteq A$ on which each j_ξ is almost constant, say $j_\xi(n) = i_\xi$ for all $n \geq b_\xi$ in B. And since $\kappa < \mathfrak{b}$ we have a function h majorizing each g_ξ from some integer c_ξ on. Let $H = \{x_0 < x_1 < \cdots\}$ be an infinite subset of B chosen so that $h(x_n) < x_{n+1}$ for all n. Then this H is almost homogeneous for each f_ξ. Indeed, if $x < y$ are elements of H larger than b_ξ and c_ξ, then $y > h(x) \geq g_\xi(x)$ and so $f_\xi(\{x,y\}) = f_{\xi,x}(y) = j_\xi(x) = i_\xi$. ⊣

One can define characteristics analogous to $\mathfrak{par}_n$ using stronger partition theorems in place of Ramsey's Theorem, for example Hindman's finite sums theorem [59] or the Galvin-Prikry theorem [49] and its extension to analytic sets by Silver [102]. It is not difficult to see that these characteristics are bounded above by $\min\{\mathfrak{b}, \mathfrak{s}\}$. The Silver and (a fortiori) the Galvin-Prikry variants of $\mathfrak{par}$ are easily seen to be bounded below by the characteristic $\mathfrak{h}$ defined in Sect. 6. Eisworth has also obtained (private communication) a lower bound of the form $\min\{\mathfrak{b}, \mathfrak{s}'\}$, where $\mathfrak{s}'$ is the following variant of $\mathfrak{s}$. A cardinal κ is $< \mathfrak{s}'$ if, for any κ reals, there exist

1. a transitive model N of enough of ZFC containing the given reals,
2. $\mathcal{U} \in N$ such that N satisfies "$\mathcal{U}$ is a non-principal ultrafilter on ω", and
3. an infinite $a \subseteq \omega$ almost included in every member of $\mathcal{U}$.

Eisworth's proof uses forcing techniques from [61], but a direct combinatorial proof can be based on [17, Theorem 4]. Note that, if we weakened requirement (2) in the definition of $\mathfrak{s}'$ to say only that $\mathcal{U}$ is a non-principal ultrafilter in the Boolean algebra of subsets of ω in N (but $\mathcal{U}$ need not be in N), then the cardinal defined would be simply $\mathfrak{s}$. It is not known whether $\mathfrak{s}' < \mathfrak{s}$ is consistent.

For the variant of $\mathfrak{par}$ based on Hindman's theorem, the best lower bound known to me is the characteristic $\mathfrak{p}$ defined in Sect. 6. The proof that this is a lower bound uses the construction from Martin's Axiom mentioned in [16, p. 93], the observation that Martin's Axiom is applied here to a σ-centered poset, and Bell's theorem (Theorem 7.12 below).

One can also consider weaker sorts of homogeneity. For example, define $\mathfrak{par}_{1,c}$ to be the smallest cardinality of a family $\mathcal{F}$ of functions $f : \omega \to \omega$ such that there is no single infinite set $A \subseteq \omega$ on which all the functions from $\mathcal{F}$ are almost one-to-one or almost constant, where "almost" means, as usual, except at finitely many points in A. (The subscript $1, c$ refers to the canonical partition theorem for sets of size 1.) Each function f gives rise to a partition $f' : [\omega]^2 \to 2$, where $f'(\{x,y\}) = 0$ just when $f(x) = f(y)$. The sets where f is one-to-one or constant are the homogeneous sets of f', so $\mathfrak{par}_{1,c} \geq \mathfrak{par}_2$. In fact equality holds here, because $\mathfrak{par}_{1,c}$ is $\leq$ both $\mathfrak{s}$ and $\mathfrak{b}$. To see the former, associate to each set X from a splitting family its characteristic function. To see the latter, fix a family of $\mathfrak{b}$ interval partitions not dominated by any single interval partition (by Theorem 2.10) and associate to each of these partitions a function f constant on exactly the intervals of the partition. Since such an f is not constant on any infinite set, it suffices to show that there is no infinite A on which each f is almost one-to-one. But if there were such an A, then we could build an interval partition in which each interval contains at least three elements of A, and this partition would dominate all the partitions in our chosen, allegedly undominated family.

We now shift our focus from counting partitions to counting candidates for homogeneous sets.

3.6 Definition. A family $\mathcal{R}$ of infinite subsets of ω is *unsplittable* if no single set splits all members of $\mathcal{R}$. It is *σ-unsplittable* if no countably many sets suffice to split all members of $\mathcal{R}$. The *unsplitting number* $\mathfrak{r}$, also called the *refining* or *reaping number*, is the smallest cardinality of any unsplittable family. The *σ-unsplitting number* $\mathfrak{r}_\sigma$ is the smallest cardinality of any σ-unsplittable family.

Obviously, $\mathfrak{r} \leq \mathfrak{r}_\sigma$. It is not known whether strict inequality here is consistent with ZFC.

We omit the proof of the following theorem since it involves nothing beyond what went into the proof of Theorem 3.2.

3.7 Theorem. $\mathfrak{r}_\sigma$ *is the minimum cardinality of any family of infinite sets $Y \subseteq \omega$ such that, for each bounded sequence $\langle x_n \rangle_{n\in\omega}$ of real numbers, the restriction $\langle x_n \rangle_{n\in Y}$ to some Y in the family converges. If we consider only sequences of zeros and ones, then the corresponding minimum cardinality is* $\mathfrak{r}$.

We emphasize that, although in Theorem 3.2 the cardinal was the same for real-valued sequences as for two-valued sequences, the analogous equality in the present theorem is an open problem.

3.8 Theorem. $\mathfrak{b} \leq \mathfrak{r}$.

Proof. As in the proof of Theorem 3.3, let φ be the operation sending any interval partition to the union of its even-numbered intervals, and let ψ be an operation sending any infinite subset X of ω to an interval partition in which every interval contains at least one member of X. Let $\mathcal{R}$ be an unsplittable family of $\mathfrak{r}$ infinite subsets of ω; thanks to Theorem 2.10, we can complete the proof by showing that no interval partition Π dominates all the partitions $\psi(X)$ for $X \in \mathcal{R}$. But, as we showed in the proof of Theorem 3.3 and recorded for reference immediately thereafter, if Π dominated all these $\psi(X)$, then $\varphi(\Pi)$ would split every $X \in \mathcal{R}$, contrary to the choice of $\mathcal{R}$. $\dashv$

We next introduce the homogeneity cardinals associated to Ramsey's Theorem and the "one-to-one or constant" theorem. As in the discussion of partition counting, we could define homogeneity cardinals from Hindman's theorem, the Galvin-Prikry theorem, etc., but (as there) not much could be said about them.

3.9 Definition. $\mathfrak{hom}_n$ is the smallest size of any family $\mathcal{H}$ of infinite subsets of ω such that every partition of $[\omega]^n$ into two pieces has an almost homogeneous set in $\mathcal{H}$. $\mathfrak{hom}_{1,c}$ is the smallest size of any family $\mathcal{H}$ of infinite subsets of ω such that every function $f : \omega \to \omega$ is almost one-to-one or almost constant on some set in $\mathcal{H}$.

This definition would be unchanged if we deleted "almost", for we could put into $\mathcal{H}$ all finite modifications of its members. Notice that $\mathfrak{hom}_1 = \mathfrak{r}$ and that $\mathfrak{hom}_n \geq \mathfrak{hom}_m$ if $n \geq m$ (the reverse of the corresponding inequality for $\mathfrak{par}$).

3.10 Theorem. *For all integers $n \geq 2$, $\mathfrak{hom}_n = \max\{\mathfrak{d}, \mathfrak{r}_\sigma\}$. In addition, $\max\{\mathfrak{d}, \mathfrak{r}\} \leq \mathfrak{hom}_{1,c} \leq \max\{\mathfrak{d}, \mathfrak{r}_\sigma\}$.*

Proof. Although this proof contains only one idea not already in the proof of Theorem 3.5 and the subsequent discussion of $\mathfrak{par}_{1,c}$, we repeat some of the earlier ideas to clarify why we now have $\mathfrak{r}$ in one assertion and $\mathfrak{r}_\sigma$ elsewhere.

To show that $\max\{\mathfrak{d}, \mathfrak{r}\} \leq \mathfrak{hom}_{1,c}$, we assume that $\mathcal{H}$ is as in the definition of $\mathfrak{hom}_{1,c}$, and we show that its cardinality is $\geq$ both $\mathfrak{r}$ and $\mathfrak{d}$. For the former, we find that $\mathcal{H}$ is unsplittable because if X splits H then the characteristic function of X is neither almost one-to-one nor almost constant on H. For the comparison with $\mathfrak{d}$, associate to each $H \in \mathcal{H}$ an interval partition Π_H such that each of its intervals contains at least three members of H. By Theorem 2.10, we need only check that every interval partition Θ is dominated by such a Π_H. Given Θ, let f be constant on exactly its intervals, and find $H \in \mathcal{H}$ on which f is almost one-to-one (as f is not constant on any infinite set). But then any interval of Π_H (except for finitely many) contains three points from H, all from different intervals of Θ, so it must contain a whole interval of Θ. So we have the required domination.

Next, we show that $\mathfrak{hom}_2 \leq \max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$ by constructing an $\mathcal{H}$ of size $\max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$ with the homogeneity property required in the definition of $\mathfrak{hom}_2$. (Note the similarity of this construction with the argument proving $\mathfrak{par}_2 \geq \min\{\mathfrak{b}, \mathfrak{s}\}$.) Let $\mathcal{D} \subseteq {}^\omega\omega$ be a dominating family of size $\mathfrak{d}$. Let $\mathcal{R}$ be a σ-unsplittable family of size $\mathfrak{r}_\sigma$. For each $A \in \mathcal{R}$, let $\mathcal{R}_A$ be an unsplittable family of $\mathfrak{r}$ subsets of A. For each $h \in \mathcal{D}$, each $A \in \mathcal{R}$, and each $B \in \mathcal{R}_A$, let $H = H(h, A, B)$ be an infinite subset of B such that, for any $x < y$ in H, $h(x) < y$. The family $\mathcal{H}$ of all these sets $H(h, A, B)$ has size at most $\max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$, and we shall now show that it contains an almost homogeneous set for every partition $f : [\omega]^2 \to 2$. Given f, define (as in the proof of Theorem 3.5) $f_n : \omega \to 2 : x \mapsto f\{n, x\}$. As $\mathcal{R}$ is σ-unsplittable, it contains an A on which each f_n is almost constant, say $f_n(x) = j(n)$ for all $x \geq g(n)$ in A. The function $j : A \to 2$ is almost constant on some B in the unsplittable family $\mathcal{R}_A$, say $j(n) = i$ for all $n \geq b$ in B. And $\mathcal{D}$ contains an h dominating g, say $h(x) \geq g(x)$ for all $x \geq c$. It is now routine to check (as in the proof of Theorem 3.5) that f is constant with value i on all pairs of elements larger than b and c in $H(h, A, B)$.

The proof that $\mathfrak{hom}_n \leq \max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$ for $n > 2$ is similar to the preceding but uses n rather than two nestings of σ-unsplittable families (with no σ needed for the last one). We omit the details.

The preceding arguments, along with the observation that "one-to-one or constant" is a special case of homogeneity for partitions of pairs, establish that

$$\max\{\mathfrak{r}, \mathfrak{d}\} \le \mathfrak{hom}_{1,c} \le \mathfrak{hom}_2 \le \mathfrak{hom}_3 \le \cdots \le \max\{\mathfrak{r}_\sigma, \mathfrak{d}\}.$$

All that remains to be proved is that $\mathfrak{r}_\sigma \le \mathfrak{hom}_2$, and this requires a method not involved in Theorem 3.5. The following argument is due to Brendle [31]. (Shelah had previously established the corresponding result for $\mathfrak{hom}_3$.)

Let $\mathcal{H}$ be as in the definition of $\mathfrak{hom}_2$, and let countably many functions $f_n : \omega \to 2$ be given. We seek a set in $\mathcal{H}$ on which each f_n is almost constant. Define, for each $x \in \omega$, the sequence of zeros and ones $\widehat{x} = \langle f_n(x) \rangle_{n\in\omega}$, so $\widehat{x}_n = f_n(x)$. Then define a partition of $[\omega]^2$ by putting $\{x < y\}$ into class 0 if $\widehat{x}$ lexicographically precedes $\widehat{y}$ and into class 1 otherwise. Let $H \in \mathcal{H}$ be almost homogeneous for this partition, let H' be a homogeneous set obtained by removing finitely many elements from H, and from now on let x and y range only over elements of H'. Suppose H' is homogeneous for class 0. (The case of class 1 is analogous.) Then as x increases, $\widehat{x}_0$ can only increase. That is, if the value of $f_0(x)$ ever changes, then it changes from 0 to 1 and remains constant forever after. Once $\widehat{x}_0$ has stabilized, $\widehat{x}_1$ can only increase and must therefore stabilize. Continuing in this way, we see that, as x increases through values in H', each $\widehat{x}_n$ eventually stabilizes. This means that each $f_n(x)$ is almost constant on H' and therefore on H, as required. $\dashv$

3.11 Remark. The last paragraph of this proof is similar to the proof that cardinals κ satisfying the partition relation $\kappa \longrightarrow (\kappa)^2_2$ are strong limit cardinals. The nature of the stabilization, where each component moves at most once after all its predecessors have stabilized, is also reminiscent of the proof that all requirements are eventually satisfied in a finite-injury priority argument.

4. Galois-Tukey Connections and Duality

We interrupt the description and discussion of particular cardinal characteristics in order to set up some machinery that is useful for describing many (though not all) of the characteristics and the relationships between them. This machinery was isolated by Vojtáš [112] under the name of "generalized Galois-Tukey connections"; the basic ideas had been used, but neither isolated nor named, in earlier work of Fremlin [47] and Miller (unpublished). The definitions of many cardinal characteristics have the form "the smallest cardinality of any set Y (of objects of a specified sort) such that every object x (of a possibly different sort) is related to some $y \in Y$ in a specified way." And many proofs of inequalities between such cardinals involve the construction of maps between the various sorts of objects involved in the definitions. This is formalized as follows.

4.1 Definition. A triple $\mathbf{A} = (A_-, A_+, A)$ consisting of two sets $A_\pm$ and a binary relation $A \subseteq A_- \times A_+$ will be called simply a *relation*. In connection with such a relation, we call A_- the set of *challenges* and A_+ the set of *responses*; we read xAy (meaning $(x, y) \in A$) as "response y *meets* challenge x".

4.2 Definition. The *norm* $\|\mathbf{A}\|$ of a relation $\mathbf{A} = (A_-, A_+, A)$ is the smallest cardinality of any subset Y of A_+ such that every $x \in A_-$ is related by A to at least one $y \in Y$. That is, it is the minimum number of responses needed to meet all challenges.

The definitions of cardinal characteristics in the preceding sections (as well as many others) amount to norms of relations. Furthermore, characteristics tend to come in pairs whose relations are dual to each other in the following sense.

4.3 Definition. If $\mathbf{A} = (A_-, A_+, A)$ then the *dual* of $\mathbf{A}$ is the relation $\mathbf{A}^\perp = (A_+, A_-, \neg\breve{A})$ where $\neg$ means complement and $\breve{A}$ is the converse of A; thus $(x, y) \in \neg\breve{A}$ if and only if $(y, x) \notin A$.

4.4 Example. Let $\mathfrak{D}$ be the relation $({}^\omega\omega, {}^\omega\omega, <^*)$. Then $\|\mathfrak{D}\| = \mathfrak{d}$ and $\|\mathfrak{D}^\perp\| = \|({}^\omega\omega, {}^\omega\omega, \not>^*)\| = \mathfrak{b}$. By Theorem 2.10, the same equations hold if we replace $\mathfrak{D}$ with $\mathfrak{D}' = (\mathrm{IP}, \mathrm{IP}, \text{is dominated by})$. (Recall from Definition 2.9 that IP is the set of interval partitions.)

Let $\mathfrak{R}$ be the relation $(\mathcal{P}(\omega), [\omega]^\omega, \text{does not split})$. Then $\|\mathfrak{R}\| = \mathfrak{r}$ and $\|\mathfrak{R}^\perp\| = \mathfrak{s}$.

Let $\mathfrak{Hom}_n$ be the relation $(P, [\omega]^\omega, H)$ where P is the set of partitions $f : [\omega]^n \to 2$ and where fHX means that X is almost homogeneous for f. Then $\|\mathfrak{Hom}_n\| = \mathfrak{hom}_n$ and $\|\mathfrak{Hom}_n{}^\perp\| = \mathfrak{par}_n$.

Let $\mathcal{I}$ be an ideal of subsets of X. Let $\mathbf{Cov}(\mathcal{I})$ be the relation $(X, \mathcal{I}, \in)$ and let $\mathbf{Cof}(\mathcal{I})$ be the relation $(\mathcal{I}, \mathcal{I}, \subseteq)$. Then we have $\|\mathbf{Cov}(\mathcal{I})\| = \mathbf{cov}(\mathcal{I})$, $\|\mathbf{Cov}(\mathcal{I})^\perp\| = \mathbf{non}(\mathcal{I})$, $\|\mathbf{Cof}(\mathcal{I})\| = \mathbf{cof}(\mathcal{I})$, and $\|\mathbf{Cof}(\mathcal{I})^\perp\| = \mathbf{add}(\mathcal{I})$.

In general, we name the relation corresponding to a characteristic by capitalizing the name of the characteristic, except when another name is readily available, e.g., as the dual of a previously defined relation.

4.5 Remark. We remarked earlier that the definition of $\mathfrak{d}$ would be unaffected if we replaced $\le^*$ by $\le$. That is, $\mathfrak{d}$ is the norm not only of the $\mathfrak{D}$ defined above but also of $({}^\omega\omega, {}^\omega\omega, \le)$. The dual of this last relation, however, has norm $\aleph_0$, not $\mathfrak{b}$.

Similar remarks apply to $\mathfrak{R}$ and $\mathfrak{Hom}$. It was for the sake of duality that we used "modulo finite" even in definitions where it could have been left out.

The following example indicates another situation where a change in a relation does not affect its norm but might affect the norm of the dual.

4.6 Example. Let $\mathfrak{R}_\sigma$ be the relation $({}^\omega\mathcal{P}(\omega), [\omega]^\omega, \text{does not split})$, where an ω-sequence of sets is said to split X if at least one term in the sequence splits X. Then $\|\mathfrak{R}_\sigma\| = \mathfrak{r}_\sigma$ and $\|\mathfrak{R}_\sigma{}^\perp\| = \mathfrak{s}$.

Thus, both $\mathfrak{r}$ and $\mathfrak{r}_\sigma$ can be regarded as duals of $\mathfrak{s}$. Duality is well-defined on relations but in general not on characteristics.

4.7 Remark. For any relation $\mathbf{A}$, one can define a relation $\mathbf{A}_\sigma$ that is related to $\mathbf{A}$ as $\mathfrak{R}_\sigma$ in the preceding example is related to $\mathfrak{R}$. That is,

$$\mathbf{A}_\sigma = ({}^\omega A_-, A_+, A_\sigma)$$

where $f A_\sigma a$ means that $f(n) A a$ for all $n \in \omega$. Thus, $\|\mathbf{A}_\sigma\|$, also written $\|\mathbf{A}\|_\sigma$, is the minimum number of responses needed so that every countably many challenges can be met simultaneously by a single one of these responses. For some relations, the σ construction produces nothing new; for example, $\mathfrak{d}_\sigma = \mathfrak{d}$. But for other relations, interesting new characteristics arise in this way. We already mentioned $\mathfrak{r}_\sigma$ above; $\mathfrak{s}_\sigma$ is studied in, for example, [64] and [73].

Clearly, $\|\mathbf{A}_\sigma\| \geq \|\mathbf{A}\|$. Whether the reverse inequality is provable in ZFC or whether strict inequality is consistent is, as we mentioned above, an open problem for $\mathbf{A} = \mathfrak{R}$. It is also open for $\mathbf{A} = \mathfrak{R}^\perp$; that is, it is not known whether $\mathfrak{s}_\sigma > \mathfrak{s}$ is consistent. On the other hand, it is known that $\mathbf{cov}(\mathcal{L})_\sigma > \mathbf{cov}(\mathcal{L})$ is consistent. See Bartoszyński's chapter in this Handbook for a proof that $\mathbf{cov}(\mathcal{L})$ can consistently have countable cofinality; it is easy to see that no $\|\mathbf{A}_\sigma\|$ can have countable cofinality.

Notice that the transformation $\mathbf{A} \mapsto \mathbf{A}_\sigma$ does not commute with duality. Indeed, in all non-trivial cases, $(\mathbf{A}_\sigma)^\perp$ has the same norm as $\mathbf{A}^\perp$, whereas, as indicated above, $(\mathbf{A}^\perp)_\sigma$ may well have a different norm.

The next definition captures the construction used in the proofs of many cardinal characteristic inequalities.

4.8 Definition. A *morphism* from one relation $\mathbf{A} = (A_-, A_+, A)$ to another $\mathbf{B} = (B_-, B_+, B)$ is a pair $\varphi = (\varphi_-, \varphi_+)$ of functions such that

- $\varphi_- : B_- \to A_-$,
- $\varphi_+ : A_+ \to B_+$,
- for all $b \in B_-$ and $a \in A_+$, if $\varphi_-(b) A a$ then $b B \varphi_+(a)$.

We use "morphism" instead of Vojtáš's "generalized Galois-Tukey connection" partly for brevity and partly because our convention differs from his as to direction. A morphism from $\mathbf{A}$ to $\mathbf{B}$ is a generalized Galois-Tukey connection from $\mathbf{B}$ to $\mathbf{A}$.

It is clear from the definitions that if $\varphi = (\varphi_-, \varphi_+)$ is a morphism from $\mathbf{A}$ to $\mathbf{B}$ then $\varphi^\perp = (\varphi_+, \varphi_-)$ is a morphism from $\mathbf{B}^\perp$ to $\mathbf{A}^\perp$.

Relations and morphisms form (as the name "morphism" suggests) a category in an obvious way, and we shall use the notation $\varphi : \mathbf{A} \to \mathbf{B}$ for morphisms. The category has products and coproducts, but these seem to be of little relevance to cardinal characteristics. Duality is a contravariant involution.

4.9 Theorem. *If there is a morphism $\varphi : \mathbf{A} \to \mathbf{B}$ then $\|\mathbf{A}\| \geq \|\mathbf{B}\|$ and $\|\mathbf{A}^\perp\| \leq \|\mathbf{B}^\perp\|$.*

Proof. It suffices to prove the first inequality, as the second follows by applying the first to the dual morphism $\varphi^\perp$.

Let $X \subseteq A_+$ have cardinality $\|\mathbf{A}\|$ and contain responses meeting all challenges in A_-. Then $Y = \varphi_+(X) \subseteq B_+$ has cardinality $\leq \|\mathbf{A}\|$, so we need only check that it contains responses meeting all challenges from B_-. Given $b \in B_-$, find in X a response x meeting $\varphi_-(b)$. Then $\varphi_+(x)$ is in Y and meets b because, by definition of morphism, $\varphi_-(b)Ax$ implies $bB\varphi_+(x)$. ⊣

Morphisms and Theorem 4.9 were implicit in several proofs of inequalities in the preceding sections. For example, the proof of Theorem 2.10 exhibits morphisms in both directions between $\mathfrak{D}$ and $\mathfrak{D}' = (\mathrm{IP}, \mathrm{IP}, \text{is dominated by})$, where IP is the set of all interval partitions. Both morphisms consist of the same two maps (in opposite order). One map sends any interval partition to the function sending any natural number x to the right endpoint of the next interval of the partition after the interval containing x. The other sends any function $f \in {}^\omega\omega$ to an interval partition $\{[j_n, j_{n+1}) : n \in \omega\}$ such that $f(x) < j_{n+1}$ for all $x \leq j_n$. The existence of this pair of morphisms implies not only that $\mathfrak{d} = \|\mathfrak{D}'\|$, but also, by duality, $\mathfrak{b} = \|\mathfrak{D}'^\perp\|$. The latter is the second assertion of Theorem 2.10, whose proof we omitted earlier.

The preceding example is somewhat atypical in that the same maps give morphisms in both directions between the same relations. Usually, one has a morphism in only one direction, and therefore an inequality rather than equality between cardinal characteristics. For example, the essential point in the proof of $\mathfrak{s} \leq \mathfrak{d}$ (Theorem 3.3), can be expressed by saying that the functions φ and ψ defined in that proof constitute a morphism $(\psi, \varphi) : \mathfrak{D}' \to \mathfrak{R}^\perp$. It follows that they also constitute a morphism $(\varphi, \psi) : \mathfrak{R} \to \mathfrak{D}'^\perp$, so we have $\mathfrak{b} \leq \mathfrak{r}$ (Theorem 3.8). Morphisms, duality, and Theorem 4.9 codify the observation that Theorems 3.3 and 3.8 have "essentially the same proof."

If $\mathcal{I}$ is an ideal on X containing all singletons, then in view of Example 4.4, the inequalities $\mathbf{add}(\mathcal{I}) \leq \mathbf{cov}(\mathcal{I}) \leq \mathbf{cof}(\mathcal{I})$ and $\mathbf{add}(\mathcal{I}) \leq \mathbf{non}(\mathcal{I}) \leq \mathbf{cof}(\mathcal{I})$ follow from the existence of morphisms from $\mathbf{Cof}(\mathcal{I}) = (\mathcal{I}, \mathcal{I}, \subseteq)$ to both $\mathbf{Cov}(\mathcal{I}) = (X, \mathcal{I}, \in)$ and its dual $\mathbf{Cov}(\mathcal{I})^\perp = (\mathcal{I}, X, \not\ni)$. The first of these can be taken to be (S, id), where S is the singleton map $x \mapsto \{x\}$ and id is the identity map. The second can be taken to be (id, N), where N sends each $I \in \mathcal{I}$ to some element of $X - I$.

The inequalities $\|\mathbf{A}_\sigma\| \geq \|\mathbf{A}\|$, for all $\mathbf{A}$, also arise from morphisms $\mathbf{A}_\sigma \to \mathbf{A}$. The map on challenges sends each $a \in A_-$ to the constant function $\omega \to A_-$ with value a, and the map on responses is the identity function.

The inequalities $\mathfrak{par}_n \leq \mathfrak{b}$ and $\mathfrak{par}_n \leq \mathfrak{s}$ in Theorem 3.5 and their duals $\mathfrak{hom}_n \geq \mathfrak{d}$ and $\mathfrak{hom}_n \geq \mathfrak{r}$ in Theorem 3.10 are also given by morphisms, as an inspection of the proofs will show. The same goes for Brendle's improvement of the last of these inequalities, with $\mathfrak{r}_\sigma$ in place of $\mathfrak{r}$, and the same goes for the analogous inequalities for $\mathfrak{par}_{1,c}$ and $\mathfrak{hom}_{1,c}$.

But the same cannot be said (yet) for the reverse inequalities, $\mathfrak{par}_n \geq \min\{\mathfrak{b}, \mathfrak{s}\}$ and its dual $\mathfrak{hom}_n \leq \max\{\mathfrak{d}, \mathfrak{r}_\sigma\}$, simply because the minimum and maximum here are not (yet) realized as the norms of natural relations. There are, fortunately, several ways to combine two relations into a third whose norm is the maximum (or the minimum) of the norms of the first two. Two of these provide what we need in order to present in terms of morphisms the proofs of the inequalities just cited; we present a third combination along with these two because of its category-theoretic naturality.

To avoid trivial exceptions, we assume in the following that, in the relations (A_-, A_+, A) under consideration, the sets $A_\pm$ are not empty. We also adopt the convention of using a boldface letter for the relation whose components are denoted by the corresponding lightface letter; thus $\mathbf{A} = (A_-, A_+, A)$.

4.10 Definition. The *categorical product* $\mathbf{A} \times \mathbf{B}$ is $(A_- \sqcup B_-, A_+ \times B_+, C)$, where $\sqcup$ means disjoint union and where $x\,C\,(a, b)$ means $x\,A\,a$ if $x \in A_-$ and $x\,B\,b$ if $x \in B_-$.

The *conjunction* $\mathbf{A} \wedge \mathbf{B}$ is $(A_- \times B_-, A_+ \times B_+, K)$, where $(x, y)\,K\,(a, b)$ means $x\,A\,a$ and $y\,B\,b$.

The *sequential composition* $\mathbf{A}; \mathbf{B}$ is $(A_- \times {}^{A_+}B_-, A_+ \times B_+, S)$, where the superscript means a set of functions and where $(x, f)\,S\,(a, b)$ means $x\,A\,a$ and $f(a)\,B\,b$.

The dual operations are the *categorical coproduct* $\mathbf{A} + \mathbf{B} = (\mathbf{A}^\perp \times \mathbf{B}^\perp)^\perp$, the *disjunction* $\mathbf{A} \vee \mathbf{B} = (\mathbf{A}^\perp \wedge \mathbf{B}^\perp)^\perp$, and the *dual sequential composition* $\mathbf{A} \check{;} \mathbf{B} = (\mathbf{A}^\perp; \mathbf{B}^\perp)^\perp$.

The two categorical operations are, as their names suggest, the product and coproduct in the category of relations and morphisms.

The conjunction was called the product in a preprint version of [112] and has therefore sometimes been called the *old product*. It is a sort of parallel composition. A challenge consists of separate challenges in both components and a (correct) response consists of (correct) responses in both components separately.

Sequential composition describes a two-inning game between the challenger and the responder. The first inning consists of a challenge x in $\mathbf{A}$ followed by a response a there; the second inning consists of a challenge $f(a)$ in $\mathbf{B}$, which may depend on the previous response a, followed by a response b there. To model this in a single inning, we regard the whole function f as part of the challenge. As in the case of conjunction, a correct response in the sequential composition must be correct in both components.

Notice that one can obtain a description of disjunction by simply changing the last "and" to "or" in the definition of conjunction. The dualization of sequential composition is more complicated; not only does "and" become "or" but the functional dependence changes so that the response in $\mathbf{B}$ can depend on the challenge in $\mathbf{A}$.

The following theorem describes the effect of these operations on norms. Its proof is quite straightforward and therefore omitted.

4.11 Theorem.

1. $\|\mathbf{A} \times \mathbf{B}\| = \max\{\|\mathbf{A}\|, \|\mathbf{B}\|\}$.

2. $\max\{\|\mathbf{A}\|, \|\mathbf{B}\|\} \leq \|\mathbf{A} \wedge \mathbf{B}\| \leq \|\mathbf{A}\| \cdot \|\mathbf{B}\|$.

3. $\|\mathbf{A}; \mathbf{B}\| = \|\mathbf{A}\| \cdot \|\mathbf{B}\|$.

4. $\|\mathbf{A} + \mathbf{B}\| = \min\{\|\mathbf{A}\|, \|\mathbf{B}\|\}$.

5. $\|\mathbf{A} \vee \mathbf{B}\| = \min\{\|\mathbf{A}\|, \|\mathbf{B}\|\}$.

6. $\|\mathbf{A} \breve{;} \mathbf{B}\| = \min\{\|\mathbf{A}\|, \|\mathbf{B}\|\}$.

When the norms are infinite, maxima and products are the same, so the second and third items in the theorem simplify to $\|\mathbf{A} \wedge \mathbf{B}\| = \|\mathbf{A}; \mathbf{B}\| = \max\{\|\mathbf{A}\|, \|\mathbf{B}\|\}$. (In the finite case there is no such simplification. Both of the inequalities involving $\|\mathbf{A} \wedge \mathbf{B}\|$ can be strict; consider $\mathbf{A} = \mathbf{B} = (3, 3, \neq)$.)

4.12 Example. In the proof of Theorem 3.10, the part showing that $\mathfrak{hom}_2 \leq \max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$ actually gives a morphism from $\mathfrak{R}_\sigma; (\mathfrak{R} \wedge \mathfrak{D})$ to $\mathfrak{Hom}_2$, as detailed below. By Theorems 4.9 and 4.11, the existence of such a morphism implies both $\mathfrak{hom}_2 \leq \max\{\mathfrak{r}_\sigma, \mathfrak{r}, \mathfrak{d}\} = \max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$ and $\mathfrak{par}_2 \geq \min\{\mathfrak{s}, \mathfrak{b}\}$ (the part of Theorem 3.5 that really involves all three cardinals simultaneously).

To exhibit the morphism implicit in the proof of Theorem 3.10, we first describe $\mathfrak{R}_\sigma; (\mathfrak{R} \wedge \mathfrak{D})$. Following the definitions, we find that a challenge here amounts to a triple (S, F, G) where S is an ω-sequence of subsets S_n of ω, F is a function assigning to each infinite $A \subseteq \omega$ a subset $F(A)$ of ω, and G is a function assigning to each such A a function $G(A) \in {}^\omega\omega$. A response is a triple (A, B, h) where A and B are infinite subsets of ω and $h \in {}^\omega\omega$. The response (A, B, h) meets the challenge (S, F, G) if (1) A is not split by any component S_n of S, (2) B is not split by $F(A)$, and (3) $G(A) <^* h$. Using the notation (f_n, j, g, H) of the proof of Theorem 3.10 and the notation e_A for the increasing enumeration of an infinite $A \subseteq \omega$, we can describe the morphism from $\mathfrak{R}_\sigma; (\mathfrak{R} \wedge \mathfrak{D})$ to $\mathfrak{Hom}_2$ as follows. The "challenge" part sends any partition $f : [\omega]^2 \to 2$ to (S, F, G), where S_n has characteristic function f_n, where $F(A)$ has characteristic function $j \circ e_A$, and where $G(A) = g$. (The j and g in the proof of Theorem 3.10 depend on A.) The "response" part of the morphism sends a triple (A, B, h) to $H(h, A, e_A(B))$. The verification that these two operations constitute a morphism is as in Theorems 3.5 and 3.10. (The need for e_A in the present discussion but not in the earlier proofs results from our tacit use, in the earlier proofs, of the equivalence between splitting phenomena in ω and the analogous phenomena in any infinite subset A. e_A serves to make the equivalence explicit.)

We remark that the formal structure, $\mathfrak{R}_\sigma; (\mathfrak{R} \wedge \mathfrak{D})$, reflects the intuitive structure of the proof of Theorem 3.5. That proof invoked the hypothesis $\kappa < \mathfrak{s}$ twice (corresponding to $\mathfrak{R}_\sigma$ and $\mathfrak{R}$) and $\kappa < \mathfrak{b}$ once (corresponding to $\mathfrak{D}$). The first use of $\kappa < \mathfrak{s}$ logically precedes the other two (corresponding to sequential composition) because the unsplit set A obtained at the first step is used to produce the j and g for the other two steps. The second use of $\kappa < \mathfrak{s}$ and the use of $\kappa < \mathfrak{b}$ can proceed in parallel, as neither depends on the other (corresponding to conjunction).

4.13 Example. Sequential composition also occurs naturally in much simpler situations. Consider, for example, the following variant of unsplitting: $\mathfrak{R}_3 = ({}^{\omega}3, [\omega]^{\omega}, \text{is almost constant on})$. Its norm $\mathfrak{r}_3$ is the minimum number of infinite subsets of ω not all split by a single partition of ω into three pieces. This cardinal is easily seen to be equal to $\mathfrak{r}$, but one direction of the proof involves a sequential composition. A "3-unsplittable" family is obtained by starting with an unsplittable family and then forming, within each of its sets, a further unsplittable family. The union of the latter families is then 3-unsplittable (and even 4-unsplittable). In terms of morphisms, one obtains $\mathfrak{R}; \mathfrak{R} \to \mathfrak{R}_3$ (as well as the trivial $\mathfrak{R}_3 \to \mathfrak{R}$).

Equipped with the concept of morphism, we can address an issue that had been glossed over in the introduction. If one believes the Continuum Hypothesis (CH), then the theory of cardinal characteristics becomes trivial, for they are all equal to $\aleph_1$. Nevertheless, there is non-trivial combinatorial content in proofs like those of Theorems 2.10 and 3.3, even if CH holds and makes the theorems themselves trivial. That combinatorial content is used to construct the morphisms $\mathfrak{D} \leftrightarrow \mathfrak{D}' \to \mathfrak{R}^{\perp}$, so one might hope that the existence of such morphisms is what the argument "really" proves, a non-trivial result even in the presence of CH. Yiparaki [114] showed that this hope is not justified; CH implies not only the equality of all our cardinal characteristics but also the existence of morphisms in both directions between the corresponding relations. The last part of the following theorem embodies this result.

4.14 Theorem. *Let $\mathbf{A} = (A_-, A_+, A)$ and $\mathbf{B} = (B_-, B_+, B)$ be two relations and let κ be an infinite cardinal.*

1. *$\|\mathbf{A}\| \le \kappa$ if and only if there is a morphism from $(\kappa, \kappa, =)$ to $\mathbf{A}$.*
2. *If $\|\mathbf{A}\| = |A_+| = \kappa$, then there is a morphism from $\mathbf{A}$ to $(\kappa, \kappa, <)$.*
3. *If $\|\mathbf{A}^{\perp}\| = |A_-| = \kappa$, then there is a morphism from $(\kappa, \kappa, <)$ to $\mathbf{A}$.*
4. *If $\|\mathbf{A}\| = |A_+| = \|\mathbf{B}^{\perp}\| = |B_-| \ge \aleph_0$, then there is a morphism from $\mathbf{A}$ to $\mathbf{B}$.*

Proof. The "if" direction of 1 is immediate from Theorem 4.9 and the fact that $\|(\kappa, \kappa, =)\| = \kappa$. For the "only if" direction, let $\varphi_+ : \kappa \to A_+$ enumerate a set of at most κ responses meeting all challenges; then for each challenge $a \in A_-$ let $\varphi_-(a)$ be any $\alpha < \kappa$ such that $\varphi_+(\alpha)$ meets a.

For 2, let $\varphi_+ : A_+ \to \kappa$ be any one-to-one map. Then, for any $\alpha < \kappa$, the set $\{a \in A_+ : \varphi_+(a) \le \alpha\}$ has cardinality smaller than $\kappa = \|\mathbf{A}\|$, so some challenge in A_- has no correct response in this set. Let $\varphi_-(\alpha)$ be any such challenge.

Note that 2 remains true if we replace $(\kappa, \kappa, <)$ with $(\kappa, \kappa, \leq)$. Then dualization gives 3.

Finally, to prove 4, just compose the morphisms $\mathbf{A} \to (\kappa, \kappa, <) \to \mathbf{B}$ given by 2 and 3. ⊣

If CH holds, then part 4 of this theorem applies to most of the relations in Example 4.4 above, for the cardinals involved are $\aleph_1$. The only exceptions are $\mathbf{Cov}(\mathcal{I})$ and $\mathbf{Cof}(\mathcal{I})$, but even here we can (indirectly) apply part 4 when $\mathcal{I}$ is the ideal of measure zero sets or the ideal of meager sets in $\mathbb{R}$ or a similar ideal. More precisely, if $\mathcal{I}$ is an ideal on $\mathbb{R}$ and $\mathcal{I}$ has a cofinal subset $\mathcal{I}_0$ of size $\leq \mathfrak{c}$, then part 4 applies directly to variants of $\mathbf{Cov}(\mathcal{I})$ and $\mathbf{Cof}(\mathcal{I})$ with $\mathcal{I}$ replaced by $\mathcal{I}_0$. But it is trivial to check that there are morphisms in both directions between these variants and the original relations. In effect then, part 4 provides morphisms in both directions between any two of the relations we are considering; CH trivializes not only the inequalities between cardinal characteristics but also the morphisms between the corresponding relations.

Nevertheless, there is still some hope of using morphisms to describe the combinatorial content of the theory in a way that makes good sense even when CH holds. This hope is based on the observation that the morphisms given by Theorem 4.14 are highly non-constructive; they involve well-orderings of the continuum (and similar sets). By contrast, the morphisms given by the proofs of cardinal characteristic inequalities are much better behaved. They consist of Borel maps with respect to the usual topologies on the sets involved (like ${}^\omega\omega$ and $\mathcal{P}(\omega)$). Two clarifications are in order here. One is that, when the sets involved are bases $\mathcal{I}_0$ for some ideals, as in the preceding paragraph, then the sets in $\mathcal{I}_0$ should be coded by reals in some standard way. For example, if $\mathcal{I}$ is the ideal of meager (resp. measure zero) sets in $\mathbb{R}$, then $\mathcal{I}_0$ can be taken to consist of the F_σ (resp. G_δ) members of $\mathcal{I}$, and there are well-known ways of coding such sets (or arbitrary Borel sets) by reals. The second clarification is that Pawlikowski and Recław have shown [85] that, with suitable coding, the morphisms can be taken to consist of continuous maps; nevertheless, we shall continue to use “Borel” as our main criterion of simplicity.

The existence of Borel morphisms seems to serve well as a codification of the combinatorial content of proofs of cardinal characteristic inequalities. On the one hand, the usual proofs provide Borel morphisms. On the other hand, when an inequality is not provable then, although it may hold in specific models and even have morphisms attesting to it (e.g., in models of CH), there will never be Borel morphisms attesting to it. The following theorem establishes this last fact for the particular unprovable inequality $\mathfrak{d} \leq \mathfrak{s}$. Similar arguments can be given for other unprovable inequalities, but they usually involve notions of forcing more complicated than the Cohen forcing used here. We remark that the theorem proves a bit more than was claimed above; a morphism φ attesting to $\mathfrak{d} \leq \mathfrak{s}$ cannot have even one of its two constituent functions $\varphi_\pm$ Borel. (The weaker result that $\varphi_\pm$ cannot both be Borel in this situation was established in [22].)

4.15 Theorem. *If φ is a morphism $\mathfrak{R}^\perp \to \mathfrak{D}$, then neither φ_+ nor φ_- is a Borel function.*

Proof. Recalling the definitions of $\mathfrak{R}$ and $\mathfrak{D}$, we see that

$$\begin{array}{rcl} \varphi_- : {}^\omega\omega & \to & [\omega]^\omega, \\ \varphi_+ : \mathcal{P}(\omega) & \to & {}^\omega\omega, \quad \text{and} \\ \varphi_-(a) \text{ is split by } b & \Longrightarrow & a <^* \varphi_+(b). \end{array}$$

Suppose first that φ_- were a Borel function, with code p (in a standard coding system for Borel sets and functions). Adjoin to the universe a Cohen-generic function $c : \omega \to \omega$, and define $d = \tilde{\varphi}_-(c)$, where $\tilde{\varphi}_-$ is the Borel function coded by p in $V[c]$. Thus $d \in [\omega]^\omega$ in $V[c]$. The ground model reals form a splitting family in the Cohen extension $V[c]$ (because they form a non-meager family there; see Sect. 11.3 and the proof of Theorem 5.19 below). So there is a real $r \in V \cap \mathcal{P}(\omega)$ that splits d. In the ground model V, let $g = \varphi_+(r)$ and notice that, because φ is a morphism,

$$\forall x \in {}^\omega\omega\, [\varphi_-(x) \text{ is split by } r \implies x <^* g].$$

This is a Π^1_1 statement about r, g, and the code p of φ_-. So it remains true in $V[c]$, where p codes $\tilde{\varphi}_-$ and where x can take c as a value. Thus we find, in $V[c]$, since $\tilde{\varphi}_-(c) = d$ is split by r, that $c <^* g$. But this is absurd; a Cohen-generic $c \in {}^\omega\omega$ cannot be dominated by a g from the ground model. This contradiction shows that φ_- cannot be a Borel map.

Now suppose instead that φ_+ were a Borel function, with Borel code p. Let $c \in \mathcal{P}(\omega)$ be Cohen-generic and let $e = \tilde{\varphi}_+(c)$, where $\tilde{\varphi}_+$ is the Borel function coded by p in $V[c]$. Thus $e \in {}^\omega\omega$ in $V[c]$. The ground model reals are unbounded in ${}^\omega\omega$ in a Cohen extension, so fix $r \in V \cap {}^\omega\omega$ with $r \not<^* e$. Let $q = \varphi_-(r)$, an infinite subset of ω in V. Because φ is a morphism,

$$\forall x \in \mathcal{P}(\omega)\, [q \text{ is split by } x \implies r <^* \varphi_+(x)].$$

As before, this is a Π^1_1 statement about q, r, and p, so it remains true in $V[c]$. There c is a possible value of x and p codes $\tilde{\varphi}_+$, so from $r \not<^* e = \tilde{\varphi}_+(c)$ we can infer that q is not split by c. This is absurd, as every infinite subset of ω in the ground model V is split by the Cohen subset c of ω. ⊣

The use of Borel morphisms can also clarify the need for sequential (and other) composition operations on relations. Specifically, a forcing argument is used in [22] to show that some naturally occurring morphisms involving sequential compositions (e.g., the proof of Theorem 5.6 below) cannot be simplified to use conjunctions or products or even sequential composition in a different order. Mildenberger [77] and Spinas [107] have obtained similar results by combinatorial methods in some cases where the forcing method of [22] does not apply. A forcing argument in [24] shows that the sequential composition $\mathfrak{R}_\sigma; (\mathfrak{R} \wedge \mathfrak{D})$ used in the proof of $\mathfrak{hom}_2 \leq \max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$ cannot be replaced by simply $\mathfrak{R}_\sigma \wedge \mathfrak{D}$. But other potential simplifications in this problem and similar simplifications in other problems, though they seem unlikely, have not been proved impossible.

4.16 Remark. Let $\mathbf{A}$ and $\mathbf{B}$ be relations where $A_\pm$ and $B_\pm$ are sets of reals. Call a morphism $\varphi : \mathbf{A} \to \mathbf{B}$ *semi-Borel* (on the positive side) if φ_+ is a Borel function. Thus, Theorem 4.15 asserts that certain morphisms cannot be semi-Borel.

Call a set X of reals *small with respect to* $\mathbf{A}$ if there is no semi-Borel morphism from $(X, X, =)$ to $\mathbf{A}$. Without "semi-Borel", this definition would say simply that $|X| < \|\mathbf{A}\|$, by the first part of Theorem 4.14. With "semi-Borel," smallness is a weaker notion, related to the topological (or Borel) structure of X, not just to its cardinality. It can be expressed as "no image of X under a Borel function to A_+ contains responses meeting all challenges from A_-."

The smallness properties associated in this way to the relations involved in Cichoń's diagram (see the end of Sect. 5) were introduced and studied by Pawlikowski and Recław [85], who connected them with various classical smallness properties of sets of reals. Bartoszyński's chapter in this Handbook contains extensive information about this topic.

5. Category and Measure

Despite their origins in real analysis, Baire category and Lebesgue measure are, to a large extent, combinatorial notions. As such, they have close ties with some of the objects discussed in the preceding sections. We give here a rather cursory presentation of some of these combinatorial aspects of category and measure. For a more complete treatment, see Bartoszyński's chapter in this Handbook and the book [5] of Bartoszyński and Judah.

Recall Definition 2.7 of the four cardinal characteristics **add**, **cov**, **non**, **cof** associated to any proper ideal (containing all singletons) on any set. We shall be interested in these and in the corresponding relations ($\mathbf{Cof}^\perp$, $\mathbf{Cov}$, $\mathbf{Cov}^\perp$, and $\mathbf{Cof}$, respectively, from Example 4.4) when the ideal is either the σ-ideal of meager (also called first category) sets or the σ-ideal of sets of Lebesgue measure zero (also called null sets). We use $\mathcal{B}$ and $\mathcal{L}$ respectively to denote these two ideals. (The notation stands for "Baire" and "Lebesgue"; other authors have used $\mathcal{C}$ for "Category," $\mathcal{K}$ for "Kategorie," $\mathcal{M}$ for "meager," $\mathcal{M}$ for "measure," and $\mathcal{N}$ for "null".) As indicated in the introduction, we do not distinguish notationally between the meager ideals on various versions of the continuum, $\mathbb{R}$, ${}^\omega 2$, ${}^\omega\omega$, etc., and similarly for measure.

The various versions of each cardinal characteristic are equal; the various versions of each relation admit morphisms in both directions. We tolerate an additional, equally innocuous ambiguity by not distinguishing between an ideal and a basis for it. Thus, we may pretend that $\mathcal{B}$ consists of meager F_σ sets and that $\mathcal{L}$ consists of G_δ null sets. If we discuss Borel morphisms, we further identify F_σ and G_δ sets with some standard encoding as reals.

We begin our treatment of Baire category by giving a convenient combinatorial description of meagerness in the space ${}^\omega 2$. This idea was introduced in a more specialized context by Talagrand [108].

5.1 Definition. A *chopped real* is a pair (x, Π), where $x \in {}^\omega 2$ and Π is an interval partition of ω. Recall that we introduced the notation IP for the set of all interval partitions; we write CR for the set ${}^\omega 2 \times \mathrm{IP}$ of chopped reals. A real $y \in {}^\omega 2$ *matches* a chopped real (x, Π) if $x \restriction I = y \restriction I$ for infinitely many intervals $I \in \Pi$.

5.2 Theorem. *A subset M of ${}^\omega 2$ is meager if and only if there is a chopped real that no member of M matches.*

Proof. The set of reals y that match a given chopped real $(x, \{I_n : n \in \omega\})$ is

$$\mathrm{Match}(x, \{I_n : n \in \omega\}) = \bigcap_k \bigcup_{n \geq k} \{y : x \restriction I_n = y \restriction I_n\},$$

the intersection of countably many dense open sets. So $\mathrm{Match}(x, \Pi)$ is comeager, and the "if" part of the theorem follows.

To prove "only if," suppose M is meager, and fix a countable sequence of nowhere dense sets F_n that cover M. Note that, for the standard (product) topology on ${}^\omega 2$, to say that a set F is nowhere dense means that for every finite sequence $s \in {}^{<\omega} 2$ there is an extension $t \in {}^{<\omega} 2$ such that no $y \in F$ extends t. Note also that the union of finitely many nowhere dense sets is nowhere dense, so we can and do arrange that $F_n \subseteq F_{n+1}$ for all n. Then we can complete the proof by constructing a chopped real $(x, \{I_n : n \in \omega\})$ such that, for each n, no real in F_n agrees with x on I_n. This suffices because then any y that matches $(x, \{I_n : n \in \omega\})$ will be outside infinitely many F_n, hence outside them all by monotonicity, and hence outside M.

To define I_n and $x \restriction I_n$, suppose the earlier I_k $(k < n)$ are already defined and are contiguous intervals. So we know the point m where I_n should start. I_n will be the union of 2^m contiguous subintervals J_i $(i < 2^m)$ defined as follows. List all the functions $m \to 2$ as u_i $(i < 2^m)$. By induction on i, choose J_i and $x \restriction J_i$ so that no element of F_n is an extension of $u_i \cup \bigcup_{j \leq i} (x \restriction J_j)$. These choices are possible because F_n is nowhere dense. Finally, let $I_n = \bigcup_{j < 2^m} J_i$; having already defined each $x \restriction J_i$, we have determined $x \restriction I_n$.

If y agrees with x on I_n, then y extends $u_i \cup \bigcup_{j \leq i} (x \restriction J_j)$ for some i, namely the i such that $u_i = y \restriction m$. Therefore, $y \notin F_n$, as required. $\dashv$

The theorem shows that the sets $\mathrm{Match}(x, \Pi)$ form a base for the filter of comeager sets and so their complements form a base for the ideal $\mathcal{B}$. We may therefore confine attention to these complements when discussing the cardinal characteristics of $\mathcal{B}$ and the associated relations. In this connection, it is useful to have the following combinatorial formulation of the inclusion relation between these sets; we leave the straightforward proof to the reader.

5.3 Proposition. $\mathrm{Match}(x, \Pi) \subseteq \mathrm{Match}(x', \Pi')$ *if and only if for all but finitely many intervals* $I \in \Pi$ *there exists an interval* $J \in \Pi'$ *such that* $J \subseteq I$ *and* $x' \upharpoonright J = x \upharpoonright J$.

We shall say that (x, Π) *engulfs* (x', Π') when the equivalent conditions in the proposition hold.

Thus, we have morphisms in both directions between $\mathbf{Cof}(\mathcal{B})$ and

$$\mathbf{Cof}'(\mathcal{B}) = (\mathrm{CR}, \mathrm{CR}, \text{is engulfed by}),$$

as well as morphisms in both directions between $\mathbf{Cov}(\mathcal{B})$ and

$$\mathbf{Cov}'(\mathcal{B}) = ({}^{\omega}2, \mathrm{CR}, \text{does not match}).$$

Notice that if (x, Π) engulfs (x', Π') then Π dominates Π'. Combining this with the characterization of $\mathfrak{d}$ and $\mathfrak{b}$ in Theorem 2.10 and the characterization of $\mathbf{add}(\mathcal{B})$ and $\mathbf{cof}(\mathcal{B})$ in Example 4.4, we obtain the following inequalities.

5.4 Corollary. $\mathbf{add}(\mathcal{B}) \le \mathfrak{b}$ *and* $\mathfrak{d} \le \mathbf{cof}(\mathcal{B})$.

Another relation between the characteristics from Sect. 2 and the characteristics of Baire category follows from Theorem 2.8.

5.5 Proposition. $\mathfrak{b} \le \mathbf{non}(\mathcal{B})$ *and* $\mathbf{cov}(\mathcal{B}) \le \mathfrak{d}$.

Proof. In ${}^{\omega}\omega$, any set of the form $\{f : f \le g\}$ is clearly nowhere dense (because every finite sequence in ${}^{<\omega}\omega$ has an extension in ${}^{<\omega}\omega$ with some values greater than the corresponding values of g). The proof of Theorem 2.8 shows, therefore, that all compact sets in ${}^{\omega}\omega$ are nowhere dense and therefore $\mathcal{K}_\sigma \subseteq \mathcal{B}$. That immediately implies $\mathbf{cov}(\mathcal{K}_\sigma) \ge \mathbf{cov}(\mathcal{B})$ and $\mathbf{non}(\mathcal{K}_\sigma) \le \mathbf{non}(\mathcal{B})$. (Indeed, whenever $\mathcal{I} \subseteq \mathcal{J}$ are ideals, we have a morphism $\mathbf{Cov}(\mathcal{I}) \to \mathbf{Cov}(\mathcal{J})$ given by the identity map on challenges and the inclusion map on responses.) Now Theorem 2.8 completes the proof. ⊣

All ZFC-provable inequalities among $\mathfrak{b}$, $\mathfrak{d}$, and the four characteristics of $\mathcal{B}$ are obtainable by transitivity from the preceding corollary and proposition and the general facts that $\mathbf{add} \le \mathbf{cov} \le \mathbf{cof}$ and $\mathbf{add} \le \mathbf{non} \le \mathbf{cof}$ for any nontrivial ideal. There are, however, two additional relations due to Miller [80] and Truss [110], each involving three of these cardinals.

5.6 Theorem.

1. *There is a morphism from* $(\mathbf{Cov}'(\mathcal{B}))^{\perp}; \mathfrak{D}'$ *to* $\mathbf{Cof}'(\mathcal{B})$.
2. $\mathbf{cof}(\mathcal{B}) = \max\{\mathbf{non}(\mathcal{B}), \mathfrak{d}\}$.

3. $\mathbf{add}(\mathcal{B}) = \min\{\mathbf{cov}(\mathcal{B}), \mathfrak{b}\}$.

Proof. Recall that $\mathfrak{D}' = (\mathrm{IP}, \mathrm{IP}, \text{is dominated by})$ where IP is the set of interval partitions, that $\|\mathfrak{D}'\| = \mathfrak{d}$, and that $\|\mathfrak{D}'^{\perp}\| = \mathfrak{b}$. Thus, if we prove part 1 of the theorem, then the $\leq$ half of part 2 and the $\geq$ half of part 3 will follow by Theorems 4.9 and 4.11. The other halves of parts 2 and 3 were already established, so we need only prove part 1.

A morphism φ as claimed in part 1 would consist of a function φ_- from the set CR of chopped reals to $\mathrm{CR} \times {}^{({}^\omega 2)}\mathrm{IP}$ and a function φ_+ from ${}^\omega 2 \times \mathrm{IP}$ to CR, satisfying an implication to be exhibited after we simplify notation a bit. As a map into a product, φ_- consists of two maps, $\alpha : \mathrm{CR} \to \mathrm{CR}$ and $\beta : \mathrm{CR} \to {}^{({}^\omega 2)}\mathrm{IP}$. We shall take α and φ_+ to be identity maps. (Recall that $\mathrm{CR} = {}^\omega 2 \times \mathrm{IP}$, so this makes sense.) It remains to define β so as to satisfy the required implication, which now reads: For all $x \in \mathrm{CR}$, all $y \in {}^\omega 2$, and all $\Pi \in \mathrm{IP}$,

$$[y \text{ matches } x \text{ and } \Pi \text{ dominates } \beta(x)(y)] \quad \Longrightarrow \quad [(y, \Pi) \text{ engulfs } x].$$

It does not matter how we define $\beta(x)(y)$ when y does not match x. If y does match x, i.e., if there are infinitely many intervals I in the partition component of the chopped real x on which x and y agree, then we define $\beta(x)(y)$ to be some interval partition each of whose intervals includes at least one such I. ⊣

5.7 Remark. It is easy to specify the β in the last part of the proof more explicitly so that $\beta(x)(y)$ is a Borel function of x and y; since the other components of φ are trivial, we can say that part 1 of the theorem is witnessed by a Borel morphism. It is shown in [22] that one cannot get a Borel morphism in part 1 if one replaces the sequential product there with the categorical product, or the conjunction, or the sequential product in the other order.

Before turning from category to measure, we give an elegant, combinatorial description of $\mathbf{cov}(\mathcal{B})$, due to Bartoszyński [4].

5.8 Definition. Call two functions $x, y \in {}^\omega\omega$ *infinitely equal* if $\exists^\infty n\,(x(n) = y(n))$ and *eventually different* otherwise, i.e., if $\forall^\infty n\,(x(n) \neq y(n))$.

5.9 Theorem.

1. $\mathbf{cov}(\mathcal{B}) = \|({}^\omega\omega, {}^\omega\omega, \text{eventually different})\|$.

2. $\mathbf{non}(\mathcal{B}) = \|({}^\omega\omega, {}^\omega\omega, \text{infinitely equal})\|$.

Proof. We prove only part 1 as part 2 is dual to it. The $\leq$ direction is clear once one observes that, for any $x \in {}^\omega\omega$, the set of $y \in {}^\omega\omega$ eventually different from x is meager. (In fact, sending x to this set defines half of a morphism from the relation on the right of part 1 to $\mathbf{Cov}(\mathcal{B})$ (when the reals are taken to be ${}^\omega\omega$); the other half of the morphism is the identity map.)

To prove the $\geq$ direction of part 1, we show how to match, with a single real y, all the chopped reals in a family $\{(x_\alpha, \Pi_\alpha) : \alpha < \kappa\}$, where

$$\kappa < \|({}^\omega\omega, {}^\omega\omega, \text{eventually different})\|.$$

Note that the norm here is trivially $\leq \mathfrak{d}$ (there's a morphism from $\mathfrak{D}$ consisting of the identity map in both directions). So by Theorem 2.10 there is an interval partition Θ not dominated by any Π_α.

Temporarily fix an arbitrary $\alpha < \kappa$. Non-domination means that Π_α has infinitely many intervals that include no interval of Θ and are therefore covered by two adjacent intervals of Θ. Call a pair of adjacent intervals of Θ good if they cover an interval of Π_α; so there are infinitely many good pairs.

Define a function f_α on ω as follows. $f_\alpha(n)$ is obtained by taking $2n+1$ disjoint good pairs, taking the union of the two intervals in each pair to obtain $2n+1$ intervals $J_0, \ldots, J_{2n}$, and then forming the set of restrictions of x_α to these intervals:

$$f_\alpha(n) = \{x_\alpha \restriction J_0, \ldots, x_\alpha \restriction J_{2n}\}.$$

Note that, although the values of f_α are not natural numbers, they can be coded as natural numbers.

Now un-fix α. By our hypothesis on κ, find a function g infinitely equal to each f_α. Without harming this property of g, we can arrange that, for each n, $g(n)$ is a set of $2n+1$ functions, each mapping an interval of ω to 2. Furthermore, we can arrange that these $2n+1$ intervals are disjoint and each of them is the union of two adjacent intervals of Θ. (Any n for which $g(n)$ is not of this form could not contribute to the agreement between g and any f_α, so we are free to modify $g(n)$ arbitrarily.)

We define a function $y : \omega \to 2$ by recursion, where at each stage we specify the restriction of y to a certain pair of adjacent intervals in Θ. After stages 0 through $n-1$ are completed, y is defined on only $2n$ intervals of Θ, so at least one of the $2n+1$ members of $g(n)$, say $z(n)$, has its domain J disjoint from where y is already defined. Extend y to agree with $z(n)$ on J. This completes the recursion; if there are places where y never gets defined, define it arbitrarily there.

To complete the proof, we show that y matches every (x_α, Π_α). Consider any α and any one of the infinitely many n for which $g(n) = f_\alpha(n)$. At stage n of the construction of y, we ensured that y extends some $z(n) \in g(n) = f_\alpha(n)$. But the construction of $f_\alpha(n)$ ensures that $z(n)$ is the restriction of x_α to an interval (the union of a good pair of intervals from Θ) that includes an interval of Π_α. Thus y agrees with x_α on that interval of Π_α. Since this happens for infinitely many n, y matches (x_α, Π_α). $\dashv$

5.10 Remark. The preceding proof exhibits a morphism from $\mathbf{Cov}'(\mathcal{B})$ to $\mathfrak{D}' \breve{;} ({}^\omega\omega, {}^\omega\omega, \text{eventually different})$. Ignoring the coding needed to make f_α and g functions into ω, we can say that the "challenge" half of the morphism is the construction of y from Θ and g and the "response" half of the morphism sends any (x, Π) (where we omit the α subscripts needed in the proof but not here) to the pair consisting of Π and the function that maps any Θ not dominated by Π to the f as in the proof (and maps Θ's that are dominated by Π arbitrarily).

It is an open problem whether one can omit the "$\mathfrak{D}$;" part, i.e., whether there is a Borel morphism from $\mathbf{Cov}'(\mathcal{B})$ to $({}^\omega\omega, {}^\omega\omega, \text{eventually different})$. An essentially equivalent question is whether any forcing that adds a real (in ${}^\omega\omega$) infinitely equal to all ground model reals (called a "half-Cohen" real) must add a Cohen real. The proof above shows that if one first adds an unbounded real and then a half-Cohen real over the resulting model, the final model contains a Cohen real over the ground model.

We now turn to Lebesgue measure (and equivalent measures on ${}^\omega 2$, ${}^\omega\omega$, etc.) and its connections with Baire category. The first such connection was given by Rothberger [90].

5.11 Theorem. $\mathbf{cov}(\mathcal{B}) \le \mathbf{non}(\mathcal{L})$ *and* $\mathbf{cov}(\mathcal{L}) \le \mathbf{non}(\mathcal{B})$.

Proof. Let Π be the interval partition whose nth interval I_n has $n+1$ elements for all n. Define a binary relation R on ${}^\omega 2$ by letting $x\,R\,y$ mean that $x\restriction I_n = y\restriction I_n$ for infinitely many n, i.e., that y matches the chopped real (x, Π). Notice that R is symmetric and, for every x, the set $R_x = \{y : x\,R\,y\}$ is a comeager set of measure zero. ("Comeager" was proved in Theorem 5.2. The calculation for "measure zero" consists of noticing that, once x is fixed, the y's that agree with it on I_n form a set of measure $2^{-(n+1)}$, so the y's that agree with x on at least one I_n beyond I_k form a set of measure at most 2^{-k}, and so the y's that do this for all k form a set of measure zero.)

Thus, letting $\mathbf{R} = ({}^\omega 2, {}^\omega 2, R)$, we have morphisms $\varphi : \mathbf{R} \to \mathbf{Cov}(\mathcal{L})$ and $\psi : \mathbf{R}^\perp \to \mathbf{Cov}(\mathcal{B})$, where φ_+ and ψ_+ send x to R_x and ${}^\omega 2 - R_x$ respectively and where both φ_- and ψ_- are the identity on ${}^\omega 2$. Composing each of these morphisms with the dual of the other, we get morphisms $\mathbf{Cov}(\mathcal{B})^\perp \to \mathbf{Cov}(\mathcal{L})$ and $\mathbf{Cov}(\mathcal{L})^\perp \to \mathbf{Cov}(\mathcal{B})$. Since $\mathbf{cov} = \|\mathbf{Cov}\|$ and $\mathbf{non} = \|\mathbf{Cov}^\perp\|$ for both ideals, the theorem follows. ⊣

5.12 Remark. The relation R in the preceding proof could be replaced by any relation of the form "$x \oplus y \in M$" where $\oplus$ is addition modulo 2 and M is any comeager set of measure zero. For example, M could be the set of 0–1 sequences in which the density of 1's in initial segments does not approach 1/2.

In this form, the proof generalizes to any pair of translation-invariant (with respect to $\oplus$) ideals that concentrate on disjoint sets.

The rest of our discussion of measure characteristics is based on a combinatorial characterization, due to Bartoszyński [3], of $\mathbf{add}(\mathcal{L})$. To formulate it, we need the following terminology.

5.13 Definition. A *slalom* is a function S assigning to each $n \in \omega$ a set $S(n) \subseteq \omega$ of cardinality n. We say that a real $x \in {}^\omega\omega$ *goes through* slalom S if $\forall^\infty n\,(x(n) \in S(n))$.

5.14 Theorem. $\mathbf{add}(\mathcal{L})$ *is the smallest cardinality of any family* $\mathcal{F} \subseteq {}^\omega\omega$ *such that there is no single slalom through which all the members of* $\mathcal{F}$ *go.*

For the proof, we refer to Bartoszyński's original paper [3], his chapter in this Handbook, his book with Judah [5, Theorem 2.3.9], or Fremlin's article [47].

5.15 Remark. The theorem would remain true if we modified the definition of "slalom" by requiring $S(n)$ to have cardinality $f(n)$ instead of n; here f can be any function $\omega \to \omega$ that grows without bound. We refer to this modified notion of slalom as an f-slalom (or $f(n)$-slalom). Suppose, for example, that κ is a cardinal such that every κ functions in ${}^\omega\omega$ go through a single f-slalom. To show that any κ functions x_α go through a single slalom in the original sense, partition ω into intervals such that the nth interval starts at or after $f(n)$. Let $y_\alpha(n)$ be (or code) the restriction of x_α to the nth interval. From an f-slalom through which all the y_α go, one easily gets a slalom in the original sense through which all the x_α go.

Despite this observation, it is not true that one could simply omit the cardinality bound (n or $f(n)$) in the definition of slalom and merely require each $S(n)$ to be finite. Indeed, with this weakening, the cardinal described in the theorem would be simply $\mathfrak{b}$, which can be strictly larger than $\mathbf{add}(\mathcal{L})$.

As indicated for example in Oxtoby's book [83], there are a great many similarities between Baire category and Lebesgue measure. The following inequality, due to Bartoszyński [3] and independently but a bit later to Raisonnier and Stern [89], was an early indication that the symmetry is not so extensive as one might have thought. (The first indication of this was Shelah's proof [98] that ZF (without choice) plus "all sets of reals have the Baire property" is consistent if ZF is, whereas the consistency of ZF plus "all sets of reals are Lebesgue measurable" requires the consistency of an inaccessible cardinal.) The theme of measure-category asymmetry is developed much further in the book [5].

5.16 Theorem. $\mathbf{add}(\mathcal{L}) \leq \mathbf{add}(\mathcal{B})$*.*

Proof. In view of Theorem 5.6, it suffices to prove that $\mathbf{add}(\mathcal{L}) \leq \mathfrak{b}$ and $\mathbf{add}(\mathcal{L}) \leq \mathbf{cov}(\mathcal{B})$. The former is immediate, in view of Theorem 5.14, for a family of reals going through a single slalom is obviously bounded. (It should be mentioned that the inequality $\mathbf{add}(\mathcal{L}) \leq \mathfrak{b}$ was originally proved by Miller [81] before Theorem 5.14 was known.) For the second inequality, we use Theorem 5.9.

If $\kappa < \mathbf{add}(\mathcal{L})$ and if we are given κ functions $x_\alpha \in {}^\omega\omega$, we must find a single function y infinitely equal to them all. Fix an interval partition Π whose nth interval I_n has cardinality $\geq n$. To each x_α associate the function $x'_\alpha \in {}^\omega\omega$ where $x'_\alpha(n)$ codes (in some standard way) $x_\alpha \restriction I_n$. Let S be a slalom through which all the x'_α go. We may assume that all n elements of $S(n)$ code functions $I_n \to \omega$, for any other elements can be replaced with such codes without harming the fact that all x'_α go through S. For each n, choose a function $y_n : I_n \to \omega$ that agrees at least once with each of the n members of $S(n)$; this is trivial to arrange, since $|I_n| \geq n$. Then the union of all the y_n is the desired y. Indeed, every x_α agrees with y at least once in each I_n except for finitely many. ⊣

5.17 Remark. The preceding proof, though short, has a defect from the point of view of morphisms between relations. Because it relies on Theorems 5.6 and 5.9, it involves sequential compositions. In fact, it provides a Borel morphism from $\mathbf{Cof}(\mathcal{L});\mathbf{Cof}(\mathcal{L});\mathbf{Cof}(\mathcal{L})$ to $\mathbf{Cof}(\mathcal{B})$. The presence of these sequential compositions is an artifact of the proof. Bartoszyński's chapter in this Handbook contains a different proof, giving a Borel morphism from $\mathbf{Cof}(\mathcal{L})$ to $\mathbf{Cof}(\mathcal{B})$.

Since the proof gave a morphism, we also have the dual result.

5.18 Corollary. $\mathbf{cof}(\mathcal{B}) \leq \mathbf{cof}(\mathcal{L})$.

Our discussion of the four standard characteristics (**add**, **cov**, **non**, and **cof**) of measure and category, along with $\mathfrak{b}$ and $\mathfrak{d}$, is now complete, in the following strong sense. If one assigns to each of these ten characteristics one of the values $\aleph_1$ and $\aleph_2$, and if the assignment is consistent with the equations and inequalities proved above, then that assignment is realized in some model of ZFC. We shall comment on a few of these models in Sect. 11 below, but we refer to [6] or [5, Chap. 7] for all the details.

The inequalities between these ten cardinal characteristics are summarized in the following picture, known as *Cichoń's diagram*, in which one goes from larger to smaller cardinals by moving down or to the left along the arrows. (A 45° counterclockwise rotation would produce a Hasse diagram in the customary orientation. We've drawn the arrows in the direction of the morphisms between the corresponding relations, hence from larger to smaller characteristics.)

$$\begin{array}{ccccccc}
\mathbf{cov}(\mathcal{L}) & \longleftarrow & \mathbf{non}(\mathcal{B}) & \longleftarrow & \mathbf{cof}(\mathcal{B}) & \longleftarrow & \mathbf{cof}(\mathcal{L}) \\
\Big\downarrow & & \downarrow & & \downarrow & & \Big\downarrow \\
 & & \mathfrak{b} & \longleftarrow & \mathfrak{d} & & \\
 & & \downarrow & & \downarrow & & \\
\mathbf{add}(\mathcal{L}) & \longleftarrow & \mathbf{add}(\mathcal{B}) & \longleftarrow & \mathbf{cov}(\mathcal{B}) & \longleftarrow & \mathbf{non}(\mathcal{L})
\end{array}$$

To conclude this section, we point out an elementary connection between the covering and uniformity numbers studied here and the splitting and refining numbers from Sect. 3.

5.19 Theorem. $\mathfrak{s} \leq \mathbf{non}(\mathcal{B}), \mathbf{non}(\mathcal{L})$ *and* $\mathfrak{r} \geq \mathbf{cov}(\mathcal{B}), \mathbf{cov}(\mathcal{L})$.

Proof. For any infinite $A \subseteq \omega$, the sets $X \subseteq \omega$ that fail to split A form a meager, measure-zero set U_A. Then the function $A \mapsto U_A$ and the identity function on $\mathcal{P}(\omega)$ constitute a morphism from $\mathfrak{R}$ to $\mathbf{Cov}(\mathcal{B})$ and also to $\mathbf{Cov}(\mathcal{L})$. ⊣

6. Sparse Sets of Integers

This section is primarily about two characteristics, $\mathfrak{t}$ and $\mathfrak{h}$, related to the idea of thinning out infinite subsets of ω, i.e., replacing them by subsets, usually so as to achieve some useful property like homogeneity for some partition. $\mathfrak{t}$ is concerned with the (transfinite) thinning process itself; $\mathfrak{h}$ focuses on what can be achieved by iterated thinning. We shall also briefly consider two characteristics, $\mathfrak{p}$ and $\mathfrak{g}$, whose definitions resemble those of $\mathfrak{t}$ and $\mathfrak{h}$, though their most significant properties are treated only in later sections.

We begin with the definition and simplest properties of $\mathfrak{t}$.

6.1 Definition. A *pseudointersection* of a family $\mathcal{F}$ of sets is an infinite set that is $\subseteq^*$ every member of $\mathcal{F}$.

6.2 Definition. A *tower* is an ordinal-indexed sequence $\langle T_\alpha : \alpha < \lambda \rangle$ such that:

1. Each T_α is an infinite subset of ω.

2. $T_\beta \subseteq^* T_\alpha$ whenever $\alpha < \beta < \lambda$.

3. $\{T_\alpha : \alpha < \lambda\}$ has no pseudointersection.

The *tower number* $\mathfrak{t}$ is the smallest λ that is the length of a tower.

6.3 Remark. Hechler [55] has constructed a model where many regular cardinals occur as the lengths of towers.

Some authors define "tower" using only the first two clauses in the definition above, i.e., an almost decreasing sequence in $[\omega]^\omega$; what we call a tower, they would call an inextendible tower. Also, some authors take towers to be almost increasing sequences of co-infinite subsets of ω rather than almost decreasing sequences of infinite sets.

We shall not always be as careful as we were in clause 3 of the definition about the distinction between a sequence like $\langle T_\alpha : \alpha < \lambda \rangle$ and the set $\{T_\alpha : \alpha < \lambda\}$ of its terms.

6.4 Proposition. $\mathfrak{t}$ *is a regular uncountable cardinal.*

Proof. Regularity is clear since any cofinal subsequence of a tower is a tower. To show that there can be no tower $\langle T_n : n \in \omega \rangle$ of length ω, note that we could form an infinite set X by taking any element of T_0, any different element of $T_0 \cap T_1$, any different element of $T_0 \cap T_1 \cap T_2$, etc., since all these sets are infinite. This X would be a pseudointersection, violating requirement 3 in the definition of tower. $\dashv$

Before continuing with further properties of $\mathfrak{t}$, we introduce $\mathfrak{h}$, its basic properties, and its connection with $\mathfrak{t}$.

6.5 Definition. A family $\mathcal{D} \subseteq [\omega]^\omega$ is *open* if it is closed under almost subsets. It is *dense* if every $X \in [\omega]^\omega$ has a subset in $\mathcal{D}$. The *distributivity number* $\mathfrak{h}$ is the smallest number of dense open families with empty intersection.

6.6 Remark. The open sets as defined here constitute a topology on $[\omega]^\omega$, which we call the *lower topology*. Density as defined here agrees with topological density in the lower topology as long as $\mathcal{D}$ is closed under finite modifications (for example if it is open). Analogous definitions can be made for any pre-ordered set in place of $([\omega]^\omega, \subseteq^*)$.

The name "distributivity number" comes from viewing $([\omega]^\omega, \subseteq)$ as a notion of forcing and asking how distributive the associated complete Boolean algebra is. Standard techniques from forcing theory show that the answer is given by $\mathfrak{h}$. More precisely, Boolean meets of fewer than $\mathfrak{h}$ terms distribute over arbitrary (finite or infinite) joins, but meets of $\mathfrak{h}$ terms need not distribute even over binary joins. Equivalently, in a forcing extension by $([\omega]^\omega, \subseteq)$, $\mathfrak{h}$ has new subsets but smaller ordinals do not (not even new functions into the ordinals). We shall see later (6.20) that this forcing extension collapses $\mathfrak{c}$ to $\mathfrak{h}$ if $\mathfrak{h} < \mathfrak{c}$.

6.7 Proposition. *The intersection of any fewer than* $\mathfrak{h}$ *dense open families is dense open.* $\mathfrak{h}$ *is a regular cardinal.*

Proof. The second sentence follows immediately from the first. (It also follows from the remark about distributivity.) To show that the intersection of fewer than $\mathfrak{h}$ dense open families $\mathcal{D}_\alpha$ is dense open, note first that it is obviously open. As for density, let X be any infinite subset of ω and consider the families $\mathcal{D}'_\alpha = \{Y \in \mathcal{D}_\alpha : Y \subseteq X\}$. These are fewer than $\mathfrak{h}$ dense open families of subsets of X, so they have a common member Y. That is, $Y \subseteq X$ and $Y \in \bigcap_\alpha \mathcal{D}_\alpha$. ⊣

The definition of $\mathfrak{t}$ is essentially about the process of thinning out infinite subsets of ω by repeatedly passing to (almost) subsets. If one attempts to iterate such a thinning process transfinitely, the definition of $\mathfrak{t}$ ensures that one will not get stuck at limit stages of cofinality $< \mathfrak{t}$.

The definition of $\mathfrak{h}$ addresses the same idea from the point of view of what such thinning can achieve. A dense open family is one that one can get into, from an arbitrary infinite subset of ω, by passing to a subset (and subsequent passages to further (almost) subsets will not undo this achievement). The next proposition is just the result of comparing these intuitions that stand behind $\mathfrak{t}$ and $\mathfrak{h}$.

6.8 Proposition. $\mathfrak{t} \le \mathfrak{h}$.

Proof. Suppose $\kappa < \mathfrak{t}$, and let κ dense open families $\mathcal{D}_\alpha$ $(\alpha < \kappa)$ be given; we must find a set in their intersection. Define an almost decreasing sequence $\langle T_\alpha : \alpha \le \kappa \rangle$ by the following recursion. $T_0 = \omega$. $T_{\alpha+1}$ is any subset of T_α

that is in $\mathcal{D}_\alpha$; this exists because $\mathcal{D}_\alpha$ is dense. If $\lambda \leq \kappa$ is a limit ordinal, then T_λ is any pseudointersection of $\{T_\alpha : \alpha < \lambda\}$; this exists because $\kappa < \mathfrak{t}$ so $\{T_\alpha : \alpha < \lambda\}$ cannot be a tower, yet the previous steps ensured that it satisfies the first two requirements for a tower. Since $T_\kappa \subseteq^* T_{\alpha+1}$ for all $\alpha < \kappa$, we have, thanks to openness, that T_κ is in all the families $\mathcal{D}_\alpha$. $\dashv$

It is consistent with ZFC to have $\mathfrak{t} < \mathfrak{h}$. In fact, Dordal [41] built a model where $\mathfrak{h} = \aleph_2 = \mathfrak{c}$ but there are no towers of length ω_2.

Upper bounds for $\mathfrak{h}$, and therefore also for $\mathfrak{t}$, can be obtained by considering specific examples of dense open families. One family of examples consists of $\{X \in [\omega]^\omega : X \text{ is not split by } Y\}$ for arbitrary Y. Another consists of $\{X \in [\omega]^\omega : \forall^\infty x \in X \, \forall y \in X \, (\text{if } x < y \text{ then } f(x) < y)\}$ for arbitrary $f : \omega \to \omega$. Using these, one easily obtains the following proposition, but we give another proof to suggest another class of examples.

6.9 Theorem. $\mathfrak{h} \leq \mathfrak{b}, \mathfrak{s}$.

Proof. By Theorem 3.5 it suffices to show $\mathfrak{h} \leq \mathfrak{par}_2$. So let $\kappa < \mathfrak{h}$ partitions f_α of $[\omega]^2$ be given; we must find an infinite set almost homogeneous for them all. For each α, let $\mathcal{D}_\alpha$ be the family of all infinite subsets of ω that are almost homogeneous for f_α. Then $\mathcal{D}_\alpha$ is dense open, thanks to Ramsey's Theorem. So there is a set H common to all the $\mathcal{D}_\alpha$. $\dashv$

6.10 Remark. The same proof shows that one can get simultaneous almost homogeneity for fewer than $\mathfrak{h}$ partitions of more complicated sorts, provided one has the analog of Ramsey's Theorem to ensure density. Thus, for example, Silver's partition theorem for analytic sets [102] implies that any $< \mathfrak{h}$ partitions of $[\omega]^\omega$ into an analytic and a coanalytic piece have a common infinite almost homogeneous set.

By Proposition 6.8, the upper bounds on $\mathfrak{h}$ apply also to $\mathfrak{t}$, but for $\mathfrak{t}$ we can improve $\mathfrak{b}$ to $\mathbf{add}(\mathcal{B})$. In order to prove this, we need the following lemma, in which $\mathbb{Q}$ denotes the set of rational numbers and "dense" has its usual topological (or order-theoretic) meaning for subsets of $\mathbb{Q}$. Both the lemma and the subsequent theorem are from [93] (stated for special cases but the proofs work in general); they were rediscovered in [86].

6.11 Lemma. *Suppose $\lambda < \mathfrak{t}$ and $\langle T_\alpha : \alpha < \lambda \rangle$ is an almost decreasing sequence of dense subsets of $\mathbb{Q}$. Then there exists a dense $X \subseteq \mathbb{Q}$ that is almost included in every T_α.*

Proof. In each interval I with rational endpoints, consider the almost decreasing sequence $\langle T_\alpha \cap I : \alpha < \lambda \rangle$ of infinite subsets of I. As it is too short to be a tower, there is an infinite $Y_I \subseteq I$ almost included in all the T_α. (The union of all the Y_I is dense, but it need not be $\subseteq^* T_\alpha$, so we must work a bit harder to get X.) Enumerate each Y_I as an ω-sequence $\langle y_{I,n} \rangle$. For each α let $f_\alpha(I) \in \omega$ be an upper bound for the finitely many n such that $y_{I,n} \notin T_\alpha$.

Since $\lambda < \mathfrak{t} \leq \mathfrak{b}$ (and the set of intervals I is countable), let g be a function to ω from the set of rational intervals such that g dominates all the f_α's. Then

$$X = \bigcup_I \{y_{I,n} : n > g(I)\}$$

is dense in $\mathbb{Q}$ (because it contains almost all of each Y_I) and is almost included in each T_α (for $X - T_\alpha$ consists of finitely many elements from each of the finitely many Y_I where $g(I) < f_\alpha(I)$). $\dashv$

6.12 Theorem. $\mathfrak{t} \leq \mathbf{add}(\mathcal{B})$.

Proof. We must show that if $\kappa < \mathfrak{t}$ then the intersection of any κ dense open subsets G_α ($\alpha < \kappa$) of $\mathbb{R}$ is comeager. We begin by defining an almost decreasing sequence $\langle T_\alpha : \alpha \leq \kappa \rangle$ of dense subsets of $\mathbb{Q}$. Start with $T_0 = \mathbb{Q}$. At limit stages, apply the lemma. At successor stages, set $T_{\alpha+1} = T_\alpha \cap G_\alpha$; this is dense because it is the intersection of two dense sets one of which is open. Note that T_κ, being $\subseteq^*$ each $T_{\alpha+1}$ ($\alpha < \kappa$) is also $\subseteq^*$ each G_α.

For $t \in T_\kappa$ and $\alpha < \kappa$, define $f_\alpha(t) \in \omega$ to be some n such that $(t - \frac{1}{n}, t + \frac{1}{n}) \subseteq G_\alpha$ if $t \in G_\alpha$, and 0 otherwise. Since T_κ is countable and $\kappa < \mathfrak{t} \leq \mathfrak{b}$, there is a $g : T_\kappa \to \omega$ dominating all the f_α's.

For each finite $F \subseteq T_\kappa$, let

$$U_F = \bigcup_{t \in T_\kappa - F} \left(t - \frac{1}{g(n)}, t + \frac{1}{g(n)} \right).$$

Then U_F is dense, because it almost includes T_κ, and it is obviously open; since there are only countably many F's, $\bigcap_F U_F$ is comeager, and it remains only to prove that this intersection is included in the intersection of the G_α's. In fact, each G_α includes one of the U_F's; given α just take F to contain the finitely many $t \in T_\kappa - G_\alpha$ and the finitely many t where $g(t) < f_\alpha(t)$. $\dashv$

6.13 Remark. By a countable support iteration of Mathias forcing over a model of CH, one obtains a model where $\mathfrak{h} = \aleph_2$ but $\mathbf{cov}(\mathcal{B})$ and therefore $\mathbf{add}(\mathcal{B})$ are only $\aleph_1$ (as no Cohen reals are produced). Thus, the preceding theorem cannot be improved by putting $\mathfrak{h}$ in place of $\mathfrak{t}$.

The next theorem can be viewed as another upper bound on $\mathfrak{t}$.

6.14 Theorem. *If* $\aleph_0 \leq \kappa < \mathfrak{t}$ *then* $2^\kappa = \mathfrak{c}$.

Proof. We need only check that $2^\kappa \leq \mathfrak{c}$, and we do this by building a complete binary tree of $\kappa + 1$ levels, whose nodes are distinct subsets of ω. More precisely, we associate to every sequence $\eta \in {}^{\leq\kappa}2$ an infinite subset T_η of ω in such a way that:

1. If η is an initial segment of θ, then $T_\theta \subseteq^* T_\eta$.
2. If neither of η and θ is an initial segment of the other, then $T_\eta \cap T_\theta$ is finite.

The construction is by recursion on the length of η, starting with $T_\emptyset = \omega$. At successor stages, we define $T_{\eta^\frown\langle 0\rangle}$ and $T_{\eta^\frown\langle 1\rangle}$ to be any two disjoint, infinite subsets of T_η. Finally, for θ of limit length λ, we observe that $\langle T_{\theta\restriction\alpha} : \alpha < \lambda\rangle$ is an almost decreasing sequence but cannot be a tower because $\lambda \le \kappa < \mathfrak{t}$. So there is an infinite X almost included in all these $T_{\theta\restriction\alpha}$; any such X can serve as T_θ.

It is immediate that the construction has the desired properties. In particular, the 2^κ sets T_η, for all η of length κ, are infinite and almost disjoint and therefore certainly distinct. $\dashv$

6.15 Corollary. $\mathfrak{t} \le \mathrm{cf}(\mathfrak{c})$.

Proof. If $\kappa < \mathfrak{t}$ then, by Theorem 6.14 and König's theorem, $\mathrm{cf}(\mathfrak{c}) = \mathrm{cf}(2^\kappa) > \kappa$. $\dashv$

Returning to consider $\mathfrak{h}$ in more detail, we first give an alternative way to view dense open families of subsets of ω.

6.16 Definition. An *almost disjoint* family is a family of infinite sets, every two of which have finite intersection. A *maximal almost disjoint* (MAD) family is an infinite almost disjoint family of subsets of ω, maximal with respect to inclusion.

6.17 Remark. Note that MAD families are required to be infinite; in the absence of this requirement, any partition of ω into finitely many infinite sets would count as MAD. Note also that, if $\mathcal{A}$ is MAD and X is any infinite subset of ω, then $X \cap A$ is infinite for at least one $A \in \mathcal{A}$.

6.18 Proposition. *If $\mathcal{A}$ is a* MAD *family, then $\mathcal{A}{\downarrow} = \{X \in [\omega]^\omega : \exists A \in \mathcal{A}\ (X \subseteq^* A)\}$ is dense open. Every dense open family includes one of this form.*

Proof. The first statement is proved by routine checking of definitions. For the second, let $\mathcal{D}$ be dense open, and let $\mathcal{A}_0$ be an infinite, almost disjoint subfamily of $\mathcal{D}$; for example, take some $X \in \mathcal{D}$ and partition it into infinitely many infinite pieces. By Zorn's Lemma, let $\mathcal{A} \supseteq \mathcal{A}_0$ be an almost disjoint family included in $\mathcal{D}$ and maximal among such families. We claim that $\mathcal{A}$ is maximal among all almost disjoint families, not just those included in $\mathcal{D}$. Once we establish this claim, we will have $\mathcal{A}$ MAD and $\mathcal{A}{\downarrow} \subseteq \mathcal{D}$ as required.

To establish maximality, consider any $X \in [\omega]^\omega$. As $\mathcal{D}$ is dense, it contains a subset Y of X. As $\mathcal{A}$ is maximal among almost disjoint subfamilies of $\mathcal{D}$, it contains a set A that has infinite intersection with Y and therefore also with X. $\dashv$

6.19 Corollary. $\mathfrak{h}$ *is the minimum number of* MAD *families such that, for each $X \in [\omega]^\omega$, one of these families contains at least two sets whose intersections with X are infinite.*

Proof. X has infinite intersection with at least two sets from a MAD family $\mathcal{A}$ if and only if $X \notin \mathcal{A}{\downarrow}$. With this observation, the corollary follows immediately from the proposition and the definition of $\mathfrak{h}$. ⊣

The following theorem of Balcar, Pelant, and Simon [2] was the original motivation for the introduction of $\mathfrak{h}$. A tree of the sort described by this theorem is called a *base matrix tree* (for $[\omega]^\omega$). The theorem would become false if $\mathfrak{h}$ were replaced by any smaller cardinal. The symbol $\mathfrak{h}$ was chosen to refer to the "height" of the base matrix tree.

6.20 Theorem. *There is a family $\mathcal{T} \subseteq [\omega]^\omega$ with the following properties.*

1. *Ordered by reverse almost inclusion, $\mathcal{T}$ is a tree of height $\mathfrak{h}$ with root ω.*
2. *Each level of $\mathcal{T}$, except for the root, is a* MAD *family.*
3. *Every $X \in [\omega]^\omega$ has a subset in $\mathcal{T}$.*

Proof. Let $\mathcal{D}_\alpha$ for $\alpha < \mathfrak{h}$ be dense open families with no common member. We define the levels $\mathcal{T}_\alpha$ of the desired tree inductively as follows. At level 0, put ω. At a limit level $\lambda < \mathfrak{h}$, use Proposition 6.7 to obtain a dense open family included in all $\mathcal{T}_\alpha{\downarrow}$ for $\alpha < \lambda$. By Proposition 6.18, shrink this to a dense open family of the form $\mathcal{A}{\downarrow}$, and let that $\mathcal{A}$ be $\mathcal{T}_\lambda$.

At an odd-numbered successor stage, say $2\alpha + 1$, choose $\mathcal{T}_{2\alpha+1}$ as a MAD family included in both $\mathcal{T}_{2\alpha}{\downarrow}$ and $\mathcal{D}_\alpha$. This can be done by Propositions 6.7 and 6.18.

At an even-numbered successor stage, say $2\alpha+2$, proceed as follows. Call a set $X \in [\omega]^\omega$ *active* at this stage if it has infinite intersection with $\mathfrak{c}$ members of $\mathcal{T}_{2\alpha+1}$. Assign to each active X some $\psi(X) \in \mathcal{T}_{2\alpha+1}$ that has infinite intersection with X, and do this in such a way that ψ is one-to-one. This is easily done by arranging all the active X's in a well-ordered sequence, of length $\le \mathfrak{c}$, and defining ψ by recursion along this ordering. At each stage of the recursion, there are $\mathfrak{c}$ elements of $\mathcal{T}_{2\alpha+1}$ that have infinite intersection with the current X and fewer than $\mathfrak{c}$ of them have already been assigned as earlier values of ψ, so there are plenty of candidates left to serve as $\psi(X)$. Once ψ has been defined, partition each $Y \in \mathcal{T}_{2\alpha+1}$ into two infinite pieces Y' and Y'', subject to the requirement that if $Y = \psi(X)$ for some (unique) X then $Y' \subseteq X$. Then let $\mathcal{T}_{2\alpha+2}$ consist of these sets Y' and Y'' for all $Y \in \mathcal{T}_{2\alpha+1}$.

This completes the construction of $\mathcal{T}$. The first two parts of the theorem are clear, and the third will be clear once we show that every $X \in [\omega]^\omega$ is active at some stage $2\alpha+2$. To this end, we consider a fixed X and we build a binary subtree of $\mathcal{T}$, of height ω, as follows. Its root is the root ω of $\mathcal{T}$. After its nth level has been constructed, consisting of 2^n nodes Z of $\mathcal{T}$, all at the same level of $\mathcal{T}$, say level α_n, and all having infinite intersection with X, we produce the next level as follows. For each node Z of level n in our subtree, $Z \cap X$ is an infinite set and cannot be in all the dense open families $\mathcal{D}_\xi$ as these were chosen to have no common member. Since $\mathcal{T}_{2\xi+1} \subseteq \mathcal{D}_\xi$, $Z \cap X$ must meet at least two sets in $\mathcal{T}_\beta$ for all sufficiently large β. Choose a β that is sufficiently large in this sense for all 2^n Z's; call it α_{n+1}, and let the successors of each Z at this level be two nodes that meet $Z \cap X$ infinitely. Note that these are necessarily $\subseteq^* Z$ (for otherwise they would be almost disjoint from Z), so we are getting a subtree of $\mathcal{T}$. After the subtree has been constructed, use the fact that $\mathfrak{h}$ is uncountable and regular to see that the supremum, say γ, of the α_n's is still $< \mathfrak{h}$, so there are a γth and a $(\gamma+1)$st level of $\mathcal{T}$.

For each path p through our subtree, the nodes along that path, intersected with X, form an almost-decreasing ω-sequence, so there is an infinite $X' \subseteq X$ almost included in all of them (as $\mathfrak{t} > \omega$). That X' has infinite intersection with some node Y in level $\gamma + 1$ of $\mathcal{T}$, because the level is a MAD family. This Y has infinite intersection with each of the nodes Z along the path p, so Y is almost included in each of these Z's (because $\mathcal{T}$ is a tree). Since distinct nodes at the same level are almost disjoint, distinct paths p must lead to distinct nodes Y. So we have $\mathfrak{c}$ nodes Y at level $\gamma + 1$, all meeting X infinitely. Since γ is a limit ordinal, $\gamma = 2\gamma$ and X is active at stage $2\gamma + 2$. ⊣

6.21 Remark. Clause 3 of the theorem implies that forcing with the poset $([\omega]^\omega, \subseteq^*)$ is equivalent to forcing with the tree $(\mathcal{T}, \subseteq^*)$. It is not difficult to modify the construction of the base matrix tree so that each node has $\mathfrak{c}$ immediate successors. Then this forcing clearly adjoins a function from $\mathfrak{h}$ onto $\mathfrak{c}$. Since $\mathfrak{h}$ is not collapsed and no reals are added (because of the distributivity), we find that $\mathfrak{h}$ is the cardinality of the continuum in the forcing extension by $([\omega]^\omega, \subseteq^*)$.

We introduce a cardinal $\mathfrak{p}$, a slight modification of $\mathfrak{t}$, that is often useful because of its connection with forcing; see Theorem 7.12 below. Notice that it makes sense to ask about pseudointersections of families more general than towers. An obvious necessary condition for a family to have a pseudointersection is the strong finite intersection property defined below; $\mathfrak{p}$ measures the extent to which this necessary condition is also sufficient.

6.22 Definition. A family $\mathcal{F}$ of infinite sets has the *strong finite intersection property* if every finite subfamily has infinite intersection. The *pseudointersection number* $\mathfrak{p}$ is the smallest cardinality of any $\mathcal{F} \subseteq [\omega]^\omega$ with SFIP but with no pseudointersection.

Since a tower is a family with SFIP and no pseudointersection, we immediately get half of the following proposition. The other half, that $\mathfrak{p}$ is uncountable, is proved exactly as for $\mathfrak{t}$ (and is improved in Proposition 6.24 below).

6.23 Proposition. $\aleph_1 \leq \mathfrak{p} \leq \mathfrak{t}$.

It is not known whether $\mathfrak{p}$ can be strictly smaller than $\mathfrak{t}$, but the next theorem shows that, for this to happen, $\mathfrak{p}$ would have to be at least $\aleph_2$ and (therefore) $\mathfrak{t}$ at least $\aleph_3$. To prove the theorem, we need a proposition that will be useful again later (in the proofs of Theorems 8.13 and 9.25) and is of some interest in its own right as it can serve as a characterization of $\mathfrak{d}$ (the $\mathfrak{d}$ in the hypothesis is easily seen to be optimal). The theorem and a version of the proposition are in [92]; a form of the proposition closer to the present one is in [66].

6.24 Proposition. *Suppose $\langle C_n : n \in \omega \rangle$ is a decreasing (or almost decreasing) sequence of infinite subsets of ω, and suppose $\mathcal{A}$ is a family of fewer than $\mathfrak{d}$ subsets of ω such that each set in $\mathcal{A}$ has infinite intersection with each C_n. Then $\{C_n : n \in \omega\}$ has a pseudointersection B that has infinite intersection with every set in $\mathcal{A}$.*

Proof. We may assume $\langle C_n : n \in \omega \rangle$ is decreasing, for if it is only almost decreasing then we can replace each C_n with $\bigcap_{k \le n} C_k$ without affecting the other hypotheses or the conclusion, as each new C_n differs only finitely from the old.

For any $h \in {}^\omega\omega$, let $B_h = \bigcup_{n \in \omega} (C_n \cap h(n))$. Each C_n includes all but the first n terms of this union, and these terms are finite, so B_h is a pseudointersection of the C_n's. It remains to choose h so that $A \cap B_h$ is infinite for all $A \in \mathcal{A}$.

For each such A, let $f_A(n)$ denote the nth element of the infinite set $A \cap C_n$. Observe that, if $h(n) > f_A(n)$ for some A and n, then $A \cap B_h$ has cardinality at least n, for it contains the first n elements of $A \cap C_n$. So B_h can serve as the B in the proposition provided $\forall A \in \mathcal{A}\, \exists^\infty n\, (h(n) > f_A(n))$. But there are fewer than $\mathfrak{d}$ functions f_A, so there is an h not dominated by any of them. $\dashv$

6.25 Theorem. *If $\mathfrak{p} = \aleph_1$, then $\mathfrak{t} = \aleph_1$.*

Proof. Since $\mathfrak{t} \le \mathfrak{h} \le \mathfrak{b} \le \mathfrak{d}$, the result is immediate if $\mathfrak{d} = \aleph_1$. So we assume for the rest of the proof that $\mathfrak{d} > \aleph_1$.

By hypothesis we have a family $\mathcal{A} = \{A_\alpha : \alpha < \aleph_1\}$ with SFIP but with no pseudointersection, and we may assume that it is closed under finite intersections. We build a tower $\langle T_\alpha : \alpha < \aleph_1 \rangle$ of length $\aleph_1$ by recursion, ensuring at each stage that T_α has infinite intersection with each $A \in \mathcal{A}$ and that $T_{\alpha+1} \subseteq A_\alpha$. We start with $T_0 = \omega$, and at countable limit stages λ we continue the tower by applying the proposition (with $\langle C_n : n \in \omega \rangle$ being a cofinal subsequence of $\langle T_\alpha : \alpha < \lambda \rangle$). At successor stages we set $T_{\alpha+1} = T_\alpha \cap A_\alpha$. It is easy to verify that this defines an almost decreasing sequence with the claimed properties. It is a tower, because any pseudointersection of the T_α's would also be a pseudointersection of the A_α's. $\dashv$

We close this section by discussing the groupwise density number $\mathfrak{g}$, a close relative of $\mathfrak{h}$. More information about it, including the motivation for its definition, is in Sect. 8.

6.26 Definition. A family $\mathcal{G} \subseteq [\omega]^\omega$ is *groupwise dense* if it is open in the lower topology (i.e., closed under almost subsets) and, for every interval partition Π, some union of (infinitely many) intervals of Π belongs to $\mathcal{G}$. The *groupwise density number* $\mathfrak{g}$ is the smallest number of groupwise dense families with empty intersection.

It is conventional, though perhaps unnatural, to include closure under almost subsets in the definition of "groupwise dense" even though it is not in the definition of "dense". The first part of the following proposition gives a convenient synonym for "groupwise dense", namely "nonmeager open" where "non-meager" refers to the usual topology of $[\omega]^\omega$ (as a subspace of $\mathcal{P}\omega \cong {}^\omega 2$) whereas "open" refers to the lower topology.

6.27 Proposition.

1. *A family $\mathcal{G} \subseteq [\omega]^\omega$ is groupwise dense if and only if it is closed under almost subsets and nonmeager in the standard topology.*
2. *The intersection of any fewer than $\mathfrak{g}$ groupwise dense families is groupwise dense.*
3. *$\mathfrak{g}$ is regular.*
4. *$\mathfrak{h} \leq \mathfrak{g} \leq \mathfrak{d}$.*

Proof. Identify $[\omega]^\omega$ with a cocountable subset of ${}^\omega 2$ via characteristic functions. Let $\mathcal{G} \subseteq [\omega]^\omega$ be closed under almost subsets. By Theorem 5.2, it is nonmeager if and only if it contains enough reals to match each chopped real (x, Π). Thanks to closure under subsets, it suffices to match those chopped reals whose first component x is the identically 1 function. But matching these chopped reals is precisely what the definition of groupwise density requires.

For part 2, suppose $\mathcal{G}_\alpha$ are fewer than $\mathfrak{g}$ groupwise dense families. Their intersection $\mathcal{G}$ is clearly closed under almost subsets, so consider an arbitrary interval partition $\Pi = \{I_n : n \in \omega\}$. We must find an infinite set $X \subseteq \omega$ such that $\bigcup_{n\in X} I_n \in \mathcal{G}$. That is, we must find an X common to the families $\mathcal{H}_\alpha = \{X \in [\omega]^\omega : \bigcup_{n\in X} I_n \in \mathcal{G}_\alpha\}$. Since there are fewer than $\mathfrak{g}$ of these families, it suffices to prove that each of them is groupwise dense. This is a routine verification; to see that $\mathcal{H}_\alpha$ contains a union of intervals from a partition Θ, use that $\mathcal{G}_\alpha$ contains a union of intervals from the partition $\{\bigcup_{n\in J} I_n : J \in \Theta\}$.

The regularity of $\mathfrak{g}$ follows immediately from part 2.

Every groupwise dense family $\mathcal{G}$ is dense. Indeed, given any infinite $X \subseteq \omega$, we can form an interval partition in which each interval contains a member of X. Then $\mathcal{G}$ contains a union of such intervals and therefore, being closed under subsets, contains an infinite subset of X. This observation immediately gives $\mathfrak{h} \leq \mathfrak{g}$.

Finally, to show that $\mathfrak{g} \leq \mathfrak{d}$, let $\mathcal{D}$ be a dominating family of size $\mathfrak{d}$, and associate to each $f \in \mathcal{D}$ the set

$$\mathcal{G}_f = \{X \in [\omega]^\omega : \exists^\infty n\ (X \cap [n, f(n)) = \emptyset)\}.$$

Then $\mathcal{G}_f$ is groupwise dense; given any interval partition Π, we can form an element of $\mathcal{G}_f$ by taking infinitely many intervals from Π, separated by gaps so long that each gap includes $[n, f(n))$ for some n. But there can be no X common to all the $\mathcal{G}_f$, for if there were then the function sending each $n \in \omega$ to the next larger member of X would not be dominated by any $f \in \mathcal{D}$. So we have $\mathfrak{d}$ groupwise dense families with empty intersection. $\dashv$

6.28 Remark. This proposition shows that, in the lattice of subsets of $[\omega]^\omega$ closed downward with respect to $\subseteq^*$, the non-meager sets form a filter, indeed a $<\mathfrak{g}$-complete filter. This may be somewhat surprising, since in the lattice (Boolean algebra) of all subsets of $[\omega]^\omega$, two non-meager sets can be disjoint; in fact there are $\mathfrak{c}$ pairwise disjoint non-meager sets.

6.29 Remark. The characteristics studied in this section, as well as $\mathfrak{s}$ and $\mathfrak{r}$ from Sect. 3 above and $\mathfrak{a}$ from Sect. 8 below, have interesting analogs in structures other than $[\omega]^\omega$. One example is the system of dense subsets of $\mathbb{Q}$, ordered by $\subseteq^*$. Little is known about these characteristics, but Lemma 6.11 says that the tower number in this situation is no smaller than the ordinary tower number.

Another example is the set of partitions of ω into infinitely many pieces, ordered by "coarser than modulo finite". Several characteristics of this sort have been studied by Krawczyk (unpublished).

7. Forcing Axioms

Forcing axioms are combinatorial statements designed to express what is achieved by certain sorts of iterated forcing constructions. They serve to hide such constructions in a "black box"; instead of showing that a statement of interest can be forced by such a construction, one derives it from the combinatorial principle. The oldest and still the most frequently used of these principles is Martin's Axiom, introduced in [74]. To state it, we need some terminology from forcing theory.

7.1 Definition. Let $(P, \leq)$ be a nonempty partially ordered set. Two elements $p, q \in P$ are *compatible* if they have a common lower bound and *incompatible* otherwise. An *antichain* is a set of pairwise incompatible elements. P satisfies the *countable chain condition* (c.c.c.) or *countable antichain condition* if all its antichains are countable. More generally, P satisfies the $<\kappa$-chain condition if all its antichains have cardinalities $< \kappa$.

A subset $D \subseteq P$ is *dense* if every element of P is $\geq$ an element of D. If $\mathcal{D}$ is a family of dense subsets of P, then $G \subseteq P$ is $\mathcal{D}$-*generic* if it is closed upward and directed downward (every two members have a common lower bound) and intersects every $D \in \mathcal{D}$.

7.2 Definition. *Martin's Axiom* (MA) is the statement that, if $\mathcal{D}$ is a family of fewer than $\mathfrak{c}$ dense subsets of a partial order P with c.c.c., then there is a $\mathcal{D}$-generic filter $G \subseteq P$. More generally, if κ is a cardinal and $\mathcal{K}$ is a class of nonempty partial orders, then we write $\mathrm{MA}_\kappa(\mathcal{K})$ for the statement that every family $\mathcal{D}$ of κ dense subsets in a member P of $\mathcal{K}$ admits a $\mathcal{D}$-generic $G \subseteq P$. $\mathrm{MA}_{<\kappa}(\mathcal{K})$ is defined analogously. One omits the subscript when it is "$<\mathfrak{c}$" and one omits the class $\mathcal{K}$ when it is the class of c.c.c. posets.

Thus, MA is $\mathrm{MA}_{<\mathfrak{c}}$(c.c.c.). Some authors write MA_κ to mean what we have called $\mathrm{MA}_{<\kappa}$.

MA describes the model obtained by a finite support forcing iteration, of length some uncountable $\kappa = \kappa^{<\kappa}$, in which all c.c.c. posets (of the extension) of size $< \kappa$ are used as forcing conditions during the iteration. This iteration, which is itself a c.c.c. forcing, produces a model of MA and $\mathfrak{c} = \kappa$. Thus, MA is consistent with the continuum being arbitrarily large. Although only small (smaller than κ) posets were used during the iteration, a reflection argument (essentially the Löwenheim-Skolem Theorem; see the second preliminary simplification in the proof of Theorem 7.12 below) shows that all c.c.c. posets, not only the small ones, acquire generic sets with respect to small families of dense subsets. For details about this, see [106] or [68, Sect. VIII.6].

For orientation, we mention that:

- MA_ω(all posets) is provable in ZFC, and therefore CH implies MA.
- $\mathrm{MA}_{\aleph_1}$(all posets) is refutable. Take P to be ${}^{<\omega}\aleph_1$ ordered by reverse inclusion, take $D_\alpha = \{p \in P : \alpha \in \mathrm{ran}(p)\}$, and observe that a generic G would give a map $\bigcup G$ of ω onto $\aleph_1$.
- $\mathrm{MA}_{\mathfrak{c}}$(Cohen) is refutable, where "Cohen" refers to the single poset ${}^{<\omega}2$ ordered by reverse inclusion. For each $f : \omega \to 2$, let $D_f = \{p : p \not\subseteq f\}$ and observe that a generic G would give a function $\bigcup G : \omega \to 2$ different from every f.

The last two of these observations indicate why MA refers only to c.c.c. posets and only to $< \mathfrak{c}$ dense sets.

The effect of MA on cardinal characteristics of the continuum is to make them large, as the next two theorems and their corollaries show. These results are from [74].

7.3 Theorem. MA *implies* $\mathbf{add}(\mathcal{L}) = \mathfrak{c}$.

Proof. Suppose $\kappa < \mathfrak{c}$ and we are given κ sets $N_\alpha \subseteq \mathbb{R}$ $(\alpha < \kappa)$ of measure zero. We must show, assuming MA, that their union has measure 0. It suffices to find, for each positive ε, a set of measure $\leq \varepsilon$ that includes all the N_α as subsets.

Given ε, let P be the set of open subsets of $\mathbb{R}$ having measure $< \varepsilon$, and order P by reverse inclusion. In order to apply MA to this P, we first verify the c.c.c. Let uncountably many elements p of P be given. Inside each of these open sets, find a finite union $q(p)$ of open intervals with rational endpoints, large enough so that $\mu(p - q(p)) < \varepsilon - \mu(p)$. Notice that this implies $\mu(p - q(p)) < \frac{1}{2}(\varepsilon - \mu(q(p)))$. There are only countably many possibilities for $q(p)$, so two (in fact uncountably many) of the $q(p)$ must be the same q. But then the union of the two corresponding p's has measure $< \varepsilon$ (because it consists of q plus the two remainders $p - q$, and each remainder has measure less than half of $\varepsilon - \mu(q)$), so it is in P and is a common lower bound for those two p's. Thus, an uncountable family of p's cannot be an antichain.

For each of the given N_α's, let $D_\alpha = \{p \in P : N_\alpha \subseteq p\}$, and notice that this is a dense subset of P (because a set of measure zero is included in open sets of arbitrarily small measure). Since $\kappa < \mathfrak{c}$, MA provides a generic G meeting all the D_α. Then $\bigcup G$ includes all the N_α. Furthermore, as a directed union of open sets of measure $< \varepsilon$, this $\bigcup G$ has measure $\leq \varepsilon$. $\dashv$

7.4 Corollary. MA *implies that all the cardinals in Cichoń's diagram are equal to* $\mathfrak{c}$ *and that* $\mathfrak{r} = \mathfrak{c}$.

7.5 Remark. The partial ordering used in the proof of the theorem is called the *amoeba* order. To understand the name, visualize the open sets in three dimensional space instead of $\mathbb{R}$, and visualize the proof of density of D_α as extruding a tentacle[1] from a given open set to engulf N_α.

The proof of c.c.c. for the amoeba actually establishes the stronger property of being σ-linked in the sense of the following definition.

7.6 Definition. In a partial order, a subset S is called *linked* if every two of its elements are compatible. It is *n-linked* if every n of its members have a common lower bound. It is *centered* if every finitely many of its members have a common lower bound. *σ-linked* means the union of countably many linked subsets. *σ-n-linked* and *σ-centered* are defined analogously.

Clearly, σ-centered implies σ-linked, which in turn implies c.c.c. σ-n-linked becomes stronger as n increases, but still remains weaker than σ-centered.

In the proof of Theorem 7.3, we essentially showed that the amoeba is σ-linked, as witnessed by the countably many sets $\{p : q(p) = q\}$, where q ranges over finite unions of rational intervals and where $q(p)$ is defined for all p as it was defined in the proof above for p in the supposed antichain. A similar argument shows that the amoeba is σ-n-linked for all n. But it is not σ-centered.

Instead of working directly with sets of measure zero, one can prove the preceding theorem by using Theorem 5.14, which described $\mathbf{add}(\mathcal{L})$ in terms of slaloms. Given fewer than $\mathfrak{c}$ functions $\omega \to \omega$, one needs a slalom through

[1] It has been pointed out to me that an amoeba has pseudopodia, not tentacles. But it seems easier to visualize tentacles.

which all of them go. This is obtainable by applying MA to a poset P consisting of pieces of slaloms. Specifically, a member p of P is a function on ω assigning to each n a finite set of natural numbers, such that, for some k, $|p(n)|$ is n for $n < k$ and k for $n \geq k$. The ordering is componentwise reverse inclusion, and the relevant dense sets are $\{p : \forall n > k\, (f(n) \in p(n))\}$, where k witnesses that $p \in P$ and where f is one of the given functions that should go through our slalom. This forcing is called localization forcing in [5, Sect. 3.1].

7.7 Theorem. MA *implies* $\mathfrak{p} = \mathfrak{c}$.

Proof. Suppose $\mathcal{F} \subseteq [\omega]^\omega$ has the strong finite intersection property and $|\mathcal{F}| < \mathfrak{c}$. To find a pseudointersection X for $\mathcal{F}$, we apply MA to the following poset P. A member of P is a pair (s, F) where s is a finite subset of ω and F is a finite subset of $\mathcal{F}$. (The "meaning" of (s, F) is that the desired X should include s and should, except for s, be included in each $A \in F$.) The ordering puts $(s', F') \leq (s, F)$ if

$$s \text{ is an initial segment of } s', \quad F' \supseteq F, \quad \text{and} \quad \forall A \in F\ (s' - s \subseteq A).$$

Any two pairs with the same first component are compatible, as one can just take the union of the second components. (In fact, any finitely many pairs with the same first component have a common lower bound. So this ordering is σ-centered.) For each $A \in \mathcal{F}$, the set $D_A = \{(s, F) \in P : A \in F\}$ is dense. So is $D_n = \{(s, F) \in P : |s| > n\}$ because of the SFIP of $\mathcal{F}$. MA provides a generic G meeting all these dense sets. Let $X = \bigcup_{(s,F)\in G} s$. This is infinite because G meets each D_n. To see that it is almost included in each $A \in \mathcal{F}$, use that G and D_A have a common member (s_0, F_0). That means $A \in F_0$, and we shall show that $X - s_0 \subseteq A$. Any member k of $X - s_0$ is in $s - s_0$ for some (s, F) in G, and, as G is directed downward, it contains some $(s', F') \leq$ both (s, F) and (s_0, F_0). Then $k \in s - s_0 \subseteq s' - s_0 \subseteq A$, as required. $\dashv$

7.8 Remark. The forcing used in the preceding proof is called *Mathias forcing with respect to* $\mathcal{F}$. One can equivalently view it as consisting of pairs (s, A) where A is the intersection of finitely many sets from $\mathcal{F}$; in this form, the ordering $(s', A') \leq (s, A)$ is defined by

$$s \text{ is an initial segment of } s', \quad A' \subseteq A, \quad \text{and} \quad s' - s \subseteq A.$$

Mathias forcing (without respect to any $\mathcal{F}$) means the similarly defined poset where the second components A can be arbitrary infinite subsets of ω. In contrast to Mathias forcing with respect to an $\mathcal{F}$ with SFIP, this Mathias forcing does not satisfy the c.c.c. It can be viewed as a two-step forcing iteration, where the first step is forcing with $([\omega]^\omega, \subseteq^*)$, which adjoins a generic ultrafilter $\mathcal{U}$ on ω, and the second step is Mathias forcing with respect to $\mathcal{U}$.

7.9 Corollary. MA *implies* $\mathfrak{p} = \mathfrak{t} = \mathfrak{h} = \mathfrak{g} = \mathfrak{s} = \mathfrak{c}$.

Thus, all the characteristics we have discussed are equal to $\mathfrak{c}$ if MA holds. The proofs actually show a bit more, if we introduce new characteristics related directly to MA.

7.10 Definition. For any class $\mathcal{K}$ of posets, $\mathfrak{m}(\mathcal{K})$ is the smallest κ for which $\mathrm{MA}_\kappa(\mathcal{K})$ is false. If $\mathcal{K}$ is the class of c.c.c. posets, we omit mention of it and write simply $\mathfrak{m}$.

Thus MA is the statement $\mathfrak{m} = \mathfrak{c}$. Clearly,

$$\mathfrak{m} \le \mathfrak{m}(\sigma\text{-linked}) \le \mathfrak{m}(\sigma\text{-3-linked}) \le \cdots \le \mathfrak{m}(\sigma\text{-centered}) \le \mathfrak{m}(\text{Cohen}).$$

See [69] for a model where $\mathfrak{m} < \mathfrak{m}(\sigma\text{-linked})$; similar techniques can be used to get strict inequalities between other such variants of $\mathfrak{m}$.

The proofs of the last two theorems and our remarks about the σ-linked and σ-centered properties of the posets in the proofs establish the following inequalities.

7.11 Corollary. $\mathfrak{m}(\sigma\text{-linked}) \le \mathbf{add}(\mathcal{L})$ *and* $\mathfrak{m}(\sigma\text{-centered}) \le \mathfrak{p}$.

Of course, one could be even more specific about the posets used; for example the proof above shows that $\mathfrak{m}(\text{amoeba}) \le \mathbf{add}(\mathcal{L})$. In fact, equality holds here; see [5, Theorem 3.4.17].

The second half of the last corollary can also be improved to an equality, Bell's Theorem [12].

7.12 Theorem. $\mathfrak{m}(\sigma\text{-centered}) = \mathfrak{p}$.

Proof. In view of Corollary 7.11, it suffices to consider an arbitrary σ-centered poset P, say the union of centered parts C_n, and to find a $\mathcal{D}$-generic G for a prescribed family $\mathcal{D}$ of fewer than $\mathfrak{p}$ dense subsets of P. It is convenient to begin with several simplifications of the problem.

First, we may assume that each $D \in \mathcal{D}$ is closed downward, because closing the dense sets will not affect $\mathcal{D}$-genericity.

Second, we may assume that $|P| < \mathfrak{p}$. Indeed, suppose the theorem were proved in this case, and suppose we are given the situation above with $|P| \ge \mathfrak{p}$. By the Löwenheim-Skolem Theorem, the structure $(P, \le, C_n, D)_{n\in\omega, D\in\mathcal{D}}$ has an elementary substructure P' of cardinality $< \mathfrak{p}$. Then P' is σ-centered and $\mathcal{D}' = \{P' \cap D : D \in \mathcal{D}\}$ is a family of $< \mathfrak{p}$ dense subsets, so there is a $\mathcal{D}'$-generic $G' \subseteq P'$. The upward closure of G' in P is then $\mathcal{D}$-generic, as required.

Third, instead of producing a $\mathcal{D}$-generic G, it suffices to produce a linked L meeting every $D \in \mathcal{D}$. Indeed, suppose we could always do this. Then, given P and $\mathcal{D}$ as above, we enlarge $\mathcal{D}$ by adjoining the sets

$$D_{p,q} = \{r \in P : r \text{ is incompatible with } p \text{ or with } q, \text{ or } r \le p, q\},$$

which are easily seen to be dense. If L is linked and meets all the sets in $\mathcal{D}$ and all the $D_{p,q}$, then the upward closure G of L is $\mathcal{D}$-generic. The only thing to check is that it is directed downward. To find a common lower bound for any $p, q \in G$, we may, by lowering both, assume that p and q are in L. Let $r \in L \cap D_{p,q}$. Then r cannot be incompatible with p or with q as L is linked; so $r \leq p, q$, as required.

Fourth, we may assume that, for each $n \in \omega$, there is some $D_n \in \mathcal{D}$ disjoint from C_n. Otherwise, C_n could serve as the required L.

Fifth, we may assume that $\mathcal{D}$ is closed under finite intersections. Closing it in this way does no harm, because the cardinality $|\mathcal{D}|$ will not be increased (unless it was finite—a trivial case) and the intersection of any finitely many dense, downward-closed sets is again dense and downward closed.

After all these simplifications, we begin the real work of the proof. For each $p \in P$ and each $D \in \mathcal{D}$, let $A(p, D)$ be the set of those $n \in \omega$ such that some member of $C_n \cap D$ is $\leq p$.

I claim that, for each $k \in \omega$, the family $\mathcal{F}_k = \{A(p, D) : p \in C_k \text{ and } D \in \mathcal{D}\}$ has the strong finite intersection property. By our fourth simplification, it suffices to show that each finite subfamily $\mathcal{F}_k^0$ of $\mathcal{F}_k$ has nonempty intersection, for we could always include in $\mathcal{F}_k^0$ sets of the form $A(p, D_n)$ for any finitely many of the D_n and so keep any finitely many n's out of the intersection. By our fifth simplification, we may assume that the sets in $\mathcal{F}_k^0$ are $A(p_i, D)$ for various $p_i \in C_k$ but just one $D \in \mathcal{D}$, for different D's could be replaced with their intersection. As C_k is centered, the p_i's have a lower bound p, and below that we can find a member q of the dense set D. If $q \in C_n$ then $n \in \bigcap \mathcal{F}_k^0$. This completes the verification of the claim.

Since $|\mathcal{F}_k| \leq |P| \cdot |\mathcal{D}| < \mathfrak{p}$ by our second simplification, $\mathcal{F}_k$ has a pseudointersection A_k.

Next, we define several labellings of the ω-branching tree ${}^{<\omega}\omega$ of height ω, a primary labeling by natural numbers and, for each $D \in \mathcal{D}$, a secondary labeling by members of P. In the primary labeling, the label of the root is (arbitrarily chosen as) 0, and if a node has label k then the labels of its immediate successors are the numbers in A_k (once each). The secondary labeling associated to a particular $D \in \mathcal{D}$ is defined as follows. The secondary label of the root is an arbitrary element of C_0. If a node has been given secondary label p and if an immediate successor of it has primary label n, then the secondary label of that successor is to be an element of $C_n \cap D$ that is $\leq p$ in P, provided such an element exists, i.e., provided $n \in A(p, D)$—in this case we call that successor node "good" for D. If no such element exists, then the secondary label of that successor node is chosen arbitrarily from C_n and the node is called "bad" for D. Notice that, whether a node is good or bad, its secondary label is always in C_n where n is its primary label.

Because A_k is a pseudointersection for $\mathcal{F}_k$, all but finitely many of the immediate successors of any node are good for any particular $D \in \mathcal{D}$. For each node s and each $D \in \mathcal{D}$, let $f_D(s)$ be a number so large that all the nodes $s^\frown\langle m\rangle$ for $m \geq f_D(s)$ are good for D. Since $|\mathcal{D}| < \mathfrak{p} \leq \mathfrak{b}$ (and since the tree has only countably many nodes), there is $g : {}^{<\omega}\omega \to \omega$ that is $>^*$ all the f_D.

Using g, we define a path X through the tree ${}^{<\omega}\omega$ by starting at the root and, after reaching a node s, proceeding to $s^\frown\langle g(s)\rangle$. Our choice of g ensures that, for each $D \in \mathcal{D}$, all but finitely many nodes along the path X are good for D. Choose, for each D, a node s_D on X such that it and all later nodes on X are good for D, and let p_D be its secondary label associated to D. Thus $p_D \in D$. This guarantees that $L = \{p_D : D \in \mathcal{D}\}$ meets every $D \in \mathcal{D}$.

To complete the proof, we verify that L is linked. Consider any two elements $p_D, p_{D'} \in L$. If $s_D = s_{D'}$ then both of $p_D, p_{D'}$ are in the same C_n, where n is the primary label of s_D, so they are compatible because C_n is centered. Suppose therefore that s_D occurs before $s_{D'}$ along the path X. By choice of s_D, all the nodes along the path X from s_D to $s_{D'}$ are good for D, so the secondary labeling associated to D puts at the node $s_{D'}$ a label q that is $\leq p_D$. But, being in the same C_n, q and $p_{D'}$ are compatible. Therefore so are p_D and $p_{D'}$. ⊣

There is a similar (but easier) result about countable partial orders.

7.13 Theorem. $\mathfrak{m}(\text{Cohen}) = \mathfrak{m}(\text{countable}) = \mathbf{cov}(\mathcal{B})$.

Proof. Since Cohen forcing is a countable poset, MA_κ(countable) implies MA_κ(Cohen). We shall complete the proof by showing that MA_κ(Cohen) implies $\kappa < \mathbf{cov}(\mathcal{B})$ and that this in turn implies MA_κ(countable).

Assume MA_κ(Cohen) and let κ nowhere dense subsets X_α of ${}^\omega 2$ be given. We must show that the X_α do not cover ${}^\omega 2$. For each α, let D_α be the set of those $s \in {}^{<\omega}2$ that have no extensions in X_α. Because X_α is nowhere dense (in the topological sense), D_α is dense (in the partial order sense). So MA_κ(Cohen) gives us a generic $G \subseteq {}^\omega 2$ meeting every D_α. Then $\bigcup G \in {}^\omega 2$ is in none of the X_α.

Finally, assume $\kappa < \mathbf{cov}(\mathcal{B})$, and let κ dense subsets D_α of a countable poset P be given. Let $T : {}^\omega P \to {}^\omega P$ be the transformation that turns any sequence $x \in {}^\omega P$ into a (weakly) decreasing sequence $T(x)$ in a greedy way; that is, $T(x)(0) = x(0)$, and $T(x)(n+1) = x(n+1)$ if this is $\leq T(x)(n)$ in P, and otherwise $T(x)(n+1) = T(x)(n)$. We similarly define T on finite sequences instead of infinite ones.

The sets $U_\alpha = \{x \in {}^\omega P : \exists n\,(T(x)(n) \in D_\alpha)\}$ are dense open subsets of ${}^\omega P$ (where P has the discrete topology and ${}^\omega P$ has the product topology so it is homeomorphic to ${}^\omega\omega$). To verify density, consider any nonempty $s \in {}^{<\omega}P$, let p be the last term of $T(s)$, and let $q \leq p$ be in D_α. Then every extension of $s^\frown\langle q\rangle$ is in U_α.

As $\kappa < \mathbf{cov}(\mathcal{B})$, there is an x in the intersection of all the U_α. Then the range of the decreasing sequence $T(x)$ meets every D_α, and the upward closure of this range is therefore the desired generic set. ⊣

As an application of Bell's Theorem 7.12, we give an analog of Proposition 6.24, weakening the hypothesis of countability (of the list of C's) and strengthening the hypothesis of cardinality $< \mathfrak{d}$ (for $\mathcal{A}$) by replacing both with the hypothesis of cardinality $< \mathfrak{p}$.

7.14 Theorem. *Suppose $\mathcal{C}$ and $\mathcal{A}$ are families of $< \mathfrak{p}$ subsets of ω, and suppose every intersection of finitely many sets from $\mathcal{C}$ and one set from $\mathcal{A}$ is infinite. Then $\mathcal{C}$ has a pseudointersection B that has infinite intersection with each set in $\mathcal{A}$.*

Proof. Let P be Mathias forcing with respect to $\mathcal{C}$, as defined in the proof of Theorem 7.7 and the remark following it. As shown there, this is σ-centered, and for each $C \in \mathcal{C}$ the set $D_C = \{(s, F) \in P : C \in F\}$ is dense. Furthermore, for each $A \in \mathcal{A}$ and each $n \in \omega$, the set $D_{A,n} = \{(s, F) \in P : |s \cap A| > n\}$ is dense because each intersection of finitely many sets from $\mathcal{C}$ and one set from $\mathcal{A}$ is infinite.

As both $|\mathcal{C}|$ and $|\mathcal{A}|$ are $< \mathfrak{p} = \mathfrak{m}(\sigma\text{-centered})$, P has a generic subset G meeting all these D_C and $D_{A,n}$. As in the proof of Theorem 7.7, we define $B = \bigcup_{(s,F)\in G} s$ and we find that this is a pseudointersection of $\mathcal{C}$. Furthermore, it has infinite intersection with each $A \in \mathcal{A}$ because G meets each $D_{A,n}$. ⊣

As a consequence, we obtain that $\mathfrak{p}$, like its relatives $\mathfrak{t}$, $\mathfrak{h}$, and $\mathfrak{g}$, is regular, but the proof is trickier than for the relatives. This proof is taken from [48, Sect. 21], where it is attributed to Szymański.

7.15 Theorem. $\mathfrak{p}$ *is regular.*

Proof. Suppose $\mathfrak{p}$ were singular with cofinality $\lambda < \mathfrak{p}$. Let $\mathcal{A}$ be a family of $\mathfrak{p}$ subsets of ω having the strong finite intersection property but having no pseudointersection. Express $\mathcal{A}$ as the union of an increasing λ-sequence of subfamilies $\mathcal{A}_\alpha$, each of cardinality $< \mathfrak{p}$. To simplify later considerations, we assume without loss of generality that $\mathcal{A}$ and all the $\mathcal{A}_\alpha$ are closed under finite intersections.

In this situation, we have the following improvement of Theorem 7.14. If $\mathcal{C}$ is any family of fewer than $\mathfrak{p}$ sets such that every intersection of finitely many sets from $\mathcal{C}$ and one set from $\mathcal{A}$ is infinite, then $\mathcal{C}$ has a pseudointersection B whose intersection with each set from $\mathcal{A}$ is infinite. (The improvement is that $\mathcal{A}$ has size $\mathfrak{p}$ rather than strictly smaller size.) To prove this, note first that each $\mathcal{C} \cup \mathcal{A}_\alpha$ has the SFIP and has size $< \mathfrak{p}$, so it has a pseudointersection Z_α. Then apply Theorem 7.14 with $\{Z_\alpha : \alpha < \lambda\}$ in the role of $\mathcal{A}$.

We intend to build an almost decreasing $\lambda + 1$-sequence $\langle C_\alpha : \alpha \le \lambda \rangle$ such that each C_α for $\alpha < \lambda$ is a pseudointersection of $\mathcal{A}_\alpha$. If we can do this then, because the C_α are almost decreasing and the $\mathcal{A}_\alpha$ are increasing and cover $\mathcal{A}$, C_λ will be a pseudointersection of $\mathcal{A}$, a contradiction.

We define the C_α by recursion. To make the recursion work, we carry along the additional requirement that each C_α must have infinite intersection with every member of $\mathcal{A}$.

Suppose $\alpha \le \lambda$ and C_β is already defined for all $\beta < \alpha$ in such a way that our requirements are satisfied. We need to define C_α so that it is $\subseteq^*$ each previous C_β, it is $\subseteq^*$ each member of $\mathcal{A}_\alpha$, and it has infinite intersection with every member of $\mathcal{A}$. Such a set is produced by applying the improvement above of Theorem 7.14 with $\mathcal{C} = \{C_\beta : \beta < \alpha\} \cup \mathcal{A}_\alpha$, provided the hypothesis of that improvement is satisfied. So we need only check that every intersection X of finitely many C_β's ($\beta < \alpha$) and finitely many members of $\mathcal{A}_\alpha$ and one member of $\mathcal{A}$ is infinite. Since the C_β's are almost decreasing, since $\mathcal{A}_\alpha \subseteq \mathcal{A}$, and since $\mathcal{A}$ is closed under finite intersection, such an X almost includes $C_\beta \cap A$ for some $\beta < \alpha$ and some $A \in \mathcal{A}$. The induction hypothesis guarantees that $C_\beta \cap A$ and therefore X are infinite. ⊣

7.16 Remark. This section has dealt almost exclusively with forcing axioms for the class of c.c.c. posets and subclasses, because these are the forcing axioms most relevant to cardinal characteristics. To avoid giving a completely unbalanced picture, however, we should at least mention that numerous other forcing axioms have been considered. The most popular of these is the *Proper Forcing Axiom* PFA, which is $\mathrm{MA}_{\aleph_1}$(proper). Proper forcing was defined by Shelah [97, Chap. III], who showed that it permits countable support iterations without collapsing $\aleph_1$; see Abraham's chapter in this Handbook. PFA summarizes the result of a countable support iteration of all small proper posets. Unlike the construction of a model for MA, where the improvement from small c.c.c. posets to all c.c.c. posets was handled by a Löwenheim-Skolem argument, the construction of a model for PFA uses a supercompact cardinal in the ground model to get the necessary reflection property for the corresponding improvement from small to all.

8. Almost Disjoint and Independent Families

This section is devoted to families of subsets of ω with various special properties, and particularly to those families that are maximal with respect to these properties.

Recall from Sect. 6 that an almost disjoint family is a family of infinite sets whose pairwise intersections are finite, and that the phrase "maximal almost disjoint (MAD) family" refers to an *infinite* family of subsets of ω maximal with respect to almost disjointness.

Although a set of size κ clearly cannot support a family of more than κ disjoint sets, the situation for almost disjoint sets is quite different.

8.1 Proposition. *On any countably infinite set, there is a family of $\mathfrak{c}$ almost disjoint subsets.*

Proof. It clearly does not matter which countably infinite set we consider. Choosing the binary tree ${}^{<\omega}2$ as the ambient set, we can use its $\mathfrak{c}$ branches as the almost disjoint family. ⊣

8.2 Remark. There are at least two other similar and equally easy proofs of this proposition. One uses the set of rationals as the ambient set and assigns to every real r a sequence of distinct rationals converging to r; sequences with different limits are clearly almost disjoint. Another uses $\omega \times \omega$ as the ambient set and assigns to each positive real r the set $\{(n, \lfloor rn \rfloor) : n \in \omega\}$.

The proposition and Zorn's lemma imply the existence of a MAD family of cardinality $\mathfrak{c}$, but there may also be smaller MAD families. For example, it is shown in [68, Theorem VIII.2.3] that if one adds any number of Cohen reals to a model of CH, then the resulting model has a MAD family of size $\aleph_1$; see also Sect. 11. Hechler [55] gives a model with MAD families of many different cardinalities.

8.3 Definition. The *almost disjointness number* $\mathfrak{a}$ is the smallest cardinality of any MAD family.

8.4 Proposition. $\mathfrak{b} \leq \mathfrak{a}$.

Proof. Let $\mathcal{A}$ be a MAD family of size $\mathfrak{a}$, let C_n $(n \in \omega)$ be any countably many members of it, and let $\mathcal{A}'$ be the rest of $\mathcal{A}$. By making finite changes to each C_n, we can arrange that these sets are really disjoint, not just almost disjoint, and that they partition ω. By a suitable bijection, identify ω with $\omega \times \omega$ in such a way that C_n is the column $\{n\} \times \omega$. Each $A \in \mathcal{A}'$ has only finitely many elements per column, so we can define $f_A : \omega \to \omega$ to be the function whose graph is the upper boundary of A. If there were a function $g : \omega \to \omega$ that is $>^*$ all the f_A, then its graph would be almost disjoint from all $A \in \mathcal{A}'$ and all C_n, contrary to maximality of $\mathcal{A}$. So the f_A's constitute an unbounded family of size $\mathfrak{a}$. ⊣

Shelah [99] showed that $\mathfrak{b} < \mathfrak{a}$ is consistent. He also showed there that, if we define $\mathfrak{a}_s$ like $\mathfrak{a}$ except that we use $\omega \times \omega$ as the ambient set and require the MAD family to consist of graphs of partial functions, then $\mathfrak{a} < \mathfrak{a}_s$ is consistent. Brendle has pointed out the following alternative proof of the consistency of $\mathfrak{a} < \mathfrak{a}_s$. By part 2 of Theorem 5.9, we have $\mathbf{non}(\mathcal{B}) \leq \mathfrak{a}_s$. We shall see in Sect. 11 that the random real model (obtained by forcing with a large measure algebra over a model of GCH) has $\mathbf{non}(\mathcal{B}) = \mathfrak{c} > \aleph_1$ and $\mathfrak{a} = \aleph_1$. Therefore it has $\mathfrak{a} < \mathfrak{a}_s$.

Little else is known about connections between $\mathfrak{a}$ and other cardinal characteristics, but Shelah has shown in [100] that $\mathfrak{a} > \mathfrak{d}$ is consistent.

8.5 Remark. Proposition 8.1 can be used to evaluate the "dual" of $\mathfrak{h}$. Unlike the definitions of $\mathfrak{t}$ and $\mathfrak{p}$, that of $\mathfrak{h}$ fits the "norm of relation" format discussed in Sect. 4. Indeed, $\mathfrak{h} = \|([\omega]^\omega, \mathrm{DO}, \notin)\|$ where DO is the family of dense open subsets of $[\omega]^\omega$. (There is an important difference between this relation and those associated to cardinal characteristics in Sects. 4 and 5. The elements of DO cannot be coded by reals, nor does DO possess a nice base whose elements can be coded by reals.) It is natural to ask about the norm of the dual relation, i.e., the minimum size of a family $\mathcal{X} \subseteq [\omega]^\omega$ such that every dense open family $\mathcal{D}$ intersects $\mathcal{X}$. It follows from Proposition 8.1 that this cardinal is $\mathfrak{c}$. In fact, the same also holds for the dual of $\mathfrak{g}$, by nearly the same proof.

8.6 Theorem. *The minimum number of sets in $[\omega]^\omega$ meeting every dense open family, or even every groupwise dense family, is $\mathfrak{c}$.*

Proof. Suppose $\mathcal{X} \subseteq [\omega]^\omega$ has cardinality $< \mathfrak{c}$; we shall find a groupwise dense (hence dense open) $\mathcal{D} \subseteq [\omega]^\omega$ disjoint from $\mathcal{X}$. Let $\mathcal{D} = \{Y \in [\omega]^\omega : \forall X \in \mathcal{X}\ (X \not\subseteq^* Y)\}$. This $\mathcal{D}$ is clearly disjoint from $\mathcal{X}$ and closed under almost subsets, so we need only check that, for any interval partition $\{I_n : n \in \omega\}$, the union of some infinitely many of its intervals is in $\mathcal{D}$. Let $\mathcal{A}$ be a family of $\mathfrak{c}$ almost disjoint subsets of ω, and for each $A \in \mathcal{A}$ let $A' = \bigcup_{n \in A} I_n$. Then the A' are also almost disjoint, so no two of them can almost include the same $X \in \mathcal{X}$. Since there are more A''s than X's, some A' must not almost include any X, i.e., some A' must be in $\mathcal{D}$. ⊣

8.7 Corollary. $\mathrm{cf}(\mathfrak{c}) \geq \mathfrak{g}$.

Proof. Let $[\omega]^\omega = \bigcup_{\alpha < \mathrm{cf}(\mathfrak{c})} \mathcal{X}_\alpha$, where each $|\mathcal{X}_\alpha| < \mathfrak{c}$. By the theorem, there are groupwise dense families $\mathcal{D}_\alpha$ each disjoint from the corresponding $\mathcal{X}_\alpha$. No set can belong to all the $\mathcal{D}_\alpha$, for it would then belong to no $\mathcal{X}_\alpha$. So we have $\mathrm{cf}(\mathfrak{c})$ groupwise dense families with empty intersection. ⊣

Notice that this corollary subsumes Corollary 6.15. The intermediate result that $\mathrm{cf}(\mathfrak{c}) \geq \mathfrak{h}$ was proved in [2]. Among the familiar cardinal characteristics of the continuum, $\mathfrak{g}$ is the largest one known (to me) to be a lower bound for $\mathrm{cf}(\mathfrak{c})$. In particular, it is consistent that $\mathfrak{b} > \mathrm{cf}(\mathfrak{c})$ and it is consistent that $\mathfrak{s} > \mathrm{cf}(\mathfrak{c})$. For the former, start with a model satisfying MA and $\mathfrak{c} = \aleph_2$ and GCH at all larger cardinals, and adjoin $\aleph_{\aleph_1}$ random reals. Then $\mathfrak{c} = \aleph_{\aleph_1}$ and $\mathfrak{b}$, unaffected by the random reals, is $\aleph_2 > \mathrm{cf}(\mathfrak{c})$. For the latter, start with a model of $\mathfrak{c} = \aleph_{\aleph_1}$, and do an $\aleph_2$-stage, finite support iteration of Mathias forcing with respect to (arbitrarily chosen) ultrafilters. The finite support iteration automatically adds Cohen reals at limit stages of cofinality ω and choosing one of them at each stage provides a splitting family of size $\aleph_2$. There is no smaller splitting family, because any $\aleph_1$ reals lie in an intermediate extension and fail to split the subsequently added Mathias reals.

8.8 Definition. A family $\mathcal{I}$ of subsets of ω is *independent* if the intersection of any finitely many members of $\mathcal{I}$ and the complements of any finitely many other members of $\mathcal{I}$ is infinite.

The "infinite" at the end of the definition could be equivalently replaced with "nonempty" if we assumed that $\mathcal{I}$ is infinite.

8.9 Proposition. *There is an independent family of cardinality $\mathfrak{c}$.*

Proof. Let C be the set of finite subsets of $\mathbb{Q}$. Since C is countably infinite, it suffices to find $\mathfrak{c}$ independent subsets of C. For each real r, let

$$E_r = \{F \in C : |F \cap (-\infty, r)| \text{ is even}\}.$$

To see that these sets E_r are independent, let any finitely many distinct reals $r_1, \dots, r_k, s_1, \dots, s_l$ be given. We must find an $F \in C$ that belongs to all the E_{r_i} and none of the E_{s_j}. But this is easy; F consists of 0 or 1 rationals from each of the $(k+l+1)$ intervals into which the r's and s's partition $\mathbb{R}$, the choice of 0 or 1 being made so as to get the right parities. ⊣

8.10 Remark. The preceding proposition is due to Fichtenholz and Kantorovich [46]. It was generalized by Hausdorff [54] who showed that any infinite cardinal κ has 2^κ independent subsets.

Hausdorff's construction (for $\kappa = \aleph_0$) uses the countable set C of pairs (a, B) where a ranges over finite subsets of ω and B ranges over subsets of $\mathcal{P}(a)$. To each $X \subseteq \omega$ associate the subset $\{(a, B) \in C : a \cap X \in B\}$ of C. It is easy to verify that all these subsets are independent.

The corresponding generalization of Proposition 8.1 fails. Baumgartner [8, Theorem 5.6] showed that $\aleph_1$ need not have $2^{\aleph_1}$ uncountable subsets with pairwise countable intersections.

The proposition and Zorn's lemma provide a maximal independent family of size $\mathfrak{c}$, but there may be smaller maximal independent families.

8.11 Definition. The *independence number* $\mathfrak{i}$ is the smallest cardinality of any maximal independent family of subsets of ω.

No upper bounds (except for the trivial $\mathfrak{c}$) are known for $\mathfrak{i}$, but there are two lower bounds.

8.12 Proposition. $\mathfrak{r} \leq \mathfrak{i}$.

Proof. Let $\mathcal{I}$ be a maximal independent family, and let $\mathcal{R}$ consist of all the sets obtainable by intersecting finitely many sets from $\mathcal{I}$ and the complements of finitely many others. The definition of independence ensures that $\mathcal{R} \subseteq [\omega]^\omega$, and $\mathcal{R}$ must be unsplittable because if X were to split all its members then $\mathcal{I} \cup \{X\}$ would be independent, contrary to the maximality of $\mathcal{I}$. So $|\mathcal{R}| \geq \mathfrak{r}$, from which it follows that $|\mathcal{I}| \geq \mathfrak{r}$. ⊣

The following more difficult estimate of $\mathfrak{i}$ is due to Shelah [111, Appendix by Shelah]. The proof we give, a simplification of Shelah's, is from [20]; the simplification was found independently by Bill Weiss.

8.13 Theorem. $\mathfrak{d} \leq \mathfrak{i}$.

Proof. Suppose $\mathcal{I}$ is an independent family of cardinality $< \mathfrak{d}$; we shall show that it is not maximal. Throughout the proof, we let $\mathcal{X}$ and $\mathcal{Y}$ stand for finite, disjoint subfamilies of $\mathcal{I}$; thus, the independence of $\mathcal{I}$ means that $\bigcap \mathcal{X} - \bigcup \mathcal{Y}$ is always infinite, and our goal is to find Z such that each $\bigcap \mathcal{X} - \bigcup \mathcal{Y}$ meets both Z and $\omega - Z$ in an infinite set.

Select any countably many sets $D_n \in \mathcal{I}$, and let $\mathcal{I}'$ be the rest of $\mathcal{I}$. Write D_n^0 for D_n and write D_n^1 for $\omega - D_n$. For each $x : \omega \to 2$, apply Proposition 6.24 with

$$C_n = \bigcap\nolimits_{k<n} D_k^{x(k)}$$

and

$$\mathcal{A} = \left\{\bigcap\mathcal{X} - \bigcup\mathcal{Y} : \mathcal{X}, \mathcal{Y} \text{ finite disjoint subfamilies of } \mathcal{I}'\right\}.$$

Independence of $\mathcal{I}$ gives the hypotheses of the proposition. So we get $B_x \subseteq \omega$ with:

1. $B_x \subseteq^* \bigcap_{k<n} D_k^{x(k)}$ for all n.
2. B_x has infinite intersection with each $\bigcap\mathcal{X} - \bigcup\mathcal{Y} \in \mathcal{A}$.

It follows from 1 that the B_x's for distinct x are almost disjoint.

Fix two disjoint, countable, dense (in the usual topology) subsets Q and Q' of ${}^\omega 2$. Removing finitely many elements from B_x for each $x \in Q \cup Q'$, we can arrange that these countably many B_x's are really disjoint, not just almost disjoint. Set

$$Z = \bigcup_{x\in Q} B_x \quad \text{and} \quad Z' = \bigcup_{x\in Q'} B_x.$$

So Z and Z' are disjoint. We shall show that Z has infinite intersection with every $\bigcap\mathcal{X} - \bigcup\mathcal{Y}$; the same argument applies to Z', so $\omega - Z$ will also have infinite intersection with every $\bigcap\mathcal{X} - \bigcup\mathcal{Y}$, and so the proof will be complete.

Let finite, disjoint $\mathcal{X}, \mathcal{Y} \subseteq \mathcal{I}$ be given, and let $\mathcal{X}'$ and $\mathcal{Y}'$ be their intersections with $\mathcal{I}'$. Fix n so large that, if D_k is in $\mathcal{X}$ or $\mathcal{Y}$ then $k < n$. Using the density of Q, fix $x \in Q$ such that if D_k is in $\mathcal{X}$ or $\mathcal{Y}$ then $x(k)$ is 0 or 1, respectively. Thus,

$$\begin{aligned}
\bigcap\mathcal{X} - \bigcup\mathcal{Y} &= \left(\bigcap\mathcal{X}' - \bigcup\mathcal{Y}'\right) \cap \bigcap_{k:D_k\in\mathcal{X}\cup\mathcal{Y}} D_k^{x(k)} \\
&\supseteq \left(\bigcap\mathcal{X}' - \bigcup\mathcal{Y}'\right) \cap \bigcap_{k<n} D_k^{x(k)} \\
&\supseteq^* \left(\bigcap\mathcal{X}' - \bigcup\mathcal{Y}'\right) \cap B_x.
\end{aligned}$$

The last intersection here is infinite, by property 2 of B_x. It is included in Z because $x \in Q$. So we have an infinite set almost included in $Z \cap (\bigcap\mathcal{X} - \bigcup\mathcal{Y})$, and the proof is complete. ⊣

9. Filters and Ultrafilters

This section is devoted to filters and ultrafilters on ω. We begin by summarizing the terminology we use. Note that we require all filters to contain the cofinite sets, so all our ultrafilters are non-trivial.

9.1 Definition. A *filter* (on ω) is a family $\mathcal{F} \subseteq \mathcal{P}\omega$ that contains all cofinite sets but not the empty set, is closed under supersets, and is closed under finite intersections. An *ultrafilter* (on ω) is a filter with the additional property that, for any $X \subseteq \omega$, either X or its complement belongs to $\mathcal{F}$. A *base* for a filter $\mathcal{F}$ is a subfamily of $\mathcal{F}$ containing subsets of all the sets in $\mathcal{F}$.

We occasionally stretch the meaning of "base" of $\mathcal{F}$ to apply to a family $\mathcal{B}$ such that for every $F \in \mathcal{F}$ there is $B \in \mathcal{B}$ with $B \subseteq^* F$ (rather than $B \subseteq F$). This stretching will make no essential difference but will simplify a few statements.

We shall need the following well-known consequences of the definition. A subset $\mathcal{X}$ of $\mathcal{P}\omega$ is included in a filter if and only if it has the strong finite intersection property, and then the smallest filter including $\mathcal{X}$ consists of the almost supersets of intersections of finite subfamilies of $\mathcal{X}$. We say that $\mathcal{X}$ generates this filter.

An ultrafilter is the same thing as a maximal filter; thus by Zorn's lemma every family with SFIP is included in an ultrafilter. Since an ultrafilter contains a set $X \subseteq \omega$ if and only if it does not contain $\omega - X$, it follows that a family $\mathcal{Y} \subseteq \mathcal{P}\omega$ is disjoint from some ultrafilter if and only if no finitely many members of $\mathcal{Y}$ almost cover ω.

9.2 Definition. Let $\mathcal{F}$ be a subset of $\mathcal{P}\omega$ (usually a filter, but the definition makes sense in general) and let $f : \omega \to \omega$. Then $f(\mathcal{F})$ is defined to be $\{X \subseteq \omega : f^{-1}(X) \in \mathcal{F}\}$.

If $\mathcal{F}$ is a filter or an ultrafilter, then so is $f(\mathcal{F})$ provided it contains all cofinite sets. This proviso is automatically satisfied if f is finite-to-one, which will usually be the case in what follows.

9.3 Definition. A filter $\mathcal{F}$ is *feeble* if, for some finite-to-one $f : \omega \to \omega$, $f(\mathcal{F})$ consists of only the cofinite sets.

The cofinite sets constitute the smallest filter, so feeble filters should also be thought of as small. They are at the opposite extreme from ultrafilters.

9.4 Proposition. *The following are equivalent for any filter $\mathcal{F}$ on ω.*

1. *$\mathcal{F}$ is feeble.*
2. *There is a partition of ω into finite sets such that every set in $\mathcal{F}$ intersects all but finitely many pieces of the partition.*
3. *There is an interval partition as in 2 above.*
4. *$\{\omega - X : X \in \mathcal{F}\}$ is not groupwise dense.*
5. *$\mathcal{F}$ is meager (in the usual topology on $\mathcal{P}\omega \cong {}^{\omega}2$).*

Proof. The equivalence of 1 and 2 is immediate if one views the pieces of a partition (as in 2) as the sets on which a finite-to-one function (as in 1) is constant. If a partition Π is as in 2, then we can find an interval partition Θ, each of whose intervals includes at least one piece of Π; then Θ works in 3. The equivalence of 3 and 4 is just the definition of groupwise density. Finally, the equivalence of 4 and 5 follows from Proposition 6.27 because complementation ($X \mapsto \omega - X$) is a homeomorphism from $\mathcal{P}\omega$ to itself and thus preserves meagerness. $\dashv$

We next consider how many sets are needed to generate a large filter, where "large" can have a strong interpretation—ultrafilter—or a weak one—non-feeble filter. The former gives a new cardinal characteristic, while the latter gives a new view of an old characteristic. Notice that any infinite generating set for a filter yields a base of the same cardinality just by closing under finite intersections. So we can equivalently ask about cardinalities of bases.

We begin with a result similar to Propositions 8.1 and 8.9, namely that ultrafilter bases can be large. Of course, any ultrafilter is a base for itself and has cardinality $\mathfrak{c}$; the following proposition, due to Pospíšil [88], shows that for some ultrafilters there are no smaller bases.

9.5 Proposition. *There is an ultrafilter on ω every base of which has cardinality $\mathfrak{c}$.*

Proof. Let $\mathcal{I}$ be an independent family of size $\mathfrak{c}$, by Proposition 8.9, and let $\mathcal{X}$ consist of

- all sets in $\mathcal{I}$ and
- the complements of all sets of the form $\bigcap \mathcal{C}$ with $\mathcal{C}$ an infinite subset of $\mathcal{I}$.

The independence of $\mathcal{I}$ easily implies that $\mathcal{X}$ has the SFIP, so there is an ultrafilter $\mathcal{U} \supseteq \mathcal{X}$. Suppose, toward a contradiction, that $\mathcal{U}$ had a base $\mathcal{Y}$ of cardinality $< \mathfrak{c}$. As each set in $\mathcal{I}$ has a subset in $\mathcal{Y}$ and $|\mathcal{I}| > |\mathcal{Y}|$, there must be infinitely many sets in $\mathcal{I}$ all including the same $Y \in \mathcal{Y}$. Then the intersection of these infinitely many sets from $\mathcal{I}$ is in $\mathcal{U}$ (because it includes Y), but its complement is in $\mathcal{X}$ and thus also in $\mathcal{U}$. This contradiction completes the proof. ⊣

Nevertheless, it is consistent that some ultrafilters have bases of cardinality smaller than $\mathfrak{c}$.

9.6 Definition. $\mathfrak{u}$, sometimes called the *ultrafilter number*, is the minimum cardinality of any ultrafilter base.

Kunen [68, Chap. 8, Ex. A10] built a finite support iterated forcing model where $\mathfrak{c} = \aleph_{\aleph_1}$ but $\mathfrak{u} = \aleph_1$. Baumgartner and Laver [11] showed that an $\aleph_2$-step, countable support iteration of Sacks forcing (over a model of GCH) produces a model where certain ultrafilters in the ground model (the selective ones) generate ultrafilters in the extension. Thus, their model has $\mathfrak{u} = \aleph_1$ while $\mathfrak{c} = \aleph_2$.

An ultrafilter base is an unsplittable family, for if X were to split it then neither X nor $\omega - X$ could be in the ultrafilter it generates. Thus, we immediately have the following inequality.

9.7 Proposition. $\mathfrak{r} \leq \mathfrak{u}$.

In most known models, $\mathfrak{r} = \mathfrak{u}$, but Goldstern and Shelah [52] showed that the inequality can be strict. A stronger connection between $\mathfrak{r}$ and ultrafilters is given by the following result of Balcar and Simon [1].

9.8 Definition. A *pseudobase* or *π-base* for a filter $\mathcal{F}$ on ω is a family $\mathcal{X} \subseteq [\omega]^\omega$ such that every set in $\mathcal{F}$ has a subset in $\mathcal{X}$.

This differs from the notion of base only in that $\mathcal{X}$ need not be a subfamily of $\mathcal{F}$.

9.9 Proposition. *$\mathfrak{r}$ is the minimum cardinality of any ultrafilter pseudobase.*

Proof. A family $\mathcal{X} \subseteq [\omega]^\omega$ is an ultrafilter pseudobase if and only if there is an ultrafilter disjoint from

$$\mathcal{Y} = \{Y \subseteq \omega : Y \text{ has no subset in } \mathcal{X}\}.$$

As mentioned above, this is equivalent to saying that ω is not almost covered by finitely many sets from $\mathcal{Y}$. Equivalently, whenever ω is partitioned into finitely many pieces, one of the pieces must have an almost subset in $\mathcal{X}$. This means that $\mathcal{X}$ must be unsplittable, 3-unsplittable (in the sense of Example 4.13), ..., n-unsplittable for all finite n. On the one hand, mere unsplittability requires $\mathcal{X}$ to have cardinality at least $\mathfrak{r}$. On the other hand we can, as in Example 4.13, produce an n-unsplittable family of size $\mathfrak{r}$ for each n and then take the union of these families to obtain an $\mathcal{X}$ as above of size $\mathfrak{r}$. ⊣

We now consider what is needed to generate a non-feeble filter. The first part of the following theorem is essentially due to Solomon [103]; the second part is an unpublished result of Petr Simon.

9.10 Theorem. *Every filter on ω generated by fewer than $\mathfrak{b}$ sets is feeble, but there is a non-feeble filter generated by $\mathfrak{b}$ sets.*

Proof. Consider first a filter with a base of fewer than $\mathfrak{b}$ sets, and associate to each set A in this base an interval partition Π_A chosen so that each interval in the partition contains an element of A. By Theorem 2.10, there is a single interval partition dominating all these Π_A's. It clearly satisfies statement 3 in Proposition 9.4, so our filter is feeble.

To produce a non-feeble filter generated by $\mathfrak{b}$ sets, we distinguish two cases, according to whether $\mathfrak{b} = \mathfrak{d}$.

If $\mathfrak{b} = \mathfrak{d}$, invoke Theorem 2.10 to get a $\mathfrak{b}$-indexed family of interval partitions Π_α ($\alpha < \mathfrak{b}$) dominating all interval partitions. We build the desired filter and a generating family $\mathcal{X}$ for it by a recursion of length $\mathfrak{b}$, starting with the family of cofinite sets, and adding at most one new set to $\mathcal{X}$ at each stage. At stage α, see whether the filter $\mathcal{F}_\alpha$ generated by the sets already put into $\mathcal{X}$ contains a set disjoint from infinitely many intervals of Π_α. If so, do nothing at stage α. If not, put into $\mathcal{X}$ the union of the even-numbered intervals of Π_α, and note that the SFIP of $\mathcal{X}$ is preserved. In either case, our final filter will contain a set missing infinitely many intervals of Π_α. After all $\mathfrak{b}$ steps have been completed, we have a filter that is not feeble because any interval partition as in statement 3 of Proposition 9.4 could not be dominated by any Π_α.

There remains the case that $\mathfrak{b} < \mathfrak{d}$. Let $\mathcal{B}$ be an unbounded family of size $\mathfrak{b}$ in ${}^\omega\omega$; without loss of generality, assume it is closed under forming the pointwise maximum of two functions and assume each function $g \in \mathcal{B}$ is non-decreasing. Since $|\mathcal{B}| < \mathfrak{d}$, let $f \in {}^\omega\omega$ be non-decreasing and dominated by no member of $\mathcal{B}$. Thus, the sets

$$X_g = \{n \in \omega : g(n) < f(n)\} \quad (g \in \mathcal{B})$$

are infinite. The family $\{X_g : g \in \mathcal{B}\}$ is closed under finite intersections (because $\mathcal{B}$ is closed under maxima), so it is a base for a filter $\mathcal{F}$. To complete the proof, we suppose that $\mathcal{F}$ is feeble and we deduce a contradiction.

Suppose therefore that $\{I_n : n \in \omega\}$ is an interval partition such that each set in $\mathcal{F}$ meets all but finitely many I_n's. Define $f' : \omega \to \omega$ by letting $f'(k)$ be the value of f at the right endpoint of the next I_n after the one containing k. Consider an arbitrary $g \in \mathcal{B}$ and a k so large that X_g, being in $\mathcal{F}$, meets the next interval I_n after the one containing k. Calling that interval $[a, b]$ and letting c be in its intersection with X_g, we have, since f and g are non-decreasing,

$$g(k) \le g(c) < f(c) \le f(b) = f'(k).$$

Thus, $g <^* f'$; since g was an arbitrary element of $\mathcal{B}$, we have a contradiction to the fact that $\mathcal{B}$ is unbounded. ⊣

9.11 Remark. The first part of the preceding proof actually shows that a filter with a pseudobase of size $< \mathfrak{b}$ must be feeble.

It is easy to see that every filter $\mathcal{F}$ is the intersection of some ultrafilters, in fact of at most $\mathfrak{c}$ ultrafilters. Indeed, for each $A \in \mathcal{P}\omega - \mathcal{F}$, the family $\mathcal{F} \cup \{\omega - A\}$ has the SFIP and is therefore included in an ultrafilter $\mathcal{U}_A$. The intersection of these $\mathcal{U}_A$'s is $\mathcal{F}$.

The next two propositions contain information about how many ultrafilters must be intersected in order to get filters that are small in one or another sense. The first one, due to Plewik [87], is another application of Proposition 8.1.

9.12 Proposition. *The intersection of fewer than $\mathfrak{c}$ ultrafilters is not feeble.*

Proof. Suppose the feeble filter $\mathcal{F}$ is the intersection of ultrafilters $\mathcal{U}_\alpha$. Let f be a finite-to-one function such that $f(\mathcal{F})$ consists only of the cofinite sets. Let $\mathcal{A}$ be a family of $\mathfrak{c}$ almost disjoint subsets of ω. For each $A \in \mathcal{A}$, we have $\omega - A \notin f(\mathcal{F})$ (as A is infinite), so $\omega - f^{-1}(A) = f^{-1}(\omega - A) \notin \mathcal{F}$, so $\omega - f^{-1}(A) \notin \mathcal{U}_\alpha$ for at least one α, and so $f^{-1}(A) \in \mathcal{U}_\alpha$. But the sets

$f^{-1}(A)$ are almost disjoint because f is finite-to-one. So no two can be in the same $\mathcal{U}_\alpha$. Therefore there must be at least as many $\mathcal{U}_\alpha$'s as there are A's, namely $\mathfrak{c}$. ⊣

9.13 Proposition. *There are $\mathfrak{d}$ ultrafilters whose intersection is not sent to an ultrafilter by any finite-to-one function.*

Proof. By Theorem 2.10, choose a family of $\mathfrak{d}$ interval partitions dominating all interval partitions, and associate to each $\Pi = \{I_n : n \in \omega\}$ in this family two ultrafilters $\mathcal{U}_\Pi$ and $\mathcal{V}_\Pi$ such that one contains $A_\Pi = \bigcup_n I_{8n}$ and the other contains $B_\Pi = \bigcup_n I_{8n+4}$. We shall show that the $\mathfrak{d}$ ultrafilters $\mathcal{U}_\Pi$ and $\mathcal{V}_\Pi$ are as required.

Suppose, to the contrary, that their intersection $\mathcal{F}$ is mapped to an ultrafilter by a finite-to-one map f. Let Θ be an interval partition such that each of the finite fibers $f^{-1}(\{n\})$ is included in the union of two adjacent intervals of Θ. (Simply build Θ inductively so that the right end of each interval is greater than all elements of all fibers whose left ends were in the previous interval.) Let Π be an interval partition in our originally chosen family that dominates Θ. Then each interval of Θ, except for finitely many, is included in the union of two consecutive intervals of Π. It follows that each fiber of f, except for finitely many, is covered by four consecutive intervals of Π and therefore cannot meet both A_Π and B_Π. So $f(A_\Pi)$ and $f(B_\Pi)$ are almost disjoint and $f(\mathcal{F})$, being an ultrafilter, must contain the complement of one of them, say $\omega - f(A_\Pi)$. But then this complement would be in $f(\mathcal{U}_\Pi)$, which is absurd as $A_\Pi \in \mathcal{U}_\Pi$. ⊣

We shall next present some consequences of the inequality $\mathfrak{u} < \mathfrak{g}$. This inequality was introduced in [23] (where $\mathfrak{g}$ was first defined) as a “black box” summary of the crucial properties of the models, due to Shelah [25, 26], in which every two ultrafilters have a common finite-to-one image. Since then, numerous additional consequences and reformulations of $\mathfrak{u} < \mathfrak{g}$ have been found, and we present some of them here.

9.14 Definition. For any family $\mathcal{F} \subseteq [\omega]^\omega$, we write $\sim\!\mathcal{F}$ for its complement and $\mathcal{F}\!\sim$ for the family of complements of its members.

$$\sim\!\mathcal{F} = [\omega]^\omega - \mathcal{F} \quad \text{and} \quad \mathcal{F}\!\sim = \{\omega - X : X \in \mathcal{F}\}.$$

We write $\breve{\mathcal{F}}$ for the dual family $\sim\!\mathcal{F}\!\sim = \{X \in [\omega]^\omega : \omega - X \notin \mathcal{F}\}$.

If $\mathcal{F}$ is closed under supersets then $\breve{\mathcal{F}}$ consists of just those $X \in [\omega]^\omega$ that intersect every member of $\mathcal{F}$. If $\mathcal{F}$ is a filter then $\mathcal{F} \subseteq \breve{\mathcal{F}}$, with equality holding exactly when $\mathcal{F}$ is an ultrafilter.

9.15 Lemma. *Suppose that $\mathcal{X}, \mathcal{Y} \subseteq [\omega]^\omega$, that $|\mathcal{X}| < \mathfrak{g}$, and that $\mathcal{Y}\!\sim$ is groupwise dense. Then there is a finite-to-one $f : \omega \to \omega$ such that*

$$\forall X \in \mathcal{X}\, \exists Y \in \mathcal{Y}\ (f(Y) \subseteq f(X)).$$

Proof. For each $X \in \mathcal{X}$ define

$$\mathcal{G}_X = \{Z \in [\omega]^\omega : \exists Y \in \mathcal{Y}\, \forall a, b \in Z \text{ (if } [a,b) \cap Y \neq \emptyset \text{ then } [a,b) \cap X \neq \emptyset)\}.$$

We verify that $\mathcal{G}_X$ is groupwise dense. $\mathcal{G}_X$ is clearly closed under subsets, and it is closed under finite modifications because $\mathcal{Y}$ is. Now suppose Π is any interval partition. Coarsening it, we may assume that each of its intervals contains an element of X. As $\mathcal{Y}\!\sim$ is groupwise dense, it contains a union of infinitely many intervals of Π. Call that union Z, and call its complement, which is in $\mathcal{Y}$, Y. We show that $Z \in \mathcal{G}_X$, witnessed by Y. Suppose $a < b$ are in Z and there is an element of Y in $[a, b)$. That means that a whole interval of Π must lie between a and b, and that interval contains a member of X. This completes the proof that $\mathcal{G}_X$ is groupwise dense.

Since there are fewer than $\mathfrak{g}$ X's in $\mathcal{X}$, there is a Z common to all the $\mathcal{G}_X$'s. Fix such a Z and define $f : \omega \to \omega$ by letting $f(n)$ be the number of elements of Z that are $\leq n$. Thus f is finite-to-one, being constant on the intervals $[a, b)$ where $a < b$ are consecutive in Z. For each $X \in \mathcal{X}$, the fact that $Z \in \mathcal{G}_X$ implies that there is $Y \in \mathcal{Y}$ with $f(Y) \subseteq f(X)$, as required. $\dashv$

9.16 Theorem. *Assume* $\mathfrak{u} < \mathfrak{g}$*. For any filter* $\mathcal{F}$ *on* ω *either* $\mathcal{F}$ *is feeble or there is a finite-to-one* f *such that* $f(\mathcal{F})$ *is an ultrafilter.*

Proof. Apply the lemma with $\mathcal{X}$ being an ultrafilter base of cardinality $< \mathfrak{g}$ and $\mathcal{Y}$ being $\mathcal{F}$. If $\mathcal{F}$ is not feeble, then $\mathcal{Y}\!\sim$ is groupwise dense by Proposition 9.4, so the lemma provides a finite-to-one f such that $f(X) \in f(\mathcal{F})$ for all $X \in \mathcal{X}$ and therefore for all X in the ultrafilter $\mathcal{U}$ generated by $\mathcal{X}$. Thus, the ultrafilter $f(\mathcal{U})$ is included in the filter $f(\mathcal{F})$. Since ultrafilters are maximal filters, the inclusion cannot be proper, and $f(\mathcal{F})$ is an ultrafilter. $\dashv$

9.17 Remark. The conclusion of this theorem is called the principle of *filter dichotomy*. It is not known whether it implies $\mathfrak{u} < \mathfrak{g}$.

The hypothesis of the theorem can be replaced by the apparently weaker $\mathfrak{r} < \mathfrak{g}$. Indeed, if $\mathcal{X}$ is not an ultrafilter base but merely unsplittable, the proof above provides a finite-to-one f such that $f(\mathcal{F})$ is also unsplittable. But an unsplittable filter is an ultrafilter.

The improvement is, however, illusory, for Mildenberger has shown that the inequalities $\mathfrak{u} < \mathfrak{g}$ and $\mathfrak{r} < \mathfrak{g}$ are equivalent. In fact, she proved $\mathfrak{r} \geq \min\{\mathfrak{u}, \mathfrak{g}\}$.

9.18 Corollary. *Assume* $\mathfrak{u} < \mathfrak{g}$ *(or just filter dichotomy). For every two ultrafilters* $\mathcal{U}$ *and* $\mathcal{V}$ *on* ω*, there is a finite-to-one function* f *with* $f(\mathcal{U}) = f(\mathcal{V})$*.*

Proof. Apply filter dichotomy to the filter $\mathcal{U} \cap \mathcal{V}$. It is not feeble, and any f that maps it to an ultrafilter must map both $\mathcal{U}$ and $\mathcal{V}$ to the same ultrafilter. $\dashv$

9.19 Remark. The conclusion of this corollary is called the principle of *near coherence of filters* (NCF). The name refers to the easily equivalent formulation: For any two filters $\mathcal{F}$ and $\mathcal{G}$ on ω, there is a finite-to-one function f such that $f(\mathcal{F})$ and $f(\mathcal{G})$ are coherent in the sense that their union generates a filter.

NCF implies $\mathfrak{u} < \mathfrak{d}$, but it is not known whether it implies $\mathfrak{u} < \mathfrak{g}$ or even filter dichotomy.

Corollary 9.18 can be improved to handle not just two ultrafilters but any number $< \mathfrak{c}$, by essentially the same proof, using Proposition 9.12 to ensure that the intersection filter is not feeble. NCF alone implies the improvement to $< \mathfrak{d}$ ultrafilters. It is also equivalent to the statement that every ultrafilter has a finite-to-one image that is generated by $< \mathfrak{d}$ sets. See [15] for these results and more information on NCF.

9.20 Corollary. *If* $\mathfrak{u} < \mathfrak{g}$ *(or just filter dichotomy) then* $\mathfrak{b} = \mathfrak{u}$ *and* $\mathfrak{d} = \mathfrak{c}$.

Proof. Without any hypothesis, we have $\mathfrak{b} \leq \mathfrak{r} \leq \mathfrak{u}$ and $\mathfrak{d} \leq \mathfrak{c}$. If we assume filter dichotomy then Proposition 9.13 provides a feeble filter that is the intersection of $\mathfrak{d}$ ultrafilters, and then Proposition 9.12 says that $\mathfrak{d} \geq \mathfrak{c}$.

Theorem 9.10 gives a non-feeble filter with a basis of $\mathfrak{b}$ sets. By filter dichotomy, some image of this filter, which also has a basis of $\mathfrak{b}$ sets (the images of the sets in the previous basis), is an ultrafilter. So $\mathfrak{u} \leq \mathfrak{b}$. $\dashv$

9.21 Remark. The conclusion $\mathfrak{d} = \mathfrak{c}$ can be strengthened to $\mathfrak{g} = \mathfrak{c}$ under the hypothesis $\mathfrak{u} < \mathfrak{g}$; see [19].

The following result of Laflamme [70] extends the preceding dichotomy to a trichotomy for all upward-closed families. Its conclusion is in fact equivalent to $\mathfrak{u} < \mathfrak{g}$ but we omit the proof of this; see [19].

9.22 Theorem. *Assume* $\mathfrak{u} < \mathfrak{g}$. *For any family* $\mathcal{Y} \subseteq [\omega]^\omega$ *that is closed under almost supersets, there is a finite-to-one* $f : \omega \to \omega$ *such that one of the following holds:*

- $f(\mathcal{Y})$ *contains only cofinite sets.*
- $f(\mathcal{Y}) = [\omega]^\omega$.
- $f(\mathcal{Y})$ *is an ultrafilter.*

Proof. Let $\mathcal{Y}$ be as in the theorem and let $\mathcal{X}$ be an ultrafilter base of cardinality $< \mathfrak{g}$. If $\mathcal{Y}\sim$ is not groupwise dense, then we have (by definition of groupwise dense) the first alternative in the theorem, and if $\sim\mathcal{Y}$ is not groupwise dense, then we have the second alternative. So we assume that both $\mathcal{Y}\sim$ and $\sim\mathcal{Y} = \breve{\mathcal{Y}}\sim$ are groupwise dense. The former lets us apply Lemma 9.15 to obtain a finite-to-one g such that each $g(X)$ with $X \in \mathcal{X}$ includes some $g(Y)$ with $Y \in \mathcal{Y}$. If $\mathcal{U}$ is the ultrafilter with base $\mathcal{X}$, then we have that $g(\mathcal{U}) \subseteq g(\mathcal{Y})$. Since finite-to-one images preserve groupwise density and commute with complementation, we also have that $g(\breve{\mathcal{Y}})\sim$ is groupwise dense, so we can apply the lemma with the base $\{g(X) : X \in \mathcal{X}\}$ of $g(\mathcal{U})$ in the role of $\mathcal{X}$ and with $g(\breve{\mathcal{Y}})$ in the role of $\mathcal{Y}$. We obtain a finite-to-one h such that $hg(\mathcal{U}) \subseteq hg(\breve{\mathcal{Y}}) = (hg(\mathcal{Y}))\breve{}$. Since dualization $(\breve{\ })$ reverses inclusions and fixes ultrafilters, we get $hg(\mathcal{U}) \supseteq hg(\mathcal{Y})$. The reverse inequality follows from $g(\mathcal{U}) \subseteq g(\mathcal{Y})$. So the finite-to-one map hg sends $\mathcal{Y}$ to an ultrafilter. $\dashv$

We conclude this section with a brief discussion of some special sorts of ultrafilters. The theory of these ultrafilters is quite extensive, but we shall consider only those aspects that directly involve some of the cardinal characteristics defined earlier.

9.23 Definition. An ultrafilter $\mathcal{U}$ on ω is *selective* if every function $f : \omega \to \omega$ becomes either one-to-one or constant when restricted to some set in $\mathcal{U}$. It is a *P-point ultrafilter* if every function $f : \omega \to \omega$ becomes either finite-to-one or constant when restricted to some set in $\mathcal{U}$. It is a *Q-point* if every finite-to-one function $f : \omega \to \omega$ becomes one-to-one when restricted to some set in $\mathcal{U}$.

9.24 Remark. Clearly, an ultrafilter is selective if and only if it is both a P-point and a Q-point.

The name "selective" refers to the fact that, when ω is partitioned into pieces that are not in $\mathcal{U}$ then some set in $\mathcal{U}$ selects one element per piece. Selective ultrafilters are also called Ramsey ultrafilters because Kunen showed (see [28]) that, if $\mathcal{U}$ is selective and $f : [\omega]^k \to 2$, then some set in $\mathcal{U}$ is homogeneous for f. Thus, any pseudobase for a selective ultrafilter must have cardinality at least $\mathfrak{hom} = \max\{\mathfrak{r}_\sigma, \mathfrak{d}\}$. Selective ultrafilters are also called RK-minimal, for they are minimal in the Rudin-Keisler ordering defined by putting $f(\mathcal{U}) \leq \mathcal{U}$ for all ultrafilters $\mathcal{U}$ and all mappings f.

An ultrafilter $\mathcal{U}$ is a P-point if and only if every decreasing (or almost-decreasing) ω-sequence of sets from $\mathcal{U}$ has a pseudo-intersection in $\mathcal{U}$. To prove the equivalence of this with the definition above, just arrange that $f(n)$ is constant exactly on the differences of consecutive sets in the decreasing sequence. (One can assume without loss of generality that the sequence begins with ω and that its intersection is empty.) There is a general topological concept of P-point (see for example [95, 50]), namely a point (in a topological space) such that every countable intersection of open neighborhoods of it includes another open neighborhood of it. When applied to the topological space $\beta\omega - \omega$, the Stone-Čech remainder of the discrete space ω, whose points are naturally identified with (non-trivial) ultrafilters on ω, this topological notion becomes the concept defined above. The "P" in "P-point" refers to prime ideals (in rings of functions); see [50, Exercises 4J and 4L].

The "Q" in "Q-point" was chosen because it is next to "P" in the alphabet. Q-points are also called rare ultrafilters.

There are ultrafilters that are neither P-points nor Q-points. Indeed, if $\mathcal{U}$ is any ultrafilter on ω then

$$\mathcal{V} = \{X \subseteq \omega^2 : \{a : \{b : \langle a, b\rangle \in X\} \in \mathcal{U}\} \in \mathcal{U}\}$$

is an ultrafilter on ω^2. It is not a P-point because the first projection $\omega^2 \to \omega$ is neither finite-to-one nor constant on any set in $\mathcal{V}$. It is not a Q-point because the second projection is finite-to-one on a set in $\mathcal{V}$, namely $\{\langle a, b\rangle : a < b\}$, but not one-to-one on any set in $\mathcal{V}$.

The existence of P-points, Q-points, and selective ultrafilters is more problematic. W. Rudin [95] showed that implies the existence of P-points, and other existence results followed, with the hypothesis weakened to MA or even to $\mathfrak{p} = \mathfrak{c}$ once these axioms had been formulated; see for example [28, 13, 14, 75, 94].

But some hypotheses beyond ZFC are needed for such existence results. Kunen [67] showed that adding $\aleph_2$ random reals to a model of GCH produces a model with no selective ultrafilters. Miller [79] showed that an $\aleph_2$-step, countable support iteration of Laver forcing over a model of GCH produces a model with no Q-points. And Shelah [97, Sect. VI.4], [113] produced a model with no P-points by iterating a product of Grigorieff forcings.

We shall be concerned here with conditions for the existence of these special ultrafilters. It turns out that cardinal characteristics can be used to give necessary and sufficient conditions for the extendibility, to special ultrafilters, of all filters with sufficiently small bases. Thus, they provide sufficient, though not necessary, conditions for the mere existence of special ultrafilters. The first result of this sort is due to Ketonen [66], who showed that $\mathfrak{c} = \mathfrak{d}$ implies the existence of P-points, by a proof that essentially gives the following result.

9.25 Theorem.

1. *If $\mathfrak{c} = \mathfrak{d}$ then every filter generated by fewer than $\mathfrak{c}$ sets is included in some P-point.*
2. *There is a filter generated by $\mathfrak{d}$ sets that is not included in any P-point.*
3. *Every ultrafilter generated by fewer than $\mathfrak{d}$ sets is a P-point.*

Proof. For part 1, assume $\mathfrak{c} = \mathfrak{d}$, let $\mathcal{F}$ be a filter generated by fewer than $\mathfrak{c}$ sets, and let $\langle S^\alpha : \alpha < \mathfrak{c}\rangle$ be an enumeration of all decreasing ω-sequences of infinite subsets of ω, $S^\alpha = \langle S^\alpha_0 \supseteq S^\alpha_1 \supseteq \cdots\rangle$. We shall define an increasing sequence of filters $\langle \mathcal{F}^\alpha : \alpha \le \mathfrak{c}\rangle$, starting with $\mathcal{F}^0 = \mathcal{F}$, taking unions at limit stages, and at successor stages adding one new generator to the filter in such a way that either the new generator is a pseudointersection of S^α or it is the complement of some S^α_n. Of course, we must make sure that the newly added generator at stage $\alpha + 1$ has infinite intersection with every set in $\mathcal{F}^\alpha$, so that $\mathcal{F}^{\alpha+1}$ will be a filter. But this is not difficult. If, for some n, $S^\alpha_n \notin \mathcal{F}^\alpha$, then $\omega - S^\alpha_n$ can be added. If, on the other hand, $S^\alpha_n \in \mathcal{F}^\alpha$ for all n, then, because $\mathcal{F}^\alpha$ is generated by fewer than $\mathfrak{d}$ sets, Proposition 6.24 provides a pseudointersection of S^α that has infinite intersection with every finite intersection of the generators of $\mathcal{F}^\alpha$ and hence with every set in $\mathcal{F}^\alpha$. That pseudointersection can serve as the new generator for $\mathcal{F}^{\alpha+1}$. Thus, the construction of the sequence of filters can be carried out, and it clearly ensures that any ultrafilter extending $\mathcal{F}^{\mathfrak{c}}$ is a P-point.

For part 2, consider the filter on ω^2 generated by the sets $\{\langle a,b\rangle : a \geq n\}$ for $n \in \omega$ and the sets $\{\langle a,b\rangle : b > f(a)\}$ for f in a dominating family $\mathcal{D} \subseteq {}^{\omega}\omega$ of cardinality $\mathfrak{d}$. An ultrafilter extending this filter cannot be a P-point, for any set on which the first projection $\omega^2 \to \omega$ is constant or finite-to-one is disjoint from a set in the filter and is therefore not in the ultrafilter.

For part 3, let $\mathcal{U}$ be an ultrafilter generated by fewer than $\mathfrak{d}$ sets and let $S = \langle S_n \rangle$ be a decreasing sequence of sets from $\mathcal{U}$. As in the proof of part 1, Proposition 6.24 provides a pseudointersection of S that meets every finite intersection of generators of $\mathcal{U}$. But as $\mathcal{U}$ is an ultrafilter, it follows that this pseudointersection is in $\mathcal{U}$. ⊣

Canjar [37] proved the following analogous result for selective ultrafilters. It was also found independently by Bartoszyński and Judah; see [5, Sect. 4.5.B].

9.26 Theorem.

1. *If* $\mathfrak{c} = \mathbf{cov}(\mathcal{B})$ *then every filter generated by fewer than* $\mathfrak{c}$ *sets is included in some selective ultrafilter.*

2. *There is a filter generated by* $\mathbf{cov}(\mathcal{B})$ *sets that is not included in any selective ultrafilter.*

Proof. For part 1, we proceed as in the corresponding proof for P-points, using an enumeration $\langle f^\alpha : \alpha < \mathfrak{c}\rangle$ of ${}^{\omega}\omega$ in place of the enumeration of decreasing sequences S^α. At stage α we have a filter $\mathcal{F}^\alpha$ with a basis $\mathcal{X}$ of fewer than $\mathbf{cov}(\mathcal{B})$ sets and we wish to form $\mathcal{F}^{\alpha+1}$ by adding one new generator, a set on which f^α is one-to-one or constant. If some set of the form $(f^\alpha)^{-1}(\{n\})$ (on which f is constant) has infinite intersection with every set in $\mathcal{F}^\alpha$, then it can serve as the new generator. So from now on we assume that this is not the case. We intend to find a "selector" $g \in \prod_{n\in R}(f^\alpha)^{-1}(\{n\})$, where $R = \mathrm{ran}(f^\alpha)$, such that for each set X in the basis $\mathcal{X}$ of $\mathcal{F}^\alpha$ we have $\exists^\infty n\,(g(n) \in X)$. Once we have such a g, its range can clearly serve as the new generator for $\mathcal{F}^{\alpha+1}$. To obtain g, notice first that the space $\prod_{n\in R}(f^\alpha)^{-1}(\{n\})$ from which we want to choose it is a product of countable (possibly finite) discrete sets, so it is not covered by fewer than $\mathbf{cov}(\mathcal{B})$ meager sets. But for each $X \in \mathcal{X}$, those g that fail to have infinitely many values in X form a meager set. So, since $|\mathcal{X}| < \mathbf{cov}(\mathcal{B})$, the desired g exists.

Part 2 is immediate from part 2 of the preceding theorem if $\mathbf{cov}(\mathcal{B}) = \mathfrak{d}$, so we may assume for the rest of the proof that $\mathbf{cov}(\mathcal{B}) < \mathfrak{d}$ (recall Proposition 5.5). By Theorem 5.2, fix a family of $\mathbf{cov}(\mathcal{B})$ chopped reals (x_α, Π_α) such that no single real matches them all. Assume without loss of generality that every finitely many of these chopped reals are engulfed by another chopped real from the chosen family, i.e., the family is directed upward with respect to the engulfing relation. Since we are assuming $\mathbf{cov}(\mathcal{B}) < \mathfrak{d}$, there is an interval partition $\Theta = \{J_n : n \in \omega\}$ not dominated by any of the Π_α. This implies that each Π_α has infinitely many intervals I_k that do not include any interval of Θ; such an I_k is covered by $J_n \cup J_{n+1}$ for some n.

Let Z be the set of functions z whose domains are unions of two consecutive intervals of Θ and whose values are 0's and 1's. For $z \in Z$, let $p(z)$ be the n such that $\mathrm{dom}(z) = J_n \cup J_{n+1}$. Thus, $p : Z \to \omega$ is finite-to-one. Let $\mathcal{F}$ be the filter on Z generated by the sets $\{z \in Z : p(z) > n\}$ for all $n \in \omega$ and the sets

$$A_\alpha = \{z \in Z : \exists I \in \Pi_\alpha\, (I \subseteq \mathrm{dom}(z) \text{ and } z{\restriction}I = x_\alpha{\restriction}I)\}$$

for all α. We must check that these sets have the SFIP, so consider any finitely many of them. We may assume only one of them is of the form $\{z \in Z : p(z) > n\}$; if there are more, keep only the one with the largest n as it is a subset of the others. Thanks to our assumption that any finitely many (x_α, Π_α) are engulfed by another, we may also assume that only one A_α is involved, for if (x_β, Π_β) engulfs certain (x_α, Π_α)'s, then the corresponding A_β is almost included in the corresponding A_α's. So our task is simply to check that each A_α contains z's with arbitrarily large $p(z)$. But this follows immediately from the fact that infinitely many intervals of Π_α are included in sets of the form $J_n \cup J_{n+1}$.

So $\mathcal{F}$ is a filter generated by $\mathbf{cov}(\mathcal{B})$ sets. Let $\mathcal{U}$ be any ultrafilter extending $\mathcal{F}$. p is a finite-to-one function, so it is certainly not constant on any set in $\mathcal{U}$. Suppose it were one-to-one on some set $X \in \mathcal{U}$. One of $X_0 = \{x \in X : p(x) \text{ even}\}$ and $X_1 = \{x \in X : p(x) \text{ odd}\}$ is in $\mathcal{U}$; say it is X_i. Then the union g of all the members of X_i is a partial function from ω to 2 such that each Π_α contains infinitely many intervals on which g agrees with x_α (because X_i meets all sets in $\mathcal{F}$). Any extension of g to a total function $\omega \to 2$ therefore matches all the (x_α, Π_α), contrary to our choice of these chopped reals. So p is not one-to-one on any set in $\mathcal{U}$. ⊣

By analogy with part 3 of Theorem 9.25, one might expect Theorem 9.26 to assert that every ultrafilter generated by fewer then $\mathbf{cov}(\mathcal{B})$ sets is selective. Though true, that assertion is vacuous, since Theorem 5.19 and Proposition 9.7 give $\mathbf{cov}(\mathcal{B}) \leq \mathfrak{r} \leq \mathfrak{u}$.

Canjar [37] also obtained an analogous result for Q-points.

9.27 Theorem.

1. *If* $\mathbf{cov}(\mathcal{B}) = \mathfrak{d}$ *then every filter generated by fewer than* $\mathfrak{d}$ *sets can be extended to a Q-point.*

2. *If* $\mathbf{cov}(\mathcal{B}) < \mathfrak{d}$ *then there is a filter generated by* $\mathbf{cov}(\mathcal{B})$ *sets that is not included in any Q-point.*

The proof of Theorem 9.26 also establishes part 2 of the present theorem, and part 1 is established similarly to parts 1 of Theorems 9.25 and 9.26.

10. Evasion and Prediction

The terminology of prediction and evasion and the evasion number $\mathfrak{e}$ were introduced in [21] on the basis of motivation from algebra. Since then, several variants have been studied, particularly in [30, 33], but we begin with the original version.

10.1 Definition. A *predictor* is a pair $\pi = (D, \langle \pi_n : n \in D \rangle)$ where $D \in [\omega]^\omega$ and where each $\pi_n : {}^n\omega \to \omega$. This predictor π *predicts* a function $x \in {}^\omega\omega$ if, for all but finitely many $n \in D$, $\pi_n(x \restriction n) = x(n)$. Otherwise, x *evades* π. The *evasion number* $\mathfrak{e}$ is the smallest cardinality of any family $\mathcal{E} \subseteq {}^\omega\omega$ such that no single predictor predicts all members of $\mathcal{E}$.

We may identify a predictor $(D, \langle \pi_n : n \in D \rangle)$ with $\bigcup_{n \in D} \pi_n$, a partial function from ${}^{<\omega}\omega$ to ω.

The idea behind the definition is that the values $x(n)$ of an unknown $x \in {}^\omega\omega$ are being revealed one at a time (in order) and we are trying to guess some of these values just before they are revealed. A predictor $(D, \langle \pi_n : n \in D \rangle)$ is a strategy for guessing $x(n)$, for each $n \in D$, after we have seen $x \restriction n$, and it predicts x if it is successful in the sense that almost all of its guesses about x are correct.

Clearly, it would make no difference if we defined predictors with $\pi_n : {}^nC \to C$ and used them to predict functions in ${}^\omega C$ for any countably infinite set C.

What was directly relevant to the algebraic subject of [21] was not $\mathfrak{e}$ but a variant, the *linear evasion number* $\mathfrak{e}_l$, whose definition is similar except that the components of a predictor are *linear* functions $\pi_n : \mathbb{Z}^n \to \mathbb{Q}$ and the functions being predicted are in ${}^\omega\mathbb{Z}$. Thus a remnant of algebra (linearity) was mixed with the combinatorics. Fortunately, it is proved in [33] that $\mathfrak{e}_l = \min\{\mathfrak{e}, \mathfrak{b}\}$, so the algebra can be eliminated in favor of pure combinatorics.

Several additional variants were defined in [30] by restricting the possible values of the functions being predicted, as follows.

10.2 Definition. Let $f : \omega \to \omega - \{0, 1\}$. Let $\mathfrak{e}_f$ be the smallest cardinality of any family $\mathcal{E} \subseteq \prod_{n \in \omega} f(n)$ such that no single predictor predicts all members of $\mathcal{E}$. When f is the constant function with value $n \geq 2$, we write $\mathfrak{e}_n$ instead of $\mathfrak{e}_f$. The *unbounded evasion number* $\mathfrak{e}_{\text{ubd}}$ is the minimum of $\mathfrak{e}_f$ over all functions f as above.

Clearly, $\mathfrak{e}_f \geq \mathfrak{e}_g$ whenever $f \leq g$, and $\mathfrak{e}_{\text{ubd}} \geq \mathfrak{e}$. The following theorem from [30] summarizes relationships between these variants and the original $\mathfrak{e}$ (as well as $\mathfrak{b}$ and $\mathfrak{s}$).

10.3 Theorem.

1. *$\mathfrak{e}_n = \mathfrak{e}_2$ for all $n \geq 2$.*

2. *$\mathfrak{e}_2 \geq \mathfrak{s}$.*

3. $\mathfrak{e} \geq \min\{\mathfrak{e}_{\mathrm{ubd}}, \mathfrak{b}\}$.

4. It is consistent that $\mathfrak{e} < \mathfrak{e}_{\mathrm{ubd}}$.

5. It is consistent that $\mathfrak{e}_{\mathrm{ubd}} < \mathfrak{e}_2$.

Proof. We only sketch the proofs, referring to [30] for details.

For part 1, the idea is to predict a function $x : \omega \to n$ (where $n \geq 3$) by predicting the two functions $k \mapsto x(k) \bmod 2$ and $k \mapsto \lfloor x(k)/2 \rfloor$, whose ranges are smaller than n. More precisely, after predicting the former on some D, one predicts (on some $D' \subseteq D$) the restriction of the latter to D.

For part 2, we show that a family $\mathcal{E} \subseteq {}^{\omega}2$ that is not splitting (when viewed in $\mathcal{P}\omega$) can be predicted. If X is an infinite set on which each $x \in \mathcal{E}$ is almost constant, then let π be the predictor, with domain $D = X - \{\min X\}$, predicting that x will take, at any point of D, the same value that it took at the last previous member of X. This guess is right almost always, for every $x \in \mathcal{E}$.

For part 3, the idea is that any fewer than $\min\{\mathfrak{e}_{\mathrm{ubd}}, \mathfrak{b}\}$ functions can be predicted by first dominating them with some f (as there are fewer than $\mathfrak{b}$ of them) and then regarding them as functions in $\prod_{n\in\omega} f(n)$, where they can be predicted (as there are fewer than $\mathfrak{e}_{\mathrm{ubd}} \leq \mathfrak{e}_f$ of them). Some care is needed as each function is below f only almost everywhere.

Part 4 is proved by an iterated forcing argument, where each step is a σ-centered forcing adding a predictor that predicts all ground-model elements of $\prod_{n\in\omega} f(n)$ for some f. A condition consists of a finite part of the desired predictor plus a promise to predict correctly all later values of finitely many functions. A finite support iteration of this clearly makes $\mathfrak{e}_{\mathrm{ubd}}$ large in the extension. We omit the hard part of the proof, namely showing that $\mathfrak{e}$ does not become large.

For part 5, iterate Mathias forcing with countable supports for $\aleph_2$ steps over a model of GCH. The resulting model has $\mathfrak{h} = \mathfrak{c} = \aleph_2$, so both $\mathfrak{b}$ and $\mathfrak{s}$ are $\aleph_2$. By part 2, we have $\mathfrak{e}_2 = \aleph_2$. On the other hand, the forcing adds no Cohen reals, so $\mathbf{cov}(\mathcal{B}) = \aleph_1$. We shall see below (Table 2 and its explanation) that $\mathfrak{e} \leq \mathbf{cov}(\mathcal{B})$. So by part 3 we have $\min\{\mathfrak{e}_{\mathrm{ubd}}, \mathfrak{b}\} \leq \aleph_1$. Since $\mathfrak{b} = \aleph_2$, we must have $\mathfrak{e}_{\mathrm{ubd}} = \aleph_1$. ⊣

Returning from the discussion of these variants to the original $\mathfrak{e}$, we have the following results.

10.4 Theorem.

1. $\mathbf{add}(\mathcal{L}), \mathfrak{p} \leq \mathfrak{e} \leq \mathbf{non}(\mathcal{B}), \mathbf{cov}(\mathcal{B})$.

2. It is consistent that $\mathfrak{e} < \mathbf{add}(\mathcal{B})$.

3. It is consistent that $\mathfrak{b} < \mathfrak{e}$.

In part 1, the inequality involving $\mathbf{cov}(\mathcal{B})$ is due to Kada [63], and the rest of part 1 is from [21]. Parts 2 and 3 are from [30] and [33] respectively.

Proof. The upper bound of $\mathbf{cov}(\mathcal{B})$ will follow from Tables 2 and 3 and their justification below. The upper bound of $\mathbf{non}(\mathcal{B})$ follows from the observation that any predictor can predict only a meager set of functions. (The set of functions predicted by any π also has measure zero in the standard measure, described in the introduction, on ${}^\omega\omega$. So $\mathbf{non}(\mathcal{L})$ is also an upper bound, but this is a weaker bound than $\mathbf{cov}(\mathcal{B})$ by Theorem 5.11.)

To establish the lower bound of $\mathfrak{p}$, we use Theorem 7.12. We assume MA_κ(σ-centered) and show that any family $\mathcal{H}$ of κ functions can be predicted by some predictor (D, π). Let P be the set of triples (d, p, F) where d is a finite subset of ω, p is a finite partial function into ω whose domain consists of sequences from ${}^n\omega$ for $n \in d$, and F is a finite subset of $\mathcal{H}$. (The "meaning" of (d, p, F) is that d is an initial segment of D, p is a finite part of π, and the functions in F will be predicted correctly at all points of $D - d$.) Partially order P by putting $(d', p', F') \le (d, p, F)$ if d is an initial segment of d', $p \subseteq p'$, $F \subseteq F'$, and whenever $n \in d' - d$ and $x \in F$ then $p'(x\restriction n)$ is defined and equal to $x(n)$. Any finitely many elements with the same first and second components have a lower bound, obtained by taking the union of the third components. So MA_κ(σ-centered) provides $G \subseteq P$ generic with respect to the dense sets $\{(d, p, F) \in P : x \in F\}$ for all $x \in \mathcal{H}$, $\{(d, p, F) \in P : s \in \mathrm{dom}(p) \text{ or } n \notin d, n < \max d\}$ for all $n \in \omega$, $s \in {}^n\omega$, and $\{(d, p, F) \in P : |d| \ge n\}$ for all $n \in \omega$. (For proving the density of the last of these, the idea is that, starting with any (d, p, F), we can enlarge d by choosing m so large that all the $x\restriction m$ for $x \in F$ are distinct and then adjoining m to d and enlarging p as required by the definition of $\le$. The choice of m ensures that the required enlargements of p do not conflict.) Then by letting D and π be the unions of the first components and second components, respectively, of the triples in G, we obtain a predictor predicting all the functions in $\mathcal{H}$.

To prove the lower bound of $\mathbf{add}(\mathcal{L})$, suppose we are given a family $\mathcal{H}$ of fewer than $\mathbf{add}(\mathcal{L})$ functions $x : \omega \to \omega$. Let $\{I_n : n \in \omega\}$ be the interval partition where $|I_n| = n+1$. To each $x \in \mathcal{H}$ associate the function defined by $x'(n) = x\restriction I_n$. By Theorem 5.14, we can assign to each n a set $S(n)$ consisting of n functions $I_n \to \omega$ in such a way that $\forall x \in \mathcal{H}\, \forall^\infty n\ (x'(n) \in S(n))$. Any n functions produce at most $n-1$ branching points, i.e., points k where two of the functions first differ. So there is some $i_n \in I_n$ that is not a branching point for any of the n functions in $S(n)$. So we can define a predictor with $D = \{i_n : n \in \omega\}$ by setting $\pi(s) = z(i_n)$ if s has length i_n and $z \in S(n)$ and s agrees with z on $I_n \cap i_n$. (Extend p arbitrarily to those s whose length is in D but which admit no such z.) This π predicts all $x \in \mathcal{H}$ because the associated x' have almost all their values in $S(n)$.

This completes (modulo Tables 2 and 3) the proof of part 1. For parts 2 and 3, we only indicate the forcings used, referring to [30, 33] for the hard parts of the proofs.

Part 2 is proved by a finite support iteration of Hechler forcing. Since this adds Cohen reals and dominating reals, both $\mathbf{cov}(\mathcal{B})$ and $\mathfrak{b}$ and therefore also their minimum $\mathbf{add}(\mathcal{B})$ are large in the extension. The hard part of the proof is to show that $\mathfrak{e}$ remains small.

Part 3 is proved by a finite support iteration where each step adds a predictor that predicts all ground model reals. As in the proof of $\mathfrak{p} \leq \mathfrak{e}$ above, a condition consists of a finite part of the desired predictor together with finitely many functions that are to be predicted correctly at all later points. This forcing clearly makes $\mathfrak{e}$ large; the hard part is to prove that $\mathfrak{b}$ remains small. $\dashv$

10.5 Remark. Laflamme has improved the inequality $\mathfrak{p} \leq \mathfrak{e}$ in Theorem 10.4 to $\mathfrak{t} \leq \mathfrak{e}$. In [71, Proposition 2.3] he shows that $\mathfrak{t} \leq \mathfrak{e}_{\mathrm{ubd}}$, and he mentions that $\mathfrak{t} \leq \mathfrak{e}$ follows via part 3 of Theorem 10.3.

We turn next to some additional variations on the theme of prediction and evasion. These variations turn out to be closely connected to cardinals studied in previous sections. We consider three sorts of variations, singly and in combination.

First, the predictor could guess less information than the exact value of the $x(n)$ being predicted. Thus, we consider predictors $(D, \langle \pi_n : n \in D \rangle)$ where each $\pi_n : {}^n\omega \to \mathcal{P}\omega$, and we consider that $x \in {}^\omega\omega$ is predicted by such a π if $\forall^\infty n\ (x(n) \in \pi_n(x \restriction n))$. To avoid trivialities, the sets that occur as values of π_n must be small in some sense. (The predictor whose values are all equal to ω predicts every x.) We shall consider the following six possibilities for the values of π_n.

- Singletons. (This is the case considered above.)
- Sets of cardinality k for some fixed $k \in \omega$.
- Sets of cardinality $f(n)$, where f is a function $\omega \to \omega$ that tends to infinity.
- Finite sets.
- Co-infinite sets.
- Proper subsets of ω.

Thus, we shall refer to "single-valued" predictors, "k-valued" predictors, etc. Each type of predictor gives rise to an evasion number, namely the minimum number of functions not all predicted by a single predictor of that type.

Clearly, as the predictor's guesses become less specific (as we go down the list above), prediction becomes easier, evasion harder, and the evasion number larger.

Notice also that we could replace "finite sets" as values for π with "initial segments of ω" without affecting the evasion number, for given any predictor π of one sort we can trivially produce a predictor π' of the other sort predicting all the functions predicted by π. For the same reason, we can replace "proper subsets of ω" with "co-singletons".

The next variation concerns which values of x a predictor must guess correctly in order to predict x; it was also considered by Kada [63]. The definitions above permit the predictor to specify an infinite set D and guess $x(n)$ only for $n \in D$; it predicts x if almost all of these guesses are correct. We can make the definition more restrictive by requiring $D = \omega$. This variation will be called *global* prediction, and the original version will, when we want to emphasize the difference, be called *local* prediction.

Alternatively, we can make the definition less restrictive by saying that π predicts x if infinitely many (rather than almost all) of the guesses are right. We refer to this as *infinite* prediction. Notice that in this situation one might as well take $D = \omega$, because extending a predictor to a larger D can only increase the collection of functions it predicts. Thus, for both global and infinite prediction, we usually regard a predictor as either a sequence $\langle \pi_n \rangle_{n\in\omega}$ or as the union of such a sequence, $\pi : {}^{<\omega}\omega \to \omega$.

Clearly, as we move from global to local to infinite prediction, prediction becomes easier, evasion harder, and the evasion number larger.

The final variation that we consider here is to make $\pi_n(s)$ independent of s. In other words, the predictor is not allowed to see $x \restriction n$ but only knows n when guessing $x(n)$. Thus, the predictor is essentially just a function π on ω or D, taking "small" values in one of the senses above. We refer to such predictors as *non-adaptive* while predictors of the original sort are *adaptive*. Clearly, adaptive prediction is easier than non-adaptive prediction, evasion harder, and the evasion number larger.

The six choices for "small", the three choices global or local or infinite, and the two choices non-adaptive or adaptive give 36 evasion numbers, one of which (singleton, local, adaptive) is $\mathfrak{e}$. Many of the others coincide with cardinals discussed earlier, and for the rest there are bounds in terms of such cardinals. This information is summarized in the following tables. The first column of each table lists the six species of smallness, with G representing a typical guess for $x(n)$.

Our remarks above imply that the entries in each table increase (weakly) from top to bottom and from left to right; also, as we go from one table to the next (global to local to infinite), the entries in any single position increase (weakly). We shall usually refer to these facts as "monotonicity" without going into any more detail.

The question marks in four of the entries indicate that I do not know the values of these evasion numbers but only the indicated bounds and the result of Mildenberger (unpublished) that the following three cardinals are equal:

- $\mathfrak{e}$,
- the smaller of $\mathfrak{e}_2$ and the question mark in the "$|G| = k$" line of Table 2,
- the smaller of $\mathfrak{e}_{\mathrm{ubd}}$ and the question mark in the "$|G|$ finite" line of Table 2.

Table 1: Evasion numbers for global prediction

	Non-adaptive	Adaptive
$\lvert G\rvert = 1$	2	$\aleph_1$
$\lvert G\rvert = k$	$k+1$	$\mathfrak{m}(\sigma\text{-}k\text{-linked}) \leq ? \leq \mathbf{add}(\mathcal{L})$
$\lvert G\rvert = f(n)$	$\mathbf{add}(\mathcal{L})$	$\mathbf{add}(\mathcal{L})$
G finite	$\mathfrak{b}$	$\mathfrak{b}$
$\omega - G$ infinite	$\mathbf{non}(\mathcal{B})$	$\mathbf{non}(\mathcal{B})$
$G \subsetneqq \omega$	$\mathbf{non}(\mathcal{B})$	$\mathbf{non}(\mathcal{B})$

Table 2: Evasion numbers for local prediction

	Non-adaptive	Adaptive
$\lvert G\rvert = 1$	2	$\mathfrak{e}$
$\lvert G\rvert = k$	$k+1$	$\mathfrak{e} \leq ? \leq \mathbf{cov}(\mathcal{B}), \mathbf{non}(\mathcal{B})$
$\lvert G\rvert = f(n)$	$\min\{\mathfrak{e}, \mathfrak{b}\}$	$\mathfrak{e} \leq ? \leq \mathbf{cov}(\mathcal{B}), \mathbf{non}(\mathcal{B})$
G finite	$\mathfrak{b}$	$\mathfrak{e}, \mathfrak{b} \leq ? \leq \mathfrak{d}, \mathbf{non}(\mathcal{B})$
$\omega - G$ infinite	$\mathbf{non}(\mathcal{B})$	$\mathbf{non}(\mathcal{B})$
$G \subsetneqq \omega$	$\mathbf{non}(\mathcal{B})$	$\mathbf{non}(\mathcal{B})$

One could regard these entries with question marks as defining four more cardinal characteristics. On the other hand, one might regard the entry $\mathfrak{e}$ in Table 2 as a euphemism for a question mark with the bounds given in Theorem 10.4. The difference between $\mathfrak{e}$ and the question marks is that the former has been studied enough to indicate that it differs from the previously studied characteristics, while the question marks might well reduce to something simpler. It is, however, known [34, p. 359] that, in the global prediction table, neither of the inequalities around the question mark can be improved to a provable equality.

In the following paragraphs, we give reasons for the table entries, leaving some details to the reader.

$\boxed{2 \text{ and } k+1}$ For both global and local prediction, $k+1$ distinct constant functions evade any non-adaptive predictor of k-element sets. And any k functions clearly can be predicted.

$\boxed{\mathbf{add}(\mathcal{L})}$ In the non-adaptive column of Table 1, the occurrence of $\mathbf{add}(\mathcal{L})$ expresses Theorem 5.14 and the remark following it. The occurrence in the adaptive column comes from the fact that an adaptive $f(n)$-valued predictor π gives rise to a non-adaptive $f'(n)$-valued predictor π' (for a larger f') such that all functions globally predicted by π are also globally predicted by π'. Given π, associate to each $s \in {}^{<\omega}\omega$ and each natural number n the set $\pi_s(n)$ of all possible values of $x(n)$ for functions $x \in {}^{\omega}\omega$ that start with s and are correctly predicted by π thereafter. (That is, $x(k)$ is $s(k)$ for $k < \text{length}(s)$ and $\pi(x{\upharpoonright}k)$ for all larger k.) Also fix an enumeration of ${}^{<\omega}\omega$ in an ω-sequence. Let $\pi'(n)$ be the union of the sets $\pi_s(n)$ as s ranges over the first n elements

Table 3: Evasion numbers for infinite prediction

	Non-adaptive	Adaptive
$\lvert G\rvert = 1$	$\mathbf{cov}(\mathcal{B})$	$\mathbf{cov}(\mathcal{B})$
$\lvert G\rvert = k$	$\mathbf{cov}(\mathcal{B})$	$\mathbf{cov}(\mathcal{B})$
$\lvert G\rvert = f(n)$	$\mathbf{cov}(\mathcal{B})$	$\mathbf{cov}(\mathcal{B})$
G finite	$\mathfrak{d}$	$\mathfrak{d}$
$\omega - G$ infinite	$\mathfrak{c}$	$\mathfrak{c}$
$G \subsetneq \omega$	$\mathfrak{c}$	$\mathfrak{c}$

of ${}^{<\omega}\omega$. It is easy to find an appropriate f' depending only on f and to verify that π' globally predicts everything that π does.

$\boxed{\mathfrak{b}}$ We may take a finite-valued predictor's guesses to be initial segments of ω, i.e., natural numbers, a guess being correct if it is greater than the actual value of the function being guessed. In this light, the occurrence of $\mathfrak{b}$ in the non-adaptive column of Table 1 expresses just the definition of $\mathfrak{b}$. The occurrence in the adaptive column is justified by an argument analogous to that in the discussion of $\mathbf{add}(\mathcal{L})$ above.

As for the occurrence in Table 2, consider any unbounded family $\mathcal{E}$ of $\mathfrak{b}$ non-decreasing functions. We shall see that they evade local prediction by any non-adaptive, finite-valued predictor (π, D). As above, we assume the values of π are natural numbers. Define $\pi' : \omega \to \omega$ by letting $\pi'(n)$ be the value of π at the next member of D after n. By our choice of $\mathcal{E}$, it contains a member x not dominated by π'. Since x is non-decreasing, if (π, D) locally predicted it then for all sufficiently large $n \in \omega$ we would have, letting k be the next element of D after n,

$$x(n) \leq x(k) < \pi(k) = \pi'(n).$$

This contradicts the choice of x, so x evades (π, D).

$\boxed{\mathbf{non}(\mathcal{B})}$ Let us consider first the bottom row in Tables 1 and 2, where the guesses are proper subsets of ω. Without loss of generality, we may assume that the guesses are complements of singletons. We'll write $\tilde{\pi}(n)$ for the number absent from $\pi(n)$ (and similarly for $\tilde{\pi}(s)$ in the adaptive case). Part 2 of Theorem 5.9 says that the bottom entry in the non-adaptive column of Table 1 is $\mathbf{non}(\mathcal{B})$. By monotonicity, the other entries in the bottom row of Tables 1 and 2 are no smaller. They are no larger because any predictor predicts globally or locally only a meager subset of ${}^{\omega}\omega$.

To justify the next-to-bottom row in Tables 1 and 2, where the guesses are co-infinite, it suffices, thanks to monotonicity, to show that a family $\mathcal{F}$ of fewer than $\mathbf{non}(\mathcal{B})$ functions cannot evade global prediction by non-adaptive co-infinite predictors. Fix a map $p : \omega \to \omega$ such that every $p^{-1}\{n\}$ is infinite. The fewer than $\mathbf{non}(\mathcal{B})$ functions $p \circ f$ for $f \in \mathcal{F}$ are globally predicted by a predictor π of proper subsets of ω (by Theorem 5.9); so the functions in $\mathcal{F}$ are predicted by $p^{-1} \circ \pi$, whose values are co-infinite.

$\boxed{\mathfrak{c}}$ Clearly, all evasion numbers are $\leq \mathfrak{c}$, since any predictor, even an adaptive predictor of co-singletons, can be completely evaded by some function. On the other hand, to evade infinite prediction even by non-adaptive predictors π of co-singletons requires $\mathfrak{c}$ functions, because one needs functions eventually equal to any prescribed $f : \omega \to \omega$ (giving the values omitted by the predictor). To obtain the same result with "co-infinite" in place of "co-singleton", use the same "compose with p" trick as in the discussion of $\mathbf{non}(\mathcal{B})$ above.

$\boxed{\mathfrak{d}}$ As in the discussion of $\mathfrak{b}$ above, we may assume that predictors give natural numbers, intended as upper bounds for the values to be guessed. Then the $\mathfrak{d}$ in the non-adaptive column of Table 3 is justified by the definition of $\mathfrak{d}$. To see that $\mathfrak{d}$ functions suffice to evade even adaptive prediction, take a family of $\mathfrak{d}$ adaptive predictors that dominate all the adaptive predictors, and choose for each of these predictors some function evading it.

$\boxed{\mathbf{cov}(\mathcal{B})}$ Of the six occurrences of $\mathbf{cov}(\mathcal{B})$ in Table 3, the top one in the non-adaptive column expresses Part 1 of Theorem 5.9. To justify the rest, it suffices by monotonicity to check that $\mathbf{cov}(\mathcal{B})$ functions suffice to evade infinite prediction by adaptive predictors whose guesses at n have cardinality $f(n)$. We do this first for non-adaptive predictors, by a modification of the argument for Theorem 5.9, and then we show how to extend the result to the adaptive case. We may assume $\mathbf{cov}(\mathcal{B}) < \mathfrak{d}$, for otherwise the desired information follows by monotonicity from the $\mathfrak{d}$'s in the next row of Table 3.

Fix $\mathbf{cov}(\mathcal{B})$ chopped reals (x_α, Π_α) with no single $y \in {}^\omega 2$ matching them all (by Theorem 5.2). Since $\mathbf{cov}(\mathcal{B}) < \mathfrak{d}$, fix an interval partition Θ not dominated by any of the Π_α. As in the proof of Theorem 5.9, this means that every Π_α contains infinitely many intervals each covered by two consecutive intervals of Θ.

Define $g(n) = 2 \cdot \sum_{k \leq n} f(k) - 1$. For each α and each n, we define a set $q_\alpha(n)$ as follows. Find $g(n)$ disjoint pairs of consecutive Θ-intervals, each pair covering a Π_α-interval; let the unions of these pairs be $J_0, \dots, J_{g(n)-1}$. Then let $q_\alpha(n) = \{x_\alpha \restriction J_0, \dots, x_\alpha \restriction J_{g(n)-1}\}$. So each $q_\alpha(n)$ is a set of $g(n)$ functions into 2, each having as domain the union of two consecutive Θ-intervals, and such that the domains of different members of $q_\alpha(n)$ are disjoint.

By coding their values as natural numbers, we can regard the q_α as functions $\omega \to \omega$. We claim that these $\mathbf{cov}(\mathcal{B})$ functions evade infinite prediction by any non-adaptive, $f(n)$-valued predictor, i.e., any f-slalom.

Suppose this failed. So there is a function S assigning to each $n \in \omega$ a set $S(n)$ of $f(n)$ elements such that for each α we have $\exists^\infty n\ (q_\alpha(n) \in S(n))$. Without loss of generality, each element s of $S(n)$ is a set of $g(n)$ functions into 2, each having as domain the union of two consecutive Θ-intervals, and such that the domains of different members of s are disjoint. Now define $y \in {}^\omega 2$ by the following recursion, defining y on $2 \cdot f(n)$ Θ-intervals at step n.

Suppose steps 0 through $n-1$ have been completed, so y is already defined on $2 \cdot \sum_{k<n} f(k)$ Θ-intervals. From each $s \in S(n)$, remove those partial

functions whose domains overlap the set where y is already defined. That removes at most $2 \cdot \sum_{k<n} f(k)$, so at least $2 \cdot f(n) - 1$ are left, since s had cardinality $g(n)$. Go through the $f(n)$ sets so obtained (one from each $s \in S(n)$) in some order, picking one function from each, making sure that the domain of each chosen function is disjoint from the domains of the previously chosen functions. Since each of the domains is the union of two consecutive Θ-intervals, each domain can overlap at most two others. Thus, there are at least $2 \cdot f(n) - 1$ options for the first choice, at least $2 \cdot f(n) - 3$ for the second, and so on down to at least 1 option for the $f(n)$th choice. So all the choices can be made. Then extend y to agree with each of the chosen functions on its domain. This completes step n of the recursion. After all steps are completed, if y is not defined on all of ω, extend it arbitrarily.

For each α, there are infinitely many n with $q_\alpha(n) \in S(n)$, so $q_\alpha(n)$ is one of the s's considered at step n in the definition of y. So some element z of $q_\alpha(n)$ becomes part of y. But that z is $x_\alpha \restriction J$ for some J that includes an interval of Π_α. So y matches each (x_α, Π_α), contrary to our choice of these chopped reals. This contradiction shows that the (coded) q_α are evasive as claimed.

It remains to extend the result to adaptive predictors whose guesses have size $f(n)$. Such a predictor is a function $\pi : {}^{<\omega}\omega \to [\omega]^{<\omega}$ (with $\pi(s) \in [\omega]^{f(n)}$ if $s \in {}^n\omega$). Identifying the domain ${}^{<\omega}\omega$ with ω via some bijective coding, we can view every such π as a non-adaptive predictor whose guesses have size $f'(n)$ for a certain f' (that depends on f and the coding). Applying the preceding argument to these non-adaptive predictors, and then reversing the coding process, we get a family $\mathcal{E}$ of $\mathbf{cov}(\mathcal{B})$ functions ${}^{<\omega}\omega \to \omega$ such that, for every adaptive predictor π as above,

$$\exists z \in \mathcal{E}\, \forall^\infty s \in {}^{<\omega}\omega\ (z(s) \notin \pi(s)).$$

Use each $z \in \mathcal{E}$ to recursively define a $z' : \omega \to \omega$ by $z'(n) = z(z' \restriction n)$. Then the family $\mathcal{E}' = \{z' : z \in \mathcal{E}\}$ evades infinite prediction by any π as above. Indeed, with π and z as above, we have, for all but finitely many n, that

$$z'(n) = z(z' \restriction n) \notin \pi(z' \restriction n).$$

$\boxed{\mathfrak{e}}$ The entry $\mathfrak{e}$ in Table 2 is just the definition of $\mathfrak{e}$. In view of what we just proved about $\mathbf{cov}(\mathcal{B})$, we get $\mathfrak{e} \leq \mathbf{cov}(\mathcal{B})$ by monotonicity. This completes the proof of Theorem 10.4 above.

$\boxed{\aleph_1}$ Any countably many functions $h_i : \omega \to \omega$ are globally predicted by the adaptive predictor defined by requiring $\pi(s) = h_i(n)$ if s has length n and i is the first index with $h_i \restriction n = s$. Such a π predicts each h_i accurately at all n beyond the points where h_i first differs from the earlier h_j's.

On the other hand, any adaptive predictor whose values are singletons can globally predict only countably many functions. Indeed, a function h globally predicted by such a π is completely determined by the finite part of h consisting of the values not correctly guessed by π.

$\boxed{\mathfrak{m}(\sigma\text{-}k\text{-linked}) \leq ? \leq \mathbf{add}(\mathcal{L})}$ Monotonicity gives us the upper bound of $\mathbf{add}(\mathcal{L})$. To establish the lower bound, we assume $\mathrm{MA}_\kappa(\sigma\text{-}k\text{-linked})$ and we prove that any family $\mathcal{H}$ of κ functions $\omega \to \omega$ can be globally predicted by an adaptive predictor π with k-element guesses, i.e., $\pi : {}^{<\omega}\omega \to [\omega]^k$. Let P be the set of pairs (p, F) where p is a finite partial map from ${}^{<\omega}\omega$ to $[\omega]^k$ and F is a finite subset of $\mathcal{H}$ with the following "branching restriction": For any two functions in F, if s is their longest common initial segment, then $s \in \mathrm{dom}(p)$. (The "meaning" of (p, F) is that p is part of the desired predictor and that each function in F will be guessed correctly except possibly at those places where p is defined.) Partially order P by putting $(p', F') \leq (p, F)$ if $p \subseteq p'$, $F \subseteq F'$, and, whenever $f \in F$ and $f \restriction n \in \mathrm{dom}(p') - \mathrm{dom}(p)$ then $f(n) \in p'(f \restriction n)$.

This partial ordering is σ-k-linked because any k elements (p, F_i) with the same first component have a common lower bound, constructed as follows. First form $(p, \bigcup_i F_i)$. If this is not the desired lower bound, it is because the branching restriction is violated. So there are some $s \notin \mathrm{dom}(p)$ that are the largest common initial segments of some $f \in F_i$ and $g \in F_j$. Then $i \neq j$ because each of the (p, F_i) satisfied the branching restriction. So any such s, say of length n, is an initial segment of at most k members of $\bigcup_i F_i$ that have different values at n. But then we can extend p by defining $p(s)$ to be a k-set containing the values at n of those $\leq k$ members of $\bigcup_i F_i$. Doing this for each such s, we get the desired lower bound.

Applying $\mathrm{MA}_\kappa(\sigma\text{-}k\text{-linked})$, we get a set $G \subseteq P$ generic with respect to the dense sets $\{(p, F) \in P : s \in \mathrm{dom}(p)\}$ for all $s \in {}^{<\omega}\omega$ and $\{(p, F) \in P : f \in F\}$ for all $f \in \mathcal{H}$. (The former is dense thanks to the branching restriction. To verify the density of the latter, given any (p, F) and any $f \in \mathcal{H} - F$, first form $(p, F \cup \{f\})$. If the branching restriction is violated, extend p so as to be defined at the new branching locations. Here we need that $k \geq 2$.) Let π be the union of all the first components of the pairs $(p, F) \in G$. It is routine to check (as in the proof of Theorem 7.7) that this π is an adaptive predictor with k-set guesses, globally predicting every function from $\mathcal{H}$.

$\boxed{\mathfrak{e} \leq ? \leq \mathbf{cov}(\mathcal{B}), \mathbf{non}(\mathcal{B})}$ Monotonicity implies all three inequalities.

$\boxed{\mathfrak{e}, \mathfrak{b} \leq ? \leq \mathfrak{d}, \mathbf{non}(\mathcal{B})}$ Again, monotonicity implies all four inequalities.

$\boxed{\min\{\mathfrak{e}, \mathfrak{b}\}}$ This is [33, Lemma 2.5]. Monotonicity gives the upper bound $\mathfrak{b}$. The proof that $\mathfrak{e}$ is also an upper bound is essentially the same as the proof of $\mathbf{add}(\mathcal{L}) \leq \mathfrak{e}$ in Theorem 10.4. The only difference is that here we are dealing with "partial slaloms", i.e., functions S defined on some infinite $D \subseteq \omega$ and satisfying $|S(n)| = f(n)$ for all $n \in D$. Instead of predicting at all i_n, as in the earlier argument, we now predict at i_n for $n \in D$.

To prove that $\min\{\mathfrak{e}, \mathfrak{b}\}$ is also a lower bound, let $\mathcal{H}$ be a family of fewer than $\min\{\mathfrak{e}, \mathfrak{b}\}$ functions; we must find a partial slalom (in the sense defined above) such that each $h \in \mathcal{H}$ satisfies $\forall^\infty n \in D\,(h(n) \in S(n))$. Since there are fewer than $\mathfrak{b}$ functions in $\mathcal{H}$, we can find a single, strictly increasing

$g : \omega \to \omega$ that dominates them all. Let $\{I_n : n \in \omega\}$ be an interval partition such that, if a is the left endpoint of any I_n, then there is some $i_n \in I_n$ with $f(i_n) \geq g(a)^a$. To each $h \in \mathcal{H}$ associate the function defined by $h'(n) = h \restriction I_n$. Since the number of such h' is $< \mathfrak{e}$, there is an adaptive predictor of singletons (D', π') that locally predicts all the h'; that is,

$$\forall h \in \mathcal{H}\, \forall^\infty n \in D' \ (h'(n) = \pi'(h' \restriction n)).$$

Do the following for each $n \in D'$. Let a be the left endpoint of I_n, and recall that our interval partition was chosen so that $g(a)^a \leq f(i_n)$ for some $i_n \in I_n$. Consider all functions s from a into $g(a)$; there are exactly $g(a)^a$, and thus no more than $f(i_n)$, of them. Each gives an s' by $s'(m) = s \restriction I_m$ for $m < n$. Then $\pi'(s')$ is some function $I_n \to \omega$; evaluate it at i_n. Doing this for each s gives no more than $f(i_n)$ numbers; let $S(i_n)$ be the set of these numbers.

Doing this for all $n \in D'$, we get a partial slalom defined on $D = \{i_n : n \in D'\}$. For each $h \in \mathcal{H}$, if π' predicted $h'(n)$ correctly (where $n \in D'$), then $h(i_n) \in S(i_n)$. So we have the desired partial slalom.

10.6 Remark. The variants of evasion discussed at the beginning of this section ($\mathfrak{e}_g$ and $\mathfrak{e}_{\mathrm{ubd}}$) can be combined with some of the variants in Tables 1 to 3. Finite and co-infinite predictors no longer make sense. When, as in the case of $\mathfrak{e}_g$, the functions to be predicted are bounded by a fixed g, we need to pay attention to the function f in the $|G| = f(n)$ lines of the tables; it is no longer the case that any function tending to infinity is equivalent to any other. Also, in this situation, the co-singleton case becomes a special case of $|G| = f(n)$ with $f(n) = g(n) - 1$. Thus, we would have three-line tables for these variants. We omit any further discussion of these, since little is known about them beyond carrying over some of the arguments presented above.

Another variation, lying between global and local, was introduced by Kamo [65]. Say that a function $\pi : {}^{<\omega}\omega \to \omega$ *constantly predicts* $x : \omega \to \omega$ if there is $n \in \omega$ such that, with finitely many exceptions, any interval $[m, m+n)$ of length n contains some k such that $x(k) = \pi(x \restriction k)$. This concept has been studied further by Kamo, Kada, and Brendle; see for example [32] and the references there.

Finally, all the evasion cardinals considered in this section have duals of the form: the smallest number of predictors needed to predict all functions. These too have been little studied, but there is one remarkable result concerning the number of f-slaloms needed to globally predict all members of $\prod_n g(n)$. Goldstern and Shelah [53] showed that this cardinal can vary with f and g and in fact that in some models of set theory uncountably many cardinals are of this form (infinitely many with recursive f and g).

11. Forcing

In this final section, we describe the effect of various forcing constructions on cardinal characteristics. We shall discuss only the most commonly used forcing notions and their most natural iterations; for a far more extensive discussion, see [5, Chaps. 3, 6, and 7].

Most of the forcing notions we consider are designed to add a real with some prescribed properties, and the properties are often closely connected with some Borel relation $\mathbf{A} = (A_-, A_+, A)$ (where we use the notation of Sect. 4). Specifically, we say that a real x in a forcing extension *solves* $\mathbf{A}$ (over the ground model) if $x \in \tilde{A}_+$ and $(a, x) \in \tilde{A}$ for all $a \in A_-$ in the ground model. Here $\tilde{A}$ denotes the relation in the extension having the same Borel code as A has in the ground model, and similarly for $\tilde{A}_+$ etc., but we shall often omit the tilde since no confusion will result.

If there is a morphism $\varphi : \mathbf{A} \to \mathbf{B}$ whose φ_+ component is Borel, so that $\tilde{\varphi}_+$ makes sense, and if x solves $\mathbf{A}$ then $\tilde{\varphi}_+(x)$ solves $\mathbf{B}$. Indeed, given any $b \in B_-$ in the ground model, let $a = \varphi_-(b) \in A_-$. The statement

$$\forall u \in A_+ \, (aAu \implies bB\varphi_+(u))$$

is true in V and absolute when expressed in terms of the Borel codes of A_+, A, B, and φ_+. Thus it is true in any forcing extension that

$$\forall u \in \tilde{A}_+ \, (a\tilde{A}u \implies b\tilde{B}\tilde{\varphi}_+(u)).$$

Since a is in the ground model, we have $a\tilde{A}x$ and therefore $b\tilde{B}\tilde{\varphi}_+(x)$ as claimed.

Notice that we do not need A_-, B_- or φ_- to be Borel in the preceding discussion.

It is easy to check that if x solves $\mathbf{A}$ and y solves $\mathbf{B}$ then (x, y) solves the conjunction $\mathbf{A} \wedge \mathbf{B}$ and the product $\mathbf{A} \times \mathbf{B}$. For sequential composition, the situation is more complicated, because even if $\mathbf{A}$ and $\mathbf{B}$ are Borel, the set of challenges in $\mathbf{A}; \mathbf{B}$ is of higher type, so this relation cannot be Borel. However, if we have a morphism $\varphi : \mathbf{A}; \mathbf{B} \to \mathbf{C}$ then under suitable Borelness hypotheses we can conclude, by a proof very similar to that above, that if $V \subseteq V' \subseteq V''$, if $x \in V'$ solves $\mathbf{A}$ over V, and if $y \in V''$ solves $\mathbf{B}$ over V' then $\tilde{\varphi}_+(x, y)$ solves $\mathbf{C}$ over V. Most of the "suitable Borelness hypotheses" are the ones obviously needed for the statement to make sense: A_+, A, B_+, B, B_-, and φ_+ must be Borel. (B_-, unlike A_-, must be Borel so that solving $\mathbf{B}$ over V', not over V, makes sense.) But one additional Borelness hypothesis is needed for the proof. If we regard $\varphi_- : C_- \to A_- \times {}^{A_+}B_-$ as a pair of functions $\alpha : C_- \to A_-$ and $\beta : C_- \to {}^{A_+}B_-$, and if we regard β as $\beta' : C_- \times A_+ \to B_-$ (where $\beta'(c, a) = \beta(c)(a)$), then we need that β' is Borel. We leave the details to the reader.

Most of the iterations we consider will be either finite support iterations of c.c.c. forcing notions or countable support iterations of proper forcing notions. For general information about iterations, see Abraham's chapter in this Handbook or [62, 9, 97]. All the proper forcing notions considered below satisfy Baumgartner's Axiom A [9], which is stronger and usually easier to check than properness. We usually write V for the ground model and V_α for the model obtained after α stages of an iteration.

11.1. Finite Support Iteration and Martin's Axiom

A finite support iteration of c.c.c. forcing is equivalent to a single c.c.c. forcing [106] and therefore preserves cardinals. Also, if the length λ of the iteration has uncountable cofinality, then every real in the final extension V_λ is already in an intermediate extension V_α, $\alpha < \lambda$. If, cofinally often in such an iteration, one adjoins a real solving $\mathbf{A}^\perp$ over the previous model, then in V_λ the norm $\|\mathbf{A}\|$ will be at least $\mathrm{cf}(\lambda)$. Indeed, given any fewer than $\mathrm{cf}(\lambda)$ members of A_+ in V_λ, we can find an $\alpha < \lambda$ such that all these reals are in V_α; increasing α if necessary, we can, by hypothesis, arrange that $V_{\alpha+1}$ contains a real $x \in A_-$ solving $\mathbf{A}^\perp$ over V_α. But that means in particular that x is A-related to none of our given fewer than $\mathrm{cf}(\lambda)$ reals.

The preceding remarks indicate a way to make a characteristic $\|\mathbf{A}\|$ large, namely iterate a c.c.c. forcing that solves $\mathbf{A}^\perp$, with finite support, for λ stages, where λ is regular and large.

Applying this method with all c.c.c. forcings of size $< \lambda$ (in all the intermediate models) suitably interleaved, one obtains a model of MA and $\mathfrak{c} = \lambda$ provided GCH held in the ground model. If one uses only σ-centered posets in the iteration, then one obtains a model of MA(σ-centered), i.e., $\mathfrak{p} = \mathfrak{c}$ (see Theorem 7.12), but MA fails and in fact $\mathbf{cov}(\mathcal{L}) = \aleph_1$ (see [5, Sect. 6.5D]). Similar constructions give models satisfying various fragments of MA while violating others; see Appendix B1 of [48] and the references therein.

To prove independence results in the theory of cardinal characteristics, one needs techniques for making one characteristic large while keeping another small. As indicated above, it is not difficult to make a chosen characteristic large, but it is usually difficult to prove that another characteristic remains small. In fact, some characteristics cannot be kept small in a non-trivial finite support iteration. The reason is that such an iteration always introduces Cohen reals at all limit stages of cofinality ω. Cohen reals solve various Borel relations (see below), notably $\mathbf{Cov}(\mathcal{B})^\perp$, and therefore finite support iterations cannot avoid making certain characteristics, notably $\mathbf{cov}(\mathcal{B})$, large.

11.2. Countable Support Proper Iteration

A countable support iteration of proper forcing is equivalent to a single proper forcing [97, Theorem 3.2] and therefore preserves $\aleph_1$. For our purposes, it will be important to also preserve larger cardinals, and this is usually ensured by an appeal to [97, Theorem 4.1], which gives the $<\aleph_2$-chain condition provided (1) CH holds in the ground model, (2) the forcing notion used to produce $V_{\alpha+1}$ from V_α has cardinality at most $\mathfrak{c}$ in V_α, and (3) the length of the iteration is at most ω_2. (See Abraham's chapter in this Handbook.) The first two of these provisos will be satisfied automatically in the situations we are interested in, but the third is a real impediment. This limitation on the length of the iteration prevents us from making the continuum arbitrarily large with countable support iterations; only $\mathfrak{c} = \aleph_2$ can be achieved. It is shown in [11] that iterating Sacks forcing (which is proper) with countable support for ω_2+1 steps collapses $\aleph_2$. Also, it is pointed out in [51, Remark 0.3] that a countable support ω_1-stage iteration of any non-trivial forcings will collapse $\mathfrak{c}$ to $\aleph_1$.

Our inability to produce larger values of $\mathfrak{c}$ with the kind of detailed control available for countable support iterations has prevented the solution of several problems. For example, although we have models with no P-points and models with no Q-points (both obtained by countable support proper iterations), we do not know how to achieve both simultaneously. By Theorems 9.25 and 9.27, such a model would need to have $\mathbf{cov}(\mathcal{B}) < \mathfrak{d} < \mathfrak{c}$ and therefore $\mathfrak{c} \geq \aleph_3$. Similarly, we have no model for $\mathfrak{p} < \mathfrak{t}$; by Theorem 6.25, such a model would need to have $\aleph_2 \leq \mathfrak{p} < \mathfrak{t}$ and therefore $\mathfrak{c} \geq \aleph_3$. (Brendle has pointed out, however, that there is no a priori reason why a model of $\mathfrak{p} < \mathfrak{t}$ could not be produced by finite support iteration. This contrasts with the situation for producing a model with neither P-points nor Q-points; here finite support iteration has no chance because the Cohen reals it introduces make $\mathbf{cov}(\mathcal{B})$ large, and then Theorem 9.26 produces a selective ultrafilter.)

The "$\aleph_3$ barrier" is widely regarded as merely a technical problem. It has, however, resisted our efforts long enough to suggest that perhaps our inability to produce certain models is caused not by our technical deficiencies but by the non-existence of the models.

In the rest of this section, countable support iterations will always be of the sort discussed above; that is, GCH will hold in the ground model, each step will be a proper forcing notion of cardinality at most $\mathfrak{c}$, and the length of the iteration will be ω_2. Thus, all cardinals are preserved. Furthermore, every real in the final model V_{ω_2} is already in some intermediate model V_α, $\alpha < \omega_2$. Thus, as with finite support iterations, we can increase a characteristic $\|\mathbf{A}\|$ (but only up to $\aleph_2$) by cofinally often adding reals that solve $\mathbf{A}^\perp$. To prove independence results, we want to simultaneously keep some other characteristic small, and for this purpose there are a large number of powerful preservation theorems; see [97, 51, 45]. For example, in a countable support proper iteration, if each $V_\alpha \cap {}^\omega\omega$ is a dominating family in $V_{\alpha+1}$ then $V \cap {}^\omega\omega$ is dominating in V_λ. In other words, if $V_{\alpha+1}$ never contains a real solving $\mathfrak{D}^\perp$ over V_α, then $\mathfrak{d}$ remains $\aleph_1$ in the final model.

11.1 Remark. Zapletal [115] has shown that, under a strong large cardinal assumption (a proper class of measurable Woodin cardinals), many cardinal characteristics $\mathfrak{y}$ admit an optimal notion of forcing $P_\mathfrak{y}$ to make them large. Optimality means that, if $\mathfrak{x}$ is any tame characteristic and $\mathfrak{x} < \mathfrak{y}$ can be forced by some set forcing notion, then it is forced by $P_\mathfrak{y}$. The notion of tameness used here is somewhat more general than being the norm of a projective relation, in that it permits some additional restrictions on the set $Y \subseteq A_+$ in Definition 4.1 of norms. All norms of Borel relations are tame, and so are, for example, $\mathfrak{p}$, $\mathfrak{t}$, and $\mathfrak{u}$, but not, for example, $\mathfrak{g}$.

Zapletal gives the following specific examples (among others) of optimal forcings for certain characteristics. See the following subsections for descriptions of these forcings. Cohen forcing is optimal for $\mathbf{cov}(\mathcal{B})$. Random forcing is optimal for $\mathbf{cov}(\mathcal{L})$. Sacks forcing is optimal for $\mathfrak{c}$. Laver forcing is optimal for $\mathfrak{b}$. Mathias forcing is optimal for $\mathfrak{h}$. Miller forcing is optimal for $\mathfrak{d}$. For a somewhat more extensive description of this work of Zapletal, see the final section of Bartoszyński's chapter of this Handbook, and for the details see [116].

11.3. Cohen Reals

The Cohen forcing poset, ${}^{<\omega}2$ ordered by reverse inclusion, adjoins a real $c : \omega \to 2$ (namely the union of the conditions in the generic set) that matches every chopped real (x, Π) from the ground model. Indeed, for each (x, Π) and each $n \in \omega$, the forcing conditions that agree with x on at least one interval of Π beyond n form a dense set in the ground model, so by genericity one of them must be included in c. Thus, a Cohen real solves $\mathbf{Cov}(\mathcal{B})^{\perp}$. (In fact, this characterizes Cohen reals.)

The usual way to iterate Cohen forcing is with finite support. Since the forcing poset is absolute, finite support iteration and finite support product are equivalent. The resulting model (when the ground model satisfies GCH) is usually called "the Cohen model" independently of the number λ of factors; for more precision, one says "the λ Cohen real model". This is the model used by Cohen [40] for his proof of the independence of GCH. Because of the c.c.c., every real in the Cohen model is already in the intermediate model generated by (the restriction of the generic filter to) some countable subproduct. Such a countable product (indeed, any countable atomless forcing notion) is equivalent to the single forcing ${}^{<\omega}2$. Thus any real in the Cohen model is in a submodel generated by a single Cohen real.

Since a Cohen real solves $\mathbf{Cov}(\mathcal{B})^{\perp}$, the λ Cohen real model (for any uncountable regular λ) has $\mathbf{cov}(\mathcal{B}) = \lambda = \mathfrak{c}$. It follows that all cardinals in the right half of Cichoń's diagram equal λ in this model. Furthermore, since

$$\mathbf{cov}(\mathcal{B}) \leq \mathfrak{r} \leq \mathfrak{u}, \mathfrak{i},$$

all these cardinals also equal $\mathfrak{c}$ in the Cohen model. (One can also see directly that a Cohen real splits all ground model reals, so $\mathfrak{r} = \lambda$.)

On the other hand, $\mathbf{non}(\mathcal{B}) = \aleph_1$ in the Cohen model, the set of ground model reals being non-meager. To prove this, we must show that every chopped real (x, Π) in the extension is matched by some ground model real. By our remarks above, we may assume that (x, Π) is in the forcing extension by a single Cohen real. In the ground model, we construct a real y such that for no condition $p \in {}^{<\omega}2$ and natural number n can p force "y does not agree with x on any interval of Π beyond n". Such a y is easily built by a recursion of length ω in which each step defines $y(k)$ for finitely many k and takes care of one pair (p, n). Taking care of (p, n) means to proceed as follows. Extend p to a condition q deciding a particular value for the restriction of x to the first interval $I \in \Pi$ whose left endpoint is greater than n and greater than all points already in the domain of y. Then extend y to agree with that restriction of x. Thus, q forces that y and x agree on an interval of Π beyond

n, so p cannot force the contrary. (Note that this proof shows more than claimed. Not only the set of all ground model reals but any non-meager set in the ground model remains non-meager in a Cohen extension.)

In fact, $\mathbf{non}(\mathcal{B}) = \aleph_1$ holds in any model obtained by adjoining at least $\aleph_1$ Cohen reals to any ground model whatsoever. The reason is that $\aleph_1$ Cohen reals constitute a non-meager set.

From $\mathbf{non}(\mathcal{B}) = \aleph_1$, it immediately follows that all cardinals in the left half of Cichoń's diagram are $\aleph_1$. Furthermore, we have

$$\mathbf{non}(\mathcal{B}) \geq \mathfrak{b} \geq \mathfrak{h} \geq \mathfrak{t} \geq \mathfrak{p} \geq \mathfrak{m}, \quad \mathbf{non}(\mathcal{B}) \geq \mathfrak{s}, \quad \text{and} \quad \mathbf{non}(\mathcal{B}) \geq \mathfrak{e},$$

so all these cardinals are also $\aleph_1$ in the Cohen model.

Kunen showed [68, Theorem VIII.2.3] that $\mathfrak{a} = \aleph_1$ in the Cohen model. The idea is to construct, by transfinite induction in the ground model (where CH is available) a MAD family that remains MAD when one adds a Cohen real to the universe. It therefore remains MAD in any Cohen extension, since a failure to remain MAD would be witnessed by a single real. We omit the construction, since a similar one is given in the discussion of random reals below.

Finally, we cite from [18] the result that $\mathfrak{g} = \aleph_1$ in the Cohen model (or indeed in any model obtained by adjoining at least $\aleph_1$ Cohen reals to any model at all).

11.4. Random Reals

The notion of forcing to add one random real is the Boolean algebra of Borel sets modulo sets of Lebesgue measure zero (in any of $[0,1]$, $\mathbb{R}$, ${}^\omega 2$, ${}^\omega\omega$; they are all equivalent). (Here and in general, when one refers to a Boolean algebra as a notion of forcing, one means the algebra minus its zero element.) Random forcing was introduced by Solovay [104, 105]. A generic G determines a real r, called "random", such that, if B is any Borel set in the ground model, then $r \in \tilde{B}$ if and only if $[B] \in G$. (For basic intervals B, this is the definition of r; for other B it is a theorem.) Thus, r solves $\mathbf{Cov}(\mathcal{L})^\perp$. This property characterizes random reals.

Although random forcing can be iterated with finite support or with countable support (being c.c.c. and therefore proper), the most common way to add many random reals uses a large measure algebra, namely the algebra of Borel subsets modulo measure zero sets in ${}^I 2$ for large I. The measure here is the product measure induced by the uniform measure on 2. This forcing adds a random function $f : I \to 2$ whose restrictions to countable subsets of I in V amount to random reals. One often starts with a ground model satisfying GCH, takes $I = \lambda \times \omega$, and regards the forcing as adding the λ random reals $r_\alpha : \omega \to 2 : n \mapsto f(\alpha, n)$. Any real in this λ random reals model is in the submodel generated by countably many of the r_α, and this submodel is equivalent to one obtained by adjoining a single random real to the ground model.

Because a random real solves $\mathbf{Cov}(\mathcal{L})^\perp$, the λ random reals model has (for uncountable regular λ) $\mathbf{cov}(\mathcal{L}) = \lambda = \mathfrak{c}$. Therefore, all the cardinals in the top row of Cichoń's diagram equal $\mathfrak{c}$ in this model, and so do $\mathfrak{r}$, $\mathfrak{u}$, and $\mathfrak{i}$.

On the other hand, $\mathfrak{d}$ and $\mathbf{non}(\mathcal{L})$ are both $\aleph_1$, as in the ground model. More generally, if uncountably many random reals are added (with the usual measure algebra forcing) to any ground model, then in the extension $\mathfrak{d}$ will have the same value as in the ground model while $\mathbf{non}(\mathcal{L})$ will be $\aleph_1$. The former follows from the fact that all reals in a random extension are majorized by ground model reals. The latter follows from the fact that any $\aleph_1$ of the added random reals form a set of positive outer measure. (A measure-zero Borel set, or rather its code, depends on only countably many of the added random reals; all the rest of the added random reals, being random over an intermediate model containing the code, must be outside that Borel set.)

It follows that all the cardinals in the middle and bottom rows of Cichoń's diagram are $\aleph_1$, and therefore so are $\mathfrak{s}$, $\mathfrak{e}$, $\mathfrak{g}$, $\mathfrak{h}$, $\mathfrak{t}$, $\mathfrak{p}$, and $\mathfrak{m}$.

Finally, we show, adapting Kunen's proof for the Cohen model, that $\mathfrak{a} = \aleph_1$ in the random model. Since every real in the random model is in a submodel that can be generated by a single random real, it suffices to construct a family $\mathcal{A}$ in the ground model that is MAD and remains so when one random real is adjoined to the universe. We proceed as follows in the ground model. Because the forcing notion to adjoin one random real has cardinality $\mathfrak{c}$ and satisfies the c.c.c., there are only $\mathfrak{c} = \aleph_1$ essentially different names for subsets of ω; enumerate them as $\langle x_\alpha : \alpha < \omega_1 \rangle$. We construct $\mathcal{A}$ by a recursion of length $\aleph_1$, starting with a partition of ω into $\aleph_0$ infinite pieces, and adding one set a_α to $\mathcal{A}$ at each step. This set will be chosen so as to be almost disjoint from the previous a_β's and to have infinite intersection with the denotation (with respect to every generic set) of x_α (unless some earlier a_β already does or x_α is finite). That will ensure that $\mathcal{A} = \{a_\alpha : \alpha < \omega_1\}$ remains MAD in the random extension. Let $[B]$ be the Boolean truth value of "x_α is not almost included in the union of finitely many $\check{a}_\beta$ with $\beta < \check{\alpha}$". We shall make sure that the truth value of "$x_\alpha \cap \check{a}_\alpha$ is infinite" is at least $[B]$. Equivalently, since we are dealing with a measure algebra, we shall make sure that for every n the Boolean truth value of "$x_\alpha \cap \check{a}_\alpha$ has a member $> n$" intersected with $[B]$ has measure at least $\mu[B] - \frac{1}{n}$. And of course we must ensure that a_α is almost disjoint from the earlier a_β's. We define a_α as follows.

Let the earlier a_β's be enumerated in an ω-sequence as a'_n. We shall construct a_α by a recursion of length ω, adding finitely many elements at each stage, and ensuring at stage n that the measure requirement at the end of the last paragraph is satisfied for n. To ensure almost disjointness, we shall not add any elements of a'_k after stage k. We now describe stage n. Let $v = \bigcup_{k<n} a'_k$, whose elements are no longer to be added to a_α. With truth value at least $[B]$, $x_\alpha - v$ is infinite. So $[B]$ is the Boolean sum of (countably many) pairwise incompatible conditions $[B_i]$ each forcing a specific value for the first element z of $x_\alpha - v$ that is $> n$. Since the measures of all the $[B_i]$ add up to the measure of $[B]$, finitely many of them come to within $\frac{1}{n}$ of that total. Put the corresponding finitely many z's into a_α. This completes the construction of a_α; we omit the routine verification that it does what was required.

11.5. Sacks Reals

The Sacks forcing notion, introduced in [96] and also called perfect set forcing, consists of perfect subtrees of ${}^{<\omega}2$, i.e., nonempty subtrees that have branching beyond each node; the partial ordering is inclusion. This is a proper forcing that adjoins a real s, namely the unique common path through all the trees in a generic set G.

The forcing extension $V[s]$ enjoys the *Sacks property*: For every function $f : \omega \to V$ in $V[s]$, there is a function $g : \omega \to V$ in V such that for all $n \in \omega$ we have $f(n) \in g(n)$ and $|g(n)| \leq 2^n$. To prove this, suppose we are given a name $\dot{f}$ for f and a condition p. Working in V, we prune the tree p in ω steps to produce a perfect subtree q forcing that a certain g is as required; by genericity, this will suffice. Begin by choosing $p_0 \leq p$ deciding a specific value for $\dot{f}(0)$. This value will be the unique element of $g(0)$. The first branching node a of p_0 will be the first branching node of the final q; i.e., neither a nor its immediate successors $a^\frown\langle 0\rangle$ and $a^\frown\langle 1\rangle$ will be pruned away later. Regard p_0 as the union of two perfect subtrees, one consisting of the nodes comparable with $a^\frown\langle 0\rangle$ and the other of the nodes comparable with $a^\frown\langle 1\rangle$. In each of these, find a perfect subtree deciding $\dot{f}(1)$ (possibly different decisions for the two subtrees). Reuniting these two subtrees, we get a perfect subtree p_1 of p_0, where a is still a branching node, and such that p_1 forces $\dot{f}(1)$ to have one of just two specific values. Those values will be the elements of $g(1)$. All later steps will preserve the two second-level branching nodes of p_1. Regard p_1 as the union of four perfect subtrees, one through each of the immediate successors of those nodes. Shrink each of the four to decide a (possibly different) value for $\dot{f}(2)$; and reunite them to get p_2. Continuing in this way, we finally obtain a tree $q = \bigcap_{n\in\omega} p_n$ that is perfect because we retain more and more branching as the construction progresses. q is an extension of p forcing each $\dot{f}(n)$ to have one of 2^n specific values known in V, so the desired g exists in V. (Although 2^n emerges naturally from the proof as the bound for $|g(n)|$, we could, as in Remark 5.15, replace 2^n by any function tending to ∞.)

This sort of construction, repeatedly pruning a tree but retaining more and more branching, is referred to as *fusion*. It can also be used to prove that adjoining a Sacks real produces a minimal extension in the sense that if $x \in V[s] - V$ is a set of ordinals then $V[x] = V[s]$.

The usual way to iterate Sacks forcing is with countable support for $\aleph_2$ steps, starting with a model of GCH. The resulting model is often called the *Sacks model*. Properness of Sacks forcing implies that cardinals are preserved. Furthermore, the Sacks model has the Sacks property, because this property is preserved by countable support proper iterations; see [5, Sect. 6.3.F], [97, Sects. VI.1–2], or [51]. It follows, by the dual of Theorem 5.14, that $\mathbf{cof}(\mathcal{L}) = \aleph_1$ in the Sacks model. Therefore, all cardinals in Cichoń's diagram as well as $\mathfrak{d}$, $\mathfrak{e}$, $\mathfrak{b}$, $\mathfrak{g}$, $\mathfrak{s}$, $\mathfrak{h}$, $\mathfrak{t}$, $\mathfrak{p}$, and $\mathfrak{m}$ are equal to $\aleph_1$ in this model. Baumgartner and Laver [11] showed that selective ultrafilters in the ground model, which exist since GCH holds there, generate ultrafilters in the Sacks model. (In fact, the same is true of P-points.) Therefore the Sacks model has $\mathfrak{u} = \mathfrak{r} = \aleph_1$.

Spinas has shown (private communication) that the Sacks model satisfies $\mathfrak{a} = \aleph_1$. In outline, his argument is as follows. By general properties of Souslin proper forcing (see [60], [51, Sect. 7], and [101]), it suffices to find, in the ground model, a MAD family $\mathcal{A}$ that remains MAD in the extension obtained by iterating Sacks forcing for ω_1 steps with countable support. List in an ω_1-sequence all pairs (τ, p) where p is a condition in this iteration and τ is a name forced by p to denote an infinite subset of ω. We define the desired $\mathcal{A} = \{A_\alpha : \alpha < \omega_1\}$ by induction in the ground model, ensuring at step α that for the αth pair (τ, p) some extension of p either forces (a) "$\tau \cap \check{A}_\alpha$ is infinite" or forces (b) "τ is almost included in $\check{A}_{\beta_1} \cup \cdots \cup \check{A}_{\beta_r}$" for some finitely many $\beta_1, \ldots, \beta_r < \alpha$. Either way, p cannot force $\mathcal{A} \cup \{\tau\}$ to be almost disjoint with $\tau \notin \mathcal{A}$, so the maximality is preserved. To define A_α, assume the previous A_β's are already defined; modifying them finitely and re-numbering them (see the proof of Proposition 8.4), we can pretend that the ω we are working in is $\omega \times \omega$ and that these earlier A_β's are the columns $\{n\} \times \omega$. We can also assume that p forces τ to meet infinitely many of these columns, as otherwise we already have alternative (b) above. We shall take A_α to be $\{(a, b) : b < f(a)\}$ for a suitably large $f : \omega \to \omega$. Then clearly A_α is almost disjoint from the previous A_β's (the columns). To obtain alternative (a) and thus complete the proof, we need only choose f large enough. Specifically, use the name τ to produce a name D for the set of n such that the nth column meets τ and a name g for a function $D \to \omega$ such that p forces "D is infinite and, for each $d \in D$, τ contains an element (d, b) with $b < g(d)$". Then, thanks to the Sacks property, p also forces "some ground model function $f : \omega \to \omega$ majorizes g". Choosing an extension of p that decides what f is, we obtain alternative (a), and the proof is complete.

Finally, Eisworth and Shelah (unpublished) have shown that $\mathfrak{i} = \aleph_1$ in the Sacks model.

For many cardinal characteristics, a recent result of Shelah gives a uniform reason why they are $\aleph_1$ in the Sacks model. Shelah has shown that a countable support proper iteration of forcings that individually add no reals can, at limit stages of cofinality ω, introduce Sacks reals. But there are numerous iteration theorems (see [97, 51, 45]) saying that certain properties of a ground model will be unchanged by a countable support proper forcing iteration provided they are unchanged by the individual steps. These properties, then, are not changed by adding Sacks reals.

Another explanation for the smallness of many cardinal characteristics in the Sacks model is that countable support iteration of Sacks forcing is the optimal forcing for increasing $\mathfrak{c}$, in the sense of Zapletal [115]; see Remark 11.1.

Thus, all tame cardinal characteristics that can be forced to remains small when $\mathfrak{c}$ is increased by some set forcing in fact remain small in the Sacks model, provided there is a proper class of measurable Woodin cardinals.

11.6. Hechler Reals

Introduced by Hechler [57] for his proof of Theorem 2.5, Hechler forcing, also called dominating forcing, is the set of pairs (s, f) where $s \in {}^{<\omega}\omega$ and $f \in {}^{\omega}\omega$. (The "meaning" of (s, f) is that the generic real in ${}^{\omega}\omega$ has s as an initial segment and thereafter majorizes f.) The ordering puts $(s', f') \leq (s, f)$ if s is an initial segment of s', $f \leq f'$, and $s'(n) \geq f(n)$ for all $n \in \mathrm{dom}(s') - \mathrm{dom}(s)$. This forcing satisfies c.c.c.; in fact it is σ-centered, since any finitely many conditions with the same first component have a lower bound. A Hechler-generic set G determines a function $g : \omega \to \omega$, namely the union of the first components of the members of G. Such a g is called a Hechler real. Genericity implies that it dominates all ground model functions $\omega \to \omega$, i.e., g solves $\mathfrak{D}$. ("Dominating real" is sometimes used as a synonym for "Hechler real" and sometimes to mean any real that dominates all ground model reals.) Replacing each of the values of g by its parity, we obtain a Cohen real, g mod 2.

By "the Hechler model" we mean the result of a finite support iteration of Hechler forcing over a model of GCH, where the number of steps is some regular uncountable cardinal λ. One can also consider countable support iterations (for up to ω_2 stages, as usual) but we shall not do so here. Hechler's original use of Hechler forcing [57] amounted to a combination of finite support iteration and product constructions.

Since a Hechler real solves $\mathfrak{D}$ and its parity solves $\mathbf{Cov}(\mathcal{B})^{\perp}$, the Hechler model satisfies $\mathbf{cov}(\mathcal{B}) = \mathfrak{b} = \lambda = \mathfrak{c}$. By Theorem 5.6, it satisfies $\mathbf{add}(\mathcal{B}) = \mathfrak{c}$. Thus, in this model, the cardinals in the second through fourth columns of Cichoń's diagram equal $\mathfrak{c}$. Those in the first column, on the other hand, equal $\aleph_1$ since this forcing adds no random reals [5, second model in 7.6.9]. Since $\mathfrak{b}$ is large, so are $\mathfrak{r}$, $\mathfrak{u}$, $\mathfrak{a}$, and $\mathfrak{i}$. Baumgartner and Dordal showed in [10] that $\mathfrak{s}$ in the Hechler model is $\aleph_1$, and therefore so are $\mathfrak{h}$, $\mathfrak{t}$, $\mathfrak{p}$, and $\mathfrak{m}$. Brendle [30, Theorem 10.4] showed that $\mathfrak{e} = \aleph_1$ in the Hechler model.

The value of $\mathfrak{g}$ in the Hechler model should be $\aleph_1$. Brendle has shown (private communication) that it is $\aleph_1$ if Hechler forcing is iterated for only ω_2 steps. Shelah has sketched a proof that it is $\aleph_1$ in general, but so far as I know this proof has yet to be written down carefully and checked (private communication from Eisworth).

Pawlikowski [84] showed that, although $\mathbf{add}(\mathcal{B})$ is large in the Hechler model, adjoining a single Hechler real to the ground model does not produce any real solving $\mathbf{Cof}(\mathcal{B})$. Such a real appears, however, when two Hechler reals are added iteratively. This last fact follows from part 1 of Theorem 5.6, which says that $\mathbf{Cof}(\mathcal{B})$ admits a morphism from a sequential composition of two relations each of which is solved when a single Hechler real is adjoined.

11.7. Laver Reals

Conditions in Laver forcing are trees $p \subseteq {}^{<\omega}\omega$ in which there is a node s, called the stem, such that all nodes are comparable with s and every node beyond s has infinitely many immediate successors. (So, starting at the root of p, one finds no branching until one reaches s and then infinite branching everywhere thereafter.) The ordering is inclusion. A generic set G determines a function $g : \omega \to \omega$ called a Laver real, namely the union of the stems of all the conditions in G, or equivalently the unique common path through all members of G. Laver forcing is proper. Genericity implies that a Laver real dominates all ground model functions $\omega \to \omega$.

The Laver model is obtained by an ω_2-stage countable support iteration of Laver forcing over a model of GCH. (Historically, Laver forcing and countable support iteration were introduced together in [72]. For the purpose of that paper, producing a model of the Borel conjecture, one needs to dominate all ground model reals, but one must not introduce Cohen reals, so neither Hechler forcing nor a finite support iteration can be used.) Since a Laver real solves $\mathfrak{D}$, the Laver model has $\mathfrak{b} = \aleph_2 = \mathfrak{c}$. It follows that the cardinals in all but the left column and bottom row of Cichon's diagram are $\aleph_2$, and so are $\mathfrak{r}$, $\mathfrak{i}$, $\mathfrak{u}$, and $\mathfrak{a}$.

Like Hechler forcing, Laver forcing even when iterated does not produce random reals, but unlike Hechler forcing it does not produce Cohen reals either. In fact, the set of ground model reals does not have measure zero in the extension. See [5, Sect. 7.3.D] for proofs of these facts. It follows that $\mathbf{cov}(\mathcal{L})$ and $\mathbf{non}(\mathcal{L})$ are both $\aleph_1$ in the Laver model, and therefore so are $\mathbf{add}(\mathcal{L})$, $\mathbf{add}(\mathcal{B})$, $\mathbf{cov}(\mathcal{B})$, $\mathfrak{e}$, $\mathfrak{s}$, $\mathfrak{h}$, $\mathfrak{t}$, $\mathfrak{p}$, and $\mathfrak{m}$.

Finally, Brendle has pointed out that the proof of $\mathfrak{g} = \mathfrak{c}$ for the Miller model [26, 18] applies also to the Laver model. The same argument was used for a slightly different purpose in [45, Lemma 4.3.5].

11.8. Mathias Reals

Mathias forcing was described in Remark 7.8. It consists of pairs (s, A) with $s \in [\omega]^{<\omega}$ and $A \in [\omega]^{\omega}$ ("meaning" that the generic subset of ω has s as an initial segment and otherwise is included in A). The ordering, defined in Remark 7.8, is based on this meaning, and the resulting forcing is proper. A generic filter G determines an infinite subset X of ω called a Mathias real, namely the union of the first components of all the members of G. Mathias forcing was used in [74] and was studied in detail in [76].

The essential property of a Mathias real X is that, if $\mathcal{D} \subseteq [\omega]^{\omega}$ is any dense open family in the ground model, then X is included in some member of $\mathcal{D}$. To prove this, consider an arbitrary condition (s, A) and use the density of $\mathcal{D}$ to extend it to (s, A') with $A' \in \mathcal{D}$. Then (s, A') forces the generic real X to be almost included in A' and therefore included in some member of $\mathcal{D}$ since dense open families are closed under finite modifications.

By the Mathias model, we mean the result of an ω_2-stage countable support iteration of Mathias forcing over a model of GCH. The preceding paragraph together with a reflection argument implies that $\mathfrak{h} = \aleph_2 = \mathfrak{c}$ in this model. Specifically, given any $\aleph_1$ dense open families $\mathcal{D}_\xi$, we can find a common member as follows. Using the $<\aleph_2$-chain condition, we obtain an $\alpha < \omega_2$ (in fact an ω_1-closed unbounded set of such α's) such that each $\mathcal{D}_\xi \cap V_\alpha$ is a member of V_α and is a dense open set in the sense of V_α. Then the Mathias real X adjoined in going from V_α to $V_{\alpha+1}$ has, by the preceding paragraph, supersets in each $\mathcal{D}_\xi \cap V_\alpha$ and therefore belongs to each $\mathcal{D}_\xi$.

Because $\mathfrak{h}$ is large, so are $\mathfrak{b}$, $\mathfrak{g}$, $\mathfrak{s}$, $\mathfrak{r}$, $\mathfrak{d}$, $\mathfrak{a}$, $\mathfrak{u}$, $\mathfrak{i}$, and **non** and **cof** of both category and measure.

On the other hand, both $\mathbf{cov}(\mathcal{B})$ and $\mathbf{cov}(\mathcal{L})$ are only $\aleph_1$ because neither Cohen nor random reals are added. See [5, Sect. 7.4.A] for the proof. It follows that $\mathbf{add}(\mathcal{L})$, $\mathbf{add}(\mathcal{B})$, $\mathfrak{e}$, $\mathfrak{t}$, $\mathfrak{p}$, and $\mathfrak{m}$ are also $\aleph_1$.

11.9. Miller Reals

The Miller forcing notion, introduced in [82], consists of superperfect trees (also called rational perfect trees), i.e., subtrees of ${}^{<\omega}\omega$ in which beyond every node there is one with infinitely many immediate successors. The order is inclusion. As with other such tree forcings, this is proper, and a generic set G determines a real $g : \omega \to \omega$, namely the union of the stems of the members of G or equivalently the unique path through all members of G. It is sometimes convenient to replace the Miller forcing notion with the isomorphic one in which the nodes of the trees are strictly increasing finite sequences from ω. Then the generic g is an increasing map $\omega \to \omega$, the enumeration of an infinite $X \subseteq \omega$. Either g or X can be called a Miller real or a superperfect real.

The Miller model is the result of an ω_2-stage countable support iteration of Miller forcing over a model of GCH. It is shown in [26, 18] that a Miller real X has supersets in all groupwise dense families from the ground model. This and a reflection argument show, just as in the discussion of Mathias forcing above, that $\mathfrak{g} = \aleph_2 = \mathfrak{c}$ in the Miller model. It follows that $\mathfrak{d}$, $\mathfrak{i}$, $\mathbf{cof}(\mathcal{B})$, and $\mathbf{cof}(\mathcal{L})$ are also $\aleph_2$.

On the other hand, it is shown in [5, 7.3.E] that both $\mathbf{non}(\mathcal{L})$ and $\mathbf{non}(\mathcal{B})$ are $\aleph_1$ in the Miller model. Therefore so are $\mathfrak{s}$, $\mathfrak{e}$, $\mathfrak{b}$, $\mathfrak{h}$, $\mathfrak{t}$, $\mathfrak{p}$, $\mathfrak{m}$, and all the cardinals in Cichoń's diagram except $\mathfrak{d}$ and the two cofinalities.

It is also shown in [26] that every P-point in the ground model generates an ultrafilter in the Miller model. Therefore this model satisfies $\mathfrak{u} = \mathfrak{r} = \aleph_1$.

Finally, the proof that $\mathfrak{a} = \aleph_1$ in the Sacks model can, as Spinas pointed out, be transferred to the Miller model with only a minor modification. At the end of the proof, instead of using the Sacks property (which fails in the Miller model), one uses the fact that the ground model is an unbounded family in ${}^\omega\omega$ to show that p forces the function g in the extension to be majorized on an infinite subset of D by an f from the ground model. Another proof that $\mathfrak{a} = \aleph_1$ in the Miller model is given in [44, Proposition 8.24]. Eisworth

Table 4: Cardinal characteristics in iterated forcing models

	MA	Cohen	Random	Sacks	Hechler	Laver	Mathias	Miller
$\mathfrak{a}$	$\mathfrak{c}$	$\aleph_1$	$\aleph_1$	$\aleph_1$	$\mathfrak{c}$	$\mathfrak{c}$	$\mathfrak{c}$	$\aleph_1$

pointed out (private communication) that the same argument applies to the Sacks model.

11.10. Summary of Iterated Forcing Results

Table 4 summarizes the preceding results concerning the values of cardinal characteristics in the iterated forcing models described above. Remember that in the countable support models, i.e., in the Sacks, Laver, Mathias, and Miller columns of the table, $\mathfrak{c}$ is just $\aleph_2$.

Figure 1 is a Hasse diagram of the main cardinal characteristics discussed in this chapter, except for the characteristics of the measure and category ideals. A line joining two characteristics in the figure means that the lower one is provably $\leq$ the upper one.

11.11. Other Forcing Iterations

The preceding sections cover only a few of the many kinds of iterated forcing, over models of GCH, that have been used in the theory of cardinal characteristics. There are other kinds of reals that one can adjoin, for example infinitely equal reals, Prikry-Silver reals, Matet reals, Grigorieff reals. Ex-

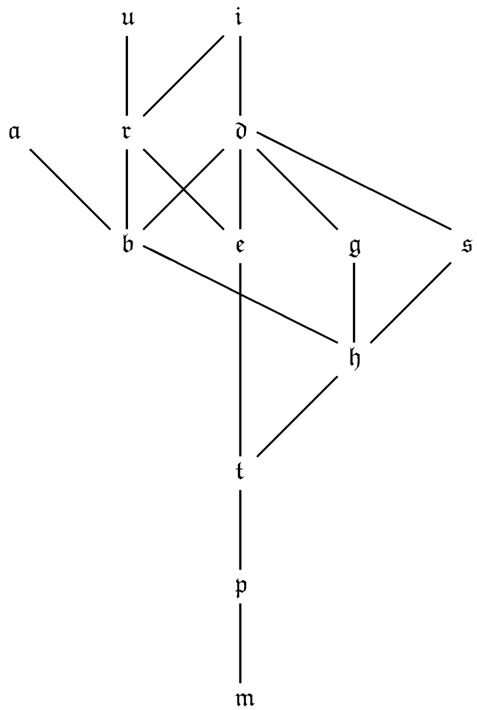

Figure 1: Hasse diagram of combinatorial characteristics

cept for Matet reals, which are defined in the last section of [18], these and many others can be found in [5] or [62]. Most of these forcing notions do not satisfy the c.c.c., so they are iterated with countable support and therefore one enlarges $\mathfrak{c}$ only to $\aleph_2$.

A model constructed in [25, Sect. 2] involves iterating a forcing that looks less natural than those discussed in the preceding sections or mentioned in the preceding paragraph, but we list its cardinal characteristics here because they are somewhat unusual, e.g., $\mathfrak{u} < \mathfrak{s}$. The model has $\mathfrak{u} = \aleph_1$ and therefore all of $\mathfrak{r}$, $\mathfrak{e}$, $\mathfrak{b}$, $\mathfrak{h}$, $\mathfrak{t}$, $\mathfrak{p}$, $\mathfrak{m}$, and the covering numbers and additivities for both category and measure are $\aleph_1$. On the other hand, it has $\mathfrak{s} = \mathfrak{c} = \aleph_2$ and therefore all of $\mathfrak{d}$, $\mathfrak{i}$, and the uniformities and cofinalities of both measure and category are $\aleph_2$. (See [25, Theorem 5.2].) In addition, this model, designed to satisfy NCF, has $\mathfrak{g} = \aleph_2$, as was shown in [23, Theorem 2]. It also has $\mathfrak{a} = \aleph_1$ by the same Souslin-forcing argument used above for Sacks and Miller reals.

A frequently useful sort of iterated forcing is one where two or more different forcings are used alternately. Numerous examples of this can be found in [5, Chap. 7]. Dow's paper [43] describes, among other things, the models obtained by alternating Laver and Mathias forcings; it turns out to make a difference which forcing one uses at limit ordinals.

Dordal [41] uses a mixed support iteration of Mathias forcings. Viewing Mathias forcing as a two-step iteration, where one first adjoins an ultrafilter generically and then does Mathias forcing with respect to this ultrafilter (see Remark 7.8), he defines an iteration in which the adjunctions of ultrafilters are done with countable support while the interleaved Mathias forcings with respect to these ultrafilters are done with finite support.

All the preceding forcing iterations began with a ground model satisfying GCH. Thus, all cardinal characteristics are $\aleph_1$ in the ground model, and the iterations are designed to raise some characteristics while leaving others small. An alternative approach is to begin with a model where $\mathfrak{c}$ and some other characteristics are already large (e.g., a model of MA) and to do an iteration, usually of small length, to lower some characteristics while leaving others large. We briefly describe two examples; many more can be found in [5, Chap. 7].

Start with a model of MA + $\neg$CH (so all the characteristics we have discussed are large) and adjoin $\aleph_1$ random reals. Since the ${}^\omega\omega$ of a random extension is dominated by that of the ground model, we obtain a model where $\mathfrak{b}$ has the same large value that it had in the ground model of MA. On the other hand, $\mathfrak{s}$ is only $\aleph_1$ in the extension, and in fact so is $\mathbf{non}(\mathcal{L})$, since the $\aleph_1$ random reals form a set of positive outer measure and thus a splitting family. This proof for the consistency of $\mathfrak{b} > \mathfrak{s}$, due to Balcar and Simon, is easier than either of the ones obtainable from Table 4 (the Hechler and Laver models).

Another application of forcing over a model with large continuum is the construction in [27] of a model where $\mathfrak{u} < \mathfrak{d}$. This model, which predates the ones in [25, 26] that establish the stronger $\mathfrak{u} < \mathfrak{g}$, has the advantage that $\mathfrak{u} < \mathfrak{d}$ can be any prescribed uncountable regular cardinals. It begins with a Cohen model, where $\mathfrak{d}$ has the desired value, and extends it by a finite support iteration of Mathias forcings with respect to carefully chosen ultrafilters. The length of the iteration is the prescribed $\mathfrak{u}$. The easier part of "carefully chosen" is that each ultrafilter contains the previously adjoined Mathias reals, so that the sequence of Mathias reals is almost decreasing and generates an ultrafilter in the final model. Thus $\mathfrak{u}$ will be small. The hard part of "carefully chosen," which we omit here, is to keep $\mathfrak{d}$ large.

11.12. Adding One Real

In this subsection, we briefly summarize some results about the effect on cardinal characteristics of adjoining one real to a model of ZFC. Here the ground model will not satisfy CH, for the single-real forcings we consider would preserve CH and leave all characteristics at $\aleph_1$. We consider situations where some characteristics are large in the ground model and we ask how adding a single real affects them. Most of what is known about this concerns the cardinals from Cichoń's diagram. The results summarized here are from

[29, 35, 7, 39, 84].

Adding a Cohen real to any model of ZFC makes $\mathbf{add}(\mathcal{L}) = \mathbf{cov}(\mathcal{L}) = \aleph_1$ and $\mathbf{non}(\mathcal{L}) = \mathbf{cof}(\mathcal{L}) = \mathfrak{c}$. The values of $\mathbf{add}(\mathcal{B})$, $\mathbf{non}(\mathcal{B})$, and $\mathfrak{b}$ in the extension are the $\mathbf{add}(\mathcal{B})$ of the ground model, and dually the values of $\mathbf{cof}(\mathcal{B})$, $\mathbf{cov}(\mathcal{B})$, and $\mathfrak{d}$ in the extension are the $\mathbf{cof}(\mathcal{B})$ of the ground model.

Adding a random real produces a value for $\mathbf{cov}(\mathcal{L})$ that is no smaller than $\max\{\mathbf{cov}(\mathcal{L}), \mathfrak{b}\}$ of the ground model, and may be strictly larger. Dually, the extension's $\mathbf{non}(\mathcal{L})$ is at most $\min\{\mathbf{non}(\mathcal{L}), \mathfrak{d}\}$ and may be strictly smaller. Except for $\mathbf{cov}(\mathcal{L})$ and $\mathbf{non}(\mathcal{L})$, the cardinals in Cichoń's diagram remain unchanged.

Adding one Hechler real makes all cardinals in the left half of Cichoń's diagram $\aleph_1$ and all those in the right half $\mathfrak{c}$. It also makes $\mathfrak{a} = \aleph_1$.

Adding one Laver or Mathias real makes the $\mathfrak{d}$ of the extension $\aleph_1$. These forcings also collapse $\mathfrak{c}$ to $\mathfrak{h}$. Since $\mathfrak{h} \leq \mathfrak{d}$, it follows that a two-step iteration of these forcings produces a model of CH.

1. Introduction

The purpose of this chapter is to discuss various results concerning the relationship between measure and category. We are mostly interested in set-theoretic properties of the associated ideals, particularly, their cardinal invariants (called characteristics in [11]). This is a very large area, and it was necessary to make some choices. We decided to present several new results and new approaches to old problems. In most cases we do not present the optimal result, but a simpler theorem that still carries most of the weight of that original result. For example, we construct Borel morphisms in the Cichoń diagram while continuous ones can be constructed. We believe however that the reader should have no problems upgrading the material presented here to the current state of the art. The standard reference for this subject is [8], and this chapter updates it as most of the material presented here was proved after [8] was published.

Measure and category have been studied for about a century. The beautiful book [36] contains a lot of classical results, mostly from analysis and topology, that involve these notions. The roles played by Lebesgue measure and Baire category in these results are more or less identical. There are, of course, classical theorems indicating lack of complete symmetry, but the difference do not seem very significant. For example, Kuratowski's theorem (cf. Theorem 3.7) asserts that for every Borel function $f : {}^{\omega}2 \longrightarrow {}^{\omega}2$ there exists a meager set $F \subseteq {}^{\omega}2$ such that $f{\restriction}({}^{\omega}2 - F)$ is continuous. The dual proposition stating that for every Borel function $f : {}^{\omega}2 \longrightarrow {}^{\omega}2$ there exists a measure one set $G \subseteq {}^{\omega}2$ such that $f{\restriction}G$ is continuous is false. We only have a theorem of Luzin which guarantees that such G's can have measure arbitrarily close to one.

The last 15 years have brought a wealth of results indicating that hypotheses relating to measure are often stronger than the analogous ones relating to category. This chapter contains several examples of this phenomenon. Before we delve into this subject let us give a little historical background. The first result of this kind is due to Shelah [47]. He showed that

- If all projective sets are measurable then there exists an inner model with an inaccessible cardinal.
- It is consistent relative to ZFC that all projective sets have the property of Baire.

In 1984 Bartoszynski [3] and Raisonnier and Stern [40] showed that additivity of measure is not greater than additivity of category, whereas Miller [33] had shown that it can be strictly smaller. In subsequent years several more results of that kind were found. Let us mention one more (cf. [10]) concerning filters on ω (treated as subsets of ${}^{\omega}2$):

- There exists a measurable filter that does not have the Baire property. In fact, every filter that has measure zero can be extended to a measure zero filter that does not have the Baire property.

- It is consistent with ZFC that every filter that has the Baire property is measurable.

All these results as well as many others concerning measurability and the Baire property of projective sets, connections with forcing and others can be found in [8].

2. Tukey Connections

The starting point for our considerations is the following list of cardinal invariants of an ideal. For a proper ideal $\mathcal{J}$ of subsets of a set X which contains singletons (i.e. $\{a\} \in \mathcal{J}$ for $a \in X$) define

1. $\mathbf{add}(\mathcal{J}) = \min\{|\mathcal{A}| : \mathcal{A} \subseteq \mathcal{J} \ \& \ \bigcup \mathcal{A} \notin \mathcal{J}\}$,
2. $\mathbf{cov}(\mathcal{J}) = \min\{|\mathcal{A}| : \mathcal{A} \subseteq \mathcal{J} \ \& \ \bigcup \mathcal{A} = X\}$,
3. $\mathbf{non}(\mathcal{J}) = \min\{|Y| : Y \subseteq X \ \& \ Y \notin \mathcal{J}\}$,
4. $\mathbf{cof}(\mathcal{J}) = \min\{|\mathcal{A}| : \mathcal{A} \subseteq \mathcal{J} \ \& \ \forall B \in \mathcal{J} \ \exists A \in \mathcal{A} \ B \subseteq A\}$.

2.1 Definition. Suppose that $\mathcal{P}$ and $\mathcal{Q}$ are partial orderings. We say that $\mathcal{P} \preceq \mathcal{Q}$ if there is function $f : \mathcal{P} \longrightarrow \mathcal{Q}$ such that for every bounded set $X \subseteq \mathcal{Q}$, $f^{-1}(X)$ is bounded in $\mathcal{P}$. Such a function f is called a *Tukey embedding*. Define $\mathcal{P} \equiv \mathcal{Q}$ if $\mathcal{P} \preceq \mathcal{Q}$ and $\mathcal{Q} \preceq \mathcal{P}$.

Note that if $f : \mathcal{P} \longrightarrow \mathcal{Q}$ is a Tukey embedding then there is an associated function $f^\star : \mathcal{Q} \longrightarrow \mathcal{P}$ defined so that $f^\star(q)$ is a bound of the set $f^{-1}(\{p : p \leq q\})$. Observe that f maps every set unbounded in $\mathcal{P}$ onto a set unbounded in $\mathcal{Q}$ and $f^\star$ maps every set cofinal in $\mathcal{Q}$ onto a set cofinal in $\mathcal{P}$.

2.2 Lemma. *Suppose that $\mathcal{I}$ and $\mathcal{J}$ are ideals. If $\mathcal{I} \preceq \mathcal{J}$, then $\mathbf{add}(\mathcal{I}) \geq \mathbf{add}(\mathcal{J})$ and $\mathbf{cof}(\mathcal{I}) \leq \mathbf{cof}(\mathcal{J})$.*

Proof. Suppose that $f : \mathcal{I} \longrightarrow \mathcal{J}$ is a Tukey function.

Let $\mathcal{A} \subseteq \mathcal{I}$ be a family of size $< \mathbf{add}(\mathcal{J})$. Find a set $B \in \mathcal{J}$ such that $\bigcup_{A \in \mathcal{A}} f(A) \subseteq B$. It follows that $\bigcup \mathcal{A} \subseteq f^\star(B)$.

Similarly, if $\mathcal{B} \subseteq \mathcal{J}$ is a basis for $\mathcal{J}$, then $\{f^\star(B) : B \in \mathcal{B}\}$ is a basis for $\mathcal{I}$. $\dashv$

We will need a slightly stronger definition which will encompass both cardinal invariants and Tukey embeddings.

2.3 Definition. Suppose that $\mathbf{A} = (A_-, A_+, A)$, where A is a binary relation between A_- and A_+. Let

$$\begin{aligned}
\mathfrak{d}(\mathbf{A}) &= \{Z : Z \subseteq A_+ \ \& \ \forall x \in A_- \ \exists z \in Z \ A(x,z)\},\\
\mathfrak{b}(\mathbf{A}) &= \{Z : Z \subseteq A_- \ \& \ \forall y \in A_+ \ \exists z \in Z \ \neg A(z,y)\},\\
\|\mathbf{A}\| &= \min\{|Z| : Z \in \mathfrak{d}(\mathbf{A})\}.
\end{aligned}$$

Define $\mathbf{A}^\perp = (A_+, A_-, A^\perp)$, where $A^\perp = \{(z, x) : \neg A(x, z)\}$. Note that $\mathfrak{b}(\mathbf{A}) = \mathfrak{d}(\mathbf{A}^\perp)$.

Note that $\|\mathbf{A}\|$ is the smallest size of the "dominating" family in A_+ and $\|\mathbf{A}^\perp\|$ is the smallest size of the "unbounded" family in A_-. With some notable exceptions such as $\mathfrak{p}, \mathfrak{t}, \mathfrak{g}, \mathfrak{h}, \mathfrak{a}, \mathfrak{u}$ (see Blass's chapter [11] for the definitions), virtually all cardinal characteristics, commonly called "invariants" of the continuum, can be expressed in this framework. For an ideal $\mathcal{J}$ of subsets of X we have:

- $\mathbf{cof}(\mathcal{J}) = \|(\mathcal{J}, \mathcal{J}, \subseteq)\|$,
- $\mathbf{add}(\mathcal{J}) = \|(\mathcal{J}, \mathcal{J}, \subseteq)^\perp\| = \|(\mathcal{J}, \mathcal{J}, \not\supseteq)\|$,
- $\mathbf{cov}(\mathcal{J}) = \|(X, \mathcal{J}, \in)\|$,
- $\mathbf{non}(\mathcal{J}) = \|(X, \mathcal{J}, \in)^\perp\| = \|(\mathcal{J}, X, \not\ni)\|$.

For $f, g \in {}^\omega\omega$ we define $f \leq^\star g$ if $f(n) \leq g(n)$ for all but finitely many $n \in \omega$. Let

- $\mathfrak{d} = \|({}^\omega\omega, {}^\omega\omega, \leq^\star)\|$,
- $\mathfrak{b} = \|({}^\omega\omega, {}^\omega\omega, \leq^\star)^\perp\| = \|({}^\omega\omega, {}^\omega\omega, \not\geq^\star)\|$.

The notion of Tukey embedding generalizes to the following:

2.4 Definition. A *morphism* φ between $\mathbf{A}$ and $\mathbf{B}$ is a pair of functions $\varphi_- : A_- \longrightarrow B_-$ and $\varphi_+ : B_+ \longrightarrow A_+$ such that for each $a \in A_-$ and $b \in B_+$,

$$A(a, \varphi_+(b)), \quad \text{whenever } B(\varphi_-(a), b).$$

If there is a morphism between $\mathbf{A}$ and $\mathbf{B}$, we say that $\mathbf{A} \preceq \mathbf{B}$.

Note that if a pair of functions $f, f^\star$ witnesses that $\mathcal{P} \preceq \mathcal{Q}$, then $\varphi = (f, f^\star)$ is a morphism between $(\mathcal{P}, \mathcal{P}, \leq)$ and $(\mathcal{Q}, \mathcal{Q}, \leq)$.

2.5 Lemma.

(1) $\mathbf{A} \preceq \mathbf{B} \iff \mathbf{A}^\perp \succeq \mathbf{B}^\perp$,

(2) If $\mathbf{A} \preceq \mathbf{B}$, *then* $\|\mathbf{A}\| \leq \|\mathbf{B}\|$ *and* $\|\mathbf{A}^\perp\| \geq \|\mathbf{B}^\perp\|$.

Proof. (1) If $\varphi = (\varphi_-, \varphi_+)$ is a morphism between $\mathbf{A}$ and $\mathbf{B}$, then $\varphi^\perp = (\varphi_+, \varphi_-)$ is a morphism between $\mathbf{B}^\perp$ and $\mathbf{A}^\perp$.

(2) Suppose that $Z \in \mathfrak{d}(\mathbf{B})$ is such that $|Z| = \|\mathbf{B}\|$. Then $\{\varphi_+(z) : z \in Z\}$ is cofinal in A_+. In other words, $\|\mathbf{A}\| \leq |Z|$. $\dashv$

For two Polish spaces X, Y (i.e. complete, metric, separable with no isolated points) define $\mathsf{BOREL}(X, Y)$ to be the space of all Borel functions from X to Y.

Given relation $\mathbf{A}$ and assuming that both A_- and A_+ are Polish spaces we define families of small sets of reals as:

$$\mathsf{D}(\mathbf{A}) = \{X \subseteq \mathbb{R} : \forall f \in \mathsf{BOREL}(\mathbb{R}, A_+)\ f``X \notin \mathfrak{d}(\mathbf{A})\}$$

and

$$\mathsf{B}(\mathbf{A}) = \{X \subseteq \mathbb{R} : \forall f \in \mathsf{BOREL}(\mathbb{R}, A_-)\ f``X \notin \mathfrak{b}(\mathbf{A})\}.$$

In other words, $\mathsf{D}(\mathbf{A})$ consists of sets of reals whose Borel images are not “dominating” and $\mathsf{B}(\mathbf{A})$ consists of sets whose Borel images are “bounded”.

2.6 Lemma.

(1) $\mathbf{non}(\mathsf{D}(\mathbf{A})) = \|\mathbf{A}\|$ *and* $\mathbf{non}(\mathsf{B}(\mathbf{A})) = \|\mathbf{A}^\perp\|$.

(2) If there exists a Borel morphism from $\mathbf{A}$ *to* $\mathbf{B}$*, then* $\mathsf{B}(\mathbf{B}) \subseteq \mathsf{B}(\mathbf{A})$ *and* $\mathsf{D}(\mathbf{A}) \subseteq \mathsf{D}(\mathbf{B})$.

Proof. (1) Clearly $\mathbf{non}(\mathsf{D}(\mathbf{A})) \geq \|\mathbf{A}\|$. To show the other inequality notice that there is a Borel function from $\mathbb{R}$ onto A_+.

(2) Suppose that $X \notin \mathsf{B}(\mathbf{A})$ and let $f : \mathbb{R} \longrightarrow A_-$ be a Borel function such that $f``X \in \mathfrak{b}(\mathbf{A})$. It follows that $\varphi_- \circ f``X \in \mathfrak{b}(\mathbf{B})$. Since $\varphi_- \circ f$ is a Borel function it follows that $X \notin \mathsf{B}(\mathbf{B})$. $\dashv$

For cardinals $\kappa = \|\mathbf{A}\|$ and $\lambda = \|\mathbf{B}\|$ the question whether the inequality $\kappa \leq \lambda$ is provable in ZFC leads naturally to the question whether $\mathbf{A} \preceq \mathbf{B}$ and $\mathsf{D}(\mathbf{A}) \subseteq \mathsf{D}(\mathbf{B})$. Even though these questions are more general, in most cases the proof that $\kappa \leq \lambda$ yields $\mathbf{A} \preceq \mathbf{B}$. Moreover, the existence of a Borel morphism witnessing that $\mathbf{A} \preceq \mathbf{B}$ uncovers the combinatorial aspects of these problems.

Historical Remarks. Tukey embeddings were defined in [59] and further studied in [24]. In context of the orderings considered here see [18, 19, 32].

The framework used in Definition 2.3 is due to Vojtáš [60]; the particular formulation used here comes from [12].

3. Inequalities Provable in ZFC

The notions defined in the previous section are quite general. The focus of this chapter is on the ideals of meager sets ($\mathcal{B}$) and of measure zero (null) sets ($\mathcal{L}$) with respect to the standard product measure on μ on ${}^\omega 2$ or the Lebesgue measure μ on $\mathbb{R}$.

For an ideal $\mathcal{J}$, by a *Borel mapping* $H : \mathbb{R} \longrightarrow \mathcal{J}$ we mean a Borel set $H \subseteq \mathbb{R} \times \mathbb{R}$ such that, with $(H)_x = \{y : (x, y) \in H\}$, H is a *Borel* $\mathcal{J}$*-set*, i.e. $(H)_x \in \mathcal{J}$ for all $x \in \mathbb{R}$.

Using this terminology we define the following classes of small sets:

- $\mathsf{COF}(\mathcal{L}) = \mathsf{D}(\mathcal{L}, \mathcal{L}, \subseteq) = \{X \subseteq \mathbb{R}$: for every Borel $\mathcal{L}$-set H, $\{(H)_x : x \in X\}$ is not a basis of $\mathcal{L}\}$,

- $\mathsf{ADD}(\mathcal{L}) = \mathsf{B}(\mathcal{L}, \mathcal{L}, \subseteq) = \{X \subseteq \mathbb{R} :$ for every Borel $\mathcal{L}$-set H, $\bigcup_{x \in X} (H)_x \in \mathcal{L}\}$,
- $\mathsf{COV}(\mathcal{L}) = \mathsf{D}(\mathbb{R}, \mathcal{L}, \in) = \{X \subseteq \mathbb{R} :$ for every Borel $\mathcal{L}$-set H, $\bigcup_{x \in X} (H)_x \neq \mathbb{R}\}$,
- $\mathsf{NON}(\mathcal{L}) = \mathsf{B}(\mathbb{R}, \mathcal{L}, \in) = \{X \subseteq \mathbb{R} :$ every image of X by a Borel function is in $\mathcal{L}\}$.

In the same way we define $\mathsf{ADD}(\mathcal{B})$, $\mathsf{COV}(\mathcal{B})$, etc.

Finally, let

- $\mathsf{D} = \mathsf{D}({}^\omega\omega, {}^\omega\omega, \leq^\star)$,
- $\mathsf{B} = \mathsf{B}({}^\omega\omega, {}^\omega\omega, \leq^\star)$.

Instead of dealing with all null and meager sets we need to consider only suitably chosen cofinal families.

1. $A \in \mathcal{L}$ if and only if there exists a family of basic open sets $\{C_n : n \in \omega\}$ such that $\sum_{n=0}^{\infty} \mu(C_n) < \infty$ and $A \subseteq \bigcap_{n \in \omega} \bigcup_{m > n} C_m$,
2. $A \in \mathcal{B}$ if and only if there is a family of $\{F_n : n \in \omega\}$ of closed nowhere dense sets such that $A \subseteq \bigcup_{n \in \omega} F_n$.

In particular every null set can be covered by a null set of type G_δ and every meager set can be covered by a meager set of type F_σ.

For every $t \in {}^{<\omega}2$ let $[t] = \{x \in {}^\omega 2 : t \subseteq x\}$, and note that the family $\{[t] : t \in {}^{<\omega}2\}$ forms a standard basis for ${}^\omega 2$. Let $\mathbb{C}$ be the collection of clopen subsets of ${}^\omega 2$.

3.1 Definition. Let $\{C^n_m : n, m \in \omega\}$ be a family of clopen subsets of ${}^\omega 2$ such that

1. $\mathbb{C} = \{C^n_m : n, m \in \omega\}$,
2. $\mu(C^n_m) \leq 2^{-n}$ for each $m, n < \omega$.

3.2 Lemma. $A \in \mathcal{L} \iff \exists f \in {}^\omega\omega\, (A \subseteq \bigcap_m \bigcup_{n > m} C^n_{f(n)})$.

Proof. ($\Longleftarrow$) Note that the set $\bigcup_{n>m} C^n_{f(n)}$ has measure at most 2^{-m}.

($\Longrightarrow$) For an open set $U \subseteq {}^\omega 2$ let

$$\widetilde{U} = \{t \in {}^{<\omega}2 : [t] \subseteq U \;\&\; \forall s \subsetneq t\ ([s] \not\subseteq U)\}.$$

Note that $\widetilde{U}$ gives a canonical representation of U as a union of disjoint basic intervals.

Find open sets $\{G_n : n \in \omega\}$ covering A such that $\mu(G_n) \leq 2^{-n}$. Let $\{t_n : n \in \omega\}$ be the lexicographic enumeration of $\bigcup_{n\in\omega} \widetilde{G}_n$. Define for $n \in \omega$,

$$h(n+1) = \min\left\{k > h(n) : \sum_{j=k}^{\infty} \mu\big([t_j]\big) \leq 2^{-n}\right\},$$

and let

$$D_n = \bigcup_{j=h(n)}^{h(n+1)} [t_j].$$

Let $f \in {}^\omega\omega$ be such that $D_n = C^n_{f(n)}$ for each n. ⊣

We will need an analogous characterization of meager subsets of ${}^{<\omega}2$.

3.3 Definition. Let $\{U_n : n \in \omega\}$ be a basis for ${}^\omega 2$ and let $\mathcal{S} = \{S^n_m : n, m \in \omega\}$ be any family of clopen sets. We say that $\mathcal{S}$ is *good* if

1. $S^n_m \cap U_n \neq \emptyset$ for $n, m \in \omega$,
2. For any open dense set $U \subseteq {}^\omega 2$ and $n \in \omega$ there is m such that $S^n_m \subseteq U$.

3.4 Lemma. *Suppose that the family $\mathcal{S} = \{S^n_m : n, m \in \omega\}$ is good. Then*

$$A \in \mathcal{B} \quad \iff \quad \exists f \in {}^\omega\omega\big(A \subseteq {}^\omega 2 - \textstyle\bigcap_m \bigcup_{n>m} S^n_{f(n)}\big).$$

Proof. ($\Longleftarrow$) Note that the set $\bigcup_{n>m} S^n_{f(n)}$ is open and dense for every m.

($\Longrightarrow$) Let $\langle F_n : n \in \omega\rangle$ be an increasing sequence of closed nowhere dense sets covering A. For each n let

$$f(n) = \min\{m : S^n_m \cap F_n = \emptyset\}.$$

It is clear that $\bigcup_n F_n \cap \bigcap_m \bigcup_{n>m} S^n_{f(n)} = \emptyset$. ⊣

Define *master sets* $N, M \subseteq {}^\omega\omega \times {}^\omega 2$ by

$$N = \textstyle\bigcap_m \bigcup_{n>m} \bigcup_{f\in{}^\omega\omega} \{f\} \times C^n_{f(n)}, \quad \text{and}$$
$$M = ({}^\omega\omega \times {}^\omega 2) - \textstyle\bigcap_m \bigcup_{n>m} \bigcup_{f\in{}^\omega\omega} \{f\} \times S^n_{f(n)}.$$

Note that N is a G_δ set while M is an F_σ set. Moreover, $\{(N)_f : f \in {}^\omega\omega\}$ is cofinal in $\mathcal{L}$ and $\{(M)_f : f \in {}^\omega\omega\}$ is cofinal in $\mathcal{B}$.

In the sequel we will need to find a good family with some additional properties. The following lemma shows that the representation of meager sets does not depend on the choice of good family:

3.5 Lemma. *Suppose that $\mathcal{S} = \{S^n_m : n, m \in \omega\}$ and $\mathcal{T} = \{T^n_m : n, m \in \omega\}$ are good and M and $\overline{M}$ are associated master sets. Then there are Borel functions $\varphi_-, \varphi_+ : {}^\omega\omega \longrightarrow {}^\omega\omega$ such that*

$$(M)_f \subseteq (M)_{\varphi_+(g)}, \quad \textit{whenever } (\overline{M})_{\varphi_-(f)} \subseteq (\overline{M})_g.$$

Proof. For $f, g \in {}^\omega\omega$ and $n \in \omega$ define

$$\varphi_-(f)(n) = \min\bigl\{k : T^n_k \subseteq \bigcup_{m\geq n} S^m_{f(m)}\bigr\}, \quad \text{and}$$
$$\varphi_+(g)(n) = \min\bigl\{k : S^n_k \subseteq \bigcup_{m\geq n} T^m_{g(m)}\bigr\}.$$

We leave it to the reader to verify that these functions have the required properties. ⊣

The following two theorems will be helpful in many subsequent constructions.

3.6 Theorem. *Suppose that $H \subseteq {}^\omega 2 \times {}^\omega 2$ is a Borel set.*

(1) $\{x : (H)_x \in \mathcal{L}\}$ is Borel,

(2) $\{x : (H)_x \in \mathcal{B}\}$ is Borel,

(3) If U is open and $(H)_x$ is compact for every x, then $\{x : U \cap (H)_x = \emptyset\}$ is Borel,

(4) If for every x, $(H)_x$ is "large", where large is either "of positive measure" or "nonmeager", then there exists a Borel function $f : {}^\omega 2 \longrightarrow {}^\omega 2$ such that for every x, $f(x) \in (H)_x$.

Proof. See [29] 16.A for (1) and (2), 18.B for (4). For (3) note that $\{x : U \cap (H)_x = \emptyset\} = \{x : (H)_x \subseteq {}^\omega 2 - U\}$ and inclusion between the compact sets does not involve quantifiers over the reals. ⊣

3.7 Theorem. *If X and Y are Polish spaces and $f : X \longrightarrow Y$ is a Borel mapping, then there is a dense G_δ set $G \subseteq X$ such that $f{\restriction}G$ is continuous.*

Proof. This is a special case of a theorem of Kuratowski; see [29, 8.I]. ⊣

Lemmas 3.2 and 3.4 have their two-dimensional analogs.

3.8 Lemma. *The following conditions are equivalent for a Borel set $H \subseteq {}^\omega 2 \times {}^\omega 2$:*

(1) $\forall x\,((H)_x \in \mathcal{L})$,

(2) For every $\varepsilon > 0$ there exists a Borel set $B \subseteq {}^\omega 2 \times {}^\omega 2$ such that

(a) $H \subseteq B$,

(b) for every x, $(B)_x$ is an open set of measure $< \varepsilon$.

(3) There exists a Borel function $x \rightsquigarrow f_x$ such that

$$\forall x((H)_x \subseteq (N)_{f_x}).$$

Proof. (2) → (3) Let $\{B_n : n \in \omega\}$ be a family of Borel sets such that

1. $H \subseteq \bigcap_n B_n$,
2. For every x, $(B_n)_x$ is an open set of measure $< 2^{-n}$.

Look at the proof of Lemma 3.2 to see that for each x, $(B)_x = (N)_{f_x}$ and the function $x \rightsquigarrow f_x$ is Borel.

(3) $\to$ (1) is obvious.

(1) $\to$ (2) By induction on complexity we show that for every $\varepsilon > 0$ and every Borel set $H \subseteq {}^\omega 2 \times {}^\omega 2$ there exists a Borel set $B \supseteq H$ such that for every x, $(B)_x$ is open and $\mu((B - H)_x) < \varepsilon$. The only nontrivial part is to show that if the theorem holds for sets in Σ^0_α, then it holds for any set $A \in \Pi^0_\alpha$. To see this write $A = \bigcap_n A_n$ where $\langle A_n : n \in \omega\rangle$ is a descending sequence of sets in Σ^0_α. For each n let B_n be the set obtained from the induction hypothesis for A_n and $\varepsilon/2$. Let $K^n = \{x : \mu((A_n - A)_x) < \varepsilon/2\}$. Each set K^n is Borel. Now define

$$B = B_0 \cap (K^0 \times {}^\omega 2) \cup \bigcup_{n\in\omega} B_{n+1} \cap ((K^{n+1} - K^n) \times {}^\omega 2).$$

$\dashv$

3.9 Lemma. *The following conditions are equivalent for a Borel set $H \subseteq {}^\omega 2 \times {}^\omega 2$:*

(1) $\forall x\ ((H)_x \in \mathcal{B})$,

(2) There exists a family of Borel sets $\{G_n : n \in \omega\} \subseteq {}^\omega 2 \times {}^\omega 2$ such that

(a) $(G_n)_x$ is a closed nowhere dense set for all $x \in {}^\omega 2$,

(b) $H \subseteq \bigcup_{n\in\omega} G_n$.

(3) There exists a Borel function $x \rightsquigarrow f_x$ such that

$$\forall x\ ((H)_x \subseteq (M)_{f_x}).$$

Proof. (1) $\to$ (2) By induction on complexity we show that for any Borel set $H \subseteq {}^\omega 2 \times {}^\omega 2$ there are Borel sets B and $\{F_n : n \in \omega\}$ such that

1. $(B)_x$ is open for every x,
2. $(F_n)_x$ is closed nowhere dense for every x and n,
3. $H \triangle B \subseteq \bigcup_n F_n$.

As before the nontrivial part is to show the theorem for the class Π^0_α given that it holds for Σ^0_α. Suppose that $A \in \Sigma^0_\alpha$ and B is the set obtained by applying the inductive hypothesis to A. Let $\langle U_n : n \in \omega\rangle$ be an enumeration of basic sets in ${}^\omega 2$. Define for $n \in \omega$,

$$Z_n = \{x : U_n \cap (B)_x = \emptyset\}.$$

Note that sets Z_n are Borel. Let $B' = \bigcup_n Z_n \times U_n$. The vertical sections of the set $F = {}^\omega 2 \times {}^\omega 2 - (B \cup B')$ are closed nowhere dense and $({}^\omega 2 \times {}^\omega 2 - A) \triangle B' \subseteq F$, which completes the proof.

(2) $\rightarrow$ (3) For $x \in {}^\omega 2$ let

$$f_x(n) = \min\{k : \forall i \leq n\ (S^n_k \cap (G_i)_x = \emptyset)\}.$$

$\dashv$

From these two lemmas it follows that:

3.10 Lemma. *Let $\mathcal{I}$ be $\mathcal{L}$ or $\mathcal{B}$ and let I be the associated master set. Then for $X \subseteq \mathbb{R}$:*

(1) $X \in \mathsf{ADD}(\mathcal{I}) \iff$
$\forall F \in \mathsf{BOREL}(\mathbb{R}, {}^\omega\omega)\ \exists f \in {}^\omega\omega\ \forall x \in X\ ((I)_{F(x)} \subseteq (I)_f)$,

(2) $X \in \mathsf{COF}(\mathcal{I}) \iff$
$\forall F \in \mathsf{BOREL}(\mathbb{R}, {}^\omega\omega)\ \exists f \in {}^\omega\omega\ \forall x \in X\ ((I)_f \not\subseteq (I)_{F(x)})$,

(3) $X \in \mathsf{COV}(\mathcal{I}) \iff \forall F \in \mathsf{BOREL}(\mathbb{R}, {}^\omega\omega)\ \exists z\ \forall x \in X\ (z \notin (I)_{F(x)})$,

(4) $X \in \mathsf{NON}(\mathcal{I}) \iff \forall F \in \mathsf{BOREL}(\mathbb{R}, {}^\omega\omega)\ \exists f\ \forall x \in X\ (F(x) \in (I)_f)$.

The goal of this section is to establish:

3.11 Theorem.

$$\begin{tikzcd}
(\mathbb{R},\mathcal{L},\in) \arrow[r, "\preceq"] & (\mathcal{B},\mathbb{R},\not\ni) \arrow[r, "\preceq"] & (\mathcal{B},\mathcal{B},\subseteq) \arrow[r, "\preceq"] & (\mathcal{L},\mathcal{L},\subseteq) \\
 & ({}^\omega\omega,{}^\omega\omega,\not\geq^*) \arrow[u, "\preceq"] \arrow[r, "\preceq"] & ({}^\omega\omega,{}^\omega\omega,\leq^*) \arrow[u, "\preceq"] & \\
(\mathcal{L},\mathcal{L},\not\supseteq) \arrow[uu, "\preceq"] \arrow[r, "\preceq"] & (\mathcal{B},\mathcal{B},\not\supseteq) \arrow[u, "\preceq"] \arrow[r, "\preceq"] & (\mathbb{R},\mathcal{B},\in) \arrow[u, "\preceq"] \arrow[r, "\preceq"] & (\mathcal{L},\mathbb{R},\not\ni) \arrow[uu, "\preceq"]
\end{tikzcd}$$

As a consequence of the fact that the above morphisms turn out to be Borel we get the following two diagrams:

$$\begin{tikzcd}
\mathsf{COV}(\mathcal{L}) \arrow[r, "\subseteq"] & \mathsf{NON}(\mathcal{B}) \arrow[r, "\subseteq"] & \mathsf{COF}(\mathcal{B}) \arrow[r, "\subseteq"] & \mathsf{COF}(\mathcal{L}) \\
 & \mathsf{B} \arrow[u, "\subseteq"] \arrow[r, "\subseteq"] & \mathsf{D} \arrow[u, "\subseteq"] & \\
\mathsf{ADD}(\mathcal{L}) \arrow[uu, "\subseteq"] \arrow[r, "\subseteq"] & \mathsf{ADD}(\mathcal{B}) \arrow[u, "\subseteq"] \arrow[r, "\subseteq"] & \mathsf{COV}(\mathcal{B}) \arrow[u, "\subseteq"] \arrow[r, "\subseteq"] & \mathsf{NON}(\mathcal{L}) \arrow[uu, "\subseteq"]
\end{tikzcd}$$

$$\begin{tikzcd}
\mathbf{cov}(\mathcal{L}) \arrow[r, "\leq"] & \mathbf{non}(\mathcal{B}) \arrow[r, "\leq"] & \mathbf{cof}(\mathcal{B}) \arrow[r, "\leq"] & \mathbf{cof}(\mathcal{L}) \\
 & \mathfrak{b} \arrow[u, "\leq"] \arrow[r, "\leq"] & \mathfrak{d} \arrow[u, "\leq"] & \\
\mathbf{add}(\mathcal{L}) \arrow[uu, "\leq"] \arrow[r, "\leq"] & \mathbf{add}(\mathcal{B}) \arrow[u, "\leq"] \arrow[r, "\leq"] & \mathbf{cov}(\mathcal{B}) \arrow[u, "\leq"] \arrow[r, "\leq"] & \mathbf{non}(\mathcal{L}) \arrow[uu, "\leq"]
\end{tikzcd}$$

The last of these diagrams is called the Cichoń diagram.

It is enough to find the following morphisms:

1. $(\mathbb{R}, \mathcal{L}, \in) \preceq (\mathcal{B}, \mathbb{R}, \not\ni)$,
2. $(\mathcal{B}, \mathcal{B}, \subseteq) \preceq (\mathcal{L}, \mathcal{L}, \subseteq)$,
3. $(\mathcal{B}, \mathcal{B}, \not\supseteq) \preceq ({}^{\omega}\omega, {}^{\omega}\omega, \not\geq^{\star})$,
4. $({}^{\omega}\omega, {}^{\omega}\omega, \not\geq^{\star}) \preceq (\mathcal{B}, \mathbb{R}, \not\ni)$,
5. $(\mathcal{L}, \mathcal{L}, \not\supseteq) \preceq (\mathbb{R}, \mathcal{L}, \in)$.

The remaining morphisms are dual to those listed above. In each case we will find a Borel morphism. Note that thanks to the master sets M and N defined earlier, Borel morphisms between these structures can be interpreted as the automorphisms of the index set i.e. ${}^{\omega}\omega$.

3.12 Theorem. *$\mathcal{B} \preceq \mathcal{L}$; there are two Borel functions $\varphi_-, \varphi_+ : {}^{\omega}\omega \longrightarrow {}^{\omega}\omega$ such that*

$$(M)_f \subseteq (M)_{\varphi_+(g)}, \quad \textit{whenever } (N)_{\varphi_-(f)} \subseteq (N)_g.$$

Thus, $\mathsf{ADD}(\mathcal{L}) \subseteq \mathsf{ADD}(\mathcal{B})$ *and* $\mathsf{COF}(\mathcal{B}) \subseteq \mathsf{COF}(\mathcal{L})$, $\mathbf{add}(\mathcal{L}) \leq \mathbf{add}(\mathcal{B})$ *and* $\mathbf{cof}(\mathcal{B}) \leq \mathbf{cof}(\mathcal{L})$.

Proof. Let

$$\mathcal{C} = \left\{ S \in {}^{\omega}({}^{<\omega}[\omega]) : \sum_{n=1}^{\infty} \frac{|S(n)|}{2^n} < \infty \right\}.$$

For $S, S' \in \mathcal{C}$ define $S \subseteq^{\star} S'$ if for all but finitely many n, $S(n) \subseteq S'(n)$.

3.13 Lemma. *$\mathcal{L} \equiv \mathcal{C}$.*

Proof. To see that $\mathcal{L} \preceq \mathcal{C}$ define $\varphi_- : {}^{\omega}\omega \longrightarrow \mathcal{C}$ and $\varphi_+ : \mathcal{C} \longrightarrow {}^{\omega}\omega$ such that for $f \in {}^{\omega}\omega$ and $S \in \mathcal{C}$ we have

$$(N)_f \subseteq (N)_{\varphi_+(S)}, \quad \text{whenever } \varphi_-(f) \subseteq^{\star} S.$$

For $f \in {}^\omega\omega$ put $\varphi_-(f) = h$, where $h(n) = \{f(2n), f(2n+1)\}$. If $S \in \mathcal{C}$ let $\varphi_+(S) = g \in {}^\omega\omega$ be such that

$$C^n_{g(n)} = \bigcup_{k \in S(n)} C^{2n}_k \cup \bigcup_{k \in S(n)} C^{2n+1}_k.$$

Note that this formula defines $g(n)$ for all but finitely many n. The verification that these functions have the required properties is straightforward.

To show that $\mathcal{C} \preceq \mathcal{L}$ we will find Borel functions $\varphi_- : \mathcal{C} \longrightarrow {}^\omega\omega$ and $\varphi_+ : {}^\omega\omega \longrightarrow \mathcal{C}$ such that for $S \in \mathcal{C}$ and $f \in {}^\omega\omega$,

$$S \subseteq^\star \varphi_+(f), \quad \text{whenever } (N)_{\varphi_-(S)} \subseteq (N)_f.$$

Let $\{G^n_m : n, m \in \omega\}$ be a family of clopen probabilistically independent sets such that $\mu(G^n_m) = 2^{-n}$. For $S \in \mathcal{C}$ define $\varphi_-(S) = f \in {}^\omega\omega$ such that

$$\bigcap_{m \in \omega} \bigcup_{n > m} \bigcup_{k \in S(n)} G^n_k \subseteq (N)_f.$$

To do this, first consider $H' \subseteq \mathcal{C} \times {}^\omega 2$ defined by

$$(H')_S = \bigcap_{m \in \omega} \bigcup_{n > m} \bigcup_{k \in S(n)} G^n_k$$

for $S \in \mathcal{C}$. Note that H' is a Borel set and $(H')_S$ has measure zero for every S. Fix a Borel isomorphism $a : \mathcal{C} \longrightarrow {}^\omega\omega$ and let $H \subseteq {}^\omega\omega \times {}^\omega 2$ be defined as $(H)_{a(S)} = (H')_S$ for $S \in \mathcal{C}$. Apply Lemma 3.8 to find a Borel function $x \rightsquigarrow f_x$ such that $(H)_x \subseteq (N)_{f_x}$ and define $\varphi_-(S) = f_{a(S)}$.

To define $\varphi_+ : {}^\omega\omega \longrightarrow \mathcal{C}$ we proceed as follows. Find a Borel set $K \subseteq {}^\omega\omega \times {}^\omega 2$ such that

1. $(K)_f$ is a compact set of measure $\geq 1/2$ for all $f \in {}^\omega\omega$.
2. $N \cap K = \emptyset$.
3. For any basic open set $U \subseteq {}^\omega 2$ and $f \in {}^\omega\omega$, if $U \cap (K)_f \neq \emptyset$ then $U \cap (K)_f$ has positive measure.

To do this, first use Lemma 3.8 to find a set K' satisfying the first two conditions. Let $\langle U_j : j \in \omega \rangle$ be an enumeration of basic open sets in ${}^\omega 2$. For each j let $Z_j = \{f : \mu(U_j \cap (K')_f) = 0\}$. By Theorem 3.6, the sets Z_j are Borel for each j. Define $K = K' - \bigcup_j (Z_j \times U_j)$.

For $f \in {}^\omega\omega, j, n \in \omega$ define

$$S^f_j(n) = \{i \in \omega : (K)_f \cap U_j \neq \emptyset \;\&\; (K)_f \cap U_j \cap G^n_i = \emptyset\}.$$

Note that

$$0 < \mu((K)_f \cap U_j) \leq \prod_n \prod_{i \in S^f_j(n)} \mu({}^\omega 2 - G^n_i).$$

Thus

$$0 < \prod_{n=1}^{\infty} \left(1 - \frac{1}{2^n}\right)^{|S^f_j(n)|}.$$

It follows that
$$\sum_{n=1}^{\infty} \frac{|S_j^f(n)|}{2^n} < \infty,$$
so $S_j^f \in \mathcal{C}$ for each j. Moreover, the function $f \rightsquigarrow \langle S_j^f : j \in \omega\rangle \in {}^\omega\mathcal{C}$ is Borel (by Theorem 3.6(3)). Fix a Borel function from ${}^\omega\mathcal{C}$ to $\mathcal{C}$ with $\langle S_j^f : j \in \omega\rangle \rightsquigarrow S_\infty^f$ such that
$$\forall j\ \forall^\infty n\ S_j^f(n) \subseteq S_\infty^f(n).$$

Finally define φ_+ by the formula:
$$\varphi_+(f)(n) = S_\infty^f(n).$$

Suppose that for some $S \in \mathcal{C}$, $(N)_{\varphi_-(S)} \subseteq (N)_f$. It follows that,
$$(K)_f \cap \bigcap_m \bigcup_{n>m} \bigcup_{k\in S(n)} G_k^n = \emptyset.$$

By the Baire Category Theorem, there is a basic open set U_j and $m_0 \in \omega$ such that $U_j \cap (K)_f \neq \emptyset$ but
$$(K)_f \cap U_j \cap \bigcup_{n>m_0} \bigcup_{k\in S(n)} G_k^n = \emptyset.$$

Therefore
$$\forall^\infty n\ S(n) \subseteq S_j^f(n) \subseteq S_\infty^f(n) = \varphi_+(f)(n),$$
which finishes the proof. ⊣

3.14 Lemma. *$\mathcal{B} \preceq \mathcal{C}$; there are Borel functions $\varphi_- : {}^\omega\omega \longrightarrow \mathcal{C}$ and $\varphi_+ : \mathcal{C} \longrightarrow {}^\omega\omega$ such that for any $f \in {}^\omega\omega$ and $S \in \mathcal{C}$,*
$$(M)_f \subseteq (M)_{\varphi_+(S)}, \quad \textit{whenever } \varphi_-(f) \subseteq^\star S.$$

Proof. We will need the following lemma:

3.15 Lemma. *There exists a good family $\{S_m^n : n, m \in \omega\}$ such that for each n,*
$$\forall X \in [\omega]^{\leq 2^n} \quad \left(\bigcap_{j\in X} S_j^n \neq \emptyset\right).$$

Proof. Fix $n \in \omega$. Let $\langle C_m : m \in \omega\rangle$ be an enumeration of all clopen sets. For $k \in \omega$ define
$$A_k = \left\{l > k : C_l \cap \bigcap_{i\in I} C_i \cap U_n \neq \emptyset \text{ when } I \subseteq k+1 \text{ and } U_n \cap \bigcap_{i\in I} C_i \neq \emptyset\right\}.$$

Consider the family
$$\mathcal{S}_n = \left\{\bigcup_{i\leq 2^n} C_{m_i} : m_0 \in \omega \text{ and } \ m_{i+1} \in A_{m_i} \text{ for } i \leq 2^n\right\}.$$

We have to check that $\mathcal{S} = \bigcup_n \mathcal{S}_n$ satisfies the two conditions of Definition 3.3 with $\mathcal{S}_n$ in the role of $\{\mathcal{S}_m^n : m \in \omega\}$.

The first condition, that each member of $\mathcal{S}_n$ intersects U_n, follows immediately from the definition of $\mathcal{S}_n$.

For the second condition, let U be a dense open subset of ${}^\omega 2$. Note that, by density of U, $A_k \cap \{l \in \omega : U_n \cap C_l \subseteq U\} \neq \emptyset$ for every $k \in \omega$. Now define by induction a sequence $\{m_i : i \leq 2^n\}$ such that $C_{m_i} \subseteq U$ and $m_{i+1} \in A_{m_i}$ for $i < 2^n$. Clearly $U \supseteq \bigcup_{i \leq 2^n} C_{m_i} \in \mathcal{S}_n$.

Suppose that $V_1, V_2, \ldots, V_{2^n} \in \mathcal{S}_n$. For any $j \leq 2^n$, $V_j = \bigcup_{i \leq 2^n} C_{m_i^j}$, where $m_i^j \in A_{m_i^j}$ for $i, j \leq 2^n$. Order the sets V_j in such a way that $m_i^i \leq m_i^j$ for $i \leq j \leq 2^n$. It is easy to show by induction that $\bigcap_{j \leq 2^n} V_j \supseteq \bigcap_{j \leq 2^n} C_{m_j^j} \neq \emptyset$. ⊣

Returning to the proof of Lemma 3.14, let $\mathcal{S} = \bigcup_n \mathcal{S}_n = \{S_m^n : n, m \in \omega\}$ be the family constructed above. For $f \in {}^\omega\omega$ define $\varphi_-(f) = f \in \mathcal{C}$. For $S \in \mathcal{C}$ let $\varphi_+(S) = f \in {}^\omega\omega$ be such that

$$(M)_f \supseteq {}^\omega 2 - \bigcap_{m \in \omega} \bigcup_{n > m} \bigcap_{i \in S(n)} S_i^n.$$

Since $|S(n)| \leq 2^n$ for all but finitely many n, by Lemma 3.15,

$$\emptyset \neq U_n \cap \bigcap_{i \in S(n)} S_i^n.$$

Now suppose that $\varphi_-(f) \subseteq^\star S$. This assumption means that there exists an $n_0 \in \omega$ such that $f(m) \in S(m)$ for $m \geq n_0$. It follows that

$$(M)_{\varphi_+(S)} \supseteq {}^\omega 2 - \bigcap_{m \in \omega} \bigcup_{n > m} \bigcap_{i \in S(n)} S_i^n \supseteq {}^\omega 2 - \bigcap_{m \in \omega} \bigcup_{n > m} S_{f(n)}^n.$$

⊣

Theorem 3.12 follows immediately; compose the morphisms constructed in Lemmas 3.13 and 3.14. ⊣

3.16 Theorem. $(\mathbb{R}, \mathcal{L}, \in) \preceq (\mathcal{B}, \mathbb{R}, \not\ni)$; *there are Borel functions* $\varphi_-, \varphi_+ : \mathbb{R} \longrightarrow {}^\omega\omega$ *such that for* $x, y \in \mathbb{R}$,

$$x \in (N)_{\varphi_+(y)}, \quad \textit{whenever } y \notin (M)_{\varphi_-(x)}.$$

Thus, $\mathsf{COV}(\mathcal{L}) \subseteq \mathsf{NON}(\mathcal{B})$ *and* $\mathsf{COV}(\mathcal{B}) \subseteq \mathsf{NON}(\mathcal{L})$, $\mathbf{cov}(\mathcal{L}) \leq \mathbf{non}(\mathcal{B})$ *and* $\mathbf{cov}(\mathcal{B}) \leq \mathbf{non}(\mathcal{L})$.

Proof. Let B be a G_δ null set whose complement is meager. Use Theorem 3.6(3) and Theorem 3.7 to find Borel functions $\varphi_-, \varphi_+ : \mathbb{R} \longrightarrow {}^\omega\omega$ such that

$$\forall x \; (B + x \subseteq (N)_{\varphi_-(x)}) \quad \text{and} \quad \forall y \; ({}^\omega 2 - (B + y) \subseteq (M)_{\varphi_+(y)}).$$

Note that in this context $+$ is the coordinatewise addition modulo 2.

If $y \notin (N)_{\varphi_-(x)}$ then $y \notin B + x$. It follows that $x \in {}^\omega 2 - (B + y) \subseteq (M)_{\varphi_+(y)}$. ⊣

3.17 Theorem. $(\mathcal{B}, \mathcal{B}, \not\supseteq) \preceq ({}^{\omega}\omega, {}^{\omega}\omega, {}^{\star}\not\geq)$*; there are Borel functions* φ_-, φ_+: ${}^{\omega}\omega \longrightarrow {}^{\omega}\omega$ *such that for* $f, g \in {}^{\omega}\omega$

$$(M)_f \not\supseteq (M)_{\varphi_+(g)}, \quad \textit{whenever } g \not\leq^{\star} \varphi_-(f).$$

In particular, $\mathsf{D} \subseteq \mathsf{COF}(\mathcal{B})$ *and* $\mathsf{ADD}(\mathcal{B}) \subseteq \mathsf{B}$, $\mathfrak{d} \leq \mathbf{cof}(\mathcal{B})$ *and* $\mathbf{add}(\mathcal{B}) \leq \mathfrak{b}$.

Proof. Let $\mathcal{S}_n$ be the family of clopen sets C such that there exists a $k > n$ and $s \in {}^{[n,k)}2$ such that

$$C = \{x \in {}^{\omega}2 : x{\restriction}[n,k) = s\}.$$

Note that the family $\mathcal{S} = \bigcup_n \mathcal{S}_n$ is good (given the appropriate choice of the sequence $\{U_n : n \in \omega\}$).

For $f \in {}^{\omega}\omega$ let $\varphi_-(f)(n) = k$ if and only if $\mathsf{dom}(S^n_{f(n)}) = [n,k)$.

For a strictly increasing function $f \in {}^{\omega}\omega$ define $\varphi_+(f) = h \in {}^{\omega}\omega$ such that

$$(M)_h = \{x \in {}^{\omega}2 : \forall^{\infty} n\ \exists i \in [n, f(n))\ (x(i) \neq 0)\}.$$

Note that the image of ${}^{\omega}\omega$ under φ_+ is rather small, $\varphi_+ {}^{``\omega}\omega$ is not even cofinal in $\mathcal{B}$.

To finish the proof it is enough to show that if $\varphi_-(f)(n) < g(n)$ for infinitely many n, then

$$\begin{aligned}&\{x \in {}^{\omega}2 : \forall^{\infty} n\ \exists i \in [n, g(n))\ x(i) \neq 0\}\\ &\quad \not\subseteq \{x \in {}^{\omega}2 : \forall^{\infty} n\ x{\restriction}[n, \varphi_-(f)(n)) \neq S^n_{f(n)}\}.\end{aligned}$$

Find a sequence $\langle n_k : k \in \omega\rangle$ such that for all k,

$$n_k < \varphi_-(f)(n_k) < g(n_k) < n_{k+1}.$$

Construct a real z such that $z{\restriction}[n_k, \varphi_-(f)(n_k)) = S^{n_k}_{f(n_k)}$. Thus $z \in (M)_f$ but $z{\restriction}[n, g(n)) \not\equiv 0$ for all n, so $z \in \{x \in {}^{\omega}2 : \forall^{\infty} n\ \exists i \in [n, f(n))\ (x(i) \neq 0)\}$. ⊣

3.18 Theorem. $({}^{\omega}\omega, {}^{\omega}\omega, \not\geq) \preceq (\mathcal{B}, \mathbb{R}, \not\ni)$*; there are Borel functions* $\varphi_- :$ ${}^{\omega}\omega \longrightarrow {}^{\omega}\omega$ *and* $\varphi_+ : \mathbb{R} \longrightarrow {}^{\omega}\omega$ *such that for* $f \in {}^{\omega}\omega$ *and* $y \in \mathbb{R}$,

$$f \not\geq^{\star} \varphi_+(y), \quad \textit{whenever } y \notin (M)_{\varphi_-(f)}.$$

In particular, $\mathsf{COV}(\mathcal{B}) \subseteq \mathsf{D}$ *and* $\mathsf{B} \subseteq \mathsf{NON}(\mathcal{B})$, $\mathbf{cov}(\mathcal{B}) \leq \mathfrak{d}$ *and* $\mathfrak{b} \leq \mathbf{non}(\mathcal{B})$.

Proof. Identify $\mathbb{R} - \mathbb{Q}$ with ${}^{\omega}\omega$ and define $\varphi_-(f) = h$ such that

$$(M)_h = \{z \in {}^{\omega}\omega : \forall^{\infty} n\ (z(n) \leq f(n))\}$$

and $\varphi_+(y) = y$. ⊣

3.19 Theorem. *$(\mathcal{L},\mathcal{L},\not\supseteq) \preceq (\mathcal{L},\mathbb{R},\in)$; there are Borel functions $\varphi_- : {}^\omega\omega \longrightarrow \mathbb{R}$ and $\varphi_+ : {}^\omega\omega \longrightarrow {}^\omega\omega$ such that for $f,g \in {}^\omega\omega$,*

$$(N)_f \not\supseteq (N)_{\varphi_+(g)}, \quad \textit{whenever } \varphi_-(f) \in (N)_g.$$

The same is true if we replace $\mathcal{L}$ by $\mathcal{B}$.

Proof. Let $\varphi_- : {}^\omega\omega \longrightarrow \mathbb{R}$ be any Borel function such that for $f \in {}^\omega\omega$, $\varphi_-(f) \notin (N)_f$ (see Theorem 3.6(4)) and let $\varphi_+(g) = g$ for $g \in {}^\omega\omega$. Verification that both functions have the required properties is straightforward. ⊣

We conclude this section with some remarks concerning Luzin sets.

3.20 Definition. Given $\mathbf{A} = (A_-, A_+, A)$ and two cardinals $\kappa \leq \lambda$ we call a set $X \subseteq A_-$ a (κ,λ)-*Luzin set for* $\mathbf{A}$ if $|X| \geq \lambda$ and for every $Y \subseteq X$, $|Y| = \kappa$, $Y \in \mathfrak{b}(\mathbf{A})$.

When $\mathbf{A} = (\mathbb{R},\mathcal{B},\in)$, $\kappa = \aleph_1$ and $\lambda > \aleph_0$ then we get the original Luzin set. The set given by $(\mathbb{R},\mathcal{L},\in)$, $\kappa = \aleph_1$ and $\lambda > \aleph_0$ is usually called a Sierpiński set.

3.21 Lemma. *Suppose that X is a (κ,λ)-Luzin set for $\mathbf{A}$ and $\kappa \leq \lambda$. Then $\|\mathbf{A}\| \geq \lambda$ and $\|\mathbf{A}^\perp\| \leq \kappa$.*

Proof. Since every set $Y \subseteq X$, $|Y| = \kappa$ belongs to $\mathfrak{b}(\mathbf{A}) = \mathfrak{d}(\mathbf{A}^\perp)$, we get the second inequality.

For the first inequality note that if $y \in A_+$ then $\{x \in X \cap A_- : A(x,y)\}$ has size $< \kappa \leq |X|$. Thus any family that dominates X has to have a size at least $|X| \geq \lambda$. ⊣

Morphisms preserve Luzin sets.

3.22 Lemma. *Suppose that $\mathbf{A} \leq \mathbf{B}$ and X is a (κ,λ)-Luzin set for $\mathbf{A}$. Then φ_-"X is a (κ,λ)-Luzin set for $\mathbf{B}$.*

Proof. Clearly every subset of size κ of φ_-"X is unbounded. Moreover, for every $b \in B_-$, $\varphi_-^{-1}(b) \cap X$ has size $< \kappa$. Thus $|\varphi_-$"$X| \geq \lambda$. ⊣

Historical Remarks. Families of small sets as defined here appeared in various contexts. Recław [42] suggested considering small sets rather than cardinal characteristics.

Many people contributed to the proof of Theorem 3.11. In the last diagram:

- Rothberger [45] showed that $\mathbf{cov}(\mathcal{B}) \leq \mathbf{non}(\mathcal{L})$ and $\mathbf{cov}(\mathcal{L}) \leq \mathbf{non}(\mathcal{B})$.
- Miller [33] and Truss [57] showed that $\mathbf{add}(\mathcal{B}) = \min\{\mathfrak{b}, \mathbf{cov}(\mathcal{B})\}$ and Fremlin showed that $\mathbf{cof}(\mathcal{B}) = \max\{\mathfrak{d}, \mathbf{non}(\mathcal{B})\}$.

- Bartoszynski [3] and Raisonnier and Stern [40] showed that $\mathbf{add}(\mathcal{L}) \leq \mathbf{add}(\mathcal{B})$ and $\mathbf{cof}(\mathcal{B}) \leq \mathbf{cof}(\mathcal{L})$. Different proofs of these inequalities have been found, in particular a forcing proof by Judah and Repický in [25].

Fremlin [17] first realized that Tukey embeddings are responsible for the inequalities in the Cichoń diagram. Pawlikowski [37] proved Lemma 3.14, which was the crucial step in the proof of $\mathcal{B} \preceq \mathcal{L}$.

The first diagram of Theorem 3.11:

- Vojtáš [60] proved it with arbitrary morphisms,
- Recław [42] proved a version with Borel morphisms (which gives the second diagram),
- Pawlikowski and Recław [39] proved the existence of continuous morphisms.

Lemma 3.22 was proved in [15].

4. Combinatorial Characterizations

This section is devoted to the combinatorics associated with the cardinal invariants of the Cichoń diagram. We will find the combinatorial equivalents of most of the invariants as well as characterize membership in the corresponding classes of small sets. We conclude the section with a characterization of the ideal $(\mathcal{L}, \subseteq)$ as maximal in the sense of Tukey connections among a large class of partial orderings.

4.1 Theorem. *The following are equivalent:*

(1) $X \in \mathsf{COV}(\mathcal{B})$*,*

(2) for every Borel function $x \rightsquigarrow f^x \in {}^\omega\omega$ *there exists a function* $g \in {}^\omega\omega$ *such that*
$$\forall x \in X\ \exists^\infty n\ (f^x(n) = g(n)).$$

Proof. (1) $\to$ (2). Suppose that $x \rightsquigarrow f^x \in {}^\omega\omega$ is a Borel function. Let $H = \{\langle x, h\rangle \in {}^\omega 2 \times {}^\omega\omega : \forall^\infty n\ (h(n) \neq f^x(n))\}$. Clearly H is a Borel set with all $(H)_x$ meager and if $g \notin \bigcup_{x\in X}(H)_x$ then g has required properties.

(2) $\to$ (1). We will need several lemmas. To avoid repetitions let us define:

4.2 Definition. Suppose that $X \subseteq {}^\omega 2$. X is *nice* if for every Borel function $x \rightsquigarrow f^x \in {}^\omega\omega$ there exists a function $g \in {}^\omega\omega$ such that
$$\forall x \in X\ \exists^\infty n\ (f^x(n) = g(n)).$$

4.3 Lemma. *Suppose that X is nice. Then for every Borel function $x \rightsquigarrow \langle Y^x, f^x\rangle \in {}^\omega[\omega] \times {}^\omega\omega$ there exists a $g \in {}^\omega\omega$ such that*

$$\forall x \in X\ \exists^\infty n \in Y^x\ (f^x(n) = g(n)).$$

Proof. Suppose that a Borel function $x \rightsquigarrow \langle Y^x, f^x\rangle$ is given. Let y^x_n denote the n-th element of Y^x for $x \in {}^\omega 2$. For every $x \in {}^\omega 2$ define a function h^x as follows:

$$h^x(n) = f^x{\restriction}\{y^x_0,\ y^x_1, \dots, y^x_n\} \quad \text{for } n \in \omega.$$

Since the function $x \rightsquigarrow h^x$ is Borel and functions h^x can be coded as elements of ${}^\omega\omega$ there is a function h such that

$$\forall x \in X\ \exists^\infty n\ (h^x(n) = h(n)).$$

Without loss of generality we can assume that $h(n)$ is a function from an $n+1$-element subset of ω into ω.

Define $g \in {}^\omega\omega$ in the following way. Recursively choose

$$z_n \in \mathsf{dom}\big(h(n)\big) - \{z_0, z_1, \dots, z_{n-1}\} \quad \text{for } n \in \omega.$$

Then let g be any function such that $g(z_n) = h(n)(z_n)$ for $n \in \omega$.

We show that the function g has the required properties. Suppose that $x \in X$. Notice that the equality $h^x(n) = h(n)$ implies that

$$f^x(z_n) = g(z_n) \quad \text{and} \quad z_n \in Y^x.$$

That finishes the proof since $h^x(n) = h(n)$ for infinitely many $n \in \omega$. ⊣

4.4 Lemma. *Suppose that X is nice. Then for every Borel function $x \rightsquigarrow f^x \in {}^\omega\omega$ there exists an increasing sequence $\langle n_k : k \in \omega\rangle$ such that*

$$\forall x \in X\ \exists^\infty k\ (f^x(n_k) < n_{k+1}).$$

Proof. Suppose that the lemma is not true and let $x \rightsquigarrow f^x$ be a counterexample. Without loss of generality we can assume that f^x is increasing for all $x \in X$. To get a contradiction we will define a Borel function $x \rightsquigarrow g^x \in {}^\omega\omega$ such that $\{g^x : x \in X\}$ is a dominating family. That will contradict the assumption that X is nice.

Define for $n \in \omega$,

$$g^x(n) = \underbrace{f^x \circ f^x \circ \cdots \circ f^x}_{n+1 \text{ times}}(n).$$

Suppose that $h \in {}^\omega\omega$ is an increasing function. By the assumption there exist $x \in X$ and k_0 such that

$$\forall k \geq k_0\ (f^x(h(k)) \geq h(k+1)).$$

In particular, for $k \geq h(k_0)$,

$$\forall k \geq h(k_0)\ (h(k) \leq g^x(k))$$

which finishes the proof. ⊣

We now return to the proof of (2) → (1) for 4.1. Let $x \rightsquigarrow f^x \in {}^\omega\omega$ be a Borel function. We want to show that $\bigcup_{x\in X}(M)_{f^x} \neq {}^\omega 2$.

Without loss of generality we can assume that M is the set built using the family from the proof of Lemma 3.17. For each x let $g^x \in {}^\omega\omega$ and $\{s^x_n : n \in \omega\}$ be such that $S^n_{f^x(n)} = \{x \in {}^\omega 2 : x\restriction[n, g^x(n)) = s^x_n\}$.

By Lemma 4.4, there exists a sequence $\langle n_k : k \in \omega\rangle$ such that

1. $n_{k+1} > \sum_{i=0}^k n_i$, for all k,
2. $\forall x \in X\ \exists^\infty n\ (g^x(n_k) < n_{k+1})$.

For $x \in X$ let $Z^x = \{k : g^x(n_k) < n_{k+1}\}$. By Lemma 4.3, there exists a sequence $\langle s_k : k \in \omega\rangle$ such that

$$\forall x \in X\ \exists^\infty k \in Z^x\ (s^x_{n_k} = s_k).$$

Without loss of generality we can assume that $s_k : [n_k, m_k) \longrightarrow 2$, where $m_k < n_{k+1}$. Choose $z \in {}^\omega 2$ such that $s_k \subseteq z$ for all k. It follows that $z \notin (M)_{f^x}$ for every $x \in X$. ⊣

As a corollary we have:

4.5 Theorem. *The following are equivalent:*

(1) $\mathbf{cov}(\mathcal{B}) > \kappa$,

(2) $\forall F \subseteq [{}^\omega\omega]^\kappa\ \exists g \in {}^\omega\omega\ \forall f \in F\ \exists^\infty n\ (f(n) = g(n))$.

The above proof can be dualized to give:

4.6 Theorem. *The following conditions are equivalent:*

(1) $X \times X \in \mathsf{NON}(\mathcal{B})$,

(2) for every Borel function $x \rightsquigarrow f^x \in {}^\omega\omega$ *there exists a function* $g \in {}^\omega\omega$ *such that*

$$\forall x \in X\ \forall^\infty n\ f^x(n) \neq g(n).$$

We only explain why we have $X \times X$ in (1) rather than X. If we analyze the proof of Theorem 4.1, we see that in order to produce a real z such that $z \notin \bigcup_{x\in X}(M)_{f_x}$ we had to diagonalize (find an infinitely often equal real) twice.

A similar situation arises here; each element of X produces two functions, and a real that avoids a given meager set is constructed from two such functions, each coming from a different point of X.

As a corollary we get:

4.7 Theorem. $\mathbf{non}(\mathcal{M})$ *is the size of the smallest family* $F \subseteq {}^\omega\omega$ *such that*

$$\forall g \in {}^\omega\omega\ \exists f \in F\ \exists^\infty n\ (f(n) = g(n)).$$

4.8 Theorem. $\mathsf{ADD}(\mathcal{B}) = \mathsf{B} \cap \mathsf{COV}(\mathcal{B})$. *In particular,* $\mathbf{add}(\mathcal{B}) = \min\{\mathfrak{b}, \mathbf{cov}(\mathcal{B})\}$.

Proof. The inclusion $\subseteq$ follows immediately from Theorem 3.11.

Suppose that $X \in \mathsf{B} \cap \mathsf{COV}(\mathcal{B})$. Let $x \rightsquigarrow f_x \in {}^\omega\omega$ be a Borel function. Since $X \in \mathsf{COV}(\mathcal{B})$ there is a real z such that $z \notin \bigcup_{x \in X} (M)_{f_x}$. For $x \in X$ define for $n \in \omega$,

$$g_x(n) = \min\bigl\{l : \forall t \in {}^n2 \ \bigl([t^\frown z\restriction[n, l)] \subseteq \bigcup_{m>n} S^m_{f_x(m)}\bigr)\bigr\}.$$

The function $x \rightsquigarrow g_x$ is also Borel. Since $X \in \mathsf{B}$, it follows that there is an increasing function $h \in {}^\omega\omega$ such that

$$\forall x \in X \ \forall^\infty n \ (g_x(n) \leq h(n)).$$

Consider the set

$$G = \bigcap_n \bigcup_{m>n} \bigcup\{[t^\frown z\restriction\bigl[m, h(m))] : t \in {}^m2\}.$$

Clearly G is a dense G_δ set. Moreover, for every $x \in X$ there is n such that

$$\bigcup_{m>n} \bigcup\{[t^\frown z\restriction\bigl[m, h(m))] : t \in {}^m2\} \subseteq \bigcup_{m>n} S^m_{f_x(m)}.$$

It follows that

$$\bigcup_{x \in X} (M)_{f_x} \subseteq {}^\omega2 - G,$$

which finishes the proof. ⊣

From Theorem 3.11 it follows that $\mathsf{D} \cup \mathsf{NON}(\mathcal{B}) \subseteq \mathsf{COF}(\mathcal{B})$. The other inclusion does not hold. We only have the following result dual to Theorem 4.8.

4.9 Theorem. *If* $X \notin \mathsf{D}$ *and* $Y \notin \mathsf{NON}(\mathcal{B})$ *then* $X \times Y \notin \mathsf{COF}(\mathcal{B})$. *In particular,* $\mathbf{cof}(\mathcal{B}) = \max\{\mathbf{non}(\mathcal{B}), \mathfrak{d}\}$.

4.10 Definition. Let $\mathbb{R}_+ = \{x \in \mathbb{R} : x \geq 0\}$ and define

$$\ell^1 = \left\{f \in {}^\omega\mathbb{R}_+ : \sum_{n=1}^{\infty} f(n) < \infty\right\}.$$

For $f, g \in \ell^1$, $f \leq^\star g$ if $f(n) \leq g(n)$ holds for all but finitely many n.

4.11 Theorem. *The following are equivalent:*

(1) $X \in \mathsf{ADD}(\mathcal{L})$,

(2) for every Borel function $x \rightsquigarrow S^x \in \mathcal{C}$ *there exists an* $S \in \mathcal{C}$ *such that*

$$\forall x \in X \ \forall^\infty n \ (S^x(n) \subseteq S(n)).$$

(3) *for every Borel function* $x \rightsquigarrow f^x \in \ell^1$ *there exists a function* $f \in \ell^1$ *such that*

$$\forall x \in X\ (f^x \leq^\star f).$$

In particular, the following conditions are equivalent:

(a) $\mathbf{add}(\mathcal{L}) > \kappa$,

(b) *for every family* $F \subseteq \mathcal{C}$ *of size* κ *there exists an* $\bar{S} \in \mathcal{C}$ *such that*

$$\forall S \in F\ \forall^\infty n\ (S(n) \subseteq \bar{S}(n)),$$

(c) *for every family* $F \subseteq \ell^1$ *of size* κ *there exists a* $g \in \ell^1$ *such that*

$$\forall f \in F\ \forall^\infty n\ (f \leq^\star g).$$

Proof. We will establish the equivalence of (1) and (2). Suppose that $X \in \mathsf{ADD}(\mathcal{L})$ and $x \rightsquigarrow S_x$ is a Borel function. Consider the morphism (φ_-, φ_+) witnessing that $\mathcal{C} \preceq \mathcal{L}$. Let f be such that $\bigcup_{x \in X} (N)_{\varphi_-(S_x)} \subseteq (N)_f$. Then $\varphi_+(f) \in \mathcal{C}$ is the object we are looking for.

Suppose that $X \notin \mathsf{ADD}(\mathcal{L})$. Let $F : X \longrightarrow {}^\omega\omega$ be a Borel function such that $\bigcup_{x \in X} (N)_{F(x)} \not\subseteq (N)_f$ for $f \in {}^\omega\omega$. Consider the morphism (φ_-, φ_+) witnessing that $\mathcal{L} \preceq \mathcal{C}$. It follows that there is no $S \in \mathcal{C}$ such that

$$\forall x \in X\ \forall^\infty n\ (\varphi_-(F(x))(n) \subseteq^\star S(n)).$$

Equivalence of (2) and (3) follows from:

4.12 Lemma. $\mathcal{C} \equiv \ell^1$.

Proof. To show that $\ell^1 \preceq \mathcal{C}$ define $\varphi_- : \ell^1 \longrightarrow \mathcal{C}$ as

$$\varphi_-(f)(n) = \{k : 2^{-n} > f(k) \geq 2^{-n-1}\}.$$

Similarly, define $\varphi_+ : \mathcal{C} \longrightarrow \ell^1$ by: $\varphi_+(S)(n) = \max\{2^{-k} : n \in S(k)\}$. It is easy to see that these functions have the required properties.

To show that $\mathcal{C} \preceq \ell^1$ identify $\omega \times \omega$ with ω via functions $L, K \in {}^\omega\omega$. For $S \in \mathcal{C}$ let

$$\varphi_-(S)(n) = \begin{cases} 2^{-n} & \text{if } K(n) \in S(L(n)), \\ 0 & \text{otherwise.} \end{cases}$$

For $f \in \ell^1$ let

$$\varphi_+(f)(n) = \left\{k : \frac{1}{2^{n-1}} > f(k) \geq \frac{1}{2^n}\right\}.$$

⊣

The second part of Theorem 4.11 follows readily from the first. ⊣

The dual version yields:

4.13 Theorem. *The following are equivalent:*

(1) $X \in \mathsf{COF}(\mathcal{L})$,

(2) for every Borel function $x \rightsquigarrow S^x \in \mathcal{C}$ *there exists an* $S \in \mathcal{C}$ *such that*

$$\forall x \in X\ \exists^\infty n\ (S(n) \not\subseteq S^x(n)),$$

(3) for every Borel function $x \rightsquigarrow f^x \in \ell^1$ *there exists a function* $f \in \ell^1$ *such that*

$$\forall x \in X\ \exists^\infty n\ (f^x(n) \leq f(n)).$$

In particular, the following are equivalent:

(a) $\mathbf{cof}(\mathcal{L}) < \kappa$,

(b) for every family $F \subseteq \mathcal{C}$ *of size* κ *there exists an* $\bar{S} \in \mathcal{C}$ *such that*

$$\forall S \in F\ \exists^\infty n\ (S(n) \not\subseteq \bar{S}(n)),$$

(c) for every family $F \subseteq \ell^1$ *of size* κ *there exists a* $g \in \ell^1$ *such that*

$$\forall f \in F\ \exists^\infty n\ (f(n) \leq g(n)).$$

Additivity of measure, $\mathbf{add}(\mathcal{L})$, has a special place among cardinal invariants of the continuum as being provably smaller than a large number of them. It has been conjectured (wrongly in [2]) that this is because additivity of measure is equivalent to Martin's Axiom for a large class of forcing notions (Suslin c.c.c.). Only very recently has this phenomenon been explained as being directly related to the combinatorial complexity of the measure ideal.

4.14 Definition. We say that an ideal $\mathcal{J} \subseteq P(\omega)$ is a *P-ideal* if for every family $\{X_n : n \in \omega\} \subseteq \mathcal{J}$ there is a $X \in \mathcal{J}$ such that $X_n \subseteq^\star X$ for $n \in \omega$.
Define

$$\mathbf{add}^\star(\mathcal{J}) = \min\{|\mathcal{A}| : \mathcal{A} \subseteq \mathcal{J}\ \&\ \neg\exists Y \in \mathcal{J}\ \forall X \in \mathcal{A}\ X \subseteq^\star Y\}.$$

It is easy to see that the $\mathbf{cof}^\star$ defined analogously is equivalent to the ordinary cofinality.

Many ideals of Borel subsets of $\mathbb{R}$ are Tukey equivalent to analytic ($\mathbf{\Sigma}^1_1$) ideals of subsets of ω. For example:

- Ideal of null sets $\mathcal{L}$. Work with $\mathcal{C}$ instead of $\mathcal{L}$. For $S \in \mathcal{C}$ let $A_S = \{(n,k) \in \omega \times \omega : k \in S(n)\}$. The family $\{A_S : S \in \mathcal{C}\}$ generates an analytic P-ideal on $\omega \times \omega \simeq \omega$.

- $({}^\omega\omega, \leq^\star)$. This is very similar. For $f \in {}^\omega\omega$ let $A_f = \{(n,k) : k \leq f(n)\}$.

- ℓ^1 is Tukey equivalent to the P-ideal of summable sets

$$\left\{X \subseteq \omega : \sum_{n \in X} \frac{1}{n} < \infty\right\}.$$

Moreover, in all these cases the additivity of the ideal is equal to the *additivity of the associated ideal on ω. For example, $\mathbf{add}(\mathcal{L}) = \mathbf{add}^\star(\ell^1) = \mathbf{add}^\star(\mathcal{C})$, etc. In the remainder of this section we will show for a (nontrivial) analytic P-ideal $\mathcal{J}$ on ω we have

$${}^\omega\omega \preceq \mathcal{J} \preceq \mathcal{L}.$$

We need a few general facts about analytic P-ideals. To simplify the notation let us identify ${}^\omega 2$ with $P(\omega)$ via characteristic functions.

Let $\mathsf{K}({}^\omega 2)$ be the collection of compact subsets of ${}^\omega 2$ with Hausdorff metric d_H defined as follows. For two nonempty compact sets $K, L \subseteq {}^\omega 2$ let

$$d_H(K, L) = \max(\rho(K, L), \rho(L, K)),$$

where $\rho(K, L) = \max_{x \in L} d(x, K)$ (d is the usual metric in ${}^\omega 2$).

Let $\mathsf{M} \subseteq \mathsf{K}({}^\omega 2)$ be the collection of compact subsets of ${}^\omega 2$ which are downward closed. We will use the following well known facts:

4.15 Lemma.

(1) $\mathsf{K}({}^\omega 2)$ *is a compact Polish space,*

(2) M *is a closed subspace of* $\mathsf{K}({}^\omega 2)$.

Proof. See [29, 4.F]. $\dashv$

Let $\mathcal{J}$ be an analytic P-ideal on ω. Define

$$\mathsf{F} = \{K \in \mathsf{M} : \forall X \in \mathcal{J}\ \exists n\ (X - n \in K)\}.$$

It is clear that F is a filter.

4.16 Lemma. *Suppose that $H \subseteq \mathsf{F}$ is a closed set. There exists a nonempty relatively clopen set $U \subseteq H$ such that*

$$\textstyle\bigcap_{K \in U} K \in \mathsf{F}.$$

In particular, $H = \bigcup_{n \in \omega} H_n$, where for each n, $\bigcap_{K \in H_n} K \in \mathsf{F}$.

Proof. Let $\langle U_n : n \in \omega\rangle$ be an enumeration of clopen subsets of $\mathsf{K}({}^\omega 2)$.

For $X \in \mathcal{J}$ and n define $H_n(X) = \{K \in H : X - n \in K\}$. The sets $H_n(X)$ are closed and $H = \bigcup_{n \in \omega} H_n(X)$ for every $X \in \mathcal{J}$. By the Baire Category Theorem for each X there is a pair $(n(X), m(X)) \in \omega \times \omega$ such that

$$H_{n(X)}(X) \cap U_{m(X)} = H \cap U_{m(X)}.$$

Since $\mathcal{J}$ is a P-ideal, we can find (n, m) such that

$$\{X : n(X) = n \;\&\; m(X) = m\} \text{ is cofinal in } \mathcal{J}.$$

It follows that $\bigcap_{K \in U_m \cap H} K$ contains $X - n$ for cofinally many X and thus belongs to F. That finishes the proof of the first part.

To prove the second part build by induction a sequence $\langle H_\alpha : \alpha < \omega_1 \rangle$ such that

1. $H_0 = H$,
2. $H_\lambda = \bigcap_{\beta<\lambda} H_\beta$ for limit λ,
3. $H_{\alpha+1} = H_\alpha - U_\alpha$, where U_α is like in the part that is already proved.

The construction has to terminate after $\alpha_0 < \omega_1$ steps with $H_{\alpha_0} = \emptyset$. ⊣

4.17 Lemma. F *is* F_σ *in* M.

Proof. Consider $\mathsf{G} = \mathsf{M} - \mathsf{F}$. Note that for $K \in \mathsf{M}$ we have

$$K \in \mathsf{G} \iff \exists X \in \mathcal{J}\ \forall n\ (X - n \notin K).$$

It follows that G is an analytic ideal. Moreover, G is a σ-ideal; if $\{K_n : n \in \omega\} \subseteq \mathsf{G}$ and $K \subseteq \bigcup_n K_n$ then $K \in \mathsf{G}$. To see this let X_n witness that $K_n \in \mathsf{G}$. Find $X \in \mathcal{J}$ such that $X_n \subseteq^\star X$ for all n. Clearly, $X - n \notin K$ for all n. Now the lemma follows immediately from the following:

4.18 Theorem. *Let $\mathcal{I}$ be an analytic σ-ideal of compact sets in a compact metrizable space E. Then $\mathcal{I}$ is actually G_δ.*

Proof. See [14], [41] or [30]. ⊣

This completes the proof of Lemma 4.17. ⊣

4.19 Lemma. F *is countably generated.*

Proof. Using Lemma 4.17 represent $\mathsf{F} = \bigcup_n H_n$, where each H_n is closed. Apply Lemma 4.16 to write for $n \in \omega$, $H_n = \bigcup_{m\in\omega} H^n_m$, where $G^n_m = \bigcap_{K \in H^n_m} K \in \mathsf{F}$. It is clear that $\{G^n_m : n, m \in \omega\}$ generates F. ⊣

Let $\langle G_n : n \in \omega \rangle$ be a descending sequence generating F. The following lemma provides a simple ($F_{\sigma\delta}$) description of $\mathcal{J}$ in terms of $\langle G_n : n \in \omega \rangle$.

4.20 Lemma. $X \in \mathcal{J} \iff \forall n\ \exists m\ (X - m \in G_n)$.

Proof. The implication ($\Longrightarrow$) is obvious.

($\Longleftarrow$) We will use the following result.

4.21 Theorem. *Suppose that $\mathcal{I} \subseteq P(\omega)$ is an ideal containing all finite sets. The following conditions are equivalent:*

(1) $\mathcal{I}$ has the Baire property,

(2) $\mathcal{I}$ is meager,

(3) there exists a partition $\{I_n : n \in \omega\}$ of ω into disjoint intervals such that
$$\forall X \in \mathcal{I}\ \forall^\infty n\ (I_n \not\subseteq X).$$

Proof. See [54] or [8]. $\dashv$

Suppose that $X \notin \mathcal{J}$. The ideal $\mathcal{J}{\restriction}X = \{Y \cap X : Y \in \mathcal{J}\} \subseteq P(X)$ is analytic and hence has the Baire property. By Theorem 4.21(3) there exists a partition $\{I_n : n \in \omega\}$ of X into finite sets such that
$$\forall Z \in \mathcal{J}\ \forall^\infty n\ (I_n \not\subseteq Z).$$

Consider the set
$$K = \{Y : \forall n\ (I_n \not\subseteq Y)\} \in \mathsf{F}.$$

Let k be such that $G_k \subseteq K$. It follows that for every $m \in \omega$,
$$X - m =^\star \bigcup_{n\in\omega} I_n \notin G_k,$$

which finishes the proof of Lemma 4.20. $\dashv$

For $K, L \in \mathsf{K}({}^\omega 2)$ define $K \oplus L = \{X \cup Y : X \in K,\ Y \in L\}$. ($\cup$ is in $P(\omega)$ the same as coordinate-wise maximum in ${}^\omega 2$).

Let $\langle G_n : n \in \omega\rangle$ continue to be a descending sequence generating F.

4.22 Lemma. *For every $K \in \mathsf{F}$ there exists an m such that $G_m \oplus G_m \subseteq K$.*

Proof. Fix $X \in \mathcal{J}$ and using the fact that $\mathcal{J}$ is a P-ideal find k such that the set
$$H_X = \{Y : (X - k) \cup Y \in K\} \in \mathsf{F}.$$

Let $n(X)$ be such that $G_{n(X)} \subseteq H_X$. We have
$$\{X - n(X)\} \oplus G_{n(X)} \subseteq K.$$

Choose an n such that $\{X : n(X) = n\}$ is cofinal in $\mathcal{J}$. The set $L = \{X : \{X - n\} \oplus G_n \subseteq K\} \in \mathsf{F}$. Let $m \geq n$ be such that $G_m \subseteq L$. It follows that $G_m \oplus G_m \subseteq K$. $\dashv$

We are ready to formulate the first result.

4.23 Theorem. *Suppose that $\mathcal{J}$ is an analytic P-ideal on ω. Then $\mathcal{J} \preceq \ell^1$. In particular, $\mathbf{add}^\star(\mathcal{J}) \geq \mathbf{add}(\mathcal{L})$ and $\mathbf{cof}(\mathcal{J}) \leq \mathbf{cof}(\mathcal{L})$.*

Proof. Use Lemma 4.22 to find a descending sequence $\langle G_n : n \in \omega \rangle$ generating F such that for each n,

$$\underbrace{G_{n+1} \oplus \cdots \oplus G_{n+1}}_{2^{2n+1} \text{ times}} \subseteq G_n.$$

For $X \in \mathcal{J}$ let $\langle k_n(X) : n \in \omega \rangle$ be an increasing sequence such that

$$\forall n \; (X - k_n(X) \in G_{n+2}).$$

Identify ω with $[\omega]^{<\omega}$ and define $\varphi_- : \mathcal{J} \longrightarrow \mathcal{C}$ and $\varphi_+ : \mathcal{C} \longrightarrow \mathcal{J}$ such that

$$X \subseteq^\star \varphi_+(S), \quad \text{whenever } \varphi_-(X) \subseteq^\star S.$$

Since $\mathcal{C} \equiv \ell^1 \equiv \mathcal{L}$ this will finish the proof. For $X \in \mathcal{J}$ and $n \in \omega$ define

$$\varphi_-(X)(n) = X \cap k_n(X) \in [\omega]^{<\omega} \simeq \omega.$$

The function φ_+ will be defined as follows. Suppose that $S \in \mathcal{C}$ is given (with $S(n) \subseteq [\omega]^{<\omega}$). For $n \in \omega$ let

$$Z_n = \{(t, s) \in S(n+1) \times S(n) : s \subseteq t \;\&\; t - \max(s) \in G_{n+2}\}.$$

Now define

$$v_n = \bigcup\nolimits_{(t,s) \in Z_n} t - \max(s).$$

Note that for sufficiently large n, v_n is a sum of at most 2^{2n} terms, each belonging to G_{n+2}, and so, $v_n \in G_{n+1}$.

The motivation for this definition is following: if $\varphi_-(X)(n) = X \cap k_n(X) \in S(n)$ and $\varphi_-(X)(n+1) = X \cap k_{n+1}(X) \in S(n+1)$, then

$$X \cap k_{n+1}(X) - \max\big(X \cap k_n(X)\big) = X \cap \big[k_n(X), k_{n+1}(X)\big) \subseteq v_n.$$

The requirements of the definition describe this situation and filter out "background noise" coming with S.

Finally define

$$\varphi_+(S) = Y = \bigcup\nolimits_n v_n.$$

By the remarks above it is clear that if $X \in \mathcal{J}$ and $S \in \mathcal{C}$ then from the fact that

$$\forall^\infty n \; (\varphi_-(X)(n) \in S(n))$$

it follows that $X \subseteq^\star Y = \varphi_+(S)$. To finish the proof it remains to show that the range of φ^+ is contained in $\mathcal{J}$.

Let $\varphi_+(S) = Y = \bigcup_n v_n$ be defined as above. For $j \in \omega$, let $Y_j = \bigcup_{n \geq j} v_n$. Since $Y - Y_j$ is finite for every j, by the lemma above, in order to show that $Y \in \mathcal{J}$ it would suffice to show that $Y_j \in G_j$.

4.24 Lemma. *For each $l \in \omega$,*

$$v_n \cup v_{n+1} \cup \cdots \cup v_{n+l} \in G_n.$$

Proof. We prove this by induction on l. For each n, $v_n \in G_{n+1}$ so the lemma is true for $l = 0$. Suppose it holds for l and all n. We have

$$v_n \cup v_{n+1} \cup v_{n+l+1} = v_n \cup (v_{n+1} \cup \ldots v_{n+1+l}) \in G_{n+1} \oplus G_{n+1} \subseteq G_n,$$

which finishes the proof. $\dashv$

Since the sets G_n are closed, we conclude that $Y_j \in G_j$. In particular, by Lemma 4.20, $Y = Y_0 \in \mathcal{J}$. This completes the proof of Theorem 4.23. $\dashv$

The last theorem gave us a lower bound for $\mathbf{add}^\star(\mathcal{J})$. The next theorem gives us an upper bound.

Suppose that $\mathcal{J} \subseteq P(\omega)$ is an ideal. We say that $\mathcal{J}$ is *atomic* if there is a $Z \in \mathcal{J}$ such that $\mathcal{J} = \{X \subseteq \omega : X \subseteq^\star Z\}$. It is clear that $\mathbf{add}^\star(\mathcal{J})$ is undefined (or equal to ∞) for an atomic ideal.

4.25 Theorem. *Suppose that $\mathcal{J}$ is an analytic P-ideal which is not atomic. Then ${}^\omega\omega \preceq \mathcal{J}$. In particular, $\mathbf{add}^\star(\mathcal{J}) \leq \mathfrak{b}$ and $\mathbf{cof}(\mathcal{J}) \geq \mathfrak{d}$.*

Proof. Let $\mathcal{J}$ be an analytic P-ideal. Use Lemma 4.22 to find a descending sequence $\langle G_n : n \in \omega\rangle$ generating F such that for each n, $G_{n+1} \oplus G_{n+1} \subseteq G_n$. To show that ${}^\omega\omega \preceq \mathcal{J}$ it suffices (by duality), to check that $(\mathcal{J}, \mathcal{J}, \not\supseteq^\star) \preceq (\omega^\omega, \omega^\omega, \not\geq^\star)$. Thus we need to find a function $\varphi_- : \mathcal{J} \longrightarrow \omega^\omega$ such that φ_-"$\mathcal{J}$ is cofinal in ω^ω.

For $X \in \mathcal{J}$ define

$$\varphi_-(X)(n) = \min\{j \geq n : X - j \in G_n\} \quad \text{for } n \in \omega.$$

Note that if $X \subseteq^\star Y$ then $\varphi_-(X) \leq^\star \varphi_-(Y)$.

Let $g \in \omega^\omega$ be an increasing function. For $X \in \mathcal{J}$ let

$$Z^g_X = \{n : X - g(n) \notin G_n\}.$$

Observe that $Z^g_{X\cup Y} \supseteq Z^g_X \cup Z^g_Y$ for $X, Y \in \mathcal{J}$, hence the family $\{Z^g_X : X \in \mathcal{J}\}$ generates an ideal which we call $\mathcal{I}^g$.

Note that we are trying to show that

$$\forall g \in \omega^\omega \ \exists X \in \mathcal{J} \ (|\omega - Z^g_X| < \aleph_0),$$

which means that all ideals $\mathcal{I}^g$ are trivial.

Suppose that for some $g \in \omega^\omega$, $\mathcal{I}^g$ is a proper ideal. We will show that $\mathcal{J}$ is an atomic ideal.

Since $\mathcal{I}^g$ is a continuous image of $\mathcal{J}$, $\mathcal{I}^g$ is an analytic ideal so it has the Baire property. By Theorem 4.21, there exists a sequence of disjoint intervals $\langle I_n : n \in \omega\rangle$ such that

$$\forall X \in \mathcal{J} \ \forall^\infty n \ (I_n \not\subseteq Z^g_X).$$

Let $h(n) = \max(I_n)$ for $n \in \omega$. It follows that

$$\forall X \in \mathcal{J}\ \forall^\infty n\ (X - g(h(n)) \in G_n).$$

For $n \in \omega$ let

$$U_n = \bigcup\{Y : Y \subseteq [g(h(n)), g(h(n+1))) : Y \in G_n\},$$

and let $U = \bigcup_n U_n$. By the choice of h, for every $X \in \mathcal{J}$, $X \cap [g(h(n)), g(h(n+1))) \subseteq U_n$ holds for all but finitely many n. Thus, $X \subseteq^\star U$ for every $X \in \mathcal{J}$. Therefore, to finish the proof it is enough to check that $U \in \mathcal{J}$.

4.26 Lemma. *$\forall^\infty n\ (U_n \in G_n)$.*

Proof. For $k \in \omega$, if $U_{k+1} \in G_{k+1}$ set $U'_{k+1} = \emptyset$. Otherwise, let $U'_{k+1} \subseteq U_{k+1}$ be such that $U'_{k+1} \in G_k - G_{k+1}$. Note that since $G_{n+1} \oplus G_{n+1} \subseteq G_n$ for every n, and U_{k+1} is a union of sets in G_{k+1}, such a set can be found. Moreover, for every $m > k$, $U'_{k+1} \cup U'_{k+2} \cup \cdots \cup U'_m \in G_k$. Thus, by compactness, $\bigcup_{l>k} U'_l \in G_k$. It follows from Lemma 4.20 that $X = \bigcup_k U'_k \in \mathcal{J}$. On the other hand, if X is infinite then

$$\exists^\infty n\ \left(X - g(h(n)) \notin G_n\right),$$

which contradicts the choice of h. ⊣

Suppose that for $n > n_0$, $U_n \in G_n$ and define $U^k = \bigcup_{j>k+n_0} U_j$, for $k \in \omega$. As above, $U =^\star U^k \in G_k$ for $k \in \omega$. Therefore, by Lemma 4.20, $U \in \mathcal{J}$. This completes the proof of Theorem 4.25. ⊣

Historical Remarks. Theorem 4.1 was proved in [39] and [7]. Theorem 4.6 is due to Pawlikowski and Recław in [39]. Theorems 4.5 and 4.7 were proved in [4]. Theorem 4.8 was proved in [39]. The second part is due to Miller [33]. The first part of Theorem 4.11 was proved in [39] and the second in [3]. Todorcevic [56] proved Theorem 4.25. Theorem 4.23 is due to Todorcevic [55] and Louveau and Velickovic [32]. Methods used in the proof, in particular Lemmas 4.17 and 4.22, are due to Solecki [50, 51]. Similar ideas were already present in [56] and earlier in [28]. Theorem 4.18 is due to Christensen and Saint Raymond. It was generalized in [30]. Theorem 4.21 was proved by Talagrand.

5. Cofinality of $\mathbf{cov}(\mathcal{J})$ and $\mathsf{COV}(\mathcal{J})$

It is clear that cardinal invariants **add**, **non** and **cof** have uncountable cofinality and families ADD, NON and COF are σ-ideals. It this section we investigate **cov** and COV for both ideals $\mathcal{B}$ and $\mathcal{L}$.

5.1 Theorem. *$\mathsf{COV}(\mathcal{B})$ is a σ-ideal. In particular,* $\mathrm{cf}(\mathbf{cov}(\mathcal{B})) > \aleph_0$.

Proof. Suppose that $\{X_n : n \in \omega\} \subseteq \mathsf{COV}(\mathcal{B})$. Let $x \rightsquigarrow f_x \in {}^\omega\omega$ be a Borel function. It is enough to find a $g \in {}^\omega\omega$ such that

$$\forall n\ \forall x \in X_n\ \exists^\infty m\ (g(m) = f_x(m)).$$

Let $\{A_k : k \in \omega\}$ be a partition of ω into infinitely many infinite pieces. For each n consider the function $x \rightsquigarrow f_x{\restriction}A_n$ and find a $g_n \in {}^{A_n}\omega$ such that

$$\forall x \in X_n\ \exists^\infty k \in A_n\ (f_x(k) = g_n(k)).$$

Then $g = \bigcup_n g_n$ is as required. $\dashv$

In the presence of many dominating reals we have a similar result for the measure ideal.

5.2 Theorem. *If* $\mathbf{cov}(\mathcal{L}) \leq \mathfrak{b}$ *then* $\mathrm{cf}(\mathbf{cov}(\mathcal{L})) > \aleph_0$.

Proof. See [5] or [8]. $\dashv$

The following surprising result of Shelah shows that without any additional assumptions it is not possible to show that $\mathbf{cov}(\mathcal{L})$ has uncountable cofinality.

5.3 Theorem. *It is consistent with* ZFC *that* $\mathsf{COV}(\mathcal{L})$ *is not a* σ*-ideal and* $\mathrm{cf}(\mathbf{cov}(\mathcal{L})) = \aleph_0$.

The proof of this theorem will occupy the rest of this section. The model will be obtained by a two-step finite support iteration. We start with a suitably chosen model V_0 satisfying $2^{\aleph_0} = \aleph_1$ and add $\aleph_\omega$ Cohen reals followed by a finite support iteration of subalgebras of the random algebra $\mathbf{B}$. We start by developing various tools needed for the construction.

The Random Real Algebra

Recall that the random real algebra can be represented as

$$\mathbf{B} = \{P \subseteq {}^\omega 2 : \mu(P) > 0 \text{ and } P \text{ is closed}\}.$$

For $P_1, P_2 \in \mathbf{B}$, $P_1 \leq P_2$ if $P_1 \subseteq P_2$. Elements of $\mathbf{B}$ can be coded by reals in the following way. Let $\widetilde{P} \in V_0$ be a universal closed set, i.e. $\widetilde{P} \subseteq {}^\omega 2 \times {}^\omega 2$ is closed and for every closed set $P \subseteq {}^\omega 2$ there is x such that $P = (\widetilde{P})_x$. Let $H = \{x : \mu((\widetilde{P})_x) > 0\}$. By Theorem 3.6(1), H is a Borel set. Define $\widetilde{B} = (H \times {}^\omega 2) \cap \widetilde{P}$. If M is a model of ZFC then we define

$$\mathbf{B}^M = \{P \in \mathbf{B} : \exists x \in M \cap {}^\omega 2\ (P = (\widetilde{B})_x)\}.$$

Δ-systems

The following concepts will be crucial for the construction of the model.

5.4 Definition. Let $\mathcal{R} \in V_0$ be a forcing notion Suppose that $\bar{p} = \langle p_n : n \in \omega\rangle$ is a sequence of conditions in $\mathcal{R}$. Let $\dot{X}_{\bar{p}}$ be the $\mathcal{R}$-name for the set $\{n : p_n \in \dot{G}_{\mathcal{R}}\}$. In other words, for every n, $p_n = [\![n \in \dot{X}_{\bar{p}}]\!]$.

At the moment we will be concerned with the case when $\mathcal{R} = \mathbf{C}_{\aleph_{\omega+1}}$ is the forcing notion adding $\aleph_{\omega+1}$ Cohen reals. For the definition below, neither the representation of $\mathbf{C}$ nor the ordering on $\mathbf{C}$ matters, so for simplicity, we will identify $\mathbf{C}$ with ω.

5.5 Definition. Let $\Delta \subseteq (\mathbf{C}_{\aleph_{\omega+1}})^\omega$ be the collection of all sequences $\bar{p} = \{p_n : n \in \omega\}$ such that there exist a $k, l \in \omega$ and $g \in {}^{l\times\omega}\omega$, $s \in {}^k\omega$ such that

1. $\mathsf{dom}(p_n) = \{\beta_1, \dots, \beta_k\} \dot\cup \{\alpha_1^n, \dots, \alpha_l^n\}$, with $\beta_1 < \cdots < \beta_k$ and $\alpha_1^n < \cdots < \alpha_l^n$ for $n \in \omega$,
2. $\alpha_l^n < \alpha_1^{n+1}$ for $n \in \omega$, (so the $\mathsf{dom}(p_n)$'s form a Δ-system with root $\{\beta_1, \dots, \beta_k\}$),
3. $p_n(\alpha_i^n) = g(i, n)$ for every $i \le l, n \in \omega$,
4. $p_n(\beta_i) = s(i)$ for $i \le k, n \in \omega$.

Let $p_{\bar{p}} = p_0 \restriction \{\beta_1, \dots, \beta_k\}$.

Note that if $\bar{p} \in \Delta$ then $f_{\bar{p}} = \bigcup_{n\in\omega} p_n$ is a function. Moreover, $p_{\bar{p}} = f_{\bar{p}} \restriction \{\beta_1, \dots, \beta_k\}$ and $p_{\bar{p}} \Vdash_{\mathbf{C}_{\aleph_{\omega+1}}} X_{\bar{p}}$ is infinite.

5.6 Definition. A subset $\Delta' \subseteq \Delta$ is *filter-like* if for any $\bar{p}^1, \dots, \bar{p}^n \in \Delta'$ there exists a q such that

$$q \Vdash_{\mathbf{C}_{\aleph_{\omega+1}}} \bigcap_{i\le n} X_{\bar{p}^i} \text{ is infinite.}$$

5.7 Theorem. *Suppose that $V \models 2^{\aleph_0} = \aleph_1$ & $2^{\aleph_1} = \aleph_{\omega+1}$. Then Δ is the union of $\aleph_1$ filter-like sets.*

Proof. Let T be the collection of $\langle k, l, v, \{f_{i,n}, g_j : i \le l, j \le k, n \in \omega\}, g, s\rangle$ such that

1. $k, l \in \omega$,
2. $v \in [\aleph_1]^{\le\aleph_0}$,
3. $g_j, f_{i,n} \in {}^v\omega$ are pairwise different for $i \le l, j \le k, n \in \omega$,
4. $g \in {}^{l\times\omega}\omega$,
5. $s \in {}^k\omega$.

From the assumption about the cardinal arithmetic in V it follows that $V \models \aleph_n^{\aleph_0} = \aleph_n$ for $n \ge 1$. In particular $V \models |T| = \aleph_1$. Moreover, since $V \models 2^{\aleph_1} = \aleph_{\omega+1}$ we can find in V an enumeration $\langle h_\alpha : \alpha < \aleph_{\omega+1}\rangle$ of ${}^{\aleph_1}\omega$.

Given $t = \langle k, l, v, \{f_{i,n}, g_j : i \le l, j \le k, n \in \omega\}, g, s\rangle \in T$ define $\Delta_t \subseteq \Delta$ to be the collection of all $\bar{p} = \langle p_n : n \in \omega\rangle$ such that

1. $\mathsf{dom}(p_n) = \{\beta_1, \dots, \beta_k\} \dot\cup \{\alpha_1^n, \dots, \alpha_l^n\}$, with $\beta_1 < \cdots < \beta_k$,

2. $p_n(\alpha_i^n) = g(i,n)$,

3. $p_n(\beta_i) = s(i)$,

4. $\forall i \leq l \ (h_{\alpha_i^n}\restriction v = f_{i,n})$,

5. $\forall j \leq k \ (h_{\beta_j}\restriction v = g_j)$.

5.8 Lemma. Δ_t *is filter-like for every* $t \in T$.

Proof. For simplicity, suppose that $\bar{p}^1, \bar{p}^2 \in \Delta_t$ (the proof is the same when a larger number of $\bar{p}$s is involved). First we show that $f_{\bar{p}^1} \cup f_{\bar{p}^2}$ is a function. Suppose that $\alpha \in \mathsf{dom}(f_{\bar{p}^1}) \cap \mathsf{dom}(f_{\bar{p}^2})$. Consider the function h_α and note that exactly one of the following possibilities happens:

1. there exists exactly one pair (n,i) such that $h_\alpha\restriction v = f_{i,n}$. In this case $f_{\bar{p}^1}, f_{\bar{p}^2}$ agree on α with the value $g(i,n)$,

2. there exists exactly one $j \leq k$ such that $h_\alpha\restriction v = g_j$ (so $f_{\bar{p}^1}(\alpha) = f_{\bar{p}^2}(\alpha) = s(j)$).

Now, put $q = p_{\bar{p}_1} \cup p_{\bar{p}_2}$ and note that q has the required property. $\dashv$

To finish the proof of Theorem 5.7 note that $\Delta = \bigcup_{t \in T} \Delta_t$. Suppose that $\bar{p} = \langle p_n : n \in \omega \rangle \in \Delta$. Let k, l, g and s be as in Definition 5.5, and put v to be a countable set such that $h_{\alpha_i^n}\restriction v$ and $h_{\beta_j}\restriction v$ are pairwise different. $\dashv$

Finitely Additive Measures on ω

5.9 Definition. A set $\mathcal{A} \subseteq P(\omega)$ is an *algebra* if

1. $X \cup Y \in \mathcal{A}$ whenever $X, Y \in \mathcal{A}$,

2. $\omega - X \in \mathcal{A}$ whenever $X \in \mathcal{A}$,

3. $\emptyset, \omega \in \mathcal{A}$, $\{n\} \in \mathcal{A}$ for $n \in \omega$.

Given an algebra $\mathcal{A}$, a function $m : \mathcal{A} \longrightarrow [0,1]$ is a *finitely additive measure* if

1. $m(\omega) = 1$ and $m(\emptyset) = m(\{n\}) = 0$ for every n,

2. if $X, Y \subseteq \omega$ are disjoint, then $m(X \cup Y) = m(X) + m(Y)$.

We say that m is atomless if for every set $A \in \mathcal{A}$, $m(A) > 0$ there exists a $B \subseteq A$, $B \in \mathcal{A}$ such that $0 < m(B) < m(A)$.

Any non-principal filter on ω corresponds to a finitely additive 2-valued measure and any ultrafilter is a maximal such measure. In the sequel we will work with measures defined on $\mathcal{A} = P(\omega)$.

5.10 Definition. For a real valued function $f : \omega \longrightarrow [0,1]$ and any finitely additive measure m define

$$\int_\omega f\, dm = \lim_{n\to\infty} \sum_{k=0}^{2^n} \frac{k}{2^n} \cdot m(A_k),$$

where

$$A_k = \left\{ n : \frac{k}{2^n} \le f(n) < \frac{k+1}{2^n} \right\}.$$

We leave it to the reader to verify that integration with respect to m has its usual properties.

The following is a special case of the Hahn-Banach theorem.

5.11 Theorem (Hahn-Banach). *Suppose that m is a finitely additive measure on an algebra $\mathcal{A}$, and $X \notin \mathcal{A}$. Let $a \in [0,1]$ be such that*

$$\sup\{m(A) : A \subseteq X \;\&\; A \in \mathcal{A}\} \le a \le \inf\{m(B) : X \subseteq B \;\&\; B \in \mathcal{A}\}.$$

Then there exists a measure $\bar{m}$ on $P(\omega)$ extending m such that $\bar{m}(X) = a$.

We will need several results concerning the existence of measures in forcing extensions.

5.12 Lemma. *Let $m_0 \in V$ be a finitely additive measure on $P(\omega)$. For $i = 1,2$ let $\mathcal{R}_i$ be a forcing notion and let $\dot{m}_i$ be an $\mathcal{R}_i$-name for a finitely additive measure on $V^{\mathcal{R}_i} \cap P(\omega)$ extending m_0. Then there exists a $\mathcal{R}_1 \times \mathcal{R}_2$-name for a measure $\dot{m}_3$ extending both $\dot{m}_1$ and $\dot{m}_2$.*

Proof. We extend the measures using the Hahn-Banach theorem and we only need to check that the requirements are consistent. Suppose that we have $\mathcal{R}_1$-name $\dot{X}$ and $\mathcal{R}_2$-name $\dot{Y}$ such that $\Vdash_{\mathcal{R}_1 \times \mathcal{R}_2} \dot{X} \subseteq^\star \dot{Y}$. A necessary and sufficient condition for both measures to have a common extension is that in such a case $m_1(\dot{X}) \le m_2(\dot{Y})$. Let $(\bar{p}, \bar{q}) \in \mathcal{R}_1 \times \mathcal{R}_2$ and $\bar{n}$ be such that

$$(\bar{p}, \bar{q}) \Vdash_{\mathcal{R}_1 \times \mathcal{R}_2} \dot{X} - \bar{n} \subseteq \dot{Y}.$$

Let

$$Z = \{n > \bar{n} : \exists p \in \mathcal{R}_1 \; (p \le \bar{p} \;\&\; p \Vdash_{\mathcal{R}_1} n \in \dot{X})\}.$$

Set Z belongs to V and $\bar{p} \Vdash_{\mathcal{R}_1} \dot{X} - \bar{n} \subseteq Z$. Similarly $\bar{q} \Vdash_{\mathcal{R}_2} Z \subseteq \dot{Y}$. In particular,

$$(\bar{p}, \bar{q}) \Vdash_{\mathcal{R}_1 \times \mathcal{R}_2} \dot{m}_1(\dot{X}) \le \dot{m}_1(Z) = m_0(Z) = \dot{m}_2(Z) \le \dot{m}_2(\dot{Y}).$$

$\dashv$

We will need the following theorem.

5.13 Theorem. *Suppose that* $m \in V$ *is a finitely additive atomless measure on* $P(\omega)$ *and* $v \in \mathbf{B}$. *For a* $\mathbf{B}$*-name* $\dot{X}$ *for an element of* $[\omega]^\omega$ *define*

$$\dot{m}^v_{\mathbf{B}}(\dot{X}) = \sup\left\{\inf\left\{\int_\omega \frac{\mu(q \cap [\![n \in \dot{X}]\!])}{\mu(q)}\, dm : q \leq p\right\} : p \leq v,\ p \in \dot{G}_{\mathbf{B}}\right\}.$$

The name $\dot{m}^v_{\mathbf{B}}$ *has the following properties:*

(1) $v \Vdash_{\mathbf{B}} \dot{m}^v_{\mathbf{B}} : P(\omega) \longrightarrow [0,1]$,

(2) $v \Vdash_{\mathbf{B}} \dot{m}^v_{\mathbf{B}}$ *is a finitely additive atomless measure,*

(3) for $X \in V \cap P(\omega)$ $v \Vdash_{\mathbf{B}} \dot{m}^v_{\mathbf{B}}(X) = m(X)$,

(4) if $\dot{X}$ *is a* $\mathbf{B}$*-name for a subset of* ω *and* $\mu([\![n \in \dot{X}]\!]_{\mathbf{B}} \cap v)/\mu(v) = a > 0$ *for all* n, *then there is a condition* $p \in \mathbf{B}$, $p \leq v$, *such that* $p \Vdash_{\mathbf{B}} \dot{m}^v_{\mathbf{B}}(\dot{X}) \geq a$.

Proof. Without loss of generality we can assume that $v = 2^\omega$ and therefore we will drop the superscript v altogether.

(1) is clear.

(2) For a $\mathbf{B}$-name $\dot{X}$ for a subset of ω and $p \in \mathbf{B}$ let

$$m_p(\dot{X}) = \int_\omega \frac{\mu(p \cap [\![n \in \dot{X}]\!])}{\mu(p)}\, dm$$

and

$$m^\star_p(\dot{X}) = \inf\{m_q(\dot{X}) : q \leq p\}.$$

Clearly, $\dot{m}_{\mathbf{B}}(\dot{X}) = \sup_{p \in \dot{G}} \inf_{q \leq p} m_q(\dot{X}) = \sup_{p \in \dot{G}} m^\star_p(\dot{X})$. Note that if $p \Vdash_{\mathbf{B}} \dot{X} \subseteq \dot{Y}$ then $p \cap [\![n \in \dot{X}]\!] \subseteq p \cap [\![n \in \dot{Y}]\!]$ for every n. It follows that $m_p(\dot{X}) \leq m_p(\dot{Y})$ and $m^\star_p(\dot{X}) \leq m^\star_p(\dot{Y})$.

Similarly, if $p \Vdash_{\mathbf{B}} \dot{X} \cap \dot{Y} = \emptyset$ and $\dot{Z}$ is a name for $\dot{X} \cup \dot{Y}$ then $m_p(\dot{X}) + m_p(\dot{Y}) = m_p(\dot{Z})$ and $m^\star_p(\dot{X}) + m^\star_p(\dot{Y}) \leq m^\star_p(\dot{Z})$.

5.14 Lemma. $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{X}) \geq r \iff m^\star_p(\dot{X}) \geq r$.

Proof. ($\Longleftarrow$) This is obvious.

($\Longrightarrow$) Suppose that $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{X}) \geq r$. Fix a rational $t < r$ and $p' \leq p$. It follows that

$$D = \{q \leq p' : m^\star_q(\dot{X}) \geq t\}$$

is dense below p'. Let $\{q_n : n \in \omega\}$ be a maximal antichain in D. We have

$m_{q_n}(\dot{X}) \geq m^\star_{q_n}(\dot{X}) \geq t$. For every $k \in \omega$,

$$\begin{aligned} m_{\bigcup_{j\leq k} q_i}(\dot{X}) &= \int_\omega \frac{\mu(\bigcup_{j\leq k} q_i \cap [\![n \in \dot{X}]\!])}{\mu(\bigcup_{j\leq k} q_i)}\, dm \\ &= \int_\omega \frac{\sum_{j\leq k} \mu(q_j \cap [\![n \in \dot{X}]\!])}{\sum_{j\leq n} \mu(q_j)}\, dm \\ &= \sum_{j\leq k} \frac{\mu(q_j)}{\sum_{i\leq k}\mu(q_i)} \int_\omega \frac{\mu(q_j \cap [\![n \in \dot{X}]\!])}{\mu(q_i)}\, dm \\ &\geq t \sum_{j\leq k} \frac{\mu(q_j)}{\sum_{i\leq k}\mu(q_i)} = t. \end{aligned}$$

We leave it to the reader to check that by passing to the limit we get that $m_{p'}(\dot{X}) \geq t$, and since t and p' were arbitrary, that $m^\star_p(\dot{X}) \geq r$. $\dashv$

Now we show that $\dot{m}_{\mathbf{B}}$ is a finitely additive measure.

Suppose that $\Vdash_{\mathbf{B}} \dot{X} \subseteq \dot{Y}$. Suppose that $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{X}) > \dot{m}_{\mathbf{B}}(\dot{Y})$. Let $q \leq p$ and r be such that $q \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{X}) > r \geq \dot{m}_{\mathbf{B}}(\dot{Y})$. Then $m^\star_q(\dot{X}) \geq r$ and $m^\star_q(\dot{Y}) < r$—contradiction.

Suppose that $\Vdash_{\mathbf{B}} \dot{X} \cap \dot{Y} = \emptyset$ and let $\dot{Z}$ be a name for $\dot{X} \cup \dot{Y}$. Let p, r_1, r_2 be such that $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{X}) \geq r_1$ and $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{Y}) \geq r_1$. It follows that $m^\star_p(\dot{X}) \geq r_1$ and $m^\star_p(\dot{Y}) \geq r_2$. Thus $m^\star_p(\dot{Z}) \geq r_1 + r_2$, so $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{Z}) \geq \dot{m}_{\mathbf{B}}(\dot{X}) + \dot{m}_{\mathbf{B}}(\dot{Y})$.

Suppose that $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{Z}) > \dot{m}_{\mathbf{B}}(\dot{X}) + \dot{m}_{\mathbf{B}}(\dot{Y})$. There are reals r_1, r_2 and $q \leq p$ such that $q \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{X}) < r_1$, $q \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{Y}) < r_2$ and $q \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(\dot{Z}) > r_1 + r_2$. Use Lemma 5.14, to find $q' \leq q$ such that $m_{q'}(\dot{X}) < r_1$ and $m_{q'}(\dot{Y}) < r_2$. By the lemma, $m_{q'}(\dot{Z}) \geq m^\star_{q'}(\dot{Z}) \geq r_1 + r_2$. On the other hand, since $m_{q'}$ is additive, $m_{q'}(\dot{Z}) < r_1 + r_2$—contradiction.

(3) Suppose that $\dot{X}$ is a $\mathbf{B}$-name and for some $p \in \mathbf{B}$ and $X \in V \cap P(\omega)$, $p \Vdash_{\mathbf{B}} \dot{X} = X$. That means that for every $q \leq p$,

$$\frac{\mu(q \cap [\![n \in \dot{X}]\!])}{\mu(q)} = \begin{cases} 1 & \text{if } n \in X, \\ 0 & \text{if } n \notin X. \end{cases}$$

It follows that $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(X) \geq m(X)$. Since $\dot{m}_{\mathbf{B}}$ is a measure, by looking at the complements we get, $p \Vdash_{\mathbf{B}} 1 - \dot{m}_{\mathbf{B}}(X) \geq 1 - m(X)$, hence $p \Vdash_{\mathbf{B}} \dot{m}_{\mathbf{B}}(X) = m(X)$.

(4) Suppose that $\mu([\![n \in \dot{X}]\!]_{\mathbf{B}}) = a > 0$ for $n \in \omega$. Let

$$D = \{p : \exists \varepsilon > 0\ m_p(\dot{X}) \leq (1 - \varepsilon) \cdot a\}.$$

If D is not dense in $\mathbf{B}$, then the condition witnessing that has the required property.

So suppose that D is dense and work towards a contradiction. Let $\{q_n : n \in \omega\}$ be a maximal antichain in D. Clearly $\sum_{n=0}^{\infty} \mu(q_n) = 1$. Let $\varepsilon_0 > 0$ be such that $m_{q_0}(\dot{X}) \leq (1-\varepsilon_0) \cdot a$, which means that

$$\int_\omega \mu(q_0 \cap [\![n \in \dot{X}]\!])\, dm \leq (1-\varepsilon_0) \cdot a \cdot \mu(q_0).$$

Similarly for $n > 0$,

$$\int_\omega \mu(q_n \cap [\![n \in \dot{X}]\!])\, dm \leq a \cdot \mu(q_n).$$

Let $q = \bigcup_{i \leq n} q_n$. We have

$$\int_\omega \mu(q \cap [\![n \in \dot{X}]\!])\, dm \leq (1-\varepsilon_0) \cdot a \cdot \mu(q_0) + \sum_{j=1}^{n} a \cdot \mu(q_j) = a \cdot \mu(q) - \varepsilon_0 \cdot a \cdot \mu(q_0).$$

This is a contradiction since

$$\lim_{\mu(q) \to 1} \int_\omega \mu(q \cap [\![n \in \dot{X}]\!])\, dm = a.$$

$\dashv$

The Iteration

Let V_0 be a model satisfying $2^{\aleph_0} = \aleph_1$ and $2^{\aleph_1} = 2^{\aleph_2} = \cdots = \aleph_{\omega+1}$. In V_0 we will define the following objects:

1. A finite support iteration $\langle \mathcal{P}_\alpha, \dot{\mathcal{Q}}_\alpha : \alpha < \aleph_{\omega+1} \rangle$.
2. A sequence $\langle A_\alpha : \aleph_\omega \leq \alpha < \aleph_{\omega+1} \rangle$.
3. A sequence $\langle \dot{m}^\xi_\alpha : \aleph_\omega \leq \alpha < \aleph_{\omega+1}, \xi < \aleph_1 \rangle$ such that
   (a) $\dot{m}^\xi_\alpha$ is a $\mathcal{P}_\alpha$-name for a finitely additive measure on ω,
   (b) $\dot{m}^\xi_\alpha$ extends $\bigcup_{\beta<\alpha} \dot{m}^\xi_\beta$. In particular, if $\mathrm{cf}(\gamma) > \aleph_0$ then $\dot{m}^\xi_\gamma = \bigcup_{\beta<\gamma} \dot{m}^\xi_\beta$.

The definition is inductive. Formally, given $\mathcal{P}_\alpha$, $\{\dot{m}^\xi_\alpha : \xi < \aleph_1\}$ and A_α we define $\{\dot{m}^\xi_{\alpha+1} : \xi < \aleph_l\}$ followed by $A_{\alpha+1}$ and then $\mathcal{P}_{\alpha+1} = \mathcal{P}_\alpha \star \dot{\mathcal{Q}}_\alpha$.

For limit α, $\mathcal{P}_\alpha$ and $\{\dot{m}^\xi_\alpha : \xi < \aleph_1\}$ will be defined by the previous values and $A_\alpha = \emptyset$. Since the definition of $\dot{m}^\xi_\alpha$ is most complicated it is more natural to proceed in the reverse order by making commitments about the defined objects as we go along.

We will use the following notation: suppose that $\langle \mathcal{P}_\alpha, \dot{\mathcal{Q}}_\alpha : \alpha < \delta \rangle$ is a finite support iteration and $A \subseteq \delta$, $A \in V_0$. Let $\mathcal{P}(A)$ be the subalgebra generated by $\dot{G}{\restriction}A$ and let $V_0[\dot{G}{\restriction}A]$ denote model $V_0[\dot{G} \cap \mathcal{P}(A)]$. As we are going to iterate c.c.c. forcing notions of size $2^{\aleph_0}$, it follows that if $|A| = \aleph_n$, $n > 0$ then $V_0[\dot{G}{\restriction}A] \models 2^{\aleph_0} = \aleph_n$.

To define the iteration we require that:

A0. $A_\alpha \subseteq \alpha$ for $\alpha < \aleph_{\omega+1}$.

Let $\langle \mathcal{P}_\alpha, \mathcal{Q}_\alpha : \alpha < \aleph_{\omega+1}\rangle$ be a finite support iteration such that

$$\Vdash_\alpha \mathcal{Q}_\alpha = \begin{cases} \mathbf{C} & \text{if } \alpha < \aleph_\omega, \\ \mathbf{B}^{V_0[\dot{G}\restriction A_\alpha]} & \text{if } \alpha \geq \aleph_\omega. \end{cases}$$

5.15 Lemma. *Suppose that G is $\mathcal{P}_\alpha$-generic over V_0 and $x \in V_0[G] \cap P(\omega)$. Then x can be computed from countably many generic reals. In other words, there exists a countable set $\{\alpha_n : n \in \omega\} \subseteq \alpha$, $\{\alpha_n : n \in \omega\} \in V_0$ and a Borel function $f \in {}^\omega({}^\omega 2) \longrightarrow {}^\omega 2$, $f \in V_0$ such that $x = f(\dot{G}(\alpha_1), \dots, \dot{G}(\alpha_n), \dots)$.*

Proof. Induction on α.

Case 1. $\alpha = \beta + 1$. Let $G \subseteq \mathcal{P}_\alpha$ be a generic filter and let $x \in V_0[G]$. Work in the model $V_0[G\restriction\beta]$. Since $\mathcal{P}_\alpha = \mathcal{P}_\beta \star \mathbf{B}^{V_0[\dot{G}\restriction A_\beta]}$ there exists a Borel function $\tilde{f} \in V_0[G \cap \mathcal{P}_\beta]$ such that

$$V_0[G \cap \mathcal{P}_\alpha] \models \tilde{f}(G(\beta)) = x.$$

Since $\tilde{f}$ is coded by a real, there exists a set $\{\alpha_n : n \in \omega\} \subseteq \beta$ and a function $f \in V_0$ such that

$$\tilde{f} = f(G(\alpha_1), \dots, G(\alpha_n), \dots).$$

The required function is constructed from f and the set $\{\alpha_n : n \in \omega\} \cup \{\beta\}$.

Case 2. $\mathrm{cf}(\alpha) = \aleph_0$. Fix an increasing sequence $\langle \alpha_n : n \in \omega\rangle$ such that $\sup_n \alpha_n = \alpha$ and suppose that x is a $\mathcal{P}_\alpha$-name for a real number (i.e. a set of countably many antichains). Let x_n be a $\mathcal{P}_{\alpha_n}$-name for a real obtained by taking those conditions in these antichains that belong to $\mathcal{P}_{\alpha_n}$. Observe that typically $x_n(i)$ is defined only for finitely many values of i, and that only below various conditions in $\mathcal{P}_{\alpha_n}$. So, formally, we need to extend this definition (arbitrarily) so that every condition in $\mathcal{P}_{\alpha_n}$ forces that x_n is a real. Note that $\Vdash_{\mathcal{P}_\alpha} \lim_n x_n = x$. Apply the induction hypothesis to x_n's to get Borel functions f_n and countable sets A_n. Let $A = \bigcup_n A_n$ and let $f : {}^{\omega\times\omega}({}^\omega 2) \longrightarrow {}^\omega 2$ be defined as

$$f(\dots, x^n_m, \dots) = \lim_n f_n(\dots, x^n_m, \dots).$$

Case 3. $\mathrm{cf}(\alpha) > \aleph_0$. Since no reals are added at the step α there is nothing to prove. ⊣

Furthermore, we will require that

A1. $|A_\alpha| < \aleph_\omega$ for any $\aleph_\omega \leq \alpha < \aleph_{\omega+1}$.

A2. For every set $A \in [\aleph_{\omega+1}]^{<\aleph_\omega} \cap V_0$ there are cofinally many α with $A \subseteq A_\alpha$.

To state the next requirement we will need the following notation: suppose that $A \subseteq \aleph_{\omega+1}$. Let $\mathcal{P}\restriction A = \{p \in \mathcal{P} : \mathsf{dom}(p) \subseteq A\}$. Suppose that $\dot{f} \subseteq {}^\omega 2 \times {}^\omega 2$ is a name for an arbitrary function from ${}^\omega 2$ to ${}^\omega 2$ (not necessarily Borel). Then $\dot{f}\restriction A = \{(\dot{x}, \dot{y}) \in \dot{f} : \dot{x}, \dot{y}$ are $\mathcal{P}\restriction A$-names$\}$.

A3. $\mathsf{dom}(\dot{m}^\xi_\alpha \restriction A_\beta) = P(\omega) \cap V_0[\dot{G}\restriction A_\beta]$ for every $\xi < \aleph_1$ and $\aleph_\omega \leq \beta \leq \alpha < \aleph_{\omega+1}$. In other words, $\dot{m}^\xi_\alpha\restriction A_\beta$ is a name for finitely additive measure on $P(\omega) \cap V_0[\dot{G}\restriction A_\beta]$.

Suppose that the measures $\{\dot{m}^\xi_{\alpha+1} : \xi < \aleph_1\}$ are given, and suppose that in order to meet the requirement A2 we have to cover certain set A of size $\aleph_n$. Define a sequence $\langle A^\gamma_{\alpha+1} : \gamma < \omega_1\rangle$ such that

1. $A^0_{\alpha+1} = A$,
2. $A^\beta_{\alpha+1} \subseteq A^\delta_{\alpha+1}$ for $\beta \leq \delta$,
3. $A^\delta_{\alpha+1} = \bigcup_{\beta<\delta} A^\beta_{\alpha+1}$ for limit δ,
4. for every set $X \in V_0[\dot{G}\restriction A^\beta_{\alpha+1}]$ and $\xi < \aleph_1$, $\dot{m}^\xi_{\alpha+1}(X) \in V_0[\dot{G}\restriction A^{\beta+1}_{\alpha+1}]$,
5. $|A^\gamma_{\alpha+1}| = \aleph_n + \aleph_1$ for all γ.

Note that since $V_0[\dot{G}\restriction A^\beta_{\alpha+1}] \models 2^{\aleph_0} = \aleph_n$, in order to produce $A^{\beta+1}_{\alpha+1}$ we have to add to $A^\beta_{\alpha+1}$ at most $\aleph_n + \aleph_1$ countable sets. Finally let $A_{\alpha+1} = \bigcup_{\gamma<\omega_1} A^\gamma_{\alpha+1}$. It is clear that $A_{\alpha+1}$ is as required.

If δ is limit then we put $A_\delta = \emptyset$. Note that in both cases condition A3 is satisfied by the induction hypothesis and the fact that $\dot{m}^\xi_\delta$ extends $\bigcup_{\alpha<\delta} \dot{m}^\xi_\alpha$.

In order to finish the construction we have to define measures $\{\dot{m}^\xi_\alpha : \aleph_\omega \leq \alpha < \aleph_{\omega+1}\}$.

We start with the definition of a certain dense subset of $\mathcal{P}$ and from now on use only conditions belonging to this subset. Let $D \subseteq \mathcal{P}$ be a subset such that $p \in D$ if

1. $\mathsf{dom}(p) \in [\aleph_{\omega+1}]^{<\omega}$,
2. $p(\alpha) \in {}^{<\omega}\omega \simeq \mathbf{C}$, for $\alpha \in \mathsf{dom}(p) \cap \aleph_\omega$,
3. for each $\alpha \in \mathsf{dom}(p) - \aleph_\omega$,
   (a) $\Vdash_\alpha p(\alpha) \in \mathbf{B}^{V_0[\dot{G}\restriction A_\alpha]}$,
   (b) there is a clopen set $C_\alpha \subseteq {}^\omega 2$ such that
   $$\Vdash_\alpha \frac{\mu(C_\alpha \cap p(\alpha))}{\mu(C_\alpha)} \geq 1 - \frac{1}{2^{n-j+5}},$$
   where $n = |\mathsf{dom}(p) - \aleph_\omega|$ and $j = |\alpha \cap (\mathsf{dom}(p) - \aleph_\omega)|$.

5.16 Lemma. *D is dense in $\mathcal{P}$.*

Proof. Induction on $\max(\mathsf{dom}(p))$. ⊣

Let $\mathbb{C}$ be the collection of clopen subsets of 2^ω. Represent $\mathbf{C}_{\aleph_{\omega+1}}$ as the collection of functions q such that $\mathsf{dom}(q) \in [\aleph_{\omega+1}]^{<\omega}$ and $q(\alpha) \in \mathbf{C}$ for $\alpha < \aleph_\omega$ and $q(\alpha) \in \mathbb{C}$ for $\alpha \geq \aleph_\omega$.

Note that there is a natural projection π from D to $\mathbf{C}_{\aleph_{\omega+1}}$ defined as

$$\pi(p)(\alpha) = \begin{cases} p(\alpha) & \text{if } \alpha < \aleph_\omega, \\ C_\alpha & \text{if } \alpha \geq \aleph_\omega. \end{cases}$$

For a sequence $\bar{p} = \langle p_n : n \in \omega \rangle$ let $\pi(\bar{p}) = \langle \pi(p_n) : n \in \omega \rangle$. Suppose that $\bar{p}$ is such that $\pi(\bar{p}) \in \Delta$, as defined in Definition 5.5. We will define a condition $p_{\bar{p}}$ in the following way; $\mathsf{dom}(p_{\bar{p}}) = \widetilde{\Delta}$, where $\widetilde{\Delta}$ is the root of the Δ-system $\{\mathsf{dom}(p_n) : n \in \omega\}$.

Case 1. $\alpha \in \widetilde{\Delta} \cap \aleph_\omega$. Let $p_{\bar{p}}(\alpha)$ be the common value of $p_n(\alpha)$ for $n \in \omega$.

Case 2. $\alpha \in \widetilde{\Delta} - \aleph_\omega$. Work in the model $V = V_0[\dot{G}\restriction A_\alpha]$ and let $C = \pi(p_n(\alpha))$. Clearly $V \models C \in \mathbf{B}$. It follows that for some $k > 0$ and every $n \in \omega$,

$$V \models \frac{\mu(C \cap p_n(\alpha))}{\mu(C)} \geq 1 - \frac{1}{2^k}.$$

Let $\dot{X}$ be a $\mathbf{B}$-name such that $[\![n \in \dot{X}]\!] = C \cap p_n(\alpha)$. Apply, Theorem 5.13 in V, to find a condition $r \in \mathbf{B}, r \leq C$ such that

$$r \Vdash_{\mathbf{B}} \dot{m}^C_{\mathbf{B}}(\dot{X}_{\bar{p}}) \geq 1 - \frac{1}{2^k}.$$

Let $p_{\bar{p}}(\alpha) = r$.

Now we turn our attention to the sequence $\langle \dot{m}^\xi_\alpha : \aleph_\omega \leq \alpha < \aleph_{\omega+1} \rangle$. By Theorem 5.7, Δ is a union of $\aleph_1$ filter-like sets and each of these sets will yield one of the measures $\dot{m}^\xi$. Specifically, let $\Delta = \bigcup_{\xi<\aleph_1} \Delta_\xi$ be the decomposition into as in Theorem 5.7. For $\xi < \aleph_1$ let

$$\Delta^\xi = \{\bar{p} \in [\mathcal{P}]^\omega : \pi(\bar{p}) \in \Delta_\xi\}.$$

The measure $\dot{m}^\xi_\alpha$ will be first defined on the set

$$\{\dot{X}_{\bar{p}} : \bar{p} \in \Delta^\xi \cap [\mathcal{P}_\alpha]^\omega\}.$$

We will do it in such a way that for $\bar{p} \in \Delta^\xi \cap [\mathcal{P}_\alpha]^\omega$

$$p_{\bar{p}} \Vdash_\alpha \dot{m}^\xi_\alpha(\dot{X}_{\bar{p}}) > 0,$$

where $p_{\bar{p}}$ is the condition defined above. Next $\dot{m}^\xi_\alpha$ will be extended arbitrarily to the set $P(\omega) \cap V_0^{\mathcal{P}_\alpha}$.

Here are the details; fix $\xi < \aleph_1$ and define $\dot{m}^\xi_\alpha$ as follows:

CASE 1. $\alpha = \aleph_\omega$. Consider the family

$$\dot{\mathcal{H}}_\xi = \{\dot{X}_{\bar{p}} : \bar{p} \in \Delta^\xi \cap [\mathcal{P}_{\aleph_\omega}]^\omega,\ p_{\bar{p}} \in \dot{G}_{\mathcal{P}}\}.$$

It is easy to see that $\dot{\mathcal{H}}_\xi$ is a $\mathcal{P}_{\aleph_\omega}$-name for a filter base. Let $\dot{\mathcal{F}}_\xi$ be any $\mathcal{P}$-name for an ultrafilter extending $\dot{\mathcal{H}}_\xi$ and let $\dot{m}^\xi_{\aleph_\omega}$ be the corresponding measure. In other words, for $\dot{X} \in \dot{\mathcal{H}}_\xi$,

$$\Vdash_{\aleph_\omega} \dot{m}^\xi_{\aleph_\omega}(\dot{X}) = 1.$$

CASE 2. $\alpha > \aleph_\omega$ and $\mathrm{cf}(\alpha) = \aleph_0$. Since $\dot{m}^\xi_\alpha$ extends $\bigcup_{\beta<\alpha} \dot{m}^\xi_\beta$, we have to define $\dot{m}^\xi_\alpha$ on the set

$$\left\{\dot{X}_{\bar{p}} : \bar{p} \in \Delta^\xi \cap \left([\mathcal{P}_\alpha]^\omega - \textstyle\bigcup_{\beta<\alpha} [\mathcal{P}_\beta]^\omega\right)\right\}.$$

Put $\mathcal{A} = \Delta^\xi \cap ([\mathcal{P}_\alpha]^\omega - \bigcup_{\beta<\alpha}[\mathcal{P}_\beta]^\omega)$ and for $\bar{p} \in \mathcal{A}$ let $j = j_{\bar{p}} \in \omega$ be such that

$$\beta = \sup_{n\in\omega} \alpha^n_{j-1} < \sup_{n\in\omega} \alpha^n_j = \alpha,$$

where α^n_i is the i'th element of $\mathsf{dom}(p_n)$. Consider sequences $\bar{p}^- = \langle p_n \restriction \alpha^n_j : n \in \omega\rangle$ and $\bar{p}^+ = \langle p_n \restriction [\alpha^n_j, \alpha) : n \in \omega\rangle$. Let $\dot{\mathcal{H}}_\xi$ be a $\mathcal{P}_\alpha$-name for the family $\{\dot{X}_{\bar{p}^+} : \bar{p} \in \mathcal{A}\}$. Note that

1. $\Vdash_\alpha \dot{\mathcal{H}}_\xi$ is a filter base,
2. $\forall \dot{X} \in \dot{\mathcal{H}}_\xi\ \forall \beta < \alpha\ \forall \dot{Y} \in [\omega]^\omega \cap V_0^{\mathcal{P}_\beta}\ \Vdash_\alpha \dot{X} \cap \dot{Y}$ is infinite.

Suppose that $\bar{p} \in \mathcal{A}$ and note that

$$p_{\bar{p}^-} \Vdash_\beta \dot{m}^\xi_\beta(\dot{X}_{\bar{p}^-}) = a > 0.$$

By the remarks made above, we can set $\dot{m}_\alpha(\dot{X}_{\bar{p}^+}) = 1$ and $\dot{m}_\alpha(\dot{X}_{\bar{p}}) = a$. Finally note that the value a is forced by $p_{\bar{p}}$.

CASE 3. α is a limit and $\mathrm{cf}(\alpha) > \aleph_0$. Let $\dot{m}^\xi_\alpha = \bigcup_{\beta<\alpha} \dot{m}^\xi_\beta$. This definition is correct since no subsets of ω are added at the step α.

CASE 4. $\alpha = \delta + 1$. As before we have to define $\dot{m}^\xi_\alpha$ on

$$\{\dot{X}_{\bar{p}} : \bar{p} \in \Delta^\xi \cap ([\mathcal{P}_\alpha]^\omega - [\mathcal{P}_\delta]^\omega)\}.$$

Set $\mathcal{A} = \Delta^\xi \cap ([\mathcal{P}_\alpha]^\omega - [\mathcal{P}_\delta]^\omega)$ and note that if $\bar{p} \in \mathcal{A}$ then $\delta \in \bigcap_{n\in\omega} \mathsf{dom}(p_n)$. Thus, let C be a clopen set such that $\pi(p_n(\delta)) = C$ for $n \in \omega$. Let $V = V_0[\dot{G}\restriction A_\delta]$. Find a forcing notion $\mathcal{R}$ such that $\mathcal{P}_\delta = (\mathcal{P}_\delta \restriction A_\delta) \star \mathcal{R}$. It follows that $V_0^{\mathcal{P}_\alpha} = V_0^{\mathcal{P}_{\delta+1}} = V^{\mathcal{R}\times\mathbf{B}}$. By the induction hypothesis $m = \dot{m}^\xi_\delta \restriction A_\delta$ is a finitely additive measure. In other words $m \in V$ is a finitely additive measure defined on $P(\omega) \cap V$. Clearly $\dot{m}^\xi_\delta$ is an extension of m to $V^{\mathcal{R}} \cap P(\omega)$. On the other hand let $\dot{m}^C_{\mathbf{B}}$ be an extension of m to $V^{\mathbf{B}}$ as given by Theorem 5.13. Let $\dot{m}^\xi_\alpha = \dot{m}^\xi_{\delta+1}$ be the common extension of $\dot{m}^\xi_\delta$ and $\dot{m}^C_{\mathbf{B}}$ guaranteed by Lemma 5.12. It is clear that $\dot{m}^\xi_\alpha$ has the required properties.

Finally let $\dot{m}^\xi = \bigcup_{\aleph_\omega \leq \alpha < \aleph_{\omega+1}} \dot{m}^\xi_\alpha$. Note that each $\dot{m}^\xi$ is a $\mathcal{P}$-name for a finitely additive measure on $P(\omega) \cap V_0^{\mathcal{P}}$.

Proof of Theorem 5.3

We are ready now for the proof of the main theorem. The following lemma gives the lower bound for $\mathbf{cov}(\mathcal{L})$.

5.17 Lemma. *$V_0^{\mathcal{P}} \models \mathbf{cov}(\mathcal{L}) \geq \aleph_\omega$. In particular, $[\mathbb{R}]^{<\aleph_\omega} \subseteq \mathsf{COV}(\mathcal{L})$.*

Proof. Suppose that $\{H_\alpha : \alpha < \kappa < \aleph_\omega\}$ is a family of measure zero sets in $V_0^{\mathcal{P}}$. Let N be a master set for $\mathcal{L}$ defined earlier. Without loss of generality we can assume that for some $f_\alpha \in {}^\omega\omega$, $H_\alpha = (N)_{f_\alpha}$, and let $\dot{f}_\alpha$ be a $\mathcal{P}$-name for f_α. As in Lemma 5.15, let $K_\alpha \in [\aleph_{\omega+1}]^{\aleph_0} \cap V_0$ be a countable set such that $f_\alpha \in V_0[\dot{G}\restriction K_\alpha]$. Find β such that $\bigcup_{\alpha<\kappa} K_\alpha \subseteq A_\beta$. The random real added by $\mathbf{B}^{V_0[\dot{G}\restriction A_\beta]}$ avoids all null sets coded in $V_0[\dot{G}\restriction A_\beta]$, in particular, all H_α's. ⊣

It remains to be checked that $\mathbf{cov}(\mathcal{L}) \leq \aleph_\omega$ in the extension.

Let $X = \{f_\alpha : \alpha < \aleph_\omega\} = \dot{G}\restriction\aleph_\omega$ be the sequence of the first $\aleph_\omega$ Cohen reals added by $\mathcal{P}$. Our intention is to show that $X \notin \mathsf{COV}(\mathcal{L})$. In fact we will show that

$$\bigcup_{\alpha<\aleph_\omega} (N)_{f_\alpha} = {}^\omega 2,$$

where N is the master set defined in the previous section. That will finish the proof since X is a countable union of sets of smaller size (so they are all in $\mathsf{COV}(\mathcal{L})$) and thus X witnesses that $\mathsf{COV}(\mathcal{L})$ is not a σ-ideal and that $\mathbf{cov}(\mathcal{L}) \leq \aleph_\omega$.

Suppose the opposite and let z be such that

$$V_0^{\mathcal{P}} \models z \notin \bigcup_{\alpha<\aleph_\omega} (N)_{f_\alpha}.$$

5.18 Lemma. *There exists a $\mathcal{P}$-name $\dot{Y}$ for a subset of $\aleph_\omega$ and $\bar{n} \in \omega$ such that*

1. *$\Vdash_{\mathcal{P}} \dot{Y} \in [\aleph_\omega]^{\aleph_1}$,*
2. *$\Vdash_{\mathcal{P}} {}^\omega 2 - \bigcup_{\alpha\in\dot{Y}} \bigcup_{n>\bar{n}} C^n_{f_\alpha(n)}$ is uncountable.*

Proof. Denote by $\dot{z}$ a $\mathcal{P}$-name for z and let $\delta < \aleph_{\omega+1}$ be the least ordinal such that $\dot{z}$ is a $\mathcal{P}_\delta$-name. We have the following two cases:

Case 1. $\delta = \lambda + 1$ is a successor ordinal. Suppose first that $\delta > \aleph_\omega$. Work in $V = V_0{}^{\mathcal{P}_\lambda}$ and let $\mathbf{B}_\lambda = \mathbf{B}^{V_0[\dot{G}\restriction A_\lambda]}$. For each $\alpha < \aleph_\omega$ choose $q_\alpha \in \mathbf{B}_\lambda$ and

$n_\alpha \in \omega$ such that $V \models q_\alpha \Vdash_{\mathbf{B}_\lambda} \dot{z} \notin \bigcup_{n>n_\alpha} C^n_{f_\alpha(n)}$. Since $\mathbf{B}_\lambda$ has a dense subset of size $< \aleph_\omega$, we can find $q \in \mathbf{B}_\lambda$ and $\bar{n} \in \omega$ such that the set

$$Y = \{\alpha : q_\alpha = q \;\&\; n_\alpha = \bar{n}\}$$

is uncountable. Consider the set $C = {}^\omega 2 - \bigcup_{\alpha\in Y} \bigcup_{n>\bar{n}} C^n_{f_\alpha(n)}$ in V. Observe that C is a closed set and if it was countable then all its elements would be in V. However, $V^{\mathbf{B}_\lambda} \models z \in C$ and $z \notin V$.

If $\delta < \aleph_\omega$, then the argument is identical except that we use $\mathbf{C}$ instead of $\mathbf{B}_\lambda$. In fact one can show that

$$V_0^{\mathcal{P}} \cap {}^\omega 2 \subseteq \bigcup_{\alpha<\omega_1} (N)_{f_\alpha} \subseteq \bigcup_{\alpha<\aleph_\omega} (N)_{f_\alpha}.$$

Case 2. δ is a limit and $\mathrm{cf}(\delta) = \aleph_0$. In $V_0^{\mathcal{P}_\delta}$ we can find an $\bar{n} \in \omega$ and an uncountable set $Z \subseteq \aleph_\omega$ such that

$$V_0^{\mathcal{P}_\delta} \models z \notin \bigcup_{\alpha\in Z} \bigcup_{n>\bar{n}} C^n_{f_\alpha(n)}.$$

Let $\dot{Z}$ be a $\mathcal{P}_\delta$-name for Z. Suppose that $G \subseteq \mathcal{P}_\delta$ is a generic filter over V_0. For each $\alpha < \omega_1$ choose $p_\alpha \in \mathcal{P}_\delta \cap G$ and η_α such that $p_\alpha \Vdash_{\mathcal{P}_\delta} \dot{Z}(\alpha) = \eta_\alpha$, where $\dot{Z}(\alpha)$ is a $\mathcal{P}$-name for the α-th element of Z.

There is an uncountable set $I \subseteq \omega_1$, and $\lambda < \delta$ such that $p_\alpha \in \mathcal{P}_\lambda \cap G$ for $\alpha \in I$. Let $Y = \{\eta_\alpha : \alpha \in I\}$ and let $\dot{Y}$ be a $\mathcal{P}_\lambda$-name for Y. As in the previous case, consider the set $C = {}^\omega 2 - \bigcup_{\alpha\in Y} \bigcup_{n>\bar{n}} C^n_{f_{\eta_\alpha}(n)}$ in $V_0^{\mathcal{P}_\lambda}$. We see that C is uncountable because it contains an element which does not belong to $V_0^{\mathcal{P}_\lambda}$. $\dashv$

Find different ordinals $\{\eta_\alpha : \alpha < \omega_1\}$ and conditions $\{p_\alpha : \alpha < \omega_1\} \subseteq \mathcal{P}$ such that $p_\alpha \Vdash_{\mathcal{P}} \eta_\alpha \in \dot{Y}$. Using the Δ-lemma we can assume that there are $\widetilde{k}, \widetilde{l} \in \omega$, $s \in {}^{\widetilde{k}}\omega$ and clopen sets $\{C_j : j \le \widetilde{l}\}$ such that

1. $\mathsf{dom}(p_\alpha)$ form a Δ-system,
2. $\mathsf{dom}(p_\alpha) = \{\gamma_1^\alpha < \cdots < \gamma_{\widetilde{k}}^\alpha < \aleph_\omega \le \delta_1^\alpha < \cdots < \delta_{\widetilde{l}}^\alpha\}$,
3. $\forall\alpha\, \forall j \le \widetilde{k}\, (p_\alpha(\gamma_j^\alpha) = s(j))$,
4. for all $j \le \widetilde{l}$
$$\Vdash_{\alpha_j} \frac{\mu(C_j \cap p_\alpha(\delta_j^\alpha))}{\mu(C_j)} \ge 1 - \frac{1}{2^{\tilde{l}-j+5}}.$$

Without loss of generality we can assume that $\eta_\alpha \in \mathsf{dom}(p_\alpha)$. Furthermore we can assume that for some $j_0 \le \widetilde{k}$, $\eta_\alpha = \gamma_{j_0}^\alpha$ and that $s(j_0) = s^\star$ with $|s^\star| = n^\star$.

Consider the first ω conditions $\bar{p} = \{p_n : n \in \omega\}$. Our next step is to extend the p_n's slightly to get a new sequence $\bar{p}^\star$. We will need the following definition.

5.19 Definition. For a clopen set $C \subseteq {}^\omega 2$ define $\mathsf{supp}(C)$ to be the smallest set $F \subseteq \omega$ such that $C = (C \cap {}^F 2) \times {}^{\omega - F} 2$. Thus, the support of C is the set of coordinates that carry information about C.

Let $K_n = \{m : \mathsf{supp}(C^{n^\star}_m) \subseteq n\}$ and let $\{J_n : n \in \omega\}$ be a partition of ω such that $|J_n| = |K_n|$ for each n. Fix a function $o \in {}^\omega\omega$ such that $o``J_n = K_n$ for every n. Define

$$p^\star_n = \begin{cases} p_n(\alpha) & \text{if } \alpha \neq \eta_n, \\ s^\star {}^\frown (n^\star, o(n)) & \text{if } \alpha = \eta_n. \end{cases}$$

Observe that there is $\xi < \aleph_1$ such that $\bar{p}^\star = \{p^\star_n : n \in \omega\} \in \Delta^\xi$. This is being witnessed by the $\widetilde{k}, \widetilde{l}$, $s \in {}^{\widetilde{k}}\omega$, clopen sets $\{C_j : j \leq \widetilde{l}\}$ and function g defined as

$$g(i, n) = \begin{cases} s(i) & \text{if } i \leq \widetilde{k},\ i \neq j_0, \\ s^\star {}^\frown (n^\star, o(n)) & \text{if } i = j_0. \end{cases}$$

Our goal is to show:

5.20 Theorem. *There exists a condition $p^{\star\star}$ and $\varepsilon > 0$ such that*

$$p^{\star\star} \Vdash_{\mathcal{P}} \exists^\infty n \ \frac{|\{m \in J_n : p^\star_m \in \dot{G}_{\mathcal{P}}\}|}{|J_n|} \geq \varepsilon.$$

Before we prove this theorem let us see that Theorem 5.3 follows readily from it. Recall that in Lemma 5.18 we showed that $\Vdash_{\mathcal{P}} {}^\omega 2 - \bigcup_{\alpha \in \dot{Y}} \bigcup_{n > \bar{n}} C^n_{f_\alpha(n)}$ is uncountable. Since this set is closed, there is a $\mathcal{P}$-name for a perfect tree $\dot{T}$ such that $\Vdash_{\mathcal{P}} \bigcup_{\alpha \in \dot{Y}} \bigcup_{n > \bar{n}} C^n_{f_\alpha(n)} \cap [\dot{T}] = \emptyset$. Let $\dot{Z}_n = \{m \in J_n : p^\star_m \in \dot{G}_{\mathcal{P}}\}$ for $n \in \omega$. It follows that for every n,

$$p^{\star\star} \Vdash_{\mathcal{P}} \left(\bigcup_{k \in \dot{Z}_n} C^{n^\star}_k\right) {\restriction} n \cap \dot{T} {\restriction} n = \emptyset.$$

This is because for a clopen set C and a tree T, if $C \cap [T] = \emptyset$ then $(C {\restriction} \mathsf{supp}(C)) \cap (T {\restriction} \mathsf{supp}(C)) = \emptyset$. Fix $n \in \omega$ and suppose that $|\dot{T} {\restriction} n| = m$. The size of the set J_n is equal to $\binom{2^n}{2^{n-n^\star}}$. On the other hand the number of sets $C^{n^\star}_k$ which are disjoint with $\dot{T} {\restriction} n$ is at most $\binom{2^n - m}{2^{n-n^\star}}$. Put $2^{-n^\star} = \epsilon$. It follows, after some elementary calculations, that for some constant $a \geq 1$:

$$\frac{|\dot{Z}_n|}{|J_n|} \leq \frac{\binom{2^n - m}{2^{n-n^\star}}}{\binom{2^n}{2^{n-n^\star}}} = \prod_{j=1}^{m} \left(1 - \frac{2^{n-n^\star}}{2^n - m + j}\right) \leq a \cdot e^{-\epsilon \cdot m}.$$

Thus

$$\frac{|\dot{Z}_n|}{|J_n|} \leq a \cdot e^{-\epsilon \cdot |\dot{T} {\restriction} n|}.$$

Since $p^{\star\star} \Vdash_{\mathcal{P}} \limsup_n \frac{|\dot{Z}_n|}{|J_n|} \geq \varepsilon$ we get that $p^{\star\star} \Vdash_{\mathcal{P}} \lim_n |\dot{T} {\restriction} n| < \infty$ (the size of $T {\restriction} n$ increases with n). In particular,

$$p^{\star\star} \Vdash_{\mathcal{P}} \dot{T} \text{ is not perfect,}$$

which gives a contradiction.

Proof of Theorem 5.3: Conclusion

In order to complete the proof of Theorem 5.3 we have to prove Theorem 5.20. We will need one more modification of the sequence $\bar{p}^\star$ and we will require the construction described below.

5.21 Lemma. *Let $\widetilde{\Delta}$ be a finite subset of $\aleph_{\omega+1} - \aleph_\omega$. Suppose that $\{q_i : i \leq N\}$ is a sequence of conditions in $\mathcal{P}$ such that*

(1) $\mathsf{dom}(q_i) = \widetilde{\Delta}$,

(2) $\forall \alpha \in \widetilde{\Delta}\ \exists a_\alpha\ \forall i \leq N\ \Vdash_\alpha \mu(q_i(\alpha)) = a_\alpha > 3/4$.

Then there exists a condition $q^\star$ such that

(a) $\mathsf{dom}(q^\star) = \widetilde{\Delta}$,

(b) $q^\star \in \mathcal{P}$,

(c) $\forall \alpha \in \widetilde{\Delta}\ \Vdash_\alpha \mu(q^\star(\alpha)) \geq 2a_\alpha - 1$,

(d) $q^\star \Vdash_{\mathcal{P}} \{k \leq N : \forall \alpha \in \widetilde{\Delta}\ q^\star{\restriction}\alpha \Vdash_\alpha \dot{x}_\alpha \in q_k(\alpha)\}$ *has at least* $2^{-|\widetilde{\Delta}|} \cdot N \cdot \prod_{\alpha \in \widetilde{\Delta}} a_\alpha$ *elements, where $\dot{x}_\alpha$ is the generic real added by $\dot{G}(\alpha)$.*

Proof. If $\widetilde{\Delta} = \emptyset$, then there is nothing to prove.

We proceed by induction on $\max(\widetilde{\Delta})$ which we denote by β. Let $q'_k = q_k{\restriction}\beta$ for $k \leq N$. Apply the induction hypothesis to get a condition q' such that

1. $\mathsf{dom}(q') = \widetilde{\Delta} - \{\beta\}$,
2. $q' \in \mathcal{P}$,
3. $\forall \alpha \in \widetilde{\Delta} - \{\beta\}\ \Vdash_\alpha \mu(q'(\alpha)) \geq 2a_\alpha - 1$,
4. $q' \Vdash_{\mathcal{P}} \{k \leq N : \forall \alpha \in \widetilde{\Delta} - \{\beta\}\ q'{\restriction}\alpha \Vdash_\alpha \dot{x}_\alpha \in q_k(\alpha)\}$ has at least $2^{-|\widetilde{\Delta}|+1} \cdot N \cdot \prod_{\alpha \in \widetilde{\Delta} - \{\beta\}} a_\alpha$ elements.

Let $\dot{W}$ be a $\mathcal{P}$-name for the set

$$\{k \leq N : \forall \alpha \in \widetilde{\Delta} - \{\beta\}\ q'{\restriction}\alpha \Vdash_\alpha \dot{x}_\alpha \in q_k(\alpha)\}.$$

Let $\{W^i : i \leq \ell\}$ be a list of subsets of N of size at least $2^{-|\widetilde{\Delta}|} \cdot N \cdot \prod_{\alpha \in \widetilde{\Delta} - \{\beta\}} a_\alpha$ and $\{q^i : i \leq \ell\}$ a maximal antichain below q' such that $q^i \Vdash_{\mathcal{P}} \dot{W} = W^i$ for $i \leq \ell$.

We will need the following easy observation.

5.22 Lemma. *Suppose that $\{A_n : n < N\}$ is a family of subsets of ${}^\omega 2$ of measure $a > 0$. Let*

$$B = \left\{x \in {}^\omega 2 : x \textit{ belongs to at least } \frac{N \cdot a}{2} \textit{ sets } A_i\right\}.$$

Then $\mu(B) \geq \max\{a/2, 2a - 1\}$.

Proof. Let χ_{A_i} be the characteristic function of the set A_i for $i \leq N$. It follows that $\int \sum_{i \leq N} \chi_{A_i} = N \cdot a$. On the other hand, estimation of this integral yields,

$$N \cdot \mu(B) + \frac{N \cdot a}{2}(1 - \mu(B)) \geq N \cdot a$$

and after simple computations we get $\mu(B) \geq \frac{a/2}{1-a/2}$. It follows that we get the following estimates:

$$\mu(B) \geq \frac{a/2}{1 - a/2} \geq \max\{a/2, 2a - 1\} = \begin{cases} a/2 & \text{if } a < \frac{2}{3}, \\ 2a - 1 & \text{if } a \geq \frac{2}{3}. \end{cases}$$

$\dashv$

Work in $V^{\mathcal{P}_\beta}$ and for each $i \leq \ell$ apply Lemma 5.22 to the family $\{q_k(\beta) : k \in W^i\}$ and obtain a condition $r^i \in \mathbf{B}^{V_0[\dot{G} \restriction A_\beta]}$ such that

$$r^i \Vdash \{k \in W^i : \dot{x}_\beta \in q_k(\beta)\} \text{ has at least } \frac{|W^i|}{2} \cdot a_\beta \text{ elements,}$$

and $\Vdash_\beta \mu(r^i) \geq 2a_\beta - 1$.

Finally, define $q^\star$ to be a $\mathcal{P}$-name such that for $i \leq \ell$, $q^i \Vdash q^\star(\beta) = r^i$. It is easy to see that $q^\star$ is as required. $\dashv$

Let $q_k = p_k^\star \restriction \widetilde{\Delta}$, where $\widetilde{\Delta} = \{\alpha_1 < \cdots < \alpha_\ell\}$ is the root of the Δ-system $\{\mathsf{dom}(p_k^\star \restriction [\aleph_\omega, \aleph_{\omega+1}) : k \in \omega\}$.

For each n apply Lemma 5.21 to the family $\{q_k : k \in J_n\}$ to get a condition $q_n^\star$ such that

1. $\mathsf{dom}(q_n^\star) = \widetilde{\Delta}$,
2. $\forall i \leq \ell \ \Vdash_{\alpha_i} \frac{\mu(q^\star(\alpha_i) \cap C_{\alpha_i})}{\mu(C_{\alpha_i})} \geq 2(1 - \frac{1}{2^{\ell-i+5}}) - 1 = \frac{1}{2^{\ell-i+4}}$,
3. $q_n^\star \Vdash_{\mathcal{P}} |\{k \leq N : \forall \alpha \in \widetilde{\Delta}\ (q_n^\star \restriction \alpha \Vdash_\alpha \dot{x}_\alpha \in q_k(\alpha))\}| \geq \frac{|J_n|}{2^{\ell+1}}$.

Define for $k \in \omega$,

$$p_k^{\star\star}(\alpha) = \begin{cases} p_k^\star(\alpha) \cap q_n^\star & \text{if } \alpha \in \widetilde{\Delta},\ k \in J_n, \\ p_k^\star(\alpha) & \text{otherwise.} \end{cases}$$

Let $\bar{p}^{\star\star} = \{p^{\star\star}_n : n \in \omega\}$. Find $\xi < \aleph_1$ such that $\bar{p}^{\star\star} \in \Delta^\xi$. According to our definitions,

$$p^{\star\star} = p_{\bar{p}^{\star\star}} \Vdash_{\mathcal{P}} \dot{m}^\xi(\dot{X}_{\bar{p}^{\star\star}}) > 0.$$

In particular,

$$p^{\star\star} \Vdash_{\mathcal{P}} \dot{X}_{\bar{p}^{\star\star}} = \{n : p^{\star\star}_n \in \dot{G}_{\mathcal{P}}\} \text{ is infinite.}$$

Let $\varepsilon = 2^{-\ell-1}$ and note that

$$p^{\star\star}_n \Vdash_{\mathcal{P}} \frac{|\{k \in J_n : p^\star_k \in \dot{G}_{\mathcal{P}}\}|}{|J_n|} \geq \varepsilon.$$

It follows that $p^{\star\star}$ is the condition required in Theorem 5.20.

Historical Remarks. Theorem 5.1 was proved by Miller [34]. Better estimates are true (see [7] and [6] or [8]). Theorem 5.2 was proved in [5] (see [8]). Theorem 5.3 is due to Shelah. His [49] contains a more a general construction, where in addition $\mathbf{MA}_{\aleph_1}$ holds.

6. Consistency Results and Counterexamples

This section is devoted to the consistency results involving cardinal invariants of the Cichoń diagram and non-inclusion between the corresponding classes of small sets. We will describe several such constructions in detail.

Suppose that $\mathcal{P}$ is a forcing notion. Let $\mathcal{D}(\mathcal{P})$ denote the family of all dense subsets of $\mathcal{P}$ and $\mathcal{G}(\mathcal{P})$ the family of all filters on $\mathcal{P}$. With $\mathcal{P}$ we can associate the following cardinal invariants:

1. $\mathfrak{ma}(\mathcal{P}) = \min\{|\mathcal{A}| : \mathcal{A} \subseteq \mathcal{D}(\mathcal{P})\ \&\ \neg\exists G \in \mathcal{G}(\mathcal{P})\ \forall D \in \mathcal{A}\ (G \cap D \neq \emptyset)\}$,
2. $\mathfrak{am}(\mathcal{P}) = \min\{|\mathcal{G}| : \mathcal{G} \subseteq \mathcal{G}(\mathcal{P})$ & for every countable sequence $\{D_n : n \in \omega\} \subseteq \mathcal{D}(\mathcal{P})\ \exists G \in \mathcal{G}(\mathcal{P})\ \forall n\ (G \cap D_n \neq \emptyset)\}$.

In other words, $\mathfrak{ma}(\mathcal{P})$ is the size of the smallest family of dense subsets of $\mathcal{P}$ for which there is no filter intersecting all of them and $\mathfrak{am}(\mathcal{P})$ is the size of the smallest family of filters such that for every countable family of dense subsets of $\mathcal{P}$ there is a filter in the family that intersects all of them.

Consider the forcing notions:

- Amoeba forcing $\mathbf{A} = \{U \subseteq {}^\omega 2 : U \text{ is open and } \mu(U) < 1/2\}$. For $U, V \in \mathbf{A}$, $U \leq V$ if $U \supseteq V$.
- Random real forcing $\mathbf{B} = \{P \subseteq {}^\omega 2 : P$ is a closed set of positive measure$\}$.
- Cohen forcing $\mathbf{C}$.
- Dominating real forcing $\mathbf{D} = \{\langle n, f\rangle : n \in \omega\ \&\ f \in {}^\omega\omega\}$. For $\langle n, f\rangle$, $\langle m, g\rangle \in \mathbf{D}$, $\langle n, f\rangle \leq \langle m, g\rangle$ if $n \geq m\ \&\ f{\restriction}m = g{\restriction}m\ \&\ \forall k\ f(k) \geq g(k)$.

We have the following result (see [8] for the proof):

6.1 Theorem.

1. $\mathbf{add}(\mathcal{L}) = \mathfrak{ma}(\mathbf{A})$ *and* $\mathbf{cof}(\mathcal{L}) = \mathfrak{am}(\mathbf{A})$.
2. $\mathbf{cov}(\mathcal{L}) = \mathfrak{ma}(\mathbf{B})$ *and* $\mathbf{non}(\mathcal{L}) = \mathfrak{am}(\mathbf{B})$.
3. $\mathbf{cov}(\mathcal{B}) = \mathfrak{ma}(\mathbf{C})$ *and* $\mathbf{non}(\mathcal{B}) = \mathfrak{am}(\mathbf{C})$.
4. $\mathbf{add}(\mathcal{B}) = \mathfrak{ma}(\mathbf{D})$ *and* $\mathbf{cof}(\mathcal{B}) = \mathfrak{am}(\mathbf{D})$.

This description is particularly well suited to use with the finite support iteration. If $\mathcal{P}$ is a c.c.c. forcing notion having "nice" definition and $\mathcal{P}_\kappa$ is a finite support iteration of $\mathcal{P}$ of length κ then

1. If $V \models 2^{\aleph_0} = \aleph_1$ then $V^{\mathcal{P}_{\omega_2}} \models \mathfrak{ma}(\mathcal{P}) = \aleph_2$.
2. If $V \models 2^{\aleph_0} = \aleph_2$ then $V^{\mathcal{P}_{\omega_1}} \models \mathfrak{am}(\mathcal{P}) = \aleph_1$.

This example motivates the following definition: a pair of models V and V' is dual if

$$V \models \mathfrak{ma}(\mathcal{P}) = 2^{\aleph_0} \quad \iff \quad V' \models \mathfrak{am}(\mathcal{P}) < 2^{\aleph_0}.$$

For our purpose we restrict our attention to the coefficients of the Cichoń diagram and define that V is dual to V' if all of the following hold for $\mathcal{J} = \mathcal{B}$ and for $\mathcal{J} = \mathcal{L}$:

1. $V \models \mathbf{cov}(\mathcal{J}) = 2^{\aleph_0} \iff V' \models \mathbf{non}(\mathcal{J}) < 2^{\aleph_0}$,
2. $V \models \mathbf{add}(\mathcal{J}) = 2^{\aleph_0} \iff V' \models \mathbf{cof}(\mathcal{J}) < 2^{\aleph_0}$,
3. $V \models \mathbf{non}(\mathcal{J}) = 2^{\aleph_0} \iff V' \models \mathbf{cov}(\mathcal{J}) < 2^{\aleph_0}$,
4. $V \models \mathbf{cof}(\mathcal{J}) = 2^{\aleph_0} \iff V' \models \mathbf{add}(\mathcal{J}) < 2^{\aleph_0}$,
5. $V \models \mathfrak{b} = 2^{\aleph_0} \iff V' \models \mathfrak{d} < 2^{\aleph_0}$,
6. $V \models \mathfrak{d} = 2^{\aleph_0} \iff V' \models \mathfrak{b} < 2^{\aleph_0}$.

To illustrate this consider the following theories:

$$\mathsf{ZFC} + \mathbf{add}(\mathcal{B}) = \mathbf{cov}(\mathcal{L}) = \aleph_2 + \mathbf{add}(\mathcal{L}) = \aleph_1$$

and

$$\mathsf{ZFC} + \mathbf{cof}(\mathcal{L}) = \aleph_2 + \mathbf{cof}(\mathcal{B}) = \mathbf{non}(\mathcal{L}) = \aleph_1.$$

A model for the first of these theories can be obtained by a finite support iteration of $\mathbf{B} \star \mathbf{D}$ of length $\aleph_2$ over a model for CH and the second by iteration of $\mathbf{B} \star \mathbf{D}$ of length $\aleph_1$ over a model for $2^{\aleph_0} = \aleph_2$. It is clear that $\mathbf{add}(\mathcal{B})$, $\mathbf{cov}(\mathcal{L})$ and $\mathbf{cof}(\mathcal{B})$ and $\mathbf{non}(\mathcal{L})$ have the required values. What is less obvious is that $\mathbf{add}(\mathcal{L}) = \aleph_1$ in the first and $\mathbf{cof}(\mathcal{L}) = \aleph_2$ in the second case. To check that we need a preservation result which ensures that the iteration which we use does not change the value of these invariants. Such theorems were proved in [27, 43, 8].

We will not study these examples any further because this method has one fundamental weakness: it can give us only some of the models we need. This is because the finite support iteration adds Cohen reals. We will use however the notion of duality outlined above. From now on we will focus on obtaining the models using countable support iteration. To this end we will associate with every cardinal invariant of the Cichoń diagram a proper forcing notion and a "preservation theorem" as follows:

- $\mathbf{add}(\mathcal{L}) \leftrightsquigarrow$ Amoeba forcing $\mathbf{A}$, preservation of "not adding amoeba reals".
- $\mathbf{cov}(\mathcal{L}) \leftrightsquigarrow$ random real forcing $\mathbf{B}$, preservation of "not adding random reals".
- $\mathbf{cov}(\mathcal{B}) \leftrightsquigarrow$ Cohen forcing $\mathbf{C}$, preservation of "not adding Cohen reals".
- $\mathbf{non}(\mathcal{B}) \leftrightsquigarrow$ forcing $\mathbf{PT}_{f,g}$, preservation of non-meager sets.
- $\mathfrak{b} \leftrightsquigarrow$ Laver forcing $\mathbf{LT}$, preservation of "not adding unbounded reals".
- $\mathfrak{d} \leftrightsquigarrow$ rational perfect set forcing $\mathbf{PT}$, preservation of "not adding dominating reals".
- $2^{\aleph_0} \leftrightsquigarrow$ Sacks forcing $\mathbf{S}$, preservation of Sacks property.
- $\mathbf{cof}(\mathcal{L}) \leftrightsquigarrow$ forcing $\mathbf{S}_2$, preservation of non-meager sets, and preservation of "not adding unbounded reals".
- $\mathbf{non}(\mathcal{L}) \leftrightsquigarrow$ forcing $\mathbf{S}_{g,g^\star}$, preservation of positive outer measure.

We do not assign anything to $\mathbf{add}(\mathcal{B})$ and $\mathbf{cof}(\mathcal{B})$ because they are expressible using the remaining invariants. We refer the reader to [8] for the definitions of all these forcing notions and the formulation of the preservation theorems. We will illustrate the problems with the following examples.

6.2 Example. Dominating number $\mathfrak{d}$. Rational perfect set forcing $\mathbf{PT}$ associated with $\mathfrak{d}$ is one of the forcing notions that increase $\mathfrak{d}$ without affecting other characteristics in the Cichoń diagram (except those bigger than $\mathfrak{d}$).

The preservation theorem can be stated as follows. We say that a proper forcing notion $\mathcal{P}$ is *${}^\omega\omega$-bounding* if

$$\forall f \in V^{\mathcal{P}} \cap {}^\omega\omega \ \exists g \in V \cap {}^\omega\omega \ \forall n \ (f(n) \leq g(n)).$$

It is clear that $\mathcal{P}$ is ${}^\omega\omega$-bounding if and only if $\mathcal{P}$ preserves dominating families. See Abraham's chapter [1] for the proof of the following theorem.

6.3 Theorem. *The countable support iteration of proper ${}^\omega\omega$-bounding forcing notions is ${}^\omega\omega$-bounding.*

This is the ideal situation—no matter what forcing notion we assign to $\mathbf{cov}(\mathcal{L})$, $\mathbf{non}(\mathcal{B})$, $\mathbf{cof}(\mathcal{L})$ and $\mathbf{non}(\mathcal{L})$ it has to be ${}^\omega\omega$-bounding and this property is preserved under countable support iteration.

6.4 Example. Covering numbers $\mathbf{cov}(\mathcal{B})$ and $\mathbf{cov}(\mathcal{L})$. The choice of forcing notions that we assign to these invariants is determined by Theorem 6.1; it has to be equivalent to Cohen and random real forcing respectively.

The preservation theorem could be stated as follows (see [26] or [8]).

6.5 Theorem. *Suppose that $\mathcal{P}_\delta = \lim_{\alpha<\delta} \mathcal{P}_\alpha$ (δ a limit) is a countable support iteration of proper forcing notions such that for every $\alpha < \delta$, $\mathcal{P}_\alpha$ does not add random reals. Then $\mathcal{P}_\delta$ does not add random reals.*

The question whether this theorem remains true if we replace words "random" by "Cohen" is open. However, even if the preservation theorem for not adding Cohen reals is true, both results cover only limit stages of the iteration. For the successor steps we do not have an analog of Theorem 6.3, and indeed we can find two c.c.c. forcing notions $\mathcal{P}$ and $\mathcal{Q}$ such that $\mathcal{P}$ does not add random reals, and $\Vdash_{\mathcal{P}}$ "$\mathcal{Q}$ does not add random reals" but $\mathcal{P} \star \mathcal{Q}$ adds random reals. Similarly for Cohen reals.

These facts impose the following requirements:

- any iteration of finite length of forcing notions assigned to $\mathfrak{b}$, $\mathbf{non}(\mathcal{B})$, $\mathfrak{d}$, $\mathbf{cov}(\mathcal{B})$, $\mathbf{non}(\mathcal{L})$ and $\mathbf{cof}(\mathcal{L})$ does not add random reals,
- iteration of any length of forcing notions assigned to $\mathfrak{b}$, $\mathbf{cov}(\mathcal{L})$, $\mathbf{non}(\mathcal{B})$, $\mathbf{non}(\mathcal{L})$ and $\mathbf{cof}(\mathcal{L})$ does not add Cohen reals.

It is easy to verify that each of the forcing notions chosen for these invariants have the required properties. However, the reasons why they, for example, do not add Cohen reals are different in each case. Thus, the preservation theorems are often difficult, technical and at the same time not very general.

The full proof that the construction outlined above is possible can be found in [8]. A preservation theorem for not adding Cohen reals that covers the cases we are interested in can be found in [44].

We will take all these constructions for granted and present some applications.

Let us consider the following examples:

6.6 Theorem. *It is consistent with* ZFC *that*

$$\mathfrak{b} = \aleph_2 + \mathbf{cov}(\mathcal{L}) = \mathbf{non}(\mathcal{L}) = \aleph_1.$$

Proof. Recall that for any tree T, $\mathsf{stem}(T)$ is the longest node of T such that for all $t \in T$, $t \subseteq \mathsf{stem}(T)$ or $\mathsf{stem}(T) \subseteq t$ and for $s \in T$, $\mathsf{succ}_T(s) = \{t : s \subseteq t \ \& \ |t| = |s| + 1\}$.

Laver forcing **LT** is the following forcing notion:

$$T \in \mathbf{LT} \iff \begin{array}{l} T \subseteq {}^{<\omega}\omega \text{ is a tree } \& \\ \forall s \in T\ (|s| \geq \mathsf{stem}(T) \rightarrow |\mathsf{succ}_T(s)| = \aleph_0). \end{array}$$

For $T, T' \in \mathbf{LT}$, $T \leq T'$ if $T \subseteq T'$.

6.7 Lemma.

(1) $V^{\mathbf{LT}} \models V \cap {}^\omega\omega$ *is bounded in* ${}^\omega\omega$.

(2) $V^{\mathbf{LT}} \models V \cap {}^\omega 2 \notin \mathcal{L}$.

(3) **LT** *does not add random reals.*

Moreover (2) *and* (3) *hold for the countable support iteration of Laver forcing as well.*

Proof. See [8]. ⊣

Let $\mathcal{P}_{\omega_2}$ be a countable support iteration of length $\aleph_2$ of Laver forcing. It follows from Lemma 6.7 that $\mathfrak{b} = \aleph_2$ in $V^{\mathcal{P}_{\omega_2}}$, while both $\mathbf{cov}(\mathcal{L})$ and $\mathbf{non}(\mathcal{L})$ are equal to $\aleph_1$. ⊣

6.8 Theorem. *It is consistent with* ZFC *that*

$$\mathfrak{d} = \aleph_1 + \mathbf{cov}(\mathcal{L}) = \mathbf{non}(\mathcal{L}) = \aleph_2.$$

Proof. We will use forcing notion **EE** defined below rather than $\mathbf{S}_{g,g^\star}$; it has a much simpler definition and has the required properties (but difficulties appear when unbounded reals are added).

The infinitely equal forcing notion **EE** is defined as follows: $p \in \mathbf{EE}$ if the following conditions are satisfied:

1. $\mathsf{dom}(p) \subseteq \omega,\ |\omega - \mathsf{dom}(p)| = \aleph_0$.
2. $p : \mathsf{dom}(p) \longrightarrow {}^{<\omega}2$.
3. $p(n) \in {}^n2$ for all $n \in \mathsf{dom}(p)$, and

for $p, q \in \mathbf{EE}$ we define $p \leq q$ if $p \supseteq q$.

6.9 Lemma. *Forcing* **EE** *has the following properties:*

1. $V^{\mathcal{P}} \models V \cap {}^\omega 2 \in \mathcal{L}$. *In fact,*

$$\forall x \in V \cap {}^\omega 2\ \exists^\infty n\ (x{\restriction}n = f_G(n)),$$

where f_G *is a generic real.*

2. $\mathcal{P}$ *does not add random reals.*
3. $\mathcal{P}$ *is* ${}^\omega\omega$*-bounding.*

Proof. See [8]. ⊣

Let $\{\mathcal{P}_\alpha, \dot{\mathcal{Q}}_\alpha : \alpha < \omega_2\}$ be a countable support iteration such that for every $\alpha < \omega_2$,

1. $\Vdash_\alpha \dot{\mathcal{Q}}_\alpha \simeq \mathbf{EE}$ if α is even, and

2. $\Vdash_\alpha \dot{\mathcal{Q}}_\alpha \simeq \mathbf{B}$ if α is odd.

Let G be a $\mathcal{P}_{\omega_2}$-generic filter over $V \models \mathsf{CH}$.

It is clear that $V[G] \models \mathbf{non}(\mathcal{L}) = \mathbf{cov}(\mathcal{L}) = \aleph_2$. To see that $\mathfrak{d} = \aleph_1$ in the extension note that both forcing notions $\mathbf{B}$ and $\mathbf{EE}$ are ${}^\omega\omega$-bounding and use Theorem 6.3. ⊣

Now consider the corresponding problem concerning the families of small sets. The question is whether the models constructed for the Cichoń diagram yield the sets witnessing the strict inclusion between the corresponding classes of sets. For example, $\mathbf{add}(\mathcal{L}) < \mathbf{cov}(\mathcal{L})$ is consistent. Is this construction of any help if we want to construct a set $X \in \mathsf{COV}(\mathcal{L}) - \mathsf{ADD}(\mathcal{L})$? It is clear that we cannot show that in ZFC alone. For example, it is consistent that $\mathsf{ADD}(\mathcal{L}) = \mathsf{COV}(\mathcal{L}) = [\mathbb{R}]^{\leq\aleph_0}$ (a model for Dual Borel Conjecture, see [8]).

However, the theory $\mathsf{ZFC}+\mathsf{CH}$ provides a sufficiently rich universe in which such constructions can be carried out. Moreover $<$-results about invariants **add**, **cov**, etc. in a natural way yield $\subsetneq$ results about ADD, COV, etc.

We will describe here several such constructions in detail. First consider those that involve only forcing notions satisfying c.c.c.

6.10 Theorem ($\mathsf{ZFC} + \mathsf{CH}$). *There is a set $X \subseteq \mathbb{R}$ such that $X \in \mathsf{D}$ and $X \notin \mathsf{NON}(\mathcal{L}) \cup \mathsf{NON}(\mathcal{B})$.*

Proof. The construction is canonical. Set the cardinal invariants corresponding to the families that X belongs to $\aleph_2$ and the other ones to $\aleph_1$. In our case $\mathfrak{d} = \aleph_2$ and $\mathbf{non}(\mathcal{L}) = \mathbf{non}(\mathcal{B}) = \aleph_1$. Now consider the forcing notion that produces the model for the dual setup, i.e. $\mathfrak{b} = \aleph_1$ and $\mathbf{cov}(\mathcal{L}) = \mathbf{cov}(\mathcal{B}) = \aleph_2$. According to our table it is the iteration of Cohen and random forcings, $\mathbf{C} \star \mathbf{B}$. Let $\langle M_\alpha : \alpha < \aleph_1\rangle$ be an increasing sequence of countable submodels of $H(\lambda)$ (here and elsewhere in this chapter $H(\lambda)$ denotes the collection of sets whose transitive closure has size $< \lambda$)) such that

1. ${}^\omega 2 \subseteq \bigcup_{\alpha<\omega_1} M_\alpha$,

2. for every $\alpha < \omega_1$, $M_{\alpha+1} \models M_\alpha$ is countable,

3. $\langle M_\beta : \beta \leq \alpha\rangle \in M_{\alpha+1}$.

For each α choose a pair $(c_\alpha, r_\alpha) \in M_{\alpha+1}$ such that (c_α, r_α) is $\mathbf{C}\star\mathbf{B}$-generic over M_α. Note that such a pair will also be generic over M_β for $\beta < \alpha$. Let z_α encode (c_α, r_α) as

$$z_\alpha(n) = \begin{cases} c_\alpha(k) & \text{if } n = 2k, \\ r_\alpha(k) & \text{if } n = 2k+1. \end{cases}$$

Let $X = \{z_\alpha : \alpha < \omega_1\}$. We will show that X has the required properties.

To show that $X \in \mathsf{D}$ fix a Borel function $F : \mathbb{R} \longrightarrow {}^\omega\omega$ and find α_0 such that F is coded in M_{α_0}. Let f be any function which dominates $M_{\alpha_0} \cap {}^\omega\omega$. For any $\alpha < \omega_1$, $F(z_\alpha) \in M_{\alpha_0}^{\mathbf{C}\star\mathbf{B}}$. Since $\mathbf{C} \star \mathbf{B}$ does not add dominating reals it follows that for every α there is a function $g \in M_{\alpha_0} \cap {}^\omega\omega$ such that $g \not\leq^\star F(z_\alpha)$. Since g is dominated by f we conclude that $f \not\leq^\star F(z_\alpha)$ for every $\alpha < \omega_1$.

To see that $X \notin \mathsf{NON}(\mathcal{B}) \cup \mathsf{NON}(\mathcal{L})$ let $Y = \{c_\alpha : \alpha < \omega_1\}$. Observe that Y is a continuous image of X. Moreover, if $F \in M_{\alpha_0}$ is a meager set then $c_\alpha \notin F$ for $\alpha > \alpha_0$ since c_α is a Cohen real over M_{α_0}. The argument that $X \notin \mathsf{NON}(\mathcal{L})$ is analogous. $\dashv$

Observe that the crucial point of the above construction is that the real z_α defined at the step α is generic not only over model M_α but also over models M_β for $\beta < \alpha$. To illustrate this point suppose that $\mathcal{P}$ is a forcing notion, $M \subseteq N$ are two submodels of $H(\lambda)$ and $\mathcal{P} \in M$. Let $\mathcal{A} \in M$ be a maximal antichain in $\mathcal{P}$. If $\mathcal{P}$ satisfies c.c.c. then $\mathcal{A} \subseteq M$, as a range of a function on ω. If $\mathcal{P}$ is absolutely c.c.c. then $N \models \mathcal{A}$ is an maximal antichain, so a $\mathcal{P}$-generic real over N is also $\mathcal{P}$-generic over M. If $\mathcal{P}$ is not absolutely c.c.c. then we no longer know if $\mathcal{A}$ is a maximal antichain in N. In fact, we do not know if $\mathcal{A}$ is an antichain at all, if the incompatibility relation is not absolute between M and N. However, if both M and N are elementary submodels of $H(\lambda)$, then $N \models \mathcal{A}$ is a maximal antichain. Finally, if $\mathcal{P}$ does not satisfy c.c.c., then it is no longer true that $\mathcal{A} \subseteq M$, so a $\mathcal{P}$-generic real over V may not be generic over M. Recall that a condition $p \in \mathcal{P}$ is $(M, \mathcal{P})$-generic if p forces that the above situation does not happen. If for every countable $M \prec H(\lambda)$ the collection of $(M, \mathcal{P})$-generic conditions is dense in $\mathcal{P}$, then $\mathcal{P}$ is proper.

The following strengthenings of properness will allow us to carry out the construction from the proof of Theorem 6.10 for non-c.c.c. posets. See Abraham's chapter [1] for more on these concepts.

6.11 Definition. Suppose that $\mathcal{P}$ is a forcing notion and $\alpha < \omega_1$ is an ordinal. We say that $\mathcal{P}$ is *α-proper* if for every sequence $\langle M_\beta : \beta \leq \alpha \rangle$ such that

1. for every β, M_β is a countable elementary submodel of $H(\lambda)$,

2. $\{M_\gamma : \gamma \leq \beta\} \in M_{\beta+1}$,

3. $M_{\beta+1} \models M_\beta$ is countable,

4. $M_\lambda = \bigcup_{\beta<\lambda} M_\beta$ for limit λ,

5. $\mathcal{P} \in M_0$,

and for every $p \in \mathcal{P} \cap M_0$, there exists a $q \leq p$ which is $(M_\beta, \mathcal{P})$-generic for $\beta \leq \alpha$.

6.12 Definition. A forcing notion $\mathcal{P}$ satisfies *Axiom* A if there exists a sequence $\langle \leq_n : n \in \omega \rangle$ of orderings on $\mathcal{P}$ (not necessarily transitive) such that

1. if $p \leq_{n+1} q$, then $p \leq_n q$ and $p \leq q$ for $p, q \in \mathcal{P}$,

2. if $\langle p_n : n \in \omega \rangle$ is a sequence of conditions such that $p_{n+1} \leq_n p_n$, then there exists a $p \in \mathcal{P}$ such that $p \leq_n p_n$ for all n, and

3. if $\mathcal{A} \subseteq \mathcal{P}$ is an antichain, then for every $p \in \mathcal{P}$ and $n \in \omega$ there exists a $q \leq_n p$ such that $\{r \in \mathcal{A} : q \text{ is compatible with } r\}$ is countable.

All forcing notions assigned to the cardinal invariants from Cichoń diagram satisfy Axiom A.

6.13 Lemma. *If $\mathcal{P}$ satisfies Axiom A, then $\mathcal{P}$ is α-proper for every $\alpha < \omega_1$.*

Proof. Proceed by induction on α. Let $\langle M_\beta : \beta \leq \alpha \rangle$ be a sequence of models having the required properties. Fix $p \in \mathcal{P} \cap M_0$ and $n \in \omega$. We will find a $q \leq_n p$ which is M_β-generic for $\beta \leq \alpha$. If $\alpha = 0$, then it is the usual proof that Axiom A implies properness. If $\alpha = \gamma + 1$, then first find a $q' \leq_n p$ which is M_δ-generic for $\delta \leq \gamma$ and then use properness of $\mathcal{P}$ to get $q \leq_n q'$ which is M_α-generic. If α is limit, then fix an increasing sequence $\langle \alpha_n : n \in \omega \rangle$ such that $\sup_n \alpha_n = \alpha$. Use the induction hypothesis to find conditions $\{p_k : k \in \omega\}$ such that

1. $p_{k+1} \in M_{\alpha_k+1}$,

2. p_k is M_γ-generic for $\gamma < \alpha_k$,

3. $p_{k+1} \leq_{n+k} p_k$ for each k.

Let q be such that $q \leq_{n+k} p_k$ for each k. It is the condition we are looking for. $\dashv$

6.14 Theorem ($\mathsf{ZFC} + \mathsf{CH}$). *There is a set $X \subseteq \mathbb{R}$ such that $X \in \mathsf{B}$ and $X \notin \mathsf{COV}(\mathcal{L}) \cup \mathsf{NON}(\mathcal{L})$.*

Proof. In terms of cardinal invariants the statement of the theorem corresponds to the dual to the model for $\mathfrak{b} = \aleph_2$ and $\mathbf{cov}(\mathcal{L}) = \mathbf{non}(\mathcal{L}) = \aleph_1$, that is, the one where $\mathfrak{d} = \aleph_1$ and $\mathbf{cov}(\mathcal{L}) = \mathbf{non}(\mathcal{L}) = \aleph_2$. The set we are looking for is defined using the forcing notion used to construct that model (cf. Theorem 6.8).

Let $\langle f_\alpha : \alpha < \omega \rangle$ be an enumeration of $\mathbb{R}$. Let $\langle M_\alpha : \alpha < \omega_1 \rangle$ be a sequence of countable elementary submodels of $H(\lambda)$ such that

1. $f_\alpha \in M_\alpha$,
2. $\langle M_\beta : \beta \le \alpha\rangle \in M_{\alpha+1}$, and $M_{\alpha+1} \models M_\alpha$ is countable,
3. $M_\gamma = \bigcup_{\alpha<\gamma} M_\alpha$ for limit γ.

Note that from (2) it follows that for every $\beta < \alpha$, $M_\alpha \models$ "M_β is countable." Let $\langle e_\alpha, r_\alpha : \alpha < \omega_1\rangle$ be a sequence of reals such that

1. $e_\alpha, r_\alpha \in M_{\alpha+1}$,
2. e_α is **EE**-generic over M_β for $\beta \le \alpha$,
3. r_α is **B**-generic over $M_\beta[e_\alpha]$ for $\beta \le \alpha$.

For $\alpha < \omega_1$ define

$$z_\alpha(n) = \begin{cases} e_\alpha(k) & \text{if } n = 2k, \\ r_\alpha(k) & \text{if } n = 2k+1. \end{cases}$$

Let $Z = \{z_\alpha : \alpha < \omega_1\}$.

$Z \notin \mathsf{NON}(\mathcal{L})$. The set $X = \{r_\alpha : \alpha \in \omega_1\}$ is a Borel image of Z. Given $f \in {}^\omega\omega$ find an α such that $f = f_\alpha$. Notice that $r_\beta \notin (N)_f$ for $\beta > \alpha$. In fact, this proof shows that no uncountable subset of Z is in $\mathsf{NON}(\mathcal{L})$.

$Z \notin \mathsf{COV}(\mathcal{L})$. Consider the set $Y = \{e_\alpha : \alpha < \omega_1\}$ which is a Borel image of X. Let $\overline{P} = \{f \in {}^\omega([\omega]^{<\omega}) : \forall n\ (f(n) \in {}^n2)\}$. Let

$$\widetilde{H} = \{(f, x) : f \in \overline{P}, x \in {}^\omega2 \ \&\ \exists^\infty n\ x{\restriction}n = f(n)\}.$$

It is easy to see that $\widetilde{H}$ is a Borel set in $\overline{P} \times {}^\omega2$ and $(\widetilde{H})_f \in \mathcal{L}$ for every f. Suppose that $x \in {}^\omega2$. Find an α such that $x \in M_\alpha$ and note that for $\beta > \alpha$, $x \in (\widetilde{H})_{e_\beta}$. It follows that no uncountable subset of Z is in $\mathsf{COV}(\mathcal{L})$.

$X \in \mathsf{D}$. Let $F : X \longrightarrow {}^\omega\omega$ be a Borel function. Find an α such that F is coded in M_α. Let $f \in {}^\omega\omega$ be such that for every $g \in M_\alpha \cap {}^\omega\omega$, $g \le^\star f$. Since M_α is countable, such an f exists. Since both **B** and **EE** are ${}^\omega\omega$-bounding (and therefore so is $\mathbf{EE}\star\mathbf{B}$) for every $\beta > \alpha$, there exists a $g \in M_\alpha$ such that $F(z_\alpha) \le^\star g \le^\star f$. ⊣

6.15 Theorem ($\mathsf{ZFC} + \mathsf{CH}$). *There is a set $X \subseteq \mathbb{R}$ such that $X \in \mathsf{COV}(\mathcal{L}) \cap \mathsf{NON}(\mathcal{L})$ and $X \notin \mathsf{D}$.*

Proof. Let $\langle M_\alpha : \alpha < \omega_1\rangle$ be a sequence of countable elementary submodels of $H(\lambda)$ as in the previous proof.

In this case we use the Laver forcing from Theorem 6.6. The only difference is that in order to ensure that the constructed set belongs to $\mathsf{COV}(\mathcal{L})$ we construct a set of witnesses for that.

Let $\langle l_\alpha, r_\alpha : \alpha < \omega_1\rangle$ be a sequence of reals such that

1. $l_\alpha, r_\alpha \in M_{\alpha+1}$,

2. l_α is **LT**-generic over M_β for $\beta \leq \alpha$,

3. r_α is **B**-generic over $M_\alpha[l_\beta]$ for all $\beta < \omega_1$.

To meet the condition (3) we need the following result:

6.16 Theorem. *Suppose that $N \prec H(\lambda)$ is a countable model of* ZFC*. Let $S \in N \cap \mathbf{LT}$ and let x be a random real over N. There exists a $T \leq S$ such that T is N-generic and $T \Vdash_{\mathbf{LT}} x$ is random over $N[\dot{G}]$.*

Proof. See [27], [38] or [8]. ⊣

Let $X = \{l_\alpha : \alpha < \omega_1\}$. The difference between this and the previous construction is that we define the set of witnesses $\{r_\alpha : \alpha < \omega_1\}$ that $X \in \mathsf{COV}(\mathcal{L})$.

$X \in \mathsf{COV}(\mathcal{L})$. Let $H \subseteq {}^\omega\omega \times {}^\omega 2$ be a Borel set with null sections. Find α such that $H \in M_\alpha$. Note that

$$r_\alpha \notin \bigcup_{\beta<\omega_1} (H)_{l_\beta},$$

since r_α is random over $M_\alpha[l_\beta]$ for all β and $(H)_{l_\beta} \in M_\alpha[l_\beta]$.

$X \in \mathsf{NON}(\mathcal{L})$. Let $F : X \longrightarrow {}^\omega 2$ be a Borel function. Find α such that F is coded in M_α. Let $B = \bigcup\{A : A \in \mathcal{L} \cap M_\alpha\}$. Since M_α is countable, B is a null set. By Lemma 6.7(3) for every $\beta > \alpha$, $F(l_\alpha) \in B$.

$X \notin \mathsf{D}$. This is obvious, since by Lemma 6.7(1), for every α

$$\forall f \in M_\alpha \cap {}^\omega\omega \ \forall^\infty n \ (f(n) < l_\alpha(n)).$$

⊣

The method of constructing counterexamples to the Cichoń diagram described above is very elegant and effective but assumes a rather large body of knowledge involving forcing, preservation theorems, and so forth. We will conclude this section with a sketch of an alternative method of constructing examples of small sets which is also quite general but more direct. Along the way we translate the forcing results that we have used into statements about sets of reals.

Suppose that $\mathcal{P}$ is a forcing notion and conditions of $\mathcal{P}$ are sets of reals. Note that all forcing notions associated with the Cichoń Diagram are (or can be taken to be) of this form. For a description of a much larger class of forcing notions of that kind see [44].

Let

$$I_{\mathcal{P}} = \{X \subseteq \mathbb{R} : \forall p \in \mathcal{P} \ \exists q \leq p \ (q \cap X = \emptyset)\}.$$

The following lemma lists the obvious observations about $I_{\mathcal{P}}$.

6.17 Lemma.

(1) $I_{\mathcal{P}}$ is an ideal,

(2) *$X \in I_{\mathcal{P}}$ iff there exists a maximal antichain $\mathcal{A} \subseteq \mathcal{P}$ such that $X \cap \bigcup \mathcal{A} = \emptyset$,*

(3) *$\forall p \in \mathcal{P}\ (p \notin I_{\mathcal{P}})$.*

Suppose that $\mathcal{P}$ is a forcing notion satisfying Axiom A. Let

$$I^{\omega}_{\mathcal{P}} = \{X \subseteq \mathbb{R} : \forall p \in \mathcal{P}\ \forall n \in \omega\ \exists q \leq_n p\ (q \cap X = \emptyset)\}.$$

Note that $I^{\omega}_{\mathcal{P}}$ is a σ-ideal contained in $I_{\mathcal{P}}$.

If $\mathcal{P}$ satisfies c.c.c., then we can witness that $\mathcal{P}$ satisfies Axiom A by putting $p \leq_0 q$ if $p \leq q$, and for $n > 0$, $p \leq_n q$ if $p = q$. In this case $I^{\omega}_{\mathcal{P}} = \{\emptyset\}$. However, for non-c.c.c. forcings as well as some c.c.c. posets (like the random real algebra $\mathbf{B}$) we can define $\leq_n$'s in such a way that $I^{\omega}_{\mathcal{P}} = I_{\mathcal{P}}$.

First we will describe how to translate the forcing theorems.

6.18 Lemma. *Suppose that $\mathcal{P}$ is a forcing notion such that*

(1) *$\mathcal{P}$ is proper,*

(2) *for every V-generic filter $G \subseteq \mathcal{P}$ there exists a real x_G such that $V[G] = V[x_G]$,*

(3) *conditions of $\mathcal{P}$ are Borel sets of reals, ordered by inclusion, and*

(4) *every countable antichain in $\mathcal{P}$ can be represented by a countable family of pairwise disjoint elements of $\mathcal{P}$.*

Then for every $\mathcal{P}$-name $\dot{x}$ such that $\Vdash_{\mathcal{P}} \dot{x} \in {}^{\omega}2$ and $p \in \mathcal{P}$ there exists a Borel function $F \in V$, $F : {}^{\omega}2 \longrightarrow {}^{\omega}2$ and a $q \leq p$ such that $q \Vdash_{\mathcal{P}} \dot{x} = F(x_{\dot{G}})$.

Proof. Fix $\dot{x}$ and let $\mathcal{A}_n$ be a maximal antichain of conditions deciding $\dot{x}\restriction n$. Use properness to find a $q \leq p$ such that each $\mathcal{A}'_n = \{r \in \mathcal{A}_n : r \text{ is compatible with } q\}$ is countable. By the assumption we can assume that elements of $\mathcal{A}'_n$ are pairwise disjoint. Define $F_n : q \longrightarrow 2^n$ as

$$F_n(x) = s \quad \text{if } x \in r \in \mathcal{A}'_n \text{ and } r \Vdash_{\mathcal{P}} \dot{x}\restriction n = s.$$

Note that $F = \lim_n F_n$ is the function we are looking for. ⊣

Let $\mathcal{P}$ be a forcing notion satisfying the assumptions of the above lemma.

- $\mathcal{P}$ does not add random reals if for every $\mathcal{P}$-name $\dot{x}$ for an element of ${}^{\omega}2$ and every $p \in \mathcal{P}$ there is a $q \leq p$ and an $H \in V \cap \mathcal{L}$ such that $q \Vdash_{\mathcal{P}} \dot{x} \in H$.

- $\mathcal{P}$ is ${}^{\omega}\omega$-bounding if for every $\mathcal{P}$-name $\dot{f}$ for an element of ${}^{\omega}\omega$ and every $p \in \mathcal{P}$ there is a $q \leq p$ and a $g \in V \cap {}^{\omega}\omega$ such that $q \Vdash_{\mathcal{P}} \dot{f} \leq^{\star} g$.

- $\mathcal{P}$ preserves outer measure if for every set of positive outer measure $X \subseteq {}^{\omega}2$, $X \in V$ and every $\dot{F}$, a $\mathcal{P}$-name for a Borel function from ${}^{\omega}2$ to ${}^{\omega}\omega$ and $p \in \mathcal{P}$ there is a $q \leq p$ such that $q \Vdash_{\mathcal{P}} X - (N)_{\dot{F}(x_{\dot{G}})}) \neq \emptyset$.

These statements translate as:

- (not adding random reals) For every Borel function $F : {}^\omega 2 \longrightarrow {}^\omega 2$ and $p \in \mathcal{P}$ there exist a set $H \in \mathcal{L}$, $q \le p$ and $A \in I_{\mathcal{P}}$ such that $F``(q - A) \subseteq H$.
- ($\mathcal{P}$ is ${}^\omega\omega$-bounding) For every Borel function $F : {}^\omega 2 \longrightarrow {}^\omega\omega$ and $p \in \mathcal{P}$ there is a function $f \in {}^\omega\omega$, $q \le p$ and $A \in I_{\mathcal{P}}$ such that $F``(q-A) \le^\star f$.
- ($\mathcal{P}$ preserves outer measure) For every set of positive outer measure $X \subseteq {}^\omega 2$, and every Borel function $F : {}^\omega 2 \longrightarrow {}^\omega\omega$ and $p \in \mathcal{P}$ there is $q \le p$ and $A \in I_{\mathcal{P}}$ such that $X - \bigcup_{x \in q-A} (N)_{F(x)} \neq \emptyset$.

If in addition $\mathcal{P}$ satisfies Axiom A and $I_{\mathcal{P}} = I^\omega_{\mathcal{P}}$, then we can put $A = \emptyset$.

Second proof of Theorem 6.14. For $p, q \in \mathbf{EE}$ and $n \in \omega$ we define $p \le_n q$ if $p \le q$ and first n elements of $\omega - \mathsf{dom}(p)$ and $\omega - \mathsf{dom}(q)$ are the same.

For $p, q \in \mathbf{B}$ and $n \in \omega$ let $p \le_n q$ if $p \le q$ and $\mu(q - p) \le 2^{-n-1} \cdot \mu(q)$.

The forcing notions $\mathbf{EE}$, $\mathbf{B}$ (and the remaining ones as well) can be represented as collections of perfect subsets of ${}^\omega 2$ (or ${}^\omega\omega$). This is not critical for the construction, but it makes it more natural.

In case of $\mathbf{EE}$ for $n \in \omega$ let $k_n = 2^{n+1} - 1$. Consider sets $P \subseteq {}^\omega 2$ of form $\bigcap_{n\in\omega}[C_n]$, where $\{C_n : n \in \omega\}$ satisfies the following conditions:

1. $C_n \subseteq {}^{[k_n, k_{n+1})}2$,
2. for every n, $|C_n| = 1$ or $|C_n| = 2^n$ (so $C_n = {}^{[k_n, k_{n+1})}2$),
3. $\exists^\infty n \; (|C_n| = 2^n)$.

It is clear that every condition $p \in \mathbf{EE}$ corresponds to a set P as above and vice versa. Therefore from now on we identify $\mathbf{EE}$ with these sets.

Let $\mathbf{B} \star \mathbf{EE}$ be the collection of subsets $H \subseteq 2^\omega \times 2^\omega$ such that

1. H is Borel and $\mathsf{dom}(H) = \{x : (H)_x \neq \emptyset\} \in \mathbf{B}$,
2. $\forall x \; ((H)_x \neq \emptyset \rightarrow (H)_x \in \mathbf{EE})$.

The elements of $\mathbf{B} \star \mathbf{EE}$ are $\mathbf{B}$-names for the elements of $\mathbf{EE}$. Thus, the set $\mathbf{B}\star\mathbf{EE}$ indeed corresponds to the iteration of $\mathbf{B}$ and $\mathbf{EE}$. For $H_1, H_2 \in \mathbf{B}\star\mathbf{EE}$ and $n \in \omega$ let $H_1 \le H_2$ mean that

1. $\mathsf{dom}(H_1) \le_n \mathsf{dom}(H_2)$,
2. $\forall x \in \mathsf{dom}(H_1) \; ((H_1)_x \le_n (H_2)_x)$.

Note that $\le_n$ on $\mathbf{B} \star \mathbf{EE}$ witnesses that it satisfies Axiom A.

Let $\langle x_\alpha : \alpha < \omega_1 \rangle$ be an enumeration of ${}^\omega 2$, $\langle F_\alpha : \alpha < \omega_1 \rangle$ an enumeration of $\mathsf{BOREL}({}^\omega 2 \times {}^\omega 2, {}^\omega\omega)$, and $\langle f_\alpha : \alpha < \omega_1 \rangle$ an enumeration of ${}^\omega\omega$. We will build an ω_1-tree $\mathbf{A}$ of elements of $\mathbf{B}\star\mathbf{EE}$. Let $\mathbf{A}_\alpha$ denote the α-th level of $\mathbf{A}$. The tree $\mathbf{A}$ satisfies the following recursive conditions:

1. $\forall \beta > \alpha\ \forall n\ \forall H \in \mathbf{A}_\alpha\ \exists H' \in \mathbf{A}_\beta\ (H' \leq_n H)$,
2. $\exists f \in {}^\omega\omega\ \forall \alpha\ \forall H \in \mathbf{A}_{\alpha+1}\ (F_\alpha``H \leq^\star f)$,
3. $\forall H \in \mathbf{A}_{\alpha+1}\ (\mathsf{dom}(H) \cap (N)_{f_\alpha} = \emptyset)$,
4. $\forall H \in \mathbf{A}_{\alpha+1}\ \forall x \in \mathsf{dom}(H)\ \exists^\infty n\ (|C^x_n| = 1\ \&\ C^x_n \subseteq x_\alpha)$, where $(H)_x = \bigcap_n [C^x_n]$.

Case 1. $\alpha = \beta + 1$. We will describe how to build a set of immediate successors of an element $H \in \mathbf{A}_\beta$. Given $H \in \mathbf{A}_\beta$ and $n \in \omega$ find an $H'_n \leq_n H$ satisfying conditions (3) and (4). By further shrinking we can ensure that (2) holds as well. Condition (2) follows from the statement that the iteration of **EE** and **B** is ${}^\omega\omega$-bounding.

Case 2. α is limit. Suppose that $H \in \mathbf{A}_{\beta_0}$ for some $\beta_0 \in \omega$ and that $n \in \omega$ is given. Fix an increasing sequence $\langle \beta_k : k \in \omega\rangle$ such that $\beta_k \to \alpha$. Choose a sequence $\langle H_k : k \in \omega\rangle$ such that

1. $H_0 = H_1 = \cdots = H_n = H$,
2. for $k \geq 0$, $H_{n+k+1} \leq_n H_{n+k}$,
3. $H_{k+n} \in \mathbf{A}_{\beta_k}$.

Use Axiom A to find an H' such that $H' \leq_k H_k$. Level $\mathbf{A}_\alpha$ will consist of elements selected in this way.

Let $X = \{(x_p, y_p) : p \in \mathbf{A}\}$ be a selector from elements of $\mathbf{A}$. Note that $\pi_1(X) = \{x_p : (x_p, y_p) \in X\} \notin \mathsf{NON}(\mathcal{L})$ (by (3)), $\pi_2(X) = \{y_p : (x_p, y_p) \in X\} \notin \mathsf{COV}(\mathcal{L})$ (by (4)) and $X \in \mathsf{D}$ (by (2)). $\dashv$

Now let us look at the set constructed in Theorem 6.15.

Second proof of Theorem 6.15. For every $T \in \mathbf{LT}$ and $s \in {}^{<\omega}\omega$ define a node $T(s)$ in the following way: $T(\emptyset) = \mathsf{stem}(T)$ and for $n \in \omega$ let $T(s^\frown n)$ be the n-th element of $\mathsf{succ}_T(T(s))$.

For $T, T' \in \mathbf{LT}$ and $n \in \omega$ define $T \leq_n T'$ if $T \leq T'\ \&\ \forall s \in n^{\leq n}\ (T(s) = T'(s))$. In particular, $T \leq_0 T'$ is equivalent to $T \leq T'$ and $\mathsf{stem}(T) = \mathsf{stem}(T')$. It is easy to check that Laver forcing satisfies Axiom A.

Suppose that

1. $\langle f_\alpha : \alpha < \omega_1\rangle$ is an enumeration of ${}^\omega\omega$,
2. $\langle F_\alpha : \alpha < \omega_1\rangle$ is an enumeration of $\mathsf{BOREL}({}^\omega\omega, {}^\omega 2)$,
3. $\langle G_\alpha : \alpha < \omega_1\rangle$ is an enumeration of $\mathsf{BOREL}({}^\omega\omega, {}^\omega\omega)$.

We build an ω_1-tree $\mathbf{A}$ satisfying the following inductive conditions:

1. $\forall \beta > \alpha\ \forall n\ \forall T \in \mathbf{A}_\alpha\ \exists S \in \mathbf{A}_\beta\ (S \leq_n T)$,

2. $\forall T \in \mathbf{A}_{\alpha+1}\ \forall x \in [T]\ (f_\alpha \leq^\star x)$ (**LT** adds a dominating real (Lemma 6.7(1))),

3. for every $T \in \mathbf{A}_{\alpha+1}$, F_α"T has measure zero (**LT** does not add random reals (Lemma 6.7(3))),

4. $\forall T \in \mathbf{A}_{\alpha+1}$ (${}^\omega 2 - \bigcup_{x\in[T]}(N)_{G_\alpha(x)}$ is uncountable) (**LT** preserves outer measure (Lemma 6.7(2))).

Next we want to chose a selector X from elements of $\mathbf{A}$. Condition (2) will guarantee that $X \notin \mathsf{D}$ and (3) that $X \in \mathsf{NON}(\mathcal{L})$. Unfortunately (4) does not suffice to show that $X \in \mathsf{COV}(\mathcal{L})$. It is conceivable that $2^\omega = \bigcup_{T\in\mathbf{A}_{\alpha+1}} \bigcup_{x\in[T]}(N)_{G_\alpha(x)}$, because $\mathsf{COV}(\mathcal{L})$ is not a σ-ideal. Therefore we need stronger property:

4′. For every Borel function $F : {}^\omega\omega \longrightarrow {}^\omega\omega$ and every sequence $\langle T_n : n \in \omega\rangle$ of conditions in **LT** there exists an uncountable set $Y \subseteq 2^\omega$ such that for each $x \in Y$we can find sequence a $\langle S^n_k : n, k \in \omega\rangle$ such that $S^n_k \leq_k T_n$ and $y \notin \bigcup_{n,k} \bigcup_{x\in[S^n_k]}(N)_{F(n)}$.

Property (4′) is a translation of Theorem 6.16.

Now we construct X along with $\mathbf{A}$. At the step α we have X_α and $\mathbf{A}_\alpha$. Let $\mathbf{A}_\alpha = \langle T_n : n \in \omega\rangle$ and pick $y \notin X_\alpha$ together with $\langle S^n_k : n, k \in \omega\rangle = \mathbf{A}_{\alpha+1}$ as in (4′). $\dashv$

Historical Remarks. Parts (1) and (4) of Theorem 6.1 are due to Truss [57] and [58] and parts (2) and (3) to Solovay [52]. Theorem 6.3 and other preservation results are due to Shelah [46]. Various presentations of these results appear in [22, 26] and most generally in [48]. Models for the Cichoń diagram were constructed by Miller in [33], more in [27] and the latest ones in [9]. Theorem 6.7(2) is due to Judah and Shelah [27], the remaining parts are due to Laver [31]. The forcing **EE** and Lemma 6.9 are due to Miller [33]. Brendle [13] constructed the counterexamples for the $\subsetneq$ for the families of small sets. Constructions of this type were already considered in [20]. The technique of "Aronszajn tree of perfect sets" was invented by Todorcevic (see [21]). Theorem 6.16 is due to Judah and Shelah.

7. Further Reading

There are new developments that occurred after the previous sections were written that to some extent relate to the subject of this chapter, and to the theory of cardinal invariants in general. We will discuss these results briefly and point the reader to the relevant publications. We will start with a brief account of Zapletal's theory. The main reference here is [62].

In the previous section we described a canonical way of building models where cardinal invariants related to measure and category have various values. Similarly, we also described a way to use forcing notions to construct sets that belong to some families of small sets but not to others. The key to these constructions was the ability to pair each cardinal invariant with a forcing notion that increased it and nothing else. The second feature was the duality, that is the ability to obtain the results in pairs. The choice of the appropriate forcing notions was dictated by the heuristics. Zapletal's theory puts those results in a more general context and explains that in most cases these choices are in fact canonical. Moreover, the constructions of the previous section are special cases of a more general phenomenon. To large extent, Zapletal's theory explains the duality as well.

7.1 Definition. A cardinal invariant $\mathfrak{y}$ is *tame* if $\mathfrak{y}$ is the minimum size of a set of reals A with properties $\phi(A)$ and such that $\forall x \in \mathbb{R}\ \exists y \in A\ \theta(x, y)$, where θ is a projective formula that does not mention A and ϕ quantifies only over ω and A. The set A is a *witness* for $\mathfrak{y}$.

It is easy to see that all cardinal invariants considered in this section are tame.

7.2 Definition. We say that a cardinal invariant $\mathfrak{inv}$ can be *isolated* if there is a forcing notion $\mathbb{P}_{\mathfrak{inv}}$ such that for every tame cardinal invariant $\mathfrak{y}$, if $\mathfrak{r} < \mathfrak{inv}$ holds in some set forcing extension then it holds in a $\mathbb{P}_{\mathfrak{inv}}$ extension of a model for CH.

Let LC stand for an unspecified large cardinal assumption; typically these are needed to show regularity properties for various families of sets.

7.3 Theorem (Zapletal [61, 62]). *Assume* LC. *The following cardinal invariants can be isolated:* $\mathfrak{c}$, $\mathfrak{b}$, $\mathfrak{d}$, $\mathbf{cov}(\mathcal{B})$, *and* $\mathbf{cov}(\mathcal{L})$. *The isolating forcing notion is the countable support iteration of length* $\aleph_2$ *of the corresponding forcing notion defined in the previous section.*

While some cardinal invariants cannot be isolated ($\mathbf{cof}(\mathcal{B})$ and $\mathbf{non}(\mathcal{B})$ for example), and some are not tame ($\mathfrak{h}$ and $\mathfrak{g}$ for example) this is a very powerful theorem which gives a lot of structure to the theory of cardinal invariants.

The duality heuristic is explained by the following result:

7.4 Theorem (Zapletal [62]). *Let* I *be an analytic* σ*-ideal of subsets of* $\mathbb{R}$. *If* ZFC *proves* $\mathbf{cov}(I) = \mathfrak{c}$ *then* ZFC *proves* $\mathbf{non}(I) \leq \aleph_2$.

Let I *be a projective* σ*-ideal of subsets of* $\mathbb{R}$. *If* $\mathsf{ZFC}+\mathsf{LC}$ *proves* $\mathbf{cov}(I) = \mathfrak{c}$ *then* $\mathsf{ZFC} + \mathsf{LC}$ *proves* $\mathbf{non}(I) \leq \aleph_2$.

The subject of Zapletal's theory is the study of posets of form $\mathbb{P}_I = \mathsf{Borel}(\mathbb{R})/I$ where I is a σ-ideal. The cardinal invariants mentioned in Theorem 7.3 are the covering numbers of various σ ideals and the isolating forcing notions are the iterations of forcings $\mathbb{P}_I$. For example, let the σ-ideal generated by bounded subsets of ${}^{\omega}\omega$ be called $\mathtt{bounded}$. Then $\mathbf{cov}(\mathtt{bounded}) = \mathfrak{d}$ and $\mathbb{P}_{\mathfrak{d}}$ is the countable support iteration of length ω_2 of $\mathbb{P}_{\mathtt{bounded}}$. Furthermore, $\mathbb{P}_{\mathtt{bounded}}$ has a dense subset isomorphic to Miller forcing.

The models that are obtained by using forcing notions that isolate cardinal invariants are very interesting because of their strong combinatorial properties as exhibited by Zapletal's theorem. His work in [61], further expanded in [62], leads to axioms that describe combinatorial properties of these models. Historically, the first such attempt was undertaken by Ciesielski and Pawlikowski in [16]. They formulated a family of axioms of varying strength capturing the combinatorics of the Sacks model. Their axioms have a form:

$\mathsf{CPA} \iff \mathfrak{c} = \aleph_2$ and for any *appropriately dense* subset $\mathcal{A}$ of Sacks forcing there is a subfamily $\mathcal{A}_0$ of size $\aleph_1$ such that $|\mathbb{R} \setminus \bigcup \mathcal{A}_0| \leq \aleph_1$.

The CPA axioms of Ciesielski and Pawlikowski are geared towards deriving the maximum number of properties of the Sacks model, which is the goal of [16]. Zapletal's work leads to more abstractly formulated family of axioms $\mathsf{CPA}(I)$, which imply the Ciesielski and Pawlikowski axioms in case of Sacks forcing. The starting point is the analysis of the forcing notions of the form $\mathbb{P}_I$, and their countable iterations. It turns out that for a large class of ideals I, for a countable ordinal α, a countable support iteration of length α of $\mathbb{P}_I$ is isomorphic with $\mathsf{Borel}(\mathbb{R}^\alpha)/I^\alpha$, where I^α is a Fubini-power of I.

7.5 Definition. Let $\alpha < \omega_1$. We say that a set $B \subseteq {}^\alpha\mathbb{R}$ is *I-perfect* if

1. for $\beta < \alpha$ and $s \in B\restriction\beta = \{u\restriction\beta : u \in B\}$, the set $\{r \in \mathbb{R} : s^\frown r \in B\restriction\beta+1\}$ is I-positive,
2. for every increasing sequence $\langle \beta_n : n \in \omega\rangle$ and $s_n \in B\restriction\beta_n$ such that $s_n \subseteq \beta_{n+1}$, $\bigcup_n s_n \in B\restriction \bigcup_n \beta_n$.

Let I^α be the ideal on ${}^\alpha\mathbb{R}$ defined as the collection of all sets $A \subseteq {}^\alpha\mathbb{R}$ such that Player I has a winning strategy in the following game $G(A)$.

The game $G(A)$ lasts α rounds; at the round $\beta < \alpha$ Player I plays $B_\beta \in I$ and Player II responds with $r_\beta \in \mathbb{R} - B_\beta$. Player II wins if $\langle r_\beta : \beta < \alpha\rangle \in A$. Otherwise, Player I wins.

It is not hard to see that Player II has a winning strategy in $G(A)$ iff A contains an I-positive set.

Now we can define $\mathsf{CPA}(I)$. Let G be a game consisting of ω_1 moves that is played as follows: at the stage $\beta < \omega_1$ Player I plays $\alpha_\beta < \omega_1$, and I-perfect set $B_\beta \subseteq {}^{\alpha_\beta}\mathbb{R}$ and a Borel function $f_\beta : B_\beta \longrightarrow \mathbb{R}$. Player II responds with a Borel I-positive set $C_\beta \subseteq B_\beta$. Player I wins iff $\bigcup_{\beta<\omega_1} f_\beta``C_\beta = \mathbb{R}$.

$\mathsf{CPA}(I)$ is the statement $\mathbf{cov}(I) > \aleph_1$ and Player II does not have a winning strategy in G.

For a large class of ideals I, and very tame cardinal invariants $\mathfrak{y}$ (a small technical modification of tame invariants) we have:

7.6 Theorem (Zapletal [62]). $\mathsf{ZFC}+\mathsf{LC}$ *proves that* $\mathfrak{y} < \mathbf{cov}(I)$ *can be forced if and only if* $\mathsf{ZFC} + \mathsf{LC} + \mathsf{CPA}(I)$ *proves that* $\mathfrak{x} < \mathbf{cov}(I)$.

A different approach to exploring the combinatorial strength of cardinal invariants is presented in [35]. Recall that $\diamondsuit$ stands for the principle:

There is a sequence $\langle S_\alpha : \alpha < \omega_1\rangle$ such that $S_\alpha \subseteq \alpha$ and for all $X \subseteq \omega_1$, $\{\alpha < \omega_1 : X \cap \alpha = S_\alpha\}$ is stationary.

Hrušák [23] initiated a study of modifications of $\diamondsuit$ that relate to cardinal invariants. This theory was further developed in [35].

7.7 Definition. Let $\mathbf{A} = (A_-, A_+, A)$ be a relation as considered in Definition 2.3. Let $\Phi(\mathbf{A})$ stand for the statement:

For every function $F : {}^{<\omega_1}2 \longrightarrow A_-$ there exists a function $g : \omega_1 \longrightarrow A_+$ such that for all $f : \omega_1 \longrightarrow 2$, $\{\alpha : F(f{\restriction}\alpha) = g(\alpha)\}$ is stationary.

We call a function $F : {}^{<\omega_1}2 \longrightarrow X$ (where X is a Polish space) *Borel* if for every $\alpha < \omega_1$, $F{\restriction}{}^{<\alpha}2 : {}^{<\alpha}2 \longrightarrow X$ is Borel. Note that ${}^{<\alpha}2$ is homeomorphic to ${}^{\omega}2$.

For a Borel $\mathbf{A}$ let $\diamondsuit(\mathbf{A})$ stand for the statement:

For every Borel function $F : {}^{<\omega_1}2 \longrightarrow A_-$ there exists a function $g : \omega_1 \longrightarrow A_+$ such that for all $f : \omega_1 \longrightarrow 2$, $\{\alpha : F(f{\restriction}\alpha) = g(\alpha)\}$ is stationary.

The function g is called a *$\diamondsuit$-sequence for F*. Moreover, we often write $\diamondsuit(\|\mathbf{A}\|)$ rather than $\diamondsuit(\mathbf{A})$. For example $\diamondsuit(\mathbf{non}(\mathcal{B}))$ stands for $\diamondsuit(\mathcal{B}, \mathbb{R}, \not\ni)$.

7.8 Lemma (Moore-Hrušák-Dzamonja [35]).

1. *$\Phi(\mathbf{A})$ implies $\diamondsuit(\mathbf{A})$ whenever $\mathbf{A}$ is Borel,*
2. *$\diamondsuit$ implies $\Phi(\mathbf{A})$,*
3. *$\diamondsuit(\mathbf{A})$ implies $\|\mathbf{A}\| = \aleph_1$,*
4. *If $\mathbf{A} \preceq \mathbf{B}$ then $\Phi(\mathbf{B})$ implies $\Phi(\mathbf{A})$,*
5. *If $\mathbf{A}, \mathbf{B}$ are Borel and $\mathbf{A} \preceq \mathbf{B}$ is witnessed by a Borel morphism then $\diamondsuit(\mathbf{B})$ implies $\diamondsuit(\mathbf{A})$.*

Proof. (1) is obvious. To see (2) let $\langle S_\alpha : \alpha < \omega_1\rangle$ be a $\diamondsuit$-sequence (for elements ${}^{\omega_1}2$). Put $g(\alpha) \in A_+$ such that $F(S_\alpha) A g(\alpha)$. Then g is a $\diamondsuit(\mathbf{A})$-sequence since $\{\alpha : f{\restriction}\alpha = A_\alpha\} \subseteq \{\alpha : F(f{\restriction}\alpha) A g(\alpha)\}$.

(3) Let $F_0 : {}^{\omega}2 \longrightarrow A_-$ be a (Borel) surjection. Extend F_0 to F by putting, for an infinite α and $s \in {}^{\alpha}2$, $F(s) = F_0(s{\restriction}\omega)$. If g is a $\diamondsuit$-sequence for F then the range of g witnesses that $\|\mathbf{A}\| = \aleph_1$.

(4) and (5) are easy to verify. $\dashv$

The diamond principles $\diamondsuit(\mathbf{A})$ are forms of anti-Martin's Axiom $\|\mathbf{A}\| = \aleph_1$. Typically $\diamondsuit(\mathbf{A})$ is stronger than $\|\mathbf{A}\| = \aleph_1$, for example $\diamondsuit(\mathfrak{d})$ implies that ${}^{\omega}\omega$ can be partitioned into $\aleph_1$ compact sets, while $\mathfrak{d} = \aleph_1$ does not [35, 53]. Similarly, in most cases $\diamondsuit(\mathbf{A})$ is consistent with the negation of CH, and $\diamondsuit(\mathbf{A})$ holds in many "natural" models for $\|\mathbf{A}\| = \aleph_1$ including all minimal models for the tame cardinal invariants considered earlier. For example, $\diamondsuit(\mathfrak{b})$, $\diamondsuit(\mathbf{non}(\mathcal{B}))$, $\diamondsuit(\mathbf{non}(\mathcal{L}))$, $\diamondsuit(\mathbf{cov}(\mathcal{B}))$, $\diamondsuit(\mathbf{cov}(\mathcal{L}))$ hold in the Miller model, and similarly for the Laver, random, Cohen and Sacks models.

We will conclude with some consequences of the $\diamondsuit$-principles from [35].

7.9 Theorem.

1. *$\diamondsuit(\mathfrak{b})$ implies that $\mathfrak{a} = \aleph_1$.*
2. *$\diamondsuit(\mathbf{non}(\mathcal{B}))$ implies that there exists a Suslin tree.*
3. *$\diamondsuit(\mathbf{non}(\mathcal{L}))$ does not imply that there exists a Suslin tree.*
4. *$\diamondsuit(\mathbf{non}(\mathcal{L})) + \diamondsuit(\mathbf{non}(\mathcal{B}))$ do not imply that there exists a Sierpiński or Luzin set.*

Acknowledgment

I would like to thank Andreas Blass, Aki Kanamori and Andrzej Rosłanowski for carefully reading various versions of this chapter and for *many* helpful suggestions and remarks.

DOI 10.1007/978-1-4020-5764-9_9,

The method of forcing has had great success in demonstrating the relative consistency and independence of set-theoretic problems with respect to the traditional ZFC axioms, or to extensions of these axioms asserting the existence of large cardinals. One begins with a model M, selects a partial ordering $P \in M$ and shows that statements of interest hold in extensions of M of the form $M[G]$, when G is P-generic over M.

However, forcing can play another role in set theory. Not only is it a tool for establishing relative consistency and independence results, it is also a tool for *proving theorems*. This theorem-proving role of forcing in set theory did not become fully apparent until the development of *class forcing*.

In class forcing, the partial ordering P is no longer assumed to be an element of M, but instead a *class* in M. Section 2 below introduces the necessary definitions. We can nevertheless in this introduction explain the special role of class forcing in set theory by beginning with the basic question:

Do P-generic classes exist?

This question never arises in the traditional use of forcing to establish consistency results, for the simple reason that, thanks to the Löwenheim-Skolem Theorem, one can assume that the model M is countable. This assumption ensures an easy construction of a P-generic class. Without the countability assumption, our question becomes a serious one, in light of the following, where L is Gödel's universe of constructible sets, and where "L-definable" means "L-definable without parameters":

There exist L-definable class forcings P_0 and P_1 such that whenever G_0, G_1 are P_0-generic, P_1-generic over L, respectively:

(a) ZFC holds in $\langle L[G_0], G_0\rangle$ and in $\langle L[G_1], G_1\rangle$.

(b) ZFC (indeed Replacement) fails in $\langle L[G_0, G_1], G_0, G_1\rangle$.

This result forces us to make a choice: we cannot preserve ZFC and have generics for all ZFC preserving L-definable class forcings.

The Silver-Solovay theory of $0^\#$ provides a useful criterion for selecting the L-definable forcings which "should" have generics. We say that L is *rigid* if there is no elementary embedding from $\langle L, \in\rangle$ to itself, other than the identity.

L is rigid in class-generic extensions of L. If L is not rigid, then there is a smallest inner model in which L is not rigid, and this inner model is $L[0^\#]$, where $0^\#$ is a real.

Now we say that an L-definable forcing P is *relevant* if there is a class which is P-generic over L and which is definable in the inner model $L[0^\#]$. If P_0 and P_1 are relevant forcings then clearly generics for P_0 and for P_1 can coexist, as they both exist definably over $L[0^\#]$. Moreover, by adopting the base theory ZFC + "$0^\#$ exists", we can hope to use the theory of relevant forcing to prove new theorems, by constructing objects which actually exist (in the inner model $L[0^\#]$) rather than objects which may exist only in a generic extension of the universe.

In this article we discuss the basic theory and applications of class forcing, with an emphasis on three problems posed by Solovay which can be resolved using it. As class forcing, unlike traditional set forcing, does not in general preserve ZFC, we first isolate the first-order property of *tameness*, necessary and sufficient for this preservation. After mentioning four basic examples, we discuss the question of the relevance of class forcing before turning to the most important technique in the subject, the technique of *Jensen coding*. Armed with these ideas we then proceed to describe the solutions to the Solovay problems. We next discuss *generic saturation*, a concept which helps to explain the special role of $0^\#$ in this theory. We end by briefly describing some other applications.

For the deeper study of class forcing, including the many proofs omitted here, we refer the reader to [5]. Two examples of class forcing not treated in this paper are due to Woodin. These are the class forcing versions of the stationary tower forcing, discussed in [20], and the extender algebra forcing, found in [13]. We also mention the paper [21], where a theory of "locally set-generic" class forcings is presented in terms of a strengthening of tameness.

1. Three Problems of Solovay

Solovay's three problems each demand the existence of a real that neither constructs $0^\#$, nor is attainable by set forcing over L.

1.1 Definition. If x, y are sets of ordinals then we write $x \leq_L y$ for $x \in L[y]$; $x <_L y$ for $x \leq_L y$ and $y \not\leq_L x$; and $x =_L y$ for $x \leq_L y$ and $y \leq_L x$.

Genericity Problem. Does there exist a real $R <_L 0^\#$ such that R does not belong to any generic extension of L?

It was to answer this question affirmatively (when "generic" is interpreted to mean "set-generic") that Jensen proved his Coding Theorem. Roughly speaking, he showed that if G is generic for *Easton forcing at successors*, the standard L-definable class forcing that adds a κ-Cohen subset to κ for each L-successor cardinal κ, then there is a real $R <_L 0^\#$, obtained by class forcing over $\langle L[G], G\rangle$, such that $L[G] \subseteq L[R]$ and G is definable over $L[R]$. Then R does not belong to a set-generic extension of L as $L[G]$ is not included in any such extension.

Solovay's second problem concerns definability of reals.

1.2 Definition. R is an *absolute singleton* if for some formula φ, R is the unique solution to φ in every inner model containing R.

Shoenfield's Absoluteness Theorem states that if φ is Π^1_2 (i.e., of the form $\forall x \exists y \psi$ where x and y vary over reals and ψ is arithmetical) then $\varphi(R) \longleftrightarrow M \vDash \varphi(R)$ where M is any inner model containing R. Thus any Π^1_2-singleton (i.e., unique solution to a Π^1_2 formula) is an absolute singleton; $0^\#$ is an example. Also 0 is trivially an example. Solovay asked if there are any less evident examples.

Π^1_2-Singleton Problem. Does there exists a real R, $0 <_L R <_L 0^\#$ such that R is a Π^1_2-singleton?

Suppose that R is set-generic over L. Then it can be shown that R belongs to a P-generic extension of L, where there are only countably many constructible subsets of P, and therefore we can build a P-generic containing any condition in P. So we conclude that if R is nonconstructible and set-generic over L, then R cannot be a Π^1_2-singleton, as there must be other P-generic extensions with reals $R' \neq R$ satisfying any given Π^1_2 formula satisfied by R. This is why the Π^1_2-singleton problem requires Jensen's method: an affirmative answer to the Π^1_2-singleton problem implies an affirmative answer to the genericity problem (for set-genericity).

Solovay's third problem concerns admissibility spectra. Let T be a subtheory of ZFC and R a real. The *T-spectrum* of R, $\Lambda_T(R)$, is the class of all ordinals α such that $L_\alpha[R] \vDash T$. A general problem is to characterize the possible T-spectra of reals for various theories T. An important special case is where $T = T_0 =$ (ZFC without the Power Set Axiom and with Replacement restricted to Σ_1 formulas). We may refer to this as "admissibility theory", as an ordinal α is R-admissible if and only if it is either ω or belongs to the T_0-spectrum, or *admissibility spectrum*, of R. We denote the latter by $\Lambda(R)$.

There are some basic facts that limit the possibilities for $\Lambda(R)$: First, if R belongs to a set-generic extension of L, then $\Lambda(R)$ contains $\Lambda - \beta$ for some ordinal β, where $\Lambda = \Lambda(0)$. This is because if $\alpha \in \Lambda$ and $P \in L_\alpha$, then $L_\alpha[G] \vDash T_0$ for P-generic G. Second, if $0^\# \leq_L R$ then $\Lambda(R) - \beta \subseteq L$-inaccessibles for some β. This is because if $0^\# \in L_\beta[R]$ then every α in $\Lambda(R) - \beta$ is in $\Lambda(0^\#)$ and hence is a "Silver indiscernible", an ordinal which is very large (and in particular inaccessible) in L.

Thus to get a nontrivial admissibility spectrum for R without $0^\#$ we need Jensen's methods. An ordinal is *recursively inaccessible* if it is admissible and also the limit of admissibles.

Admissibility Spectrum Problem. Does there exist a real $R <_L 0^\#$ such that $\Lambda(R) =$ the recursively inaccessible ordinals?

Before we can say more about the solutions to the Solovay problems, we must first develop the basic theory of class forcing, to which we turn next.

2. Tameness

We want our class forcings to preserve ZFC. First we isolate a first-order condition that guarantees this.

2.1 Definition. A *ground model* is a structure $\langle M, A\rangle$ where:

(a) $\langle M, A\rangle$ is a transitive model of ZFC; i.e., M is a transitive model of ZFC, $A \subseteq M$ and Replacement holds in M for formulas mentioning A as a unary predicate.

(b) $M \vDash V = L(A) = \bigcup\{L(A \cap V_\alpha) \mid \alpha \in \mathrm{On}\}$, the smallest inner model containing each of the sets $A \cap V_\alpha$, $\alpha \in \mathrm{On}$.

Property (a) implies that $\langle M, A\rangle$ is *amenable*: for x in M, $A \cap x$ also belongs to M. Property (b) guarantees that if $M \subseteq N \vDash \mathrm{ZFC}$, then M is definable over $\langle N, A\rangle$.

From now on, $\langle M, A\rangle$ will always denote a ground model. Suppose that $G \subseteq P$ where $P \subseteq M$ is an $\langle M, A\rangle$*-forcing*, i.e., a pre-ordering (reflexive, transitive relation) with greatest element 1^P, definable over $\langle M, A\rangle$. G is P*-generic over* $\langle M, A\rangle$ if G is compatible, upward-closed and $G \cap D \neq \emptyset$ whenever $D \subseteq P$ is dense and $\langle M, A\rangle$-definable.

For any $G \subseteq M$ we define $M[G]$ as follows: A *name* is a set $\sigma \in M$ whose elements are of the form $\langle \tau, a\rangle$, τ a name and $a \in M$ (defined recursively). Interpret names by: $\sigma^G = \{\tau^G \mid \langle \tau, a\rangle \in \sigma$ for some $a \in G\}$. Then $M[G] = \{\sigma^G \mid \sigma$ a name$\}$. A P*-generic extension of* $\langle M, A\rangle$ is a model $\langle M[G], A, G\rangle$ where G is P-generic over $\langle M, A\rangle$. P is an M*-forcing* if it is an $\langle M, A\rangle$-forcing for some A. A *generic extension of* M is a model $\langle M[G], A, G\rangle$ for some choice of A, P and of G P-generic over $\langle M, A\rangle$. $X \subseteq M$ is *generic over* M if X is definable in a generic extension of M.

Set forcings always preserve ZFC but class forcings in general do not. Fix a ground model $\langle M, A\rangle$ and $\langle M, A\rangle$-forcing P. P is ZFC *preserving* if $\langle M[G], A, G\rangle$ is a model of ZFC for all G which are P-generic over $\langle M, A\rangle$. For countable M there is a useful first-order property equivalent to ZFC preservation, called *tameness*, which we now describe. First we consider $\mathrm{ZFC}^- = \mathrm{ZFC}$ without the Power Set Axiom:

2.2 Definition. $D \subseteq P$ is *predense* $\leq p \in P$ if every $q \leq p$ is compatible with an element of D. $q \in P$ *meets* D if q extends an element of D. P is *pretame* if whenever $p \in P$ and $\langle D_i \mid i \in a\rangle$, $a \in M$, is an $\langle M, A\rangle$-definable sequence of classes predense $\leq p$ there exists a $q \leq p$ and a $\langle d_i \mid i \in a\rangle \in M$ such that for each $i \in a$, $d_i \subseteq D_i$ and d_i is predense $\leq q$.

2.3 Proposition. *Suppose that M is countable and P is* ZFC^- *preserving. Then P is pretame.*

Proof. Given $\langle D_i \mid i \in a\rangle$ and p as in the statement of pretameness choose G such that $p \in G$, G P-generic over $\langle M, A\rangle$ and consider $f(i) =$ least rank of an element of $G \cap D_i$. If pretameness failed for $p, \langle D_i \mid i \in a\rangle$ then for every $q \le p$ and $\alpha \in \mathrm{On}(M)$ there would be an $r \le q$ and $i \in a$ with r incompatible with each element of $D_i \cap V_\alpha$. But then by genericity, no ordinal of M can bound the range of f, so Replacement fails in $\langle M[G], A, G, M\rangle$. As $\langle M, A\rangle$ is a ground model, Replacement fails in $\langle M[G], A, G\rangle$. ⊣

The forcing relation $p \Vdash \varphi(\sigma_1, \ldots, \sigma_n)$ is defined by: $\langle M[G], A, G\rangle \models \varphi(\sigma_1^G, \ldots, \sigma_n^G)$ for each G which is P-generic over $\langle M, A\rangle$.

2.4 Proposition. *Supose that P is pretame, P-forcing is definable (i.e., for each formula φ, the relation $p \Vdash \varphi(\sigma_1, \ldots, \sigma_n)$ of $p, \sigma_1, \ldots, \sigma_n$ is $\langle M, A\rangle$-definable) and the Truth Lemma holds for P-forcing (i.e., for G P-generic over $\langle M, A\rangle$, $\langle M[G], A, G\rangle \models \varphi(\sigma_1^G, \ldots, \sigma_n^G)$ iff $\exists p \in G, p \Vdash \varphi(\sigma_1, \ldots, \sigma_n)$). Then P is* ZFC$^-$ *preserving.*

Proof. Suppose that G is P-generic over M. As $M[G]$ is transitive and contains ω, it is a model of all axioms of ZFC$^-$ with the possible exception of Pairing, Union and Replacement.

For Pairing, given σ_1^G, σ_2^G consider $\sigma = \{\langle \sigma_1, 1^P\rangle, \langle \sigma_2, 1^P\rangle\}$. Then $\sigma^G = \{\sigma_1^G, \sigma_2^G\}$.

For Replacement, suppose that $f : \sigma^G \longrightarrow M[G]$, f definable (with parameters) in $\langle M[G], A, G\rangle$ and by the Truth Lemma choose $p \in G$, $p \Vdash f$ is a total function on σ. Then for each σ_0 of rank $<$ rank σ, $D(\sigma_0) = \{q \mid$ for some τ, $q \Vdash \sigma_0 \in \sigma \longrightarrow f(\sigma_0) = \tau\}$ is dense $\le p$. Thus by the definability of P-forcing and pretameness we get that for each $q \le p$ there is an $r \le q$ and $\alpha \in \mathrm{On}(M)$ such that $D_\alpha(\sigma_0) = \{s \mid s \in V_\alpha$ and for some τ of rank $< \alpha$, $s \Vdash \sigma_0 \in \sigma \longrightarrow f(\sigma_0) = \tau\}$ is predense $\le r$ for each σ_0 of rank $<$ rank σ. By genericity there is a $q \in G$ and $\alpha \in \mathrm{On}(M)$ such that $q \le p$ and $D_\alpha(\sigma_0)$ is predense $\le q$ for each σ_0 of rank $<$ rank σ. Thus $\mathrm{ran}(f) = \pi^G$ where $\pi = \{\langle \tau, r\rangle \mid \mathrm{rank}\,\tau < \alpha, r \in V_\alpha, r \Vdash \tau \in \mathrm{ran}(f)\}$. So $\mathrm{ran}(f) \in M[G]$.

For Union, given σ^G consider $\pi = \{\langle \tau, p\rangle \mid p \Vdash \tau \in \bigcup \sigma\}$. This is not a set, but for each α we may consider $\pi_\alpha = \pi \cap V_\alpha^M$. By Replacement in $\langle M[G], A, G\rangle$, π_α^G is constant for sufficiently large $\alpha \in \mathrm{On}(M)$. For such α we have $\pi_\alpha^G = \bigcup \sigma^G$. ⊣

Thus the work in establishing the equivalence (for countable M) of ZFC$^-$ preservation with pretameness resides in:

2.5 Lemma (Main Lemma). *If P is pretame and M is countable, then P-forcing is definable and the Truth Lemma holds for P-forcing.*

Proof. We define a relation $\Vdash^*$, prove the lemma for $\Vdash^*$, and finally show that $\Vdash$ and $\Vdash^*$ are the same.

2.6 Definition (of $\Vdash^*$). We say that $D \subseteq P$ is dense $\le p$ if $\forall q \le p \exists r$ ($r \le q$ and r belongs to D).

(a) $p \Vdash^* \sigma \in \tau$ iff $\{q \mid \exists \langle \pi, r\rangle \in \tau$ such that $q \le r, q \Vdash^* \sigma = \pi\}$ is dense $\le p$.

(b) $p \Vdash^* \sigma = \tau$ iff for all $\langle \pi, r\rangle \in \sigma \cup \tau$, $p \Vdash^* (\pi \in \sigma \longleftrightarrow \pi \in \tau)$.

(c) $p \Vdash^* \varphi \wedge \psi$ iff $p \Vdash^* \varphi$ and $p \Vdash^* \psi$.

(d) $p \Vdash^* \sim\varphi$ iff $\forall q \leq p(\sim q \Vdash^* \varphi)$.

(e) $p \Vdash^* \forall x\varphi$ iff for all names $\sigma, p \Vdash^* \varphi(\sigma)$.

Note that circularity is avoided in (a), (b) as $\max(\operatorname{rank}\sigma, \operatorname{rank}\tau)$ goes down (in at most three steps) when these definitions are applied.

2.7 Sublemma.

(a) If $p \Vdash^* \varphi$ and $q \leq p$, then $q \Vdash^* \varphi$.

(b) If $\{q \mid q \Vdash^* \varphi\}$ is dense $\leq p$ then $p \Vdash^* \varphi$.

(c) If $\sim p \Vdash^* \varphi$ then there is $q \leq p$ such that $q \Vdash^* \sim\varphi$.

Proof of Sublemma 2.7.
(a) Clear, by induction on φ, as dense $\leq p \longrightarrow$ dense $\leq q$.
(b) Again by induction on φ. The proof uses the following facts: if $\{q \mid D$ is dense $\leq q\}$ is dense $\leq p$ then D is dense $\leq p$; if $\{q \mid q \Vdash^* \sim\varphi\}$ is dense $\leq p$ then $\forall q \leq p(\sim q \Vdash^* \varphi)$, using (a).
(c) Immediate by (b). ⊣

2.8 Sublemma (Definability of $\Vdash^*$). *For each formula φ, the relation $p \Vdash^* \varphi(\sigma_1 \cdots \sigma_n)$ of $p, \sigma_1, \ldots, \sigma_n$ is $\langle M, A\rangle$-definable.*

Proof of Sublemma 2.8. It suffices to show that the relations $p \Vdash^* \sigma \in \tau$ and $p \Vdash^* \sigma = \tau$ are $\langle M, A\rangle$-definable. Note that by modifying A if necessary, we may assume that the relations "$x = V_\alpha^M$", "p, q are compatible", "d is predense below p", as well as $(P, \leq)$, are Δ_1-definable over $\langle M, A\rangle$.

Using pretameness we shall define a function F from pairs $(p, \sigma \in \tau)$, $(p, \sigma = \tau)$ into M such that:

(a) $F(p, \sigma \in \tau) = (i, d)$ where $\emptyset \neq d \in M$, $d \subseteq P$, $q \in d \longrightarrow q \leq p$ and either ($i = 1$ and $q \Vdash^* \sigma \in \tau$ for all $q \in d$) or ($i = 0$ and $q \Vdash^* \sigma \notin \tau$ for all $q \in d$).

(b) The same holds for $\sigma = \tau$, $\sigma \neq \tau$ instead of $\sigma \in \tau, \sigma \notin \tau$.

(c) F is Σ_1-definable over $\langle M, A\rangle$.

Given this we can define $p \Vdash^* \sigma \in \tau$ by: $p \Vdash^* \sigma \in \tau$ iff for all $q \leq p$, $F(q, \sigma \in \tau) = (1, d)$ for some d. This definition is correct because Lemma 2.7 gives us that $p \Vdash^* \sigma \in \tau \longleftrightarrow \{q \mid q \Vdash^* \sigma \in \tau\}$ is dense $\leq p$. Similarly for $p \Vdash^* \sigma = \tau$.

Now define F by recursion on $\sigma \in \tau$, $\sigma = \tau$. We consider the cases separately.

$\underline{\sigma \in \tau}$ Given p, search for $\langle\pi, r\rangle \in \tau$ and $q \leq p$, $q \leq r$ such that $F(q, \sigma = \pi) = (1, d)$ for some d. If such exist, let $F(p, \sigma \in \tau) = (1, e)$ where e is the union of all such d which appear by the least possible stage α (i.e., this Σ_1 property is true in $\langle V_\alpha^M, A \cap V_\alpha^M\rangle$, α least). If not, then $\bigcup\{d \mid \text{for some } q \leq r,\ F(q, \sigma = \pi) = (0, d)\} \cup \{q \mid q \text{ is incompatible with } r\} = D(\pi, r)$ is dense below p for each $\langle\pi, r\rangle \in \tau$. So also search for $\langle d(\pi, r) \mid \langle\pi, r\rangle \in \tau\rangle \in M$ and $q \leq p$ such that $d(\pi, r) \subseteq D(\pi, r)$ for each $\langle\pi, r\rangle$ and each $d(\pi, r)$ is predense $\leq q$; if this latter search terminates then set $F(p, \sigma \in \tau) = (0, e)$, where e consists of all such q witnessed by the least possible stage α. One of these searches must terminate (by pretameness) and hence $F(p, \sigma \in \tau)$ is defined and either of the form $(1, e)$ where $q \in e \longrightarrow q \leq p$, $q \Vdash^* \sigma \in \tau$, or of the form $(0, e)$ where $q \in e \longrightarrow q \leq p$, $q \Vdash^* \sigma \notin \tau$.

$\underline{\sigma = \tau}$ Given p, search for $\langle\pi, r\rangle \in \sigma \cup \tau$ and $q \leq p$, r such that $F(q, \pi \in \sigma) = (i, d)$, $q' \in d$, $F(q', \pi \in \tau) = (1 - i, e)$ and if this search terminates then set $F(p, \sigma = \tau) = (0, f)$ where f is the union of all such e which appear by the least possible stage α. If this search fails then for each $\langle\pi, r\rangle \in \sigma \cup \tau$, $D(\pi, r) = \bigcup\{e \mid \text{for some } q \leq p, \text{ some } q', d, i,\ F(q, \pi \in \sigma) = (i, d),\ q' \in d,\ F(q', \pi \in \tau) = (i, e)\} \cup \{q \mid q \text{ is incompatible with } r\}$ is dense $\leq p$. So also search for $\langle d(\pi, r) \mid \langle\pi, r\rangle \in \sigma \cup \tau\rangle \in M$ and $q \leq p$ such that for each $\langle\pi, r\rangle \in \sigma \cup \tau$, $d(\pi, r) \subseteq D(\pi, r)$ and $d(\pi, r)$ is predense $\leq q$. If this latter search terminates then $q \Vdash^* \sigma = \tau$ for all such q and let $F(p, \sigma = \tau) = (1, f)$, where f consists of all such q witnessed to obey the above by the least stage α. One of these searches must terminate (by pretameness) and hence $F(p, \sigma = \tau)$ is defined and either of the form $(0, f)$ where $q \in f \to q \leq p$, $q \Vdash^* \sigma \neq \tau$, or of the the form $(1, f)$ where $q \in f \to q \leq p$, $q \Vdash^* \sigma = \tau$.

⊣

Now that we have the definability of $\Vdash^*$ we can prove:

2.9 Sublemma. *For G P-generic over M:*

$$\langle M[G], A, G\rangle \vDash \varphi(\sigma_1^G, \ldots, \sigma_n^G) \quad \text{iff for some } p \in G, \quad p \Vdash^* \varphi(\sigma_1, \ldots, \sigma_n).$$

Proof of Sublemma 2.9. By induction on φ.

$\underline{\sigma \in \tau}$ $(\longrightarrow)$ If $\sigma^G \in \tau^G$ then choose a $\langle\pi, r\rangle \in \tau$ such that $\sigma^G = \pi^G$ and $r \in G$. By induction we can choose $p \in G$, $p \leq r$, $p \Vdash^* \sigma = \pi$. Then $p \Vdash^* \sigma \in \tau$. $(\longleftarrow)$ If $p \in G, \{q \mid \exists\langle\pi, r\rangle \in \tau \text{ such that } q \leq r,\ q \Vdash^* \sigma = \pi\} = D$ is dense $\leq p$ then by genericity we can choose $q \in G$, $\langle\pi, r\rangle \in \tau$ such that $q \leq r$, $q \Vdash^* \sigma = \pi$; then by induction $\sigma^G = \pi^G$ and as $r \geq q \in G$ we get $r \in G$ and hence by definition of $\tau^G, \pi^G \in \tau^G$. So $\sigma^G \in \tau^G$.

$\underline{\sigma = \tau}$ $(\longrightarrow)$ Suppose that $\sigma^G = \tau^G$. Consider $D = \{p \mid \text{either } p \Vdash^* \sigma = \tau \text{ or for some } \langle\pi, r\rangle \in \sigma \cup \tau,\ p \Vdash^* \sim(\pi \in \sigma \longleftrightarrow \pi \in \tau)\}$. Then

D is dense, using the definition of $p \Vdash^* \sigma = \tau$ and Lemma 2.7(c). By genericity there is a $p \in G \cap D$ and by induction it must be that $p \Vdash^* \sigma = \tau$. $(\longleftarrow)$ Suppose that $p \in G$, $p \Vdash^* \sigma = \tau$. Then by induction, $\pi^G \in \sigma^G \longleftrightarrow \pi^G \in \tau^G$ for all $\langle \pi, r \rangle \in \sigma \cup \tau$. So $\sigma^G = \tau^G$.

$\underline{\varphi \wedge \psi}$ Clear by induction, using the fact that if P and q belong to G then for some r in G, $r \le p$ and $r \le q$.

$p, q \in G \longrightarrow \exists r \in G$ $(r \le p$ and $r \le q)$.

$\underline{\sim \varphi}$ Clear by induction, using the density of $\{p \mid p \Vdash^* \varphi$ or $p \Vdash^* \sim \varphi\}$.

$\underline{\forall x \varphi}$ $(\longrightarrow)$ Suppose that $M[G] \vDash \forall x \varphi$. As in the proof of $(\longrightarrow)$ for $\sigma = \tau$, there is a $p \in G$ such that either $p \Vdash^* \forall x \varphi$ or for some σ, $p \Vdash^* \sim \varphi(\sigma)$. By induction the latter is impossible so $p \Vdash^* \forall x \varphi$. $(\longleftarrow)$ Clear by induction.

$\dashv$

2.10 Sublemma. *The relations* $\Vdash^*$ *and* $\Vdash$ *are the same.*

Proof of Sublemma 2.10. By Sublemma 2.9, $p \Vdash^* \varphi(\sigma_1, \dots, \sigma_n) \longrightarrow p \Vdash \varphi(\sigma_1, \dots, \sigma_n)$. And $\sim p \Vdash^* \varphi(\sigma_1, \dots, \sigma_n) \longrightarrow q \Vdash^* \sim \varphi(\sigma_1, \dots, \sigma_n)$ for some $q \le p$ (by Sublemma 2.7(c)) $\longrightarrow \sim p \Vdash \varphi(\sigma_1, \dots, \sigma_n)$ using the countability of M to obtain a generic G, $p \in G$. $\dashv$

This completes the proof of Lemma 2.5. $\dashv$

P is *tame* if P is pretame and in addition $1^P \Vdash$ "Power Set Axiom". The latter is first-order for pretame P as pretameness yields the definability of P-forcing. By the Truth Lemma for P-forcing we get:

2.11 Theorem (Stanley [19], Friedman [5]; Tameness Theorem). *Suppose that M is countable. Then P is* ZFC *preserving iff P is tame.*

3. Examples

We next discuss the four basic examples of tame class forcings, which serve as prototypes for more complex examples, such as Jensen coding. In each of these basic examples we take the ground model to be $\langle L, \emptyset \rangle$. We shall show that these forcings *preserve cofinalities* (i.e., for any ordinal α, $\mathrm{cf}(\alpha)^L = \mathrm{cf}(\alpha)^{L[G]}$, for P-generic G) and *preserve* GCH (i.e., P-generic extensions satisfy GCH).

Easton Forcing

A condition in P is a function $p : \alpha(p) \to L$ where $\alpha(p) \in \mathrm{On}$ and $p(\alpha) = \emptyset$ unless α is infinite and regular, in which case $p(\alpha) \in 2^{<\alpha} = \{f \mid f : \beta \to 2$ for some $\beta < \alpha\}$. We also require *Easton support* which means that $\{\beta <$

$\alpha \mid p(\beta) \neq \emptyset\}$ is bounded in α for inaccessible α. For any α, and $p \in P$, $p(\leq\alpha)$ denotes $p\restriction[0,\alpha]$ and $p(>\alpha)$ denotes $p\restriction(\alpha,\alpha(p))$. Also, for $X \subseteq P$, $X(\leq\alpha) = \{p(\leq\alpha) \mid p \in X\}$ and $X(>\alpha) = \{p(>\alpha) \mid p \in X\}$.

3.1 Proposition. *P is tame and preserves both cofinalities and* GCH.

Proof. First we verify pretameness. Suppose that $p \in P$, $\langle D_i \mid i < \kappa\rangle$ is an L-definable sequence of classes predense $\leq p$ and κ is regular. Let $\langle q_i \mid i < \kappa\rangle$ list all elements of $P(\leq\kappa) = \{q(\leq\kappa) \mid q \in P\}$, using the Easton support requirement. View each $i < \kappa$ as a pair $\langle i_0, i_1\rangle$ and define $p_0 = p$; $p_{i+1} =$ least $r \leq p_i$ such that $r(\leq\kappa) = p_i(\leq\kappa)$ and $q_{i_0} \cup r(>\kappa)$ is a condition meeting some $r_i \in D_{i_1}$, if possible ($p_{i+1} = p_i$ otherwise); $p_\lambda = \bigcup\{p_i \mid i < \lambda\}$ for limit $\lambda \leq \kappa$. Then $p^* = p_\kappa \leq p$ has the property: if $r \leq p^*$ meets D_i then r extends r_j for some $j < \kappa$. Thus $d_i = \{r_j \mid r_j \in D_i\}$ is predense $\leq p^*$ for each i, proving pretameness.

To verify the remaining properties we may use:

3.2 Lemma (Product Lemma). *Suppose that $P = P_0 \times P_1$ where P_0 and P_1 are $\langle M, A\rangle$-definable.*

(a) If G_0 is P_0-generic over $\langle M, A\rangle$ and G_1 is P_1-generic over $\langle M[G_0], A, G_0\rangle$, then $G_0 \times G_1$ is P-generic over $\langle M, A\rangle$.

(b) If G is P-generic over $\langle M, A\rangle$, then $G = G_0 \times G_1$ where G_0 is P_0-generic over $\langle M, A\rangle$. If in addition P_0-forcing is definable, then G_1 is P_1-generic over $\langle M[G_0], A, G_0\rangle$.

Proof. (a) Suppose that $D \subseteq P$ is dense and $\langle M, A\rangle$-definable. Then $D_1 = \{p_1 \mid$ for some p_0 in G_0, (p_0, p_1) meets $D\}$ is $\langle M[G_0], A, G_0\rangle$-definable. We claim that it is dense on P_1: given $p_1 \in P_1$ form $D_0(p_1) = \{p_0 \mid (p_0, p_1')$ meets D for some $p_1' \leq p_1\}$. Then $D_0(p_1)$ is dense since D is, so $G_0 \cap D_0(p_1) \neq \emptyset$. Thus (p_0, p_1') meets D for some $p_0 \in G_0$ and some $p_1' \leq p_1$, and therefore p_1' is an extension of p_1 in D_1.

As D_1 is dense we can choose a $p_1 \in G_1 \cap D_1$ and so we get $(p_0, p_1) \in G_0 \times G_1$ with (p_0, p_1) meeting D. As $G_0 \times G_1$ is compatible and closed upwards (since G_0, G_1 are) we have shown that $G_0 \times G_1$ is P-generic over $\langle M, A\rangle$.

(b) Let $G_0 = \{p_0 \in P_0 \mid (p_0, p_1)$ belongs to G for some $p_1\}$, $G_1 = \{p_1 \mid (p_0, p_1)$ belongs to G for some $p_0\}$. Clearly $G \subseteq G_0 \times G_1$ and conversely if $(p_0, p_1) \in G_0 \times G_1$ then (p_0, p_1) is compatible with every element of G, and hence by the genericity of G, (p_0, p_1) belongs to G. If $D_0 \subseteq P_0$ is dense and $\langle M, A\rangle$-definable then $D = \{(p_0, p_1) \mid p_0$ belongs to $D_0\} \subseteq P$ is dense and $\langle M, A\rangle$-definable, and since G meets D we get that G_0 meets D_0. So G_0 is P_0-generic over $\langle M, A\rangle$, as compatibility and upward closure for G_0 follow from these properties for G.

Suppose that $D_1 \subseteq P_1$ is $\langle M[G_0], A, G_0\rangle$-definable and dense. Then $D = \{(p_0, p_1) \mid p_0 \Vdash p_1 \in D_1\}$ is $\langle M, A\rangle$-definable by the definability of P_0-forcing (where "$p_1 \in D_1$" is expressed using a defining formula for D_1). Also D is dense $\leq (p_0, p_1)$ provided $p_0 \Vdash D_1$ is dense. As G_0 is P_0-generic over $\langle M, A\rangle$ we can choose a $p_0 \in G_0$ so that $p_0 \Vdash D_1$ is dense, and then the genericity of G over $\langle M, A\rangle$ produces $(p_0', p_1) \in G$ such that $p_0' \Vdash \hat{p}_1 \in D_1$; then $p_1 \in G_1 \cap D_1$ and as compatibility, upward closure for G_1 are clear, we have shown that G_1 is P_1-generic over $\langle M[G_0], A, G_0\rangle$. ⊣

In the case of Easton forcing, $P \simeq P(>\kappa) \times P(\leq\kappa)$ and if G is P-generic, then $L[G] = L[G(>\kappa)][G(\leq\kappa)]$; (b) applies as $P(>\kappa)$ is pretame and hence $P(>\kappa)$-forcing is definable. As $P(>\kappa)$ is $\leq\kappa$-closed and $P(\leq\kappa)$ has cardinality κ for regular κ (by Easton support), we get the preservation of "cofinality $> \kappa$" for regular κ and hence all cofinalities are preserved. And we have that for regular κ any subset of κ in $L[G]$ belongs to $L[G(\leq\kappa)]$. As $G(\leq\kappa)$ is equivalent to a subset of κ, GCH follows at regular κ. For singular κ we get $\mathcal{P}(\kappa) = \mathcal{P}(\kappa)^{L[G(\leq\kappa^+)]}$ and hence $2^\kappa = (2^\kappa)^{L[G(\leq\kappa^+)]} = \kappa^+$. ⊣

Long Easton Forcing

We drop the Easton support requirement. For *successor* cardinals κ we still have that $P(\leq\kappa)$ has cardinality κ, $P(>\kappa)$ is $\leq\kappa$-closed, and so the previous arguments show us that P is tame, "cofinality $> \kappa$" is preserved for *successor* cardinals κ and GCH is preserved. But not all cardinals need be preserved. Recall that a cardinal κ is *Mahlo* if it is inaccessible and in addition $\{\alpha < \kappa \mid \alpha \text{ is regular}\}$ is stationary in κ.

3.3 Theorem. *If κ is Mahlo, then κ^+ is collapsed by P; otherwise κ^+ is preserved.*

Proof. Let $G = \langle G_\alpha \mid \alpha \text{ infinite, regular}\rangle$ be P-generic. For each $\alpha < \kappa$ consider $A_\alpha \subseteq \kappa$ defined by: $\beta \in A_\alpha$ iff $\alpha \in G_\beta$.

3.4 Claim. *Suppose that κ is Mahlo. Then $\{A_\alpha \mid \alpha < \kappa\} \subseteq L$ but for no $\gamma < (\kappa^+)^L$ do we have $\{A_\alpha \mid \alpha < \kappa\} \subseteq L_\gamma$.*

Proof of Claim. For any $\alpha < \kappa$ and condition p, we can extend p to q so that $\alpha < \bar\kappa < \kappa$, $\bar\kappa$ regular implies that $p(\bar\kappa)$ has length greater than α. Thus A_α is forced to belong to L.

Given $\gamma < (\kappa^+)^L$ and a condition p, define $f(\bar\kappa) = \text{length}(p(\bar\kappa))$ for regular $\bar\kappa < \kappa$. As κ is Mahlo, f has stationary domain and hence by Fodor's Theorem we may choose $\alpha < \kappa$ such that $\text{length}(p(\bar\kappa))$ is less than α for stationary many regular $\bar\kappa < \kappa$. Then p can be extended so that A_α is guaranteed to be distinct from the κ-many subsets of κ in L_γ. ⊣

Thus κ^+ is collapsed if κ is Mahlo. Conversely, if κ is not Mahlo, then choose a closed unbounded $C \subseteq \kappa$ consisting of cardinals which are not inaccessible (we may assume that κ is a limit cardinal). Suppose that $\langle D_\alpha \mid \alpha \in C\rangle$ is a definable sequence of dense classes. Given p we can successively extend $p(\geq \alpha^+)$ for α in C so that $\{q \leq p \mid q \text{ and } p \text{ agree at or above } \alpha^+$

and q belongs to $D_\alpha\}$ is predense $\leq p$. There is no difficulty in obtaining a condition at a limit stage *less than* κ precisely because conditions are trivial at limit points of C. Thus we have shown that $P({<}\kappa) \times P({>}\kappa)$ preserves κ^+ as κ-many dense classes can be *simultaneously reduced* to predense subsets of size $< \kappa$ (i.e., for any p in P and definable sequence $\langle D_\alpha \mid \alpha < \kappa\rangle$ of dense classes there are $q \leq p$ and $\langle d_\alpha \mid \alpha < \kappa\rangle$ such that $d_\alpha \subseteq D_\alpha$, $\mathrm{Card}(d_\alpha) < \kappa$ and d_α is predense $\leq q$ for each α). Finally $P \simeq P({<}\kappa) \times P({>}\kappa) \times P(\kappa)$ and $P(\kappa)$ preserves κ^+ as it has size κ. $\dashv$

The previous proof shows that full cofinality preservation is obtained if we consider *long Easton forcing at successors*, where κ-Cohen sets are added only for infinite *successor* cardinals κ. We shall consider this and other variants of long Easton forcing in the next section, on relevant forcing.

Reverse Easton Forcing

We consider the iteration defined by: $P(0) = \{\emptyset\}$, the trivial forcing; $P({\leq}\alpha)$ is the two-step iteration $P({<}\alpha) * P(\alpha)$, where $P(\alpha)$ is the trivial forcing unless α is regular, in which case $P(\alpha) = 2^{<\alpha} = \alpha$-Cohen forcing; for limit λ, $P({<}\lambda) =$ Direct Limit $\langle P({<}\alpha) \mid \alpha < \lambda\rangle$ if λ is regular and $P({<}\lambda) =$ Inverse Limit $\langle P({<}\alpha) \mid \alpha < \lambda\rangle$ if λ is singular. (Thus conditions in $P({<}\lambda)$ are trivial on a final segment of λ if λ is regular, and are unrestricted otherwise. That is, Easton supports are being used.) Let P be Direct Limit $\langle P({<}\alpha) \mid \alpha \in \mathrm{On}\rangle$.

3.5 Proposition (See Sect. 2.3 of [5]).

(a) If κ is regular, then $P({\leq}\kappa)$ has a dense suborder of size κ.

(b) For $\alpha < \beta$, $P({<}\beta) \simeq P({\leq}\alpha) * P(\alpha, \beta)$ where $P(\alpha, \beta)$ is the natural reverse Easton iteration of γ-Cohen forcings, $\alpha < \gamma < \beta$, defined in $L[G({\leq}\alpha)]$.

(c) If κ is regular, then $P({\leq}\kappa) \Vdash P(\kappa, \mathrm{On})$ is ${\leq}\kappa$-closed, where $P(\kappa, \mathrm{On})$ is the direct limit of $\langle P(\kappa, \alpha) \mid \kappa \leq \alpha \in \mathrm{On}\rangle$.

It follows that $P =$ Direct Limit $\langle P({<}\alpha) \mid \alpha \in \mathrm{On}\rangle$ is tame and preserves cofinalities and GCH.

Amenable Forcing

In amenable forcing, the generic class G is *amenable* to the ground model, in the sense that $G \cap V_\alpha$ belongs to the ground model for every ordinal α. The basic example P of amenable forcing over L consists of all $p : \alpha \to 2$, ordered by extension. P is ${\leq}\kappa$-closed for all κ and hence tame. Cofinality and GCH preservation are trivial as P adds no new sets.

4. Relevance

We now address the issues raised in the introduction by discussing when generic classes exist for L-definable forcings. For this purpose we shall recall the Silver-Solovay theory of $0^\#$.

4.1 Proposition. *There exist tame L-definable forcings P_0 and P_1 such that not both P_0 and P_1 have generics.*

Proof. For any ordinal α, let $n(\alpha)$ be the least n such that L_α is not a model of Σ_n-Replacement, if such an n exists. Let $S_0 = \{\alpha \mid n(\alpha)$ exists and is even$\}$. P_0 consists of all closed p such that $p \subseteq S_0$, ordered by $p \leq q$ iff q is an initial segment of p.

Note that S_0 is unbounded in On: Given α, let β be least such that $\beta > \alpha$ and $L_\beta \vDash \Sigma_1$-Replacement; then $n(\beta) = 2$ so $\beta \in S_0$. If $G_0 \subseteq P_0$ is P_0-generic over L then $\bigcup G_0$ is therefore a closed unbounded subclass of On included in S_0. To show that P_0 is tame, it suffices to show that it is κ^+-distributive for every L-regular κ : If $\langle D_i \mid i < \kappa \rangle$ is an L-definable sequence of classes dense in P_0 and $p \in P_0$, then choose n odd so that $\langle D_i \mid i < \kappa \rangle$ is Σ_n definable and choose $\langle \alpha_i \mid i < \kappa \rangle$ to be the first κ-many α such that L_α is Σ_n-elementary in L and $\kappa, p, x \in L_\alpha$ where x is the defining parameter for $\langle D_i \mid i < \kappa \rangle$. We can define $p \geq p_0 \geq p_1 \geq \cdots$ so that p_{i+1} meets D_i and $\bigcup p_i = \alpha_i$, using the Σ_n-elementarity of L_{α_i} in L. As $n(\alpha_i) = n + 1$ and $n + 1$ is even, we have no problem in defining p_λ to be $\bigcup\{p_i \mid i < \lambda\} \cup \{\alpha_\lambda\}$ for limit $\lambda \leq \kappa$ and we see that $q = p_\kappa \leq p$ meets each D_i.

Now define P_1 in the same way, but using $S_1 = \{\alpha \mid n(\alpha)$ is defined and odd$\}$. Then P_1 is also tame yet if G_0 and G_1 are P_0 and P_1-generic over L respectively, then $\bigcup G_0$ and $\bigcup G_1$ are disjoint closed unbounded subclasses of On. ⊣

Thus we need a criterion for choosing L-definable forcings for which we can have a generic. Our approach is to isolate a "property of transcendence" (#) such that:

(a) In tame class-generic extensions of L, (#) fails.

(b) If (#) is true in V, then there is a least inner model $L(\#)$ satisfying (#).

Then our criterion for generic class existence is: P has a generic iff it has one definable over $L(\#)$.

4.2 Definition. An amenable $\langle L, A \rangle$ is *rigid* if there is no nontrivial elementary embedding $\langle L, A \rangle \to \langle L, A \rangle$. L is *rigid* if $\langle L, \emptyset \rangle$ is rigid.

We take (#) to be: L is not rigid. First we discuss property (b) above, i.e., that there is a least inner model in which L is not rigid (if there is one at all).

4.3 Theorem (Kunen; Silver [16], Solovay [17]). *Suppose that L is not rigid. Then there is a unique closed unbounded class $I = \{i_\alpha \mid \alpha \in \mathrm{On}\}$ of L-indiscernibles whose Skolem hull is L. Moreover, I is unbounded in every uncountable cardinal and if $0^\#$ = first-order theory of $\langle L, \in, i_0, i_1, \ldots\rangle$ (where the first ω elements $i_0, i_1, \ldots$ of I are introduced as constants) then we have the following:*

(a) $0^\# \in L[I]$, I is $\Delta_1(L[0^\#])$ in the parameter $0^\#$ and I is unbounded in α whenever $L_\alpha[0^\#] \models \Sigma_1$-Replacement.

(b) $0^\#$, viewed as a real, is the unique solution to a Π^1_2 formula (i.e., a formula of the form $\forall x \exists y \psi$ where x, y vary over reals and ψ is arithmetical).

(c) If $f : I \to I$ is increasing and not the identity, then there is a unique $j : L \to L$ extending f with critical point in I, and every $j : L \to L$ is of this form.

(d) If $\langle L, A\rangle$ is amenable, then A is $\Delta_1(L[0^\#])$, $\langle L, A\rangle$ is not rigid and a final segment of I is a class of $\langle L, A\rangle$-indiscernibles.

4.4 Remark.

(i) As I is closed and unbounded in every uncountable cardinal, it follows that every uncountable cardinal belongs to I and $0^\#$ = first-order theory of $\langle L, \in, \omega_1, \omega_2, \ldots\rangle$.

(ii) The Σ^1_2-absoluteness of L ([15]) implies that the unique solution to a Σ^1_2 formula is constructible; so in a sense (b) is best possible.

(iii) I is a class of *strong* indiscernibles: if $\vec{i}, \vec{j}$ are increasing tuples from I of the same length and $x < \min(\vec{i}), \min(\vec{j})$, then for any φ, $L \models \varphi(x, \vec{i}) \longleftrightarrow \varphi(x, \vec{j})$.

In case the conclusion of Theorem 4.3 holds (i.e. in case L is not rigid) we say that "$0^\#$ exists" and refer to I as the *Silver indiscernibles.* Note that Theorem 4.3 implies that if L is not rigid, then $L[0^\#]$ is the smallest inner model in which L is not rigid, verifying that "L is not rigid" obeys condition (b) of our property of transcendence (#).

Before turning to condition (a) of property (#) we mention Jensen's Covering Theorem and some of its consequences. A set X is *covered in L* if there is a constructible Y such that $X \subseteq Y$, $\mathrm{Card}(Y) = \mathrm{Card}(X)$.

4.5 Theorem (Jensen [4]). *Suppose that there exists an uncountable set of ordinals which is not covered in L. Then $0^\#$ exists.*

For proofs of Theorems 4.3, 4.5 see [5, Sect. 3.1].

Using the Covering Theorem, we see that the existence of $0^\#$ takes many equivalent forms.

4.6 Theorem. *Each of the following is equivalent to the existence of* $0^\#$*:*

(a) L *is not rigid.*

(b) $\langle L, A\rangle$ *is not rigid whenever* $\langle L, A\rangle$ *is amenable (i.e., whenever* $A \subseteq L$ *and* $A \cap L_\alpha \in L$ *for every ordinal* α*).*

(c) Some uncountable set of ordinals is not covered in L*.*

(d) Some singular cardinal is regular in L*.*

(e) $\kappa^+ \neq (\kappa^+)^L$ *for some singular cardinal* κ*.*

(f) Every constructible subset of ω_1 *either contains or is disjoint from a closed, unbounded subset of* ω_1*.*

(g) $\{\alpha \mid \alpha$ *is an* L*-cardinal*$\}$ *is* Δ_1*-definable with parameters.*

(h) There exists a $j : L_\alpha \to L_\beta$, $\mathrm{crit}(j) = \kappa, \kappa^+ \leq \alpha$.

(i) There exists a $j : L_\alpha \to L_\beta$, $\mathrm{crit}(j) = \kappa, (\kappa^+)^L \leq \alpha$, $\alpha \geq \omega_2$.

Proof. It is straightforward to show that these all follow from the existence of $0^\#$; using Theorem 4.3. Also (a), (b) imply the existence of $0^\#$ by Theorem 4.3. Conditions (d), (e) each easily imply (c), and we get $0^\#$ from (c) via Theorem 4.5. Condition (f) implies (a), since we get an elementary embedding $L \to L \simeq \mathrm{Ult}(L, U)$ = ultrapower of L by U, where U consists of all constructible subsets of ω_1 containing a closed unbounded subset. (g) implies that $(\kappa^+)^L < \kappa^+$ for κ a sufficiently large cardinal; by taking κ singular we get $0^\#$ via condition (e). To see that (h) implies the existence of $0^\#$, define an ultrafilter U on constructible subsets of κ by: $X \in U$ iff $\kappa \in j(X)$. Then $\mathrm{Ult}(L, U)$ is well-founded, for if not then by Löwenheim-Skolem there would be an infinite descending chain in $\mathrm{Ult}(L_{\kappa^+}, U)$ which contradicts $\kappa^+ \leq \alpha$.

Finally we show that (i) implies the existence of $0^\#$. Define U as before by: $X \in U$ iff $\kappa \in j(X)$. First suppose that κ is at least ω_2. We shall argue that U is *countably complete*, i.e. that if $\{X_n \mid n \in \omega\} \subseteq U$, then $\bigcap\{X_n \mid n \in \omega\} \neq \emptyset$. (This gives $0^\#$ as it implies that $\mathrm{Ult}(L, U)$ is well-founded.) By the Covering Theorem 4.5, there is an $F \in L$ of cardinality ω_1 such that $X_n \in F$ for each n. Then as we have assumed that $\kappa \geq \omega_2$, F has L-cardinality less than κ. We may assume that F is a subset of $\mathcal{P}(\kappa) \cap L$, and hence as α is an L-cardinal, F belongs to L_α and there is a bijection $h : F \longleftrightarrow \gamma$ for some $\gamma < \kappa$, $h \in L_\alpha$. But then $F^* = \{X \in F \mid \kappa \in j(X)\}$ belongs to L_α as $X \in F^* \longleftrightarrow \kappa \in j(h^{-1})(h(X))$ and F^* has nonempty intersection as $j(F^*) = \mathrm{ran}(j \restriction F^*)$ and $\kappa \in \bigcap j(F^*)$. Thus $\{X_n \mid n \in \omega\}$ has nonempty intersection since it is a subset of F^*. If κ is less than ω_2, then we have $\alpha \geq \omega_2 \geq \kappa^+$ so we have a special case of (h). ⊣

The next theorem verifies (a) of transcendence property (#).

4.7 Theorem (Beller [1], Friedman [5]). *Suppose that G is P-generic over $\langle L, A\rangle$ and P is tame. Then $L[G] \models 0^\#$ does not exist.*

Proof. Suppose that $p_0 \in P$, $p_0 \Vdash$ "I, the class of Silver indiscernibles, is a closed unbounded class satisfying $i < j$ in $I \rightarrow L_i \prec L_j$". Suppose that $p \leq p_0$ and $p \Vdash \alpha \in I$. Then $L_\alpha \prec L$ in any P-generic extension $\langle L[G], A, G\rangle$ with $p \in G$. (By Löwenheim-Skolem we can assume that such a G exists for the sake of this argument.) Thus, an L-Satisfaction predicate is definable over $\langle L, A\rangle$ as $L \models \varphi(x)$ iff for some $p \in P$ below p_0, some α with $x \in L_\alpha$, $p \Vdash \varphi(x)$ is true in L_α. This is a contradiction if $A = \emptyset$, for then L-satisfaction would be L-definable. But note that for any A such that $\langle L, A\rangle$ is amenable we can apply the same argument to get the $\langle L, A\rangle$-definability of $\langle L, A\rangle$-satisfaction, using the fact that by Theorem 4.3(d), $\langle L_\alpha, A \cap L_\alpha\rangle \prec \langle L, A\rangle$ for α in a final segment of I. ⊣

4.8 Definition. A forcing P defined over a ground model $\langle L, A\rangle$ is *relevant* if there is a G P-generic over $\langle L, A\rangle$ which is definable (with parameters) over $L[0^\#]$.

Examples of Relevance

Assume that $0^\#$ exists. Then any $L[0^\#]$-*countable* $P \in L$ is relevant, as there are only countably many constructible subsets of P (using the fact that $\omega_1^{L[0^\#]}$ is inaccessible in L). Note that this includes the case of any forcing $P \in L$ definable in L without parameters.

The situation is far less clear for uncountable $P \in L$. The next result treats the case of κ-Cohen forcing.

4.9 Proposition. *Suppose that κ is L-regular and let $P(\kappa)$ denote κ-Cohen forcing in L: conditions are constructible $p : \alpha \rightarrow 2$, $\alpha < \kappa$ and $p \leq q$ iff p extends q.*

(a) If κ has cofinality ω in $L[0^\#]$, then $P(\kappa)$ is relevant.

(b) If κ has uncountable cofinality in $L[0^\#]$, then $P(\kappa)$ is not relevant.

Proof. Let j_n denote the first n Silver indiscernibles $\geq \kappa$.

(a) We use the fact that $P(\kappa)$ is κ-distributive in L. Let $\kappa_0 < \kappa_1 < \cdots$ be an ω-sequence in $L[0^\#]$ cofinal in κ. Then any $D \subseteq P(\kappa)$ in L belongs to $\mathrm{Hull}(\kappa_n \cup j_n)$ for some n, where Hull denotes Skolem hull in L. As $\mathrm{Hull}(\kappa_n \cup j_n)$ is constructible of L-cardinality $< \kappa$ we can use the κ-distributivity of $P(\kappa)$ to choose $p_0 \geq p_1 \geq \cdots$ successively below any $p \in P(\kappa)$ to meet all dense $D \subseteq P(\kappa)$ in L.

(b) Note that in this case $\kappa \in \mathrm{Lim}\, I$, as otherwise $\kappa = \bigcup\{\kappa_n \mid n \in \omega\}$ where $\kappa_n = \bigcup(\kappa \cap \mathrm{Hull}(\bar\kappa + 1 \cup j_n)) < \kappa$, $\bar\kappa = \max(I \cap \kappa)$, and hence κ has $L[0^\#]$-cofinality ω. Suppose that $G \subseteq P(\kappa)$ were $P(\kappa)$-generic over L. For any $p \in P(\kappa)$ let $\alpha(p)$ denote the domain of p. Define $p_0 \geq p_1 \geq \cdots$ in G so that $\alpha(p_{n+1}) \in I$ and p_{n+1} meets all dense $D \subseteq P(\kappa)$ in $\mathrm{Hull}(\alpha(p_n) \cup j_n)$.

Then $p = \bigcup\{p_n \mid n \in \omega\}$ meets all dense $D \subseteq P(\kappa)$ in $\mathrm{Hull}(\alpha \cup j)$ where $\alpha = \bigcup\{\alpha(p_n) \mid n \in \omega\} \in I$ and $j = \bigcup\{j_n \mid n \in \omega\}$. But then p is $P(\alpha)$-generic over L, as every constructible dense $\bar{D} \subseteq P(\alpha)$ is of the form $D \cap P(\alpha)$ for some D as above. So p is not constructible, contradicting $p \in G$. $\dashv$

As a consequence of Proposition 4.9(b) we see that the basic class forcing examples of Easton and long Easton forcing are not relevant. However, we can recover relevance for these forcings by restricting to successor cardinals, thereby not adding κ-Cohen sets for κ of uncountable $L[0^\#]$-cofinality. *Easton forcing at successors* is defined as follows: Conditions are constructible $p : \alpha(p) \to L$ where $p(\alpha) = \emptyset$ unless α is a successor cardinal of L, in which case $p(\alpha) \in \alpha$-Cohen forcing; we also require that if α is L-inaccessible then $\{\beta < \alpha \mid p(\beta) \neq \emptyset\}$ is bounded in α and define $p \leq q$ iff $p(\alpha)$ extends $q(\alpha)$ for each $\alpha < \alpha(q)$.

4.10 Theorem. *Let P be Easton forcing at successors. Then P is relevant.*

Proof. By recursion on $i \in I$, the class of Silver indiscernibles, we define $G(<i)$ to be $P(<i)$-generic over L, where $P(<i)$ is Easton forcing at successors restricted to L_i. For $i = \min I$ take $G(<i)$ to be any $P(<i)$-generic (note that $P(<i)$ is countable in $L[0^\#]$). If $G(<i)$ has been defined, we now define $G(<i^*)$ as follows (where $i < i^*$ are adjacent in I) : $P(<i^*)$ factors as $P(<i) \times P(i, i^*)$ where $P(i, i^*)$ is i^+-closed in L, so it suffices to define a $P(i, i^*)$-generic $G(i, i^*)$, for then $G(<i^*) = G(<i) \times G(i, i^*)$ is $P(<i^*)$-generic. To obtain $G(i, i^*)$, successively choose $p_0 \geq p_1 \geq \cdots$ in $G(i, i^*)$ so that p_{n+1} meets all dense $D \subseteq P(i, i^*)$ in $\mathrm{Hull}(i \cup j_n)$ where $j_n =$ first n Silver indiscernibles $\geq i$. Then set $G(i, i^*) = \{p \mid p \geq p_n \text{ for some } n\}$.

Finally if $i \in \mathrm{Lim}\, I$, let $G(<i) = \bigcup\{G(<j) \mid j \in I \cap i\}$. Note that if $D \subseteq P(<i)$ is dense and constructible then for some $j \in I \cap i$, $D \cap P(<j)$ is dense and constructible and hence is met by $G(<j) \subseteq G(<i)$. So $G(<i)$ is $P(<i)$-generic. Similarly, $G = \bigcup\{G(<i) \mid i \in I\}$ is P-generic over L (and in fact meets all L-amenable dense $D \subseteq P$). $\dashv$

Reverse Easton forcing is relevant, without restriction.

4.11 Theorem. *Let P be the basic example of reverse Easton forcing defined in the last section. Then P is relevant.*

Proof. Recall that $P(<\alpha)$ has a dense subset of L-cardinality $\leq (\alpha^+)^L$ for each α. By recursion on $i \in I$ we define $G(\leq i) = G(<i) * G(i)$ to be $P(\leq i)$-generic over L, where $P(\leq i) = P(<i) * P(i)$, the first $i + 1$ stages in the iteration defining P. We will have that $i \leq j$ in I implies $G(j)$ extends $G(i)$; this will enable us to get through limit stages. For $i = \min I$, take $G(\leq i)$ to be any $P(\leq i)$-generic in $L[0^\#]$. If $G(\leq i)$ has been defined and $i^* = I$-successor to i, then write $P(<i^*)$ as $P(\leq i) * P[i+1, i^*)$ and as $P(\leq i) \Vdash P[i+1, i^*)$ is i^+-closed we can select $G[i+1, i^*)$ to be $P[i+1, i^*)^{G(\leq i)}$-generic over $L[G(\leq i)]$ (the collection of dense sets that must be met is the countable union of

subcollections of size i in $L[G(\leq i)]$, using the Hull$(i \cup j_n)$'s as in the previous proof). Then $G(<i^*) = G(\leq i) * G[i+1, i^*)$ is $P(<i^*)$-generic over L. We also choose $G(i^*)$ to be $P(i^*)^{G(<i^*)}$-generic over $L[G(< i^*)]$, extending the condition $G(i)$ in this forcing.

For $i \in \operatorname{Lim} I$ take $G(<i)$ to be $\bigcup\{G(<j) \mid j \in I \cap i\}$; as in the previous proof $G(<i)$ is $P(<i)$-generic over L. And we take $G(i) = \bigcup\{G(j) \mid j \in I \cap i\}$, which by our construction extends each $G(j)$ for $j \in I \cap i$. Again we get genericity for $G(\leq i)$ from that of $G(\leq j)$ for $j \in I \cap i$, as $G(<i)$ and $G(i)$ extend $G(<j)$ and $G(j)$ respectively for each $j \in I \cap i$. $\dashv$

Before turning to *long Easton forcing at successors* (obtained from Easton forcing at successors by dropping the support condition that $\{\beta < \alpha \mid p(\beta) \neq \emptyset\}$ be bounded in α for L-inaccessible α), we establish the relevance of *thin Easton forcing at successors*. The latter is obtained by weakening the support condition in Easton forcing at successors to: $\{\beta < \alpha \mid p(\beta^+) \neq \emptyset\}$ is nonstationary in α for L-inaccessible α.

4.12 Theorem. *Let P be thin Easton forcing at successors. Then P is relevant.*

Proof. This proof uses, as do later proofs, the notion of *reduction of dense sets*. For any L-cardinal δ, P can be factored as $P(\leq\delta) \times P(>\delta)$. If α is an L-cardinal greater than δ and $D \subseteq P(\leq\alpha)$ is open dense, then we say that $p \in P(\leq\alpha)$ *reduces D below δ* if for some successor L-cardinal $\bar{\delta} \leq \delta$, any extension q of p can be extended into D without changing q above $\bar{\delta}$. (In case δ is itself a successor L-cardinal, then we can of course take $\bar{\delta}$ to be δ itself.)

Now let i be any indiscernible and for any n let j_n be the first n indiscernibles $\geq i$. We can define $p_0^i \geq p_1^i \geq \cdots$ in $P(\leq i^+)$ such that if $D \subseteq P(\leq i^+)$ is open dense and belongs to Hull$(\gamma^+ \cup j_n)$ then p_{n+1}^i reduces D below γ^+ for any L-cardinal $\gamma < i$. This is possible by successively extending on $[\gamma^{++}, i^+]$ (without violating the nonstationary support requirement). Let $G_0^i = \{p \in P(\leq i^+) \mid p \geq p_n^i \text{ for some } n\}$.

G_0^i is *not* $P(\leq i^+)$-generic over L as $p \in G_0^i \to p(j^+) = \emptyset$ for all $j \in I \cap i$. Notice that for $i_0 < i_1 < \cdots < i_n \leq i$ in I, $G_0^{i_0} \cup \cdots \cup G_0^{i_n}$ is a compatible set of conditions. We take $G(\leq i^+) = \{p \in P(\leq i^+) \mid p \geq q_0 \wedge \cdots \wedge q_n$ for some $q_l \in G_0^{i_l}$, where $i_0 < \cdots < i_n \leq i$ in $I\}$. Now we claim that $G(\leq i^+)$ is $P(\leq i^+)$- generic over L. Indeed if $D \subseteq P(\leq i^+)$ is dense and belongs to Hull$(\{k_0, \ldots, k_m\} \cup j_n)$ with $k_0 < \cdots < k_m < i$ in I, then p_{n+1}^i reduces D below k_m^+, $p_{n+1}^i \wedge p_{n+2}^{k_m}$ reduces D below $k_{m-1}^+, \ldots$ and eventually we get $p_{n+1}^i \wedge p_{n+2}^{k_m} \wedge \cdots \wedge p_{n+m+2}^{k_0}$ in $G(\leq i^+)$ meeting D.

Now note that in the above we could have chosen our initial $p_0^i \in P(\leq i^+)$ to reduce every dense $D \subseteq P \cap L_i$ in Hull$(\gamma^+ \cup \{i\})$ below γ^+, for any $\gamma < i$. Thus the resulting generic $G(\leq i^+)$ meets every dense $D \subseteq P \cap L_i$ definable over L_i. Now let $G = \bigcup\{G(\leq i^+) \mid i \in I\}$ and we see that G is P-generic over L. $\dashv$

In the above proof we use thin supports to guarantee that for $i < j$ in I, the "pre-generics" G_0^i and G_0^j agree at i^+ (indeed they equal $\emptyset$ at i^+). A less severe restriction is to require coherence on a closed unbounded set:

4.13 Definition. Let P denote long Easton forcing at successors and suppose that p belongs to $P(\leq\kappa^+)$, where κ is L-regular. For $\xi \in [\kappa, \kappa^+)$ let f_ξ be the L-least 1-1 function from κ onto ξ. For $s \in P(\kappa^+) = \kappa^+$-Cohen forcing and $\alpha < \kappa$ define s_α as follows: If $\xi = \text{length}(s) \leq \kappa$ or $\alpha \neq \kappa \cap f_\xi[\alpha]$, then $s_\alpha = \emptyset$. Otherwise s_α has domain $[\alpha, \bar{\xi})$ where $\bar{\xi} = \text{ordertype}\, f_\xi[\alpha]$ and $s_\alpha(\delta) = s(f_\xi(\delta))$. We say that p is *coherent* at κ if $p(\kappa^+)_\alpha$ and $p(\alpha^+)$ are compatible for closed unboundedly many $\alpha < \kappa$. A condition p in P is *coherent* if for each L-inaccessible κ in the domain of p, p is coherent at κ. Coherent Easton forcing at successors is the forcing whose conditions are the coherent conditions in long Easton forcing at successors.

4.14 Theorem. *Let P be coherent Easton forcing at successors. Then P is relevant.*

Proof. Follow the proof of the previous Theorem. The only new observation is that by virtue of coherence at indiscernibles, we again have the compatibility of G_0^i and G_0^j for $i < j$ in I. ⊣

4.15 Remark. Thin Easton forcing at successors and coherent Easton forcing at successors serve as prototypes for Jensen coding, introduced in the next section. In Jensen coding, conditions are sequences of pairs (p_α, p_α^*) where coherence is used on the "coding strings" p_α and thinness is used on the "restraints" p_α^*.

Finally we turn to long Easton forcing at successors.

4.16 Theorem. *Let P be long Easton forcing at successors. Then P is relevant.*

Proof. Suppose that p belongs to P and i is a Silver indiscernible. We say that p is *coherent at i* if $p(i^+)$ and $\pi(p)(i^+)$ are compatible, where $\pi : L \to L$ is an elementary embedding with critical point i. Equivalently: $p(i^+)_\alpha$ and $p(\alpha^+)$ are compatible for all α in a set X belonging to the "L-ultrafilter" derived from the embedding π (cf. the proof of Theorem 4.6). It suffices to show that if p belongs to $P(\leq i^+)$ and is coherent at indiscernibles $\leq i$ and $D \subseteq P(\leq i^+)$ where $D \in L$ is L-definable from indiscernibles $\geq i$, then p has an extension meeting D which is coherent at indiscernibles $\leq i$. For then, we can repeat the proof of Theorem 4.12, using conditions which are coherent at indiscernibles $\leq i$ to construct G_0^i, and therefore again obtain the compatibility of G_0^i and G_0^j for $i < j$ in I.

Given p and D as above, recursively extend $p(\alpha^+)$ for $\alpha < i$ an L-limit cardinal to $q(\alpha^+)$ as follows: if $q{\restriction}\alpha$ has been defined, then let $q(\alpha^+)$ be least so that for some least $r_\alpha \in P(< \alpha)$, $r_\alpha \cup \{q(\alpha^+)\}$ extends $q{\restriction}\alpha \cup \{p(\alpha^+)\}$ and meets D. Now choose X in the ultrafilter derived from π (X containing all indiscernibles $< i$) such that the r_α cohere for α in X to a condition r in $P(<i)$. Also define $r(i^+)$ to be $\pi(r)(i^+)$. Then r extends p, is coherent at indiscernibles $\leq i$, and meets D. $\dashv$

Indiscernible Preservation

Though we have shown a number of variants of Easton forcing to be relevant, we can ask for more, namely that our generic classes preserve indiscernibles. This will be important in the next section, where Jensen coding is introduced, as we can only code a class by a real (in $L[0^\#]$) if the class preserves (a periodic subclass of) the class I of Silver indiscernibles.

4.17 Definition. A class $A \subseteq L$ *preserves indiscernibles* if I is a class of indiscernibles for the structure $\langle L[A], A\rangle$.

4.18 Theorem. *For each of Easton at successors, reverse Easton, thin Easton at successors, coherent Easton at successors and long Easton at successors there is a generic class G that preserves indiscernibles.*

Proof. The generic classes built earlier for thin Easton at successors, coherent Easton at successors, and long Easton at successors preserve indiscernibles. We now treat the case of reverse Easton forcing. It suffices, for i_ω the ωth indiscernible, to build an $H \subseteq L_{i_\omega}$ which is $P(<i_\omega)$-generic over L_{i_ω} and such that $t(j_1, \dots, j_n) \in H$ iff $t(j'_1 \dots j'_n) \in H$ whenever $j_1 < \dots < j_n$ and $j'_1 < \dots < j'_n$ belong to $I \cap i_\omega$. For then define G by: $t(k_1, \dots, k_n) \in G$ for $k_1 < \dots < k_n$ in I iff $t(i_1, \dots, i_n) \in H$ for $i_1 < \dots < i_n$ the first n indiscernibles. This is well-defined using the above property of H. And G is P-generic over L: it suffices to consider predense $D \in L$ as P has the ∞-chain condition. Write $D \in L$ as $s(l_1, \dots, l_m)$ where $l_1 < \dots < l_m$ in I; then $\overline{D} = s(i_1, \dots, i_m)$ is predense on $P(<i_\omega)$. If $\bar{p} = t(i_1, \dots, i_n) \in H$ meets $\overline{D}$, then $p = t(l_1, \dots, l_m, l_{m+1}, \dots, l_n)$ meets D, where $l_m < l_{m+1} < \dots < l_n$ belong to I. Also $p \in G$ by definition of G. Finally, note that if $k_1 < \dots < k_m < l_1 < \dots < l_m$, $k_1, \dots, k_m$ in I and $l_1, \dots, l_m$ are limit members of I, then for any φ, $\langle L[G], G\rangle \vDash \varphi(k_1, \dots, k_m) \longleftrightarrow \varphi(l_1, \dots, l_m)$ by the Truth Lemma and the fact that G obeys the same invariance property that characterized H. So I is a class of indiscernibles for $\langle L[G], G\rangle$.

Now we build H. Let $H_2 \subseteq P(<i_2)$ be a $P(<i_2)$-generic in $L[0^\#]$ and $H_1 = H_2 \cap P(<i_1)$. We must now define $H_3 \subseteq P(<i_3)$ to be $P(<i_3)$-generic so that $t(i_1, \vec{j}\,) \in H_2$ iff $t(i_2, \vec{j}\,) \in H_3$, where $\vec{j}$ is an increasing sequence from $I - i_\omega$. Note that $H_2(i_1)$, a subset of i_1 generic over $L[H_1]$, is a condition in the i_2-Cohen forcing defined over $L[H_2]$; choose $H_3(i_2)$ to be a generic for this forcing extending $H_2(i_1)$. Now note that for each n there is a $t_n(i_1, \vec{j}_{n^*}) = p_n \in H_2$ which reduces all predense $D \subseteq P(<i_2)$ in $\mathrm{Hull}(i_1 \cup \{i_1, k_1, \dots, k_n\})$ below i_1, where $i_\omega \leq k_1 < \dots < k_n$ belong to I, using the i_1^+-distributivity of $P(>i_1)^{H_2(\leq i_1)}$ in $L[H_2(\leq i_1)]$. So if we define $H'_3 = \{t_n(i_2, \vec{j}_n) \mid n \in \omega\}$ we have that H'_3 reduces all predense $D \subseteq P(<i_3)$ with $D \in L$ below i_2. So, the desired H_3 can be defined by $H_3 = \{p \in P(<i_3) \mid p(\leq i_2) \in H_3(\leq i_2)$

and p compatible with $H_3'\}$. By construction, $t(i_1, \vec{j}\,) \in H_2$ iff $t(i_2, \vec{j}\,) \in H_3$. Note that H_3 was uniquely determined by this last condition, once a choice of $H_3(i_2)$ was made.

H_4 is uniquely determined by $P({<}i_4)$-genericity and the condition that $t(i_1, i_2, \vec{j}\,)$ belongs to H_3 iff $t(i_2, i_3, \vec{j}\,)$ belongs to H_4, as the forcing to add $H_3(i_2)$ is i_1^+-distributive (and the forcing to add $H_3({>}i_2)$ is i_2^+-distributive). We must check that $t(i_1, i_3, \vec{j}\,) \in H_4$ iff $t(i_2, i_3, \vec{j}\,) \in H_4$. Now any condition in H_4 is extended by one of the form $p = (p_0, p_1)$ where $p_0 \in H_4({\le}i_3)$ and $p_1 = t(i_3, \vec{j}\,)$, as such p reduce all dense $D \subseteq P({<}i_4)$ with $D \in L$ below i_3. So, it suffices to show that $t(i_1, i_3, \vec{j}\,) \in H_4({\le}i_3)$ iff $t(i_2, i_3, \vec{j}\,) \in H_4({\le}i_3)$. By definition of H_4 we have $t(i_2, i_3, \vec{j}\,) \in H_4({\le}i_3)$ iff $t(i_1, i_2, \vec{j}\,) \in H_3({\le}i_2)$. But the latter implies that $t(i_1, i_2, \vec{j}\,) = t(i_1, i_3, \vec{j}\,)$, and as $H_3({\le}i_2)$ extends $H_2({\le}i_1)$, we have that $H_4({\le}i_3)$ extends $H_3({\le}i_2)$. So $t(i_1, i_2, \vec{j}\,) \in H_3({\le}i_2)$ iff $t(i_1, i_2, \vec{j}\,) \in H_4({\le}i_3)$ iff $t(i_1, i_3, \vec{j}\,) \in H_4({\le}i_3)$.

In general, define H_{m+3} by the condition that $t(i_m, i_{m+1}, \vec{j}\,)$ belong to H_{m+2} iff $t(i_{m+1}, i_{m+2}, \vec{j}\,)$ belongs to H_{m+3}. As above we get that H_{m+3} is $P({<}i_{m+3})$-generic and $t(i_1, \dots, i_{m+1}, \vec{j}\,) \in H_{m+2}$ iff $t(i_1, \dots, i_m, i_{m+2}, \vec{j}\,) \in H_{m+3}$. Finally let $H = \bigcup\{H_m \mid m \in \omega\}$. Then H is $P({<}i_\omega)$-generic over L and for any $k_1 < \dots < k_{l+2} < \vec{j}$ in $I, k_{l+2} < i_\omega \le \vec{j}$ we have $t(k_1, \dots, k_{l+1}, \vec{j}\,) \in H$ iff $t(k_1, \dots, k_l, k_{l+2}, \vec{j}\,) \in H$. This is enough to imply that $t(\vec{k}_0) \in H$ iff $t(\vec{k}_1) \in H$ whenever $\vec{k}_0$ and $\vec{k}_1$ are increasing sequences from $I \cap i_\omega$. This completes the proof in the case of reverse Easton forcing.

Easton forcing at successors can be handled in the same way without need to consider $H(i)$ for $i \in I$, as $H(\alpha)$ is nontrivial only when α is a successor L-cardinal. (Indeed, without the latter restriction the construction fails as there is no available choice for $H(i_2)$.) $\dashv$

5. The Coding Theorem

Class forcing became an important tool in set theory as a result of the following theorem of Jensen (see [1]):

5.1 Theorem (Coding Theorem). *Suppose that $\langle M, A\rangle$ is a ground model. Then there is an $\langle M, A\rangle$-definable class forcing P such that if $G \subseteq P$ is P-generic over $\langle M, A\rangle$, then:*

(a) $\langle M[G], A, G\rangle \vDash \mathrm{ZFC}$.

(b) For some $R \subseteq \omega$, $M[G] \vDash V = L[R]$, and $\langle M[G], A, G\rangle \vDash A, G$ are definable from the parameter R.

Before discussing the proof of this theorem, we mention the following corollary, which constitutes a partial positive solution to Solovay's genericity problem (for set-genericity):

5.2 Corollary. *There is an L-definable class forcing for producing a real R which is not set-generic over L.*

Proof. Let P_0 be Easton forcing, G_0 P_0-generic over L, and $P_0 * P_1 = P$ a two-step iteration where P_1 adds a real R as in Theorem 5.1 such that G_0 is definable over $L[R]$. Then in $L[R]$ there are κ-Cohen sets for every L-regular κ. Thus R is not set-generic over L as no forcing of size κ can add a κ^+-Cohen set. $\dashv$

In fact R as in Corollary 5.2 can be chosen to satisfy $R <_L 0^\#$, but this property makes use of the relevance of Jensen coding, a topic to be discussed later.

The proof of the Coding Theorem is far easier if one makes the further assumption that $0^\# \notin M$. Indeed, with this extra hypothesis there is a proof, which we provide below, making no use of Jensen's fine structure theory. Instead one uses the following consequence of Jensen's Covering Theorem (Theorem 4.5), expressed by Theorem 4.6(i):

5.3 Proposition. *Suppose that $0^\#$ does not exist, and $j : L_\alpha \to L_\beta$ is Σ_1-elementary with $\alpha \geq \omega_2$. If $\kappa = \mathrm{crit}(j)$ then $\alpha < (\kappa^+)^L$.*

We now give a brief introduction to the coding proof, assuming $0^\# \notin M$. We may assume that $M \vDash \mathrm{GCH}$, as this can be easily arranged by a preliminary class forcing. Moreover, we need not code into a real R; it suffices to code into a *reshaped* subset of ω_1:

5.4 Definition. $b \subseteq \omega_1$ is *reshaped* if for any $\xi < \omega_1$, ξ is countable in $L[b \cap \xi]$.

The following result of [9] provides one of the key ideas in the proof.

5.5 Proposition. *Suppose that $V = L[b]$, b a reshaped subset of ω_1. Then there is a c.c.c. forcing R^b for adding a real R such that $b \in L[R]$.*

Proof. Using the fact that b is reshaped we may define $\langle R_\xi \mid \xi < \omega_1\rangle$ by: $R_\xi = L[b \cap \xi]$-least real distinct from the $R_{\xi'}$ for $\xi' < \xi$. Separate the R_ξ's by setting $R^*_\xi = \{n \mid n \text{ codes a finite initial segment of } R_\xi\}$.

A condition in R^b is $p = (s(p), s^*(p))$ where $s(p)$ is a finite subset of ω, $s^*(p)$ is a finite subset of b. Extension is defined by: $p \leq q$ iff $s(p) \supseteq s(q)$, $s^*(p) \supseteq s^*(q)$ and $\xi \in s^*(q)$ implies $s(p) - s(q)$ is disjoint from R^*_ξ. This is c.c.c. as $s(p) = s(q)$ implies p and q are compatible. If G is R^b-generic, then let $R = \bigcup\{s(p) \mid p \in G\}$. We get:

$$\xi \in b \longleftrightarrow R \cap R^*_\xi \quad \text{finite.}$$

Thus, given R we can test "$\xi \in b$" if we know R_ξ; as R_ξ is computable in $L[b \cap \xi]$ this gives an inductive calculation of $b \cap \xi$ from R. $\dashv$

There is a perfectly analogous notion of *reshaped subset of* κ^+ for any infinite cardinal κ and if κ is an infinite *successor* cardinal, an analogous forcing R^b for b a reshaped subset of κ^+.

Now we do not necessarily have reshaped sets in our ground model; instead we must force them. A *reshaped string at* κ is a function $s : \alpha \to 2$ for some $\alpha < \kappa^+$ such that $\xi \leq \alpha \to L[s{\restriction}\xi] \vDash \mathrm{Card}(\xi) \leq \kappa$. Reshaped strings at κ of arbitrary length $\alpha < \kappa^+$ do exist and serve to approximate the desired reshaped subsets of κ^+.

We now give a rough description of the forcing conditions. P consists of sequences $p = \langle (p_\alpha, p^*_\alpha) \mid \alpha \in \mathrm{Card}, \alpha \leq \alpha(p)\rangle$ where $\alpha(p) \in \mathrm{Card}$ and:

(a) $p_{\alpha(p)}$ is a reshaped string at $\alpha(p)$ and $p^*_{\alpha(p)} = \emptyset$.

(b) For $\alpha \in \mathrm{Card} \cap \alpha(p)$, $(p_\alpha, p^*_\alpha) \in R^{p_{\alpha^+}}$, the forcing for coding p_{α^+}, $A \cap \alpha^+$ by a subset of α^+ using reshaped strings at α.

(c) For α a limit cardinal $\leq \alpha(p)$, $p{\restriction}\alpha$ "exactly codes" p_α.

(d) For α inaccessible $\leq \alpha(p)$ there is a closed unbounded $C \subseteq \alpha$ such that $\beta \in C$ implies $p^*_\beta = \emptyset$.

Clause (d) is over-simplified in that "inaccessible" should really be (something like) "$L[p_\alpha] \vDash \alpha$ is inaccessible" and C should be required to belong to (something like) $L[p_\alpha]$. Clause (c) refers to the limit coding, as yet undefined. The key idea that enables one to carry out a fine structure-free proof of the Coding Theorem (assuming $0^\#$ does not exist) is the use of *coding delays* in the limit coding. The details are supplied in the proof below.

The two main properties of P that must be demonstrated are:

(Extendibility) Suppose that $p \in P$ and $f : \alpha \to \alpha$ with $f(\beta) < \beta^+$ for successor cardinals $\beta < \alpha$. Then there exists a $q \leq p$ with length $q_\beta \geq f(\beta)$ for each successor cardinal $\beta < \alpha$.

(Distributivity) Suppose that D_i is i^+*-dense on* P for each $i < \alpha$, i.e. for all p there is a $q \leq p$ with $q \in D_i$ satisfying $(q_\beta, q^*_\beta) = (p_\beta, p^*_\beta)$ for all $\beta \leq i$. Then for all p there is $q \leq p$, q meets each D_i.

Proposition 5.3 is used to facilitate the proof of Distributivity. Extendibility is not difficult, taking advantage of the coding delays.

Proof of Theorem 5.1, assuming $0^\# \notin M$. We make the following assumption about the predicate A: If H_α, with α an infinite $L[A]$-cardinal, denotes $\{x \in L[A] \mid \text{transitive closure } (x) \text{ has } L[A]\text{-cardinality} < \alpha\}$ then $H_\alpha = L_\alpha[A]$. This is easily arranged using the fact that GCH holds in $L[A]$.

Let Card denote all infinite $L[A]$-cardinals. Also $\mathrm{Card}^+ = \{\alpha^+ \mid \alpha \in \mathrm{Card}\}$ and $\mathrm{Card}' =$ all uncountable limit cardinals.

Let α belong to Card.

5.6 Definition (Strings). S_α consists of all $s : [\alpha, |s|) \longrightarrow 2$, $\alpha \leq |s| < \alpha^+$ such that $|s|$ is a multiple of α and for all $\eta \leq |s|$, $L_\delta[A \cap \alpha, s \restriction \eta] \vDash \mathrm{Card}(\eta) \leq \alpha$ for some $\delta < (\eta^+)^L \cup \omega_2$.

Thus for $\alpha = \omega$ or ω_1, elements of S_α are "reshaped" in the natural sense mentioned above, but for $\alpha \geq \omega_2$ we insist that $s \in S_\alpha$ be "quickly reshaped" in that $\eta \leq |s|$ is collapsed relative to $A \cap \alpha$, $s \restriction \eta$ before the next L-cardinal. This will be important when we use the nonexistence of $0^\#$ to establish cardinal-preservation, via Proposition 5.3. Elements of S_α are called "strings". Note that we allow the empty string $\emptyset_\alpha \in S_\alpha$, where $|\emptyset_\alpha| = \alpha$. For $s, t \in S_\alpha$ write $s \leq t$ for $s \subseteq t$ and $s < t$ for $s \leq t$, $s \neq t$.

5.7 Definition (Coding Structures). For $s \in S_\alpha$ define $\mu^{<s}$, μ^s recursively by: $\mu^{<\emptyset_\alpha} = \alpha$, $\mu^{<s} = \bigcup\{\mu^t \mid t < s\}$ for $s \neq \emptyset_\alpha$ and $\mu^s =$ least $\mu > \mu^{<s}$ which is a limit of multiples of α such that $L_\mu[A \cap \alpha, s] \vDash s \in S_\alpha$. And $\mathcal{A}^s = L_{\mu^s}[A \cap \alpha, s]$.

Thus by definition there is $\delta < \mu^s$ such that $L_\delta[A \cap \alpha, s] \vDash \mathrm{Card}(|s|) \leq \alpha$ and $L_{\mu^s} \vDash \mathrm{Card}(\delta) \leq |s|$, when $\alpha \geq \omega_2$.

5.8 Definition (Coding Apparatus). For $\alpha > \omega$, $s \in S_\alpha$, $i < \alpha$ let $H^s(i) =$ Σ_1 Skolem hull of $i \cup \{A \cap \alpha, s\}$ in $\mathcal{A}^s$ and $f^s(i) =$ ordertype $(H^s(i) \cap \mathrm{On})$. For $\alpha \in \mathrm{Card}^+, b^s = \mathrm{ran}(f^s \restriction B^s)$ where $B^s =$ the successor elements of $\{i < \alpha \mid i = H^s(i) \cap \alpha\}$.

Using the above we will construct a tame, cofinality-preserving forcing P for coding $\langle L[A], A\rangle$ by a subset G_ω of ω_1 which is reshaped in the sense that proper initial segments of (the characteristic function of) G_ω belong to S_ω.

5.9 Definition (Partition of the Ordinals). Let B, C, D, and E denote the classes of ordinals congruent to $0, 1, 2$, and 3 mod 4, respectively. Also for any ordinal α and $X = B, C, D$ or E, we write α^X for the α^{th} element of X (when X is listed in increasing order). If Y is a set of ordinals then $Y^X = \{\alpha^X \mid \alpha \in Y\}$.

5.10 Definition (The Successor Coding). Suppose that $\alpha \in \mathrm{Card}$ $s \in S_{\alpha^+}$. A *condition* in R^s is a pair (t, t^*) where $t \in S_\alpha$, $t^* \subseteq \{b^{s \restriction \eta} \mid \eta \in [\alpha^+, |s|)\} \cup |t|$, $\mathrm{Card}(t^*) \leq \alpha$. Extension of conditions is defined by: $(t_0, t_0^*) \leq (t_1, t_1^*)$ iff $t_1 \leq t_0, t_1^* \subseteq t_0^*$ and:

(a) $|t_1| \leq \gamma^B < |t_0|$, $\gamma \in b^{s \restriction \eta} \in t_1^* \longrightarrow t_0(\gamma^B) = 0$ or $s(\eta)$.

(b) $|t_1| \leq \gamma^C < |t_0|$, $\gamma = \langle \gamma_0, \gamma_1\rangle$, $\gamma_0 \in A \cap t_1^* \longrightarrow t_0(\gamma^C) = 0$.

In (b), $\langle \cdot, \cdot \rangle$ is an L-definable pairing function on On so that $\mathrm{Card}(\langle \gamma_0, \gamma_1 \rangle) = \mathrm{Card}(\gamma_0) + \mathrm{Card}(\gamma_1)$ in L for infinite γ_0, γ_1. An R^s-generic over $\mathcal{A}^s$ is determined by a function $T : \alpha^+ \longrightarrow 2$ such that $s(\eta) = 0$ iff $T(\gamma^B) = 0$ for sufficiently large $\gamma \in b^{s \restriction \eta}$ and such that for $\gamma_0 < \alpha^+ : \gamma_0 \in A$ iff $T(\langle \gamma_0, \gamma_1 \rangle^C) = 0$ for sufficiently large $\gamma_1 < \alpha^+$. Note that R^s is an element of $\mathcal{A}^s$.

Now we come to the definition of the Limit Coding, which incorporates the idea of "coding delays". Suppose that $s \in S_\alpha$, $\alpha \in \mathrm{Card}'$ and $p = \langle (p_\beta, p^*_\beta) \mid \beta \in \mathrm{Card} \cap \alpha \rangle$ where $p_\beta \in S_\beta$ for each $\beta \in \mathrm{Card} \cap \alpha$. A natural definition of "p codes s" would be: for $\eta < |s|$, $p_\beta(f^{s \restriction \eta}(\beta)) = s(\eta)$ for sufficiently large $\beta \in \mathrm{Card} \cap \alpha$. There are a number of problems with this definition however. First, to avoid conflict with the Successor Coding we should use $f^{s\restriction\eta}(\beta)^D$ instead of $f^{s\restriction\eta}(\beta)$. Second, to lessen conflict with codings at $\beta \in \mathrm{Card}' \cap \alpha$ we only require the above for $\beta \in \mathrm{Card}^+ \cap \alpha$. However there are still serious problems in making sure that the coding of s is consistent with the coding of p_β by $p\restriction\beta$ for $\beta \in \mathrm{Card}' \cap \alpha$.

We introduce coding delays to facilitate extendibility of conditions. The rough idea is to code not using $f^{s\restriction\eta}(\beta)^D$, but instead to code just after the least ordinal $\geq f^{s\restriction\eta}(\beta)^D$ where p_β takes the value 1. In addition, we "precode" s by a subset of α, which is then coded with delays by $\langle p_\beta \mid \beta \in \mathrm{Card} \cap \alpha\rangle$; this "indirect" coding further facilitates extendibility of conditions.

5.11 Definition. Suppose that $\alpha \in \mathrm{Card}$, $X \subseteq \alpha$, $s \in S_\alpha$. Let $\tilde{\mu}^s$ be defined just as we defined μ^s but with the requirement "limit of multiples of α" replaced by the weaker condition "multiple of α". Then note that $\tilde{\mathcal{A}}^s = L_{\tilde{\mu}^s}[A \cap \alpha, s]$ belongs to $\mathcal{A}^s$, contains s and Σ_1 Hull$(\alpha \cup \{A \cap \alpha, s\})$ in $\tilde{\mathcal{A}}^s = \tilde{\mathcal{A}}^s$. Now X precodes s if X is the Σ_1 theory of $\tilde{\mathcal{A}}_s$ with parameters from $\alpha \cup \{A \cap \alpha, s\}$ (viewed as a subset of α).

5.12 Definition (Limit Coding). Suppose that $s \in S_\alpha$, $\alpha \in \mathrm{Card}'$ and $p = \langle (p_\beta, p^*_\beta) \mid \beta \in \mathrm{Card} \cap \alpha\rangle$ where $p_\beta \in S_\beta$ for each $\beta \in \mathrm{Card} \cap \alpha$. We wish to define "$p$ codes s". First we define a sequence $\langle s_\gamma \mid \gamma \leq \gamma_0\rangle$ of elements of S_α as follows. Let $s_0 = \emptyset_\alpha$. For limit $\gamma \leq \gamma_0$, $s_\gamma = \bigcup\{s_\delta \mid \delta < \gamma\}$. Now suppose that s_γ is defined and let $f^{s_\gamma}_p(\beta) =$ least $\delta \geq f^{s_\gamma}(\beta)$ such that $p_\beta(\delta^D) = 1$, if such a δ exists. If for cofinally many $\beta \in \mathrm{Card}^+ \cap \alpha$, $f^{s_\gamma}_p(\beta)$ is undefined, then set $\gamma_0 = \gamma$. Otherwise define $X \subseteq \alpha$ by: $\delta \in X$ iff $p_\beta((f^{s_\gamma}_p(\beta) + 1 + \delta)^D) = 1$ for sufficiently large $\beta \in \mathrm{Card}^+ \cap \alpha$. If Even $(X) = \{\delta \mid 2\delta \in X\}$ precodes an element t of S_α extending s_γ such that $f^{s_\gamma}_p, X \in \mathcal{A}^t$ then set $s_{\gamma+1} = t$. Otherwise let $s_{\gamma+1}$ be $s_\gamma * X^E$ (the concatenation of s_γ with the characteristic function of X^E), if this results in $f^{s_\gamma}_p \in \mathcal{A}^{s_{\gamma+1}}$; if not, then $\gamma_0 = \gamma$. Now p exactly codes s if $s = s_\gamma$ for some $\gamma \leq \gamma_0$ and p codes s if $s \leq s_\gamma$ for some $\gamma \leq \gamma_0$.

Note that the Successor Coding only restrains p_β from taking certain nonzero values, so there is no conflict between the Successor Coding and these delays. The advantage of delays is that they give us more control over *where* the Limit Coding takes place, thereby enabling us to avoid conflict between the Limit Codings at different cardinals.

5.13 Definition (The Conditions). A *condition* in P is a sequence $p = \langle (p_\alpha, p^*_\alpha) \mid \alpha \in \mathrm{Card}, \alpha \leq \alpha(p)\rangle$ where $\alpha(p) \in \mathrm{Card}$ and:

(a) $p_{\alpha(p)}$ belongs to $S_{\alpha(p)}$ and $p^*_{\alpha(p)} = \emptyset$.

(b) For $\alpha \in \text{Card} \cap \alpha(p)$, (p_α, p^*_α) belongs to $R^{p_{\alpha^+}}$.

(c) For $\alpha \in \text{Card}'$, $\alpha \le \alpha(p)$, $p \restriction \alpha$ belongs to $\mathcal{A}^{p_\alpha}$ and exactly codes p_α.

(d) For $\alpha \in \text{Card}'$, $\alpha \le \alpha(p)$, α inaccessible in $\mathcal{A}^{p_\alpha}$ there exists a closed unbounded $C \subseteq \alpha$ such that C belongs to $\mathcal{A}^{p_\alpha}$ and $p^*_\beta = \emptyset$ for β in C.

For $\alpha \in \text{Card}, P^{<\alpha}$ denotes the set of all conditions p such that $\alpha(p) < \alpha$. Conditions are ordered by: $p \le q$ iff $\alpha(p) \ge \alpha(q)$, $p(\alpha) \le q(\alpha)$ in $R^{p_{\alpha^+}}$ for $\alpha \in \text{Card} \cap \alpha(p) \cap (\alpha(q)+1)$ and $p_{\alpha(p)}$ extends $q_{\alpha(p)}$ if $\alpha(q) = \alpha(p)$. Also for $s \in S_\alpha$, $\omega < \alpha \in \text{Card}$, P^s denotes $P^{<\alpha}$ together with all $p \restriction \alpha$ for conditions p such that $\alpha(p) = \alpha$, $p_{\alpha(p)} \le s$. P^s is an element of $\tilde{\mathcal{A}}^s$. To order conditions in P^s, define $p^+ = p$ for $p \in P^{<\alpha}$ and for $p \in P^s - P^{<\alpha}$, $p^+ \restriction \alpha = p$ and $p^+(\alpha) = (s \restriction \eta, \emptyset)$ where η is least such that $p \in P^{s \restriction \eta}$; then $p \le q$ iff $p^+ \le q^+$ as conditions in P. Finally, $P^{<s} = \bigcup\{P^{s\restriction\eta} \mid \eta < |s|\} \cup P^{<\alpha}$.

It is worth noting that (c) above implies that f^{p_α} dominates the coding of p_α by $p \restriction \alpha$, in the sense that f^{p_α} strictly dominates each $f^{p_\alpha \restriction \eta}_{p \restriction \alpha}$, $\eta < |p_\alpha|$ on a tail of $\text{Card}^+ \cap \alpha$. The purpose of (d) is to guarantee that extendibility of conditions at (local) inaccessibles is not hindered by the Successor Coding (see the proof of Extendibility below).

We now embark on a series of lemmas which together show that P preserves cofinalities and if G is P-generic over $\langle L[A], A\rangle$ then for some reshaped $X \subseteq \omega_1$, $L[A, G] = L[X]$ and A is $L[X]$-definable from the parameter X. Then X can be coded by a real via a c.c.c. forcing using the Solovay method described earlier.

5.14 Lemma (Distributivity for R^s). *Suppose that $\alpha \in \text{Card}$ and $s \in S_{\alpha^+}$. Then R^s is α^+-distributive in $\mathcal{A}^s$: if $\langle D_i \mid i < \alpha\rangle \in \mathcal{A}^s$ is a sequence of dense subsets of R^s and $p \in R^s$ then there is a $q \le p$ such that q meets each D_i.*

Proof. Choose $\mu < \mu^s$ to be a large enough limit ordinal such that $p, \langle D_i \mid i < \alpha\rangle, \mu^{<s} \in \mathcal{A} = L_\mu[A \cap \alpha^+, s]$. Let $\langle \alpha_i \mid i < \alpha\rangle$ enumerate the first α elements of $\{\beta < \alpha^+ \mid \beta = \alpha^+ \cap \Sigma_1 \text{ Hull of } (\beta \cup \{p, \langle D_i \mid i < \alpha\rangle, \mu^{<s}\}) \text{ in } \mathcal{A}\}$.

Now write p as (t_0, t^*_0) and successively extend to (t_i, t^*_i) for $i \le \alpha$ as follows: (t_{i+1}, t^*_{i+1}) is the least extension of (t_i, t^*_i) meeting D_i such that t^*_{i+1} contains $\{b^{s\restriction\eta} \mid \eta \in H_i \cap [\alpha^+, |s|)\}$ where $H_i = \Sigma_1$ Hull of $\alpha_i \cup \{p, \langle D_i \mid i < \alpha\rangle, \mu^{<s}\}$ in $\mathcal{A}$ and: (a) If $b^{s\restriction\eta} \in t^*_i, s(\eta) = 1$ then $t_{i+1}(\gamma^B) = 1$ for some $\gamma \in b^{s\restriction\eta}, \gamma > |t_i|$. (b) If $\gamma_0 \notin A, \gamma_0 < |t_i|$ then $t_{i+1}(\langle \gamma_0, \gamma_1\rangle^C) = 1$ for some $\gamma_1 > |t_i|$.

The lemma reduces to:

5.15 Claim. *(t_λ, t^*_λ), the greatest lower bound to $\langle (t_i, t^*_i) \mid i < \lambda\rangle$, exists for limit $\lambda \le \alpha$.*

Proof of Claim. We must show that $t_\lambda = \bigcup\{t_i \mid i < \lambda\}$ belongs to S_α. Note that $\langle t_i \mid i < \lambda\rangle$ is definable over $\overline{H}_\lambda$ = transitive collapse of H_λ and by construction, t_λ codes $\overline{H}_\lambda$ definably over $L_{\bar{\mu}_\lambda}[t_\lambda]$, where $\bar{\mu}_\lambda$ = height of $\overline{H}_\lambda$. So t_λ is reshaped, as $|t_\lambda|$ is singular, definably over $L_{\bar{\mu}_\lambda}[t_\lambda]$. By Proposition 5.3, $\bar{\mu}_\lambda < (|t_\lambda|^+)^L$ if $\alpha \geq \omega_2$. So t_λ belongs to S_α. ⊣

⊣

The next lemma illustrates the use of coding delays.

5.16 Lemma (Extendibility for P^s). *Suppose that α is a limit cardinal, $p \in P^s$, $s \in S_\alpha$, $X \subseteq \alpha$ and $X \in \mathcal{A}^s$. Then there exists a $q \leq p$ such that $X \cap \beta \in \mathcal{A}^{q_\beta}$ for each $\beta \in \mathrm{Card} \cap \alpha$.*

Proof. Let $Y \subseteq \alpha$ be chosen so that $\mathrm{Even}(Y)$ precodes s and $\mathrm{Odd}(Y)$ is the Σ_1 theory of $\mathcal{A}$ with parameters from $\alpha \cup \{A \cap \alpha, s\}$, where $\mathcal{A}$ is an initial segment of $\mathcal{A}^s$ of limit height large enough to extend $\widetilde{\mathcal{A}}^s$ and contain X, p. For $\beta \in \mathrm{Card} \cap \alpha$ let $\overline{\mathcal{A}}_\beta$ =transitive collapse of $\Sigma_1\,\mathrm{Hull}(\beta \cup \{A \cap \alpha, s\})$ in $\mathcal{A}$. Then for sufficiently large $\beta \in \mathrm{Card}' \cap \alpha$, either Even $(Y \cap \beta)$ precodes $s_\beta \in S_\beta$ where s_β = pre-image of s under the natural embedding $\overline{\mathcal{A}}_\beta \longrightarrow \mathcal{A}$, or $|p_\beta| < (\beta^+)^{\overline{\mathcal{A}}_\beta}$ in which case f^{p_β} is dominated by the function $g(\gamma) = (\gamma^+)^{\overline{\mathcal{A}}_\gamma}$ on a final segment of $\mathrm{Card}^+ \cap \beta$.

Define q as follows: $q_\beta = s_\beta$ if Even $(Y \cap \beta)$ precodes $s_\beta \in S_\beta$. For other $\beta \in \mathrm{Card}' \cap \alpha$, $q_\beta = p_\beta * (Y \cap \beta)^E$, the concatenation of p_β with the characteristic function of $(Y \cap \beta)^E$. For $\beta \in \mathrm{Card}^+ \cap \alpha$, $q_\beta = p_\beta * \vec{0} * 1 * (Y \cap \beta)^D$ where $\vec{0}$ has length $g(\beta)$.

As $g \restriction \beta, Y \cap \beta$ are definable over $\overline{\mathcal{A}}_\beta$ for $\beta \in \mathrm{Card}' \cap \alpha$ we get $g \restriction \beta, Y \cap \beta \in \mathcal{A}^{s_\beta}$ when Even $(Y \cap \beta)$ precodes $s_\beta \in S_\beta$. Also $g \restriction \beta, Y \cap \beta \in \mathcal{A}^{q_\beta}$ for other $\beta \in \mathrm{Card}' \cap \alpha$ as Odd $(Y \cap \beta)$ codes $\overline{\mathcal{A}}_\beta$. And note that for all $\beta \in \mathrm{Card}' \cap \alpha$, $g \restriction \beta$ dominates f^{p_β} on a final segment of $\mathrm{Card}^+ \cap \alpha$ (and hence $q \restriction \beta$ exactly codes q_β), unless Even $(Y \cap \beta)$ precodes s_β and $s_\beta = p_\beta$, in which case $q \restriction \beta$ exactly codes $q_\beta = s_\beta$ because $p \restriction \beta$ does.

So we conclude that for sufficiently large $\beta \in \mathrm{Card}' \cap \alpha$, $q \restriction \beta$ exactly codes q_β and $X \cap \beta \in \mathcal{A}^{q_\beta}$. Apply induction on α to obtain this for all $\beta \in \mathrm{Card}' \cap \alpha$. Finally, note that the only problem in verifying $q \leq p$ is that the restraint p^*_β may prevent us from making the extension q_β of p_β when $q_\beta = s_\beta$, Even $(Y \cap \beta)$ precodes s_β. Note that this case can be avoided for sufficiently large $\beta < \alpha$ if α is not inaccessible in $\mathcal{A}^s$, by enlarging $\mathcal{A}$. So assume that α is inaccessible in $\mathcal{A}^s$. But property (d) in the definition of condition guarantees that $p^*_\beta = \emptyset$ for β in a closed unbounded $C \subseteq \alpha$, $C \in \mathcal{A}^s$. We may assume that $C \in \mathcal{A}$ and hence for sufficiently large β as above we get $\beta \in C$ and hence $p^*_\beta = \emptyset$. So $q \leq p$ on a final segment of $\mathrm{Card} \cap \alpha$, and we may again apply induction to get $q \leq p$ everywhere. ⊣

The key idea of Jensen's proof lies in the verification of distributivity for P^s. Before we can state and prove distributivity we need some definitions.

5.17 Definition. Suppose that $i < \beta \in \mathrm{Card}$ and $D \subseteq P^s$, $s \in S_{\beta^+}$. D is i^+-predense on P^s if $\forall p \in P^s \exists q \in P^s$ $(q \leq p, q$ meets D and $q \restriction i^+ = p \restriction i^+)$. $X \subseteq \mathrm{Card} \cap \beta^+$ is thin if for each inaccessible $\gamma \leq \beta$, $X \cap \gamma$ is not stationary in γ. A function $f : \mathrm{Card} \cap \beta^+ \longrightarrow V$ is small if for each $\gamma \in \mathrm{Card} \cap \beta^+$,

$\mathrm{Card}(f(\gamma)) \leq \gamma$ and Support $(f) = \{\gamma \in \mathrm{Card} \cap \beta^+ \mid f(\gamma) \neq \emptyset\}$ is thin. If $D \subseteq P^s$ is predense and $p \in P^s$, $\gamma \in \mathrm{Card} \cap \beta^+$ we say that p reduces D below γ if for some $\delta \in \mathrm{Card}^+$ with $\delta \leq \gamma$, $q \leq p \longrightarrow \exists r \leq q$ (r meets D and $r \restriction [\delta, \beta] = q \restriction [\delta, \beta]$). Finally, for $p \in P^s$, f small, $f \in \mathcal{A}^s$ we define $\Sigma^p_f =$ all $q \leq p$ in P^s such that whenever $\gamma \in \mathrm{Card} \cap \beta^+$, $D \in f(\gamma), D$ predense on $P^{p_{\gamma^+}}$, we have that q reduces D below γ.

5.18 Lemma (Distributivity for P^s). *Suppose that $s \in S_{\beta^+}$ where $\beta \in$ Card.*

(a) If $\langle D_i \mid i < \beta \rangle$ belongs to $\mathcal{A}^s$, D_i is i^+-dense on P^s for each $i < \beta$ and p belongs to P^s, then there is a $q \leq p$ such that q meets each D_i.

(b) If p belongs to P^s and f is small in $\mathcal{A}^s$ then there exists a $q \leq p$ such that q belongs to Σ^p_f.

Proof. We demonstrate (a) and (b) by a simultaneous induction on β. If $\beta = \omega$ or belongs to Card^+ then by induction, (a) and (b) reduce to the following: If S is a collection of β-many predense subsets of P^s, $S \in \mathcal{A}^s$ then $\{q \in P^s \mid q$ reduces each $D \in S$ below $\beta\}$ is dense on P^s. The latter follows from Lemma 5.14, since P^s factors as $R^s * Q$ where $1^{R^s} \Vdash Q$ is β^+-c.c., and hence any $p \in P^s$ can be extended to a $q \in P^s$ such that $D^q = \{r \mid r \cup q(\beta)$ meets $D\}$ is predense $\leq q \restriction \beta$ for each $D \in S$.

Now suppose that β is inaccessible. We first show that (b) holds for f, provided $f(\beta) = \emptyset$. First select a closed unbounded $C \subseteq \beta$ in $\mathcal{A}^s$ such that $\gamma \in C \rightarrow f(\gamma) = \emptyset$ and extend p so that $f \restriction \gamma$, $C \cap \gamma$ belong to $\mathcal{A}^{p_\gamma}$ for each $\gamma \in \mathrm{Card} \cap \beta^+$. Then we can successively extend p on $[\beta_i^+, \beta_{i+1}]$ in the least way so as to meet Σ^p_f on $[\beta_i^+, \beta_{i+1}]$, where $\langle \beta_i \mid i < \beta \rangle$ is the increasing enumeration of C. At limit stages λ, we still have a condition, as the sequence of first λ extensions belongs to $\mathcal{A}^{p_{\beta_\lambda}}$. The final condition, after β steps, is an extension of p in Σ^p_f.

Now we prove (a) in this case. Suppose that $p \in P^s$ and $\langle D_i \mid i < \beta \rangle \in \mathcal{A}^s$, D_i is i^+-dense on P^s for each $i < \beta$. Let $\mu_0 < \mu^s$ be a large enough limit ordinal so that $\langle D_i \mid i < \beta \rangle$, p, $\tilde{\mu}^s \in L_{\mu_0}[A \cap \beta^+, s]$ and for $i < \beta$ let $\mu_i = \mu_0 + \omega \cdot i < \mu^s$. For any X we let $H_i(X)$ denote $\Sigma_1 \,\mathrm{Hull}(X \cup \{\langle D_i \mid i < \beta \rangle, p, \tilde{\mu}^s, s, A \cap \beta^+\})$ in $L_{\mu_i}[A \cap \beta^+, s]$.

Let $f_i : \mathrm{Card} \cap \beta \rightarrow V$ be defined by: $f_i(\gamma) = H_i(\gamma)$ if $i < \gamma \in H_i(\gamma)$ and $f_i(\gamma) = \emptyset$ otherwise. Then each f_i is small in $\mathcal{A}^s$ and we recursively define $p = p^0 \geq p^1 \geq \cdots$ in P^s as follows: $p^{i+1} =$ least $q \leq p^i$ such that:

(a) $q(\beta)$ meets all predense $D \subseteq R^s$, $D \in H_i(\beta)$,

(b) q meets $\Sigma^{p^i}_{f_i}$ and D_i,

(c) $q \restriction i^+ = p^i \restriction i^+$.

For limit $\lambda \leq \beta$ we take p^λ to be the greatest lower bound to $\langle p^i \mid i < \lambda \rangle$, if it exists.

5.19 Claim. *p^λ is a condition in P^s, where for each $\gamma \in \mathrm{Card} \cap \beta^+$,*

$$p^\lambda(\gamma) = \left(\bigcup\{p^i_\gamma \mid i < \lambda\}, \bigcup\{{p^i_\gamma}^* \mid i < \lambda\}\right).$$

Suppose that γ belongs to $H_\lambda(\gamma) \cap \beta$. First we verify that $p^\lambda_\gamma = \bigcup\{p^i_\gamma \mid i < \lambda\}$ belongs to S_γ. Let $\bar{H}_\lambda(\gamma)$ be the transitive collapse of $H_\lambda(\gamma)$ and write $\bar{H}_\lambda(\gamma)$ as $L_{\bar{\mu}}[\bar{A}, \bar{s}]$, $\bar{P}$ = image of $P^s \cap H_\lambda(\gamma)$ under transitive collapse, $\bar{\beta}$ = image of β under collapse. Also write $\bar{P}$ as $\bar{R}^{\bar{s}} * P^{\bar{G}_{\bar{\beta}}}$ where $\bar{G}$ denotes an $\bar{R}^{\bar{s}}$-generic (just as P^s factors as $R^s * P^{G_\beta}$, G_β denoting an R^s-generic).

Now the construction of the p^i's (see conditions (a), (b)) was designed to guarantee: (i) $\bar{G}_{\bar{\beta}} = \{\bar{p} \in R^{\bar{s}} \mid \bar{p}$ is extended by some $\bar{p}^i(\bar{\beta}), i < \lambda\}$ is $R^{\bar{s}}$-generic over $\bar{H}_\lambda(\gamma)$, where $\bar{p}^i$ = image of p^i under collapse, and (ii) for each $\bar{\delta}$ in (Card^+ of $\bar{H}_\lambda(\gamma)$), $\gamma < \bar{\delta} < \bar{\beta}$, $\{\bar{p} \mid \bar{p}$ is extended by some $\bar{p}^i\restriction[\gamma, \bar{\delta})$ in $\bar{P}^{\bar{p}^i_{\bar{\delta}}}_\gamma\}$ is $\bar{P}^{\bar{G}_{\bar{\delta}}}_\gamma$-generic over $\mathcal{A}^{\bar{G}_{\bar{\delta}}} = \bigcup\{\mathcal{A}^{\bar{p}^i_{\bar{\delta}}} \mid i < \lambda\}$, where $\bar{P}^{\bar{G}_{\bar{\delta}}}_\gamma = \bigcup\{\bar{P}^{\bar{p}^i_{\bar{\delta}}}_\gamma \mid i < \lambda\}$ and $\bar{P}^{\bar{p}^i_{\bar{\delta}}}_\gamma$ denotes the image under collapse of $P^{p^i_\delta}_\gamma = \{q\restriction[\gamma, \delta) \mid q \in P^{p^i_\delta}\}$, $\bar{\delta}$ = image of δ under collapse.

5.20 Remark. We do not necessarily have property (ii) above for $\bar{\delta} = \bar{\beta}$, and this is the source of our need for the nonexistence of $0^\#$ in this proof.

By induction, we have the distributivity of P^t for $t \in S_\delta$, $\delta \in \mathrm{Card}^+ \cap \beta$, and hence that of $\bar{P}^{\bar{t}}$ for $\bar{t} \in \bar{S}_{\bar{\delta}}$, $\bar{\delta} \in$ (Card^+ of $\bar{H}_\lambda(\gamma)$), $\bar{\delta} < \bar{\beta}$. So the "weak" genericity of the preceding paragraph implies that:

(d) $L_{\bar{\beta}}[A \cap \gamma, p^\lambda_\gamma] \vDash |p^\lambda_\gamma|$ is a cardinal.

Also:

(e) $L_{\bar{\mu}}[A \cap \gamma, p^\lambda_\gamma] \vDash |p^\lambda_\gamma|$ is Σ_1-singular.

Thus $p^\lambda_\gamma \in S_\gamma$ (by (e)) provided we can show that when $\gamma \geq \omega_2$, $\bar{\mu} < (|p^\lambda_\gamma|^+)^L$. But $\bar{H}_\lambda(\gamma) \xrightarrow{\sim} H_\lambda(\gamma)$ gives a Σ_1-elementary embedding with critical point $|p^\lambda_\gamma|$, so by Proposition 5.3, this is true. Also note that we now get $p^\lambda\restriction\gamma \in \mathcal{A}^{p^\lambda_\gamma}$ as well, since $p^\lambda\restriction\gamma$ is definable over $\bar{H}_\lambda(\gamma)$ and we defined $\mathcal{A}^{p^\lambda_\gamma}$ to be large enough to contain $\bar{H}_\lambda(\gamma)$, since $L_{\bar{\beta}} \vDash |p^\lambda_\gamma|$ is a cardinal by (d) and $\bar{\beta}$ is a cardinal of $L_{\bar{\mu}}$.

The previous argument applies also if $\gamma = \beta$, using the distributivity of R^s, or if $\gamma = \beta \cap H_\lambda(\gamma)$, using the fact that p^λ_β collapses to p^λ_γ. If $\gamma < \gamma^* = \min(H_\lambda(\gamma) \cap [\gamma, \beta))$ then we can apply the first argument to get the result for γ^*, and then the second argument to get the result for γ.

Finally, to prove the Claim we must verify the restraint condition (d) in the definition of P. Suppose that γ is inaccessible and for $i < \lambda$ let C^i be the least closed unbounded subset of γ in $\mathcal{A}^{p^i_\gamma}$ disjoint from $\{\bar{\gamma} < \gamma \mid {p^i_{\bar{\gamma}}}^* \neq \emptyset\}$. If $\lambda < \gamma$ then $\bigcap\{C^i \mid i < \lambda\}$ witnesses the restraint condition for p^λ at γ, if $\gamma < \lambda$ then the restraint condition for p^λ at γ follows by induction on λ and if $\gamma = \lambda$ then $\Delta\{C^i \mid i < \lambda\}$ witnesses the restraint condition for p^λ at γ, where Δ denotes diagonal intersection.

Thus the Claim and therefore (a) is proved in case β is inaccessible. To verify (b) in this case, note that as we have already proved (b) when $f(\beta) = \emptyset$ it suffices to show: if $\langle D_i \mid i < \beta\rangle \in \mathcal{A}^s$ is a sequence of dense subsets of P^s then $\forall p \exists q \leq p$ (q reduces each D_i below β). But using distributivity we see that $D_i^* = \{q \mid q$ reduces D_i below $i^+\}$ is i^+-dense for each $i < \beta$, so again by distributivity there is $q \leq p$ reducing D_i below i^+ for each i.

We are now left with the case where β is singular. The proof of (a) can be handled using the ideas from the inaccessible case as follows. Choose $\langle \beta_i \mid i < \lambda_0\rangle$ to be a continuous and cofinal sequence of cardinals $< \beta$, $\lambda_0 < \beta_0$. First we argue that $p \in P^s$ can be extended to meet Σ^p_f for any f small in $\mathcal{A}^s$ provided $f(\beta) = \emptyset$: extend p if necessary so that for each $\gamma \in \mathrm{Card} \cap \beta^+$, $f\restriction\gamma$ and $\{\beta_i \mid \beta_i < \gamma\}$ belong to $\mathcal{A}^{p_\gamma}$. Now perform a construction like the one used to prove distributivity in the inaccessible case, extending p successively on $[\beta_0, {\beta_i}^+]$ so as to meet Σ^p_f on $[\beta_0, {\beta_i}^+]$ as well as appropriate $\Sigma^{p^i}_{f_i}$'s defined on $[\beta_0, {\beta_i}^+]$ to guarantee that p^λ is a condition for limit $\lambda \leq \lambda_0$. Note that each extension is made on a bounded initial segment of $[\beta_0, \beta)$ and therefore by induction $\Sigma^p_f, \Sigma^{p^i}_{f_i}$ can be met on these intervals. The result is that p can be extended to meet Σ^p_f on a final segment of $\mathrm{Card} \cap \beta$ and therefore by induction can be extended to meet Σ^p_f. Second, use the density of Σ^p_f when $f(\beta) = \emptyset$ to carry out the distributivity proof as we did in the inaccessible case. And again, (b) follows from (a). This complete the proof of Lemma 5.18. ⊣

Theorem 5.1 now follows, as the argument of the previous lemma also shows:

5.21 Lemma (Distributivity for P). *If $\langle D_i \mid i < \kappa\rangle$ is $\langle M, A\rangle$-definable where D_i is i^+-dense for each $i < \kappa$ and $p \in P$ then there exists a $q \leq p$ such that q meets each D_i.*

Thus P is tame and preserves cofinalities. ⊣

The proof of Theorem 5.1 in the general case is far more difficult; we refer the reader to [5, Sect. 4.3].

The forcing used to prove the Coding Theorem preserves a number of large cardinal properties consistent with $V = L[R]$, $R \subseteq \omega$, such as the Mahlo and α-Erdős properties. In addition for any m, n a predicate A^* can be adjoined to $\langle M, A\rangle$ so that if κ is Σ^n_m-indescribable then κ is Σ^n_m-indescribable relative to A^*, and then A^* can be coded by a real, via a modification of the forcing described above, so as to preserve Σ^n_m-indescribability (see [5, Sect. 4.4]). Preservation of Π^n_m-indescribability for $n > 1$ is an open problem.

When considering the relevance of Jensen coding, we see the importance of indiscernible preservation:

5.22 Proposition. *Suppose that $A \subseteq L$ preserves indiscernibles. Then there is a real $R \in L[A, 0^\#]$ generic over $\langle L[A], A\rangle$ such that A is definable in $L[R]$. Moreover, R preserves indiscernibles.*

The following proof of Proposition 5.22 is reminiscent of the proof of relevance for coherent Easton forcing at successors.

Proof. First assume that $A = \emptyset$. For any indiscernible i let j_n be the first n indiscernibles $\geq i$. Then define $s_n \in S^{i^+}$ and $p^n \in P^{s_n}$ recursively, meeting the following conditions: $s_0 = \emptyset$, $p^0 =$ the trivial condition. $s_{n+1} = \pi_i(p^n)_{i^+}$ where $\pi_i : L \to L$ is an elementary embedding with critical point i, $p^{n+1} =$ least $q \leq p^n$ in P^{s_n} meeting $\Sigma^{p^n}_{f_n}$ where $f_n(\beta) = \mathrm{Hull}(\beta \cup j_n)$ if $\beta \in \mathrm{Hull}(\beta \cup j_n)$, $f_n(\beta) = \emptyset$ otherwise. (β ranges over $\mathrm{Card} \cap i^+$ and when $\beta = i$ we take $p^n_{\beta+}$ to be s_n.) Let $G^i_0 = \{p \mid p \text{ is extended by some } p^n\}$.

G^i_0 is *not* P^{s_n}-generic over $\mathcal{A}^{s_n}$ in general as all conditions in G^i_0 have empty restraint at indiscernibles $< i$. But notice that for $i_0 < i_1 < \cdots < i_n \leq i$ in I, $G^{i_0}_0 \cup \cdots \cup G^{i_n}_0$ is a compatible set of conditions. We take G^i to be $\{p \mid p \text{ is extended by } q_0 \wedge \cdots \wedge q_n \text{ for some } q_l \in G^{i_l}_0,\ i_0 < \cdots < i_n \leq i \text{ in } I\}$. Now we claim that G^i is P^{s_n}-generic over $\mathcal{A}^{s_n}$ for each n. Indeed, if D is predense on P^{s_n} and belongs to $\mathcal{A}^{s_n}$, $D \in \mathrm{Hull}(\{k_0, \ldots, k_m\} \cup j_n)$ with $k_0 < \cdots < k_m < i$ in I then p^{n+1} reduces D below k^+_m, p^{n+2} reduces D below $k^+_{m-1}, \ldots$ and eventually we get p^{n+m+2} in G^i meeting D.

It follows that $G^i(<i) = G^i \cap P^i$ is generic over L_i (for L_i-definable dense sets) and hence G is P-generic over L where $G = \bigcup\{G^i(<i) \mid i \in I\}$. Clearly G preserves indiscernibles.

If $A \neq \emptyset$ then first force to obtain GCH, preserving indiscernibles, and then apply the above argument. ⊣

5.23 Corollary (Jensen). *There is a real $R <_L 0^\#$, R not set-generic over L. Hence the genericity problem has an affirmative solution when "generic" is interpreted to mean "set-generic".*

Not every $A \subseteq L$ can be coded generically by a real, in the presence of $0^\#$, as a result of Paris's work on "patterns of indiscernibles":

5.24 Definition. For $\alpha, \beta \in \mathrm{On}$, $\beta \neq 0$ let $I_{\alpha,\beta} = \{i_{\alpha+\beta\gamma} \mid \gamma \in \mathrm{On}\}$ where $\langle i_\alpha \mid \alpha \in \mathrm{On}\rangle$ is the increasing enumeration of I.

For any real R with $L[R]$ not rigid, the *Silver indiscernibles for* $L[R]$ are defined just like the Silver indiscernibles for L, replacing L by $L[R]$. In this case we say that "$R^\#$ exists".

5.25 Theorem (Paris [14]). *If $R \subseteq \omega$ and $0^\# \notin L[R]$, then for some $\alpha, \beta < \omega_1$, $I_{\alpha,\beta} =$ the Silver indiscernibles for $L[R]$.*

There exist classes $A \subseteq L$ which are generic over L, yet relative to which $I_{\alpha,\beta}$ is *not* a class of indiscernibles for any pair α, β. (For any $B \subseteq I$, there is A generic over L such that $A \cap I = B$; but B can be chosen to split each

$I_{\alpha,\beta}$.) It follows that A cannot be generically coded by a real R, as any such R satisfies the hypothesis of Paris's theorem. However this is the only restriction.

5.26 Theorem. *If $I_{\alpha,\beta}$ is a class of indiscernibles for $\langle L[A], A\rangle$ for some $\alpha, \beta < \omega_1$, then there is a real $R \in L[A, 0^{\#}]$ generic over $\langle L[A], A\rangle$ such that A is definable in $L[R]$. Moreover, $I_{\alpha,\beta}$ is a class of indiscernibles for $L[R]$.*

In addition:

5.27 Theorem. *For any $\alpha, \beta < \omega_1$ there exists a real R such that $I_{\alpha,\beta} =$ the Silver indiscernibles for $L[R]$.*

Theorems 5.26 and 5.27 are proved by first using reverse Easton methods to create $A^* \subseteq L$ such that $I_{\alpha,\beta}$ is a *generating* class of indiscernibles for $\langle L[A^*], A^*\rangle$ and then using the method of Proposition 5.22 to code A^* by a real, preserving the indiscernibility of $I_{\alpha,\beta}$.

6. The Solovay Problems

We are now prepared to discuss the solutions to the three problems posed in Sect. 1. For a full treatment of this material, we refer the reader to Chaps. 5, 6, 7 of [5].

The Genericity Problem

We show that there is a real $R <_L 0^{\#}$ which is not class-generic over L. First recall the statement of the Truth Lemma, which holds for all tame L-forcings:

Truth Lemma. If G is P-generic over $\langle L, A\rangle$ then

$$\langle L[G], A, G\rangle \vDash \varphi(\sigma_1^G, \ldots, \sigma_n^G) \quad \text{iff for some } p \in G, \quad p \Vdash \varphi(\sigma_1 \ldots \sigma_n).$$

We also have:

Uniform Definability Lemma. The relation "$p \Vdash \varphi(\sigma_1, \ldots, \sigma_n)$" is definable as a relation of $p, \varphi, \langle\sigma_1, \ldots, \sigma_n\rangle$ over $\langle L, \mathrm{Sat}\langle L, A\rangle\rangle$ where $\mathrm{Sat}\langle L, A\rangle$ denotes the Satisfaction relation for $\langle L, A\rangle$.

6.1 Remark. $\langle L, \mathrm{Sat}\langle L, A\rangle\rangle$ is amenable, as $\langle L, A\rangle$ amenable implies that $\langle L_i, A \cap L_i\rangle \prec \langle L, A\rangle$ for sufficiently large $i \in I$.

A consequence is the following:

If G is P-generic over $\langle L, A\rangle$, then $\mathrm{Sat}\langle L[G], A, G\rangle$ is definable over the structure $\langle L[G], \mathrm{Sat}\langle L, A\rangle, G\rangle$.

Using this, we can see a strategy for producing a real R *not* generic over L: If $R \in L[G]$ where G is P-generic over $\langle L, A\rangle$, then by the above and Tarski's Undefinability of Satisfaction, $\mathrm{Sat}\langle L, A\rangle$ *cannot* be definable over $\langle L[G], A, G\rangle$ and hence *cannot* be definable over $\langle L[R], A\rangle$. Thus:

6.2 Proposition. *If $R \subseteq \omega$ is generic over L, then for some amenable $\langle L, A\rangle$, $\mathrm{Sat}\langle L, A\rangle$ is not definable over $\langle L[R], A\rangle$.*

6.3 Theorem. *There is a real $R <_L 0^\#$ such that $\mathrm{Sat}\langle L, A\rangle$ is definable over $\langle L[R], A\rangle$ for every amenable $\langle L, A\rangle$.*

To prove Theorem 6.3 we define for each $i \in I$ a forcing $P_i \subseteq L_{i^+}$ for producing $X_i \subseteq i$ such that for each constructible $A \subseteq i$, $\mathrm{Sat}\langle L_i, A\rangle$ is definable over $\langle L_i[X_i], A, X_i\rangle$. This forcing P_i is of the Easton variety and hence preserves cofinalities. The main part of the proof consists in showing that there is a single $X \subseteq \mathrm{On}$ definable in $L[0^\#]$ such that $X \cap i$ is P_i-generic for all $i \in I$ simultaneously, and such that X preserves indiscernibles. Then for each amenable $\langle L, A\rangle$, $\mathrm{Sat}\langle L, A\rangle$ is definable over $\langle L[X], A, X\rangle$ and X can be coded by a real $R <_L 0^\#$ with the same property, using the fact that X preserves indiscernibles and Proposition 5.22.

The proof is not special to the Sat operator and can be used to prove:

6.4 Theorem. *Suppose that $F : \mathcal{P}^L(\omega_1) \to \mathcal{P}^L(\omega_1)$ is constructible, where $\mathcal{P}^L(\omega_1)$ is the set of constructible subsets of ω_1. Then there is a real $R <_L 0^\#$ such that $F(A)$ is definable over $\langle L_{\omega_1}[R], A\rangle$ for all $A \in \mathcal{P}^L(\omega_1)$.*

The Π^1_2-Singleton Problem

The following result gives an affirmative solution to this problem:

6.5 Theorem. *There is a real R such that $0 <_L R <_L 0^\#$ and R is the unique solution to a Π^1_2 formula.*

The heart of the matter is to build an L-definable forcing with a unique generic, in the form of a real. To guarantee uniqueness we design our forcing so as to make our generic "guess" at which ordinals belong to I, the class of Silver indiscernibles. Of course no generic can correctly answer this question, but we arrange that only one generic does a reasonable job of guessing, in the sense that other potential generics would in fact produce closed unbounded classes disjoint from I, an impossibility. More precisely, a generic consists of a real R and a class A such that:

(a) R codes A as in Jensen coding.

(b) There is a $\Sigma_1(L)$ procedure $(i_1, \dots, i_n) \mapsto p(i_1, \dots, i_n)$ such that the generic corresponding to (R, A) is $\{p(i_1, \dots, i_n) \mid i_1 < \cdots < i_n \text{ in } I\}$.

(c) A adds closed unbounded sets so as to "kill" any $(i_1, \dots, i_n)$ such that $p(i_1, \dots, i_n)$ disagrees with R (in the sense that any generic containing $p(i_1, \dots, i_n)$ corresponds to (R', A') for some real R' different from R).

(d) No $(i_1, \dots, i_n) \in I^n$ can be killed.

It follows that $\{p(i_1, \ldots, i_n) \mid i_1 < \cdots < i_n \text{ in } I\}$ is the *only* generic, as by (c) another generic R' would kill $(i_1, \ldots, i_n) \in I^n$ such that $p(i_1, \ldots, i_n)$ disagrees with R', an impossibility by (d).

Of course there is a circularity here, as to design P we need the procedure in (b), which is defined assuming that we know P. This is resolved using the Recursion Theorem.

The killing method above involves forcing of the reverse Easton variety and the coding of A by R uses Jensen coding, a variety of coherent Easton forcing at successors. Thus unlike the solution to the genericity problem, here we must mix the relevance arguments for two different types of class forcing together, to obtain a generic in $L[0^\#]$ for P.

The Admissibility Spectrum Problem

We first describe the proof of:

6.6 Theorem (David [3], Friedman [5]). *There is a real $R <_L 0^\#$ such that $\Lambda(R) \subseteq$ the recursively inaccessible ordinals.*

We wish to arrange that R-admissibles be recursively inaccessible. Suppose that we have a $D \subseteq \omega_1$ such that D-admissibles are recursively inaccessible. (α is *D-admissible* if $L_\alpha[D]$ obeys ZFC^-, with Replacement restricted to formulas which are Σ_1 and mention D as a predicate.) Then we may hope to code D by a real R with the same property. However, if we code D by R in the usual way (with almost disjoint forcing) we only obtain:

$$\alpha \text{ is } R\text{-admissible} \to \alpha \text{ is } D \cap \omega_1^{L_\alpha}\text{-admissible}.$$

The reason is that to decode D from R we need to know the almost disjoint coding reals R_ξ and it is only for $\xi < \omega_1^{L_\alpha}$ that we have $R_\xi \in L_\alpha$. Thus the recovery of D from R is not "fast enough". On the other hand we would be in good shape if D were to have the following stronger properties:

($*$) If α is $D \cap \xi$-admissible and $L_\alpha[D \cap \xi] \vDash \xi = \omega_1$, then α is recursively inaccessible.

($**$) If α is D-admissible and $L_\alpha[D] \vDash \omega_1$ does not exist, then α is recursively inaccessible.

For then we need only recover $D \cap \omega_1^{L_\alpha}$ inside $L_\alpha[R]$ to guarantee that α be recursively inaccessible (or inadmissible relative to R), a recovery that can be successfully made.

The question is how to obtain $D \subseteq \omega_1$ obeying ($*$), ($**$). The natural thing to do is to force with conditions d which are bounded subsets of ω_1 obeying ($*$), ($**$) for $\xi \leq \sup(d)$, ordered by end extension. We now come to the key part of the argument, which is contained in the following two observations:

(a) Extendibility for this forcing is trivial because given d and $\xi > \sup(d)$ we are free to extend d to length ξ by killing all admissibles between $\sup(d)$ and ξ. It is important for this argument that we are only concerned with killing admissibility, not with preserving it.

(b) Distributivity for this forcing is easily established assuming the following: There exists a $D' \subseteq \omega_2$ such that:

$(*')$ If α is $D' \cap \xi$-admissible and $L_\alpha[D' \cap \xi] \vDash \xi = \omega_2$ then α is recursively inaccessible.

$(**')$ If α is D'-admissible and $L_\alpha[D'] \vDash \omega_2$ does not exist, then α is recursively inaccessible.

Thus, we are faced with the original difficulty, but one cardinal higher! However note that we need not already have all of D' before we can start building D; thus the idea of the proof (as in other Jensen coding constructions) is to build $R, D, D', D'', \ldots$ simultaneously and check distributivity for any final segment of the forcing.

To solve the admissibility spectrum problem we must introduce the requirement of admissibility *preservation* into the above. This requires the method of *strong coding*.

6.7 Theorem. *There is a real $R <_L 0^\#$ such that $\Lambda(R) =$ the recursively inaccessible ordinals.*

We approach the problem as in the previous proof. Of course the Extendibility property is more difficult to establish (Distributivity is approximately the same). Indeed the desired extension of d to d' of length $\geq \xi$ must be made so as to preserve the admissibility of recursively inaccessible ordinals. Thus our conditions must be constructed out of sets which are generic for "local" versions of the full forcing. In fact we construct a strong coding forcing $P^\beta \subseteq L_\beta$ at each admissible β and then inductively build P^β out of sets which are generic for the various $P^{\beta'}$ for $\beta' < \beta$.

The main difficulty is in showing that the desired locally generic sets actually exist; note that we want a P^β-generic over L_β to exist where β may be uncountable. The proof of local generic existence is by a simultaneous induction with the proofs of Extendibility and Distributivity and requires a substantial use of the kind of fine structure theory used in the construction of higher gap morasses.

7. Generic Saturation

Suppose that P is an L-forcing which has a generic; need it have a generic definable in $L[0^\#]$? Not necessarily, as the forcing P could produce a real R that guarantees the countability of $\omega_1^{L[0^\#]}$, and clearly no such real can exist in $L[0^\#]$. However, we can weaken this slightly to obtain a positive result:

7.1 Definition. Suppose that $M \subseteq N$ are inner models of ZFC. We say that N is *generically saturated over* M if whenever an M-forcing has a generic, then it has one definable in a set-generic extension of N.

With a mild assumption about On = the class of all ordinals, it can be shown that $L[0^\#]$ is generically saturated over L. This assumption involves the concept of an *Erdős cardinal*.

7.2 Definition. A cardinal κ is α-*Erdős* if whenever $A \subseteq \kappa$ and C is closed unbounded in κ, there exists an $X \subseteq C$ such that ordertype $X = \alpha$ and $\gamma \in X$ implies $X - \gamma$ is a set of indiscernibles for $\langle L[A], A, \delta\rangle_{\delta<\gamma}$. We say that On is α-Erdős if this holds where κ is replaced by On and indiscernibility is only required for Σ_1 formulas.

7.3 Theorem. *Suppose that* On *is* $\omega+\omega$*-Erdős. Then* $L[0^\#]$ *is generically saturated over* L.

Theorem 7.3 is proved by starting with G P-generic over $\langle L, A\rangle$ and using $\omega+\omega$ indiscernibles for $\langle L[G, 0^\#], A, G\rangle$ to produce another P-generic G^*, which is "periodic". The latter means that for some $\alpha \in$ On and $0 < \beta \in$ On, $I_{\alpha,\beta} = \{i_{\alpha+\beta\gamma} \mid \gamma \in \text{On}\}$ is a class of indiscernibles for $\langle L[G^*], A, G^*\rangle$, where $I = \langle i_\alpha \mid \alpha \in \text{On}\rangle$ is the increasing enumeration of I. Then by an absoluteness argument, such a G^* may be defined in a set-generic extension of $L[0^\#]$ in which α and β are countable.

Proof of Theorem 7.3. Suppose that $G \subseteq P$ is P-generic over $\langle L, A\rangle$. We shall construct another P-generic G^* (in a set-generic extension of V) such that G^* has periodic indiscernibles.

Let X be a set of indiscernibles for $\langle L[0^\#, G], G, A\rangle$ of ordertype $\omega+\omega$ such that $\alpha \in X \to \alpha$ is Σ_1-stable in $0^\#, G, A$. The latter means that $\langle L_\alpha[0^\#, G\cap L_\alpha], G\cap L_\alpha, A\cap L_\alpha\rangle$ is Σ_1-elementary in $\langle L[0^\#, G], G, A\rangle$. We can obtain X as $C = \{\alpha \mid \alpha \text{ is } \Sigma_1\text{-stable in } 0^\#, G, A\}$ is closed unbounded.

Choose $\langle D(\alpha_1, \dots, \alpha_n) \mid \alpha_1 < \dots < \alpha_n \text{ in On}\rangle$ such that each $\langle L, A\rangle$-definable open dense $D \subseteq P$ is of the form $D(\alpha_1, \dots, \alpha_n)$ for some $\alpha_1 < \dots < \alpha_n$ in I. Also assume that this sequence is $\Delta_1\langle L, \text{Sat}\langle L, A\rangle\rangle$. Let $D^*(\alpha_1, \dots, \alpha_n) = \bigcap\{D(\vec\beta) \mid \vec\beta \text{ a subsequence of } \langle\alpha_1, \dots, \alpha_n\rangle\}$.

For $j_0 \in X$ choose $t_{j_0}(\vec{k_0}(j_0), j_0, \vec{k_1}(j_0))$ to be least in $D(j_0) \cap G$. By the choice of the indiscernibles X, we can write this as $t_0(\vec{k_0}, j_0, \vec{k_1}(j_0))$, and in addition $\vec{k_1}(j_0) < j_1$ for $j_0 < j_1$ in X.

Next for $j_0 < j_1$ in X choose $t_{j_0,j_1}(\vec{k_0^1}(j_0, j_1), j_0, \vec{k_1^1}(j_0, j_1), j_1, \vec{k_2^1}(j_0, j_1))$ to be least in $D^*(\vec{k_0}, j_0, \vec{k_1}(j_0), j_1, \vec{k_1}(j_1)) \cap G$. By the choice of X we can write this as $t_1(\vec{k_0^1}, j_0, \vec{k_1^1}(j_0), j_1, \vec{k_2^1}(j_0, j_1))$, and by Σ_1-stability this is less than j_2 whenever $j_1 < j_2$ in X. But we want to argue that in fact $\vec{k_2^1}(j_0, j_1)$ can be chosen *independently of* j_0.

Assuming the latter, we have $t_1(\vec{k_0^1}, j_0, \vec{k_1^1}(j_0), j_1, \vec{k_2^1}(j_1))$ belongs to $D^*(\vec{k_0}, j_0, \vec{k_1}(j_0), j_1, \vec{k_1}(j_1)) \cap G$ for $j_0 < j_1$ in X. By modifying t_1 we can guarantee that $\vec{k^1_1}(j_0) = \vec{k^1_2}(j_0)$ for all $j_0 \in X$, $j_0 \neq \min X$. Also we can arrange that $\vec{k_0} \subseteq \vec{k^1_0}$, $\vec{k_1}(j_0) \subseteq \vec{k^1_1}(j_0)$ for $j_0 \in X$. By indiscernibility, the structure $\langle \vec{k^1_1}(j_0), < \rangle$ with a unary predicate for $\vec{k_1}(j_0)$ has isomorphism type independent of the choice of $j_0 \in X$.

Similarly choose an element $t_2(\vec{k^2_0}, j_0, \vec{k^2_1}(j_0), j_1, \vec{k^2_1}(j_1), j_2, \vec{k^2_1}(j_2))$ of $D^*(\vec{k^1_0}, j_0, \vec{k^1_1}(j_0), j_1, \vec{k^1_1}(j_1), j_2, \vec{k^1_1}(j_2)) \cap G$ so that $\vec{k^1_0} \subseteq \vec{k^2_0}$ and for $j_0 \in X$, $\vec{k^1_1}(j_0) \subseteq \vec{k^2_1}(j_0)$ with the isomorphism type of $\langle \vec{k^2_1}(j_0), < \rangle$ with unary predicates for $\vec{k_1}(j_0), \vec{k^1_1}(j_0)$ independent of j_0. Continue with $t_3, t_4, \ldots$.

Let i_α be the minimum of X and β be the ordertype of $\bigcup\{\vec{k^n_1}(j_0) \mid n \in \omega\}$, an ordinal independent of the choice of $j_0 \in X$. In a generic extension where α is countable we may also arrange that $\bigcup\{\vec{k^n_0} \mid n \in \omega\} = I \cap i_\alpha$.

For any indiscernible i_γ define $\vec{k^n_1}(i_\gamma) \subseteq I \cap (i_\gamma, i_{\gamma+\beta})$ so that we have that $\langle I \cap (i_\gamma, i_{\gamma+\beta}), < \rangle$ with a predicate for $\vec{k^n_1}(i_\gamma)$ is isomorphic to $\langle \bigcup\{\vec{k^n_1}(j_0) \mid n \in \omega\}, < \rangle$ with a predicate for $\vec{k^n_1}(j_0)$, for $j_0 \in X$. Define: $G^* = \{p \in P \mid p$ is extended by some $t_n(\vec{k^n_0}, i_{\alpha_1}, \vec{k^n_1}(i_{\alpha_1}), \ldots, i_{\alpha_n}, \vec{k^n_1}(i_{\alpha_n}))$ where $\alpha \leq \alpha_1 < \cdots < \alpha_n$ are of the form $\alpha + \beta\gamma$ for some $\gamma \in \mathrm{On}\}$. Using the indiscernibility of $I - i_\alpha$ in $\langle L, A \rangle$, G^* is compatible and meets every $\langle L, A \rangle$-definable open dense subclass of P. Thus G^* is P-generic and $I_{\alpha,\beta}$ is a class of indiscernibles for $\langle L[G^*], A, G^* \rangle$.

To complete the proof we return to the problem of making $\vec{k^1_2}(j_0, j_1)$ independent of j_0. First a lemma:

7.4 Lemma. *Let $x < y$ by the maximum difference order on finite sets of ordinals: $x < y$ iff $\alpha \in y$ where α is the greatest element of the symmetric difference of x and y. For any $j_0 < j_1$ in X and any open dense D definable in $\langle L, A \rangle$ there exists a $t(\vec{\ell_0}, j_0, \vec{\ell_1}, j_1, \vec{\ell_2}, \vec{\ell}) \in L_{\min(\vec{\ell})} \cap D \cap G$ such that $\vec{\ell_0} < j_0 < \vec{\ell_1} < j_1 < \vec{\ell_2} < \vec{\ell}$ belong to I and $\vec{\ell_0} \cup \vec{\ell_1} \cup \vec{\ell_2}$ is the $<$-least finite set of ordinals (not necessarily indiscernibles) x such that $t(x \cap j_0, j_0, x \cap (j_0, j_1), j_1, x - j_1, \vec{\ell})$ belongs to $L_{\min(\vec{\ell})} \cap D \cap G$.*

Proof. Let x be $<$-least such that for some t and indiscernibles $\vec{\ell} > \max(x)$, $t(x \cap j_0, j_0, x \cap (j_0, j_1), j_1, x - j_1, \vec{\ell}) \in L_{\min(\vec{\ell})} \cap D \cap G$. If some $\alpha \in x$ were not in I then there would be a $t^*(x^* \cap j_0, j_0, x^* \cap (j_0, j_1), j_1, x^* - j_1, \vec{\ell^*}) = t(x \cap j_0, j_0, x \cap (j_0, j_1), j_1, x - j_1, \vec{\ell})$ with $\vec{\ell}$ an initial segment of $\vec{\ell^*}$ and $x^* - \alpha = x^* - (\alpha + 1)$, as α is L-definable from indiscernibles $< \alpha$ and indiscernibles $> \vec{\ell}$. So let $\vec{\ell_0}, \vec{\ell_1}, \vec{\ell_2}$ be $x \cap j_0, x \cap (j_0, j_1), x - j_1$. ⊣

For $j_0 < j_1$ in X choose

$$t_{j_0,j_1}(\vec{k^1_0}(j_0, j_1), j_0, \vec{k^1_1}(j_0, j_1), j_1, \vec{k^1_{2,0}}(j_0, j_1), \vec{k^1_{2,1}}(j_0, j_1))$$

to be least satisfying Lemma 7.4 with $D = D^*(\vec{k_0}, j_0, \vec{k_1}(j_0), j_1, \vec{k_1}(j_1))$, and

$\vec{\ell}$ denoted by $k^{\vec{1}}_{2,1}(j_0, j_1)$. By the choice of X we can write this as

$$t_1(k^{\vec{1}}_0, j_0, k^{\vec{1}}_1(j_0), j_1, k^{\vec{1}}_{2,0}(j_0, j_1), \vec{\infty}),$$

where $\vec{\infty}$ denotes an arbitrary sequence of large indiscernibles (of the appropriate length). Note that $\langle k^{\vec{1}}_0, k^{\vec{1}}_1(j_0), k^{\vec{1}}_{2,0}(j_0, j_1)\rangle$ is definable in $\langle L[G], A, G\rangle$ from $\vec{k_0}, j_0, \vec{k_1}(j_0), j_1, \vec{k_1}(j_1), \vec{\infty}$ and so $k^{\vec{1}}_{2,0}(j_0, j_1)$ is definable in $\langle L[G], A, G\rangle$ from $\vec{k_1}(j_1), \vec{\infty}$ and ordinals $\leq j_1$.

7.5 Claim. $k^{\vec{1}}_{2,0}(j_0, j_1)$ *is independent of* j_0.

Proof. Let $j_0 < j_1 < \cdots < j$ be the first $\omega + 1$ elements of X and for any n, m let $\vec{k}(j_n, j)(m) = m$th element of $k^{\vec{1}}_{2,0}(j_n, j)$. If the Claim fails then for some fixed m, $\vec{k}(j_0, j)(m) < \vec{k}(j_1, j)(m) < \cdots$ is an increasing sequence of indiscernibles with supremum $\ell \in I$ (using the fact that $X - j$ has ordertype $>$ length$(\vec{\infty})$). As these ordinals are definable in $\langle L[G], A, G\rangle$ from ordinals in $(j+1) \cup \vec{k_1}(j) \cup \vec{\infty}$ we get that ℓ has cofinality $\leq j$ in $L[G]$. But $0^\# \notin L[G]$ (as G is generic over L) so by Jensen's Covering Theorem, ℓ has L-cofinality $< (j^+$ in $L[G])$. As $\ell \in I$, ℓ is L-regular and hence j^+ in $L < j^+$ in $L[G]$.

But then in $L[G]$ there is a closed unbounded $C \subseteq j$ such that $D \subseteq j$, D closed unbounded, $D \in L \to C \subseteq D \cup \alpha$ for some $\alpha < j$. Now $I \cap j$ is the intersection of countably many such D's and therefore as j has uncountable cofinality (in $L[G, 0^\#]$) we get $C \subseteq I \cup \alpha$ for some $\alpha < j$. This yields $0^\# \in L[G]$, contradiction.

This proves the claim. ⊣

With the claim we see that there is a P-generic G^* (in a set-generic extension of V) such that $\langle L[G^*], A, G^*\rangle$ has a periodic class of indiscernibles $I_{\alpha,\beta}$. It now follows by absoluteness that there is such a G^* definable in a set-generic extension of $L[0^\#]$ in which α and β are countable. This completes the proof of Theorem 7.3. ⊣

It can be shown that there can be no countable bound on the α and β of the previous proof, using the solution to the Π^1_2-singleton problem. (See [5, Sect. 8.2].)

8. Further Results

The material below is discussed in [5, Chap. 8].

Strict Genericity

In set forcing, one may show that an inner model of a generic extension is itself a generic extension. This can fail for class forcing.

8.1 Definition. Let M be a an inner model of ZFC. A real R is *generic* over M if it belongs to a generic extension of M (via a forcing defined over a ground model of the form $\langle M, A\rangle$). R is *strictly generic* over M if for some ground model $\langle M, A\rangle$, some forcing P definable over $\langle M, A\rangle$ and some G P-generic over $\langle M, A\rangle$, R belongs to $M[G]$ and G is definable over $\langle M[R], A\rangle$.

8.2 Theorem. *There is a real $R <_L 0^\#$ such that R is generic over L (for an L-definable forcing) but R is not strictly generic over L.*

As with the solution to the genericity problem, Theorem 8.2 is reduced to the violation of a definability property: If R is strictly generic over L then for some A amenable to L, $\mathrm{Sat}\langle L[R], \emptyset\rangle$ is definable over $\langle L[R], A\rangle$. The latter can be violated using class forcing.

Minimal Universes

The minimal model of $V = L[0^\#]$ can be "minimized" by a class which does *not* construct $0^\#$:

8.3 Theorem. *Suppose that for no α is $L_\alpha[0^\#]$ a model of* ZFC*. Then there is an $A \subseteq \mathrm{On}$ definable in $L[0^\#]$ such that $0^\# \notin L[A]$ and for no α is $\langle L_\alpha[A], A \cap \alpha\rangle$ elementary in $\langle L[A], A\rangle$.*

This result is partial evidence for the conjecture that $0^\#$ is generic over some proper inner model of $L[0^\#]$.

Countable Π^1_2 Sets

Assume that $R^\#$ exists for every real R (i.e. that $L[R]$ is not rigid, for every real R). Kechris and Woodin [10] showed that a nonempty countable Π^1_2 set must have an ordinal-definable element; we show that in a sense their result is optimal. First some definitions.

8.4 Definition. A set of reals X is *n-absolute* if for some formula φ, $R \in X \leftrightarrow L[R] \models \varphi(R, \omega_1, \ldots, \omega_n)$, where ω_k denotes the ω_k of V. An n-absolute singleton is a real R such that $\{R\}$ is n-absolute. We say *absolute* for 0-absolute, and *absolute singleton* for 0-absolute singleton.

8.5 Theorem (Kechris-Woodin [10]). *Assume $R^\#$ exists for every real R. A nonempty countable Π^1_2 set contains an n-absolute singleton for some n.*

Our next result demonstrates the optimality of the previous theorem.

8.6 Theorem. *For each n there is a countable Π^1_2 set X_n such that $R \in X_n$ implies that R is not an n-absolute singleton.*

Not all elements of countable Π^1_2 sets are n-absolute singletons for some n:

8.7 Theorem. *There exists a countable Π^1_2 set X and $R \in X$ such that for all n, R is not an n-absolute singleton.*

Not every absolute singleton belongs to a countable Π^1_2 set: If a set is Σ^1_2 (with a constructible parameter) and contains a non-constructible real, then it has a constructibly-coded perfect closed subset, and a code for this perfect closed set can be computed as a Σ^1_2 function applied to an index $n \in \omega$ for the given Σ^1_2 set X_n. Moreover, $\{n \mid X_n$ has a perfect closed subset$\}$ is Σ^1_2. It follows that in L there is a perfect closed set C, with code recursive in the complete Σ^1_2 subset of ω, such that $R \in C$ implies R does not belong to any Π^1_2 set whose complement contains a non-constructible real. In particular $R \in C$ implies R does not belong to a countable Π^1_2 set. As the set C has code recursive in the complete Σ^1_2 set, it contains elements which are Δ^1_3 in L, and hence which are absolute singletons.

An open problem is to provide a revealing characterization of the reals which belong to a countable Π^1_2 set.

In [8] it is proved: If X is a nonempty Π^1_2 set then X has an element R such that either $R \leq_L 0^\#$ or $0^\# \leq_L R$. Our next result implies that $0^\#$ has least nonzero L-degree among reals with this property, even when X is restricted to have a unique element.

8.8 Theorem. *There exists a sequence $\langle (R^n_0, R^n_1) \mid n \in \omega \rangle$ of pairs of reals such that:*

(a) If a real $R \leq_L R^n_0$ and $R \leq_L R^n_1$, then $R \in L$.

(b) $\{\langle R, n, i\rangle \mid R = R^n_i\}$ is Π^1_2.

(c) $n \in 0^\# \longleftrightarrow n \in R^n_0 \longleftrightarrow n \in R^n_1$.

8.9 Corollary. *Suppose that R is a non-constructible real and every Π^1_2-singleton is $\leq_L$-comparable with R. Then $0^\# \leq_L R$.*

Thus $0^\#$ is the least "canonical" Π^1_2-singleton.

New Σ^1_3 Facts

If M is an inner model with $0^\# \notin M$, then of course there is a true Σ^1_3 sentence not holding in M, namely the sentence asserting the existence of $0^\#$; can this effect be achieved by forcing over M?

8.10 Theorem. *There exists an ω-sequence of Σ^1_3 sentences $\langle \varphi_n \mid n \in \omega\rangle$ such that if M is an inner model, $0^\# \notin M$:*

(a) φ_n is false in M for some n.

(b) For each n, some generic extension of M satisfies φ_n.

Moreover, if $M = L[R]$ for some real R, then the generic extensions in (b) can be taken to be inner models of $L[R, 0^\#]$.

The proof is based on the following, which may be of independent interest.

8.11 Theorem. *There exists an L-definable function $n : L\text{-Singulars} \to \omega$ such that if M is an inner model with $0^\# \notin M$:*

(a) For some n, $M \models \{\alpha \mid n(\alpha) \le n\}$ is stationary.

(b) For each n there is a generic extension of M in which $0^\#$ does not exist and $\{\alpha \mid n(\alpha) \le n\}$ is non-stationary.

In (a) of the previous theorem, we intend that whenever $C \subseteq \mathrm{On}$ is closed unbounded and M-definable, then there is an $\alpha \in C$, $n(\alpha) \le n$. In (b) we intend that the generic extension satisfy ZFC and have a definable closed unbounded class $C \subseteq \mathrm{On}$ such that $\alpha \in C \to n(\alpha) > n$.

Killing Admissibles Revisited

8.12 Definition. α is *quasi R-admissible* if every well-ordering in $L_\alpha[R]$ has ordertype less than α.

R-admissibility implies quasi R-admissibility, but not conversely, as the limit of the first ω R-admissibles is quasi R-admissible but not R-admissible. Let $\Lambda^*(R)$ denote $\{\alpha > \omega \mid \alpha \text{ is quasi } R\text{-admissible}\}$, a closed unbounded class of ordinals containing $\Lambda(R)$.

8.13 Theorem. *Suppose that φ is Σ_1 and $L \models \varphi(\kappa)$ whenever κ is an L-cardinal. Then there is a real $R <_L 0^\#$ such that $\Lambda^*(R) \subseteq \{\alpha \mid L \models \varphi(\alpha)\}$.*

8.14 Corollary (Beller [1]). *Suppose that α is countable, $L_\alpha \models \mathrm{ZF}$. Then for some real R, α is the least ordinal such that $L_\alpha[R] \models \mathrm{ZF}$.*

8.15 Corollary. *There is a real $R <_L 0^\#$ such that $\Lambda^*(R) \subseteq \{\alpha \mid L_\alpha \models \mathrm{ZFC}^-\}$.*

Non-Characterizability of Admissibility Spectra

There cannot be a simple characterization of admissibility spectra, by virtue of the following result.

8.16 Theorem. *Let $X = \{A \subseteq \omega_1^L \mid A \in L$ and for some real R, $\omega_1^{L[R]} = \omega_1^L$ and $\Lambda(R) \cap \omega_1^L = A\}$. Then $X =_L 0^\#$.*

Δ_1-Coding

The results described here (with the exception of Theorem 8.27) are taken from [6]. A real R Δ_1*-codes* a class $A \subseteq \mathrm{On}$ iff A is Δ_1-definable over $L[R]$. Every L-amenable class A is Δ_1-coded by $0^\#$. The next result provides a converse to this result.

8.17 Proposition. *Suppose that L-Card $= \{\alpha \mid \alpha$ is a cardinal of $L\}$ is Σ_1 over $L[R]$, for a real R. Then $0^\# \le_L R$.*

Proof. Suppose that the Σ_1 definition has parameters less than κ, where κ is a singular cardinal. As κ^+ is an L-cardinal, by reflection there must be unboundedly many $\alpha < \kappa^+$ such that $\alpha \in L$-Card. But then $(\kappa^+)^L < \kappa^+$, which implies that $0^\#$ exists. As this argument can be carried out in $L[R]$, in fact $0^\# \leq_L R$. ⊣

We introduce a sufficient condition for an L-amenable class to be Δ_1-coded by a real which is class-generic over L. To motivate it we first indicate a necessary condition for Δ_1-codability:

8.18 Definition. Suppose that x is an extensional set (i.e., $\langle x, \in\rangle$ satisfies the Axiom of Extensionality). Let $\bar{x}$ denote the transitive collapse of x. For $A \subseteq \mathrm{On}$ we say that x *preserves* A if $\langle \bar{x}, \in, A \cap \bar{x}\rangle$ is isomorphic to $\langle x, \in, A \cap x\rangle$.

8.19 Definition. For a set x and ordinal δ, $x[\delta]$ denotes $\{f(\gamma) \mid \gamma < \delta,$ $f \in x$, f a function whose domain contains $\gamma\}$. We say that x strongly preserves $A \subseteq \mathrm{On}$ if $x[\delta]$ is extensional and preserves A for each cardinal δ. A sequence of extensional sets $t_0 \subseteq t_1 \subseteq \cdots$ is tight if it is continuous (i.e., $t_\lambda = \bigcup\{t_i \mid i < \lambda\}$ for limit λ) and for each i: $t_i = t_{i+1}$ or $t_i \in t_{i+1}$, $\langle \bar{t}_j \mid j < i\rangle$ belongs to the least ZFC^- model containing $\bar{t}_i$ as an element which correctly computes $\mathrm{Card}(\bar{t}_i)$.

Condensation Condition. Suppose that t is transitive, κ is regular, $\kappa \in t$ and $x \in t$. Then:

(a) There is a tight κ-sequence $t_0 \prec t_1 \prec \cdots \prec t$ such that $x \in t_0$ and for each $i < \kappa$: $\mathrm{Card}(t_i) = \kappa$ and t_i strongly preserves A.

(b) If κ is inaccessible, then there exists a $t_0 \prec t_1 \prec \cdots \prec t$ as above, but where each $\mathrm{Card}(t_i) = \omega_i$.

8.20 Theorem (Δ_1-Coding Theorem). *Suppose that A is L-amenable and obeys the Condensation Condition in L. Then A is Δ_1-coded in a tame class-generic extension of $\langle L, A\rangle$ by a real R such that $L, L[R]$ have the same cofinalities.*

8.21 Corollary. *Suppose that A is L-amenable, obeys the Condensation Condition in L and preserves indiscernibles. Then A is Δ_1-definable over $L[R]$ for some indiscernible preserving real R such that L and $L[R]$ have the same cofinalities.*

We can apply the above to show that $L\text{-Cof}(\omega) = \{\alpha \mid \alpha \text{ has } L\text{-cofinality } \omega\}$ is Δ_1-definable in $L[R]$, where R is a real not constructing $0^\#$.

8.22 Lemma. *There is a real R_0, class-generic over L, such that $R_0 <_L 0^\#$, the cardinals of $L[R_0]$ are those of L, excluding ω_1^L, and the Condensation Condition holds for $A = L\text{-Cof}(\omega)$ in $L[R_0]$.*

8.23 Corollary. *There is a real $R <_L 0^\#$ such that R is class-generic over L, R preserves indiscernibles, the cardinals of $L[R]$ are those of L, excluding ω_1^L, and L-$\mathrm{Cof}(\omega)$ is Δ_1 over $L[R]$.*

8.24 Corollary. *There is a real $R <_L 0^\#$ such that every quasi R-admissible has uncountable L-cofinality.*

8.25 Corollary. *There is a real $R <_L 0^\#$ such that the function $f(\alpha) = [\alpha]^\omega \cap L$ is Δ_1 over $L[R]$.*

An *immune partition* is $F : \mathrm{On} \to 2$ such that neither $\{\alpha \mid F(\alpha) = 0\}$ nor $\{\alpha \mid F(\alpha) = 1\}$ contains an infinite constructible set.

8.26 Corollary. *There is a real $R <_L 0^\#$ such that some immune partition is $\Delta_1(L[R])$.*

We consider the "characterization problem" for Δ_1-definability in a real: Is there an exact constructible criterion for a subset of an L-cardinal κ to be the intersection with κ of a predicate which is Δ_1-definable in $L[R]$ for some real R that preserves L-cardinals? The answer is "No" when κ is ω_3^L.

8.27 Theorem. *Let $S = \{X \subseteq \omega_3^L \mid X = \omega_3^L \cap A$ for some $A \subseteq \mathrm{On}$, A Δ_1-definable in $L[R]$ for some real R such that $L[R]$ and L have the same cardinals$\}$. Then $S =_L 0^\#$.*

Theorem 8.27 rules out any simple characterization of when an L-amenable predicate can be Δ_1-definable in a real not constructing $0^\#$.

Minimal Coding

We have the following strengthening of the Coding Theorem.

8.28 Theorem. *Suppose that $A \subseteq \mathrm{On}$ and $\langle L[A], A\rangle$ is a model of $\mathrm{ZFC} + \mathrm{GCH}$. Then there is an $\langle L[A], A\rangle$-definable class forcing P such that if $G \subseteq P$ is P-generic over $\langle L[A], A\rangle$:*

(a) $\langle L[A, G], A, G\rangle$ is a model of $\mathrm{ZFC} + \mathrm{GCH}$.

(b) $L[A, G] = L[R]$ for some real R and A, G are definable over $L[R]$ from the parameter R.

(c) $L[A]$ and $L[R]$ have the same cofinalities.

(d) R is minimal over $L[A]$: if $x \in L[R]$, then either $x \in L[A]$ or $R \in L[A, x]$.

Thus a universe obeying GCH can be "coded minimally" by a real. Note that in clause (d) of the Theorem, x is any set constructible from R, not necessarily a real.

Further Applications to Descriptive Set Theory

Solovay [70] established the consistency of a number of regularity properties for projective sets of reals, using a natural model in which ω_1 *is inaccessible to reals* (i.e., ω_1 is an inaccessible cardinal in $L[R]$ for each real R). In this section we construct other models with this property, which can be applied to the study of regularity properties for projective sets and projective prewellorderings.

Recall that a set of reals is $\mathbf{\Sigma^1_1}$ if it is the continuous image of a Borel set and is $\mathbf{\Pi^1_1}$ if its complement is $\mathbf{\Sigma^1_1}$. It is $\mathbf{\Sigma^1_{n+1}}$ if it is the continuous image of a $\mathbf{\Pi^1_n}$ set and is $\mathbf{\Pi^1_{n+1}}$ if its complement is $\mathbf{\Sigma^1_{n+1}}$. A set of reals is $\mathbf{\Delta^1_n}$ if both it and its complement are $\mathbf{\Sigma^1_n}$. Similar definitions apply to k-ary relations on the reals. It a set of reals (or k-ary relation in reals) is $\mathbf{\Sigma^1_n}$ for some n then we say that it is *projective*.

Regularity Properties

8.29 Definition. Measure ($\mathbf{\Sigma^1_n}$) is the assertion that every $\mathbf{\Sigma^1_n}$ set of reals is Lebesgue Measurable. Category ($\mathbf{\Sigma^1_n}$) is the assertion that every $\mathbf{\Sigma^1_n}$ set of reals has the Baire Property, i.e., has meager symmetric difference with some Borel set. Perfect ($\mathbf{\Sigma^1_n}$) is the assertion that any uncountable $\mathbf{\Sigma^1_n}$ set of reals contains a perfect closed subset. Similar definitions apply to $\mathbf{\Pi^1_n}, \mathbf{\Delta^1_n}$.

In ZFC one may prove Measure ($\mathbf{\Sigma^1_1}$), Category ($\mathbf{\Sigma^1_1}$), Perfect ($\mathbf{\Sigma^1_1}$). In Gödel's model L one has $\sim$Measure ($\mathbf{\Delta^1_2}$), $\sim$Category ($\mathbf{\Delta^1_2}$), $\sim$Perfect ($\mathbf{\Pi^1_1}$) using the fact that in L there is a $\mathbf{\Delta^1_2}$ wellordering of the reals (and the Kondo-Addison Uniformization Theorem for $\mathbf{\Pi^1_1}$). By extending ZFC slightly we get:

8.30 Theorem (Solovay [18]). *Assume that ω_1 is inaccessible to reals. Then the following hold: Measure ($\mathbf{\Sigma^1_2}$), Category ($\mathbf{\Sigma^1_2}$), Perfect ($\mathbf{\Sigma^1_2}$).*

Our next result implies that the previous Theorem is optimal. The proof is based on [2].

8.31 Theorem. *Assume the consistency of an inaccessible cardinal. Then there is a model in which:*

(a) ω_1 is inaccessible to reals.

(b) There is a Δ^1_3 wellordering of the reals, and hence $\sim$Measure (Δ^1_3), $\sim$Category (Δ^1_3).

(c) $\sim$Perfect (Π^1_2).

8.32 Remark. We use $\Sigma^1_n, \Pi^1_n, \Delta^1_n$ to denote the "effective" versions of $\mathbf{\Sigma^1_n}$, $\mathbf{\Pi^1_n}$, $\mathbf{\Delta^1_n}$; see [12] for details.

Another axiom with consequences for regularity properties of projective sets is Martin's Axiom (MA). (We take MA to include the hypothesis $\sim$ CH.)

8.33 Theorem. MA *implies Measure* $(\mathbf{\Sigma^1_2})$, *Category* $(\mathbf{\Sigma^1_2})$.

Again this is optimal.

8.34 Theorem. *This is a model of* MA *in which:*

(a) $\omega_1 = \omega_1^L$.

(b) There is a Δ^1_3 *wellordering of the reals.*

8.35 Remark. Perfect (Π^1_1) fails in the above model, as this property implies that ω_1^L is countable. It is not known if (a) can be replaced by "ω_1 is inaccessible to reals" in the previous theorem (assuming the consistency of a weakly compact cardinal; this is a necessary assumption for the consistency of MA + "ω_1 is inaccessible to reals").

Theorem 8.31 generalizes to higher levels of the projective hierarchy. Recall again that κ is *Mahlo* if κ is inaccessible and $\{\alpha < \kappa \mid \alpha \text{ is regular}\}$ is stationary.

8.36 Theorem. *Assume the consistency of a Mahlo cardinal. Then there is a model in which:*

(a) Measure $(\mathbf{\Sigma^1_3})$, *Category* $(\mathbf{\Sigma^1_3})$. *Perfect* $(\mathbf{\Sigma^1_3})$.

(b) There is a Δ^1_4 *wellordering of the reals.*

(c) $\sim$*Perfect* (Π^1_3).

8.37 Remark. To go further, one must replace L by a sufficiently $\mathbf{\Sigma^1_3}$ correct model. Thus, assuming the consistency of a Mahlo cardinal κ, together with "$x^\#$ exists for every bounded subset x of κ", one obtains a model of Measure $(\mathbf{\Sigma^1_4})$, Category $(\mathbf{\Sigma^1_4})$, Perfect $(\mathbf{\Sigma^1_4})$, $\sim$Perfect (Π^1_4) with a Δ^1_5 wellordering of the reals. However the author does not know if this use of #'s is necessary.

Prewellorderings

A *prewellordering* is a reflexive, transitive well-founded relation. A wellordering is obtained by identifying two elements a, b when $a \leq b$, $b \leq a$; the *length* of the prewellordering is the ordertype of its associated wellordering.

$\delta^1_{\mathbf{n}}$ denotes the supremum of the lengths of all $\mathbf{\Delta^1_n}$ prewellorderings of the reals.

8.38 Theorem (Classical). $\delta^1_{\mathbf{1}} = \omega_{\mathbf{1}}$.

Kunen and Martin showed that $\delta^1_{\mathbf{2}}$ is at most ω_2 (see [11]). The next result shows that this result is the best possible.

8.39 Theorem. *It is consistent with* ZFC *that* $\delta^1_{\mathbf{2}} = \omega_{\mathbf{2}}$.

Using the Condensation Condition, we can simultaneously have ω_1 inaccessible to reals:

8.40 Theorem (Friedman-Woodin [7]). *Assuming the consistency of an inaccessible, there is a model in which $\boldsymbol{\delta^1_2} = \omega_2$ and ω_1 is inaccessible to reals.*

There is no explicit bound on $\boldsymbol{\delta^1_3}$ provable in ZFC, even with the added hypothesis that ω_1 is inaccessible to reals.

8.41 Theorem (Sect. 8.4 of Friedman [5]). *Assuming the consistency of an inaccessible, there is a model in which ω_1 is inaccessible to reals and there is a Π^1_2 wellordering of some set of reals of length κ, for any pre-chosen L-definable cardinal κ (and hence $\boldsymbol{\delta^1_3} \geq \kappa$).*

9. Some Open Problems

1. Can one code a class by a real preserving Π^n_m-indescribability for $n > 1$?
2. Define *n-generic over L* as follows: R is *0-generic over L* iff R is generic over L. R is *$n+1$-generic over L* iff R is generic over an inner model of $L[S]$, where S is n-generic over L. Does $n+1$-genericity imply n-genericity for some n? Is there a real $R <_L 0^\#$ which is *not* n-generic over L for any n?
3. Is $0^\#$ generic over some proper inner model of $L[0^\#]$?
4. Can one prove that $L[0^\#]$ is generically saturated over L in the theory ZFC + "$0^\#$ exists"?
5. Is $L[0^\#]$ the *least* inner model which is generically saturated over L?
6. Is there a reasonable notion of "forcing" with the property that every real either constructs $0^\#$ or can be obtained by "forcing" over L?
7. Is there a real R such that $0 <_L R <_L 0^\#$ which is the unique solution to a Π^1_2 formula φ which *provably in* ZFC has at most one solution?
8. Is there a simple characterization of the reals which belong to a countable Π^1_2 set?
9. Assuming only the consistency of an inaccessible cardinal, is it consistent for each n that all $\boldsymbol{\Sigma^1_n}$ sets of reals be Lebesgue Measurable and have the Baire and Perfect Set properties, while there is a Δ^1_{n+1} wellordering of the reals?
10. Assuming only the consistency of a weakly compact cardinal, is it consistent to have Martin's Axiom, ω_1 inaccessible to reals, and a Δ^1_3 wellordering of the reals?
11. Is it consistent for Δ^1_3-reducibility and L-reducibility to coincide?

12. Assuming only the consistency of an inaccessible cardinal, is it consistent for Post's problem to fail in HC = the hereditarily countable sets?

13. Is there a *remarkable real*; i.e., a real $R <_L 0^{\#}$ such that R is not generic over L, R is a Π^1_2-singleton, $\Lambda(R) =$ the recursively inaccessible ordinals and R has minimal L-degree? It has not yet been shown that there is a real $R <_L 0^{\#}$ which has more than one of these properties simultaneously.

14. Is it consistent that any parameter-free Σ^1_3 sentence true in a class forcing extension of V, be already true in V?

Fine structure theory is an in-depth study of definability over levels of constructible hierarchies. It was invented by Ronald B. Jensen (cf. [3]), and later pursued by Jensen, Mitchell, Steel, and others (cf. for instance [7] and [4]). Our aim here is to give a self-contained introduction to this theory.

Fine structure theory is a necessary tool for a detailed analysis of Gödel's L and of more complicated constructible models; in fact, it is unavoidable even for the construction of an important class of such models, the so-called core models. The present chapter is thus intended as an introduction to chapters [5], [9], and [12], where core model theory is developed and applied. It may also be read as an introduction to [7], [4], or [15].

An important result of [3] is the Σ_n-uniformization theorem (cf. [3, Theorem 3.1]), which implies that for any ordinal α and for any positive integer n there is a Σ_n-Skolem function for J_α, i.e., a Skolem function for Σ_n relations over J_α which is itself Σ_n-definable over J_α. The naïve approach for obtaining such a Skolem function only works for $n = 1$; for $n > 1$, fine structure theory is called for.

Classical applications of the fine structure theory are to establish Jensen's results that $\square_\kappa$ holds in L for every infinite cardinal κ (cf. [3, Theorem 5.2]) and his Covering Lemma: If $0^\#$ does not exist, then every uncountable set of ordinals can be covered by a set in L of the same size (cf. [2]). We shall prove $L \models \square_\kappa$ as well as a slight weakening of Jensen's Covering Lemma in the final section of this chapter (cf. [5] on a complete proof of the Covering Lemma); they have been generalized by recent research (cf. [10] and [8]; cf. also [9]).

The present chapter will discuss the "pure" part of fine structure theory, the part which is not linked to any particular kind of constructible model one might have in mind. We shall discuss Jensen's classical version of this theory. We shall not, however, deal with Jensen's Σ^* theory (which may be found in [15, Sects. 1.6–1.8] or in [14]), and we shall also ignore other variants of the fine structure theory which have been created. What we shall deal with here is tantamount to what is presented in (parts of) [7, §2 and 4].

The authors would like to thank Gunter Fuchs, Paul Larson, Adrian Mathias, Grigor Sargsyan, and the referee for carefully reading earlier versions of this chapter and for bringing many errors to their attention. The second author was partially supported by the NSF Grants DMS-0204728 and DMS-0500799.

1. Acceptable J-structures

An inner model is a transitive proper class model of ZF. If A is a set or a proper class, then $L[A]$ is the least inner model which is closed under the operation $x \mapsto A \cap x$. An important example is $L = L[\emptyset]$, Gödel's constructible universe. V itself, the universe of all sets, is of the form $L[A]$

in a class forcing extension that does not add any new sets.[1]

Any model of the form $L[A]$ may be stratified in two ways: into levels of the L-hierarchy and into levels of the J-hierarchy. The former approach was Gödel's original one, but it turned out that the latter one (which was introduced by Jensen in [3]) is more useful.

In order to define the J-hierarchy we need the concept of rudimentary functions (cf. [3, p. 233]).

1.1 Definition. Let A be a set or a proper class. A function $f : V^k \to V$, where $k < \omega$, is called *rudimentary in A* (or, rud_A) if it is generated by the following schemata:

$$\begin{aligned}
f(\langle x_1, \ldots, x_k\rangle) &= x_i, \\
f(\langle x_1, \ldots, x_k\rangle) &= x_i \setminus x_j, \\
f(\langle x_1, \ldots, x_k\rangle) &= \{x_i, x_j\}, \\
f(\langle x_1, \ldots, x_k\rangle) &= h(g_1(\langle x_1, \ldots, x_k\rangle), \ldots, g_\ell(\langle x_1, \ldots, x_k\rangle)), \\
f(\langle x_1, \ldots, x_k\rangle) &= \textstyle\bigcup_{y \in x_1} g(\langle y, x_2, \ldots, x_k\rangle), \\
f(x) &= x \cap A
\end{aligned}$$

f is called *rudimentary* (or, rud) if f is $\mathrm{rud}_\emptyset$.

Let us write $\vec{x}$ for $\langle x_1, \ldots, x_k\rangle$. It is easy to verify that for instance the following functions are rudimentary: $f(\vec{x}) = \bigcup x_i$, $f(\vec{x}) = x_i \cup x_j$, $f(\vec{x}) = \{x_1, \ldots, x_k\}$, and $f(\vec{x}) = \langle x_1, \ldots, x_k\rangle$. Proposition 1.3 below will provide more information.

If U is a set and A is a set or a proper class then we shall denote by $\mathrm{rud}_A(U)$ the rud_A closure of U,[2] i.e., the set

$$U \cup \{f(\langle x_1, \ldots, x_k\rangle) \mid f \text{ is } \mathrm{rud}_A \text{ and } x_1, \ldots, x_k \in U\}.$$

It is not hard to verify that if U is transitive, then so is $\mathrm{rud}_A(U \cup \{U\})$. We shall now be interested in $\mathcal{P}(U) \cap \mathrm{rud}_A(U \cup \{U\})$ (cf. Lemma 1.4 below).

1.2 Definition. Let A be a set or a proper class. A relation $R \subseteq V^k$, where $k < \omega$, is called *rudimentary in A* (or, rud_A) if there is a rud_A function $f : V^k \to V$ such that $R = \{\vec{x} \mid f(\vec{x}) \neq \emptyset\}$. R is called *rudimentary* (or, rud) if R is $\mathrm{rud}_\emptyset$.

1.3 Proposition. *Let A be a set or a proper class.*

(a) The relation $\notin$ *is* rud.

(b) Let f, R *be* rud_A. *Let* $g(\vec{x}) = f(\vec{x})$ *if* $R(\vec{x})$ *holds, and* $g(\vec{x}) = \emptyset$ *if not. Then* g *is* rud_A.

---

[1] This class forcing extension is obtained simply by forcing with enumerations $p : \alpha \to V$, ordered by end-extension.

[2] This is in contrast to [3, p. 238], where $\mathrm{rud}_A(U)$ stands for the rud_A closure of $U \cup \{U\}$.

(c) If R, S are rud_A*, then so is* $R \cap S$*.*

(d) Membership in A is rud_A*.*

(e) If R is rud_A*, then so is its characteristic function* χ_R*.*

(f) R is rud_A *iff* $\neg R$ *is* rud_A*.*

(g) Let R be rud_A*. Let* $f(\langle y, \vec{x}\,\rangle) = y \cap \{z; R(\langle z, \vec{x}\,\rangle)\}$*. Then f is* rud_A*.*

(h) If $R(\langle y, \vec{x}\,\rangle)$ *is* rud_A *then so is* $\exists z \in y R(\langle z, \vec{x}\,\rangle)$*.*

Proof. (a) $x \notin y$ iff $\{x\} \setminus y \neq \emptyset$. (b) If $R(\vec{x}) \leftrightarrow r(\vec{x}) \neq \emptyset$, where r is rud_A, then $g(\vec{x}) = \bigcup_{y \in r(\vec{x})} f(\vec{x})$. (c) Let $R(\vec{x}) \leftrightarrow f(\vec{x}) \neq \emptyset$, where f is rud_A. Let $g(\vec{x}) = f(\vec{x})$ if $S(\vec{x})$ holds, and $g(\vec{x}) = \emptyset$ if not. g is rud_A by (b), and thus g witnesses that $R \cap S$ is rud_A. (d) $x \in A$ iff $\{x\} \cap A \neq \emptyset$. (e): by (b). (f) $\chi_{\neg R}(\vec{x}) = 1 \setminus \chi_R(\vec{x})$. (g) Let $g(\langle z, \vec{x}\rangle) = \{z\}$ if $R(\langle z, \vec{x}\rangle)$ holds, and $g(\langle z, \vec{x}\rangle) = \emptyset$ if not. We have that g is rud_A by (b), and $f(\langle y, \vec{x}\rangle) = \bigcup_{z \in y} g(z, \vec{x})$. (h) Set $f(y, \vec{x}) = y \cap \{z; R(\langle z, \vec{x}\rangle)\}$. f is rud_A by (g), and thus f witnesses that $\exists z \in y R(\langle z, \vec{x}\rangle)$ is rud_A. $\dashv$

We shall be concerned here with structures of the form $\langle U, \in, A_0, \ldots, A_m\rangle$, where U is transitive. (By $\langle U, \in, A_0, \ldots, A_m\rangle$ we shall mean the structure $\langle U, \in\restriction U, A_0 \cap U, \ldots, A_m \cap U\rangle$.) Each such structure comes with a language $\mathcal{L}_{\dot{A}_0, \ldots, \dot{A}_m}$ with predicates $\dot{\in}$, $\dot{A}_0, \ldots, \dot{A}_m$. We shall restrict ourselves to the case where $m = 0$ or $m = 1$.

If $M = \langle |M|, \ldots\rangle$ is a structure, $X \subseteq |M|$, and $n < \omega$ then we let $\Sigma_n^M(X)$ denote the set of all relations which are Σ_n-definable over M from parameters in X. We shall also write $\mathbf{\Sigma}_n^M$ for $\Sigma_n^M(M)$, and we shall write $\mathbf{\Sigma}_\omega^M$ for $\bigcup_{n<\omega} \mathbf{\Sigma}_n^M$. Further, we shall write Σ_n^M for $\Sigma_n^M(\emptyset)$, where $n \leq \omega$.

The following lemma says that $\mathrm{rud}_A(U \cup \{U\})$ is just the result of "stretching" $\mathbf{\Sigma}_\omega^{\langle U, \in, A\rangle}$ without introducing additional elements of $\mathcal{P}(U)$.

1.4 Lemma. *Let U be a transitive set, and let A be a set or proper class such that* $A \cap V_{\mathrm{rk}(U)+\omega} \subseteq U$*. Then* $\mathcal{P}(U) \cap \mathrm{rud}_A(U \cup \{U\}) = \mathcal{P}(U) \cap \mathbf{\Sigma}_\omega^{\langle U, \in, A\rangle}$*.*

Proof. Notice that $\mathcal{P}(U) \cap \mathbf{\Sigma}_\omega^{\langle U, \in, A\rangle} = \mathcal{P}(U) \cap \mathbf{\Sigma}_0^{\langle U \cup \{U\}, \in, A \cap U\rangle}$, so that we have to prove that

$$\mathcal{P}(U) \cap \mathrm{rud}_A(U \cup \{U\}) = \mathcal{P}(U) \cap \mathbf{\Sigma}_0^{\langle U \cup \{U\}, \in, A\rangle}$$

"$\supseteq$": By Proposition 1.3 (a) and (d), $\notin$ and membership in A are both rud_A. By Proposition 1.3 (f), (c), and (h), the collection of rud_A relations is closed under complement, intersection, and bounded quantification. Therefore we get inductively that every relation which is Σ_0 in the language $\mathcal{L}_{\dot{A}}$ with $\dot{\in}$ and $\dot{A}$ is also rud_A.

Now let $x \in \mathcal{P}(U) \cap \mathbf{\Sigma}_0^{\langle U \cup \{U\}, \in, A\rangle}$. There is then some rud_A relation R and there are $x_1, \ldots, x_k \in U \cup \{U\}$ such that $y \in x$ iff $y \in U$ and $R(\langle y, x_1, \ldots, x_k\rangle)$

holds. But then $x = U \cap \{y; R(\langle y, x_1, \ldots, x_k\rangle)\} \in \mathrm{rud}_A(U \cup \{U\})$ by Proposition 1.3 (g).

"$\subseteq$": Call a function $f : V^k \to V$, where $k < \omega$, *simple* iff the following holds true: if $\varphi(v_0, v_1, \ldots, v_m)$ is Σ_0 in the language $\mathcal{L}_{\dot{A}}$ with $\dot{\in}$ and $\dot{A}$, then $\varphi(f(v'_1, \ldots, v'_k), v_1, \ldots, v_m)$ is equivalent over transitive rud_A closed structures to a Σ_0 formula in the same language. It is not hard to verify inductively that every rud_A function is simple. (Here we use the hypothesis that $A \cap V_{\mathrm{rk}(U)+\omega} \subseteq U$ which ensures that in this situation quantifying over A is tantamount to quantifying over $A \cap U$.)

Now let $x \in \mathcal{P}(U) \cap \mathrm{rud}_A(U \cup \{U\})$, say $x = f(\langle x_1, \ldots, x_k\rangle)$, where $x_1, \ldots, x_k \in U \cup \{U\}$ and f is rud_A. Then "$v_0 \in f(\langle v_1, \ldots, v_k\rangle)$" is (equivalent over $\mathrm{rud}_A(U \cup \{U\})$ to) a Σ_0 formula in the language $\mathcal{L}_{\dot{A}}$, and hence $x = \{y \in U \mid y \in f(\langle x_1, \ldots, x_n\rangle)\}$ is in $\Sigma_0^{\langle U \cup \{U\}, \in, A\rangle}(\{x_1, \ldots, x_n\})$. $\dashv$

Of course Lemma 1.4 also holds with $\mathcal{P}(U)$ being replaced by the set of all relations on U. The hypothesis that $A \cap V_{\mathrm{rk}(U)+\omega} \subseteq U$ in Lemma 1.4 is needed to avoid pathologies; it is always met in the construction of fine structural inner models.

Let U be rud_A closed, and let $x \in U$ be transitive. Suppose that $B \in \Sigma_0^{\langle U, \in, A\rangle}(\{x_1, \ldots, x_k\})$, where $x_1, \ldots, x_k \in x$. Then $B \cap x \in \mathbf{\Sigma}_0^{\langle x, \in, A\rangle}$, and hence $B \cap x \in \mathrm{rud}_A(x \cup \{x\})$ by Lemma 1.4. But $\mathrm{rud}_A(x \cup \{x\}) \subseteq U$, and therefore $B \cap x \in U$. We have shown the following.

1.5 Lemma. *Let U be a transitive set such that for every $x \in U$ there is some transitive $y \in U$ with $x \in y$, let A be a set or a proper class, and suppose that U is* rud_A *closed. Then $\langle U, \in, A\rangle$ is a model of Σ_0 Comprehension in the sense that if $B \in \mathbf{\Sigma}_0^{\langle U, \in, A\rangle}$ and $x \in U$ is transitive then $B \cap x \in U$.*

In the next section we shall start with studying possible failures of Σ_1 Comprehension in rud_A closed structures. Lemma 1.5 provides the key element for proving that (all but two of) the structures we are now about to define are models of "basic set theory" (cf. [1, p. 36]), a theory that consists of Σ_0 Comprehension together with Extensionality, Foundation, Pairing, Union, Infinity, and the statement that Cartesian products exist.[3]

We may now define the J^A_α hierarchy as follows. For later purposes it is convenient to index this hierarchy by limit ordinals.[4]

1.6 Definition. Let A be a set or a proper class.

$$\begin{aligned} J^A_0 &= \emptyset, \\ J^A_{\alpha+\omega} &= \mathrm{rud}_A(J^A_\alpha \cup \{J^A_\alpha\}), \\ J^A_{\omega\lambda} &= \textstyle\bigcup_{\alpha<\lambda} J^A_{\omega\alpha} \quad \text{for limit } \lambda, \\ L[A] &= \textstyle\bigcup_{\alpha\in\mathrm{On}} J^A_{\omega\alpha}. \end{aligned}$$

[3] Said structures will also be models of "the transitive closure of any set exists", a statement which—despite of a claim made in [1]—is not provable even in Zermelo's set theory.
[4] This is again in contrast with [3].

Every J^A_α is rud_A closed and transitive. We shall also denote by J^A_α the structure $\langle J^A_\alpha, \in\restriction J^A_\alpha, A \cap J^A_\alpha\rangle$.

An important special case is obtained by letting $A = \emptyset$ in Definition 1.6. We write J_α for $J^\emptyset_\alpha$, and L for $L[\emptyset]$. L is Gödel's constructible universe; it will be studied in the last section of this chapter. Other important examples are obtained by letting A code a (carefully chosen) sequence of extenders; such models are discussed in [5, 9, 12].

The following is an immediate consequence of Lemma 1.4.

1.7 Lemma. *Let A be a set or proper class such that $A \cap V_{\mathrm{rk}(U)+\omega} \subseteq U$, and let α be a limit ordinal. Then $\mathcal{P}(J^A_\alpha) \cap J^A_{\alpha+\omega} = \mathcal{P}(J^A_\alpha) \cap \boldsymbol{\Sigma}^{J^A_\alpha}_\omega$.*

It is often necessary to work with the auxiliary hierarchy S^A_α of [3, p. 244] which is defined as follows:

$$\begin{aligned}
S^A_0 &= \emptyset,\\
S^A_{\alpha+1} &= \mathbf{S}^A(S^A_\alpha),\\
S^A_\lambda &= \textstyle\bigcup_{\xi<\lambda} S^A_\xi \quad \text{for limit } \lambda
\end{aligned}$$

where $\mathbf{S}^A$ is an operator which, applied to a set U, adds images of members of $U \cup \{U\}$ under rud_A functions from a certain carefully chosen fixed *finite* list. We may set

$$\mathbf{S}^A(U) = \textstyle\bigcup_{i=0}^{15} F_i``(U \cup \{U\})^2,$$

where

$$\begin{aligned}
F_0(x,y) &= \{x,y\},\\
F_1(x,y) &= x \setminus y,\\
F_2(x,y) &= x \times y,\\
F_3(x,y) &= \{\langle u,z,v\rangle \mid z \in x \wedge \langle u,v\rangle \in y\},\\
F_4(x,y) &= \{\langle u,v,z\rangle \mid z \in x \wedge \langle u,v\rangle \in y\},\\
F_5(x,y) &= \textstyle\bigcup x,\\
F_6(x,y) &= \mathrm{dom}(x),\\
F_7(x,y) &= \in \cap (x \times x),\\
F_8(x,y) &= \{x``\{z\} \mid z \in y\},\\
F_9(x,y) &= \langle x,y\rangle,\\
F_{10}(x,y) &= x``\{y\},\\
F_{11}(x,y) &= \langle \mathrm{left}(y), x, \mathrm{right}(y)\rangle,\\
F_{12}(x,y) &= \langle \mathrm{left}(y), \mathrm{right}(y), x\rangle,\\
F_{13}(x,y) &= \{\mathrm{left}(y), \langle \mathrm{right}(y), x\rangle\},\\
F_{14}(x,y) &= \{\mathrm{left}(y), \langle x, \mathrm{right}(y)\rangle\},\\
F_{15}(x,y) &= A \cap x.
\end{aligned}$$

(Here, $\langle x_1, x_2, \ldots, x_n\rangle = \langle x_1, \langle x_2, \ldots, x_n\rangle\rangle$, and $\mathrm{left}(y) = u$ and $\mathrm{right}(y) = v$ if $y = \langle u, v\rangle$ and $\mathrm{left}(y) = 0 = \mathrm{right}(y)$ if y is not an ordered pair.) It is not difficult to show that each F_i, $0 \leq i \leq 15$, is rud_A. A little bit more work is necessary to show that every rud_A function can be generated by using functions from this list. The functions F_i, $0 \leq i \leq 15$, are therefore a *basis* for the set of rud_A functions (cf. [3, Lemma 1.8]).

Every S^A_α is transitive,[5] and moreover

$$J^A_\alpha = S^A_\alpha \tag{9.1}$$

for all limit ordinals α. It is easy to see that there is only a finite jump in rank from S^A_α to $S^A_{\alpha+1}$. A straightforward induction shows that $J^A_\alpha \cap \mathrm{On} = \alpha$ for all limit ordinals α.

Recall that a structure $\langle U, \in, A_1, \ldots, A_m\rangle$ is called *amenable* if and only if $A_i \cap x \in U$ whenever $1 \leq i \leq m$ and $x \in U$. Lemma 1.5 together with (9.1) readily gives the following.

1.8 Lemma. *Let A be a set or proper class, and let α be a limit ordinal. Let $B \in \mathbf{\Sigma}_0^{J^A_\alpha}$. Then $\langle J^A_\alpha, B\rangle$ is amenable, i.e., J^A_α is a model of Σ_0 Comprehension in the language $\mathcal{L}_{\dot{A},\dot{B}}$ with $\dot{\in}$, $\dot{A}$ and $\dot{B}$.*

1.9 Definition. A *J-structure* is an amenable structure of the form $\langle J^A_\alpha, B\rangle$ for a limit ordinal α and predicates A, B.

Here, $\langle J^A_\alpha, B\rangle$ denotes the structure $\langle J^A_\alpha, \in\restriction J^A_\alpha, A \cap J^A_\alpha, B \cap J^A_\alpha\rangle$. Any J^A_α is a J-structure.

1.10 Lemma. *Let J^A_α be a J-structure.*

(1) For all $\beta < \alpha$, $\langle S^A_\gamma \mid \gamma < \beta\rangle \in J^A_\alpha$. In particular, $S^A_\beta \in J^A_\alpha$ for all $\beta < \alpha$.

(2) $\langle S^A_\gamma \mid \gamma < \alpha\rangle$ is uniformly $\Sigma_1^{J^A_\alpha}$. That is, "$x = S^A_\gamma$" is Σ_1 over J^A_α as witnessed by a formula that does not depend on α.

Proof. (1) and (2) are shown simultaneously by induction on $\langle \alpha, \beta\rangle$, ordered lexicographically. Fix α and $\beta < \alpha$. If β is a limit ordinal then inductively by (2), $\langle S^A_\gamma \mid \gamma < \beta\rangle$ is $\Sigma_1^{J^A_\beta}$, and hence $\langle S^A_\gamma \mid \gamma < \beta\rangle \in J^A_\alpha$ by Lemma 1.7. If $\beta = \delta + 1$ then inductively by (1), $\langle S^A_\gamma \mid \gamma < \delta\rangle \in J^A_\alpha$. If δ is a limit ordinal then $S^A_\delta = \bigcup_{\gamma<\delta} S^A_\gamma \in J^A_\alpha$, and if $\delta = \bar{\delta} + 1$ then $S^A_\delta = S^A_{\bar{\delta}} \cup \mathbf{S}^A(S^A_{\bar{\delta}}) \in J^A_\alpha$ as well. It follows that $\langle S^A_\gamma \mid \gamma < \beta\rangle \in J^A_\alpha$. (2) is then not hard to verify. ⊣

We may recursively define a well-ordering $<^A_\beta$ of S^A_β as follows. If β is a limit ordinal then we let $<^A_\beta = \bigcup_{\gamma<\beta} <^A_\gamma$. Now suppose that $\beta = \bar{\beta} + 1$. The

[5] The above list in fact contains more functions than the list from [3, Lemma 1.8]; this enlargement yields the transitivity of each S^A_α.

order $<^A_\beta$ induces a lexicographical order, call it $<^A_{\bar\beta,\mathrm{lex}}$, of $16 \times S^A_{\bar\beta} \times S^A_{\bar\beta}$. We may then set

$$x <^A_\beta y \quad\Longleftrightarrow\quad \begin{cases} x, y \in S^A_{\bar\beta} \quad \text{and} \quad x <^A_{\bar\beta} y, \quad \text{or else} \\ x \in S^A_{\bar\beta} \wedge y \notin S^A_{\bar\beta}, \quad \text{or else} \\ x, y \notin S^A_{\bar\beta} \quad \text{and} \quad (i, u_x, v_x) <^A_{\bar\beta,\mathrm{lex}} (j, u_y, v_y) \\ \quad \text{where } (i, u_x, v_x) \text{ is } <^A_{\bar\beta,\mathrm{lex}}\text{-minimal with } x = F_i(u_x, v_x) \\ \quad \text{and } (j, u_y, v_y) \text{ is } <^A_{\bar\beta,\mathrm{lex}}\text{-minimal with } y = F_j(u_y, v_y). \end{cases}$$

The following is easy to prove.

1.11 Lemma. *Let J^A_α be a J-structure.*

(1) For all $\beta < \alpha$, $\langle <^A_\gamma \mid \gamma < \beta\rangle \in J^A_\alpha$. In particular, $<^A_\beta \in J^A_\alpha$ for all $\beta < \alpha$.

(2) $\langle <^A_\gamma \mid \gamma < \alpha\rangle$ is uniformly $\Sigma_1^{J^A_\alpha}$. That is, "$x = <^A_\gamma$" is Σ_1 over J^A_α as witnessed by a formula that does not depend on α.

If $M = J^A_\alpha$, then we shall also write $<_M$ for $<^A_\alpha$.

We shall now start working towards showing that J-structures have Σ_1-definable Σ_1-Skolem functions.

In what follows we shall fix a recursive enumeration $\langle \varphi_i ; i \in \omega\rangle$ of all Σ_1 formulae of the language $\mathcal{L}_{\dot A}$. (What we shall say easily generalizes to $\mathcal{L}_{\dot A_1,\ldots,\dot A_m}$.) We shall denote by $\ulcorner\varphi\urcorner$ the Gödel number of φ, i.e., $\ulcorner\varphi\urcorner = i$ iff $\varphi = \varphi_i$. We may and shall assume that if $\bar\varphi$ is a proper subformula of φ then $\ulcorner\bar\varphi\urcorner < \ulcorner\varphi\urcorner$. We shall write $v(i)$ for the set of free variables of φ_i. Recall that all the relevant syntactical concepts are representable in (weak fragments of) Peano arithmetic, so that the representability of these concepts is immediate.

Let M be a structure for $\mathcal{L}_{\dot A}$. We shall express by $\models^{\Sigma_1}_M \varphi_i[\mathsf{a}]$ the fact that $\mathsf{a} : v(i) \to M$, i.e., a assigns elements of M to the free variables of φ_i, and φ_i holds true in M under this assignment. We shall also write $\models^{\Sigma_1}_M$ for the set of $\langle i, \mathsf{a}\rangle$ such that $\models^{\Sigma_1}_M \varphi_i[\mathsf{a}]$. We shall express by $\models^{\Sigma_0}_M \varphi_i[\mathsf{a}]$ the fact that $\models^{\Sigma_1}_M \varphi_i[\mathsf{a}]$ holds, but with φ_i being a Σ_0 formula, and we shall write $\models^{\Sigma_0}_M$ for the set of $\langle i, \mathsf{a}\rangle$ such that $\models^{\Sigma_0}_M \varphi_i[\mathsf{a}]$.

It turns out that once we have verified that $\models^{\Sigma_0}_M$ is uniformly Δ_1 over J-structures M (which are structures of $\mathcal{L}_{\dot A}$), we easily get that $\models^{\Sigma_1}_M$ is Σ_1-definable over such structures and that these structures admit Σ_1-definable Σ_1-Skolem functions. R on M is Δ_1 iff R, $\neg R$ are both Σ_1.

Let us fix a J-structure $M = J^A_\alpha$, a structure for $\mathcal{L}_{\dot A}$.

1.12 Proposition. *Let $N \in M$ be transitive. For each $n < \omega$, there is a unique $f = f^N_n \in M$ such that* $\mathrm{dom}(f) = n$ *and for all $i < n$, if φ_i is not a Σ_0 formula then $f(i) = \emptyset$, and if φ_i is a Σ_0 formula then*

$$f(i) = \{\mathsf{a} \in {}^{v(i)}N \mid \models^{\Sigma_0}_N \varphi_i[\mathsf{a}]\}.$$

Proof. As uniqueness is clear, let us verify inductively that $f_n^N \in M$. Well, $f_0^N = \emptyset \in M$. Now suppose that $f_n^N \in M$. If φ_n is not Σ_0, then $f_{n+1}^N = f_n^N \cup \{\langle n, \emptyset\rangle\} \in M$. Now let φ_i be Σ_0. We have that ${}^{v(n)}N \in M$, and if

$$T = \{\mathsf{a} \in {}^{v(n)}N \mid \models_N^{\Sigma_0} \varphi_n[\mathsf{a}]\}$$

then $T \in \mathcal{P}({}^{v(n)}N) \cap \mathbf{\Sigma}_0^M$, and thus $T \in M$ by Lemma 1.8. Therefore,

$$f_{n+1}^N = f_n^N \cup \{\langle n, T\rangle\} \in M.$$

$\dashv$

Now let $\Theta(f, N, n)$ denote the following formula.

$$\begin{aligned}
&N \text{ is transitive} \wedge f : n \to N \wedge \forall i < n \\
&\quad [(i = \ulcorner v_{i_0} \in v_{i_1} \urcorner, \text{ some } v_{i_0}, v_{i_1} \to f(i) = \{\mathsf{a} \in {}^{v(i)}N \mid \mathsf{a}(v_{i_0}) \in \mathsf{a}(v_{i_1})\}) \\
&\quad \wedge (i = \ulcorner \dot{A}(v_{i_0}) \urcorner, \text{ some } v_{i_0} \to f(i) = \{\mathsf{a} \in {}^{v(i)}N \mid \mathsf{a}(v_{i_0}) \in A\}) \\
&\quad \wedge (i = \ulcorner \psi_0 \wedge \psi_1 \urcorner, \text{ some } \psi_0, \psi_1 \\
&\quad\ \to f(i) = \{\mathsf{a} \in {}^{v(i)}N \mid \mathsf{a}{\restriction} v(\ulcorner \psi_0 \urcorner) \in f(\ulcorner \psi_0 \urcorner) \wedge \mathsf{a}{\restriction} v(\ulcorner \psi_1 \urcorner) \in f(\ulcorner \psi_1 \urcorner)\}) \\
&\quad \wedge (i = \ulcorner \exists v_{i_0} \in v_{i_1} \psi \urcorner, \text{ some } v_{i_0}, v_{i_1}, \psi, \text{ where } \psi \text{ is } \Sigma_0 \\
&\quad\ \to f(i) = \{\mathsf{a} \in {}^{v(i)}N \mid \exists x \in \mathsf{a}(v_{i_1})(\mathsf{a} \cup \{\langle v_{i_0}, x\rangle\}){\restriction} v(\ulcorner \psi \urcorner) \in f(\ulcorner \psi \urcorner)\}) \\
&\quad \wedge (i = \ulcorner \varphi \urcorner, \text{ some } \varphi, \text{ where } \varphi \text{ is not } \Sigma_0 \to f(i) = \emptyset)].
\end{aligned}$$

It is straightforward to check that $\Theta(f, N, n)$ holds (in M) if and only if $f = f_n^N$. Now Proposition 1.12 and the fact that every element of M is contained in a transitive element of M (for instance in some S_β^A; cf. Lemma 1.10) immediately gives the following.

1.13 Proposition. *Let φ_i be Σ_0, and let $\mathsf{a} : v(i) \to M$. Then $\models_M^{\Sigma_0} \varphi_i[\mathsf{a}]$ if and only if*

$$M \models \exists f\, \exists N\, (\mathrm{ran}(\mathsf{a}) \subseteq N \wedge \Theta(f, N, i+1) \wedge \mathsf{a} \in f(i)),$$

if and only if

$$M \models \forall f\, \forall N\, ((\mathrm{ran}(\mathsf{a}) \subseteq N \wedge \Theta(f, N, i+1)) \to \mathsf{a} \in f(i)).$$

In particular, the relation $\models_M^{\Sigma_0}$ is Δ_1^M.

We are now ready to prove two important results.

1.14 Theorem. *Let M be a J-structure. The Σ_1-satisfaction relation $\models_M^{\Sigma_1}$ is then uniformly Σ_1^M.*

If M is a structure then h is a Σ_1-*Skolem function* for M if

$$h : \textstyle\bigcup_{i<\omega} (\{i\} \times {}^{v(i)}|M|) \to |M|,$$

where h may be partial, and whenever $\varphi_i = \exists v_{i_0} \varphi_j$ and $\mathsf{a} : v(i) \to |M|$,

$$\begin{aligned}
&\exists y \in |M| \models_M^{\Sigma_1} \varphi_j[(\mathsf{a} \cup \{\langle v_{i_0}, y\rangle\}){\restriction} v(j)] \\
&\quad \Longrightarrow \quad \models_M^{\Sigma_1} \varphi_j[(\mathsf{a} \cup \{\langle v_{i_0}, h(i, \mathsf{a})\rangle\}){\restriction} v(j)].
\end{aligned}$$

1.15 Theorem. *Let M be a J-structure. There is a Σ_1-Skolem function h_M which is uniformly Σ_1^M.*

The above two theorems are to be understood as follows. There are Σ_1 formulae Φ, Ψ such that whenever M is a J-structure,

(a) Φ defines $\models_M^{\Sigma_1}$, i.e. $\models_M^{\Sigma_1} \varphi_i[\mathsf{a}] \iff M \models \Phi(i, \mathsf{a})$, and

(b) Ψ defines h_M, i.e. $y = h_M(i, \mathsf{a}) \iff M \models \Psi(i, \mathsf{a}, y)$.

Proof of Theorem 1.14. We have that $\models_M^{\Sigma_1} \varphi_i[\mathsf{a}]$ iff

$$\begin{aligned}&\exists \mathsf{b} \in M\, \exists \langle v_{i_0}, \ldots, v_{i_k}, j, \rangle, \text{ some } v_{i_0}, \ldots, v_{i_k},\\ &\quad j[i = \ulcorner \exists v_{i_0} \cdots \exists v_{i_k} \varphi_j \urcorner \wedge \varphi_j \text{ is } \Sigma_0 \;\wedge\; \mathsf{a}, \mathsf{b} \text{ are functions}\\ &\quad \wedge \operatorname{dom}(\mathsf{a}) = v(i) \wedge \operatorname{dom}(\mathsf{b}) = v(j) \wedge \mathsf{a} = \mathsf{b} \restriction v(i) \wedge \models_M^{\Sigma_0} \varphi_j[\mathsf{b}]].\end{aligned}$$

Here, $\models_M^{\Sigma_0}$ is uniformly Δ_1^M by Proposition 1.13. The rest follows. ⊣

Proof of Theorem 1.15. The idea here is to let $y = h_M(i, \mathsf{a})$ be the "first component" of a minimal witness to the Σ_1 statement in question (rather than letting y be minimal itself). We may let $y = h_M(i, \mathsf{a})$ iff

$$\begin{aligned}&\exists N\, \exists \beta\, \exists R\, \exists \mathsf{b}, \text{ all in } M, \exists \langle v_{i_0}, \ldots, v_{i_k}, j \rangle, \text{ some } v_{i_0}, \ldots, v_{i_k}, j\\ &\quad [N = S_\beta^A \wedge R = <_\beta^A \wedge i = \ulcorner \exists v_{i_0} \cdots \exists v_{i_k} \varphi_j \urcorner \wedge \varphi_j \text{ is } \Sigma_0\\ &\quad \wedge \mathsf{a}, \mathsf{b} \text{ are functions } \wedge \operatorname{dom}(\mathsf{a}) = v(i) \wedge \operatorname{dom}(\mathsf{b}) = v(j) \wedge \mathsf{a} = \mathsf{b} \restriction v(i)\\ &\quad \wedge \operatorname{ran}(\mathsf{b}) \subseteq N \wedge \models_M^{\Sigma_0} \varphi_j[\mathsf{b}] \wedge \forall \bar{\mathsf{b}} \in N((\bar{\mathsf{b}} \text{ is a function} \wedge \operatorname{dom}(\bar{\mathsf{b}}) = v(j)\\ &\quad \wedge \mathsf{a} = \bar{\mathsf{b}} \restriction v(i) \wedge \operatorname{ran}(\bar{\mathsf{b}}) \subseteq N \wedge \bar{\mathsf{b}}\ R\ \mathsf{b}) \rightarrow \neg \models_M^{\Sigma_0} \varphi_j[\bar{\mathsf{b}}]) \wedge y = \mathsf{b}(v_{i_0})].\end{aligned}$$

Here, "$N = S_\beta^A$" and "$R = <_\beta^A$" are uniformly Σ_1^M by Lemmata 1.10 (2) and 1.11 (2), and $\models_M^{\Sigma_0}$ is uniformly Δ_1^M by Proposition 1.13. Therefore, the rest follows. ⊣

If we were to define a Σ_2-Skolem function for M in the same manner then we would end up with a Σ_3 definition. Jensen solved this problem by showing that under favorable circumstances Σ_n over M can be viewed as Σ_1 over a "reduct" of M. Reducts will be introduced in the fifth section of this chapter.

Another useful fact is the so-called *Condensation Lemma.*[6]

1.16 Theorem. *Let $M = \langle J_\alpha^A, B \rangle$ be a J-structure, and let $\pi : \bar{M} \xrightarrow[\Sigma_1]{} M$ where $\bar{M}$ is transitive. Then $\bar{M}$ is a J-structure, i.e., there are $\bar{\alpha} \leq \alpha$, $\bar{A}$, and $\bar{B}$ such that $\bar{M} = \langle J_{\bar{\alpha}}^{\bar{A}}, \bar{B} \rangle$.*

[6] For $n < \omega$, $X \prec_{\Sigma_n} M$ means that Σ_n formulae with parameters taken from X are absolute between X and M. To have $\pi : \bar{M} \xrightarrow[\Sigma_n]{} M$ means that $\operatorname{ran}(\pi) \prec_{\Sigma_n} M$.

Proof. Set $\bar{\alpha} = \bar{M} \cap \mathrm{On} \le \alpha$, $\bar{A} = \pi^{-1}``A$, and $\bar{B} = \pi^{-1}``B$. We claim that $\bar{M} = \langle J_{\bar{\alpha}}^{\bar{A}}, \bar{B} \rangle$.

Well, Lemma 1.10 easily gives that $S_{\beta}^{\bar{A}} \in \bar{M}$ whenever $\beta < \bar{\alpha}$. Therefore, $J_{\bar{\alpha}}^{A} \subseteq \bar{M}$. On the other hand, let $x \in \bar{M}$. Then $\pi(x) \in S_{\beta}^{A}$ for some $\beta < \alpha$, and hence $x \in S_{\beta}^{\bar{A}}$ for some $\beta < \bar{\alpha}$. ⊣

We also want to write $h_M(X)$ for the closure of X under h_M, more precisely:

Convention. Let $M = J_{\alpha}^{A}$ be a J-structure, and let $X \subseteq |M|$. We shall write $h_M(X)$ for $h_M``(\bigcup_{i<\omega}(\{i\} \times {}^{v(i)}X))$.

Using Theorem 1.15, it is easy to verify that $h_M(X) \prec_{\Sigma_1} M$. There will be no danger of confusing the two usages of "h_M". $[X]^{<\omega}$ denotes the set of all finite subsets of X.

1.17 Lemma. *Let $M = J_{\alpha}^{A}$ be a J-structure. There is then some surjective $f : [\alpha]^{<\omega} \to M$ which is Σ_1^M.*

If α is closed under the Gödel pairing function, then there is a surjection $g : \alpha \to J_{\alpha}^{A}$ which is Σ_1^M. For an arbitrary α, there is a surjection $h : \alpha \to J_{\alpha}^{A}$ which is $\mathbf{\Sigma}_1^M$.

Proof. We have that $h_M(\alpha) \prec_{\Sigma_1} M$, and hence $h_M(\alpha) = M$. But it is straightforward to construct a surjective $g' : [\alpha]^{<\omega} \to \bigcup_{i<\omega}(\{i\} \times {}^{v(i)}\alpha)$ which is Σ_1^M. We may then set $f = h_M \circ g'$.

As to the existence of g, let $\Phi : \mathrm{otp}(<_{\alpha}^{A}) \to J_{\alpha}^{A}$ denote the enumeration of J_{α}^{A} according to $<_{\alpha}^{A}$. It is not hard to verify by a simultaneous induction (cf. the proof of Lemma 1.10) that for all limit ordinals $\beta \le \alpha$, $\Phi \restriction \beta$ is $\Sigma_1^{J_{\beta}^{A}}$ and for all $\gamma < \beta$, $\Phi \restriction \gamma \in J_{\beta}^{A}$. But now if α is closed under the Gödel pairing function then $\mathrm{otp}(<_{\alpha}^{A}) = \alpha$.

The existence of h is established by [3, Lemma 2.10]. ⊣

In the following we describe a useful class of formulae, which lies somewhere between Σ_1 and Π_2. It turns out that many notions can be expressed by statements belonging to this class.

1.18 Definition. We say that φ is a *Q-formula* iff φ is of the form

$$\forall u\, \exists v \supseteq u\ \psi(v),$$

where ψ is Σ_1 and does not contain u. Instead of $\forall u\, \exists v \supseteq u$ we write briefly Qv. The above formula then has the form $Qv\ \psi(v)$ and we read "for cofinally many v, $\psi(v)$". A map π that preserves Q formulae is called *Q-preserving* and we write

$$\pi : \bar{M} \underset{Q}{\longrightarrow} M.$$

A property characterized by a Q-formula is also called a *Q-condition*.

1.19 Definition. Let U, V be transitive structures. A map $\sigma : U \to V$ is *cofinal* iff for all $y \in V$ there is some $x \in U$ such that $y \subseteq \sigma(x)$.

Let $\sigma : U \underset{\Sigma_1}{\longrightarrow} V$, where U, V are transitive structures, and let φ be a Q-formula. It is easy to see that

(a) φ is preserved downwards,

(b) if σ is cofinal, then φ is preserved upwards.

Note also that Q-formulae are closed under $\wedge$ and $\vee$ (modulo the "basic set theory" of [1, p. 36]).

We now introduce the notion of acceptability which is fundamental for the general fine structure theory. As will follow from the definition, acceptability can be considered as a strong version of GCH.

1.20 Definition. A J-structure $M = \langle J^A_\alpha, B\rangle$ is *acceptable* iff the following holds: Whenever $\xi < \alpha$ is a limit ordinal and $\mathcal{P}(\tau) \cap J^A_{\xi+\omega} \not\subseteq J^A_\xi$ for some $\tau < \xi$, there is a surjective map $f : \tau \to \xi$ in $J^A_{\xi+\omega}$. (This means that $\mathrm{Card}(\xi) \le \tau$ in $J^A_{\xi+\omega}$.)

1.21 Lemma. *Being an acceptable J-structure is a Q-property. More precisely: There is a fixed Q-sentence Ψ such that for any $M = \langle |M|, A, B\rangle$ which is transitive and closed under pairing, M is an acceptable J-structure iff $M \models \Psi$.*

Proof. The statement $\langle |M|, A\rangle = J^A_\alpha$ is a Q-condition for $\langle |M|, A\rangle$, as we may write this as

$$Qu\,\exists\beta\; u = S^A_\beta.$$

Here, "$u = S^A_\beta$" is the Σ_1 formula from Lemma 1.10 (2). Amenability can be expressed by

$$Qu\,\exists z\; z = B \cap u.$$

It only remains to prove that the fact that we collapse ξ whenever we add a new bounded subset is expressible in a Q-fashion. We note first that a J-structure M is acceptable iff the following holds in M:

$$\begin{aligned}&\forall \text{ limit ordinals } \xi\ \exists n \in \omega\ \forall m \ge n\ \forall \tau < \xi\\ &\qquad [\mathcal{P}(\tau) \cap S^A_{\xi+m} \not\subseteq S^A_\xi \to \exists f \in S^A_{\xi+m}\ f : \tau \xrightarrow{\text{onto}} \xi].\end{aligned} \tag{9.2}$$

Denote the sentence (9.2) by ψ. It is easy to see that if M satisfies ψ then M is acceptable. To see the converse, fix a limit ordinal ξ and suppose that there is a $\tau < \xi$ such that $\mathcal{P}(\tau) \cap S^A_{\xi+\omega} \not\subseteq S^A_\xi$. Let τ be minimal with this property. By acceptability of M, there is an $n \in \omega$ such that $S^A_{\xi+n}$ contains a function f mapping τ onto ξ. Using f, it is easy to construct a surjective map $f_{\tau'} : \tau' \to \xi$ for any $\tau' < \xi$ whose power set in $S^A_{\xi+\omega}$ is larger than that in S^A_ξ (since $\tau' \ge \tau$) and it follows immediately that $f_{\tau'} \in S^A_{\xi+n+k}$ for some $k < \omega$; so we have a uniform bound for all such functions.

If the height of M is $\omega\alpha$ for some limit α, then acceptability is equivalent to the statement

$$Q\xi\ S_\xi^A \models \psi.$$

Otherwise, we have to state (9.2) explicitly for the last level. Hence, the desired condition is then

$$\begin{aligned} &\langle |M|, A, B\rangle \text{ is an amenable } J\text{-structure} \\ &\quad \wedge Q\zeta\ (\lim(\zeta) \to S_\zeta^A \models \psi) \wedge [Q\zeta\ (\zeta \text{ is a limit}) \vee \varphi] \end{aligned} \tag{9.3}$$

where φ is the sentence

$$Q\zeta\exists\beta < \zeta\ [\lim(\beta) \wedge \forall\eta < \zeta\ (\eta > \beta \to \mathrm{succ}(\eta)) \wedge \varphi'(\beta,\zeta)]$$

and $\varphi'(\beta,\zeta)$ is the formula

$$\forall\tau < \beta\ [\exists u \in S_\zeta^A\ (u \notin S_\beta^A \wedge u \subseteq \tau) \to \exists f \in S_\zeta^A f : \tau \xrightarrow{\text{onto}} \beta].$$

φ is clearly a Q-sentence, hence (9.3) is a Q-sentence as well. Denote this formula by Ψ. Then M is an acceptable J-structure iff $M \models \Psi$. ⊣

1.22 Corollary.

(a) *If $\pi : \bar{M} \xrightarrow[\Sigma_1]{} M$ and M is acceptable, then so is $\bar{M}$.*

(b) *If $\pi : \bar{M} \xrightarrow[Q]{} M$ and $\bar{M}$ is acceptable, then so is M. This holds in particular if π is a Σ_0 preserving cofinal map.*

1.23 Lemma. *Let $M = J_\alpha^A$ be acceptable and let $\rho \in M$ be an infinite cardinal in M. Given $u \in J_\rho^A$, any $a \in M$ which is a subset of u is in fact an element of J_ρ^A.*

Proof. Since $u \in J_\rho^A$, there is some $\tau < \rho$ and a surjective map $g : \tau \to u$ in J_ρ^A (cf. Lemma 1.17). Set $\bar{a} = g^{-1}``a$. Then $\bar{a} \subseteq \tau$ and $a \in J_\rho^A \iff \bar{a} \in J_\rho^A$. But if $\bar{a} \notin J_\rho^A$, then there is an $f : \tau \xrightarrow{\text{onto}} \xi$, where ξ is such that $\bar{a} \in J_{\xi+\omega}^A \setminus J_\xi^A$; hence $\xi \geq \rho$. This contradicts the fact that ρ is a cardinal in J_α^A. Consequently, $a \in J_\rho^A$. ⊣

1.24 Lemma. *Let M be as above and ρ an infinite successor cardinal in M. Let $a \subseteq J_\rho^A$ be such that $a \in M$ and* Card$(a) < \rho$ *in M. Then $a \in J_\rho^A$.*

Proof. Let $\gamma < \rho$ and $g \in M$ be such that $g : \gamma \xrightarrow{\text{onto}} a$. Define $f : \gamma \to \rho$ by

$$\zeta = f(\xi) \iff g(\xi) \in S_{\zeta+\omega}^A \setminus S_\zeta^A.$$

Then $f \in M$.

Claim. f is bounded in ρ.

Suppose that this Claim holds. Let $\delta < \rho$ be such that $\mathrm{ran}(f) \subseteq \delta$. Then $a \subseteq S^A_\delta \in J^A_\rho$ and, by Lemma 1.23, $a \in J^A_\rho$. Hence it suffices to prove the Claim.

Suppose that f is unbounded in ρ. Define $G : \rho \to M$ by

$$G(\eta) = \text{ the } <^A_\alpha\text{-least function of } \gamma \text{ onto } \eta.$$

This is possible since ρ is a successor cardinal in M, so we can pick γ large enough that all we have done so far goes through. Clearly G is definable over J^A_ρ, hence $G \in M$. Now define $F : \gamma \times \gamma \xrightarrow{\text{onto}} \rho$ by

$$F(\xi, \eta) = G(f(\xi))(\eta).$$

Then $F \in M$. By Lemma 1.17, there is some surjection $g : \gamma \to \gamma \times \gamma$ which is $\mathbf{\Sigma}_1^{J^A_\gamma}$; hence $g \in M$. But then $F \circ g \in M$ witnesses that ρ is not a cardinal in M. This contradiction yields the Claim. ⊣

1.25 Corollary. *Let M, ρ be as in Lemma 1.24. Then $J^A_\rho \models \mathrm{ZFC}^-$.*

Proof. The point here is to verify the Separation and Replacement Schemata in J^A_ρ, since the rest of the axioms hold in J^A_ρ automatically. The former follows from Lemma 1.23 and the latter from Lemma 1.24 in a straightforward way. ⊣

1.26 Corollary. *Let M be as above where $\rho > \omega$ is a limit cardinal in M. Then $J^A_\rho \models \mathrm{ZC}$ (where ZC is Zermelo set theory with choice).*

Proof. We only have to verify the power set axiom; the rest goes through as before. Let $a \in J^A_\rho$. Pick $\gamma < \rho$ such that γ is a cardinal in J^A_ρ and $a \in J^A_\gamma$. Then for every $x \in \mathcal{P}(a) \cap J^A_\rho$, $x \in J^A_\gamma$. Hence $\mathcal{P}(a) \cap J^A_\rho \in J^A_\rho$. ⊣

1.27 Corollary. *Let M, ρ be as above. Then*

$$|J^A_\rho| = H^M_\rho \stackrel{\text{def}}{=} \{x \in M \mid \mathrm{Card}\,(\mathrm{tc}(x)) < \rho \textit{ in } M\}.$$

Proof. Clearly $|J^A_\rho| \subseteq H^M_\rho$. So it is sufficient to prove the converse. Suppose that it fails. Let ρ be the least counterexample. Then ρ is a successor cardinal in M. Let $x \in H^M_\rho$ be $\in$-minimal such that $x \notin J^A_\rho$. Then $x \subseteq J^A_\rho$. Since $\mathrm{card}(x) < \rho$ in M, $x \in J^A_\rho$ by Lemma 1.23. Contradiction. ⊣

2. The First Projectum

We now introduce the central notions of fine structure theory—the notions *projectum, standard code* and *good parameter.* We stress that we are working with arbitrary J-structures and that these structures have, in general, very few closure properties. This means that there might be bounded definable subsets of these structures (in a precise sense) failing to be *elements.*

However, each J-structure has an initial segment which is "firm" in the sense that it does contain all sets reasonably definable over the whole structure. The height of this "firm" segment is called the *projectum. Standard codes* are (boldface) definable relations computing truth and *good parameters* are parameters that occur in the definitions of standard codes.

2.1 Definition. The Σ_1 *projectum* (or, *first projectum*) $\rho(M)$ of an acceptable J-structure $M = J_\alpha^A$ is defined by

$$\rho(M) = \text{ the least } \rho \in \mathrm{On} \text{ such that } \mathcal{P}(\rho) \cap \boldsymbol{\Sigma}_1^M \not\subseteq M.$$

2.2 Lemma. *Let M be as above. If $\rho(M) \in M$, then $\rho(M)$ is a cardinal in M.*

Proof. Suppose not. Set $\rho = \rho(M)$. Let $f \in M$ be such that $f : \gamma \xrightarrow{\text{onto}} \rho$ for some $\gamma < \rho$ and $A \in \boldsymbol{\Sigma}_1^M$ be such that $a = A \cap \rho \notin M$. Let $\bar{a} = f^{-1}``a$. Then $\bar{a} \notin M$, since otherwise $a = f``\bar{a} \in M$. On the other hand, $\bar{a} \in M$ by the definition of ρ, since $\bar{a} \subseteq \gamma$ and $\bar{a} \in \boldsymbol{\Sigma}_1^M$. Contradiction. ⊣

2.3 Lemma. *Let M be as above and $\rho = \rho(M)$. Then ρ is a Σ_1 cardinal in M (i.e. there is no $\boldsymbol{\Sigma}_1^M$ partial map from some $\gamma < \rho$ onto ρ).*

Proof. Suppose that there is such a map, say $f : \gamma \xrightarrow{\text{onto}} \rho$. We know that there is a $\boldsymbol{\Sigma}_1^{J_\rho^A}$ map of ρ onto J_ρ^A (cf. Lemma 1.17). Hence there is a $\boldsymbol{\Sigma}_1^M$ map $g : \gamma \xrightarrow{\text{onto}} J_\rho^A$. Define a set b by

$$\xi \in b \iff \xi \notin g(\xi).$$

Then b is clearly $\boldsymbol{\Sigma}_1^M$ and $b \subseteq \gamma$. Moreover, $b \notin J_\rho^A$ by a diagonal argument: if $b \in J_\rho^A$ then $b = g(\xi_0)$ for some $\xi_0 < \gamma$ which would give $\xi_0 \in b = g(\xi_0)$ iff $\xi_0 \notin g(\xi_0)$. Hence $b \notin M$: this follows from Lemma 1.23 if $\rho \in M$ and is immediate otherwise. On the other hand, $\gamma < \rho$, and therefore $b \in M$. Contradiction! ⊣

Lemma 1.17 and Lemma 1.23 now immediately give the following.

2.4 Corollary. *Let M be acceptable and $\rho = \rho(M)$.*

(a) If $B \subseteq J_\rho^A$ is $\boldsymbol{\Sigma}_1^M$, then $\langle J_\rho^A, B\rangle$ is amenable.

(b) $|J_\rho^A| = H_\rho^M$.

Recall that we fixed a recursive enumeration $\langle \varphi_i \mid i < \omega\rangle$ of all Σ_1 formulae. In what follows it will be convenient to pretend that each φ_i has exactly *one* free variable. For instance, if $\varphi_i = \varphi_i(v_{i_1}, \ldots, v_{i_\ell})$ with all free variables shown then we might confuse φ_i with

$$\exists v_{i_1} \ldots \exists v_{i_\ell}(u = \langle v_{i_1}, \ldots, v_{i_\ell}\rangle \wedge \varphi_i(v_{i_1}, \ldots, v_{i_\ell})).$$

To make things even worse, we shall nevertheless often write $\varphi_i(x_1,\ldots,x_\ell)$ instead of $\varphi_i(\langle x_1,\ldots,x_\ell\rangle)$. If $\mathsf{a} : v(i) \to V$ assigns values to the free variable(s) $v_{i_1},\ldots,v_{i_\ell}$ of φ_i then, setting $x_1 = \mathsf{a}(v_{i_1}),\ldots,x_\ell = \mathsf{a}(v_{i_\ell})$ we shall use the more suggestive $M \models \varphi_i(x_1,\ldots,x_\ell)$ rather than $\models^{\Sigma_1}_M \varphi_i[\mathsf{a}]$ in what follows. We shall also write $h_M(i,\vec{x})$ instead of $h_M(i,\mathsf{a})$.

2.5 Definition. Let $M = \langle J^B_\alpha, D\rangle$ be an acceptable J-structure, $\rho = \rho(M)$ and $p \in M$. We define

$$A^p_M = \{\langle i,x\rangle \in \omega \times H^M_\rho \mid M \models \varphi_i(x,p)\}.$$

A^p_M is called the *standard code* determined by p. Let us stress that A^p_M is the intersection of $\omega \times H^M_\rho$ with a set $\tilde{A}^p_M$ (defined in an obvious way) which is $\Sigma^M_1(\{p\})$. We shall often write $A^p_M(i,x)$ instead of $\langle i,x\rangle \in A^p_M$. The structure

$$M^p = \langle J^B_\rho, A^p_M\rangle$$

is called the *reduct* determined by p. If $\delta = \rho$ or $\delta < \rho$ where δ is a cardinal in M, we also set

$$A^{p,\delta}_M = A^p \cap J^B_\delta,$$
$$M^{p,\delta} = \langle J^B_\delta, A^{p,\delta}_M\rangle.$$

We shall omit the subscript $_M$ whenever there is no danger of confusion.

2.6 Definition. Let M be acceptable and $\rho = \rho(M)$.

$$\begin{aligned} P_M = {} & \text{the set of all } p \in [\rho(M), M \cap \mathrm{On})^{<\omega} \text{ for which} \\ & \text{there is a } B \in \Sigma^M_1(\{p\}) \text{ such that } B \cap \rho \notin M. \end{aligned}$$

The elements of P_M are called *good parameters*.

2.7 Lemma. *Let M be as before, $p \in M$ and $A = A^p_M$. Then*

$$p \in P_M \iff A \cap (\omega \times \rho(M)) \notin M.$$

Proof. ($\Longrightarrow$) Pick B which witnesses that $p \in P_M$. Suppose that B is defined by φ_i. Hence $B(\xi) \leftrightarrow \langle i,\xi\rangle \in A$, which means that if $A \cap (\omega \times \rho(M))$ is in M, then so is $B \cap \rho(M)$. Hence the former is not an element of M.

($\Longleftarrow$) Suppose that $A \cap (\omega \times \rho(M)) \notin M$. Let $f : \omega \times \rho(M) \longrightarrow \rho(M)$ be defined by $f(i, \omega\xi + j) = \omega\xi + 2^i{\cdot}3^j$. Clearly f is Σ^M_1 uniformly and if $\rho(M) \in M$ then $f \in M$. Let $B = f``A$. Then $B$ is $\Sigma^M_1(\{p\})$ and $B \cap \rho(M) \notin M$: if $\rho(M) \in M$, this follows from the fact that $f \in M$ and $A \cap (\omega \times \rho(M)) = f^{-1}``(B \cap \rho(M))$; if $\rho(M) \notin M$, it follows from the fact that B is cofinal in $\rho(M)$. $\dashv$

2.8 Definition. Let M be acceptable and $\rho = \rho(M)$. We set

$$R_M = \text{ the set of all } r \in [\rho(M), M \cap \mathrm{On})^{<\omega} \text{ such that } h_M(\rho \cup \{r\}) = |M|.$$

The elements of R_M are called *very good parameters*.

2.9 Lemma. *$R_M \subseteq P_M \neq \emptyset$.*

Proof. By the proof of Lemma 1.17, $h_M(M \cap \mathrm{On}) = M$ for any J-structure M. Given an acceptable structure M, if A is a relation which is $\Sigma_1^M(\{p\})$ for some $p \in M$ then A is therefore also $\Sigma_1^M(\{q\})$ for some $q \in [M \cap \mathrm{On}]^{<\omega}$. As $\rho(M)$ is closed under the Gödel pairing function (if $\rho(M) < M \cap \mathrm{On}$), the inequality easily follows. As to the inclusion, define the set $a \subseteq \omega \times M \cap \mathrm{On}$ by

$$\langle i, \xi \rangle \in a \quad \Longleftrightarrow \quad \langle i, \xi \rangle \notin h_M(i, \langle \xi, p \rangle)$$

for a $p \in R_M$. By a diagonal argument, $a \cap \omega \times \rho(M) \notin M$ and a is $\Sigma_1(M)$ in p. Using the map f from the proof of Lemma 2.7 it is easy to turn the set a into some $b \subseteq M \cap \mathrm{On}$ such that b is Σ_1^M in p and $b \cap \rho(M) \notin M$. ⊣

We remark that P_M and R_M are often defined differently so as to include arbitrary elements of M rather than just finite sequences of ordinals in the half-open interval $[\rho(M), M \cap \mathrm{On})$.

3. Downward Extension of Embeddings

Given a Σ_0 preserving map between the reducts of two acceptable structures, the question naturally arises whether the map can be extended to a map between the original structures. It turns out that this is possible. The conjunction of the following three lemmas is called the *Downward Extension of Embeddings Lemma.*

3.1 Lemma. *Let $\pi : \bar{M}^{\bar{p}} \underset{\Sigma_0}{\longrightarrow} M^p$, where $\bar{p} \in R_{\bar{M}}$. Then there is a unique $\tilde{\pi} : \bar{M} \underset{\Sigma_0}{\longrightarrow} M$ such that $\tilde{\pi} \supseteq \pi$ and $\tilde{\pi}(\bar{p}) = p$. Moreover, $\tilde{\pi} : \bar{M} \underset{\Sigma_1}{\longrightarrow} M$.*

Proof. Uniqueness: Assume that $\tilde{\pi}$ has the above properties. Let $x \in \bar{M}$. Then $x = h_{\bar{M}}(i, \langle \xi, \bar{p} \rangle)$ for some $i \in \omega$ and $\xi < \rho(M)$. Let $\bar{H}$ be $\Sigma_0^{\bar{M}}$ such that $\exists z\, \bar{H}(z, x, i, \xi, \bar{p})$ defines the Skolem function $h_{\bar{M}}$ (this involves a slight abuse of notation). $\bar{H}$ has a uniform definition, so let H have the same definition over M. Pick z such that $\bar{H}(z, x, i, \xi, \bar{p})$. Since $\tilde{\pi}$ is Σ_0 preserving, we have $H(\tilde{\pi}(z), \tilde{\pi}(x), i, \tilde{\pi}(\xi), p)$, i.e. $\tilde{\pi}(x) = h_M(i, \langle \tilde{\pi}(\xi), p \rangle) = h_M(i, \langle \pi(\xi), p \rangle)$. Hence, there is at most one such $\tilde{\pi}$.

Existence: The above proof of uniqueness suggests how to define the extension $\tilde{\pi}$. Here we show that such a definition is correct. We first observe:

Claim. Suppose that $\varphi(v_1, \dots, v_\ell)$ is a Σ_1 formula. Let $\bar{x}_i = h_{\bar{M}}(j_i, \langle \bar{\xi}_i, \bar{p} \rangle)$ for some $j_i \in \omega$, $\bar{\xi}_i < \rho(M)$ and $x_i = h_M(j_i, \langle \xi_i, p \rangle)$ where $\xi_i = \pi(\bar{\xi}_i)$ $(i = 1, \dots, \ell)$. Then

$$\bar{M} \models \varphi(\bar{x}_1, \dots, \bar{x}_\ell) \quad \Longleftrightarrow \quad M \models \varphi(x_1, \dots, x_\ell).$$

Proof. $\bar{M} \models \varphi(\bar{x}_1, \ldots, \bar{x}_\ell)$ is equivalent to

$$\bar{M} \models \varphi(h_{\bar{M}}(j_1, \langle \bar{\xi}_1, \bar{p} \rangle), \ldots, h_{\bar{M}}(j_\ell, \langle \bar{\xi}_\ell, \bar{p} \rangle)).$$

Since $h_{\bar{M}}$ has a uniform Σ_1 definition over $\bar{M}$, there is a Σ_1 formula ψ such that the above is equivalent to

$$\bar{M} \models \psi(\bar{\xi}_1, \ldots, \bar{\xi}_\ell, \bar{p}). \tag{9.4}$$

The formula ψ clearly does not depend on the actual structure in question, so the statement $M \models \varphi(x_1, \ldots, x_\ell)$ is equivalent to

$$M \models \psi(\xi_1, \ldots, \xi_\ell, p). \tag{9.5}$$

Now suppose that $\psi(\xi_1, \ldots, \xi_\ell, p) \iff \varphi_k(\langle \xi_1, \ldots, \xi_\ell \rangle, p)$ in our fixed recursive enumeration of Σ_1 formulae, hence (9.4) is equivalent to

$$A_{\bar{M}}^{\bar{p}}(k, \langle \bar{\xi}_1, \ldots, \bar{\xi}_\ell \rangle) \tag{9.6}$$

and (9.5) is equivalent to

$$A_M^p(k, \langle \xi_1, \ldots, \xi_\ell \rangle). \tag{9.7}$$

Since π is Σ_0 preserving, (9.6) and (9.7) are equivalent. $\dashv$

Now define $\tilde{\pi}$ by

$$\tilde{\pi}(h_{\bar{M}}(i, \langle \xi, \bar{p} \rangle)) \simeq h_M(i, \langle \pi(\xi), p \rangle)$$

for $i \in \omega$ and $\xi < \rho(\bar{M})$. We have to verify several facts:

- $\tilde{\pi}$ is well defined.
  Let $h_{\bar{M}}(j_1, \langle \bar{\xi}_1, \bar{p} \rangle) = h_{\bar{M}}(j_2, \langle \bar{\xi}_2, \bar{p} \rangle)$ for some $j_1, j_2 \in \omega$ and $\bar{\xi}_1, \bar{\xi}_2 < \rho(\bar{M})$. We have to show that $h_M(j_1, \langle \xi_1, p \rangle) = h_M(j_2, \langle \xi_2, p \rangle)$, where $\xi_i = \pi(\bar{\xi}_i)$ $(i = 1, 2)$. By the above claim, this follows immediately.

- $\tilde{\pi}$ is Σ_1 preserving.
  Since $\tilde{\pi}$ is a well defined map, this follows immediately from the above claim.

- $\tilde{\pi} \supseteq \pi$.
  There is an $i \in \omega$ such that the equality $x = h_M(i, \langle x, q \rangle)$ holds uniformly and independently of q. In particular, for $\xi < \rho(\bar{M})$ we have $\xi = h_{\bar{M}}(i, \langle \xi, \bar{p} \rangle)$, so

  $$\tilde{\pi}(\xi) = h_M(i, \langle \pi(\xi), p \rangle) = \pi(\xi).$$

- $\tilde{\pi}(\bar{p}) = p$.
  Similarly as above, there is an $i \in \omega$ such that $q = h(i, \langle x, q \rangle)$ uniformly. Hence $\bar{p} = h_{\bar{M}}(i, \langle 0, \bar{p} \rangle)$ and $\tilde{\pi}(\bar{p}) = h_M(i, \langle 0, p \rangle) = p$.

$\dashv$

3.2 Lemma. *Let $\bar{M}$, M, $\bar{p}$, p, π, $\tilde{\pi}$ be as above. Suppose moreover that $p \in R_M$. Let $\pi : \bar{M}^{\bar{p}} \underset{\Sigma_n}{\longrightarrow} M^p$. Then*

$$\tilde{\pi} : \bar{M} \underset{\Sigma_{n+1}}{\longrightarrow} M.$$

Proof. We shall proceed by induction. Suppose that the lemma holds for n. Suppose that we have a Σ_{n+1} formula φ which is of the form

$$\exists z_1 \, \forall z_2 \ldots \exists/\forall z_{n+1} \, \bar{\varphi}(z_1, \ldots, z_{n+1}, x_1, \ldots, x_\ell), \tag{9.8}$$

where $\bar{\varphi}$ is Σ_0. For notational simplicity, assume that $n = 2$ and $\ell = 1$. Given a J-structure N and an arbitrary $q \in R_N$, the structure N satisfies (9.8) iff it satisfies the formula

$$\begin{aligned} &\exists \xi_1 < \rho(N) \exists i_1 \forall \xi_2 < \rho(N) \forall i_2 [\exists y \, y = h_N(i_2, \langle \xi_2, q \rangle) \\ &\quad \to \exists y_1 \exists y_2 \exists x \exists z_3 (y_1 = h_N(i_1, \langle \xi_1, q \rangle) \wedge y_2 = h_N(i_2, \langle \xi_2, q \rangle) \wedge \\ &\qquad\qquad x = h_N(j_1, \langle \zeta_1, q \rangle) \wedge \bar{\varphi}(y_1, y_2, z_3, x))] \end{aligned} \tag{9.9}$$

where $x_1 = h_N(j_1, \langle \zeta_1, q \rangle)$. (For an arbitrary n, the analogous fact can be verified by a straightforward induction on n using that q is a very good parameter.) Notice that the matrix in (9.9) is of the form $\psi_1 \to \psi_2$, where both ψ_1 and ψ_2 are Σ_1 via a uniform transformation, i.e., there are k_1, $k_2 \in \omega$ depending only on $\bar{\varphi}$ such that (9.9) can be expressed in a Σ_2-fashion over N^q in the following way:

$$\begin{aligned} &\exists \xi_1 \, \exists i_1 \, \forall \xi_2 \, \forall i_2 \, [A^q_N(k_1, \langle \xi_1, i_1, \xi_2, i_2, \zeta_1, j_1 \rangle) \\ &\quad \to A^q_N(k_2, \langle \xi_1, i_1, \xi_2, i_2, \zeta_1, j_1 \rangle)]. \end{aligned}$$

Then, if in fact $x_1 = h_{\bar{M}}(j_1, \langle \zeta_1, \bar{p} \rangle)$,

$$\begin{aligned} \bar{M} \models \varphi(x_1) \quad &\iff \quad \exists \xi_1 \, \exists i_1 \, \forall \xi_2 \, \forall i_2 \, [A^{\bar{p}}_{\bar{M}}(k_1, \langle \xi_1, i_1, \xi_2, i_2, \zeta_1, j_1 \rangle) \\ &\qquad\quad \to A^{\bar{p}}_{\bar{M}}(k_2, \langle \xi_1, i_1, \xi_2, i_2, \zeta_1, j_1 \rangle)] \\ &\iff \quad \exists \xi_1 \, \exists i_1 \, \forall \xi_2 \, \forall i_2 \, [A^p_M(k_1, \langle \xi_1, i_1, \xi_2, i_2, \pi(\zeta_1), j_1 \rangle) \\ &\qquad\quad \to A^p_M(k_2, \langle \xi_1, i_1, \xi_2, i_2, \pi(\zeta_1), j_1 \rangle)] \\ &\iff \quad M \models \varphi(\tilde{\pi}(x_1)). \end{aligned}$$

Similar, but slightly more complicated reductions can be done for arbitrary n; we leave this to the reader. ⊣

3.3 Lemma. *Let $\pi : N \underset{\Sigma_0}{\longrightarrow} M^p$, where N is a J-structure and $p \in R_M$. Then there are unique $\bar{M}$, $\bar{p}$ such that $\bar{p} \in R_{\bar{M}}$ and $N = \bar{M}^p$.*

Proof. Let $M = \langle J^B_\alpha, D \rangle$, $M^p = \langle J^B_\rho, A \rangle$ and $N = \langle J^{\bar{B}'}_{\bar{\rho}}, \bar{A} \rangle$. (In particular, $A = A^p_M$.) Let also $X = \mathrm{ran}(\pi)$, $Y = h_M(X \cup \{p\})$, let $\bar{M}$ be the transitive collapse of Y and let $\tilde{\pi} : \bar{M} \to Y$ be the inverse of the Mostowski collapse.

The map $\tilde{\pi}$ is clearly Σ_1-preserving, hence $\bar{M}$ is of the form $\langle J^{\bar{B}}_{\bar{\alpha}}, \bar{D}\rangle$. We shall show that $\bar{M}$ is the desired structure. We prove first

$$\tilde{\pi} \supseteq \pi \quad \text{and} \quad J^{\bar{B}'}_{\bar{\rho}} = J^{\bar{B}}_{\bar{\rho}}, \tag{9.10}$$

which follows immediately from

$$\text{if} \quad x \in X,\ y \in Y \text{ and } y \in x, \quad \text{then} \quad y \in X \tag{9.11}$$

since the latter tells us that the collapsing map for Y restricted to X coincides with π^{-1}.

So suppose that $y = h_M(i, \langle z, p\rangle)$ for some $z \in X$. Since both $y, z \in M^p$, this can be equivalently expressed in the form $A(k, \langle y, z\rangle)$ for some $k \in \omega$. Thus we have

$$\exists v \in x\ A(k, \langle v, z\rangle)$$

which is preserved by a Σ_0 map, so

$$\exists v \in \bar{x}\ \bar{A}(k, \langle v, \bar{z}\rangle)$$

where $(\bar{x}, \bar{z}) = \pi^{-1}(x, z)$. Let $\bar{y} \in \bar{x}$ be such that $A(k, \langle \bar{y}, \bar{z}\rangle)$. Such a $\bar{y}$ is uniquely determined: if $\bar{y}_1$ were another one, we would have

$$A(k, \langle \pi(\bar{y}), z\rangle) \wedge A(k, \langle \pi(\bar{y}_1), z\rangle),$$

which means that $\pi(\bar{y}) = h_M(i, \langle z, p\rangle) = \pi(\bar{y}_1)$, hence $\bar{y} = \bar{y}_1$. This argument also shows $\pi(\bar{y}) = y$. Hence $y \in X$.

We have shown (9.10) and (9.11).

Now let

$$\bar{p} = \tilde{\pi}^{-1}(p).$$

Note that there is a $\mathbf{\Sigma}^{\bar{M}}_1$ map of $\bar{\rho}$ onto $\bar{M}$; this follows immediately from the fact that $\bar{M} = h_{\bar{M}}(J^{\bar{B}}_{\bar{\rho}} \cup \{\bar{p}\})$ and that there is a $\mathbf{\Sigma}^{\bar{M}}_1$ map of $\bar{\rho}$ onto $J^{\bar{B}}_{\bar{\rho}}$. So we have

$$\rho(\bar{M}) \leq \bar{\rho}. \tag{9.12}$$

Note also that if $i \in \omega$ and $x \in N$, then

$$\bar{A}(i, x) \iff A(i, \tilde{\pi}(x)) \iff M \models \varphi_i(\tilde{\pi}(x), p) \iff \bar{M} \models \varphi_i(x, \bar{p}) \tag{9.13}$$

where $\langle \varphi_i\rangle_i$ is the fixed recursive enumeration of the Σ_1 formulae. Our aim is to show

$$\rho(\bar{M}) = \bar{\rho} \tag{9.14}$$

which reduces to proving the inequality $\bar{\rho} \leq \rho(\bar{M})$. Let P be $\mathbf{\Sigma}^{\bar{M}}_1(\{\bar{q}\})$. By the fact that $h_{\bar{M}}(J^{\bar{B}}_{\bar{\rho}} \cup \{\bar{p}\}) = \bar{M}$ we can find an R which is $\Sigma^{\bar{M}}_1$ and such that

$$P(z) \iff R(z, x, \bar{p})$$

for some fixed $x \in N$. By (9.13), there is an $i \in \omega$ such that

$$P(z) \iff \bar{A}(i, \langle z, x\rangle).$$

Hence if $\gamma < \bar{\rho}$ then $P \cap \gamma$ is a projection of $\bar{A} \cap (\{i\} \times \gamma \times \{x\}) \in N \subseteq \bar{M}$, thus it is itself in $\bar{M}$. This proves (9.14).

As an immediate consequence of (9.13) and (9.14) we get

$$\bar{A} = A^{\bar{p}}_{\bar{M}}. \tag{9.15}$$

It only remains to prove that

$$\bar{p} \in R_{\bar{M}}. \tag{9.16}$$

If $\bar{M} = N$ this is trivial. Otherwise there is a Σ_1^M map of $\bar{\rho}$ onto $J^{\bar{B}}_{\bar{\rho}}$. Since $h_{\bar{M}}(J^{\bar{B}}_{\bar{\rho}} \cup \{\bar{p}\}) = \bar{M}$, the proof is complete. ⊣

4. Upward Extension of Embeddings

In this section we present a method which gives a solution to the problem dual to that from the previous section, where we formed the extension of an embedding from the reduct of a J-structure to the whole structure: namely, we now aim to build a target model that can serve as the codomain of an extended embedding. This problem is a bit more delicate than the previous one, since such an extension need not always exist; therefore we have to strengthen our requirements on the embeddings we intend to extend. The difference between forming downward and upward extensions lies in the fact that the former ones are related to taking hulls and collapsing them, which is always possible, whilst the latter ones are related to forming ultrapowers, which have transitive isomorphs only if they are well-founded.

4.1 Definition. $\pi : \bar{M} \to M$ is a *strong embedding* iff

(a) $\pi : \bar{M} \underset{\Sigma_1}{\longrightarrow} M$.

(b) For any $\bar{R}$, R such that $\bar{R}$ is rudimentary over $\bar{M}$ and R is rudimentary over M by the same definition the following holds:

If $\bar{R}$ is well-founded, then so is R.

The *Upward Extension of Embeddings Lemma* is the conjunction of the following lemma together with Lemmata 3.1 and 3.2.

4.2 Lemma. *Let $\pi : \bar{M}^{\bar{p}} \to N$ be a strong embedding, where N is acceptable and $\bar{p} \in R_{\bar{M}}$. Then there are unique M, p such that $N = M^p$ and $p \in R_M$. Moreover, $\tilde{\pi}$ is strong, where $\tilde{\pi} \supseteq \pi$, $\tilde{\pi} : \bar{M} \underset{\Sigma_1}{\longrightarrow} M$ and $\tilde{\pi}(\bar{p}) = p$.*

Proof. Uniqueness. Suppose that $\tilde{\pi}_1 : \bar{M} \to M_1$ and $\tilde{\pi}_2 : \bar{M} \to M_2$ are two extensions of π satisfying the conclusions of the lemma and that p_1, p_2 are the corresponding parameters. Then $A^{p_1}_{M_1} = A^{p_2}_{M_2}$, call it A, and every $x \in M_k$ is of the form $h_{M_k}(i, \langle \xi, p_k \rangle)$ for some $i \in \omega$ and $\xi \in N \cap \mathrm{On}$ $(k = 1, 2)$. Let $\sigma : M_1 \to M_2$ be the map sending $h_{M_1}(i, \langle \xi, p_1 \rangle)$ to $h_{M_2}(i, \langle \xi, p_2 \rangle)$. Then σ is well defined since

$$\exists z\, z = h_{M_1}(i, \langle \xi, p_1 \rangle) \iff A(j, \langle i, \xi \rangle) \iff \exists z\, z = h_{M_2}(i, \langle \xi, p_2 \rangle) \tag{9.17}$$

for an appropriate j (i.e., j is such that $\exists z\, z = h_{M_k}(i, \langle \xi, p_k \rangle)$ can be expressed as $M_k \models \varphi_j(\langle i, \xi \rangle)$ for $k = 1, 2$). Also, σ is Σ_1-preserving, since given any Σ_1 formula $\psi(v_1, \ldots, v_\ell)$ and $x_s = h_{M_1}(i_s, \langle \xi_s, p_1 \rangle)$ $(s = 1, \ldots, \ell)$,

$$\begin{aligned} M_1 \models \psi(x_1, \ldots, x_\ell) &\iff M_1 \models \psi(h_{M_1}(i_1, \langle \xi_1, p_1 \rangle), \ldots, h_{M_1}(i_\ell, \langle \xi_\ell, p_1 \rangle)) \\ &\iff A(j, \langle \langle i_1, \xi_1 \rangle, \ldots, \langle i_\ell, \xi_\ell \rangle \rangle) \\ &\iff M_2 \models \psi(h_{M_2}(i_1, \langle \xi_1, p_2 \rangle), \ldots, h_{M_2}(i_\ell, \langle \xi_\ell, p_2 \rangle)) \\ &\iff M_2 \models \psi(\sigma(x_1), \ldots, \sigma(x_\ell)) \end{aligned}$$

for a suitable j (which only depends on ψ). It is then easy to see that σ is structure preserving and $\sigma \circ \tilde{\pi}_1 = \tilde{\pi}_2$. Furthermore, (9.17) implies that $\mathrm{ran}(\sigma) = M_2$. Thus, $M_1 = M_2$, $\tilde{\pi}_1 = \tilde{\pi}_2$ and $p_1 = p_2$.

Existence. The idea of the construction is simple: using the fact that $\bar{p} \in R_{\bar{M}}$, we encode the whole structure $\bar{M}$ and its satisfaction relation in a rudimentary fashion over $\bar{M}^{\bar{p}}$. The preservation properties of π then guarantee that the corresponding relations with the same rudimentary definitions over N encode the required structure M; the process of decoding will also yield the extension $\tilde{\pi}$. However, the verification of all details is somewhat technical.

Suppose that $\bar{M} = \langle J^{\bar{B}}_{\bar{\alpha}}, \bar{D} \rangle$. Let $\bar{k}(\langle i, z \rangle) \simeq h_{\bar{M}}(i, \langle z, \bar{p} \rangle)$ and $\bar{d} = \mathrm{dom}(\bar{k})$. Then membership in $\bar{d}$ is expressible by a Σ_1 statement over $\bar{M}$ in $\bar{p}$ as

$$x \in \bar{d} \iff \exists i\, \exists z\ (i \in \omega \wedge x = \langle i, z \rangle \wedge \exists y\ y = h_{\bar{M}}(i, \langle z, \bar{p} \rangle).$$

So there is an $i_0 \in \omega$ such that for every $x \in \bar{M}^{\bar{p}}$ we have $x \in \bar{d}$ iff $A^{\bar{p}}_{\bar{M}}(i_0, x)$. Note that the latter is a rudimentary relation over $\bar{M}^{\bar{p}}$. Similarly, the identity and membership relations as well as the membership in $\bar{B}$ and $\bar{D}$ can be expressed in a Σ_1 fashion over $\bar{M}$ in $\bar{p}$, and therefore in a rudimentary fashion over $\bar{M}^{\bar{p}}$. More precisely, we introduce relations $\bar{I}, \bar{E}, \bar{B}^*$ and $\bar{D}^*$ over $\bar{d}$ as follows

$$\begin{aligned} x\, \bar{I}\, y &\iff \bar{k}(x) = \bar{k}(y), \\ x\, \bar{E}\, y &\iff \bar{k}(x) \in \bar{k}(y), \\ \bar{B}^*(x) &\iff \bar{B}(\bar{k}(x)), \\ \bar{D}^*(x) &\iff \bar{D}(\bar{k}(x)) \end{aligned}$$

and set

$$\bar{\mathbb{D}} = \langle \bar{d}, \bar{I}, \bar{E}, \bar{B}^*, \bar{D}^* \rangle.$$

The symbol for $=$ is interpreted in $\bar{\mathbb{D}}$ as $\bar{I}$, the symbol for $\in$ as $\bar{E}$, and the symbols for $\bar{B}, \bar{D}$ as $\bar{B}^*$ and $\bar{D}^*$, respectively. Thus $\bar{\mathbb{D}}$ encodes the structure $\bar{M}$: $\bar{I}$ is a congruence relation on $\bar{\mathbb{D}}$, $\bar{E}$ represents the membership relation and $\bar{k}$ is the Mostowski collapsing isomorphism between $\bar{\mathbb{D}}/\bar{I}$ and $\bar{M}$. We denote the Σ_1-satisfaction relation for $\bar{\mathbb{D}}$ by $\bar{T}$. More precisely, for $x_1, \ldots, x_\ell \in \bar{d}$ and $i \in \omega$ we have

$$\bar{T}(i, \langle x_1, \ldots, x_\ell \rangle) \quad \Longleftrightarrow \quad \bar{\mathbb{D}} \models \varphi_i(x_1, \ldots, x_\ell)$$

where $\langle \varphi_i; i \in \omega \rangle$ is our fixed recursive enumeration of Σ_1 formulae (remember that $\langle x_1, \ldots, x_\ell \rangle = \langle x_1, \langle x_2, \ldots, x_\ell \rangle \rangle$ and that we write $\varphi_i(x_1, \ldots, x_\ell)$ instead of $\varphi_i(\langle x_1, \ldots, x_\ell \rangle)$). One can easily show the following equivalence by induction:

$$\bar{T}(i, \langle x_1, \ldots, x_\ell \rangle) \quad \Longleftrightarrow \quad \bar{M} \models \varphi_i(\bar{k}(x_1), \ldots, \bar{k}(x_\ell)).$$

For atomic formulae this follows immediately from the definitions of the relations $\bar{I}, \bar{E}, \bar{B}^*$ and $\bar{D}^*$. To illustrate how the induction steps go we show the induction step for the formula $\varphi_j(v)$ of the form $\exists z \in \operatorname{left}(v)\ \varphi_i(z, v)$ (recall that $\operatorname{left}(v) = v_1$ and $\operatorname{right}(v) = v_2$ if $v = \langle v_1, v_2 \rangle$ and undefined otherwise). Then

$$\begin{aligned}
\bar{\mathbb{D}} \models \varphi_j(x_1, \ldots, x_\ell) \quad & \Longleftrightarrow \quad \exists w \in \bar{d}[w \bar{E} x_1 \wedge \bar{\mathbb{D}} \models \varphi_i(w, x_1, x_2, \ldots, x_\ell)] \\
& \Longleftrightarrow \quad \exists w[\bar{k}(w) \in \bar{k}(x_1) \\
& \qquad\quad \wedge \bar{M} \models \varphi_i(\bar{k}(w), \bar{k}(x_1), \bar{k}(x_2), \ldots, \bar{k}(x_\ell))] \\
& \Longleftrightarrow \quad \bar{M} \models \varphi_j(\bar{k}(x_1), \ldots, \bar{k}(x_\ell)).
\end{aligned}$$

The middle equivalence follows by the induction hypothesis, the last one by the fact that if there is a z witnessing the bottom formula, then such a z is always of the form $\bar{k}(w)$ for some w.

Let d, I, E, B^* and D^* be rudimentary over N by the same rudimentary definitions as their counterparts over $\bar{M}^{\bar{p}}$. It follows from the above that $\bar{T}$ is $\Sigma_1^{\bar{M}}$ in $\bar{p}$ and therefore rudimentary over $\bar{M}^{\bar{p}}$. Let

$$\mathbb{D} = \langle d, I, E, B^*, D^* \rangle$$

and T be a relation which is rudimentary over N by the same rudimentary definition as $\bar{T}$. We show that T is the Σ_1-satisfaction predicate for $\mathbb{D}$. Strictly speaking, we must show that the following equivalences hold, where $\varphi_i(v)$

has the form indicated on the left hand side:

$$\begin{array}{lrcl}
\text{left}(v) = \text{right}(v) & T(i, \langle x, y \rangle) & \iff & x\, I\, y \\
\text{left}(v) \in \text{right}(v) & T(i, \langle x, y \rangle) & \iff & x\, E\, y \\
B(v) & T(i, x) & \iff & B^*(x) \\
D(v) & T(i, x) & \iff & D^*(x) \\
\varphi_{i_1}(v) \wedge \varphi_{i_2}(v) & T(i, \vec{x}\,) & \iff & T(i_1, \vec{x}\,) \wedge T(i_2, \vec{x}\,) \\
\neg\varphi_j(v) & T(i, \vec{x}\,) & \iff & \neg T(j, \vec{x}\,) \\
\exists z \in \text{left}(v)\ \varphi_j(z, v) & T(i, \langle x, \vec{y}\,\rangle) & \iff & \exists z \in d\ (z\, E\, x \wedge T(j, \langle z, x, \vec{y}\,\rangle)) \\
\forall z \in \text{left}(v)\ \varphi_j(z, v) & T(i, \langle x, \vec{y}\,\rangle) & \iff & \forall z \in d\ (z\, E\, x \wedge T(j, \langle z, x, \vec{y}\,\rangle)) \\
\exists z\ \varphi_j(z, v) & T(i, \vec{x}\,) & \iff & \exists z \in d\ T(j, \langle z, \vec{x}\,\rangle).
\end{array}$$

Here $\vec{x}$ stands for $\langle x_1, \ldots, x_\ell \rangle$. We again proceed by induction on formulae. Suppose first that φ_i is an atomic formula, say the formula $\text{left}(v) = \text{right}(v)$. Then

$$\forall x, y \in \bar{d}\ (\bar{T}(i, \langle x, y \rangle) \iff x\, \bar{I}\, y).$$

This is a Π_1 statement over $\bar{M}^{\bar{p}}$, since the predicates $\bar{d}, \bar{T}$ and $\bar{I}$ are rudimentary. Since π is Σ_1-preserving, $T(i, \langle x, y \rangle)$ iff $x\, I\, y$ iff $\mathbb{D} \models \varphi_i(x, y)$ for all $x, y \in d$.

Now suppose that $\varphi_i(v)$ is the formula $\varphi_{i_1}(v) \wedge \varphi_{i_2}(v)$. Then

$$\begin{aligned}
&\forall x_1, \ldots, x_\ell \in \bar{d} \\
&\qquad [\bar{T}(i, \langle x_1, \ldots, x_\ell \rangle) \iff \bar{T}(i_1, \langle x_1, \ldots, x_\ell \rangle) \wedge \bar{T}(i_2, \langle x_1, \ldots, x_\ell \rangle)].
\end{aligned}$$

This is again a Π_1-statement over $\bar{M}^{\bar{p}}$, so we obtain

$$\begin{aligned}
T(i, \langle x_1, \ldots, x_\ell \rangle) &\iff T(i_1, \langle x_1, \ldots, x_\ell \rangle) \wedge T(i_2, \langle x_1, \ldots, x_\ell \rangle) \\
&\iff \mathbb{D} \models \varphi_{i_1}(x_1, \ldots, x_\ell) \wedge \varphi_{i_2}(x_1, \ldots, x_\ell) \\
&\iff \mathbb{D} \models \varphi_i(x_1, \ldots, x_\ell);
\end{aligned}$$

the second equivalence follows from the induction hypothesis. We proceed similarly if $\varphi_i(v)$ is of the form $\neg\varphi_j(v)$.

Finally, suppose that $\varphi_i(v)$ introduces a quantifier; say $\varphi_i(v)$ is of the form $\exists z \in \text{left}(v)\, \varphi_j(z, v)$. The implication ($\Longleftarrow$) follows easily: Since $\bar{T}$ is a satisfaction relation for $\bar{\mathbb{D}}$, we have

$$\forall x, y\, [\exists z\, (z\, \bar{E}\, x \wedge \bar{T}(j, \langle z, x, y \rangle)) \to \bar{T}(i, \langle x, y \rangle)].$$

This is a Π_1-statement over $\bar{M}^{\bar{p}}$ and is therefore preserved upwards by π. To see the converse, let $\bar{g}$ be a $\Sigma_1^{\bar{M}}$-function in $\bar{p}$ uniformizing the relation

$$z \in \bar{k}(x) \wedge \varphi_j(z, \bar{k}(x), \bar{k}(y)).$$

Then $\bar{g}(u) \simeq h_{\bar{M}}(m, \langle u, \bar{p} \rangle) \simeq \bar{k}(\langle m, u \rangle)$ for an appropriate $m \in \omega$; hence,

$$\begin{aligned}
&\varphi_i(\bar{k}(x), \bar{k}(y)) \to \langle m, x, y \rangle \in \text{dom}(\bar{k}) \wedge \bar{k}(\langle m, x, y \rangle) \in \bar{k}(x) \\
&\quad \wedge \varphi_j(\bar{k}(\langle m, x, y \rangle), \bar{k}(x), \bar{k}(y))
\end{aligned}$$

holds in $\bar{\mathbb{D}}$ for all x, y in $\bar{M}^{\bar{p}}$. Translating this into the language of $\bar{\mathbb{D}}$ we obtain

$$\forall x, y\ [\bar{T}(i, \langle x, y\rangle) \to \langle m, x, y\rangle \in \bar{d} \wedge \langle m, x, y\rangle \bar{E} x \wedge \bar{T}(j, \langle\langle m, x, y\rangle, x, y\rangle)],$$

which is again a Π_1-statement over $\bar{M}^{\bar{p}}$. The required implication for $\mathbb{D}$ then follows immediately.

One consequence of the fact that T is a satisfaction relation for $\mathbb{D}$ is:

$$\pi : \bar{\mathbb{D}} \underset{\Sigma_2}{\longrightarrow} \mathbb{D},$$

as follows immediately by the fact that $\bar{T}, T$ are rudimentary over $\bar{M}^{\bar{p}}, N$ respectively by the same rudimentary definition. This implies that I is a congruence relation on $\mathbb{D}$ and E is extensional modulo this congruence relation; the map π simply carries both properties from $\bar{\mathbb{D}}$ over to $\mathbb{D}$ (Extensionality being Π_2). Note also that $\bar{E}$ is well-founded modulo the congruence relation $\bar{I}$ (in other words, the relation $x\bar{E}y \wedge \neg(x\bar{I}y)$ is well-founded). Hence E is well-founded modulo the congruence relation I by the strongness of π.

Let M be the transitive collapse of $\mathbb{D}$ and k be the collapsing map. Define $\tilde{\pi} : \bar{M} \to M$ by

$$\tilde{\pi}(\bar{k}(x)) = k(\pi(x)) \quad \text{for all } x \in \bar{d}.$$

It follows immediately that

$$\tilde{\pi} : \bar{M} \underset{\Sigma_2}{\longrightarrow} M.$$

In the following we show that M has all the required properties. Note first that M is a J-structure, say $M = \langle J_\alpha^B, D\rangle$. For the rest of the proof fix $i, i^* \in \omega$ so that

$$\begin{aligned}
&x = h_Q(i, \langle x, q\rangle) \quad \text{holds uniformly over any } J\text{-structure } Q,\\
&\bar{p} = h_{\bar{M}}(i^*, \langle 0, \bar{p}\rangle).
\end{aligned}$$

Then

$$x = \bar{k}(\langle i, x\rangle) \quad \text{for all } x \in \bar{M}^{\bar{p}} \text{ and } \bar{p} = \bar{k}(\langle i^*, 0\rangle).$$

We first observe that $|N| \subseteq M$. Given any $x \in \bar{M}^{\bar{p}}$, $\bar{k}(\langle j, z\rangle) \in x = \bar{k}(\langle i, x\rangle)$ iff $\bar{k}(\langle j, z\rangle) = w = \bar{k}(\langle i, w\rangle)$ for some $w \in x$; in other words,

$$\langle j, z\rangle \in \bar{d} \quad \Longrightarrow \quad [\langle j, z\rangle \bar{E} \langle i, x\rangle \iff \exists w \in x\, (\langle j, z\rangle \bar{I} \langle i, w\rangle)]$$

holds for all $x, y \in \bar{M}^{\bar{p}}$ and $j \in \omega$. Quantifying over $\bar{M}^{\bar{p}}$ we obtain a Π_1-statement, which is preserved under π. This allows us to conclude: Whenever $x \in N$ (note: $\langle i, x\rangle \in d$ by the fact that π is Σ_1-preserving and the "same" holds for $\bar{M}^{\bar{p}}$),

$$k(\langle i, x\rangle) = \{k(\langle i, w\rangle); w \in x\}.$$

It follows by $\in$-induction that $k(\langle i,x\rangle)=x$ for all $x\in N$. Furthermore, given any $x\in\bar{M}^{\bar{p}}$,

$$\tilde{\pi}(x)=\tilde{\pi}(\bar{k}(\langle i,x\rangle))=k(\pi(\langle i,x\rangle))=k(\langle i,\pi(x)\rangle)=\pi(x),$$

and hence $\tilde{\pi}\supseteq\pi$.

Let B', A and ρ be such that $N=\langle J_\rho^{B'},A\rangle$ (recall that, by our assumption, N is an acceptable structure). Set $p=k(\langle i^*,0\rangle)$. It is easy to check that $\tilde{\pi}(\bar{p})=p$. We now prove that $A=A_M^p$. Given an $x\in\bar{M}^{\bar{p}}$ and $j\in\omega$, we have $A_{\bar{M}}^{\bar{p}}(j,x)\iff\bar{M}\models\varphi_j(x,\bar{p})\iff\bar{M}\models\varphi_j(\bar{k}(\langle i,x\rangle),\bar{k}(\langle i^*,0\rangle))\iff\bar{T}(j,\langle\langle i,x\rangle,\langle i^*,0\rangle\rangle)$. Hence, the Π_1-statement

$$\forall x\,\forall j\in\omega\;[A_{\bar{M}}^{\bar{p}}(j,x)\leftrightarrow\bar{T}(j,\langle\langle i,x\rangle,\langle i^*,0\rangle\rangle)]$$

is preserved by π, which means that

$$A(j,x)\quad\iff\quad T(j,\langle\langle i,x\rangle,\langle i^*,0\rangle\rangle)\quad\iff\quad M\models\varphi_j(x,p)\tag{9.18}$$

for every $x\in N$ and $j\in\omega$.

This equivalence easily yields that $B'=B\cap N$ and $N=\langle J_\rho^B,A\rangle$ for ρ as above. Pick a j such that $\varphi_j(u,v)$ is the formula "$B^*(u)$" for any acceptable structure of the form $\langle J_{\alpha^*}^{B^*},D^*\rangle$. Since $\bar{B}(x)\iff A_{\bar{M}}^{\bar{p}}(j,x)$ holds for every $x\in\bar{M}^{\bar{p}}$, the preservation properties of π guarantee that $A(j,x)\iff B'(x)$. However, $A(j,x)$ is equivalent to $B(x)$ for all $x\in N$, as follows from (9.18).

To see that $A=A_M^p$ it suffices to show that $\rho=\rho(M)$, as $|N|=H_\rho^M$ then follows immediately (recall that $\rho=N\cap\mathrm{On}$). The computation below will also yield that $p\in R_M$. Notice that

$$\bar{k}(\langle j,x\rangle)=h_{\bar{M}}(j,\langle x,\bar{p}\rangle)=h_{\bar{M}}(\bar{k}(\langle i,j\rangle),\langle\bar{k}(\langle i,x\rangle),\bar{k}(\langle i^*,0\rangle)\rangle),$$

where the left equality is simply the definition of $\bar{k}$. Leaving out the middle term we obtain a Σ_1 statement, so it can be represented by some $m\in\omega$. More precisely, $\bar{T}(m,\langle\langle j,x\rangle,\langle i,j\rangle,\langle i,x\rangle,\langle i^*,0\rangle\rangle)$ holds for all $x\in\bar{M}^{\bar{p}}$ and $j\in\omega$. As above we apply π to obtain the corresponding statement for T and all $x\in N$. Using the fact that the Σ_1-Skolem functions have uniform definitions we infer that $k(\langle j,x\rangle)=h_M(k(\langle i,j\rangle,\langle k(\langle i,x\rangle),k(\langle i^*,0\rangle)\rangle))=h_M(j,\langle x,p\rangle)$. Note that there is a *lightface* Σ_1^M map[7] from ρ onto $|N|$; since the values $k(\langle j,x\rangle)$ range over all of M, we have

$$M=h_M(\rho\cup\{p\})\quad\text{and}\quad\rho(M)\leq\rho.$$

The latter is obviously a consequence of the former. On the other hand, given any $r\in M$ we can pick a $\xi\in N\cap\mathrm{On}$ such that $r=h_M(j,\langle\xi,p\rangle)$ for some j. For any Σ_1 formula ψ, $M\models\psi(\eta,r)$ iff $M\models\varphi_m(\eta,\xi,p)$ for a suitable m; the latter is equivalent to $A(m,\langle\eta,\xi\rangle)$ by (9.18). Taken together, $M\models\psi(\eta,r)$ can be expressed in a rudimentary fashion over N. Since N is

[7] "Lightface" means that no parameters are needed in the definition of such a function.

amenable, every bounded $\mathbf{\Sigma}_1^M$ subset of ρ is an element of N, which means that $\rho \leq \rho(M)$. Thus,

$$\rho = \rho(M) \quad \text{and} \quad p \in R_M.$$

It only remains to show that $\tilde{\pi}$ is strong. Let $\bar{R}, R$ be binary relations which are rudimentary over $\bar{M}, M$ respectively by the same rudimentary definition. Define $\bar{R}^*, R^*$ as follows

$$\begin{aligned} x\,\bar{R}^*\,y \quad &\Longleftrightarrow \quad x, y \in \bar{d} \wedge \bar{k}(x)\,\bar{R}\,\bar{k}(y) \\ x\,R^*\,y \quad &\Longleftrightarrow \quad x, y \in d \wedge k(x)\,R\,k(y). \end{aligned}$$

Then $\bar{R}^*$ is well-founded since $\bar{R}$ is—any decreasing chain $x_0, x_1, \ldots, x_n, \ldots$ in $\bar{R}^*$ yields a decreasing chain $\bar{k}(x_0), \bar{k}(x_1), \ldots, \bar{k}(x_n), \ldots$ in $\bar{R}$, hence no such chain can be infinite. Furthermore, $\bar{R}^*, R^*$ are rudimentary over $\bar{M}^{\bar{p}}, N$ respectively by the same rudimentary definition. As π is strong, R^* must be well-founded. Hence R must be well-founded as well, since every infinite decreasing chain $x_0, x_1, \ldots, x_n, \ldots$ in R has form $k(z_0), k(z_1), \ldots, k(z_n), \ldots$ for some $z_0, z_1, \ldots, z_n, \ldots$ and the latter would be an infinite decreasing chain in R^*. $\dashv$

5. Iterated Projecta

In this section we shall show how to iterate the process of defining a projectum and forming a standard code, and we shall introduce the notion of nth projectum, nth standard code, and nth reduct.

5.1 Definition. Let $M = \langle J_\beta^B, D\rangle$ be an acceptable J-structure. For $n < \omega$ we recursively define the *nth projectum* $\rho_n(M)$, the *nth standard code* $A_M^{n,p}$, and the *nth reduct* $M^{n,p}$ as follows:

$$\begin{aligned} \rho_0(M) &= \beta, \qquad \Gamma_M^0 = \{\emptyset\}, \qquad A_M^{0,\emptyset} = \emptyset, \qquad M^{0,\emptyset} = M, \\ \rho_{n+1}(M) &= \min\{\rho(M^{n,p}); p \in \Gamma_M^n\}, \\ \Gamma_M^{n+1} &= \textstyle\prod_{i \in n+1} [\rho_{i+1}(M), \rho_i(M))^{<\omega}, \end{aligned}$$

and for $p \in \Gamma_M^{n+1}$,

$$\begin{aligned} A_M^{n+1,p} &= A_{M^{n,p\restriction n}}^{p(n),\rho_{n+1}(M)} \quad \text{and} \\ M^{n+1,p} &= (M^{n,p\restriction n})^{p(n),\rho_{n+1}(M)}. \end{aligned}$$

We also set $\rho_\omega(M) = \min\{\rho_n(M) \mid n < \omega\}$. The ordinal $\rho_\omega(M)$ is called the *ultimate projectum* of M.

The reader will gladly verify that $\rho_1(M) = \rho(M)$. On the other hand, if M is not 1-sound (cf. Definition 5.7 below) then it need not be the case that $\rho_2(M)$ is the least ρ such that $\mathcal{P}(\rho) \cap \mathbf{\Sigma}_2^M \not\subseteq M$.

Supposing that we know $\rho_n(M) \leq \cdots \leq \rho_1(M)$ we may identify $p = \langle p(0), \ldots, p(n)\rangle \in \Gamma_M^{n+1}$ with the (finite) set $\bigcup \mathrm{ran}(p)$ of ordinals; this will play a role in the next section.

5.2 Definition. We define $P_M^n, R_M^n \subseteq \Gamma_M^n$ as follows:

$$\begin{aligned} P_M^0 &= \{\emptyset\} \\ P_M^{n+1} &= \{p \in \Gamma_M^{n+1}; p{\restriction}n \in P_M^n \wedge \rho(M^{n,p\restriction n}) = \rho_{n+1}(M) \wedge p(n) \in P_{M^{n,p\restriction n}}\} \end{aligned}$$

R_M^n is defined in the same way but with $R_{M^{n,p\restriction n}}$ in place of $P_{M^{n,p\restriction n}}$.

As before, we call the elements of P_M^n *good parameters* and the elements of R_M^n *very good parameters*.

5.3 Lemma. *Let M be acceptable.*

(a) $R_M^n \subseteq P_M^n \neq \emptyset$.

(b) Let $p \in R_M^n$. If $q \in \Gamma_M^n$ then $A^{n,q}$ is $\mathrm{rud}_{M^{n,p}}$ in parameters from $M^{n,p}$.

(c) Let $p \in R_M^n$. Then $\rho(M^{n,p}) = \rho_{n+1}(M)$.

(d) $p \in P_M^n \Longrightarrow \forall i \in n\ p(i) \in P_{M^{i,p\restriction i}}$, and similarly for R_M^n. Moreover, if $p{\restriction}(n-1) \in R_M^{n-1}$ then equivalence holds.

Proof. (a) This is easily shown inductively by using Lemma 2.9 and by amalgamating parameters.

(b) By induction on $n < \omega$. The case $n = 0$ is trivial. Now let $n > 0$, and suppose that (b) holds for $n - 1$. Write $m = n - 1$. Let $p \in R_M^n$ and $q \in \Gamma_M^n$. We have to show that $A_{M^{m,q\restriction m}}^{q(m),\rho_n(M)}$ is $\mathrm{rud}_{M^{n,p}}$ in parameters from $M^{n,p}$. Inductively, $M^{m,q\restriction m}$ is $\mathrm{rud}_{M^{m,p\restriction m}}$ in a parameter $t \in M^{n,p}$. As $p(m) \in R_{M^{m,p\restriction m}}$, there are e_0 and e_1 and $z \in M^{n,p}$ such that

$$q(m) = h_{M^{m,p\restriction m}}(e_0, \langle z, p(m)\rangle)$$

and

$$t = h_{M^{m,p\restriction m}}(e_1, \langle z, p(m)\rangle).$$

For $i < \omega$ and $x \in M^{n,p}$, we have that

$$\begin{aligned} \langle i, x\rangle \in A_{M^{m,q\restriction m}}^{q(m),\rho_n(M)} &\iff M^{m,q\restriction m} \models \varphi_i(x, q(m)) \\ &\iff M^{m,q\restriction m} \models \varphi_i(x, h_{M^{m,p\restriction m}}(e_0, \langle z, p(m)\rangle)) \\ &\iff M^{m,p\restriction m} \models \varphi_j(\langle x, z\rangle, p(m)) \\ &\iff \langle j, \langle x, z\rangle\rangle \in A_{M^{m,p\restriction m}}^{p(m)}, \end{aligned}$$

for some j which is recursively computable from i, as $M^{m,q\restriction m}$ is $\mathrm{rud}_{M^{m,p\restriction m}}$ in the parameter $t = h_{M^{m,p\restriction m}}(e_1, \langle z, p(m)\rangle)$. Thus, $A^{q(m),\rho_n(M)}_{M^{m,q\restriction m}}$ is $\mathrm{rud}_{A^{p(m)}_{M^{m,p\restriction m}}}$ in the parameter z.

(c) Let $\rho_{n+1}(M) = \rho(M^{n,q})$, where $q \in \Gamma^n_M$. By (b), $M^{n,q}$ is $\mathrm{rud}_{M^{n,p}}$ in parameters from $M^{n,p}$, which implies that $\boldsymbol{\Sigma}_1^{M^{n,q}} \subseteq \boldsymbol{\Sigma}_1^{M^{n,p}}$. But then $\rho(M^{n,p}) \leq \rho(M^{n,q}) = \rho_{n+1}(M)$, and hence $\rho(M^{n,p}) = \rho_{n+1}(M)$.

(d) This is shown inductively by using (c). ⊣

The following is given just by the definition of R^{n+1}_M. Let M be acceptable, and let $p \in R^{n+1}_M$. Then

$$M = h_M(h_{M^{1,p\restriction 1}}(\cdots h_{M^{n,p\restriction n}}(\rho_{n+1}(M) \cup \{p(n)\}) \cdots) \cup \{p(0)\}).$$

We thus can, uniformly over M, define a function h^{n+1}_M basically as the iterated composition of the Σ_1-Skolem functions of the i^{th} reducts of M, $0 \leq i \leq n$, such that M is the h^{n+1}_M-hull of $\rho_{n+1}(M) \cup \{p\}$ whenever $p \in R^{n+1}_M$. The precise definition of the (partial) function $h^{n+1}_M : {}^{<\omega}\omega \times {}^{<\omega}|M^{n+1,p}| \to |M|$ is by recursion on $n < \omega$; we set $h^1_M = h_M$ and

$$\begin{aligned} &h^{n+1}_M(\langle \vec{i}, i_0, \ldots, i_k\rangle, \langle \vec{x}_{i_0}, \ldots, \vec{x}_{i_k}\rangle) \\ &\quad = h^n_M(\vec{i}, \langle h_{M^{n,p\restriction n}}(i_0, \vec{x}_{i_0}), \ldots, h_{M^{n,p\restriction n}}(i_k, \vec{x}_{i_k})\rangle). \end{aligned}$$

5.4 Lemma. *Let $n < \omega$, and let M be acceptable. Then h^{n+1}_M is in Σ^M_ω, and*

$$M = h^{n+1}_M {}``(\rho_{n+1}(M) \cup \{p\}),$$

whenever $p \in R^{n+1}_M$.

5.5 Lemma. *Let $0 < n < \omega$. Let M be acceptable, and let $p \in R^n_M$. Then $\boldsymbol{\Sigma}^M_\omega \cap \mathcal{P}(M^{n,p}) = \boldsymbol{\Sigma}^{M^{n,p}}_\omega$.*

Proof. It is easy to verify that $\boldsymbol{\Sigma}^{M^{n,p}}_\omega \subseteq \boldsymbol{\Sigma}^M_\omega \cap \mathcal{P}(M^{n,p})$. Let us prove the other direction.

It is straightforward to verify by induction on $m \leq n$ that if φ is Σ_0 and x, $y \in M^{m,p\restriction m}$, then

$$\varphi(x, h^m_M(y)) \text{ is uniformly } \Delta_1^{M^{m-1,p\restriction(m-1)}}(x, y). \tag{9.19}$$

Now let $A \in \boldsymbol{\Sigma}^M_\omega \cap \mathcal{P}(M^{n,p})$, say

$$x \in A \iff M \models \exists x_1\, \forall x_2 \cdots \exists/\forall x_k\; \varphi(x, y, x_1, x_2, \ldots, x_k),$$

where φ is Σ_0 and $y \in M$. By Lemma 5.4, we may write

$$\begin{aligned} x \in A \iff\; &\exists x'_1 \in M^{n,p}\, \forall x'_2 \in M^{n,p} \cdots \exists/\forall x_k \in M^{n,p} \\ &\varphi(x, h^n_M(y'), h^n_M(x'_1), h^n_M(x'_2), \ldots, h^n_M(x'_k)), \end{aligned}$$

where $y' \in M^{n,p}$. But then $A \in \boldsymbol{\Sigma}^{M^{n,p}}_\omega$, with the help of (9.19) for $m = n$. ⊣

A more careful look at the proofs of Lemmata 5.4 and 5.5 shows the following.

5.6 Lemma. *Let $n < \omega$. Let M be acceptable and $p \in R^n_M$. Let $A \subseteq M^{n,p}$ be $\mathbf{\Sigma}^M_{n+1}$. Then A is $\mathbf{\Sigma}_1^{M^{n,p}}$.*

5.7 Definition. M is *n-sound* iff $R^n_M = P^n_M$. M is *sound* iff M is n-sound for all $n < \omega$.

We shall prove later (cf. Lemma 9.2) that every J_α is sound. In fact, a key requirement on initial segments of a core model is that they be sound.

We can now formulate a general downward extension of embeddings lemma as the conjunction of the following three lemmata which, in turn, are immediate consequences of the corresponding lemmata for the first projectum.

5.8 Lemma. *Let $\bar{M}$, M be acceptable and $\pi : \bar{M}^{n,\bar{p}} \underset{\Sigma_0}{\longrightarrow} M^{n,p}$, where $\bar{p} \in R^n_{\bar{M}}$. Then there is a unique map $\tilde{\pi} \supseteq \pi$ such that $\mathrm{dom}(\tilde{\pi}) = \bar{M}$, $\tilde{\pi}(\bar{p}) = p$ and, setting $\tilde{\pi}_i = \tilde{\pi} \restriction H^i_{\bar{M}}$,*

$$\tilde{\pi}_i : \bar{M}^{i,\bar{p}\restriction i} \underset{\Sigma_0}{\longrightarrow} M^{i,p\restriction i} \quad \textit{for } i \leq n.$$

The map $\tilde{\pi}_i$ is in fact Σ_1-preserving for $i \in n$.

5.9 Lemma. *Suppose that $\bar{M}$, M, $\bar{p}$, p, π, $\tilde{\pi}$, $\tilde{\pi}_i$, $i \leq n$, are as above and $p \in R^n_M$. Let $\pi : \bar{M}^{n,\bar{p}} \underset{\Sigma_\ell}{\longrightarrow} M^{n,p}$ where $\ell \in \omega$. Then*

$$\tilde{\pi}_i : \bar{M}^{i,\bar{p}\restriction i} \underset{\Sigma_{\ell+n-i}}{\longrightarrow} M^{i,p\restriction i} \quad \textit{for } i \leq n.$$

Hence, $\tilde{\pi}_0 : \bar{M} \underset{\Sigma_{\ell+n}}{\longrightarrow} M$.

5.10 Lemma. *Let $\pi : N \underset{\Sigma_0}{\longrightarrow} M^{n,p}$, where M is as above. Then there are unique $\bar{M}$, $\bar{p}$ such that $\bar{p} \in R^n_{\bar{M}}$ and $N = \bar{M}^{n,\bar{p}}$.*

The general upward extension of embeddings lemma is the conjunction of the following lemma together with Lemmata 5.8 and 5.9.

5.11 Lemma. *Let $\pi : \bar{M}^{n,\bar{p}} \to N$ be strong, where $\bar{M}$ is an acceptable J-structure and $\bar{p} \in R^n_{\bar{M}}$. Then there are unique M, p such that M is acceptable, $p \in R^n_M$ and $M^{n,p} = N$. Moreover, if $\tilde{\pi}$ is as in Lemma 5.8, then $\tilde{\pi}$ is strong.*

If π and $\tilde{\pi}$ are as in Lemma 5.8 then $\tilde{\pi}$ is often called the *n-completion* of π.

If we take $\pi : \bar{M}^{n,\bar{p}} \to M^{n,p}$ as in Lemma 5.8 and form the corresponding extension $\tilde{\pi}$, we can in fact do better than stated there. It is easy to see that for every appropriate $\bar{q}$ and $q = \tilde{\pi}(\bar{q})$,

$$\tilde{\pi}_i : \bar{M}^{i,\bar{q}\restriction i} \underset{\Sigma_1}{\longrightarrow} M^{i,q\restriction i} \quad \text{for } i \in n. \tag{9.20}$$

This suggests the general notion of a $\Sigma_\ell^{(n)}$-preserving embedding, where n indicates preservation at the nth level, i.e. if $\tilde{\pi}(\bar{q}) = q$ then (9.20) and

$$\tilde{\pi}_n : \bar{M}^{n,\bar{q}} \underset{\Sigma_\ell}{\longrightarrow} M^{n,q}. \tag{9.21}$$

It turns out that there is a canonical class of formulae, the so called $\Sigma_\ell^{(n)}$-formulae, such that the above embeddings are exactly those which are elementary with respect to this class. This idea leads towards Jensen's elegant Σ^* theory which is dealt with in [15, Sects. 1.6 ff.].

Following [7, §2], though, we shall call $\Sigma_1^{(n)}$ elementary maps $r\Sigma_{n+1}$ elementary. Here is our official definition, which presupposes that the structures involved possess very good parameters; it will play a role in the last two sections.

5.12 Definition. Let M, N be acceptable, let $\pi : M \to N$, and let $n < \omega$. Then π is called $r\Sigma_{n+1}$ *elementary* provided that there is $p \in R_M^n$ with $\pi(p) \in R_N^n$, and for all $i \leq n$,

$$\pi \restriction H_{\rho_i(M)}^M : M^{i,p\restriction i} \underset{\Sigma_1}{\longrightarrow} N^{i,\pi(p)\restriction i}. \tag{9.22}$$

The map π is called *weakly* $r\Sigma_{n+1}$ *elementary* provided that there is $p \in R_M^n$ with $\pi(p) \in R_N^n$, and for all $i < n$, (9.22) holds, and

$$\pi \restriction H_{\rho_n(M)}^M : M^{n,p} \underset{\Sigma_0}{\longrightarrow} N^{n,\pi(p)}.$$

If $\pi : M \to N$ is (weakly) $r\Sigma_{n+1}$ elementary then typically both M and N will be n-sound; however, neither M nor N has to be $(n+1)$-sound. It is possible to generalize this definition so as to not assume that very good parameters exist (cf. [7, §2]).

Lemma 5.8 therefore says that the map π can be extended to its n-completion $\tilde{\pi}$ which is weakly $r\Sigma_{n+1}$ elementary, and Lemma 5.9 says that if π is Σ_1 elementary to begin with then the n-completion $\tilde{\pi}$ will end up being $r\Sigma_{n+1}$ elementary.

Moreover, if a map $\pi : M \to N$ is $r\Sigma_{n+1}$ elementary then it respects h^{n+1} by Theorem 1.15, i.e.:

5.13 Lemma. *Let $n < \omega$, and let M, N be acceptable. Let $\pi : M \to N$ be $r\Sigma_{n+1}$ elementary. Then for all appropriate x,*

$$\pi(h_M^{n+1}(x)) = h_N^{n+1}(\pi(x)).$$

6. Standard Parameters

Finite sets of ordinals are well-ordered in a simple canonical way.

6.1 Definition. Let $a, b \in [\mathrm{On}]^{<\omega}$. Set

$$a <^* b \iff \exists \alpha \in b\ (a \setminus (\alpha + 1) = b \setminus (\alpha + 1) \wedge \alpha \notin a).[8]$$

The ordering $<^*$ has a rudimentary definition, therefore it is absolute for transitive rudimentarily closed structures and is also preserved under embeddings which are Σ_0 elementary. If we view finite sets of ordinals as finite decreasing sequences, $a <^* b$ precisely when a precedes b lexicographically. Moreover, we easily get the following.

6.2 Lemma. $[\mathrm{On}]^{<\omega}$ *is well-ordered by* $<^*$.

Let M be acceptable, and $n < \omega$. The well-ordering $<^*$ induces a well-ordering of Γ^n_M by confusing $p \in \Gamma^n_M$ with $\bigcup \mathrm{ran}(p)$ (i.e., by identifying p with the obvious set of ordinals; cf. above). We shall denote this latter well-ordering also by $<^*$.

6.3 Definition. Let M be acceptable. The $<^*$-least $p \in P^n_M$ is called the *nth standard parameter of M* and is denoted by $p_n(M)$. We shall write M^n for $M^{n,p_n(M)}$; M^n is called the nth *standard reduct of M*.

6.4 Lemma. *Let $p \in R^n_M$. Then p can be lengthened to some $p' \in P^{n+1}_M$, i.e., there is some $p' \in P^{n+1}_M$ with $p' \restriction n = p$.*

Proof. This follows immediately from Lemma 5.3 (c). ⊣

6.5 Corollary. *Let $n > 0$ and M be n-sound. Then*

$$p_{n-1}(M) = p_n(M) \restriction (n-1)$$

Proof. By Lemma 6.4. ⊣

6.6 Definition. Let M be acceptable. Suppose that for all $n < \omega$, $p_n(M) = p_{n+1}(M) \restriction n$. Then we set $p(M) = \bigcup_{n<\omega} p_n(M)$. $p(M)$ is called the *standard parameter of M*.

We shall often confuse $p(M)$ with $\bigcup \mathrm{ran}(p(M))$.

6.7 Corollary. *Let M be sound. Then $p(M)$ exists, i.e., for all $n < \omega$, $p_n(M) = p_{n+1}(M) \restriction n$.*

Proof. By Corollary 6.5. ⊣

6.8 Lemma. *M is sound iff $p_n(M) \in R^n_M$ for all $n \in \omega$.*

[8] I.e., $\max(a \triangle b) \in b$.

Proof. We shall prove the non-trivial direction ($\Longleftarrow$). For each $n > 0$ we shall prove

$$p_n(M) \in R^n_M \quad \Longrightarrow \quad R^n_M = P^n_M. \tag{9.23}$$

This holds trivially for $n = 0$. Now suppose that $n > 0$ is least such that the statement (9.23) fails. Hence $P^n_M \setminus R^n_M \neq \emptyset$ (cf. Lemma 5.3 (a)). Let q be the $<^*$-least element of $P^n_M \setminus R^n_M$. This means that $p <^* q$, where $p = p_n(M)$. By Lemma 5.3, we may let $i < n$ be least such that $q(i) \notin R_{M^{i,q\restriction i}}$.

Let us first consider the case $n = 1$.

Then, of course, $p(0) <^* q(0)$. Using the downward extension of embeddings lemma, we may let $\bar{M}$, $\bar{q}$, π be unique such that

$$\begin{aligned} &\bar{q} \in R_{\bar{M}} \\ &\pi : \bar{M} \to M \text{ is } \Sigma_1 \text{ elementary} \\ &\pi(\bar{q}) = q(0) \\ &\pi \restriction H^M_{\rho_1(M)} = \text{id}. \end{aligned} \tag{9.24}$$

As $q(0) \notin R_M$, $\pi \neq \text{id}$. Because $p(0) \in R_M$, there are e and $z \in [\rho_1(M), M \cap \text{On})^{<\omega}$ such that

$$q(0) = h_M(e, \langle z, p(0) \rangle).$$

As $p(0) <^* q(0)$, by elementarity we get that

$$\bar{M} \models \exists p' <^* \bar{q} \; (\bar{q} = h(e, \langle z, p' \rangle)).$$

Letting p^* be a witness, we may conclude that by elementarity again

$$\pi(p^*) <^* q(0) \wedge q(0) = h_M(e, \langle z, \pi(p^*) \rangle), \tag{9.25}$$

where we may and shall assume that $\pi(p^*) \in [\rho_1(M), M \cap \text{On})^{<\omega}$. We have that $\pi(p^*) \in P_M$ by (9.25). But $\pi(p^*) \in \text{ran}(\pi)$ and $\pi \neq \text{id}$, so that we must also have that $\pi(p^*) \notin R_M$. Because $\pi(p^*) <^* q(0)$, we have a contradiction to the choice of q.

Now let us consider the case $n > 1$.

If $p \restriction (n-1) = q \restriction (n-1)$ then we may apply the above argument to the reduct $M^{n-1, p\restriction(n-1)}$. We may thus assume that $p \restriction (n-1) <^* q \restriction (n-1)$. Let $i < n$ be least such that $p \restriction i <^* q \restriction i$. We shall assume that $i = 1$ and $n = 2$ for notational convenience. The general case is similar to this special case and is left to the reader.

As $p_2(M) \in R^2_M$, Lemma 5.3 (d) yields that $P^1_M = R^1_M$. As $p(0) <^* q(0)$, there is some $j \in \omega$ and $z \in [\rho_1(M), M \cap \text{On})^{<\omega}$ such that

$$\exists p' \; (p' <^* q(0) \wedge q(0) = h_M(j, \langle z, p' \rangle)).$$

If i is the Gödel number of this Σ_1 formula, we thus have that $A^{q(0)}_M(i, z)$ holds true. Let X be the smallest Σ_1 submodel of the (first) reduct $M^{q(0)}$. There is then some $z_0 \in X$ such that $A^{q(0)}_M(i, z_0)$ holds true. Therefore,

$$\exists p' \; (p' <^* q(0) \wedge q(0) = h_M(j, \langle z_0, p' \rangle)). \tag{9.26}$$

So there is some p', call it $\bar{q}(0)$, witnessing (9.26) which is an element of the smallest Σ_1 substructure of M which contains both $q(0)$ and z_0. There is then also some k with $\bar{q}(0) = h_M(k, \langle z_0, q(0)\rangle)$.

Now set $\bar{q} = \bar{q}(0) \cup q(1)$. Then $\bar{q} \in P^2_M$, because $q(0) = h_M(j, \langle z_0, \bar{q}(0)\rangle)$ and $q \in P^2_M$. We will now show that $\bar{q} \notin R^2_M$. As $\bar{q}(0) <^* q(0)$ (and hence $\bar{q} <^* q$) this will contradict the choice of q and finish the proof.

Well, to see that $\bar{q} \notin R^2_M$ it suffices to verify that if

$$Y = h_{M^{\bar{q}(0)}}(\rho_2(M) \cup \{q(1)\})$$

then $Y \neq M^{\bar{q}(0)}$. As $\bar{q}(0) = h_M(k, \langle z_0, q(0)\rangle)$, we can find a recursive $f : \omega \to \omega$ such that for all $\ell \in \omega$ and for all x,

$$A^{\bar{q}(0)}_M(\ell, x) \iff A^{q(0)}_M(f(\ell), \langle x, z_0\rangle).$$

Therefore, as $z_0 \in X$,

$$Y \subseteq h_{M^{q(0)}}(\rho_2(M) \cup \{q(1)\}).$$

But $q(1) \notin R^{M^{q(0)}}$, and so $Y \neq M^{\bar{q}(0)}$. ⊣

There is a class of structures, for which the above characterization of soundness has a particularly nice form. This class comprises all of the structures J_α where α is a limit ordinal. Moreover, the same applies to sufficiently iterable premice, which are the building blocks of core models.

7. Solidity Witnesses

Solidity witnesses are witnesses to the fact that a given ordinal is a member of the standard parameter. The key fact will be that being a witness is preserved under Σ_1 elementary maps, so that witnesses can be used for showing that standard parameters are mapped to standard parameters.

Whereas the pure theory of witnesses is easy to grasp, it is one of the deepest results of inner model theory that the structures considered there (viz., iterable premice) do contain witnesses.

7.1 Definition. Let M be an acceptable structure, let $p \in [M \cap \mathrm{On}]^{<\omega}$, and let $\nu \in p$. Let W be another acceptable structure with $\nu \subseteq W$, and let $r \in [W \cap \mathrm{On}]^{<\omega}$. We say that (W, r) is a *witness for $\nu \in p$ w.r.t. M, p* iff for every Σ_1 formula $\varphi(v_0, \ldots, v_{l+1})$ and for all $\xi_0, \ldots, \xi_l < \nu$

$$M \models \varphi(\xi_0, \ldots, \xi_l, p \setminus (\nu + 1)) \implies W \models \varphi(\xi_0, \ldots, \xi_l, r). \tag{9.27}$$

In this situation, we shall often suppress r and call W a witness. The proof of Lemma 7.2 will show that if a witness exists then there is also one where $\Longrightarrow$ may be replaced by $\Longleftrightarrow$ in (9.27).

7.2 Lemma. *Let M be an acceptable structure, and let $p \in P_M$. Suppose that for each $\nu \in p$ there is a witness W for $\nu \in p$ w.r.t. M, p such that $W \in M$. Then $p = p_1(M)$.*

Proof. Suppose not. Then $p_1(M) <^* p$, and we may let $\nu \in p \setminus p_1(M)$ be such that $p \setminus (\nu+1) = p_1(M) \setminus (\nu+1)$. Let us write q for $p \setminus (\nu+1) = p_1(M) \setminus (\nu+1)$. Let $(W, r) \in M$ be a witness for $\nu \in p$ w.r.t. M, p. Let $A \in \Sigma_1^M(\{p_1(M)\})$ be such that $A \cap \rho_1(M) \notin M$.

Let k be the number of elements of $p \cap \nu$, and if $k > 0$ then let $\xi_1 < \cdots < \xi_k$ be such that $p_1(M) \cap \nu = \{\xi_1, \ldots, \xi_k\}$. There is a Σ_1 formula $\varphi(v_0, \ldots, v_{k+1})$ such that

$$\xi \in A \iff M \models \varphi(\xi, \xi_1, \ldots, \xi_k, q).$$

Because $(W, r) \in M$ is a witness for $\nu \in p$ w.r.t. M, p, we have that

$$M \models \bar{\varphi}(\xi, \xi_1, \ldots, \xi_k, q) \implies W \models \bar{\varphi}(\xi, \xi_1, \ldots, \xi_k, r)$$

for every $\xi < \rho_1(M) \leq \nu$ and every $\bar{\varphi}$ which is Σ_1.

Let $\alpha = \sup(h_W(\nu \cup \{r\}) \cap \mathrm{On})$, and let $\bar{W} = J_\alpha^B$ (where $W = J_\beta^B$, some $\beta \geq \alpha$). By looking at the canonical elementary embedding from $h_M(\nu \cup \{q\})$ into $\bar{W}$, which is Σ_0 elementary and cofinal (and hence Σ_1 elementary) we get that

$$M \models \bar{\varphi}(\xi, \xi_1, \ldots, \xi_k, q) \iff \bar{W} \models \bar{\varphi}(\xi, \xi_1, \ldots, \xi_k, r) \tag{9.28}$$

for every $\xi < \rho_1(M) \leq \nu$ and every $\bar{\varphi}$ which is Σ_1. In particular, (9.28) holds with $\bar{\varphi}$ replaced by φ and every $\xi < \rho_1(M) \leq \nu$. As $\bar{W} \in M$, this shows that in fact $A \cap \rho_1(M) \in M$. Contradiction! ⊣

7.3 Definition. Let M be acceptable, let $p \in [M \cap \mathrm{On}]^{<\omega}$, and let $\nu \in p$. We denote by $W_M^{\nu,p}$ the transitive collapse of $h_M(\nu \cup (p \setminus (\nu+1)))$. We call $W_M^{\nu,p}$ the *standard witness for $\nu \in p$ w.r.t. M, p.*

7.4 Lemma. *Let M be acceptable, and let $\nu \in p \in P_M$. The following are equivalent.*

(1) $W_M^{\nu,p} \in M$.

(2) There is a witness W for $\nu \in p$ w.r.t. M, p such that $W \in M$.

Proof. We have to show (2) $\implies$ (1). Let $\sigma : W_M^{\nu,p} \to M$ be the inverse of the transitive collapse. We may also let $\sigma^* : W_M^{\nu,p} \to W$ be defined by $h_{W_M^{\nu,p}}(\xi, \sigma^{-1}(p \setminus \nu+1)) \mapsto h_W(\xi, r)$, $\xi < \nu$. Set $\alpha = \sup(h_W(\nu \cup \{r\}) \cap \mathrm{On})$, and let $\bar{W} = J_\alpha^A$ (where $W = J_\beta^A$, some $\beta \geq \alpha$). Again, $\sigma^* : W_M^{\nu,p} \to \bar{W}$ is Σ_1 elementary.

Let us assume without loss of generality that $W_M^{\nu,p}$ is not an initial segment of M.

Now if $\sigma(\nu) = \nu$ then a witness to $\rho_1(M)$ is definable over $W_M^{\nu,p}$, and hence over $\bar{W}$. But as $\bar{W} \in M$, this witness to $\rho_1(M)$ would then be in M. Contradiction!

We thus have that ν is the critical point of σ. Thus, if $M = J^B_\gamma$, we know that $\sigma(\nu)$ is regular in M and so $J^B_{\sigma(\nu)} \models \mathsf{ZFC}^-$. We may code $W^{\nu,p}_M$ by some $a \subseteq \nu$, Σ_1-definably over $W^{\nu,p}_M$. Using σ^*, a is definable over $\bar{W}$, so that $a \in M$. In fact, $a \in J^B_{\sigma(\nu)}$ by acceptability. We can thus decode a in $J^B_{\sigma(\nu)}$, which gives $W^{\nu,p}_M \in J^B_{\sigma(\nu)} \subseteq M$. ⊣

7.5 Definition. Let M be an acceptable structure. We say that M is 1-*solid* iff

$$W_M^{\nu,p_1(M)} \in M$$

for every $\nu \in p_1(M)$.

7.6 Lemma. *Let $\bar{M}$, M be acceptable structures, and let $\pi : \bar{M} \xrightarrow[\Sigma_1]{} M$. Let $\bar{\nu} \in \bar{p} \in [\bar{M} \cap \mathrm{On}]^{<\omega}$, and set $\nu = \pi(\bar{\nu})$ and $p = \pi(\bar{p})$. Let $(\bar{W}, \bar{r})$ be a witness for $\bar{\nu}$ w.r.t. $\bar{M}$, $\bar{p}$ such that $\bar{W} \in \bar{M}$, and set $W = \pi(\bar{W})$ and $r = \pi(\bar{r})$. Then (W, r) is a witness for ν w.r.t. M, p.*

Proof. Let $\varphi(v_0, \ldots, v_{l+1})$ be an arbitrary Σ_1 formula. We know that

$$\bar{M} \models \forall \xi_0, \ldots, \xi_l < \bar{\nu}[\varphi(\xi_0, \ldots, \xi_l, \bar{p} \setminus (\bar{\nu}+1)) \Longrightarrow \bar{W} \models \varphi(\xi_0, \ldots, \xi_l, \bar{r})].$$

As π is Π_1 elementary, this yields that

$$M \models \forall \xi_0, \ldots, \xi_l < \nu[\varphi(\xi_0, \ldots, \xi_l, p \setminus (\nu+1)) \Longrightarrow W \models \varphi(\xi_0, \ldots, \xi_l, r)].$$

We thus conclude that (W, r) is a witness for ν w.r.t. M, p. ⊣

7.7 Corollary. *Let $\bar{M}$, M be acceptable structures, and let $\pi : \bar{M} \xrightarrow[\Sigma_1]{} M$. Suppose that $\bar{M}$ is 1-solid and $\pi(p_1(\bar{M})) \in P_M$. Then $p_1(M) = \pi(p_1(\bar{M}))$, and M is 1-solid.*

The proof of the following lemma is virtually the same as the proof of Lemma 7.6.

7.8 Lemma. *Let $\bar{M}$, M be acceptable structures, and let $\pi : \bar{M} \xrightarrow[\Sigma_1]{} M$. Let $\bar{\nu} \in \bar{p} \in [On \cap \bar{M}]^{<\omega}$, and set $\nu = \pi(\bar{\nu})$ and $p = \pi(\bar{p})$. Let $(\bar{W}, \bar{r}) \in \bar{M}$ be such that, setting $W = \pi(\bar{W})$ and $r = \pi(\bar{r})$, (W, r) is a witness for ν w.r.t. M, p. Then $(\bar{W}, \bar{r})$ is a witness for $\bar{\nu} \in \bar{p}$ w.r.t. $\bar{M}$, $\bar{p}$.*

7.9 Corollary. *Let $\bar{M}$, M be acceptable structures, and let $\pi : \bar{M} \xrightarrow[\Sigma_1]{} M$. Suppose that M is 1-solid, and that in fact $W_M^{\nu,p_1(M)} \in \mathrm{ran}(\pi)$ for every $\nu \in p_1(M)$. Then $p_1(\bar{M}) = \pi^{-1}(p_1(M))$, and $\bar{M}$ is 1-solid.*

The following definition just extends Definition 7.5.

7.10 Definition. Let M be an acceptable structure. If $0 < n < \omega$ then we say that M is *n-solid* if for every $k < n$, $p_1(M^k) = p_{k+1}(M)(k) = p_n(M)(k)$ and M^k is 1-solid, i.e., if

$$W_{M^k}^{\nu,p_1(M^k)} \in M^k$$

for every $\nu \in p_1(M^k)$.

7.11 Lemma. *Let $\bar{M}$, M be acceptable, let $n > 0$, and let $\pi : \bar{M} \to M$ be $r\Sigma_n$ elementary as being witnessed by $p_{n-1}(M)$. If $\bar{M}$ is n-solid and $\pi(p_1(\bar{M}^{n-1})) \in P_{M^{n-1}}$ then $p_n(M) = \pi(p_n(\bar{M}))$ and M is n-solid.*

7.12 Lemma. *Let $\bar{M}$, M be acceptable, let $n > 0$, and let $\pi : \bar{M} \to M$ be $r\Sigma_n$ elementary as being witnessed by $\pi^{-1}(p_{n-1}(M))$. Suppose that M is n-solid, and in fact $W_{M^k}^{\nu,p_1(M^k)} \in \operatorname{ran}(\pi)$ for every $k < n$. If $\pi^{-1}(p_{n-1}(M)) \in P_{\bar{M}}^{n-1}$ then $p_n(\bar{M}) = \pi^{-1}(p_n(\bar{M}))$ and $\bar{M}$ is n-solid.*

The ultrapower maps we shall construct in the next section shall be elementary in the sense of the following definition. (Cf. [7, Definition 2.8.4].)

7.13 Definition. Let both M and N be acceptable, let $\pi : M \to N$, and let $n < \omega$. Then π is called an *n-embedding* if the following hold:

(1) Both M and N are n-sound,

(2) π is $r\Sigma_{n+1}$ elementary,

(3) $\pi(p_k(M)) = p_k(N)$ for every $k \leq n$, and

(4) $\rho_n(N) = \sup(\pi``\rho_n(M))$.

Other examples for n-embeddings are typically obtained as follows. Let M be acceptable, and let, for $n \in \omega$, $\mathfrak{C}_n(M)$ denote the transitive collapse of $h_M^n``(\rho_n(M) \cup \{p_n(M)\})$. $\mathfrak{C}_n(M)$ is called the nth *core of M*. The natural map from $\mathfrak{C}_{n+1}(M)$ to $\mathfrak{C}_n(M)$ will be an n-embedding under favorable circumstances.

8. Fine Ultrapowers

This section deals with the construction of "fine structure preserving" embeddings. Inner model theory is in need of such maps in two main contexts: first, in "lift up arguments" which are crucial for instance in the proof of the Covering Lemma for L or higher core models and in the proof of $\square_\kappa$ in such models (cf. [5] and the next section), and second, in performing iterations of premice (cf. [5, 9, 12]). This section will deal with the construction of such embeddings from an abstract point of view. The combinatorial objects which are used for defining such maps are called "extenders".

The following definition makes use of notational conventions which are stated right after it.

8.1 Definition. Let M be acceptable. Then $E = \langle E_a \mid a \in [\nu]^{<\omega}\rangle$ is called a *(κ,ν)-extender over M with critical points* $\langle \mu_a \mid a \in [\nu]^{<\omega}\rangle$ provided the following hold:

(1) (Ultrafilter property) For $a \in [\nu]^{<\omega}$ we have that E_a is an ultrafilter on the set $\mathcal{P}([\mu_a]^{\mathrm{Card}(a)}) \cap M$ which is κ-complete with respect to sequences in M; moreover, μ_a is the least μ such that $[\mu]^{\mathrm{Card}(a)} \in E_a$.

(2) (Coherence) For $a, b \in [\nu]^{<\omega}$ with $a \subseteq b$ and for $X \in \mathcal{P}([\mu_a]^{\mathrm{Card}(a)}) \cap M$ we have that $X \in E_a \Longleftrightarrow X^{ab} \in E_b$.

(3) (Uniformity) $\mu_{\{\kappa\}} = \kappa$.

(4) (Normality) Let $a \in [\nu]^{<\omega}$ and $f : [\mu_a]^{\mathrm{Card}(a)} \to \mu_a$ with $f \in M$. If

$$\{u \in [\mu_a]^{\mathrm{Card}(a)} \mid f(u) < \max(u)\} \in E_a$$

then there is some $\beta < \max(a)$ such that

$$\{u \in [\mu_a]^{\mathrm{Card}(a\cup\{\beta\})} \mid f^{a,a\cup\{\beta\}}(u) = u_\beta^{a\cup\{\beta\}}\} \in E_{a\cup\{\beta\}}.$$

We write $\sigma(E) = \sup\{\mu_a + 1 \mid a \in [\nu]^{<\omega}\}$. The extender E is called *short* if $\sigma(E) = \kappa + 1$; otherwise E is called *long*.

Let $b = \{\beta_1 < \cdots < \beta_n\}$, and let $a = \{\beta_{j_1} < \cdots < \beta_{j_m}\} \subseteq b$. If $u = \{\xi_1 < \cdots < \xi_n\}$ then we write u_a^b for $\{\xi_{j_1} < \cdots < \xi_{j_m}\}$; we also write $u_{\beta_i}^b$ for ξ_i. If $X \in \mathcal{P}([\mu_a]^{\mathrm{Card}(a)})$, then we write X^{ab} for $\{u \in [\mu_b]^{\mathrm{Card}(b)} \mid u_a^b \in X\}$. Finally, if f has domain $[\mu_a]^{\mathrm{Card}(a)}$ then we write $f^{a,b}$ for that g with domain $[\mu_b]^{\mathrm{Card}(b)}$ such that $g(u) = f(u_a^b)$. Finally, we write pr for the function which maps $\{\beta\}$ to β (i.e., $\mathrm{pr} = \bigcup$).

Notice that if E is a (κ,ν)-extender over the acceptable J-model M with critical points μ_a, and if N is another acceptable J-model with $\mathcal{P}(\mu_a) \cap N = \mathcal{P}(\mu_a) \cap M$ for all $a \in [\nu]^{<\omega}$, then E is also an extender over N.

The currently known core models are built with just short extenders on their sequence (cf. [5, 9, 12]). On the other hand, already the proof of the Covering Lemma for L has to make use of long extenders.

The following is easy to verify.

8.2 Theorem. *Let M and N be acceptable, and let $\pi : M \underset{\Sigma_0}{\longrightarrow} N$ cofinally with critical point κ. Let $\nu \leq N \cap \mathrm{On}$. For each $a \in [\nu]^{<\omega}$ let μ_a be the least $\mu \leq M \cap \mathrm{On}$ such that $a \subseteq \pi(\mu)$, and set*

$$E_a = \{X \in \mathcal{P}([\mu_a]^{\mathrm{Card}(a)}) \cap M \mid a \in \pi(X)\}.$$

Then $E = \langle E_a \mid a \in [\nu]^{<\omega}\rangle$ is a (κ,ν)-extender over M.

8.3 Definition. If $\pi : M \to N$, E, κ, and ν are as in the statement of Theorem 8.2 then E is called the *(κ,ν)-extender derived from* π.

8.4 Theorem. *Let $M = \langle J_\alpha^A, B\rangle$ be acceptable, and let $E = \langle E_a \mid a \in [\nu]^{<\omega}\rangle$ be a (κ,ν)-extender over M. There are then N and π such that the following hold:*

(a) $\pi : M \xrightarrow[\Sigma_0]{} N$ cofinally with critical point κ,

(b) the well-founded part $\mathrm{wfp}(N)$ of N is transitive and $\nu \subseteq \mathrm{wfp}(N)$,

(c) $N = \{\pi(f)(a) \mid a \in [\nu]^{<\omega}, f : [\mu_a]^{\mathrm{Card}(a)} \to M, f \in M\}$, and

(d) for $a \in [\nu]^{<\omega}$ we have that $X \in E_a$ if and only if $X \in \mathcal{P}([\mu_a]^{\mathrm{Card}(a)}) \cap M$ and $a \in \pi(X)$.

Moreover, N and π are unique up to isomorphism.

Proof. We do not construe (c) in the statement of this theorem to presuppose that N be well-founded; in fact, this statement makes perfect sense even if N is *not* well-founded.

Let us first argue that N and π are unique up to isomorphism. Suppose that N, π and N', π' are both as in the statement of the Theorem. We claim that

$$\pi(f)(a) \mapsto \pi'(f)(a)$$

defines an isomorphism between N and N'. Note for example that $\pi(f)(a) \in \pi(g)(b)$ if and only if, setting $c = a \cup b$,

$$c \in \pi(\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{a,c}(u) \in g^{b,c}(u)\}),$$

which by (d) yields that

$$\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{a,c}(u) \in g^{b,c}(u)\} \in E_c,$$

and hence by (d) once more that

$$c \in \pi'(\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{a,c}(u) \in g^{b,c}(u)\},$$

i.e., $\pi'(f)(a) \in \pi'(g)(b)$.

The existence is shown by an ultrapower construction. Let us set

$$D = \{\langle a, f\rangle \mid a \in [\nu]^{<\omega}, f : [\mu_a]^{\mathrm{Card}(a)} \to M, f \in M\}.$$

For $\langle a, f\rangle$, $\langle b, g\rangle \in D$ let us write

$$\langle a, f\rangle \sim \langle b, g\rangle \iff \{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{a,c}(u) = g^{b,c}(u)\} \in E_c, \quad \text{for } c = a \cup b.$$

We may easily use (1) and (2) of Definition 8.1 to see that $\sim$ is an equivalence relation on D. If $\langle a, f\rangle \in D$ then let us write $[a, f] = [a, f]_E^M$ for the equivalence class $\{\langle b, g\rangle \in D \mid \langle a, f\rangle \sim \langle b, g\rangle\}$, and let us set

$$\tilde{D} = \{[a, f] \mid \langle a, f\rangle \in D\}.$$

Let us also define, for $[a,f]$, $[b,g] \in \tilde{D}$,

$$\begin{aligned} [a,f] \mathrel{\tilde{\in}} [b,g] \quad &\Longleftrightarrow \quad \{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{a,c}(u) \in g^{b,c}(u)\} \in E_c, \\ &\qquad\qquad \text{for } c = a \cup b, \\ \tilde{A}([a,f]) \quad &\Longleftrightarrow \quad \{u \in [\mu_a]^{\mathrm{Card}(a)} \mid f(u) \in A\} \in E_a, \\ \tilde{B}([a,f]) \quad &\Longleftrightarrow \quad \{u \in [\mu_a]^{\mathrm{Card}(a)} \mid f(u) \in B\} \in E_a. \end{aligned}$$

Notice that the relevant sets are members of M, as M is rud_A-closed and amenable. Moreover, by (1) and (2) of Definition 8.1, $\tilde{\in}$, $\tilde{A}$, and $\tilde{B}$ are well-defined. Let us set

$$N = \langle \tilde{D}, \tilde{\in}, \tilde{A}, \tilde{B} \rangle.$$

Claim 1. (Łoś's Theorem) Let $\varphi(v_1, \ldots, v_k)$ be a Σ_0 formula, and let $\langle a_1, f_1 \rangle$, $\ldots, \langle a_k, f_k \rangle \in D$. Then

$$\begin{aligned} &N \models \varphi([a_1, f_1], \ldots, [a_k, f_k]) \\ &\quad \Longleftrightarrow \quad \{u \in [\mu_c]^{\mathrm{Card}(c)} \mid M \models \varphi(f_1^{a_1,c}(u), \ldots, f_k^{a_k,c}(u))\} \in E_c \\ &\qquad\qquad \text{for } c = a_1 \cup \cdots \cup a_k. \end{aligned}$$

Notice again that the relevant sets are members of M. Claim 1 is shown by induction on the complexity of φ, by exploiting (1) and (2) of Definition 8.1. Let us illustrate this by verifying the direction from right to left in the case that, say, $\varphi \equiv \exists v_0 \in v_1 \; \psi$ for some Σ_0 formula ψ.

We assume that, setting $c = a_1 \cup \cdots \cup a_k$,

$$\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid M \models \exists v_0 \in v_1 \; \psi(f_1^{a_1,c}(u), \ldots, f_k^{a_k,c}(u))\} \in E_c.$$

Let us define $f_0 : [\mu_c]^{\mathrm{Card}(c)} \to \mathrm{ran}(f_1)$ as follows.

$$f_0(u) = \begin{cases} \text{the } <_M\text{-smallest } x \in \mathrm{ran}(f_1) \text{ with} & \\ \quad M \models \psi(x, f_1^{a_1,c}, \ldots, f_k^{a_k,c}(u)) & \text{if some such } x \text{ exists,} \\ \emptyset & \text{otherwise.} \end{cases}$$

The point is that $f_0 \in M$, because M is rud_A-closed and amenable. But we then have that

$$\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid M \models f_0(u) \in f_1^{a_1,c}(u) \wedge \psi(f_1^{a_1,c}(u), \ldots, f_k^{a_k,c}(u))\} \in E_c,$$

which inductively implies that

$$N \models [c, f_0] \in [a_1, f_1] \wedge \psi([a_1, f_1], \ldots, [a_k, f_k]),$$

and hence that

$$N \models \exists v_0 \in v_1 \psi([a_1, f_1], \ldots, [a_k, f_k]).$$

Given Claim 1, we may and shall from now on identify, via the Mostowski collapse, the well-founded part $\mathrm{wfp}(N)$ of N with a transitive structure. In particular, if $[a, f] \in \mathrm{wfp}(N)$ then we identify the equivalence class $[a, f]$ with its image under the Mostowski collapse.

Let us now define $\pi : M \to N$ by

$$\pi(x) = [0, c_x], \quad \text{where } c_x : [\mu_0]^0 \to \{x\}.$$

We aim to verify that N, π satisfy (a), (b), (c), and (d) from the statement of Theorem 8.4.

Claim 2. If $\alpha < \nu$ and $[a, f] \,\tilde{\in}\, [\{\alpha\}, \mathrm{pr}]$ then $[a, f] = [\{\beta\}, \mathrm{pr}]$ for some $\beta < \alpha$.

In order to prove Claim 2, let $[a, f] \,\tilde{\in}\, [\{\alpha\}, \mathrm{pr}]$. Set $b = a \cup \{\alpha\}$. By Łoś's Theorem,

$$\{u \in [\mu_b]^{\mathrm{Card}(b)} \mid f^{a,b}(u) \in \mathrm{pr}^{\{\alpha\},b}(u)\} \in E_b.$$

By (4) of Definition 8.1, there is some $\beta < \alpha$ such that, setting $c = b \cup \{\beta\}$,

$$\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{a,c}(u) = \mathrm{pr}^{\{\beta\},c}(u)\} \in E_c,$$

and hence, by Łoś's Theorem again,

$$[a, f] = [\{\beta\}, \mathrm{pr}].$$

Claim 2 implies, via a straightforward induction, that

$$[\{\alpha\}, \mathrm{pr}] = \alpha \quad \text{for } \alpha < \nu. \tag{9.29}$$

In particular, (b) from the statement of Theorem 8.4 holds.

Claim 3. If $a \in [\nu]^{<\omega}$ then $[a, \mathrm{id}] = a$.

If $[b, f] \,\tilde{\in}\, [a, \mathrm{id}]$ then by Łoś's Theorem, setting $c = a \cup b$,

$$\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{b,c}(u) \in u^c_a\} \in E_c.$$

However, as E_c is an ultrafilter, there must then be some $\alpha \in a$ such that

$$\{u \in [\mu_c]^{\mathrm{Card}(c)} \mid f^{b,c}(u) = u^c_\alpha\} \in E_c,$$

and hence by Łoś's Theorem and (9.29)

$$[b, f] = [\{\alpha\}, \mathrm{pr}] = \alpha.$$

On the other hand, if $\alpha \in a$ then it is easy to see that $\alpha \in [a, \mathrm{id}]$. This shows Claim 3.

Claim 4. $[a, f] = \pi(f)(a)$.

Notice that this statement makes sense even if $[a, f] \notin \mathrm{wfp}(N)$.

Let $b = a \cup \{0\}$. We have that

$$\{u \in [\mu_b]^{\mathrm{Card}(b)} \mid f^{a,b}(u) = ((c_f)^{\{0\},b}(u))(\mathrm{id}^{a,b}(u))\} = [\mu_b]^{\mathrm{Card}(b)} \in E_b,$$

by (1) of Definition 8.1, and therefore by Łoś's Theorem and Claim 3,

$$[a, f] = [0, c_f]([a, \mathrm{id}]) = \pi(f)(a).$$

Claim 4 readily implies (c) from the statement of Theorem 8.4.

Claim 5. $\kappa = \mathrm{crit}(\pi)$.

Let us first show that $\pi \restriction \kappa = \mathrm{id}$. We prove that $\pi(\xi) = \xi$ for all $\xi < \kappa$ by induction on ξ.

Let $\xi < \kappa$. Suppose that $[a, f] \,\tilde{\in}\, \pi(\xi) = [0, c_\xi]$. Set $b = a \cup \{\xi\}$. Then

$$\{u \in [\mu_b]^{\mathrm{Card}(b)} \mid f^{a,b}(u) < \xi\} \in E_b.$$

As E_b is κ-complete with respect to sequences in M (cf. (1) of Definition 8.1), there is hence some $\bar{\xi} < \xi$ such that

$$\{u \in [\mu_b]^{\mathrm{Card}(b)} \mid f^{a,b}(u) = \bar{\xi}\} \in E_b,$$

and therefore $[a, f] = \pi(\bar{\xi})$ which is $\bar{\xi}$ by the inductive hypothesis. Hence $\pi(\xi) \subseteq \xi$. It is clear that $\xi \subseteq \pi(\xi)$.

We now prove that $\pi(\kappa) > \kappa$ (if $\pi(\kappa) \notin \mathrm{wfp}(N)$ we mean that $\kappa \,\tilde{\in}\, \pi(\kappa)$) which will establish Claim 5. Well, $\mu_{\{\kappa\}} = \kappa$, and

$$\{u \in [\kappa]^1 \mid \mathrm{pr}(u) < \kappa\} = [\kappa]^1 \in E_{\{\kappa\}},$$

from which it follows, using Łoś's Theorem, that $\kappa = [\{\kappa\}, \mathrm{pr}] < [0, c_\kappa] = \pi(\kappa)$.

The following, together with Claim 1 and Claim 5, will establish (a) from the statement of Theorem 8.4.

Claim 6. For all $[a, f] \in N$ there is some $y \in M$ with $[a, f] \,\tilde{\in}\, \pi(y)$.

To verify Claim 6, it is easy to see that we can just take $y = \mathrm{ran}(f)$.

It remains to prove (d) from the statement of Theorem 8.4.

Let $X \in E_a$. By (1) of Definition 8.1,

$$X = \{u \in [\mu_a]^{\mathrm{Card}(a)} \mid u \in X\} \in E_a,$$

which, by Łoś's Theorem and Claim 3, gives that $a = [a, \mathrm{id}] \,\tilde{\in}\, [0, c_X] = \pi(X)$.

On the other hand, suppose that $X \in \mathcal{P}([\mu_a]^{\mathrm{Card}(a)}) \cap M$ and $a \in \pi(X)$. Then by Claim 3, $[a, \mathrm{id}] = a \in \pi(X) = [0, c_X]$, and thus by Łoś's Theorem

$$X = \{u \in [\mu_a]^{\mathrm{Card}(a)} \mid u \in X\} \in E_a.$$

We have shown Theorem 8.4. ⊣

8.5 Definition. Let M, E, N, and π be as in the statement of Theorem 8.4. We shall denote N by $\mathrm{Ult}_0(M; E)$ and call it the Σ_0 ultrapower of M by E, and we call $\pi : M \to N$ the Σ_0 *ultrapower map* (*given by* E). We shall also write π_E for π.

8.6 Definition. Let M be acceptable, and let E be a (κ, ν)-extender over M. Let $n < \omega$ be such that $\rho_n(M) > \sigma(E)$. Suppose that M is n-sound, and set $p = p_n(M)$. Let

$$\pi : M^{n,p} \to \bar{N}$$

be the Σ_0 ultrapower map given by E. Suppose that

$$\tilde{\pi} : M \to N$$

is as given by the proof of Lemmata 4.2 and 5.11. Then we write $\mathrm{Ult}_n(M; E)$ for N and call it the $r\Sigma_{n+1}$ *ultrapower of* M *by* E, and we call $\tilde{\pi}$ the $r\Sigma_{n+1}$ *ultrapower map* (*given by* E).

A comment is in order here. Lemmata 4.2 and 5.11 presuppose that π is strong (cf. Definition 4.1). However, the construction of the term model in Sect. 4 does not require π to be strong, nor does it even require the target model $\bar{N}$ to be well-founded. Consequently, we can make sense of $\mathrm{Ult}_n(M; E)$ even if π is not strong or $\bar{N}$ is not well-founded. This is why we have "the proof of Lemmata 4.2 and 5.11" in the statement of Definition 8.6. We shall of course primarily be interested in situations where $\mathrm{Ult}_n(M; E)$ is well-founded after all. In any event, we shall identify the well-founded part of $\mathrm{Ult}_n(M; E)$ with its transitive collapse.

One can also construct $r\Sigma_{n+1}$ ultrapower maps without assuming that the model one takes the ultrapower of is n-sound; this is done by pointwise lifting up a directed system converging to the model in question. However, the construction of Definition 8.6 seems to be broad enough for most applications.

Recall Definition 5.12. It is clear in the light of the Upward Extension of Embeddings Lemma that any $r\Sigma_{n+1}$ ultrapower map is $r\Sigma_{n+1}$ elementary (and hence the name). The following will give more information.

8.7 Theorem. *Let M be acceptable, and let E be a (κ, ν)-extender over M. Let $n < \omega$ be such that $\rho_n(M) > \sigma(E)$. Suppose that M is n-sound and $(n + 1)$-solid. Let*

$$\pi : M \to \mathrm{Ult}_n(M; E)$$

be the $r\Sigma_{n+1}$ ultrapower map given by E. Assume that $\mathrm{Ult}_n(M; E)$ is transitive, and that $\pi(p_{n+1}(M)) \in P_N^{n+1}$.

Then π is an n-embedding, $\mathrm{Ult}_n(M; E)$ is $(n + 1)$-solid, and $\pi(p_{n+1}(M)) = p_{n+1}(N)$.

Proof. Set $N = \mathrm{Ult}_n(M; E)$. That N is n-sound follows from the Upward Extension of Embeddings Lemma. N is $(n + 1)$-solid and $\pi(p_{n+1}(M)) =$

$p_{n+1}(N)$ by Lemma 7.11. By construction we have that π is the upward Extension of

$$\pi\restriction M^n : M^n \to \mathrm{Ult}_0(M^n; E),$$

so that by the Upward Extension of Embeddings Lemma we shall now have that $N^n = \mathrm{Ult}_0(M^n; E)$, and therefore $\rho_n(N) = N^n \cap \mathrm{On} = \mathrm{Ult}_0(M^n; E) \cap \mathrm{On}$; however, $\pi\restriction M^n$ is cofinal in $\mathrm{Ult}_0(M^n; E)$ by Theorem 8.4, and thus $\rho_n(N) = \sup(\pi``\rho_n(M))$. The Upward Extension of Embeddings Lemma also implies that $\pi(\rho_k(M)) = \rho_k(N)$ for all $k < n$. ⊣

The following is sometimes called the "Interpolation Lemma." We leave the (easy) proof to the reader.

8.8 Lemma. *Let $n < \omega$. Let $\bar{M}$, M be acceptable, and let*

$$\pi : \bar{M} \longrightarrow M$$

be $r\Sigma_{n+1}$ elementary. Let $\nu \leq M \cap \mathrm{On}$, and let E be the (κ, ν)-extender derived from π.

There is then a weakly $r\Sigma_{n+1}$ elementary embedding

$$\sigma : \mathrm{Ult}_n(\bar{M}; E) \to M$$

such that $\sigma\restriction\nu = \mathrm{id}$ and $\sigma \circ \pi_E = \pi$.

If π is as in Theorem 8.7 then it is often crucial to know that $\rho_{n+1}(M) = \rho_{n+1}(\mathrm{Ult}_n(M; E))$. In order to be able to prove this we need that $\langle M, E\rangle$ satisfies additional hypotheses.

8.9 Definition. Let M be acceptable, and let $E = \langle E_a \mid a \in [\nu]^{<\omega}\rangle$ be a (κ, ν)-extender over M. Then E is *close to M* if for every $a \in [\nu]^{<\omega}$,

(1) E_a is $\Sigma_1^M(\{q\})$ for some $q \in M$, and

(2) if $Y \in M$, $M \models \mathrm{Card}(Y) \leq \kappa$, then $E_a \cap Y \in M$.

The following theorem is the key tool for proving the preservation of the standard parameter in iterations of mice.

8.10 Theorem. *Let M be acceptable, and let $E = \langle E_a \mid a \in [\nu]^{<\omega}\rangle$ be a short (κ, ν)-extender over M which is close to M. Suppose that $n < \omega$ is such that $\rho_{n+1}(M) \leq \kappa < \rho_n(M)$, M is n-sound, and $\mathrm{Ult}_n(M; E)$ is transitive. Then*

$$\mathcal{P}(\kappa) \cap M = \mathcal{P}(\kappa) \cap \mathrm{Ult}_n(M; E), \quad \text{and}$$
$$\rho_{n+1}(M) = \rho_{n+1}(\mathrm{Ult}_n(M; E)).$$

In particular, if M is $(n+1)$-solid then $\mathrm{Ult}_n(M; E)$ is $(n+1)$-solid and $\pi(p_{n+1}(M)) = p_{n+1}(\mathrm{Ult}_n(M; E))$.

Proof. Set $N = \mathrm{Ult}_n(M; E)$. Trivially, $\mathcal{P}(\kappa) \cap M \subseteq \mathcal{P}(\kappa) \cap N$. To show that $\mathcal{P}(\kappa) \cap N \subseteq \mathcal{P}(\kappa) \cap M$, let $X \in \mathcal{P}(\kappa) \cap N$. Let $X = [a, f]_E^{M^n}$. As E is short, $\mu_a \leq \kappa$; in fact, without loss of generality, $\mu_a = \kappa$. Hence for $\xi < \kappa$, if we set

$$X_\xi = \{u \in [\kappa]^{\mathrm{Card}(a)} \mid \xi \in f(u)\}$$

then $\{X_\xi \mid \xi < \kappa\} \in M^n \subseteq M$. But $\xi \in X \iff X_\xi \in E_a$ by Łoś's Theorem, and since E is close to M we get that $X \in M$.

If $q \in M^n$ and $A \in \Sigma_1^{M^n}(\{q\})$, $A \cap \rho_{n+1}(M) \in \Sigma_1^{N^n}(\{\pi(q), \rho_{n+1}(M)\})$. Because $\mathcal{P}(\kappa) \cap N \subseteq \mathcal{P}(\kappa) \cap M$, we thus have that $\rho_{n+1}(N) \leq \rho_{n+1}(M)$.

To show that $\rho_{n+1}(M) \leq \rho_{n+1}(N)$, let $A \in \Sigma_1^{N^n}(\{q\})$ for some $q \in N^n$. Let $q = [a, f]_E^{M^n}$, and let

$$x \in A \quad \iff \quad N^n \models \varphi(x, [a, f]),$$

where φ is Σ_1. If $M^n = \langle J_\alpha^B, A\rangle$ and $\delta < \alpha$ then we shall write $M^{n,\delta}$ for $\langle J_\delta^B, A \cap J_\delta^B\rangle$. For $\delta < N^n \cap \mathrm{On}$, $N^{n,\delta}$ is defined similarly. Because $\pi_E : M^n \to N^n$ is cofinal, we have that

$$x \in A \quad \iff \quad \exists \delta < M^n \cap \mathrm{On}\ N^{n,\pi_E(\delta)} \models \varphi(x, [a, f]).$$

By Łoś's Theorem, we may deduce that for $\xi < \kappa$,

$$\xi \in A \quad \iff \quad \exists \delta < M^n \cap \mathrm{On}\ \{u \in [\kappa]^{\mathrm{Card}(a)} \mid M^{n,\delta} \models \varphi(\xi, f(u))\} \in E_a.$$

But now E is close to M, so that E_a is $\Sigma_1^{M^n}(\{q'\})$ for some $q' \in M^n$, which implies that $A \cap \kappa$ is $\Sigma_1^{M^n}(\{q', \kappa, f\})$.

We now finally have that $\pi(p_{n+1}(M)) \in P_M^{n+1}$. Therefore, if M is $(n+1)$-solid then $\mathrm{Ult}_n(M; E)$ is $(n+1)$-solid and $\pi(p_{n+1}(M)) = p_{n+1}(\mathrm{Ult}_n(M; E))$ by Lemma 7.12. ⊣

We now turn towards criteria for $\mathrm{Ult}_n(M; E)$ being well-founded.

8.11 Definition. Let M be acceptable, and let $E = \langle E_a \mid a \in [\nu]^{<\omega}\rangle$ be a (κ, ν)-extender over M. Let $\lambda < \mathrm{Card}(\kappa)$ be an infinite cardinal (in V). Then E is called λ-*complete* provided the following holds true. Suppose that $\langle\langle a_i, X_i\rangle \mid i < \lambda\rangle$ is such that $X_i \in E_{a_i}$ for all $i < \lambda$. Then there is some order-preserving map $\tau : \bigcup_{i<\lambda} a_i \to \sigma(E)$ such that $\tau``a_i \in X_i$ for every $i < \lambda$.

8.12 Lemma. *Let M be acceptable, and let $E = \langle E_a \mid a \in [\nu]^{<\omega}\rangle$ be a (κ, ν)-extender over M. Let $\lambda < \mathrm{Card}(\kappa)$ be an infinite cardinal. Then E is λ-complete if and only if for every $U \underset{\Sigma_0}{\prec} \mathrm{Ult}_0(M; E)$ of size λ there is some $\varphi : U \underset{\Sigma_0}{\longrightarrow} M$ such that $\varphi \circ \pi_E(x) = x$ whenever $\pi_E(x) \in U$.*

Proof. ($\Longrightarrow$) Let $U \underset{\Sigma_0}{\prec} \mathrm{Ult}_0(M; E)$ be of size λ. Write $U = \{[a, f] \mid \langle a, f\rangle \in \bar{U}\}$ for some $\bar{U}$ of size λ. Let $\langle\langle a_i, X_i\rangle \mid i < \lambda\rangle$ be an enumeration of all pairs $\langle c, X\rangle$ such that there is a Σ_0 formula ψ and there are $\langle a^1, f_1\rangle, \ldots,$ $\langle a^k, f_k\rangle \in \bar{U}$ with $c = a^1 \cup \cdots \cup a^k$ and

$$X = \{u \in [\mu_c]^{\mathrm{Card}(c)} \mid M \models \psi(f_1^{a^1,c}(u), \ldots, f_k^{a^k,c})\} \in E_c.$$

Let $\tau : \bigcup_{i<\lambda} a_i \to \sigma(E)$ be order-preserving such that $\tau``a_i \in X_i$ for every $i < \lambda$. Let us define $\varphi : U \to M$ by setting $\varphi([a, f]) = f(\tau``(a))$ for $\langle a, f\rangle \in \bar{U}$.

We get that φ is well-defined and Σ_0 elementary by the following reasoning. Let $\psi(v_1, \ldots, v_k)$ be Σ_0, and let $\langle a^j, f_j\rangle \in U$, $1 \leq j \leq k$. Set $c = a^1 \cup \cdots \cup a^k$. We then get that

$$\begin{aligned}
&U \models \psi([a^1, f_1], \ldots, [a^k, f_k])\\
&\quad\iff \quad \mathrm{Ult}_0(M; E) \models \psi([a^1, f_1], \ldots, [a^k, f_k])\\
&\quad\iff \quad \{u \in [\mu_c]^{\mathrm{Card}(c)} \mid M \models \psi(f_1^{a^1,c}(u), \ldots, f_k^{a^k,c}(u))\} \in E_c\\
&\quad\iff \quad \tau``c \in \{u \in [\mu_c]^{\mathrm{Card}(c)} \mid M \models \psi(f_1^{a^1,c}(u), \ldots, f_k^{a^k,c}(u))\}\\
&\quad\iff \quad M \models \psi(f_1(\tau" a^1), \ldots, f_k(\tau``a^k)).
\end{aligned}$$

We also get that $\varphi \circ \pi_E(x) = \varphi([\emptyset, c_x]) = c_x(\emptyset) = x$.

($\Longleftarrow$) Let $\langle\langle a_i, X_i\rangle \mid i < \lambda\rangle$ be such that $X_i \in E_{a_i}$ for all $i < \lambda$. Pick $U \underset{\Sigma_0}{\prec} \mathrm{Ult}_0(M; E)$ with $\{a_i, X_i \mid i < \lambda\} \subseteq U$, $\mathrm{Card}(U) = \lambda$, and let $\varphi :$ $U \underset{\Sigma_0}{\longrightarrow} M$ be such that $\varphi \circ \pi_E(x) = x$ whenever $\pi_E(x) \in U$. Set $\tau = \varphi \restriction \bigcup_{i<\lambda} a_i$. Then $\tau``a_i = \varphi(a_i) \in \varphi \circ \pi_E(X_i) = X_i$ for all $i < \lambda$. Clearly, $\mathrm{ran}(\tau) \subseteq \sigma(E)$. ⊣

8.13 Corollary. *Let M be acceptable, and let E be an $\aleph_0$-complete (κ, ν)-extender over M. Then $\mathrm{Ult}_0(M; E)$ is well-founded. In fact, if $n < \omega$ is such that $\rho_n(M) \geq \sigma(E)$ then $\mathrm{Ult}_n(M; E)$ is well-founded.*

The concept of $\aleph_0$-completeness is relevant for constructing inner models below the "sharp" for an inner model with a proper class of strong cardinals (cf. [11]). There are strengthenings of the concept of $\aleph_0$-completeness which are needed for the construction of inner models beyond the "sharp" for an inner model with a proper class of strong cardinals (cf. for instance [13, Definition 1.2], [6, Definition 1.6]).

8.14 Lemma. *Let λ be an infinite cardinal, and let θ be regular. Let $\pi :$ $\bar{H} \to H_\theta$, where $\bar{H}$ is transitive and ${}^\lambda\bar{H} \subseteq \bar{H}$. Suppose that $\pi \neq \mathrm{id}$, and set $\kappa = \mathrm{crit}(\pi)$. Let M be acceptable, let ρ be regular in M, and suppose that $H^M_\rho \subseteq \bar{H}$. Set $\nu = \sup(\pi``\rho)$, and let E be the (κ, ν)-extender derived from $\pi \restriction H^M_\rho$. Then E is λ-complete.*

Proof. Let $\langle\langle a_i, X_i\rangle \mid i < \lambda\rangle$ be such that $X_i \in E_{a_i}$, and hence $a_i \in \pi(X_i)$, for all $i < \lambda$. As ${}^\lambda\bar{H} \subseteq \bar{H}$, $\langle X_i \mid i < \lambda\rangle \in \bar{H}$. Let $\sigma : \mathrm{otp}(\bigcup_{i<\lambda} a_i) \cong \gamma$ be the transitive collapse; notice that $\gamma < \lambda^+ < \kappa$. For each $i < \lambda$ let $\bar{a}_i = \sigma``a_i$. We have that $\langle \bar{a}_i \mid i < \lambda \rangle \in \bar{H}$. But now

$$H_\theta \models \exists \tau : \gamma \tilde{\to} \mathrm{On}\ \forall i < \lambda\ \tau``\bar{a}_i \in \pi(\langle X_j \mid j < \lambda \rangle)(i),$$

as witnessed by σ. Therefore,

$$\bar{H} \models \exists \tau : \gamma \tilde{\to} \mathrm{On}\ \forall i < \lambda\ \tau``\bar{a}_i \in X_i.$$

Hence, if $\tau \in \bar{H}$ is a witness to this fact then $\tau \circ \sigma : \bigcup_{i<\lambda} a_i \to \mathrm{On}$ is such that $\tau \circ \sigma``a_i \in X_i$ for every $i < \lambda$. ⊣

We leave it to the reader to find variants of this result. For instance, extenders derived from canonical ultrapower maps witnessing that a given cardinal κ is measurable are λ-complete for every $\lambda < \kappa$.

9. Applications to L

In this final section we shall illustrate how to use the above machinery in the simplest case—in the constructible universe L. The theory developed above is, however, general enough so that it can be used for all the currently known core models.

We shall first prove two important lemmata. Recall that we index the J-hierarchy with limit ordinals.

9.1 Lemma. *For each limit ordinal α, J_α is acceptable.*

9.2 Lemma. *For each limit ordinal α, J_α is sound.*

We shall prove these two lemmata simultaneously. The proof goes by induction on α in a zig-zag way in the sense that we use soundness of J_α to prove the acceptability of $J_{\alpha+\omega}$ and then, knowing this, its soundness.

Proof. The case $\alpha = \omega$ is trivial. Now suppose that both lemmata hold for all limit ordinals $\beta < \alpha$.

Claim 1. J_α is acceptable.

This is trivial for α being a limit of limit ordinals. For $\alpha = \beta + \omega$ it is clear that the only thing we have to prove is the following:

$$\begin{aligned} &\text{If there is a } \tau < \beta \text{ and an } a \subseteq \tau \text{ such that } a \in J_{\beta+\omega} \setminus J_\beta, \\ &\qquad\qquad \text{then there is an } f \in J_{\beta+\omega} \text{ such that } f : \tau \xrightarrow{\text{onto}} \beta. \end{aligned} \tag{9.30}$$

We prove (9.30). Suppose that there are such τ, a and take τ to be the least one such that there is a as above. Then

$$\tau = \rho_\omega(J_\beta). \tag{9.31}$$

To see (9.31) note first that if n is such that $\rho_n(J_\beta) = \rho_\omega(J_\beta)$, then we have a new $\mathbf{\Sigma}_1^{J_\beta^n}$ subset of $\rho_\omega(J_\beta)$. Such a set is $\mathbf{\Sigma}_\omega^{J_\beta}$ by Lemma 5.5, and is hence in $J_\beta + \omega \setminus J_\beta$ by Lemma 1.7. Therefore, $\tau \leq \rho_\omega(J_\beta)$.

Let $a \subseteq \tau$ such that $a \in J_{\beta+\omega} \setminus J_\beta$. Then $a \in \mathbf{\Sigma}_n^{J_\beta}$ for some $n \in \omega$ by Lemma 1.7. By the above inequality, $a \subseteq \rho_n(J_\beta)$. Lemma 5.6 then yields that a is $\mathbf{\Sigma}_1^{J_\beta^{n-1}}$, since, by the induction hypothesis, J_β is sound. Consequently, $\rho_\omega(J_\beta) \leq \tau$. This proves (9.31).

Now we use the induction hypothesis once again to verify (9.30). By the soundness of J_β and by Lemmata 5.4 and 5.5, there is some $f \in \mathbf{\Sigma}_\omega^{J_\beta}$ such that $f : \rho_\omega(J_\beta) \to J_\beta$ is surjective. By Lemma 1.7, $f \in J_{\beta+\omega}$. This shows (9.30) and therefore also Claim 1.

Claim 2. J_α is sound.

We shall make use of Lemma 6.8 here. Hence, for $n < \omega$ we prove

$$p_n(J_\alpha) \in R^n_{J_\alpha}. \tag{9.32}$$

Suppose that this is false. Pick the first n such that $p = p_n(J_\alpha) \notin R^n_{J_\alpha}$. Let a be $\Sigma_1^{J_\alpha^{n-1}}(\{p\})$ such that $a \cap \rho_n(J_\alpha) \notin J_\alpha$. Using the Downward Extension of Embeddings Lemma we construct unique $J_{\bar\alpha}$, $\bar p$, π such that

$$\begin{aligned}
&\bar p \in R^n_{J_{\bar\alpha}},\\
&\pi : J_{\bar\alpha}^{n-1,\bar p\restriction(n-1)} \to J_\alpha^{n-1,p\restriction(n-1)} \text{ is } \Sigma_1 \text{ elementary},\\
&\pi(\bar p(n-1)) = p(n-1),\\
&\pi\restriction J_{\rho_n(J_\alpha)} = \mathrm{id}.
\end{aligned} \tag{9.33}$$

Hence $a \cap \rho_n(J_\alpha) = \bar a \cap \rho_n(J_{\bar\alpha})$ where $\bar a$ is $\Sigma_1^{J_{\bar\alpha}^{n-1}}(\{\bar p(n-1)\})$ by the same definition. Hence $\bar\alpha$ cannot be less than α, since otherwise $a \cap \rho_n(J_\alpha) \in J_\alpha$. Consequently, $\bar\alpha = \alpha$. It is also clear by the construction that $\bar p \leq^* p$. But $p \leq^* \bar p$ since p is the standard parameter. Hence, $p = \bar p$. But this means $p \in R^n_{J_\alpha}$. Contradiction. ⊣

Classical applications of the fine structure theory include Jensen's results that $\Diamond$ and $\Box$ hold in L and that L satisfies the Covering Lemma. The following is Jensen's Covering Lemma for L.

9.3 Theorem. *Suppose that $0^\#$ does not exist. Let X be a set of ordinals. Then there is a $Y \in L$ with $Y \supseteq X$ and* $\mathrm{Card}(Y) \leq \mathrm{Card}(X) \cdot \aleph_1$.

This result is shown in [2] (cf. also [5]). In order to illustrate the fine structural techniques we have developed we shall now give a proof of a corollary to Theorem 9.3. Recall that a cardinal κ is called *countably closed* if $\lambda^{\aleph_0} < \kappa$ whenever $\lambda < \kappa$.

9.4 Corollary. *Let κ be a countably closed singular cardinal. If $0^{\#}$ does not exist then $\kappa^{+L} = \kappa^{+}$.*

Proof. We shall use the fact that the existence of $0^{\#}$ is equivalent with the existence of a non-trivial elementary embedding $\pi : L \to L$. Suppose that $0^{\#}$ does not exist and κ is a countably closed singular cardinal such that $\kappa^{+L} < \kappa^{+}$. We aim to derive a contradiction.

Let $X \subseteq \kappa^{+L}$ be cofinal with $\mathrm{otp}(X) < \kappa$. We may pick an elementary embedding

$$\pi : \bar{H} \to H_{\kappa^+}$$

such that $\bar{H}$ is transitive, ${}^{\omega}\bar{H} \subseteq \bar{H}$, $X \subseteq \mathrm{ran}(\pi)$, and $\mathrm{Card}(\bar{H}) = \mathrm{otp}(X)^{\aleph_0}$. As κ is countably closed, $\mathrm{Card}(\bar{H}) < \kappa$, which implies that $\pi \neq \mathrm{id}$. Set $\lambda = \pi^{-1}(\kappa^{+L})$, and let E be the $(\kappa, \pi(\lambda))$-extender over J_λ derived from $\pi \restriction J_\lambda$.

By Lemma 8.14, E is $\aleph_0$-complete. By Corollary 8.13, this implies the following.

Claim. Let $\alpha \geq \lambda$, $\alpha \in \mathrm{On} \cup \{\mathrm{On}\}$. Suppose that λ is a cardinal in J_α (which implies that E is an extender over J_α). Suppose that $\rho_n(J_\alpha) \geq \lambda$. Then $\mathrm{Ult}_n(J_\alpha; E)$ is transitive, and therefore $\mathrm{Ult}_n(J_\alpha; E) = J_\beta$ for some $\beta \in \mathrm{On} \cup \{\mathrm{On}\}$. (If $\alpha = \mathrm{On}$ then by J_α we mean L, and we want $n = 0$; we shall then have $J_\beta = L$ as well.)

Now because $0^{\#}$ does not exist, we cannot have that $\alpha = \mathrm{On}$ satisfies the hypothesis of the Claim. Let $\alpha \in \mathrm{On} \setminus \lambda$ be largest such that λ is a cardinal in J_α. Let $n < \omega$ be such that $\rho_{n+1}(J_\alpha) < \lambda \leq \rho_n(J_\alpha)$. By Lemma 9.2, we have that

$$J_\alpha = h_{J_\alpha}^{n+1}``(\rho_{n+1}(J_\alpha) \cup \{p\}),$$

where $p = p_{n+1}(J_\alpha)$. (Cf. Lemma 5.4.) Because π_E is $r\Sigma_{n+1}$ elementary by Theorem 8.7, Lemma 5.13 implies that

$$X \subseteq \pi``J_\alpha \subseteq h_{J_\beta}^{n+1}``(\pi(\rho_{n+1}(J_\alpha)) \cup \{\pi(p)\}).$$

But $\pi(\rho_{n+1}) \leq \kappa$, so that in particular

$$J_{\beta+\omega} \models \pi(\lambda) \text{ is not a cardinal.}$$

However, $\pi(\lambda) = \kappa^{+L}$. Contradiction! ⊣

We finally aim to prove $\square_\kappa$ in L. This is the combinatorial principle the proof of which most heavily exploits the fine structure theory.

Let κ be an infinite cardinal. Recall that we say that $\square_\kappa$ holds if and only if there is a sequence $\langle C_\nu \mid \nu < \kappa^+ \rangle$ such that if ν is a limit ordinal, $\kappa < \nu < \kappa^+$, then C_ν is a club subset of ν with $\mathrm{otp}(C_\nu) \leq \kappa$ and whenever $\bar{\nu}$ is a limit point of C_ν then $C_{\bar{\nu}} = C_\nu \cap \bar{\nu}$.

9.5 Theorem. *Suppose that $V = L$. Let $\kappa \geq \aleph_1$ be a cardinal. Then $\square_\kappa$ holds.*

Proof. We shall verify that there is a club $C \subseteq \kappa^+$ and some $\langle C_\nu \mid \nu \in C \wedge \mathrm{cf}(\nu) > \omega\rangle$ such that if ν is a limit ordinal, $\kappa < \nu < \kappa^+$, then C_ν is a club subset of ν with $\mathrm{otp}(C_\nu) \leq \kappa$ and whenever $\bar{\nu}$ is a limit point of C_ν then $C_{\bar{\nu}} = C_\nu \cap \bar{\nu}$. It is not hard to verify that this implies $\square_\kappa$ (cf. [1, pp. 158ff.]).

Let $C = \{\nu < \kappa^+ \mid J_\nu \prec_{\Sigma_\omega} J_{\kappa^+}\}$, a closed unbounded subset of κ^+.

Let $\nu \in C$. Obviously, κ is the largest cardinal of J_ν. We may let $\alpha(\nu)$ be the largest $\alpha \geq \nu$ such that either $\alpha = \nu$ or ν is a cardinal in J_α. By Lemma 1.7, $\rho_\omega(J_{\alpha(\nu)}) = \kappa$. Let $n(\nu)$ be that $n < \omega$ such that $\kappa = \rho_{n+1}(J_{\alpha(\nu)}) < \nu \leq \rho_n(J_{\alpha(\nu)})$.

If $\nu \in C$, then we define D_ν as follows. D_ν consists of all $\bar{\nu} \in C \cap \nu$ such that $n(\bar{\nu}) = n(\nu)$, and there is a weakly $r\Sigma_{n(\nu)+1}$ elementary embedding

$$\sigma : J_{\alpha(\bar{\nu})} \longrightarrow J_{\alpha(\nu)}$$

such that $\sigma{\restriction}\bar{\nu} = \mathrm{id}$, $\sigma(p_{n(\bar{\nu})+1}(J_{\alpha(\bar{\nu})})) = p_{n(\nu)+1}(J_{\alpha(\nu)})$, and if $\bar{\nu} \in J_{\alpha(\bar{\nu})}$ then $\nu \in J_{\alpha(\nu)}$ and $\sigma(\bar{\nu}) = \nu$. It is easy to see that if $\bar{\nu} \in D_\nu$ then there is exactly one map σ witnessing this, namely the one with

$$\sigma(h^{n(\bar{\nu})+1}_{J_{\alpha(\bar{\nu})}}(\xi, p_{n(\bar{\nu})+1}(J_{\alpha(\bar{\nu})}))) = h^{n(\nu)+1}_{J_{\alpha(\nu)}}(\xi, p_{n(\nu)+1}(J_{\alpha(\nu)}))$$

$\xi < \kappa$; we shall denote this map by $\sigma_{\bar{\nu},\nu}$.

Claim 1. Let $\nu \in C$. The following hold:

(a) D_ν is closed.

(b) If $\mathrm{cf}(\nu) > \omega$ then D_ν is unbounded.

(c) If $\bar{\nu} \in D_\nu$ then $D_\nu \cap \bar{\nu} = D_{\bar{\nu}}$.

Proof of Claim 1. (a) and (c) are easy. Let us show (b). Suppose that $\mathrm{cf}(\nu) > \omega$. Set $\alpha = \alpha(\nu)$ and $n = n(\nu)$. Let $\beta < \nu$. We aim to show that $D_\nu \setminus \beta \neq \emptyset$.

Let $\pi : J_{\bar{\alpha}} \underset{\Sigma_{n+1}}{\longrightarrow} J_\alpha$ be such that $\bar{\alpha}$ is countable, $\beta \in \mathrm{ran}(\pi)$, and

$$\{W^{\nu, p_1(J^k_\alpha)}_{J^k_\alpha} \mid \nu \in p_1(J^k_\alpha), k \leq n\} \subseteq \mathrm{ran}(\pi).$$

Let $\bar{\nu} = \pi^{-1}(\nu)$ (if $\nu = \alpha$, we mean $\bar{\nu} = \bar{\alpha}$). Let

$$\pi' = \pi_{E_{\pi\restriction J_{\bar{\nu}}}} : J_{\bar{\alpha}} \underset{r\Sigma_{n+1}}{\longrightarrow} \mathrm{Ult}_n(J_{\bar{\alpha}}; E_{\pi\restriction J_{\bar{\nu}}}).$$

Write $J_{\alpha'} = \mathrm{Ult}_n(J_{\bar{\alpha}}; E_{\pi\restriction J_{\bar{\nu}}})$. By Lemma 8.8, we may define a weakly $r\Sigma_{n+1}$ elementary embedding

$$k : J_{\alpha'} \longrightarrow J_\alpha$$

with $k \circ \pi' = \pi$. As $\beta \in \mathrm{ran}(\pi)$, $k^{-1}(\nu) > \beta$. Moreover, $k^{-1}(\nu) = \sup(\pi``\bar{\nu}) < \nu$, as $\mathrm{cf}(\nu) > \omega$. Therefore $\beta < k^{-1}(\nu) \in D_\nu$. $\dashv$

Now let $\nu \in C$. We aim to define C_ν. Set $\alpha = \alpha(\nu)$, and $n = n(\nu)$. Recursively, we define sequences $\langle \nu_i \mid i \leq \theta(\nu)\rangle$ and $\langle \xi_i \mid i < \theta(\nu)\rangle$ as follows. Set $\nu_0 = \min(D_\nu)$. Given ν_i with $\nu_i < \nu$, we let ξ_i be the least $\xi < \kappa$ such that

$$h^{n+1}_{J_\alpha}(\xi, p_{n+1}(J_\alpha)) \setminus \mathrm{ran}(\sigma_{\nu_i,\nu}) \neq \emptyset.$$

Given ξ_i, we let ν_{i+1} be the least $\bar{\nu} \in D_\nu$ such that

$$h^{n+1}_{J_\alpha}(\xi_i, p_{n+1}(J_\alpha)) \in \mathrm{ran}(\sigma_{\bar{\nu},\nu}).$$

Finally, given $\langle \nu_i \mid i < \lambda\rangle$, where λ is a limit ordinal, we set $\nu_\lambda = \sup(\{\nu_i \mid i < \lambda\}$. Naturally, $\theta(\nu)$ will be the least i such that $\nu_i = \nu$. We set $C_\nu = \{\nu_i \mid i < \theta(\nu)\}$.

The following is now easy to verify.

Claim 3. Let $\nu \in C$. Then The following hold:

(a) $\langle \xi_i \mid i < \theta(\nu)\rangle$ is strictly increasing.

(b) $\mathrm{otp}(C_\nu) = \theta(\nu) \leq \kappa$.

(c) C_γ is closed.

(d) If $\bar{\nu} \in C_\nu$ then $C_\nu \cap \bar{\nu} = C_{\bar{\nu}}$.

(e) If D_ν is unbounded in ν then so is C_ν.

We have shown that $\Box_\kappa$ holds. ⊣

1. Σ^* Fine Structure

Why is fine structure necessary? One answer is that, although the constructible hierarchy is an extremely uniform creation, it is not *that* uniform. We have for any level of our J_α hierarchy uniform Σ_1-Skolem functions. In attempting to generalise this and prove the existence of Σ_n-uniformising functions one runs immediately into the difficulty that these cannot be given a completely uniform definition. The following example taken from [17] shows why (see also the related [8, pp. 106–107]).

For any $\tau < \omega_1$, $\{\zeta \mid J_{\omega_1+\tau} \models$ "$\omega_1+\zeta$ does not exist"$\}$ is a Π_1-relation over $J_{\omega_1+\tau}$ whose least member, i.e. τ itself, has a Σ_2 definition via applications of a posited uniformly definable Σ_2-Skolem function. For such τ we should have a resulting Σ_2 definition, which, by Fodor's Lemma, on a stationary set $D \subseteq \omega_1$ of τ, would be given by the same Σ_2 formula over J_τ, $\exists u \forall v \Phi(u, v, t)$ say. By Fodor again we may shrink D further to a stationary E so that for some constant δ, and some fixed $u_0 \in J_{\omega_1+\delta}$, and taking any $\eta < \omega_1$, if η is in $E \setminus (\delta+1)$ then $(\forall v \Phi(u_0, v, \eta))$ holds in $J_{\omega_1+\eta}$. In particular for any other $\gamma \in E \setminus (\delta+1)$ below η this Π_1 fact about η also holds in $J_{\omega_1+\gamma}$, where γ is supposed to be the unique solution. This is absurd.

We deduce from this that parameters must be involved in defining Σ_2-Skolem functions. Jensen's solution in [24] is to reduce the problem of Σ_2-uniformisation over J_τ to that of Σ_1-uniformisation over a *projectum structure* $\langle J_{\rho_\tau}, A_\tau \rangle$ with A_τ a Σ_1-*mastercode* essentially coding up Σ_1 truth over J_τ. $\Sigma_2(J_\tau) \cap J_{\rho_\tau}$ relations are transformed to $\Sigma_1(\langle J_{\rho_\tau}, A_\tau \rangle)$ relations, which can be Σ_1-uniformised, and such a uniformising function can be translated back up to a Σ_2 function over J_τ. This is because ρ_τ has been chosen so that there is a uniform (in τ) Σ_1-Skolem function mapping (a subset of) J_{ρ_τ} onto J_τ (although uniform, a *parameter* is inserted here dependent on τ). In this, admittedly very scantily sketched, manner we can effectively Σ_2-uniformise all of J_τ. This machinery can be generalised for all $n \geq 2$, and thus prove Jensen's Σ_n-*Uniformisation Theorem*: *Any $\Sigma_n(J_\tau)$ relation can be uniformised by a $\Sigma_n(J_\tau)$ function.* However as we have observed, there can be no uniform way of performing Σ_2-uniformisations: there was the notion of the projectum, and the parameter in the above, which will vary between J_τ's. All the objects concerned (the projects, the parameters etc.) nevertheless have definitions over J_τ; however these definitions are not at the same level of complexity in the Levy hierarchy of formulae as the level we are working at, and at which we would wish. The Σ^* hierarchy of formulae replaces the Levy hierarchy and seeks to encapsulate the idea that somehow Σ_{n+1} is "Σ_1-in-Σ_n" much as the above talked about Σ_2 (with $2 = n+1$) as "Σ_1-in-Σ_n" over the *first reduct* or projectum structure $\langle J_{\rho_\tau}, A_\tau \rangle$. Then we think of $\Sigma_1^{(n+1)}$ as Σ_1 in $\Sigma_1^{(n)}$—and that is why $\Sigma_1^{(n)}$ plays a part in the "atomic" clause definition of $\Sigma_1^{(n+1)}$ below. $\Sigma_1^{(n)}$ formulae then refer to nth reducts only indirectly through the type of the variables.

The Σ^* hierarchy then, is not at all necessary for an exposition of a fine structure theory for L: we have chosen on illustrative grounds to rework the proofs of, say, global $\Box$ for L below, using it. Although for a structure M the $\Sigma_1^{(n)}(M)$ hierarchy of relations is different from the usual $\Sigma_n(M)$ hierarchy *qua* hierarchy, the totality of relations $\boldsymbol{\Sigma^*}(M) = \bigcup_{n<\omega} \boldsymbol{\Sigma_1^{(n)}}(M)$ are the same: $\boldsymbol{\Sigma_\omega}(M)$. The gain in the Σ^* hierarchy comes chiefly in the development of the theory of fine structure suitable for mice, for fine-structural ultrapowers, and $L[E]$ models. One should further make the remark that much of the work in defining the notions of projects, good and very good parameters (the sets P_M and R_M), nth codes, and reducts etc., is prior to the notion of $\Sigma_1^{(n)}$ relation: we shall exploit this here by referring back to the chapter of Schindler and Zeman in this Handbook [46] for these concepts.

Each section consists of one or more fine structural constructions followed by some discussion on variants, extensions, and a necessarily brief list of some sample applications. Thus this first section will continue after these introductory remarks to introduce the $\Sigma_1^{(n)}$ hierarchy of formulae, and the accompanying relations on acceptable structures. Although these pages look notationally complex the proofs are essentially elementary. The notion of $\Sigma_k^{(n)}$*-preserving embeddings* as those embeddings that preserve formulae of the correct type, is of course natural and by Lemma 1.15 we can restate the Downward Extension of Embeddings Lemma and Jensen's uniformisation result as a $\Sigma_1^{(n)}$-Uniformisation Theorem. Notions of $\Sigma_1^{(n)}$-Skolem function and of the Condensation Lemma for L in a strong form follow.

In Sect. 1.1 variant fine structures are discussed: the original form of fine structure for the Dodd-Jensen core model [10]; the use of Skolem hulls to potentially replace parts of the fine structure apparatus, and the hyperfine structure theory. In Sect. 1.2 the important theory of Σ^* ultrapowers is developed. This is a natural notion of ultrapower based on the $\Sigma_1^{(n)}$ hierarchy. Section 1.3 reworks this material for so-called pseudo-ultrapowers, otherwise known as long extender ultrapowers. Section 2 is devoted to using this apparatus to a proof of Global $\Box$ in L. As remarked later, we do not actually need the $\Sigma_1^{(n)}$ hierarchy and the corresponding analysis of the constructible hierarchy to effect this. However it is illustrative of the kind of arguments one uses in this arena. Section 2.1 gives some variants of $\Box$ principles. We only very briefly mention some applications, but do discuss consequences of the failure of $\Box_\kappa$. The fascinating question of whether it can be proven that $\Box$ holds in fine structural inner models is discussed in Sect. 2.2. Recent work identifies for which κ in certain classes of $L[E]$ models we can have $\Box_\kappa$. Section 3 discusses morasses and gives constructions of both a gap-1 morass and the simplifying variant of a coarse gap-1 morass in L.

We shall not discuss in any great depth the two major applications of contemporary fine structure: the Covering Lemma and $L[E]$-Inner Models. Although we shall want to refer to these later, these two major topics are properly covered elsewhere in the Handbook, in the chapters by Mitchell and by Schimmerling.

Acknowledgements

Although this chapter is an expansion of a brief outline in [56] that was based on Jensen's original [28], the authoritative published reference to the $\Sigma_1^{(n)}$ theory is Zeman's [62]. We are very much indebted to his volume for much of the early part of the exposition here, as well as to the authors of [18] and [32], and would like to thank them. We should like to thank those who have commented helpfully on previous versions of this chapter, and again we are particularly grateful to Martin Zeman in this regard.

By "Lim" ("Sing") we mean the class of limit ordinals (singular limit ordinals, respectively), by "Card" we mean the class of cardinals, and by "Reg", we shall mean the class of regular cardinals. For h_M a Σ_1-Skolem function (see [46, 1.15]) for a structure M, we shall denote by $h_M(X)$ the Skolem hull inside M generated from the set $X \subseteq M$; more properly we should have written $h_M``(\omega \times [X]^{<\omega})$, where in turn $[X]^{<\omega}$ denotes the class of finite subsets of X. We use $\vec{y}$ to denote the list $y_0, \ldots, y_h$, and $\langle \vec{y} \rangle =_{\mathrm{df}} \langle y_0, \ldots, y_h \rangle$ is the ordered sequence, i.e. a finite function. Order type is abbreviated as ot. If $X \subseteq \mathrm{On}$ then X^* denotes the class of limit points of X. We use the following rudimentarily defined well-order on $[\mathrm{On}]^{<\omega}$: $a <^* b \leftrightarrow \max(a \triangle b) \in b$.

In what follows we assume that $M = \langle J_\alpha^A, \in, A, B \rangle$ is an acceptable J-structure in the sense of [46, 1.20] with J_α^A a level of a relativised J-hierarchy. That is, it is a structure satisfying the *axiom of acceptability*: $\forall \tau < \alpha \forall \xi < \tau$:

$$\mathcal{P}(\xi) \cap J_{\tau+1}^A \backslash J_\tau^A \neq \varnothing \longrightarrow (\exists f \in J_{\tau+1}^A)\,(f : \xi \overset{\text{onto}}{\to} \tau).$$

We further recall from there that being acceptable can be expressed as a *Q-property* (see [46, 1.18]). We shall write $\rho_M = \rho(M)$ as usual for the Σ_1-projectum of M. ([46] prefers the notation $\rho(M)$ here; we have also adhered to Jensen's notation, and that of [62], in writing here "J_α" for what [46] would name "$J_{\omega\alpha}$".) Similarly we shall write for the $(n+1)$*st projectum* $\rho_M^{n+1} =_{\mathrm{df}} \min\{\rho_{M^{n,p}} \mid p \in \Gamma_M^n\}$. ([46] would write $\rho_{n+1}(M)$ for ρ_M^{n+1} here, and similarly $\rho(M^{n,p})$ for $\rho_{M^{n,p}}$; as here, we keep in general to the notation of [62].) We can, and do, assume that parameters are finite sets of ordinals (cf. the comment of [46] before 6.3). This applies as well to the *nth-standard parameter* and the *standard parameter* [46, 6.3, 6.6] denoted here p_M^n, p_M respectively for a structure M as above. For the notions of *soundness* and *n-soundness* the reader can refer to [46] Definition 5.2—and see Lemma 6.8.

The Σ^* Hierarchy of Formulae

Notions of "fine-structural" preserving maps (and ultimately ultrapowers) can be smoothly presented in terms of Jensen's Σ^* hierarchy of formulae. As already intimated, this is a hierarchy of definability over a J-structure, with a different order of stratification than the usual Levy hierarchy of formulae. Although the relations Σ^*-definable over M are also the usual Σ_ω-definable relations, the intermediate levels of Σ_n-definability do not in general correspond to those within Σ^*. More complex initially, the Σ^* hierarchy possesses nice properties the Levy hierarchy lacks: again for example, over L, Jensen's Σ_n-Uniformisation Theorem states that such relations may be Σ_n-uniformised albeit *in a parameter*. When given the Σ^* analysis, $\Sigma_1^{(n)}(J_\alpha)$ relations enjoy *uniform* $\Sigma_1^{(n)}(J_\alpha)$-uniformising functions. Moreover the hierarchy encapsulates the notion of elementarity that the reader of [46] Sects. 3 and 4 on downward and upward extensions of embeddings will have already seen expressed by those results. As mentioned above, the hierarchy and all the results here of this first section were first exposited in [28] by Jensen.

We start by defining the language $\mathcal{L}^* = \mathcal{L}^*_{\{\dot{\in},\dot{=},\dot{A},\dot{B}\}}$. This has *variables* v^i_j $(i,j<\omega)$ of *type* i. The *atomic formulae* are those of the form $v^i_j \in \dot{A}$, $v^i_j \in \dot{B}$, $v^i_j \in v^k_l$, $v^i_j = v^k_l$ $(i,j,k,l<\omega)$. The *formulae* are those obtained from the atomic formulae by closing under $\neg, \wedge$ and *typed quantification* $\exists v^i_j, \forall v^i_j$. An $\mathcal{L}^*$-*structure* is then a structure of the form $\mathfrak{H} = \langle H, A, B, \in, H^0, H^1, \ldots\rangle$ with $H = H^0$ and $H^i \supseteq H^j \neq \varnothing$ for $i \leq j < \omega$, all H^j being transitive. The variables v^n_m are intended to range over H^n. An acceptable J-model $M = \langle J^A_\alpha, \in, A, B\rangle$ can be viewed as the $\mathcal{L}^*$-structure $M = \langle J^A_\alpha, \in, A, B, H^0_M, H^1_M, \ldots\rangle$, which amounts to the *standard interpretation.* Here the variables v^n_m are intended to range over $H^n_M =_{\mathrm{df}} H^M_{\omega\rho^n_M}$. Note that $n \leq m$ implies $\rho^n_M \geq \rho^m_M$, so this makes sense. In what follows we shall use extra variable symbols such x^n, u^m ad lib.

The stratification we referred to earlier is as follows:

1.1 Definition.

(a) The $\Sigma_0^{(n)}$ *formulae* are the formulae in the smallest class $\Sigma \subseteq \mathcal{L}^*$ such that:

  (i) Σ contains the atomic formulae, and the formulae $\Sigma_1^{(m)}$ for any $m < n$;

  (ii) Σ is closed under $\neg, \wedge$, and quantification which binds variables of type n by a higher type; that is if $\varphi \in \Sigma$, so are $\forall x^n \in y^m \varphi$, $\exists x^n \in y^m \varphi$, where $m \geq n$;

(b) $\Sigma_k^{(n)}$ *formulae* are obtained by alternating k blocks of quantifiers of type n: $\exists \vec{x}^n_1 \forall \vec{x}^n_2 \ldots \mathfrak{Q} \vec{x}^n_k \varphi$ where $\varphi \in \Sigma_0^{(n)}$ (and $\mathfrak{Q}$ is $\forall$ or $\exists$ depending on whether k is even or odd).

(c) $\Pi_0^{(n)} = \Sigma_0^{(n)}$, and $\Pi_k^{(n)}$ *formulae* as those of the form: $\forall \vec{x}^n_1 \exists \vec{x}^n_2 \ldots \mathfrak{Q} \vec{x}^n_k \varphi$ for the appropriate $\mathfrak{Q}$; and we define:

$$\Sigma^* = \bigcup\nolimits_n \Sigma_0^{(n)} (= \bigcup\nolimits_n \Sigma_1^{(n)}).$$

The notions of $\Sigma_k^{(n)}$ relation and function are defined fairly straightforwardly, using these formulae. We need to analyse such relations and functions, and we need a notion of *good* $\Sigma_1^{(n)}$ *functions* as those functions that may be substituted into a $\Sigma_1^{(n)}$ relation and still yield a $\Sigma_1^{(n)}$ relation. These will be defined below.

Over a model M $\Sigma_k^{(n)}$ relations involve a defining $\Sigma_k^{(n)}$ formula whose variables are of a certain *type*.

1.2 Definition.

(i) Let M be a J-structure; $R(x_1^{i_1}, \ldots, x_k^{i_k})$ is a $\Sigma_k^{(n)}(M)$ *relation of type* $\langle i_1, \ldots i_k\rangle$ *in parameters* $\vec{q} \in M^{<\omega}$, if and only if R is defined over M by a $\Sigma_k^{(n)}$ formula $\varphi(v_1^{i_1}, \ldots, v_k^{i_k}, \vec{q})$. (If we wish to mention the parameters we shall say that R is "$\Sigma_k^{(n)}(M)$ in the parameters $\vec{q}$.")

(ii) R is $\boldsymbol{\Sigma}_k^{(n)}(M)$ if and only if it is $\Sigma_k^{(n)}(M)$ in some parameters $\vec{q}$.
